Darlington Rectory

regiment of
George Meade

AN

ILLUSTRATED WEEKLY JOURNAL

OF

HORTICULTURE IN ALL ITS BRANCHES.

FOUNDED

W. Robinson, F.L.S., Author of "Alpine Flowers," etc.

"You see, sweet maid, we marry
A gentle scion to the wildest stock:
And make conceive a bark of baser kind
By bud of nobler race: This is an art
Which does mend nature; change it rather:
The art itself is nature."—*Shakespeare.*

VOL. XIV:—CHRISTMAS, 1878.

LONDON:

OFFICE: 37, SOUTHAMPTON STREET, COVENT GARDEN, W.C.

TO

GEORGE MAW, F.L.S.,

Of Lenthall Hall, Broseley, Salop,

THIS FOURTEENTH VOLUME OF "THE GARDEN" IS DEDICATED

IN RECOGNITION OF HIS LABOURS TOWARDS ENRICHING THE FLORA

OF BRITISH GARDENS:

 Absurdities, Horticultural, 570
 Abutilon Anna Crozy, 486; igneum, 474, 613; insignis, 613; in winter, 557
 Acaciae, dealbata, 170, 190, 323; Dealbata, 407; melanoxylon, 190; as window plants, 454; culture of, 329
 Acacia, the Rose, as a standard, 154
 Acanthines in shade, 244
 Acer, 77; Wagneri laciniatum, 131; Schwedleri, 213
 Achimenes, 162; wintering, 385
 Acorus Calamus, 160
 Acrostichum peltatum, 499
 Actaea racemosa, 284
 Adiantum candatum, 67; Capillus-Veneris on walls, 549; Farleyanae, 254; ditto, on water-tanks, 644; Hendersoni, 257, 611; palmatum, 525; Edgeworthi, 555
 Adonia cirrhosa, 108
 Adonia Lohbi Anaworthi, 147
 Agapanthus minor Mooreanae, 805; the double, 73; umbellatus, out-of-doors, 191; in Wigtonshire, 199
 Ageratum Imperial Blue, 141
 Ageratum as annuals, 48
 Ailanthus as a standard, 391
 Alders, the, 437
 Aliama sinensis, 169
 Alamanda, culture of the, 396
 Allocasia Jenningsi, 101
 Aloc, American, in flower, 169; wintering American, 464
 Aloine Poppies, 124
 Alstroemeria in wild garden, 3
 Alyssum in London, 199
 Alyssum, variegated rock, 412
 Amaryllidaceae, new key to, 332
 Amaryllis, Mrs. Rawson, 332; O'Brieni delicata, 191; Prince Teck, 332
 Amaryllis and their treatment, 49
 America, notes from, 452
 American Aloe in flower, 169
 American Cork, 130
 American Elm, variegated, 121
 American Star Grass, 54
 Ampelopsis Veitchi, 416; how to grow, 462
 Anacochili, 112; culture of, 492
 Anchusa incarnata, 191
 Androsace sarmentosa, 102
 Anemone, Honorine Jobart, propagating, 356; japonica, 408; white and rose-coloured, 345
 Anemones from seed, 75
 Anemones, Phloxes, and Begonias, 190
 Anemoneopsis macrophylla, 3
 Anemoneidioton Phylliditia tessellata, 687
 Annuals as bedding plants, 5; Ageratum as, 6; new, 93
 Anthers of flowers, 114
 Anthonomus pomorum, 491
 Anthomyia ceparum, 347
 Anthrium Scherzerianum in winter, 411; album, 384; variety of, 465
 Antirrhinum, 28; in poor soils, 288; dwarf, at Tottenham, 213
 Ants in Grass, 95
 Aphelandras, varieties of, 222
 Apocynum tuberosum, 234
 Apogoneton spathaceum, 8; distachyon, 149; ditto in small aquaria, 555
 Apples, early, 120; crops of in Kent, 344; Devonshire Quisen, 281; mildew on, 119; origin of, 10; Redleaf Russet, 278; the cultivated, 10; the wild Balsam, 303; Warner's King, 261; Worcester Pearmain, 279; and Pear heat bearing, 118; classification of, 81; for northern districts, 380, 419;

gathering, 260; in June, 153; notes on, 380, 534; pruning cordon, 209; Russian, 120; Dr. Hobb, 574
 Apple trees, blight on, 143
 Apple-tree-boring caterpillars, 297
 Apricots, nailing, 99; treatment of in autumn, 187
 Aquaria, fresh water, 245
 Aquatic plants, hardy, 102, 192
 Aquilegias and their culture, 1; hybrid, 1; corulea hybrida, 663
 Aralia Sieboldi, 62, 374; in flower, 454; spinosa, 580
 Arboretum, Kew, 3
 Arbutus Andrachne, 190, 231; Menziesi, 154, 210; ditto and provera, 170, 210
 Arctostaphylos from seed, 477
 Argemone hispida, 235
 Aristolochia altissima, 125; trilobata, 399
 Armeria, dwarf Alpine, 266
 Arrowhead, 150
 Artichoke, Jerusalem, 76; and rabbits, 501, 628
 Arum italicum in Cornwall, 141; the hog, 149
 Arums at Kew, 125; tropical, long roots of, 382
 Aruncus sylvestris, 302
 Arundo conspicua, 152, 235; mauritanica, 217
 Ash, Mountain, an avenue of, 350
 Asparagus, beetle, 276; beds, 429; making ditto, 231; culture at Argentin, 294; at Chester, 132; ditto, improved, 457; Couch Grass in beds of, 143; and salt, 530, 570
 Asparagus decumbens, 478; failure of, 204; from seed without transplanting, 251; in July, 3; removing the seed from, 468; all the year round, 569
 Aspidium crinitum, 384
 Aspidistra lurida variegata, 243
 Asplenium nobile, 478
 Aster Amellus, 451; Curtisi, 346; Novae-Belgii var. minimus, 280; grandiflorus for the conservatory, 451; select, 582
 Astragalus adsurgens, 310
 Atractaxis spinosa, 380
 Auriculas, 395; in September, 219
 Avena, double scarlet, 532
 Avenua trees, 104; two good, 172
 Azaleas, 113; Duke of Edinburgh, 221; and Camellias from seed, 1; hardy, autumn tints in, 428, 441; re-potting, 386; white, in the open air, 430, 493, 454, 510, 534
 Azaras, select, 350

B.

Balaninus nucum, 318
 Balsams, annual, 323; at Forest Hill, 125; Indian, 234; in pots, 395; out-of-doors, 395
 Balm of Gilead, 164
 Bamboo mats, 482, 649, 570
 Bamboos at Tottenham, 366; for conservatories, 146
 Bambusa Razamowski, 170
 Bananas at Wimbledon House, 451; in Covent Garden, 301
 Barberry, Coral-bearing, 78
 Basket plants, Begonias as, 30, 100; Othonna crassifolia as, 78
 Battersea Park, gardening in, 176
 Bean, Canadian Wonder, for forcing, 397, 429, 454
 Beans, French, and Scarlet Runners, 458, 569

Beaucarnea recurvifolia, 436
 Bedding, carpet, merits of, 4; with hardy plants, 76; Lobelias for, 85; Pterargoniums for, 176; summer and winter combined, 460
 Bedding plants, annuals as, 6; propagating, 111, 552; yellow, 106; Tropaeolums as, 6
 Bed straws, 28
 Bee plant, Pentstemon as a, 133
 Beech trees and underwood, 510, 634, 671, 579
 Beet, Dell's black-leaved, 423
 Beetles, Mushroom-eating, 231
 Begonia, a new, 169; Chiswick Blush, 144; Erchel in winter, 389; geranioides, 276; Lonia Thibaut, 276; Mrs. Dr. Todd, 144; Mrs. A. Patts, 191; Nellie May, 278; polypetala, 631; Queen of the Whites, 213, 302; Roelzi, 438; Weltoniensis, 347; Saundersi, 567
 Begonias at M. Lemoine's, 189; as basket plants, 30, 100; for the conservatory, 211; Mr. Laing's, 212; new hybrid, 438; and Phloxes and Anemones, 190; planted out, 63; seedling, 101; flower-shedding in, 75; tuberous rooted, 101, 392; propagating, 467, 573, 586; of 1878, 503
 Berberis pallida, 104
 Berberis for wine, 120
 Berberisopsis corallina, 78
 Berkeley Portrait, 389
 Berry-bearing plants, 101
 Biennials, Helichrysums as, 106
 Bignonia erecta, 169; caprotata, hardy, 305; venusta, 478
 Billiardiera longiflora, hardy, 100
 Bindweed, a pretty, 3; the great, 78; eradicating, 143, 185, 197, 430
 Birch, purple-leaved, 172
 Birch wood, a, 343
 Blackberries, 242
 Blackheath, improvements at, 172
 Blight, 143
 Blue Gum Tree, 187, 190 (see Eucalyptus)
 Boiler, Gold Medal, 439; French, and pipes for heating, 349
 Bomarea Carderi, 384
 Borders, Thalictrums in, 12
 Boronia serrulata, propagating, 390
 Botanical discovery, 102
 Botanic Gardens, Regent's Park, harriers at, 3
 Botanic Garden, Glasgow, 166
 Botany, garden, 81, 114, 159, 182
 Bougainvillea glabra, flowering of, 244
 Bouquets, Roses in, 48, 76; French, 101; English and foreign, 145
 Bouvardia angustifolia, 191; triphylla, 225
 Bouvardias at Christmas, 360; at St. John's Wood, 478; cool grown, 495, 483; for the flower garden, 331; in market gardens, 622; planting out in summer, 312, 508; propagating, 267; warm treatment of, 438; winter-flowering, 543
 Box edgings, 184; planting, 408
 Box, the Golden Japanese, 189
 Boxhill, Roses at, 29
 Bramble, double-flowered, 147
 Bridge, rustic, without nails, 474; the new Regent's Park, 197
 Briers, propagating, 319
 British Orchids, 25
 Brocoli, autumn, 445; Veitch's Autumn Self-protecting, 457, 570
 Broussa and Mount Olympus, 27
 Brownea erecta var. princeps, 235
 Browallia elata in winter, 574
 Bruggmania, large, 451; as a tub plant, 272
 Bryonia divica in the garden, 399
 Buckbean, the, 150

Budding Roses, 13
 Buddleia globosa, 101; insignis, 349
 Buildings, ancient, 648
 Bulbs and tubers, wintering, 322, 369, 569
 Bulbous plants, exotic, 101
 Bullace, a prolific, 323, 435, 521
 Burdock exterminator, 8, 229
 Burial grounds, St. Lukes, 15
 Burning Bush, 2
 Burnt earth for potting, 644
 Butomus umbellatus, 160
 Buttercups, double, 305; double and semi-double, 285; eradicating, 253
 Butterfly, Cabbage, 94; Turnip, 107

C.

Cabbage butterfly, 94
 Cabbages, clubbing in, 254; crowbar-planted, 207, 252; for early use, 342; when to plant, 131, 249; when to sow, 87, 131
 Cacti, free-flowering, 185
 Caladium argyrites, 411
 Calanthe Sedeni, 475; Turneri, 549
 Calanthes in flower in small pans, 410, 686
 Calandrina nitida, 101
 Calceolaria crinitiflora, 94
 Calceolarias, herbaceous, 113; shrubby, propagating, 318; wintering bedding, 524
 Calendula officinalis, 285
 Californian Dicotyles at home, 177
 Callas in trenches, 414; planting out, 14, 463, 493, 509; ditto, in water, 432
 Calceolaria sylvatica, 507
 Camellias and Azaleas from seed, 1; and Roses, 318; and Euryas, 323; American, 500; group of new, 354; treatment of, 66; watering, 494; ditto and thinning, 512
 Campanulas, culture of, 141
 Campanula nobilis, 23, 54; pyramidalis, 14; punila alba, 94
 Canna iridiflora, 313; iridiflora hybrida, 235
 Cannas, culture of, 637, 563; in Ireland, 346; propagation of, 637; with Gladioli, 639
 Cape Gooseberry out-of-doors, 123
 Cape Pondweed, 149
 Cardinal Prince of Wales, 530, 570
 Cardif Castle, Melons at, 74
 Carnation and Picotee Society, 96
 Carnation Souvenir de la Malmaison, 185, 221, 341
 Carnations, 55; culture of, 121; disfiguring, 142; dressing, 145; exhibition, 106, 191; propagating, 111; removing, 185; seedling, 93; two good, 221; tree, 525; yellow, and insects, 75; and Picotees, 338, 414; do., yellow, 580; perpetual, planted out, 524; ditto at St. John's Wood, 301; at Slough, 574
 Carpet bedding, merits of, 4; plants for, 285
 Carpopapsa pomonana, 391
 Carrots for main crops, 295
 Cascades in pleasure grounds, 65
 Cassia corymbosa, 88; out-of-doors, 278, 343
 Castanea chrysophylla, 77
 Castings, elabourate, 494
 Casuarina australis, 396, 644; ericoideae, 558
 Catalpa for economic planting, 19; fruit of the, 301
 Catchfly, Sickle-leaved, 629
 Caterpillars and Dill, 276; and Oak, 107; Apple tree boring, 297

- Cattleya, a new, 147; *crispa*, 87; *El-dorado* var. 213; *Leopoldi*, 101; *Mitchelli*, 188; *Veitchiana*, 188
 Cattleyas, treatment of, 492
 Caucasian Scabions, 125
 Cauliflower, Autumn Giant, 143, 336, 458, 187
 Cauliflowers, autumn-plants, 1, 312, 423; early, 33; pricking out, 295; Sutton's King of the, 386
 Ceanothus Arnoldi, 55; *azureus*, 301, 610; *Gloire de Versailles*, 101; *vulcanis*, 172
 Cedars at Gunnersbury, 105; at Lebanon, 589
 Cedrus Deodara, 170; cones of, 260
 Celery, 182; earthing, 209; free from worms, 630; maggots, 341; worm-eaten, 363; running to seed, 363; and Scarlet Runners, 67
 Celosias, 88
 Celosia pyramidalis in the conservatory, 649
 Centaurea macrocephala, 65
 Centropogon Lucyanus, 576
 Cerasus Watereriana, 572
 Cereus serpentinus, 134
 Cestrum aurantiacum, 466
 Cestonia aurea, 428
 Chalk herbaceous plants on, 177
 Chamæropus excelsa in flower, 367
 Charring weeds, 15
 Chelsea, Pitcher Plants at, 65; Orchids at, 549
 Cherry Plum as a hedge plant, 430
 Cherry, Morello, the, 222; fruit falling off ditto, 501; black fly on the, 526, 550
 Cherries in Rhenish Bavaria, 196
 Chervil, curled, 295
 Cheesnut, Roses at, 123
 Clematis, golden-leaved, 77; Sports, 241
 Chestnuts, sweet, 405
 Chiswick, rockwork at, 235
 Chlora perfoliata grandiflora, 306
 Chorozemas, culture of, 556
 Christmas decorations, 551
 Christmas Roses, 173
 Chrysanthemum, frutescens aureum, 235; M. Crousse, 475
 Chrysanthemums, Anemone-flowered, 375; at Isleworth, 436; at St. John's Wood, 390; exhibition, 483, 544; in a cut estate, 614; in pots, 375; in the Temple Gardens, 411; feeding and disbudding, 194; Japanese, 156, 600; potting, 14; protecting in windy weather, 265; show of, at the Aquarium, 478; at Liverpool, 621; summer-flowering, 99; tortured, 431
 Chusan Palm, New England, 31
 Churches, floral decoration in, 373
 Churchyards, flowers in, 105, 152; plants for, 146
 Cinerarias, culture of, 24
 Cineraria maritima, 251; from seed, 289, 330, 399
 Classification of Apples, 61
 Clay, burnt, 477
 Clematis, Henry, 213; lanuginosa, 101; *Richardi*, 213, 466
 Clematis, hybridation of, 370; in mixed beds, 331; and 179, 100; on trees, 552
 Clethra paniculata, 167
 Clanthus puniceus, 610; *Dampieri*, 101
 Climate of north of France, 545
 Climbers, conservatory, at Birmingham, 396; greenhouse, winter-blooming, 363, 395; regulating conservatory, 434; stoves, 556
 Climbing Roses and Holly, 56
 Cloches, price of, 458, 592
 Clove Carnation, Miss Askey, 231, 331
 Cluster Pine, 20
 Cock-scandens variegata, 201
 Cock-combs, large, 279, 323, 373
 Cocoa-nut fibre, mulching with, 539
 Coffea, Liberia, 250
 Coffee tree, Kentucky, 77, 219
 Colchicums in flower at (July 27), 73
 Colchicums at Tooting, 279
 Colchicum speciosum, 289
 Coluses, new, 315; propagating, 547
 Collecting plants, notes on, 85
 Collector's outfit, 85
 Coloured-leaved trees, 77
 Columbian Orchids, 123
 Combination, a pretty, 455
 Comfrey variegata, 191
 Compass plants, 55
 Composition, binding, 556
 Conifers at Preston Show, 76; Golden, 103, 124; in towns, 321; notes on, 240; pruning, 258; variations in, 441
 Conservatory, Begonias for the, 211
 Convolvulus altheoides, 3; sepium, 78
 Cologne Hookeriana, 399
 Cool Orchids, Columbian, 126
 Cordyline indivia from seed, 211
 Coreopsis medata, 199
 Cork, American, 130
 Corn, green, for the table, 430
 Correa propagating, 13
 Corydalis lutea, 301
 Cotoneasters in masses, 3:2
 Cotagers' Kale, 38
 Cotton Thistles, 29
 Covent Garden, bouquets in, 396; Grapes in, 166; improvement in, 295
 Crane fly, 131
 Cranberry culture in England, 435
 Crassula lactea, 577
 Creepers for training over doore and windows, 265
 Crinum Mackenii, 101
 Crocosmia and Sparaxis, 429
 Crocus Elwesi, 345; vitellina, 420
 Crocuses, winter and early spring, 420; autumn, 305
 Crocus Bergmannianus, 259
 Crops, Peach, 76; Potato, Ireland, 76; market, 424; fruit, 28, 39, 71
 Croton Prince of Wales, 55, 613; Williamsi, 189
 Crotons at Anerley, 411; at Holloway, 367
 Crowfoot, the water, 151
 Cucumbers, 163, 181; and woodlice, 98; bitter, 250; diseased, 143; in the East, 262; ridge, 164; winter, 32; new v. old seeds of, 342; Telegraph, 397, 530
 Cuphea Zampari, 389
 Cupressus Lawsoniana, propagating, 157
 Cure for Rats, 49
 Currants, losing their bloom buds, 550, 673; standard, 326, 344, 382; summer pruning, 167
 Cuttings, Rose, 67; striking, 181; Osenkoss method of ditto, 223; new mode of ditto, 616
 Cyca revoluta in fruit, 625
 Cyclamen Mount Blanc, 475
 Cyclamens, 181; at Reading, 323; planted out, 372; sweet-scented, 257
 Cymbidium Parishii, 23
 Cyperus longus, 213
 Cyphokentia macrocarpa, 315
 Cypripedium, 112; hardy, 69
 Cypripedium insignis in cold pits, 322
 Cypress, a fine-leaved, 172
 Cyprus, vegetation of, 140
 D.
 Daddy-long-legs, 131
 Dahlia Aurora, 276; Clara, 276; Ellen Maegregor, 188; imperialis, 625; Joseph Ashby, 276; Little Beauty, 235; lutea, 276; Paragon, 276; Prince Bismarck, 188; species of, 124
 Dahlias on Grass, 323; Pom-pone, bouquet of, 218; single, 102, 169, 257; various, 276
 Daisy, a sky-blue, 65
 Daisies, Michelmas, 662; on walls, 257
 Dahlias, Alpine, 350; of China and Japan, 412
 Daphne Blagayana, 200, 212; propagating ditto, 339; indica, 66; rupestris, 301
 Datisca cannabina, 257
 Deathless flower, the, 12
 Decorations, table, 3, 25, 60, 53, 97, 145; wild flowers in, 67; at Charing Cross, 76
 Deherainae smaragdina, 531
 Dell in Hyds Park, 78
 Delphinium cardinalis, 66, 147; Victory, 235; George Taylor, 55
 Delphiniums, perennial, 87; double, 87; from seed, 106; single, 87
 Dendrobium, a new, 65; barbatulum grandiflorum, 65; bigibbum at Chelsea, 345; bigibbum album, 500; d'Alherstii, 65, 144; noble, culture of, 289; Goldiei, 244
 Desfontainia spinosa, 147, 190
 Desmodium psuduliflorum for the conservatory, 323
 Desmodium racemosum in September, 257
 Destroying slugs, 21
 Diary, extracts from, 15, 33, 67, 89, 114, 138, 163, 182, 201, 224, 248, 289, 302, 313, 330, 358, 379, 402, 423, 445, 494, 518, 612
 Dianthus as bedding plants, 257
 Dianthus Heddwigi, 6
 Dicentra, Californian, at home, 177
 Dicentra eximia, 100; formosa, 451; Ruc-leaved, 95; thalictrifolia, 95
 Dictamnus Fraxinella, 2
 Digitalis gloxinoides, 7
 Digging, best spades for, 570
 Dill and caterpillars, 276
 Dioreocera retusa, 138
 Diospyros lucida, 282
 Dipladenia boliviensis in winter, 478
 Dipladenias, finely-flowered, 367; at Holloway, 85
 Disa grandiflora, culture of, 99; in the open air, 497
 Dog's-tooth Violet, 177
 Double Agapanthus, 79; Edelweiss, 60; flowers, 9; Wistaria, 106; Zinnias, 191; zonal Polyanthems, 2
 Dracena Fredericki, 436
 Dracenas at Anerley, 411; striped-leaved, 23
 Dracophyllum lusitanicum, 126
 Drought in the Eastern Counties, 73
 Drying everlasting, 98; herbs, 89
 Duration of flowers, 10
 Dye plants, 23, 75
 Dynamite and tree roots, 534
 E.
 Early Cauliflowers, 33
 Earnings, 253
 Eastern counties, drought in, 70; Japanese Primroses out-of-doors in, 5-9
 Echeveria De Swetiana, 436; winter quarters for, 498
 Economic planting, Catalpa for, 19
 Edgings, Box, 164; brick, 509
 Edelweiss, 100; a double, 50
 Edwaldia, grandiflora, 510
 Elder, red-berried shedding of, 363, 429, Elder, 476, 533
 Elm, the Western Rock, 131
 Elms in Kensington Gardens, 411; 429

GEORGE MAW, F.L.S., &c.

MR. GEORGE MAW, to whom this volume of the "Garden" is dedicated, was born in London on December 10, 1832. In 1853 he became associated with his brother, Mr. Arthur Maw, in the proprietorship and management of the well-known encaustic tile and majolica works at Benthall, near Broseley in Shropshire, where their energy, perseverance, and skill have brought the art of tile-making to an almost unrivalled perfection, and deservedly earned for them a world-wide reputation. From an early age Mr. Maw developed a great liking for geological research, and pursued it with unwearied diligence and assiduity. From the year 1864 up to the present time he has contributed a series of papers of great ability to the "Geological Magazine." His accurate knowledge of the character and distribution of the various kinds of clay has been of material service in bringing the Benthall tile pottery to such perfection. Having also devoted much time and diligence to the study of archaeology, especially to that portion of it which relates to the ancient tessellated pavements of the Romans, he has been able to bring his knowledge to bear with much effect at the Benthall works. He has for many years past taken an active and prominent part in all matters connected with the religious, social, and political welfare of the country, and has been a frequent and powerful contributor to the Press. It is, however, with his eminence as a botanist of almost unrivalled keenness, and a collector, introducer, and discoverer of new, rare, and little-known plants, that we are more immediately concerned. Having, in his earlier years, made himself intimately and thoroughly acquainted with the botany of the United Kingdom, Mr. Maw commenced in the spring of 1869 a series of foreign botanical excursions, of which the following is a summary:—

- | | |
|--|--|
| <p>1. April, 1869.—Gibraltar, Tetuan, Tangier, Escorial Mountains, and Tolosa Pyrenees.</p> <p>2. July, 1869.—Zermatt.</p> <p>3. October, 1869.—Volcanic district of Auvergne.</p> <p>4. February, 1870.—Montpellier.</p> <p>5. April, 1870.—The Riviera and Corsica.</p> <p>6. June, 1870.—Central Spain and Pyrenees.</p> <p>7. August, 1870.—Dauphiné and Mount Cenis.</p> <p>8. January, 1871.—Lisbon and Cintra.</p> <p>9. May, 1871.—Gibraltar, Tangier, Tetuan, Morocco, and the Great Atlas. Mr. Maw accompanied in this excursion Dr. now Sir Joseph Hooker, and Mr. T. Ball, F.R.S.</p> <p>10. August, 1871.—Lyonnais Pyrenees and Auvergne.</p> <p>11. May, 1872.—Maritime Alps.</p> <p>12. July, 1872.—The Engadine.</p> <p>13. April, 1873.—Algeria and L'Agbonat Sabara.</p> <p>14. July, 1873.—Dolomite district.</p> | <p>15. May, 1874.—Florence and Carara.</p> <p>16. September, 1874.—Mont Cenis, Maritime Alps, and South-west Tyrol.</p> <p>17. April, 1875.—Corsica and the Riviera.</p> <p>18. July, 1875.—Mont Cenis, Maritime Alps, and South-west Tyrol.</p> <p>19. October, 1875.—Lisbon, Cintra, Oporto, and Coimbra.</p> <p>20. April, 1876.—Trieste, Italy, and the Riviera.</p> <p>21. July, 1876.—Mont Cenis and Dauphiné.</p> <p>22. September, 1876.—Spain and Majorca.</p> <p>23. March, 1877.—Corfu, Athens, Syra, Constantinople, and Asia Minor.</p> <p>24. October 1877.—Italy and Santa Maura.</p> <p style="text-align: center;">[In the latter island he met with his singular and remarkable adventure with Ionian Brigands, the tale of which he so graphically told in the "Gardener's Chronicle" of December 1, 1877, under the heading "Perils of a Botanist."]</p> <p>25. April, 1878.—United States and Canada.</p> |
|--|--|

Mr. Maw succeeded in bringing home living specimens of most of the new, rare, and interesting plants which he collected during these excursions, and has since cultivated them with almost unflinching success in his garden at Benthall Hall, a fine old Elizabethan mansion overhanging the Severn, which has for many years been his residence, and where he has gathered together a collection of plants, books, and pottery as unique in character as it is replete with interest. His knowledge as a botanist is only equalled by his kindness and hospitality as a neighbour and a friend, and the large-handed liberality with which he distributes his plants amongst his numerous horticultural friends. Mr. Maw has made the hardier bulbous plants of Europe, Asia Minor, and the Mediterranean region of Africa his more special study, and has *par excellence* taken up the genus *Crocus*, a family first monographed by the lamented Dean Herbert some years ago. By the most patient and unwearied perseverance he has succeeded in importing living bulbs of almost every known species, which are, at the present moment growing in his garden at Benthall; the few remaining species are on their way to the same happy home. Mr. Maw has in active preparation an elaborate monograph of the genus, which will shortly be published, and for beauty of delineation and exhaustive accuracy of description, will rank second to no work which has as yet left the Press. Mr. Maw married a daughter of the Rev. Thomas Brown, rector of Hemingston, near Ipswich, by whom he has a numerous family, and whose kindly welcome and genial hospitality are never forgotten by any visitor to Benthall Hall.

Mr. Maw's frequent botanical excursions have resulted in the discovery of several species of plants new to science, including

- Saxifraga Mawiana* (Baker), Mountains of Tetuan, 1869
Buerbavia marocana (Ball), Hills of Morocco, 1871
Draba Mawi (Hooker), Pancorbo, Spain, 1870
Stachya Mawiana (Ball), between Sektana and Frouza, Morocco, 1871
Ononia Mawiana (Ball), Tangier
Crocus coraicus (Vannucci), Corsica, April, 1875

Mr. Maw's published papers, which are too numerous even to give their titles here, may be found in the "Royal Agricultural Society's Journal," "Phytologist," "Encyclopædia Britannica," "Zoologist," "Times," "British Association Reports," "Edinburgh Botanical Society's Transactions," "Quarterly Journal of the Geological Society," "Builder," "Art Journal," and in our own columns, as well as in those of contemporary horticultural journals.

THE GARDEN.

VOL. XIV.

TABLE PLANTS.

I HAVE been asked to reply to the question, "How tall should table plants be for exhibiting?" and I am obliged to confess my inability to answer it in a few words, because I am not informed what is the kind of table upon which they are to be exhibited. To give information upon the heights of plants which may be used upon tables of different kinds, it will be necessary to run through the various uses to which tables are applied. These uses may be divided into two classes—tables not used for meals, and tables at which meals are served. First, as regards tables at which meals are not served. These relate to halls, drawing-rooms, boudoirs, &c., and it must be evident to all that it is impossible to lay down any law as to the height of plants for such purposes, since so much depends upon the size and mode of construction of the table, and also upon the other furniture and decorations in the room. The size of the plant cannot be determined upon by the size of the table only; it must also be governed by the lightness or the solidity with which a table is made. A heavy Oak or Mahogany table, 4 ft. in diameter, would look well if decorated with a plant which would be quite out of place upon a wicker table of the same size, notwithstanding that the latter table might be strong enough to support it. As a general rule, large heavy plants should be placed on tables in halls, and plants of lighter character and habit in sitting-rooms; but the height of the plants that would look best cannot be determined upon without seeing the table and its surroundings. It is equally impossible to fix upon a height for plants to stand upon a sideboard or dinner-waggon; and such plants may fairly be included under the title of table plants. Secondly, as regards tables for meals. These tables require to be treated in different ways, according to whether the meal be partaken of sitting or standing. If it is wished to decorate a table at which a standing supper is to be served, the height of the plants need not arbitrarily be determined upon, though some of the prettiest effects are produced by using, alternately, plants that one can see over and see under, the latter having their long stems ornamented in some tasteful manner, but so as not to interfere with people seeing each other as they stand at opposite sides of the table. The same principle should be applied to tables at which people sit to partake of their meals. There should be nothing upon the table which can interfere with seeing and talking across the table; hence the invariable rule observed by all the best dinner-table decorators, that nothing should intercept the view between the heights of 15 in. and 20 in. above the cloth. From whence it follows, that dinner-table plants, and, consequently, plants upon breakfast, lunch, and supper-tables, at which chairs are used, may be either short or tall, that short dinner-table plants must not exceed 15 in. in height, and that tall dinner-table plants must not have any branches below 20 in. from the bottom of the pot, but may be of any height that will look well upon the particular table and in the particular room which it is intended to decorate. The ignorance of these common-sense principles, which is so often manifested in the wording of schedules for flower shows, has surprised me much and has given great trouble to judges on many occasions.

W. T. T.

CAMELLIAS AND AZALEAS FROM SEED.

It is stated (see Vol. XIII, p. 530) in reference to seedlings of these that "ninety-nine plants in one hundred would produce flowers not worthy of notice." Such is far from my experience; on the contrary, I should say that, unless the writer of the sentences in question takes the very best named flowers as models, he will get, through careful fertilisation, "ninety-nine" as good or better than the parents. In 1836, with no varieties to work with but the old Azalea indica, A. phœnicea, the variety called Smithi, and one or two more of about the same stamp, I raised a batch of seedlings, not one of which was as poor as the parents, and three of them are to this day equal or superior to any other of the same shade of colour in cultivation. The variegata type had not then been introduced into this country. Again it is said that "four or five years would elapse before the seedlings bloomed." In the summer of 1875 we fertilised about a dozen plants of Bijou de Paris, William Bull, and similar sorts with each other. The seeds were sown in December of the same year, and now, as I write, I have still in bloom several of these seedlings, at least 200 out of 500 having been in flower ever since April 1. The last one which opened this week was a very distinct, beautiful, double rosy-pink, quite equal in fullness and size to that best of doubles that I have seen—Madame Paul de Schryven. Of the 200 that have bloomed I have marked twenty equal or superior to any of the best Belgian varieties, and at least 100 of them are quite equal to the average character of any good collection. Several of them flowered in March of last year only fifteen months from seed. My experience has been of this character in the production of all kinds of plants and fruits that I have tried. Hovey's Seedling Strawberry and Boston Pine, raised in 1833, were selected from 1000 or more seedlings, but I might almost say hundreds, certainly dozens, were large and fine Strawberries. With the Camellia I have had still greater success, having produced twenty-five very fine double varieties out of probably 1000 seedlings, all superior to the parent of many of them (C. Warratah). Two-thirds of them, indeed, are quite as good as the greater part of the kinds grown at that time, such as Kingi, Colvillei, Pressi, conspicua, and other doubles, but irregular-shaped flowers, and five of them, I think, are unequalled by any yet produced. One of my Azaleas you will soon see at some of your London exhibitions, as the original plant, twenty years old, was purchased by one of your leading nurserymen. Our seedling hardy Azaleas and Rhododendrons have all been quite equal or superior to their parents. Judicious fertilisation is sure to effect changes and combinations which it is impossible to conceive, and results are sometimes as remarkable as they are unexpected. That all seedlings are deserving of a name and description, I do not admit; they should, indeed, be a very decided advance on what is already in cultivation to merit a name.

C. M. HOVEY.

Boston, Mass.

Aquilegias.—In addition to the remarks made lately by various correspondents of THE GARDEN in reference to the culture of the North American Columbine, I may mention that the other day I

as a long bed of them in robust health, flowering and seeding abundantly. The kinds included *A. cœrulea* pure and simple, *A. chrysantha*, and the hybrid known as *A. cœrulea hybrida*. This gave me another proof that this fine hybrid is a natural cross, as I was assured that no artificial means had been employed in its production, and not the result of "careful hybridising," as sometimes remarked. This circumstance well illustrates the close affinity of the two kinds, which are, in my opinion, but two forms of one species. The soil in which they were growing was of a very stiff character, with a retentive subsoil, thus showing that a light warm soil is not a proper medium for Columbieæ. It seems odd that cultivators should expect that these, and also a host of other hardy plants, will remain in a border year after year and give no more trouble than a common German Iris, as in their native habitats they are under quite different conditions from those usually found in a garden border; and, besides, they are not subject to such climatal changes as we experience in this country. To be successful in their culture it is necessary to substitute seedlings for old plants every two or three years. Seedlings may be raised with comparatively little trouble, which they will amply repay by a fine display of flowers such as I saw the other day.—W.

THE GARDENERS' ROYAL BENEVOLENT INSTITUTION.

ON Wednesday evening last the thirty-fifth anniversary festival of this charitable institution was held at the Albion Tavern, Aldersgate Street, under the presidency of Mr. Robert Marnock, and was one of the most successful meetings on record. The chairman, in proposing the toast of the evening, "Prosperity to the Gardeners' Royal Benevolent Institution," asked the assembly to sympathise with the cause and object which they had met to support. The Society (he said) was instituted forty years ago, since which time it had steadily progressed. There were at present seventy-seven poor gardeners on the pension list, who were each receiving pensions at the rate of £16 per annum, and £12 per annum for the widows. At the same time the Society had relieved during its existence 252 pensioners at a total cost of £22,780, and had funded £11,380 in the Three per Cent. Consols. It was a significant and gratifying fact to know that they had accomplished so much good, especially when they remembered that since the formation of the Society some 500 charitable institutions had been brought into existence. Speaking of the extended work of the gardener of the present day, he said about fifty or sixty years ago it was only the highest in the land who employed gardeners, but now we had many merchants and successful tradesmen, and others who had their gardeners. That was not less cheering for horticulture than for the country itself. In the work of the Society there was something for all to do. Those who could do so should become subscribers, and others could say a word in season concerning the objects of the charity.

Mr. Robert Wrenoh (whose name was coupled with the toast) hoped that not only the rich but the poor would contribute to the Society, for no one could tell what might happen to him. He knew of a case of a person being in receipt of £12,000 a year coming down to want the aid of a public charity. He regretted to say that the gardeners were far too backward in supporting the Institution.

Prof. Bentley gave the "Health of the Chairman," and spoke in high admiration of the good taste of Mr. Marnock as displayed in his designs for landscape gardening at the Royal Botanic Gardens, Regent's Park, and other gardens. He also alluded to the great improvement in the attendance at those grounds, stating that he had seen nearly 20,000 persons present in a single afternoon. The chairman briefly acknowledged the compliment, and proposed the "Health of the Secretary," warmly thanking Mr. Cutler for his unceasing advocacy of the interests of the Society, and for his long continued labours on behalf of the Institution.

Mr. E. R. Cutler said that only on one previous occasion had their anniversary festival resulted so favourably for the Institution, and that one occasion was when Baron Rothschild presided. The subscriptions on the present occasion amounted to over 600 guineas. After alluding to the great respect and popularity enjoyed by the chairman, Mr. Cutler said that there were present gentlemen from the west of England, from Liverpool, Manchester, Yorkshire, and other places, who had attended to do honour to the chairman. Thanking the assembly for the toast, Mr. Cutler said, that so long as he enjoyed their confidence he should continue to do his very best for the Society.

Mr. A. Philbrick, Q.C., proposed "Success to the Horticulture and Botanical Societies of London." He desired the success of a the great societies of the metropolis and elsewhere which were devoted to the practice and interest of horticulture. A great deal was

due to the two societies he had mentioned, for they had been and were still the pioneers in the path of progress in the science of horticulture.

Dr. Brewer looked upon horticulture as a great friend, and as being of great use in sanitary matters. He thought that plants and their effect upon health was a subject of special interest at the present time. Their cultivation now in large cities like London was a matter of actual necessity to the health of the people. All that could be done in that direction and for the prevention of the spread of epidemic diseases had not yet been done, and he hoped that the work to that end would be persevered in. They were responsible in a great measure for the moral education of the people, and he hoped that the power they thus possessed would be used with all their energy.

New Irises.—Among the varieties of *Iris Kämpferi* in Messrs. Hooper's collection, a large white one is remarkable for its purity of colour and a kind of beauty of line and form, which reminds one of a work in marble of the higher type. This variety is called Alexander Von Humboldt. De Vreese, a purple kind, is also an improvement on existing ones; and so is Sieboldi, a mauve variety. Others, representing different shades of lilac and other colours, are equally pretty.

Tuberous-rooted Begonias.—Messrs. Veitch's collection of these is just now in full bloom and well worth seeing. The plants are large, bushy, and healthy, and their flowers vary in colour from pure white to rose, and through all the shades of scarlet and crimson. Different types, both as regards habit, foliage, and flowers, are all well represented here, and afford a good opportunity for selection.

Double-flowered Zonal Pelargoniums.—New kinds of these are now so numerous that to select the best has become a difficult matter. In a collection of them in the Fulham Nurseries, however, the following seemed well worth attention, viz., Madame Thibaut, dwarf in habit, and with flowers of a clear rose colour; Fille de Honour, bluish; Guillion Mangilli, semi-double flowers, bright crimson in colour; Talbot, bright magenta, very double; Lucie Lemoine, pink; and Venus, white. Either in bouquets or on the plants of these kinds are exceedingly effective.

Spiræa palmata elegans.—This has just flowered here and has greatly disappointed me, having nothing at all to recommend it. It does not appear to be a hybrid and intermediate between *S. palmata* and japonica, for, with the exception of the pinkish tinge on the anthers, it possesses no rosy hue at all, and I am afraid that this (unless in the case of those who usually search for effects by means of a microscope) will not be considered satisfactory. My impression is that 8s., the price at which the plant was sent out, ought to have been 3s., and that would even be too much. The palming off of plants at high prices by means of tempting descriptions and finely got up plates, cannot, I think, be too strongly condemned.—T. SMITH, *Newry*.

Epilobium obcordatum.—This little gem, which is now in flower, affords another striking instance of the richness of the Californian flora. Unlike the majority of the Willow herbs, it is very dwarf, not being more than a few inches in height and of a trailing habit. The leaves are, as the specific name implies, of a reversed heart-shaped form, of a bright green colour, about $\frac{3}{4}$ in. long and $\frac{1}{2}$ in. in breadth. The flowers, which are borne singly yet profusely on short stalks from the axils of the leaves, measure about 1 in. across, and their colour much resembles that of *Clarkia pulchella*. It grows on an exposed part of the rockery at Kew, in a compost of rich loam and grit. As it is quite hardy and easily propagated, both by means of seeds and cuttings, it may be expected to soon become common in rock gardens.—W.

Epidendrum vitellinum.—This Mr. Wills finds extremely useful in a cut state. He therefore grows large quantities of it for that purpose, and, associated with the delicately-tinted blooms of *Odontoglossum Alexandræ*, in floral decorations the effect which it produces is excellent.

Lilium davuricum.—Many varieties of this beautiful hardy Lily may now be seen in good condition in the herbaceous beds of some of the London nurseries, and it is astonishing that they do not find their way into the London parks. They are subjects that may be seen at a distance, and a few beds of them would fill up a gap at a season when flowers are not over plentiful. The effect of these beautiful Lillies cannot, however, be shown by a single spike; they must be seen in quantity if their full beauty is to be realised.—JAMES GROOM.

Burning Bush (see p. 609).—This name is frequently applied to *Dictamnus Fraxinella*, because the plant is one of several which, under certain peculiar conditions of the atmosphere, has been frequently observed to emit a phosphorescent light.—S. GARLANDS, *Castle Street, Salisbury*.

NOTES OF THE WEEK.

Dinner-table "Decorations" do not seem to be improving. There are endless pains bestowed on them, and much delicate intricacy, but no advance in the direction of simplicity. What is wanted are good effects from materials few and simple, and such arrangements as could be carried out in a few minutes. The Royal Botanic Society might fittingly open up some improvement in this direction.

The Potato Disease.—This, we learn, was never known to be so bad so early in the year. The early Potatoes from the Channel Islands come in such a diseased state that they are unsaleable. On the spot even, when fresh out of the ground, the effect of this early prevalence of disease is to reduce the price of Potatoes to a very low figure, the round ones being offered at about 2d. per stone.

Barriers at the "Botanic."—We have to complain of the barriers erected in the Botanic Gardens in the Regent's Park to protect the Royal and other visitors from being mobbed by the well-dressed crowd. These seem to us to increase the danger of mobbing, and they certainly are an inconvenience to the public. In parts where there were no barriers the Royal party did not seem to suffer any inconvenience.

Convolvulus althæoides.—This pretty Bindweed, with large pink flowers and small cut leaves, which runs about among the stones and rocks on the shores of the Mediterranean, is quite hardy on light sandy soils in England. It is now flowering abundantly and running about as freely in Mr. Wilson's garden at Weybridge Heath as ever we have seen it in its native country.

Stuartia virginica.—This rare shrub thrives in moist peat soil about London, where it has lately been, and is still, in flower. The habit, though compact, is free and somewhat open. The flower-buds, before they open, are beautiful in all stages. There are crimson stripes towards the base of the petals in at least some individuals.

Evening Primroses.—The large-flowered and tall forms of these, now so beautiful and fragrant in the evenings and throughout the night, are plants that seed freely and take care of themselves in half-wild places—thin shrubberies, copses, and the like; so that anyone may enjoy their beauty without trouble or cost. They add a new charm to the garden in the evenings, and their odour is not of an overpowering kind.

Rosa Brunoni.—This beautiful and vigorous single Rose has recently been very attractive in Mr. McIntosh's garden at Oatlands Park. A specimen there growing on the margin of a shrubbery, and about 12 ft. high, throws its long shoots as freely forth as a Bamboo, and they bend towards the earth laden with showers of white flowers. It is a lovely Rose, and will prove of great value for shrubberies and wild gardens.

Alstroemerias in the Wild Garden.—All who care for hardy flowers must, at this season, be struck with the beauty of *Alstroemeria aurantiaca*, especially when it spreads into bold healthy tufts, and when there is a great variety in the height of the flowering stems. A valuable quality of the plant is, that in any free soil it spreads freely, and it is quite hardy. For dry places between shrubs, for dry or sandy banks (either wooded or bare), copses, or heathy places, the plant is admirable. We have even noticed it thriving under the shade of trees.

Shrubby and Herbaceous Spiræas Grouped Together.—We have lately seen a peculiarly beautiful effect afforded by a fine group of *Spiræas*—the finer shrubby and herbaceous kinds. Most conspicuous were two fine tufts of *Spiræa arisæfolia*, bearing picturesque tufts of feathery plumes; and near them were other shrubby kinds. On one side on the Grass were planted three of the finer herbaceous kinds—*S. Aruncus*, *S. palmata*, and *S. japonica palmata*, the last a fine plant in abundant bloom. There was not a trace of formality or awkwardness in the planting, the grouping being perfect. The effect of the fine deep rosy flowers of the one healthy tuft of *S. palmata* near the clouds of spray of the large shrubby kind was charming. The arrangement is suggestive of improvements in grouping in gardens—public and private. The stiff lines in some of our botanic gardens are far behind this even from a teaching point of view. From a similar group, more complete as to species, one would get a far more comprehensive idea of this beautiful family of plants than from anything we have ever seen in a botanic garden.—W. R.

New Gardens and Arboretum.—We have authority for stating that the Botanic Gardens and Arboretum at Kew are open to botanists and horticulturists from 6 a.m. in summer and daylight in winter on application at the curator's office. The houses and museums are closed during the hours of breakfast (8 to 8.45 a.m.) and dinner (12

to 1 p.m.). It is satisfactory that a matter of some importance to many concerned with horticulture is thus put beyond doubt. As for ourselves, none can be more willing to defend all the essential rights and needs of the Gardens, and we particularly hope that the question recently mooted of increased refreshment facilities in the parks will not crop up as regards Kew. The slightest liberty in that way would be a great injury to the Gardens. Some of the best Continental gardens are seriously marred by restaurants and the like that would be quite as conveniently placed outside the gates.

Asparagus in July.—The finest Asparagus which we have ever seen cut in July has just come to us from Mr. Harwood, Colchester. Mr. Harwood is one of the English growers who cut their Asparagus at about the same length as that of *Argenteuil*, i.e., when it has grown about 1 in. above the ground. It is also, we think, as delicate in flavour as any Asparagus which we have ever tasted.

Ivy.—We have lately noticed at Mr. Parker's nursery at Tooting a novel and beautiful effect from a mixture of two very different Ivies in the same border—a very large shield-leaved kind (*dentata*) and the small, narrow-lobed (*palmata*). In the same place the same large-leaved sort has entered a lofty shed, which its fine foliage now adorns. The leaves seem nearly as green and no less ornamental than they are outside.

A Pretty Rock Scabious.—*Scabiosa Parnassi* is now a very beautiful object in sandy borders, spreading forth into grey tufts dotted with brownish-red flowers. It is one of the many rock plants the value of which cannot generally be seen, owing to the fashion of making rockwork of miserable, narrow "pockets," out of which the plants cannot spread, even if they succeed in living in them.

Pig Plants.—There is, at least, one species of *Escallonia* which emits a very powerful odour as of the sty. I write so that any of your plant-loving readers who notice this peculiar and far from agreeable odour may put the saddle on the right horse. Are there not other plants guilty of this bad behaviour? I think I remember detecting it in an *Alaternus* a good many years ago, having first looked in all directions for a more likely source for such an odour. I am greatly surprised that any vegetable should behave in such a manner.—T. O. B.

Anemonopsis macrophylla.—This rare and beautiful member of the Crowfoot family at first sight reminds one of the Japanese Anemone (*A. japonica*), but it is smaller in all its parts. The thick and shining leaves rise to a height of 12 in., the flower-stems are slender, about 18 in. in height, on which are borne numerous drooping blossoms, about 1½ in. across, of a pale purple colour. The flowers differ from the Anemone in having two rows of petals, one outside and spreading, the other forming a cone in the centre. It is a native of Japan. A specimen of it in flower may be seen on a rockery at Kew, where it seems to delight in shade.—A.

Coloured Plant Portraits.—Mr. B. S. Williams has sent us coloured illustrations of new *Azalea* Princess Beatrice, Mrs. Carmichael, and William Carmichael, varieties obtained by crosses effected between *Azalea amœna* and varieties belonging to the Indian section, which are valuable for decorative purposes; also *Croton mutabile*, Prince of Wales, and *Sonset*, remarkable for their bright colours; *Ixora* Duchess of Teck, a hybrid with orange flowers; and several new *Dracœnas* and zonal *Pelargoniums*, all of which are well worth having in any good garden.

The Crimson Stonecrop (*Sedum sempervivoides*).—This fine species, now in flower on a rockery at Kew, is certainly one of the most desirable of hardy succulents. Its foliage, which is quite unlike that of most of its congeners, is of a pale green colour, marked with dark brown spots, and arranged into a compact rosette about 2 in. across, like that of a House-leek. The flower-stem is about 6 in. in height, and bears a multitude of blossoms in a dense head about 3 in. across. The individual flowers are about ½ in. in diameter, of a bright crimson colour, and they last a long time in good condition. It is a native of Iberia and is an old introduction, having been figured in the "Botanical Magazine" as far back as 1824; nevertheless, it is rarely seen in gardens. Associated with it at Kew is another charming plant—the *Sempervivum*-like Navel-wort (*Umbilicus Sempervivum*), which seems to be confused by some cultivators with the preceding, but the two are quite distinct. In foliage the last-named plant resembles a House-leek even more strikingly than the *Crimson Stonecrop*, inasmuch as it has a rosette of bright green leaves edged with a reddish colour. Its rosy-pink blossoms are borne profusely on stems springing from the base of the rosette, and therefore procumbent. It is a native of stony hills near the Caucasian Mountains. Both of these plants are quite hardy in this country, and are of easy propagation—the former by means of seeds, the latter by off-shoots. Both will thrive under the conditions generally afforded to hardy succulents.—A.

NOTES FROM KEW.

Hardy Shrubs.—*Philadelphus Gordonianus*, a tall shrub from British Columbia, now in flower in the Pleasure Grounds, has large white flowers, which are, moreover, strongly scented; it is a useful kind for the shrubby border. *Spiræa Douglasi*, a very fine North American species, grows about 6 ft. or 8 ft. high, and bears dense panicles of red flowers. *Veronica devoniensis* makes a very charming single specimen plant for a lawn; the one at Kew is a compact, cushion-like bush, 3 ft. or more in height, covered with spikes of white flowers, the purity of which is enhanced by the purple anthers.

Hardy Herbaceous Plants.—*Troutvetteria palmata* is an interesting and somewhat rare North American plant; it has lobed leaves and numerous, rather small, white flowers; the great number of the stamens, however, helps to render the plant tolerably conspicuous. *Thalictrum rugosum*, also a native of North America, is a noble kind with large panicles of straw-coloured blossoms; it attains a height of 6 ft., and is, altogether, one of the most striking of all the Meadow Rues. *Dianthus Segesivi* var. *Atkinsoni* is one of the most handsome of the beautiful genus to which it belongs; the brilliant crimson-scarlet blossoms are freely borne on branches which are about 1 ft. high. *Oxalis incarnata*, a very dwarf sort, has pale bluish flowers; and *O. floribunda alba*, growing about 1 ft. high, is one mass of white. The most noteworthy of the *Potentillas* at present to be seen in flower in the Kew collection are *P. Dethomaii*, 1½ ft. high, with large lemon-yellow flowers; *P. argrophylla*, 3 ft. to 4 ft. high, with clear yellow blossoms (the colour of the variety *P. argrophylla insignis* is slightly different from that of the type, and its height is only 2 ft.); *P. atrosanguinea*, 3 ft. to 4 ft. high, with blackish-crimson flowers; and *P. nepalensis*, 2 ft. high, with rosy-pink blossoms bearing a deeper blotch at the base of each petal. A distinct and handsome plant is *Sedum sempervivoides*; in habit it is remarkably like some of the House-leeks, and the flowers, which are borne in rather long panicles, are pink in colour. *Astragalus slopencroideus*, a Siberian Milk-vetch, growing about 3 ft. high, has whitish pinnate leaves, seated in the axils of which are dense clusters of large yellow flowers. *Centaurea macrocephala* is a splendid plant, which grows about 2 ft. high and has very large golden-yellow heads. *Cirsium aculeatum* has very pretty spiny leaves and purple flowers; it grows from 1½ ft. to 2 ft. high. *Senecio artemisioides*, worth a place in the herbaceous border, if only for its finely-cut leaves, has Groundsel-like heads of orange-yellow flowers, which are borne in large numbers on flower-stems about 3 ft. high. A Japanese species of this enormous genus (*S. Kämpferi*) is a beautiful and peculiar plant, with large, heart-shaped leaves and stout scapes, 4 ft. high, bearing numerous, shortly-stalked, large, golden-yellow flower-heads, for the topmost third or more of their length. *Arotheca grandiflora*, from the Cape of Good Hope, is a desirable plant, growing from 6 in. to 12 in. high; it is now a dense mass of bright yellow blossoms. Two very handsome Loose-strifeæ are *Lysimachia verticillata*, 18 in. high, a pale yellow-flowered species from the Caucasus, and *L. clethroides*, a Japanese plant, of much more recent introduction; in habit and colour the latter is totally distinct from all the other species of the genus known in gardens; the smooth, shining leaves set off beautifully the terminal, drooping spikes of white flowers. *Allium acuminatum*, from California, a charming plant with purple flowers borne on scapes 3 in. or 4 in. high, is an excellent plant for the front of the mixed border. *Milla ixioides* (or, as it is sometimes called, *Calliprora lutea*), another Californian bulb, has umbels of large, yellow, green-striped flowers surmounting scapes about 12 in. high. *Milla* (*Hesperocordium*) *hyacinthinum* var. *lactentum* grows 18 in. high and bears umbels of showy white flowers. An Anthericum named *A. Renarni*, a dwarf sort, little more than 12 in. high, has grassy leaves and white flowers, and is altogether a graceful plant. *A. ramoosum* is double the size of the last-named in all its parts, if we except the flowers, and these, too, are rather larger than those of *A. Renarni*. *Cypella Herberti*, a very lovely lily from Buenos Ayres, has large, handsome, orange-yellow flowers; the Kew plants grow well in the open border, and attain a height of 2 ft. or 3 ft. Two of the finest members of the Lily family are the gorgeously beautiful *Cslochortia venustus* (figured in THE GARDEN for February 5, 1876) and *C. splendens*; the first-named has blossoms about 3 in. in diameter and pure white, except towards the base of the wedge-shaped petals, where a blotch of deep crimson shades off into yellow and dark and light red. *C. venustus* has large flowers of a delicate pale rose colour.

Greenhouse Plants.—Few cool house plants surpass in beauty the Cape lily (*Dietes bicolor*); by far the larger part of the flower is snow-white, but yellow, brown, and pale purple help to make one of the most pleasing combinations imaginable. *Anomatheca cruenta*, one of the smaller-growing lilies, is a lovely little plant with scarlet blossoms. *Dyckia frigida*, a Brazilian Bromeliad, is an Aloe-like

plant; a tall, stout scape springs from the rosette of thick, green leaves, and bears a large number of orange-yellow flowers. The Mexican *Bouvardia triphylla* makes a splendid show when planted out in the conservatory, the rich scarlet of its numerous flowers being very vivid. *Callistemon rigidum* is a handsome New South Wales shrub, with very deep red flowers. *Beaufortia purpurea*, another Australian plant, is a neat-habited little bush with blood-red blossoms clustered at the extremities of the branches.

Stove Plant.—*Nelumbium aspericnle*, a garden hybrid of which one of the parents is *N. speciosum*—the Sacred Lotus of the early Egyptians—is, in some respects, even much more beautiful than that very lovely aquatic; the leaves are larger, as are also the flowers, which are as well a shade or two deeper and brighter in colour; the leaf-stalk, too, is much rougher.—†

THE MERIT OF CARPET BEDDING.

In a recent communication ("Art in Gardens," Vol. XIII., p. 539) I endeavoured to show what is, in my opinion, the demerit of the now dying "taste" known as architectural, geometrical, or carpet bedding. This crying demerit is, as I think, the unnaturalness of the whole system. However, I have long said to myself that it is impossible that any system altogether faulty can have for several years obtained the allegiance of numerous cultivated persons who can and do appreciate the beauties of landscape nature. Looking for the merits of carpet bedding, I found what is, I think, also a defect in the old-fashioned "mixed border" system, and in many attempts of gardeners unaccustomed to look at large and distant effects, viz., the absence of masses of colour, I appealed to my ever-ready teacher, Nature, in the matter. The answer I got was this: A varying sheet of greens, the old and young Grasses stretching into the blue of distance, interrupted here and there by billowy trees, green still but of varying shades; a woodland carpeted now with Violets dark or pale, now with Primroses, now with Anemones, again with Hyacinths or Foxgloves, as Nature flashes forth the varied lamps of her phantasmagoria; a meadow white with Daisies or Lady's-smock, golden with Buttercups or Marsh Marigolds, or ruddy with Fritillary; a down-side all ablaze with Furze or Broom, or left burnt in a brown robe of autumnal Bracken; a Cornfield red with Poppies, yellow with Charlock, or in its own glory of blue, green, silver, gold, and orange. Large masses of colour, now of shades softly blending, now in sharpest contrast, are extremely common in natural landscape; therefore, the lover of Nature wants them in his garden, and in the "carpet bed" he gets them. But he gets them unnaturally, for Nature's carpets are not geometrical like those of Kidderminster, Hyde Park, and elsewhere. The masses of colour I have spoken of generally mingle at their edges or "thin out" into a few scattered "outliers." They are sometimes roughly lenticular in outline, but hardly ever angular, never regular. The effect is one which may be readily obtained by the landscape gardener in the coppice, on the lawn, in the marsh, or in such a strip of unkempt Cornfield as I have formerly suggested might, in conjunction with a hawthorn, replace with advantage the high hedge or wall too often unsightly itself and also shutting out wild beauty beyond. Yellow has been fashionable this season, so I need not apologise for illustrating what I have just said by the following passage from a contemporary how Nature shades: "The cliffs present in different places, within an area of half a mile, different shades of yellow, very perceptible at a considerable distance. Thus in one set of places the cliffs are resplendent with the clear yellow of *Lotus corniculatus*; in another with the rich orange-yellow of *Hippocrepis comosa*; in another with the pale primrose of *Anthyllis vulneraria*; in another with the yellow heads of *Trifolium procumbens*, or the less conspicuously flowered, but leaf-spotted *Medicago denticulata*. Close by are large patches of Charlock, differing in tint, and a little later in point of opening than its near ally *Brassica nigra*. All these different shades of yellow are most marked and distinct, all occur within a few yards one of the other, and all exhale a marked perfume of their own not to be described in words, but easily recognisable." G. S. BOULGER.

11, Burlington Road, Westbourne Park.

THE FLOWER GARDEN.

GARDENING IN THE PARKS.

My time is chiefly spent in the country, but every year I endeavour to get a look at the London parks and their decorations, and I find that striving after the impossible is still the "order of the day." Tender plants, that should never be moved from under the shelter of glass, continue to be planted out-of-doors, the result of which is that bedding-out, as it is termed, lasts the whole year round; for as soon as a bed or a portion of a design shows signs of failing fresh arrangements have to be made. Under such circumstances the finished beauty of a place is sadly marred; even on the longest day I saw more empty flower-beds than one expects to see at Christmas, and the only sign of the fine foliaged plants (Palms, Musas, and Tree Ferns) that usually figure largely in sheltered nooks, was the holes in the turf from which they were removed at least eight months ago, and some even more; can anything be more unsatisfactory than this? Surely something more lasting should be substituted. London trees and shrubs are this year exceptionally fine in foliage, and, owing to the continuous heavy rains which we have had, as clean and bright as in a country park or hedgerow. Why, therefore, should the beds be bare? Our turf, as regards verdure, cannot be equalled; it forms the best and most natural groundwork for showing off to advantage the natives of any clime. But why we should almost exclusively employ subjects that cannot be ventured out-of-doors until the days are drawing in and London society just going away, passes comprehension. The effect is by no means improved, and, worst of all, the greatest charm of a garden, viz., repose, is effectually destroyed. I am by no means of opinion that visitors to a garden cannot enjoy its contents while the workmen are pursuing their duties, as the necessary work of a garden gives life to the scene; but when the system of planting causes such an accumulation of labour on one spot as to render it soiled and trampled like a battlefield, some alteration is desirable. If better results were obtained by the use of tender plants instead of hardy ones, such a state of things might be tolerated, but such is not the case; for side by side are usually found beds platted with more permanent subjects that do not require one-half the labour that those filled with tender plants do, and yet they are equally attractive both earlier and later in the season. The Maples, both plain-leaved, coloured, and variegated, are a host in themselves, and what can be more handsome than the Ailantus annually cut down, Aralias, and similar plants? while as to hardy flowering plants, are there not Delphiniums of every shade of blue, Irises in colours unequalled even by those of the choicest Orchids, Enotheras, Pæonies, Lilies, both delicate and showy, and Funkias, abundant in fine foliage? Musas and Tree Ferns are useful where proper situations can be provided for them, but they lose

their effect by too close and constant repetition, while the extra labour and attention which they require might be otherwise employed. It is not so much the extent of a garden as its condition that gives pleasure, and if hardy subjects be used in its decoration instead of tender ones, more time can be bestowed upon routine work.

J. GROOM.

ANNUALS AS BEDDING PLANTS.

It is generally admitted that the bedding-out system, as at present practised, cannot be satisfactorily carried out without the aid of considerable numbers of what are familiarly known as bedding plants, such as the Pelargonium, Verhena, Ageratum, &c., and this to a certain extent is true, and the preparation and protection of the requisite number of these tender plants in places where glass accommodation is constricted is frequently found to be a task of no inconsiderable difficulty. It is possible, however, to supplement the number of plants required for this purpose to a greater extent than is usually done, by the use of annuals, and of various kinds of perennial plants raised from seed sown during the spring of the season in which they are expected to bloom, or, in some cases, during the previous autumn, and treated as annuals. It is even found to be possible to induce the Zonal Pelargonium, the admitted *sine quâ non* of the bedding-out system, to conform to this treatment, although seedlings must not be expected to bloom so early as plants propagated by means of cuttings. To ensure as far as possible, however, their early flowering, the seed should be sown not later than September, or as early as the seed can be obtained in a ripe condition. And the young plants may be wintered in the pans in which the seed was sown, keeping them in a light, airy situation, and near the

Rustic Garden Bridge, with Weeping Evergreen and Deciduous Trees on Shores of Islands.

glass. Each ordinary or 10-in. seed-pan may contain from fifty to one hundred plants, so that during winter they will occupy but little space; and towards the latter part of February they should be pricked out into other pans or boxes, in order to give them additional space; and for a week or two they should be kept in a somewhat close atmosphere until the young plants become established. In April they may be potted off singly into 3-in. pots, shortening or cutting the rootlets well back at the same time, with the view of somewhat checking the luxuriance incidental to seedling plants, and promoting the early production of bloom. On this account rich soil should also be avoided. As soon as the plants have become established in their pots, the shelter of a cold pit or frame will be all that is required in the way of protection until the state of the weather will permit them to be planted in the beds or borders which they are intended to occupy. It will thus be seen that seedlings will occupy less space during the greater part of the winter than a similar number of rooted cuttings, or plants lifted from beds in autumn; and, if treated as recommended, they will generally begin to bloom about the middle

of July. Beds furnished with such plants may not be so gay early in the season as those filled with plants raised from cuttings; their general appearance may be somewhat irregular, owing to diversity in habit of growth, and there may also be considerable variety in the shades of colour, but these and similar little drawbacks will be amply compensated for by the interest which is inseparable from watching the gradual development of seedling plants, and the knowledge that new and improved forms may possibly be detected amongst them. With the view, however, of securing meritorious varieties, it is, of course, necessary to save the seed from the very best sorts.

The *Petunia* is also a plant which may be raised from seed sown in the early part of the season in which it is intended to flower—say about the middle of February—and thus treated, it proves to be a most effective bedding plant. Its seed should be sown in pans and placed in heat until the plants have fairly vegetated, when they may be subjected to the temperature of an ordinary greenhouse until they have become sufficiently strong to bear handling; they should then be pricked out into other pans or boxes, in order to give them increased space, and afterwards they should be potted into 3-in. pots in April or early in May, so as to be fit for planting out in beds at the end of the last-named month. *Petunias* make exceedingly pretty beds, and continue in good condition until the very end of the season. If the seed be saved from any particular variety, placed at some considerable distance from other plants of the same species, the probability is that the seedlings will differ but little, if at all, from the parent plants. If, on the other hand, however, the seed be saved from a mixed collection, the varieties obtained will exceed in number those of the plants which produced the seed. If beds of double-flowered kinds be desired, a few of the best single kinds should be selected and grown in a light pit or frame, and, as these come into flower, carefully remove the anthers of a few of the blooms of each plant before the pollen is ripe, and about two days afterwards apply to the stigma, by means of a small camel's-hair pencil, a portion of pollen from the flowers of some of the best double kinds. Such plants, however, do not generally produce pollen in great abundance, so that it must be carefully searched for. When the bloom has been properly fertilised each ped will be found to contain a great number of seeds, so that the produce of even a few blooms will furnish sufficient plants to fill a bed of considerable dimensions. Not more, however, than 25 per cent., if so many, can be expected to produce double flowers, and although these may almost be selected by their foliage and general appearance before they have even bloomed, it is, nevertheless, best to get the plants as forward as possible, and to select them as their first blooms expand and furnish the intended bed progressively. Few beds can be more gay and attractive than one planted with single-flowered *Petunias* of good sorts, whether of one colour or mixed, and a bed of the double-flowered kinds; although, in the latter case, there may be less profusion of bloom, the bed has, nevertheless, a very rich and remarkable appearance.

The *Lantanas* are suitable plants for the flower garden, and during late years they have been greatly improved. They flower freely enough if not over luxuriant, and in order to check this tendency the soil composing the bed should be light, and stimulating manures should, in their case, be avoided. The seed should be sown in heat about the middle of March, and the seedlings should be pricked off into pans when sufficiently large, and afterwards potted singly. They will be fit to plant out about the end of May, and will continue to bloom throughout the season. The only drawback to the use of these plants is their somewhat disagreeable odour.

Lobelia speciosa or some of its varieties is indispensable in all styles of flower gardening. It can be and often is increased by means of cuttings, but seedling plants from a good strain give less trouble, occupy less space during winter, and are much to be preferred. The seeds, which are very minute, may be sown in heat in March, but the plants come more robust when the seeds are sown earlier, say about the end of January, in a cool pit or greenhouse, and the pot or pan in which they are sown should be covered with a piece of glass until they have fairly germinated. The seedlings, when large enough, should be pricked off into pans, in order to give them addi-

tional space, but in their case potting singly is not at all necessary, and they may be allowed to remain in the pans until they can be transferred to the beds or borders which they are intended to occupy. There are various varieties, most of which are good, and they generally come true from seed, if the latter has been carefully selected, *i.e.*, from plants which have not been in contact with other varieties.

Pyrethrum Golden Feather, on account of the delicate yellow colour of its leaves, is of great value in the flower garden, in which it is much used as an edging plant for beds and borders, ribbon lines, carpet bedding, &c. It is a perennial and quite hardy, but seedlings are better than plants propagated by means of cuttings, being less prone to run to flower. It ought to be always treated as an annual, and the seed should be sown early in March in pans placed in a gentle heat. From these the plants should be pricked off into other pans or boxes until they can be transferred to their places in the open air. There is a variety of this plant with cut leaves of the same shade of colour, but quite distinct in form, and this, as well as the type, comes true from seed.

The dwarf varieties of *Ageratum*s may all be treated as annuals, and the seed should be sown in heat about the end of February or early in March. The plants will begin to bloom soon after they are planted out, but, being somewhat tender, they should not be put out before the last week in May. Seedlings, however, sometimes lack the uniformity of plants propagated by means of cuttings, and on that account the latter are generally preferred.

Some of the hybrid annual varieties of *Tropæolum*s are useful as bedding plants, and some of the climbing kinds are invaluable for clothing pillars, trellis-work, rough walls, rock-work, &c. In preparing beds for the dwarf kinds the soil should not be made too rich, and the seeds may be sown where the plants are intended to remain; or they may be sown in pans under glass about the middle of April and planted out about the third week in May. Some of the best bedding kinds are *Advancer*, *Ball of Fire*, *Eclipse*, *Firefly*, and *Mrs. Treadwell*.

Rhodanthe Manglesi is one of our prettiest annuals, and, where soil and situation can be made to suit it, it forms a very pretty bed in the flower garden. The beds intended for its reception should be of considerable depth, and should consist of light, rich materials, such as turfy loam and leaf-mould. The young plants should be raised in gentle heat and should be pricked off into pans when large enough to handle, or they may be potted singly into small pots and planted out soon after the middle of May.

Dwarf kinds of *Antirrhinum*s form interesting beds. The only objection to their use for this purpose is their want of persistence, although they are exceedingly floriferous and ornamental for a time. Seeds of them should be sown in slight heat about the beginning of March.

Dianthus Heddewigi is a remarkably pretty bedding annual, and one which continues in bloom during the greater part of the season. The double-flowering kinds are great improvements upon the single sorts, and for the production of cut flowers they are invaluable, the individual blooms being full, beautifully imbricated, and of various shades of colour, from pale lilac to the darkest crimson and violet-black. The central part of the blooms is generally barred or mottled, while the margins are elegantly fringed with silvery-white. All the varieties of this *Dianthus* continue in great beauty throughout the greater part of the season, and they may be safely recommended as interesting and beautiful bedding plants. The seed should be sown in pans about the end of March, be gradually hardened off, and finally planted out about the middle of May.

The numerous varieties of *Phlox Drummondii* may be regarded as among the very best of annual bedding plants, and many greatly improved kinds have of late been introduced. Possibly the best of all, however, is a new variety which has been sent out under the name of *P. Drummondii alba oculata superba*, which certainly appears to be a gem. Although it is vigorous in habit, it does not exceed 10 in. in height, and it produces numerous large, full trusses of flowers of good form and substance, the individual blooms being fully 1 in. in diameter. The colour is pure white, with a bright crimson

centre or eye covering one-third the diameter of the bloom, which has altogether a peculiarly rich and waxy appearance, and the plant appears to come remarkably true from seed. It is quite possible that this variety may become a popular bedding plant. There are several other varieties of this beautiful Phlox, such as *P. Drummondii grandiflora splendens* and *P. nana compacta*, the last named being remarkably dwarf in its habit of growth, and the flowers are of a bright fiery-red colour. The seeds of the various annual Phloxes may be sown in slight heat about the end of March, and the treatment should, in all respects, be similar to what has been recommended for other half-hardy annuals.

To the above list of annual flowers many others might doubtless be added. Those named, however, will, I think, be found to be amongst the most effective and suitable for associating with the various varieties of ordinary bedding-out plants.

Culford.

P. GRIEVE.

VARIETIES OF FOXGLOVE.

I KNOW of many good things which may be had for threepence. You may go a long way in an omnibus for that sum. You may buy a copy of the "Times" with it. In beer or Tobacco it will procure a real amount of satisfaction. You may for that modest sum insure yourself before taking your seat in a railway carriage for an almost fabulous sum; and if in this case you receive nothing in return for your money, at least you can hardly grumble that it is because you came off with a whole skin. But of all the threepenny bits I ever spent, I have got most satisfaction out of one which early in last year I gave to Mr. Thompson, the seedsmen of Ipswich. In return he gave me a small packet of seed of *Digitalis gloxinoides*. This was scattered at the back of a peat border newly planted with Rhododendrons, and the result at this season is a really wonderful display of beauty. The flower-spikes are unusually tall; I measured one to-day over 8 ft. high, and with more than 180 blossoms and buds on it. The colouring of some varieties is pure white; others, white with large or small blotches of black or purple; others, again, are rose, with large blotches of black. The effect of the group against a background of dark trees is very fine. As the Foxglove is a biennial, the seed should be scattered yearly over bare places; for instance, where hedges or bushes have been removed, or in the back lines of shrubberies. If the ground be kept without Grass the Foxgloves will reproduce themselves in the same spot year by year, but if not then, bare places must be sought for them. They appear to do remarkably well in peat.

SALMONICEPS.

IRISES IN FLOWER AT KEW.

To the section of Iris to which the well-known English and Spanish Irises belong the generic term *Xiphion* is now applied, and, as defined, includes those kinds which have a bulbous root-stock, combined with certain other peculiarities in the structure of the flowers. Of this section there are at present in flower three or four species worthy of mention, both on account of their beauty and rarity. *X. tingitanum* is a noble kind, about 2 ft. in height, and of very robust habit; its flower-stems, which are freely produced, bear from one to three blossoms, about 5 in. across, and of a deep rich purple colour. It most resembles the English Iris (*X. latifolium*), but is a much finer plant. It is a native of Tangiers, discovered a long time ago, but is very rare in cultivation. The plant figured recently in the "Botanical Magazine" under the above name is not identical with it, but is a broad-leaved variety of the slender-leaved *Xiphion* (*X. filifolium*), which is also in flower. It is not so fine as the preceding, but is, nevertheless, a very desirable kind. It is distinguished by well-marked characters. The outer membranous leaves are profusely spotted with a reddish-purple colour, and its flowers, which are borne singly on stems about 1 ft. high, are of a bright purple colour, which agreeably contrast with the bright yellow throat. It is a native of the Mediterranean region, and was introduced about ten years ago by Mr. Maw. The Rush-leaved *Xiphion* (*X. junceum*) is a charming kind, with Rush-like and spirally-twisted leaves, much resembling the Portuguese sort (*X. lusitanicum*),

but is more slender in all its parts and later in flowering; it is also a native of the Mediterranean region, but is still rare. *X. Sisyrinchium* is a little gem about 6 in. high, bearing blossoms, about 2 in. across, of a lilac-purple colour, with a creamy-white centre, but which unfortunately lasts but a day; several flowers are, however, borne in succession from the same flower-stems; it is an old garden favourite, having been cultivated by Gerard as long ago as 1591. Of the true Irises, three of the yellow-flowered kinds are worth mention. *I. Monnieri*, a kind growing about 3 ft. in height, has pure bright yellow blossoms about 6 in. across; it is a native of Crete, and is one of the finest of the genus, though rarely seen. The Himalayan Golden Iris (*I. aurea*) much resembles the preceding, but has flowers a shade darker in colour and much crisped at the edges. *I. ochroleuca*, better known perhaps as *I. gigantea*, is also a desirable kind with the habit of the last two sorts, but with very large white flowers with a yellow throat. *I. notha* is a near ally of the better known *I. spuria*, but has blossoms of a delicate lavender colour. The tawny Iris (*I. fulva* or *I. cuprea*) is one of the few kinds which have all the divisions of the flower spreading; it also possesses a colour quite distinct from that of any other Iris, being of a reddish-brown, much resembling *Hemerocallis fulva*; it is a native of the United States, and, although it has been introduced many years, is still rare in gardens. A.

ORCHIS LATIFOLIA.

IN THE GARDEN (Vol. XIII., p. 565) there is a well-deserved recommendation of this Orchis as a garden plant, the only objection to its general adoption being the high price charged for it by the dealers. I also observe that this week *Orchis latifolia* is mentioned as well worthy of cultivation. I believe that, under the right conditions, it might be made to rival *O. foliosa*, for I have seen it in a wild state with flower-heads as large as any I have seen of *O. foliosa* in gardens. In the corner of a meadow, about two miles from Eton, is a swampy spot planted with Willows for pollarding, and covered with *Arundo phragmites* (common Reed), the black soil being saturated almost to the surface with water for a great part of the year. Early in 1876 the Willow branches were cut and the surface was cleared. There followed, in June, an abundant and luxuriant flowering of *O. latifolia*, some of the flower-heads being fully 1 ft. long and closely set with blossom. In 1877, when the surrounding growth of Reeds and other rank herbage was greater, the number and size of the flowers were much diminished, and this year there are hardly any to be seen, though I believe the bulbs are still dormant in the ground, and would produce a growth similar to that of 1876 under similar circumstances. Another spot in which I have more than once seen *Orchis latifolia* with flowers equally conspicuous for size is a Willow bed on the north side of the railroad between Reading and Theale, about a mile from the latter place whilst passing in the train about the middle of June. Will any of your readers tell me whether *O. latifolia* is really specifically distinct from *O. maculata*? In the locality mentioned, near Eton, they grow side by side; where the ground lies higher the form is maculata, but where a swampy hollow intervenes *latifolia* (or *incarnata*) is the prevailing type. The extremes are distinct enough, but I find amongst them intermediate connecting forms in which no distinct line of difference can be drawn—the lighter the colour of the flowers, the slenderer the stalk, and the greater the tendency to spotted leaves; but this rule is not without exceptions. By *O. latifolia* I understand the commoner form of the Marsh Orchis, without spots on the leaves and with rosy-purple flowers, though this form is figured in Sowerby's "British Botany" under the name *incarnata*. C. W. Dod.

The Night-scented Stock.—In Vol. XIII., p. 629, are some remarks on a picture entitled "The Night-blowing Stock," which should evidently have been "The Night-scented Stock," a plant that, I presume, passes under several names, as what the writer calls *Mathiola tristis* is clearly the same as I have seen growing under the name of *Cheiranthus odoratissimus*, but in procuring it from a nursery the best way would be to describe it as the night-scented Stock. It is a plant that is singularly unfit for a picture, as its flowers are

of a dingy stone colour, and, from a decorative point of view, are valueless, but after sunset they emit a delightful fragrance. For this reason the plant is useful in balconies and window boxes. It is easily increased by means of cuttings made of half-ripened shoots, and it grows freely in ordinary garden soil. It is tolerably hardy, having withstood ordinary winters in open boxes, but it is best to keep some reserve plants of it under slight protection. That the artist in question should have selected Poppies and Rockets in preference to so dingy a flower, and yet borrowed its more romantic title, is not to be wondered at while the rage for brilliant colours lasts. Really, night-flowering plants, of which *Ipomœa Bona Nox* is a familiar example, are totally distinct from night-scented flowers, but most of these are curiosities rather than valuable for their serviceable qualities.—J. GROOM.

LILIUM HANSONI.

"A. W." (Vol. XIII., p. 613) states: "L. *Hansonii* we had over from Japan in the winter of 1869-70, and offered three bulbs of it for sale at Stevens', one of which was purchased by Mr. Wilson, another by Mr. Barr, and the third by Mr. Bull." Will you allow me to say that if this statement is intended either to assert or to imply that the bulb of the Lily exhibited by me, and named first *L. avenaceum* and afterwards *Hansonii*, was bought either at Stevens' in 1869-70, or from Dr. Wallace, or from the Colchester New Bulb and Plant Company at any time, it is entirely incorrect. As *L. Hansonii*, from its beauty of foliage, fine and distinct flowers, and pleasant scent, is likely, when introduced in larger quantities, to be a very popular Lily, you may, perhaps, like a short account of its first appearance in England. Having bought a remarkable Lily bulb, it was kept by itself; the next year, on re-potting, the bulb was found to be decayed, but with signs of life in some pieces of it; these were carefully nursed (morul, use of amsters; in a busy nursery these would have had no chance), and the result was in 1875 a Lily with very remarkable foliage and buds. As these opened when I was fishing in Scotland, a flower was sent me by post, when, seeing it to be new, I directed the pot to be sent up to the Royal Horticultural Society's Floral Committee, and a flower-stem to be sent to Kew. At the committee meeting it was awarded only a second-class certificate (in its not fully-developed state it scarcely does itself justice), and at Kew it was considered to be *L. avenaceum*. Afterwards, owing to the bulb not showing the Ost-like scales characterising *L. avenaceum*, further research showed it to be *L. Hansonii*.

In October, 1877, my friend M. Max Leichtlin, of Baden, sent me a small bulb of *L. Hansonii*. On his reading the account of the *L. avenaceum* exhibited by me, and seeing that it corresponded with the description of *L. Hansonii*, he wrote asking if I had not made a mistake, and if the plant exhibited was not from his bulb of *Hansonii*. My garden book of course proved the contrary, showing two pots of *L. avenaceum* and the one of *L. Hansonii* received from him; this last had not yet bloomed, but its foliage made it probable that it would prove identical with *L. avenaceum*. I lately showed, at South Kensington, *L. Hansonii* in full flower, when it was greatly admired and awarded its proper honour—a first-class certificate.

"A. W." speaks of *L. Szovitzianum*. It bloomed well here, but to see it in perfection a visit should be paid to the Edinburgh Botanic Garden, where Mr. McNab, who appears to concentrate his energies on this particular Lily, grows it beautifully under the name of *monadelphum*, and, having raised a large bed of seedlings, has numerous varieties of form and colour and of spotting and non-spotting.

I am glad to see that "A. W." is growing *Alice Wilson*; it is a most distinct Lily. When I took the first plant (named after my daughter) to Kew, Mr. Baker told me that he and Mr. Elwes had just been questioning the correctness of a Japanese drawing of it. I believe the Japanese descriptions and drawings to be at least as trustworthy as some from nearer home, and therefore that there are still treasures in the Lily way to be expected from Japan, notably, a *L. Kramerii* of much more intense colour than has ever been exhibited here. I once had a small abortive flower which went far to confirm this.

GEORGE F. WILSON.

Heatherbank, Weybridge.

Aponogeton spathaceum, growing at Kew among the aquatic, promises to be a lovely hardy water plant. The leaves are Rush-like, and blossoms miniature, white twin flowers of great beauty; the plant is very dwarf.—FRANK MILLS, Bingham, Notts.

Spiræa palmata.—This is truly a glorious plant; the foliage, which is always ornamental, assuming beautiful tints in autumn; the stems too are of a deep red and carry broad corymbs of crimson-purple flowers. It makes a fine plant for herbaceous or shrubby borders, and it is a useful plant for pot culture, combining, as it does, a flowering and fine foliage plant in one and the same specimen.—J. GROOM.

GARDEN BOTANY.

(Continued from Vol. XIII., p. 627.)

SUPERPOSITION AND ALTERNATION OF THE PARTS OF A FLOWER.—The usual mode of insertion of the parts or members of one organ in relation to those of others, or rather those of one whorl in relation to those of another, is alternation; that is to say, the median lines or centres of the petals are midway between the median lines or centres of the sepals, or coincident with

Fig. 281.—Diagram of flower of *Sedum oppositifolium*.

Fig. 282.—Diagram of flower of Violet.

the line where two sepals meet, or are joined, the stamens midway between two petals and standing straight before the sepals, and the carpels in the same position with regard to the stamens (see fig. 281, &c.). In *Sedum* (fig. 281) the petals alternate with the sepals, and five of the stamens are alternate with the petals, while the other five are superposed to the petals, or what is generally termed opposite to the petals.

Fig. 283.—Diagram of flower of Grape Vine.

Fig. 284.—Diagram of flower of *Cyclamen europæum*.

Opposite is the word commonly used to indicate that one stamen stands immediately in front of a petal, or a petal in front of a sepal, &c.; but as these organs are not opposite to each other, not inserted in the same horizontal plane as opposite leaves, the term superposed is preferable. In the Grape

Fig. 285.—Four-parted flower of *Asperula*.

Fig. 286.—Six-parted flower of *Eurycles*.

Vine and *Cyclamen* (figs. 283 and 284) the stamens are of the same number and superposed to the petals.

FLOWERS OF MONOCOTYLEDONS AND DICOTYLEDONS.—There are no absolute characters in the flowers of these two classes of plants by which they may be distinguished, but generally speaking the parts of the flowers of dicotyledons are in fives or fours, or some multiples of five or four (figs. 283, 284, and 285), and when the floral envelope is single the parts are not usually petaloid, that is, like petals. The parts of the flowers of

monocotyledons, on the other hand are commonly in threes or some multiple of three, and the parts of the perianth are nearly alike in shape (except in Orchids, &c.), and petaloid (fig. 286). There are many exceptions to these rules, notably the Grasses and Sedges among monocotyledons, which have their flowers enclosed in chaffy scales.

REGULAR AND IRREGULAR FLOWERS.—A flower is regular when all the parts of each whorl are alike, no matter what their shape, as those of the Buttercup, Columbine, and Peganum (fig. 287), irregular when the sepals differ in shape, as in the Violet and Aconite (fig. 288), or when the petals are unequal in size, as in Pelargonium and in Salvia (fig. 289).

DOUBLE FLOWERS.—What are termed double flowers by gardeners belong to three or four distinct classes. First, there are the so-called double flowers of plants belonging to the natural order Compositæ, the capitules or flower-heads of which

Fig. 287.—Regular flower of Peganum

Fig. 288.— Irregular flower of Aconite.

have already been adequately described. The ordinary wild Dahlia (fig. 290) has flower-heads with broad, flat, ray flowers, whilst those of a different colour. In a double Dahlia all the flowers are alike, and different from either the ray or disk flowers of the wild form, being large, like the ordinary ray flowers, with the margins rolled inwards. This metamorphosis or transformation of the flowers is not uncommon in the Compositæ, and includes Zinnia, Aster, Chrysanthemum, Marigold, and Daisy. In Zinnia and Marigold all the disk flowers are transformed into strap-shaped (ligulate) ones similar to those of the ray. Of Asters there are several races of varieties. The Quilled varieties have the

Fig. 289.—Irregular flower of Salvia.

disk flowers elongated, though retaining their tubular shape and forming a hemispherical or almost globular head; and in the Pæony-flowered and other varieties the disk flowers are flattened like those of the ray. Some of the Japanese varieties of Chrysanthemum have all the flowers, or those of the ray only, enormously elongated. Secondly, there are double flowers, resulting from a transformation of some or all of the stamens into petals, as in the double-flowered Cherry (fig. 292) and the Wood Anemone (fig. 293). In the former there is often every stage of transition from a perfect stamen to a perfect petal; and, what is still more remarkable, the pistil is transformed into or replaced by green leaves similar to the ordinary foliage leaves. Anemones, as is explained elsewhere, have no true petals, the white or coloured organs being petaloid sepals; and in the double-flowered varieties the stamens are transformed into petaloid bodies. A gradual transition from petals into stamens occurs in the normal flowers of the white Water Lily

(fig. 294). Double flowers of this class occur in very many different natural orders, but they are extremely common in those having numerous stamens, as the Ranunculaceæ (Clematis, Anemone, Ranunculus, Aquilegia, Delphinium, &c.) and Rosaceæ (Rosa, Rubus, Pyrus, Prunus, Cratægus, Spiræa, Kerria, &c.). The Camellia also belongs to this class. Thirdly, there are double flowers resulting not alone from the transformation of stamens into petals, but mainly from a multiplication of the number of floral whorls. The normal Violet has only five petals and five stamens, the Pink five petals and ten stamens, the Balsam five petals and five stamens, the Pelargonium five petals and ten stamens, the Fuchsia four petals and eight stamens, and the Primula five petals and five stamens; whereas, many of the double-flowered varieties of each and all of these plants have exceedingly numerous petals or petaloid organs. Where there is an actual increase in the number of floral whorls there is a real doubling of the flower.

Fig. 290.—Dahlia, in which the flowers of the disk are different in shape from those of the ray.

Fig. 291.—Dahlia, in which all the flowers of the head are alike, forming what is called a double Dahlia.

Double flowers of these three classes are not necessarily barren, for the pistil is often quite perfect, and occasionally some of the stamens, but there are some double Tulips in which both stamens and pistil are transformed into petals. Fourthly, there are the so-called double flowers of Hydrangea and Viburnum Opulus. In the single Hydrangea (fig. 295) the flowers around the circumference are larger than the others and barren; and, on examination, it will be found that it is the sepals which are enlarged, all the other parts being rudimentary or suppressed altogether. In what is called the double-flowered Hydrangea, all or nearly all the flowers are thus transformed. The wild Guelder Rose (Viburnum Opulus) has the outer flowers enlarged and sterile; and in a cultivated variety, known as the Snowball tree, all the flowers are so, forming a globular inflorescence.

SIZE OF FLOWERS.—Perfect flowers range from 1-16th in. in diameter (Bæckea arbuscula) to 3 ft. or more, as in Rafflesia Arnoldi.

DURATION OF FLOWERS.—Flowers of considerable substance, such as Fuchsia, Magnolia, Nymphaea, Echeveria, Yucca, Stapelia, last for many days; on the other hand, there are some that open in the morning and close in the evening, never to re-open. One of the most striking examples of this ephemeral duration is offered by the genus *Cistus*. Banks of these

Fig. 292.—Double flower of Cherry.

Fig. 293.—Double flower of Wood Anemone.

shrubs during the flowering season are an attractive sight on a sunny morning, when the bushes are covered with fully-expanded blossoms; but by sunset of the same day not a flower is visible, and it seems almost impossible that they can be the same we saw in the morning. The individual flowers of the Day Lilies, Poppies, Flax, &c., last only one day, though this short duration of the separate flowers is amply compensated for by the long succession of flowers produced by most plants having this peculiarity.

Fig. 294.—Transition of petals to stamens in *Nymphaea*.

HOOR AT WHICH FLOWERS EXPAND.—Different plants exhibit great diversity in this respect. *Cereus Macdonaldiae*, the night-flowering Cactus, as its popular name implies, blooms only during the night. The flowers expand after sunset, and close again on the break of day. Some flowers open only under the influence of sunlight, and soon close again if the sun is obscured; and there are flowers which open at nearly every hour of the day. Payer enumerates the following plants and the hours at which they expand at Paris: *Convolvulus sepium*

Fig. 295.—Single-flowered *Hydrangea*.

begins to open at 3 a.m., *Tragopogon pratense* (Salsify) at 4, *Papaver nudicaule* (Alpine Poppy) at 5, *Convolvulus tricolor* at 6, *Nymphaea alba* (white Water Lily) at 7, *Anagallis arvensis* (Poor Man's Weather-glass) at 8, *Calendula arvensis* (common Marigold) at 9, *Mesembryanthemum glaciale* (Ice plant) at 10, *Ornithogalum umbellatum* at 11, *Portulaca oleracea* at noon, *Scilla pomeridiana* at 2 p.m., *Mirabilis jalapa* at 5, *Silene noctiflora* at 6, *Cereus grandiflorus* at 8, and *Convolvulus purpureus* at 10. The time of opening and closing of flowers

and the influences under which they open and close are more deserving of the attention of the practical gardener.

ODOURS OF FLOWERS.—The odours of flowers are almost as diversified as their colouration, but we can merely touch upon this subject here. White flowers, as a rule, exhale the most agreeable odours, though there are not wanting brilliantly-coloured flowers, as well as some with very inconspicuous greenish flowers, which are highly fragrant. To the latter category belongs Mignonette. Lavender, Violets, Tea Roses, &c., have characteristic scents. The Dandelion has an unpleasant smell, whilst those of most *Stapelia*s are absolutely fetid, and as offensive as carrion. W. B. HEMSLEY.

THE FRUIT GARDEN.

ORIGIN OF THE CULTIVATED APPLE.*

THERE is evidence that the Apple was employed as food in certain parts of Europe at a very ancient period, perhaps even before the period of written history. The carbonised seeds and fragments of Apples and other fruits are found in the mud of certain lakes in Switzerland, where the pile-builders or lake-dwellers had their habitations. These remains have an age variously estimated at from 5000 to 50,000 years. It might be supposed that these vestiges were wild or Crab Apples, the native produce of the country, and such is probably the fact. But, according to Prof. Karl Koch, there are no species of Apples truly indigenous in Europe, those which are found growing without cultivation being only escapes from cultivation, or the result of accidental sowings of common Apple seeds. If this statement is correct, the question arises, Whence came the Apples and fruits of the pile-builders? The same question might be propounded with respect to the Wheat which is found in the *débris* of their dwellings, and the answer to the one question would probably be an answer for the other. It is not improbable that the distribution of grains and fruits among the nations of the earth has a much greater antiquity than has commonly been admitted. In attempting to determine the original specific character of our common Apple we have to deal with a difficult question. The Apple of the present day is the product of centuries of cultivation and horticultural skill, and the transformations and modifications effected thereby are such that we need not be surprised if we are now unable to recognise the original or parent stock. Linnaeus named the common Apple of cultivation *Pyrus Malus*, taking as the type the common seedling Apple, which he appears to have considered a good species, and the same view has been generally entertained by succeeding botanists. But scientific inquiry has been greatly stimulated and extended within the past half century, and theories and opinions that once passed current have been subjected to the severest scrutiny. In the investigation of scientific as of moral questions, when doubt obtains license, it sometimes happens that new ideas are pushed to an extreme. Let us, then, briefly consider the argument in this case.

In the first place, it is asserted that if our cultivated Apple were a distinct species, it would yet be found growing in a wild state in the country or countries where it originated. It is generally admitted that the earliest human civilisation took place in Western Asia, and in that country, or in Southern Europe, we should naturally expect to find the Apple in its native condition. But, according to Prof. Koch, there is no truly wild Apple to be found in these countries, the so-called wild Apples being merely such as have escaped from cultivation. According to his view, the Apple of cultivation is the result of crossing and intermingling through many generations of four and perhaps five species of *Pyrus*, some of which are still growing in an indigenous condition in some parts of Asia. These original species he considers to be, first, *Pyrus pumila*; second, *P. dasycphylla*; third, *P. sylvestris*; fourth, *P. prunifolia*, and perhaps *P. spectabilis*. These will be subsequently mentioned more particularly. I will here only state that of these five species Prof. Koch expresses doubts as to the true specific character of two, and suggests that they may have originated

*By Dr. George Vasey, Washington, D. C., in proceedings American Pomological Society.

through long culture by the hybridising of some of the other species. The native country of one is China, and of the others, Northern China, Siberia, Caucasus, and Tartary. The remote localities of these species from the supposed centre of early civilisation will, to some minds, bear argument against counting them as the parents of the present cultivated Apple. It may also be said that the fact of the common Apple being nowhere now found in a truly wild state, does not amount to proof that it had not a separate specific origin, for it is well known that many other cultivated plants of the greatest importance as food for the human family are not now found in a wild state. Many plants in their native condition have comparatively feeble hold on existence, growing very sparsely and in a few restricted localities, and we can readily understand that such plants, unless taken up and fostered by cultivation, would soon disappear before the advance of civilisation. For example, although it is probable that the original of our Potato (*Solanum tuberosum*) is yet to be found in some localities in South America, it is not at all improbable that in a few centuries the botanist may search its native land in vain for any vestige of the wild plant.

If our cultivated Apple were a hybrid, the produce of a mixture of several species, we might expect that the law of reversion would reveal to us its true parentage. It is claimed that a correct and satisfactory result from the action of this law could be reached only by a series of experiments continued with the greatest care for many generations. Prof. Koch states that experiments with the common garden Aster, which is cultivated in a great variety of forms, have taught him that all the forms of that plant after six, eight, or ten years revert to the original type. We would inquire if it may not be possible that Prof. Koch has not over-estimated the changes and modifications which cultivation has made upon our Apple. There are, it is true, several hundred varieties known to cultivators, but the larger portion of them have originated in recent times. That all these varieties have a not very distant origin would seem to be indicated by the substantial resemblance of the seedlings raised from such widely diverse varieties. In tracing the history of this fruit it is not necessary to go back to an imaginary period when it was so inferior in size and flavour as to be unpalatable and totally unfit for use. Of all the eastern species which have been claimed as parents of the cultivated Apple, not one probably equals the common American Crab in acerbity. Nature produces many other fruits of acknowledged excellence in a wild state, as, for instance, delicious Strawberries, Raspberries, Blackberries, &c., to say nothing of very passable wild Oranges, Figs, and numberless other tropical fruits. Having once obtained a superior variety of fruit, the skill of the horticulturist is employed to multiply and perpetuate it by the processes of grafting and budding, processes which preclude to a great extent any further deviation, because they are asexual and artificial processes. Natural variation manifests itself principally through the action of the floral or sexual organs of plants. This action, whatever may be its nature, is impressed upon and fixed in the seed. The most of our cultivated varieties, including some of the best, have originated spontaneously, that is, without purpose or anticipation on the part of man, but we are unable to perpetuate those varieties by means of the seed, the common course of seedlings from all varieties being to revert to an inferior form; hence, we may reasonably suppose that the ordinary seedling represents somewhat fairly the original form of the species.

Having thus stated various opinions respecting the origin of our cultivated Apple, we will now give a brief sketch of the different wild species, all of which are inhabitants of the Northern Temperate Zone.

The genus *Pyrus* is classed in the natural order Rosaceæ, the family which includes the Rose. It will not be necessary here to give the botanical characters of the genus, but we will only state that it is subdivided into several sections, as the Apple section (*Malus*), the Pear section (*Pyrophorum*), and some botanists add as another section *Sorbus*, or the Mountain Ash section. We do not propose to speak of any but the section *Malus*.

In enumerating the species, we will place first in order the five species which Prof. Koch supposes to have contributed to the production of our cultivated Apple, and of these, as we

have before stated, he expresses doubts respecting the real specific nature of two, thus reducing the number of fundamental species to three; then we will add the remaining indigenous species, which he does not suspect to have had any participation in what he regards as our hybrid.

1. *Pyrus pumila*—Mill (*P. Malus* var. *Paradisiaca*—L.).—This is called the Paradise Apple, and in France the *Dumica* and *St. John's* Apple. Its native country is said to be South-eastern Russia, Caucasus, Tartary, and the Altai Mountains. It forms only a low tree, or sometimes a tall shrub. The leaves are elliptical, and woolly on the under surface. On account of its rapid and low growth this is principally used as a stock for dwarf Apples.

2. *P. dasycphylla* (Bork).—This is enumerated by Professor Koch as a species, and yet he says that it is certainly nothing more than an Apple tree become wild, and was counted by the elder Koch in 1843 as *P. Malus*, variety *tomentosa*. Prof. Koch says it does not now grow truly indigenous in the East, and asks if it may not have arisen through long culture. Linnaeus, indeed, considered this as the original of the cultivated Apple. It is found in cultivation in Europe under many different names, among which are *P. pulverulenta* and *armeniacaefolia*.

3. *P. sylvestris* (Mill).—Prof. Koch says that probably Southern Siberia and Northern China is the native country of this species, and that it is frequently found growing wild in Europe as an escape and not as a true native. He remarks that by cultivation a series of varieties has arisen from this species, some of which resemble *P. pumila*, and some *P. prunifolia*. Indeed he suggests that it may possibly have arisen by cultivation from *P. prunifolia*.

4. *P. prunifolia* (Willd).—The Plum-leaved Apple. The native country of this species is said to be Southern Siberia, Northern China, and Tartary. It is the tree, or at least one of the forms of the tree, which is so commonly cultivated as the Siberian Crab. It is a beautiful tree both in flower and in fruit.

5. *Pyrus spectabilis* (Ait).—The native country of this species is China. It is closely related to *P. prunifolia*, but is distinguished by its longer and narrower leaves (2 in. by 3 in.), which are duller in colour, and retain longer the hairiness of the under surface; by the larger size of the flowers and the more numerous cells of the fruit. There are several varieties in cultivation, as *Malus floribunda*, *Malus Kadio*, and *Malus Ringo*.

6. *P. Ussuriensis* (Max.).—This is a handsome small tree, a native of South-eastern Siberia. Prof. Koch says that this agrees in the main with *P. sylvestris*, and he suggests that it may be the mother plant of that species.

7. *P. baccata* (L.).—The popular name which Prof. Koch gives to this species is the Apple with berry-like fruit. Its native land is said to be Siberia. It is more commonly a bush than a tree, with roundish or short lanceolate leaves, which are always pointed, mostly smooth and without wooliness, and toothed on the margin. Not only has the tree a pleasing appearance at the time of flowering, but it is much more pleasing when the branches are covered with the clusters of long-stalked, berry-like Apples. Several varieties of this species have been produced by cultivation, of which those called *cerasifolia* and *sphaerocarpa* are the principal.

8. *P. Toringo* (Lieb.).—The native country of this species is Japan. It is both bushy and tree-like. It has most resemblance to that variety of *P. baccata* called *sphaerocarpa*, but is distinguished by smaller fruit, by darker-coloured and somewhat thicker leaves, which are also more or less incisely toothed.

We next come to consider the American species of this group. They are three in number.

9. *Pyrus coronaria*—L. (Our common Crab Apple).—This species is found wild over a large part of the eastern portion of the United States and Canada. It is a small-sized tree, attaining the height of 20 ft., branching low with stiff horizontal limbs. The fruit is about 1 in. in diameter, generally very acerb and unpalatable.

10. *P. angustifolia*—Ait. (The narrow-leaved Crab Apple).—This species differs little from the common Crab Apple. Its leaves are longer, narrower, and less disposed to be lobed, and in the flowers there is less union of the styles than in the preceding. Its range is not as well known, but it occurs in Virginia, in the Western States, and in Kansas. It is doubted by some botanists if it should be considered more than a variety of *P. coronaria*.

11. *P. rivularis*.—This is the only Crab Apple known on the western coast of North America. It occurs in Alaska, and descends to Oregon, Northern California, and Nevada. Its fruit is about the

size of a small Cherry, and is employed by the Indians of Alaska as a part of their food supply. Prof. Koch thinks that it is probably identical with the Japan species (*P. Toringo*), but we hardly know sufficient about either to decide this point.

THE SETTING AND SWELLING OF MELONS.

It cannot be too well understood by all Melon growers that the Melon needs to be artificially fertilised to insure setting; secondly, that all the fruits set will not swell beyond a certain size if the blossoms be not all set about the same time—within a day or two of each other. This applies chiefly to the first crop, which is always the most important as well as the most certain. It is, therefore, important, so to train the plants that a good number of female flowers be produced at or about the same time; male flowers are always to be had from some of the plants, and generally from the same plant on which fruit is set. The way to secure this result is to originate and maintain an evenly balanced growth. For example, if a plant has two limbs trained in opposite directions, as is frequently the case in frame culture, the limbs should be started off from the base at the same time, by means of pinching the leader, and when they have grown 2 ft. or 3 ft. they should be stopped simultaneously; this will cause them to produce side laterals, which, as a rule, show female flowers at the same time, and which can all be set once. If the first offshoots from the main limbs do not show fruit, or if only one limb shows fruit, or if the fruits are fewer for the size of the plant than is desirable, then the female flowers should be picked off altogether, and the laterals pinched again to induce sub-laterals, which generally show plenty of fruit. This is the only way to get a plentiful crop. It often happens, however, that when plenty of fruits are set they do not all swell beyond the size of a small marble, while a certain number will take the lead. Some of those that do not advance will sometimes turn yellow, and finally drop off; while others will remain green, but at a standstill. These latter should be left on the plant, and it will be found, as soon as the fruits which swell have reached their full size and begin to ripen, that they will in their turn begin to swell, and ripen off equally fine fruit, perhaps three weeks or a month later. This is called a second crop, but it really is from the first "set." A second crop properly so called is produced upon fresh growth made after the first crop has been all cut. Those who grow Melons must pay attention to these matters if they desire a good crop. Other means of insuring a plentiful first crop is to have plenty of plants. Suppose you have one plant to a light, which is a common thing, there is a chance that you may only have three fruits upon it; but if you put two plants in a light, there is a good chance of your having six fruits to a light, because there are two independent plants to work upon. This plan is often very successfully carried on in lean-to Melon houses by planting twice as thickly as usual, say 1 ft. apart, and stopping every other plant when it has grown half-way up the rafters, and the others when they have grown 1 ft. or 1½ ft. higher. This plan requires methodical training, but there is nothing at all difficult about it, and it is a sure way of getting a plentiful and even crop. Of course, fewer fruits are allowed to a plant; but a greater average quantity is secured than could be hoped for by planting fewer, and growing them larger. The quantity of fruit which one Melon plant will carry and finish off to a good size, depends, of course, upon the vigour of the plant and its size. Sometimes plants will show fruit very early, before they are well established; such should be picked off at once, for it is useless setting fruit before the plant has made a considerable breadth of good foliage, without which, fruit of either good size or flavour cannot be expected. Taking care of the foliage is indeed a far more important matter than soil, for the Melon will succeed in any ordinary good garden soil of which the staple is a good sound loam, while good turfy loam is the best material that can be procured for it.

J. S.

Two Good Strawberries.—In looking over the collection of Strawberries in Messrs. Veitch's fruit nursery, I was particularly struck with Pioneer and Loxford Hall Seedling, both of which promise to become valuable additions to the list of really good sorts. I may remark that amongst young plants lifted from the open ground and potted for comparison as to date of ripening, Pioneer bids fair to be one of the very earliest; it has a good deep colour, its flesh is firm, and the flavour brisk and rich. It is also a great cropper and the fruit is extra large in size. Loxford Hall Seedling is of the British Queen type, and a fine handsome Strawberry it is; one, I imagine, which will become as popular for later forcing as Pioneer will be for early work. It was, as its name implies, raised by Mr. Douglas, of Loxford Hall, and Pioneer is from Laxton's stock, a name closely identified with many of our best hybrids.—J. G.

PLATE CXXXV.

A GROUP OF HARDY IRISES.

Drawn by A. MACFARLANE.

THE flowers which we figure are three varieties of beautiful hardy Irises, which are so valuable for the decoration of our gardens in early summer. At one time good varieties of Irises were scarcer than at present, and the plants were seldom well grown; but recently about London fine collections have been established in various nurseries, and the beauty of their flowers during the past month could scarcely be imagined by those who have not been fortunate enough to see such displays. These plants have every good quality which one could desire as regards hardiness, freedom of bloom, and easy culture. Like a good many other plants, their season of bloom is not long enough to please all; but by cultivating them in various places where they are not in the way when out of flower, this is not felt to be a drawback. Among large shrubs, which ought to be more widely apart than they are generally placed, in thin copses; among dwarf shrubs, in tufts near water, and in isolated groups on the Grass near, but not in masses of shrubs, are some of the positions in which they may be enjoyed in addition to mixed borders and beds. In such places they would mark the season agreeably, and not be in the way when their bloom was over, which they are sometimes found to be in borders. In the smallest gardens, where people have not the space to plant them in these various ways, one of the best modes would be to establish healthy tufts in the fringes of the shrubbery. Another good way is to place them here and there in carpets of low evergreens, above which their flowers would be seen in early summer. It is worth the while of all who care for hardy flowers to devote a little attention to establishing a good stock of these plants in their gardens. They have all the beauty of the finest tropical flowers without their cost, and will well repay the trouble of first arranging and planting them, so that their beauty may be seen to the best advantage, and so that they may not be in the way of the imperious needs of "bedding out." We may add that tufts of the finest kinds look very beautiful here and there among dwarf Roses. The flowers from which our plate was prepared were supplied from Mr. Barr's garden at Tooting. They consist of varieties of *I. plicata*, *pallida*, and *variegata*.

THE DEATHLESS FLOWER.

Yes! hope may with my strong desire keep pace,
And I be undeluded, unbetrayed;
For if of our affections none find grace
In sight of heaven, then, wherefore hath God made
The world which we inhabit? Better plea
Love cannot have, than that in loving thee
Glory to that eternal peace is paid,
Who such divinity to thee imparts
As hallows and makes pure all gentle hearts.
His hope is treacherous only whose love dies
With beauty, which is varying every hour:
But, in chaste hearts uninfluenced by the power
Of outward change, there blooms a deathless flower,
That breathes on earth the air of paradise.

FROM THE ITALIAN OF MICHAEL ANGELO.

Gladiolus Colvillei.—This is a charming early flowering variety and a perfect gem in a cut state. It is of medium growth, and the flower-spikes, which are produced in great abundance, are in full beauty out-of-doors about the end of June. Forwarded under glass, it would be most effective during the spring months for conservatory and other indoor decorations.—J. GAOCH.

Libertia formosa.—It seems odd how little this lovely plant is grown in the open air. A week or two ago I thought it the most exquisite plant in the garden—white three-petaled flowers, like gems, on their grassy stems. The Sedge-like leaves are more than 3 ft. long on an old plant at Kew, where the wet spring seems to be agreeable to the plant. The *Libertia* is perfectly hardy, and one of the loveliest known border plants.—FRANK MILLS, *Bingham, Notts.*

Thalictrums in Borders.—Mr. Williams (*Vol. XIII., p. 622*) has directed attention to the value of these for the wild garden, but some of the kinds, such as *T. anemonoides* and *alpinum*, are equally suitable for mixed borders, where their delicate, Fern-like foliage is not only an ornament, but proves welcome for many purposes for which tender Ferns have often now to be used; their leaves are also much more lasting than those of Ferns.—J. GAOCH.

PROPAGATING.

CORREAS.—These may be increased either by means of cuttings, or by grafting. The cutting pots may be prepared either to accommodate bell-glasses, or to stand in a close box. The soil used should consist of peat, a little yellow loam, and a fourth part of sand, the whole sifted rather fine. Well drain the pots, which should be 6-in. or $4\frac{1}{2}$ -in., and fill them with the soil, which should be pressed in rather firmly, and $\frac{1}{4}$ in. of sand should be put on the top. Water the sand with a fine-rosed pot and insert the cuttings, which should be made as shown

Fig. 1.

Fig. 2.

Fig. 3.

in fig. 1. When put in give a good watering, and place the pots on a cool bottom in the propagating house. April is the best month in which to strike cuttings. For grafting, take a free, strong-growing sort for a stock, which should be in the propagating house for a week or two before operating on it; cut the stock as shown in fig. 2, and the graft as represented in fig. 3; unite them, tie round with matting or worsted, and put them in a close box; do not water them overhead. H. H.

Refreshments in the Parks.—The First Commissioner of Works, the Right Hon. Gerard Noel, M.P., received a deputation lately from the Working Men's Club and Institute Union. Sir Harcourt Johnstone, M.P., stated that working men had represented to the Society that the poorer classes were unable to pay the prices demanded by those who supplied refreshments in the parks, and that permission was sought for stalls at which tea, coffee, &c., should be sold at the prices generally charged in the streets. Mr. C. Symons, of the South London Institute, showed that the inability to obtain what was wanted at prices which the poorer classes could afford prevented many families from passing the Saturday or Sunday afternoon together in the park. Consequently, the children strayed about the streets, while the father, perhaps, found his way to the beer-shop, Mr. Gerard Noel expressed his sympathy with the object in view, and said he would allow the experiment to be tried in the first instance in one park, selecting Battersea Park for this purpose.—“Daily Paper.” [The sale of refreshments in the parks, if not conducted with the greatest care, will lead to evil results. We have strenuously advocated the opening of public gardens at all hours, but there are good reasons why their precious space should not be devoted to beer or other shops of any kind. In fact, there is no greater danger to public gardens. Few of our parks are so large that what is required may not be had near enough for most people. The opportunity for boozing, smoking, and tea-drinking is already large enough without stealing any of the ground that belongs to the trees and flowers and Grass. We would urge that Mr. Noel in making the experiment should insist on any structures for this purpose being erected in spots where the space was of the least importance, and where their aspect could not mar any of the quiet beauty which we seek in parks and public gardens—as, for example, in clumps of trees and in woody corners.]

Prophetic Language of Flowers.—A report of a flower show informs us that Messrs. Veitch showed a new Begonia, high and stately in growth, with a leaf tending towards the Strawberry. The plant is called the Earl of Beaconsfield. Messrs. Veitch perhaps contemplate the probability of having to raise their plants a step in the Peerage. They will prove themselves prophets, as well as florists, should the sequel of the Congress confirm the indication of the leaf of their Begonia “tending towards the Strawberry.” Then they will also, of course, have foretold a pacific solution of the Eastern Question.—“Punch.”

GARDENING FOR THE WEEK.

Pot Roses Out-of-doors.—In gardens, large or small, the many demands, more particularly at this season, upon the labour at command often results in something or other only receiving partial attention. There is nothing more likely to thus suffer neglect than pot Roses that are turned out, yet it is well to impress upon those who are comparatively new beginners in the cultivation of pot Roses for winter and spring flowering that upon the attention which the plants require at the present time being given them more than upon any treatment they receive during the winter depends their ability to flower satisfactorily at the time they are wanted. Roses are essentially sun and air-loving plants, and on this account the place chosen for them to stand through the summer should be under the full influence of sun and not too much sheltered by surrounding trees or walls, which always is likely to cause mildew. Where the plants, as is frequently the case after blooming, have been turned out at the north side of walls and other places, or in the shade of trees, they should at once be put for the remaining portion of the summer in the best open position that can be found for them, and, as advised some time ago, should have their pots plunged, as, without the latter precaution is taken to prevent the soil in the pots drying up too quickly, it entails almost an incessant use of the water-pot to keep the roots sufficiently moist, the neglect of which has a tendency to stunt their growth. Independent of this it is necessary to plunge the pots, so as to protect them from the direct influence of the sun. By some it is considered requisite that only the pots in which the roots of tender hard-wooded plants are confined should be shielded from the full force of the sun's rays, but it is quite necessary to similarly protect all plants when out-of-doors, as when the soil gets full of roots these lay thickly against the inner surface of the pot, more especially the tender extremities which portion acts as absorbents, through which the food is conveyed to the plants, and suffer severely from the unnatural heat they receive when the full sun comes upon the sides of the pots, especially whenever the soil gets a little over-dry. After being in this condition I have frequently turned free strong-growing plants out of the pots to examine them, and generally found all the small rootlets on the side next the sun completely stagnated, affording sufficient evidence of the necessity for plunging.

Re-potting where Required.—Roses differ from many plants in there being no stated season that potting operations must be restricted to. Strong growers, particularly of the Tea varieties, that were potted early in the spring, only then receiving a small shift, will many of them have filled their pots with roots to a greater extent than the weaker growers will have by the end of the season. In this case it is advisable to give them more room at once, an operation that will well repay the labour by the size and vigour that it will impart to the plants, and, as I have frequently urged, a given number of strong examples will furnish more flowers than treble the quantity of smaller plants. During hot weather the soil should be well moistened before potting, and there is not the necessity for withholding water after potting, as in the case of tender-rooted subjects. I would again urge that in potting it is scarcely possible to ram the soil too close, providing there is a little sand in the compost, which will prevent it becoming an impervious mass; but Roses are not partial to near so much sand in the soil as many plants; neither, on the score of keeping it in a condition that the water will percolate through it freely, is it necessary that it should have as much sand incorporated with it as required in the case of plants that are not periodically partially shook out and have their soil renewed.

Rose Insects.—The worst of all insects upon Roses—red spider—which the late very hot weather will have favoured, is sure to make its appearance. There are no insects, not even the worst species of aphides, that so soon paralyse and destroy the leaves to an extent that renders them of little service to the plant as does red spider. Tobacco water is still the best remedy that I have found with a little Gishurst added; but syringing the plants with it in the position in which they stand is an extravagant way of effecting the destruction of the insects; if, instead of this, the plants be laid on their sides while being syringed over a vessel large enough to catch the liquid, one gallon will go as far as a dozen will where applied otherwise; the work can also be much more effectually accomplished in this way, as it is easier to get the liquid to the undersides of the leaves where the insects most congregate. If there be any mildew on them this washing will also effect its destruction.

Roses in the Open Ground and Planted Out Generally.—Aphides usually exist in the spring and after a time disappear, but in the present season there seems to be no end to them, as up to this time they have gone on increasing unless where vigorous efforts were made to destroy them. On walls, especially where the plants were not dressed thoroughly early in the spring, they have subsequently been almost impossible to deal with, but where they received a good washing with insecticide before the buds burst into leaf, in the way practised with wall Peaches, they have in many places not afterwards been troublesome, showing the advantage of taking timely measures to save the plants from their ravages.

Budding should be continued as the shoots of the stocks and the buds of the kinds desirable to be in this manner propagated can be obtained in a fit state. With the limited numbers usually grown in private collections the exact time for carrying out the operation when these are in the most suitable condition can be taken advantage of to an extent not possible where a very large quantity—such as grown by those

who cultivate for sale—have to be got through; through a like cause the most suitable weather for budding can also be chosen, which is when it is dull and cloudy. The intense heat we have lately experienced has been such that I have noticed in many cases, particularly where the bark of the wood of the buds used had got a little hard and, consequently, did not part very freely, a good many failures through drying up.—T. BAINES.

Flower Garden.

Pay all requisite attention to bedding plants by giving them sufficient water as often as required, and in this way, so far as possible, endeavour to make up for the late, unsatisfactory condition they are in. In applying water in dry weather, it is much better to give as much once or twice a week as will moisten the soil to a depth of 3 in. or 4 in., than to sprinkle the surface daily, which latter operation is far too generally practised, and tends to promote root-action near the top alone, leaving the lower and more important feeding fibres in almost a dormant condition.

Walks.—Where salting walks for the destruction of weeds is resorted to, dry weather is much the best in which to apply it; salt dissolved in water is the most approved method, but it should be as near boiling heat as possible. There is one objection to salting walks, viz., that it gives to most kinds of gravel a dark, damp appearance; and if the value of the salt thus used were spent in labour in hand-picking before the weeds became numerous and were allowed to seed, it would be found the most economical. Through the difficulty of extracting weeds from a gravel walk when dry and hard, they are often allowed to remain until moistened by rain, during which time they may be maturing and scattering seeds by the thousand, whereas if a few pots of water be poured on with a rose-spouted can, a considerable space may be thus moistened in a very short time, and the work of weeding greatly facilitated, as a man will do as much in one hour with the walk in a moist condition as he will in three when dry.

Indoor Plant Department.

Greenhouse Plants in Small Pots, that have their leaf-surface large in proportion to the amount of soil in which they are grown, will require constant attention as to water, of which a frequent supply, sufficient to saturate the whole of the soil, should be given, as they invariably suffer more from a scarcity of water than those plants whose foliage surface is more limited. Primulas of the cortusoides section, grown in pots, should be kept plunged through the summer in a bed of ashes on the north side of a wall, and well attended to with water, for, if at all neglected at this season, no subsequent attention can remedy the injury they will have sustained. *P. japonica* is not often seen in the condition in which it is capable of being produced, and through this cause has disappointed many. Instead of confining it to the small pots in which it is often flowered, if the plants have more room (say 10-in. or 12-in. pots), be grown in good soil, and supplied with manure water as often and as strong as a *Calceolaria* will bear, the appearance of both leaf and flower will be materially improved.

Campanula pyramidalis is one of the best summer-flowering plants that can be grown; it will now have made considerable progress, and will be much benefited by an application of manure water every week. Young plants raised from seed this spring should, as soon as ready, be pricked off into small pots and encouraged to make growth, for upon the strength they attain before autumn a great measure depends their blooming capabilities during the ensuing year; when well managed they will make flower-stems 8 ft. or 10 ft. high.

Mignonette should now be sown in pots for winter flowering; this will not attain the size it would if sown a month or six weeks earlier, but for general decorative purposes it will be rather an advantage than otherwise, as a number of comparatively small plants, when well flowered, will in most cases be more useful than larger specimens. Take as many 4-in. pots as will be required, in the bottom of which put $\frac{1}{2}$ in. of drainage material, over this a little dry rotten manure, such as has been used for mulching, then fill up to within $\frac{1}{2}$ in. of the rim with good ordinary loam, to which has been added one-fifth of rotten manure and a little sand, pressing it firmly in the pots; on this sow the seeds (six or eight to each, ultimately thinning them down to half the number); place the pots as close as they will stand on a bed of ashes in a cold frame, and keep the lights off until autumn, unless the weather should be excessively wet.

Chrysanthemums.—Plants of these that were struck in spring, if not already in their blooming pots, should at once be placed in them; later-struck plants require pots quite as large as those that were struck at the end of December or beginning of January, and for ordinary decorative use will do as well, but under no course of treatment will they produce such a number of perfectly-developed flowers, simply because the growth has not the chance of getting so thoroughly matured, which, even in the case of soft-wooded subjects, is indispensable. The earliest-struck plants that were transferred to their flowering pots some time ago, should, so soon as the roots get fully in possession of the soil, receive a regular supply of manure water. Even to Chrysanthemums it is possible to apply it too strong, but they will bear it much less diluted than most plants. The frequent advice given not to use liquid stimulants to them until the flowers are set is a mistake. Chrysanthemums, like most other Chinese plants, are exceedingly gross feeders, and to grow them well they require, in all stages of their existence, the application of rich manure water such as few plants will bear, and, in the absence of which, their flowers will neither be so perfect nor so abundant, nor the plants so well clothed with foliage down to the base.

Richardias that have done blooming, or that are wanted early in the winter for that purpose, should be planted out at once in partially shaded situations, where water can be easily administered, of which they will take unlimited quantities. In turning them out, dig and mix some manure well in with the soil in the positions it is intended the plants should occupy, and in planting keep the crowns low, that a slight basin may be formed round them for the purpose of holding sufficient water, in order to soak their roots well. To prevent the escape of this by evaporation, they should be mulched by having some half-rotten manure laid round them to shade the soil and prevent it from cracking open, which is invariably the case after frequent applications of water. Keep them free from blooms, so as to concentrate the strength of the plants in forming fresh crowns, and induce them to make a vigorous growth, without which they will not flower freely when wanted. Treated in this way they produce at least twice the quantity of bloom that can be got from them when confined to pots during the summer, independently of the saving of labour there is in watering and attending to them.

Spiræas.—These, like Callas, are half aquatic in their nature, and seldom get enough water if confined to pots; after they have done blooming, they should, therefore, be planted out, and treated after the same manner as recommended for the latter. Before doing so, they should be divided, if it be desired to have them in the same sized pots again at the time of lifting, as the effects of any mutilation of the roots that must necessarily take place in so doing is more readily overcome now than when the plants are going to rest in the autumn. A little fresh, rich soil filled it round the balls of the plants, and made solid and firm, will be of the greatest assistance in inducing them to make fresh roots and strong, vigorous crowns, without which their capacity for blooming will be of the most limited kind. As soon as they get a start, manure water may be frequently given them with the most beneficial results, and a syringing or damping overhead is equally acceptable to them.

Indoor Fruit Department.

Vines.—The progress made by newly-planted Vines the first season has so much influence on their subsequent condition that their requirements should be a matter for careful consideration. The principal young shoots should be tied as each wire is reached; the side growths should not be pinched unless they are obstructing the light. One-year-old canes, especially of Black Alicante, Barbarossa, and Syrian, are often months in starting into growth freely; the shoots grow until they are 6 in. or 8 in. long and then stop. The lowermost shoot is frequently more vigorous than the top one, and, when such is the case, the strongest one may be taken up as the principal leader. Except in the case of Muscats, no fire-heat is now needed in Vineries, either during the night or at any other time, as a temperature of 65° can be maintained by subsiding the heat of the sun in the afternoon. Muscats will ripen, in a certain fashion, in a night temperature a few degrees below 70°, but, where perfection is desired, nothing under that need be tried.

Pines.—The first batch of suckers may now be taken off and potted. Queens, from which the earliest fruit was cut, should have them in a fine mature condition. Plants bearing fruit may have large suckers also, but the size should not be taken as a guide to their fitness for being taken off, for no sucker should be cut from the parent plant, unless the base of it is hard and nut-brown in colour, let its size be ever so great. Those taken off and potted with blanched tender bases seldom succeed, and should be allowed to remain on the plant for a month, or even longer if necessary. In taking off the suckers, be careful not to bruise their leaves or injure their stem. Some of them may be twisted off with the hand; others with a firmer hold require to be cut closely into the old stem with a knife. But this mode of operation needs a little care when the plants are in fruit, as the foliage is easily damaged. Pull all the small bottom leaves off with the hand, but do not go above the point where the brown colour terminates, and do not touch any of the small roots which will be seen protruding round the bottom of the stem. Where accommodation is available, each sucker should be placed in a 6-in. pot, into which 2 in. of broken crocks should be put as drainage. The compost used should be the best fibrous loam, to each barrow-load of which should be added an 8-in. pot full of fine bone dust. When the soil is somewhat retentive, some horse droppings may be intermixed with it. The soil should be firmly pressed about the sucker with the hand, and the pots plunged in any pit or frame where a bottom-heat of from 85° to 90° can be obtained for five or six weeks. The suckers should not be watered until their roots have reached the sides of the pots. Syringe overhead every hot afternoon, and shade closely until enough roots are formed to prevent the leaves from shrivelling, or a check may be given, from which it will take them a considerable time to recover. By putting the largest suckers in now the growth may be so far advanced that there will be every chance of their fruiting next autumn, instead of the following spring.

Hardy Fruit.

Peaches and Nectarines on Open Walls.—As these increase in size attend to thinning any that may be too thick, bearing in mind that it is a decided loss to have them too crowded. When more are left on the trees than they can support, not only is permanent injury done to the trees, but the weight of the crop is by no means increased in proportion to the numbers grown. When too many are left there is a preponderance of skin and stones in place of full-fleshed, large, handsome fruit; gradually, and not all at once, expose each fruit to the full action of the sun by removing all the leaves that obstruct its coming directly upon them. By

this means only can the requisite colour be imparted to them, without which the largest examples are deficient in both flavour and appearance. At the same time do not by any means denude the trees of leaves too much or the root power will be correspondingly weakened. Where the portion of a leaf at its extremity only overhangs a fruit, break the leaf off in the middle; the part that is left, if free from insects, will remain in a healthy state upon the tree to fulfil its allotted functions, so far as its reduced dimensions will permit, as long as if it had been left entire. Never remove an entire leaf, to thus expose the fruit to sun and air, when taking away one-half will answer the object. Keep the trees regularly syringed with clean water, standing sideways in doing the work, so as to get the water well to the underside of the leaves, or it will only be partially effectual. Give abundance of water at the roots also when the weather is dry. Remove all superfluous shoots, so that the full strength of the trees will be directed to the production of good bearing wood for another year.

Strawberries.—Those who intend to grow pot Strawberries should at once see to laying some runners in pots as soon as any are ready; there is nothing like doing this work in time, for upon the thorough preparation of the plants depends the crop they can be induced to bear. For the purpose 3-in. pots should be used; put a bit of turfy loam in the bottom of each for drainage, fill up with fine rich soil of a moderately heavy nature such as accords best with this fruit, and then with an ordinary planting trowel make holes in the ground where the pots are to be, in which plunge them up to the rim; so managed they will not dry so quickly, consequently a good deal of labour will be saved in watering, for if ever allowed to get very dry they will be seriously injured; after the pots are plunged, the runners must be placed on them, laying a stone the size of a hen's egg upon each to keep it in its place until rooted, when they will need transferring to 6-in. pots.

Kitchen Garden.

There is no such period as a "slack time" for the kitchen gardener; at least, I have not yet been able to discover it, for no sooner is one crop planted or sown than another requires thinning, another earthing and weeding, and another lifting or harvesting, in order that the ground may be again prepared for cropping. Such is now the case with Shallots and Garlic, which, in many instances, will be ready to be taken up; they should not be allowed to remain after the tops have dried off, but pulled up and left on the ground a day or two to dry, and afterwards tied up in convenient bundles for use, and hung up in the vegetable shed or other airy, cool, dry room. The ground where they have been grown, if well dressed when they were planted, will not now require digging, but simply levelling and weeding, drawing drills afterwards for the sowing of Endive, or black-seeded Bath Cos Lettuce for early winter use. If it be thought desirable to preserve the stock of any good variety of vegetables, such as Cauliflowers, Lettuce, &c., select the most perfect types for seeding, and stake or otherwise mark them in order that they do not get cut when the crop is being used. No two kinds of Cabbages, Brussels Sprouts, or Cauliflowers should ever be seeded together if the stock be desired pure, for bees are wonderful hybridists, but not particular as to how or on what they operate. Tomatoes are now growing freely, and will require to have their growths trained or tied in; if there be a tendency to strong growth, repress it by severe pinching of the lateral growth, an operation which also promotes fruitfulness. If the fruit set too quickly, thin it out, and remove all the large leaves that keep the light off it. As a rule, high feeding is not necessary for Tomatoes, but if bearing freely, they may be assisted by an occasional watering with weak liquid manure. Where Spinach is required all through the season, seed must be sown regularly every fortnight, as it will not stand much beyond that period without running to seed; any vacant spot that can be cleared from other plants may be used for this purpose. As the crop of Cabbage is cut, strip the leaves from the stumps, as they only harbour slugs and caterpillars; give the ground a good soaking with manure water to assist the stools to throw out fresh side shoots, which will furnish through the remainder of the season a useful supply of tender sprouts.

Leeks.—If these have been treated as advised earlier in the season, by being sown at the proper time, and thinned out in the seed-bed, so as to give them enough room to grow, they will now be in good order for planting. The ground they are to occupy should be well dug to the depth of 15 in. and broken fine, so as not to leave any large, hard lumps. Plant in rows, 15 in. apart, with 8 in. or 9 in. between the plants, and, in planting, use a stout dibber, that will make holes 3 in. deep and 2 in. (or a little more) in diameter. In these place the plants, dropping in soil to the depth of 1 in. or 2 in., but no more, leaving the rest of the hole open, and giving a good watering, so as to settle the soil. By only partially filling the hole, the requisite air gets down to the roots, and the opening above affords space for the stems of the plants to thicken, and also blanches them in a way thus imparts the peculiar delicate flavour which a well-grown Leek possesses. If the ground be good and well enriched, they will, under this treatment, grow almost as thick as a man's wrist, and are far superior to the small, tough, strong-flavoured specimens of this vegetable which are often to be met with.

Killing and Charring Weeds, &c.—Hand weeding is very slow work, and where all the culinary vegetables are grown in rows, as they ought to be, there is comparatively little of it required; but the late showery weather has much retarded the use of the hoe, and in many cases the removal of weeds by hand will have to be resorted to. It may be well to remind those who are novices in gardening that it will not suffice to merely pull up weeds that have got to a considerable size and leave them

on the surface of the ground, as with many of the annual species, especially Groundsel and Chickweed, it would merely hasten their increase, for the seeds in a very short time become sufficiently developed to grow if the plants are pulled up when they are apparently just opening their flowers. There is no safe way with them but removal to the refuse heap, where, if mixed with Grass mowings, green Potato tops, and other vegetable haulm, they quickly get so hot by fermentation as to destroy the vitality of the seeds. Treated in this way, and soaked with soapy water and house slops, they become valuable fertilisers, and as such will be found more effective than animal manure used alone. The right principle upon which to act is to return to the soil, in a decomposed harmless condition, all that it has produced of a useless description, without recourse to burning, which, under the impression that there is no other way of killing some weeds that are unusually tenacious of life, is sometimes resorted to. With good management this is unnecessary, and, as it is wasteful, should never take place. It may be necessary to point out that there is a great difference between charring and burning; in the former the bulk is comparatively slightly reduced, in the latter little is left. In a garden nothing should be burnt except it be too woody to rot, such as prunings and strong hedge clippings. When hedges have received their summer dressing the clippings may be partially dried and afterwards used for charring weeds, such as Couch Grass. They should be mixed with clay or other earthy matter sufficient to prevent the whole from blazing, a smouldering heat, sufficient to destroy vegetable life, being all that is required. The material so treated will not be very much reduced in bulk, and is very useful for digging into the kitchen garden, especially where the soil is of a heavy nature.

Extracts from my Diary.

July 8.—Sowing Cucumbers for late crops. Potting Tree Carnations; also a large batch of Roses in good strong loam. Planting out Veitch's Autumn Giant and Self-protecting Broccoli. Thinning Turnips and Early Horn Carrots. Gathering Strawberries for preserving. Sticking Peas and getting them earthed up. Pulling up all blind-hearted Cauliflowers and Broccoli, and filling up their places with good strong plants.

July 9.—Planting out a pit with Tender and Tree Cucumbers. Training out and pegging down bedding plants. Staking and tying in plants on borders and clearing away decayed leaves and flowers. Taking the nets off early Strawberries and putting them over Currants. Weeding amongst Leeks and giving them a little earthing up. Thinning out Cardoons and lightly moving the soil amongst them.

July 10.—Sowing Spinach. Potting on a batch of Queen Pine suckers and placing them in a brisk bottom-heat. Digging up a large piece of Gloucester Kidney Potatoes and placing them out thinly in the sun to ripen well for seed next season. Watering Celery and Cardoons; also Lettuce and Endive beds. Drawing drills for Spinach and well watering them previous to sowing. Nailing and tying in all the leading shoots of fruit trees on walls and pinching back all the breast wood. Potting up a large batch of President and Sir Charles Napier Strawberry runners for forcing.

July 11.—Sowing Sweet Basil and Chervil. Potting on Campanula pyramidalis; also young Cyclamens. Taking up Shallots and Potato Onions and laying them out in the sun to ripen. Gathering Camomile flowers; also Sweet Basil, Horehound, and other herbs for drying. Weeding and cleaning all Box edgings in kitchen garden. Hoeing and weeding amongst Peas. Nailing and tying in Roses on walls and picking off all dead flowers. Watering all newly-planted Broccoli, Cauliflowers, and Tomatoes, and renovating bins round manure frames.

July 12.—Sowing Lettuces and Endive. Potting up Strawberry runners for forcing. Nailing in Tomatoes and closely stopping them. Tying up Dahlias and thinning them out where growing too thickly. Earthing up Celery when the soil is dry and in workable condition. Looking over Vineries, stopping laterals, and giving the roots a good soaking of gnanu water where required. Gathering Raspberries and Red Currants for preserving.

July 13.—Potting off herbaceous Calceolarias. Layering Carnations. Looking over Cucumbers and Melons, and stopping them where required. Weeding and picking over carpet bedding plants. Cutting up turf and putting it in water to soak for layering Strawberries on. Watering Pines all through; also Celery, Cardoons, and flower borders. Mowing and cleaning in the pleasure grounds, and rolling down all gravel and Grass that require it. Fruit in use for dessert: Pines, Grapes, Melons, Figs, Peaches, Nectarines, Strawberries, Raspberries, and Cherries.—W. G. P., Dorset.

St. Luke's Burial Grounds.—These, having been converted into a recreation ground, were opened the other day to the public. Some time back these burial grounds were in a most deplorable condition, and the church itself, a very fine specimen of classical architecture, built by a pupil of Sir Christopher Wren, was fast going to decay. An energetic committee, under the title of the Church Restoration and Burial Grounds Committee, with Bishop Claghton as its chairman, however, took the matter in hand, and worked so earnestly that on the 21st November last the restored church, upon which upwards of £7000 had been spent, was opened to the public, and now the gardens formed upon the old burial grounds, at a cost of about £1000, are also opened. They were formed by Mr. J. F. Meston, of 20, Spring Gardens, the well-known horticultural contractor.

SEWAGE IRRIGATION AT GENNEVILLIERS, NEAR PARIS.

The plain of Gennevilliers is situated on the north of Paris, about five or six miles from the centre of that city, and forms a long peninsula, so to speak, being almost entirely surrounded by one of the numerous windings of the River Seine. This spot, being one of the most barren and badly cultivated in the neighbourhood of Paris, was selected some ten years ago by the Prefecture of the Seine as a trial ground for ascertaining the value of liquid sewage as applied to the cultivation of vegetables. A couple of years ago a commission was appointed to investigate the matter from a cultural point of view, and a sub-committee, formed from amongst its members, and consisting of a number of well-known horticulturists, has just presented the Prefecture with a somewhat optimistic report on the value of liquid sewage as an irrigating and fertilising agent in the cultivation of the commoner kinds of vegetables. The president of the sub-committee is M. Hardy, the Director of the Horticultural School at Versailles, and the reporter is M. H. Vilmorin, of the well-known firm of that name. The experiment was begun in 1869, when only 2½ acres were put under sewage cultivation. The first trials being promising, this small plot gradually increased, until in 1877 it reached 134 acres. It must be remembered that around Paris vegetables are grown on two systems. First, we have the high culture system, in which forcing is carried to the highest perfection; and, secondly, ordinary vegetable growing on a scale suitable to the richness of the soil and the capital of the market gardener. It need hardly be said that the method of cultivation about to be described is only applicable in the latter case. The sewage is pumped into a large conduit pipe at Asnières, on the west of the city, and distributed over the fields in a series of open canals, as shown in the annexed figure. These canals are above the level of the soil, and are provided with sluices at regular intervals. The fields are divided into round-backed mounds by channels about 1 ft. deep and 4 ft. or 5 ft. apart, and running at right angles to each other. By opening the sluices in the sides of the canal the channels can be filled whenever it is found necessary. As the water is absorbed a deposit is formed at the bottom of the channels, which is collected from time to time and distributed over the beds. So much for the method of applying the sewage. Let us now speak of the results as obtained on the spot by the sub-committee. It must be premised that in several cases double crops have been obtained. Several Cabbage growers have grown a spring and autumn crop, or have alternated vegetables with green Rye for fodder.

The following is the list as given in the report:—

Artichokes	14,000 to 32,000 heads	per acre
Cauliflowers	8,000 to 12,000 heads	"
	(weighing from 10 to 16 tons)	
Garlic	about 15 tons	"
Carrots	50 "	"
Celery	40 "	"
Cabbage	56 "	"
Onions	24 to 32 "	"
Leeks	24 "	"
Potatoes	12 to 16 "	"
Pumpkins	48 to 52 "	"
Salsify	about 10 "	"

These results, it may be remarked incidentally, are evidently the best that could be obtained. A commission, appointed by the Minister of Agriculture in 1874, puts the Cabbage crop at a little more than half, and the Carrot crop about two-fifths of the amount stated above; we may therefore take the half of these figures as being somewhere near the truth, a remark that will apply to the other data quoted from this *couleur de rose* report. If we make a comparison between vegetables cultivated with and without sewage irrigation, goes on the reporter, we shall find that the crops yielded by the latter method are doubled, trebled, and even quadrupled in certain instances. In October, 1877, the first prize at the exhibition of the Société Centrale d'Horticulture was carried away by M. Rothberg, a market gardener at Gennevilliers, for the excellence of his vegetables, against all the market gardeners of the valley of the Seine. Land which has been hitherto perfectly barren may, therefore, be made to yield as much as that which has been well watered and

fertilised. Trees and shrubs for transplanting thrive well if irrigation is discontinued some time before winter sets in. Peppermint, Absinthe, Angelica, and other plants used in distillation or perfumery may be grown successfully if similar precautions are taken on the approach of gathering time.

The following are the figures for three of these plants:—

Peppermint	16 to 20 tons per acre (two crops).
Absinthe	44 to 48 " " "
Angelica	11 tons per acre the second year.

This method seems particularly well adapted for vegetables whose value depends on the succulence of their leaves or stems, such as green forage, Cabbages, Celery, Endive, Salads, and green herbs for distillation. Young Almond and Peach stocks planted in spring and grafted in August throw out shoots 5 ft. and 6 ft. long, and nearly 3 in. in circumference at the base during their second year. Swiss Poplars and Willows also grow most luxuriantly, but the Osier succeeds best of all, especially when fertilised with the deposit that collects in the channels. With Potatoes the system does not succeed so well, but this may be accounted for by their necessarily receiving a larger amount of water than is good for them. The report then goes into the pecuniary part of the question, after having stated positively that the vegetables sent to the Paris market enjoy as great favour as those sent from other places. This part of the report seems somewhat exaggerated, for an Argenteuil correspondent informs us that although Cabbage and other vegetables grow most luxuriantly at Gennevilliers, their tissues are watery. Cabbages, the staple produce of the locality, are looked on with disfavour by the *sauer kraut* makers. He admits, however, that the Tomato thrives wonderfully at Gennevilliers, but no mention is made of it in the report. He adds that Asparagus, although it grows to a large size there, is of poor quality. The report goes on to say that before 1869 all that was grown on the plain were a few meagre crops of Oats and Rye, which rarely exceeded 13½ bushels to 14½ bushels per acre, but that now the fields yield at the rate of 27½ bushels per acre, and that Wheat and Lucerne are beginning to be grown; vegetables, however, seem to yield the most profit. The following figures are for rough crops; it must be remembered, therefore, that in some cases two, and even three, crops may be grown in one year.

Cabbages	£48 to £64	per acre.
Cauliflowers	£80 to £160	"
Carrots	£48	"
Peppermint	£64 to £80	"
Artichokes	£80 to £96	"
Onions	£140	"
Absinthe	£64 to £80	"

or on an average £64 per acre—the exact amount realised at Aubervilliers and in the neighbourhood of St. Denis in market gardens cultivated in the ordinary way. No comparison is intended to be made between these results and those obtained under the highest cultivation, but only with those obtained by ordinary vegetable growers. The report states definitely that the Gennevilliers produce fetches the same price in the market as that from Aubervilliers and St. Denis. The amount of liquid sewage necessary for a given surface of ground does not seem to have been yet fixed. The sewage at present, being distributed gratis, it is very likely that an excess has been hitherto used. Up to the present time the rate of supply has been 24,500 cubic yards per acre per annum, but this amount is excessive, the consequence being that a large amount of the sewage matter has been absorbed by the earth without being decomposed by the plant. The amount of sewage produced by the city of Paris amounts to 110,900,000 cubic yards per annum.

C. W. QUIN.

Geum coccineum fl.-pl.—Conspicuous amongst herbaceous plants at this season is the double-scarlet *Geum*, the blossoms of which are produced in profusion and as double as those of a *Ranunculus*. In a cut state they are most valuable, being brilliant in colour.—J. GROOM.

Cure for Rats.—Baron von Baskhofen has discovered a cheap and simple method of exterminating rats. It consists of a mixture of two parts of well bruised common Squills and three parts of finely chopped bacon made into a stiff mass, with as much meal as may be required, and then baked into small cakes; these are put down for the rats to eat, and are said to effect their complete extirpation.

After Rose

Method of Sewage Irrigation in the Plain of Gennevilliers, near Paris.

THE INDOOR GARDEN.

SWEET-SCENTED PLANTS.

THERE can be but one opinion as to the desirability of furnishing our conservatories and apartments with plants which are distinguished for their perfumes. From time immemorial sweet-scented flowers have been in great demand, and many plants owe their popularity to the delicate odours which they exhale. The Violet and the Mignonette, pretty though they may be, would hardly be held in such universal esteem were it not that they possess a sweetness that does not prevail amongst flowers in general. It is rather singular that the greater portion of our sweetly-scented flowers are of unassuming proportions, thus rendering them amenable to pot culture, and consequently adapted to the requirements of the million. It is not at all difficult to have a sweet-smelling plant in our window the whole year through, and just those which are possessed of the most pleasing perfume are of easy culture, and are, therefore, within the reach of all who may wish to enjoy them.

Probably, amongst scented flowers, there is not one which can boast of such universal popularity as does the Violet. Indigenous to our native isles, it is often the subject of pleasing associations and reminiscences; and the fine varieties which cultivation has given us have served to greatly increase its value. Every one who has the convenience of a frame should make a point of securing a few potsful of Violets for winter enjoyment. Good clusters of the Neapolitan and double Parma are delightful in winter and early spring. It is seldom that one sees really good pots of Violets, and this is owing to the fact that no special provision is made to get them. It is true that Violets in favourable situations will, even if left to themselves, thrive and make luxuriant growth; but in a general way, to insure good results, they must receive some special care. A shady, sheltered position, where the sun goes off about midday, will fulfil their requirements. If exposed to the full glare of the sun, they are apt to get infested with red spider, and will not attain that hearty growth which is desirable. If young healthy pieces are set out early, in good soil, and are kept well watered during the summer, they may be potted up early in September, placed in a cold frame, and employed as required.

Next in order of merit comes the Mignonette, which is in truth everybody's plant. This favourite of the million may be had in bloom the whole year through; a result which, it is almost needless to say, is to be effected by judicious sowing. A few seeds should be sown in 4-in. pots several times during August and September; three plants should be left in each pot, and at housing time they should be placed upon a shelf in a light, dry, airy house, giving no artificial heat, admitting plenty of air, and suffering no lack of moisture at the root. They will thus flower successively during the winter months. Early in the year more seed may be sown, and a succession kept up until it comes in out-of-doors. Of Mignonette one can scarcely have too much, as what is not required for decoration in pots can be utilised in a cut state. A sprig or two of Mignonette amongst the table decorations, or in a bouquet, has a very refreshing appearance. The amount of space at the disposal of the grower will, of course, regulate the quantity grown.

A most delightfully perfumed plant is the Lemon-scented Verbena, as it is commonly called. It is an old and well-known plant, a general favourite, and is largely grown for market. It may be propagated from the half-ripened shoots, inserted in a shady place in the summer, or the young growing tips may be taken off in early spring, and placed in bottom-heat. As this plant is deciduous, and the fragrance lies in the foliage, it must be placed in heat to push it into growth if required early in the year. The plants should be cut in, leaving about 2 in. of wood, and as soon as they break they should be shaken out and re-potted in 4-in. pots, which size is quite large enough. This plant, if placed against a wall or in some similarly sheltered situation, is hardy enough, and a good bush or two is very pleasing in the summer season. The fragrance of this plant is very penetrating, and so peculiarly sweet that few are able to resist plucking a leaf. I once heard a lover of plants somewhat petulantly exclaim that he "would never grow it again," as "every one that came into the place carried away a

shoot," so that the plants, much to his disgust, suffered from a chronic state of disfigurement.

In the Musk we have a plant which, great favourite though it now is, is likely to play a still more important part in floral decoration. We shall probably see ere long a new race of showy flowering plants which will retain the grateful perfume of the old species. Unless I am much mistaken, the Musk has a great future before it. Nothing can be more simple than the culture of this plant; the roots have merely to be divided into short pieces, placing about a dozen in a 4-in. pot, using some good, free, rich soil. Place in gentle heat, and support the young growth by means of three or four neat stakes, and pieces of bast being run from stick to stick. If liberally treated, they will form bushy masses of fragrance for early spring work. The tender, green foliage and bright yellow flowers present a very refreshing appearance.

Everyone is acquainted with the Heliotrope or Cherry-pie, of which there are now so many admirable varieties. Everyone, however, does not know how well adapted for pot culture this plant really is. There are now many varieties which are admirably suited to this kind of work, inasmuch as they are of a close compact habit and very floriferous. Some cuttings should be struck in May, and kept growing on until they become established in 4-in. pots, keeping them stopped till about the middle of August, when a portion should be allowed to form their flower-bud, pinching back the remainder a fortnight later. These plants will come well into flower during the early winter months, and are very acceptable when all outdoor bloom is past, for cut flower or other purposes. About February the plants may be cut back and started in warmth, when they will come into flower again in the spring. The Heliotrope may be planted out in a structure where it gets a little gentle warmth during the winter, or it may be grown on into specimens, in which latter condition it is but seldom seen. A specimen Heliotrope is, however, very pretty, and not at all difficult to obtain. It should be made to assume somewhat of a pyramidal form by training up one or two shoots in the centre, and judiciously pinching in the remainder. A good specimen may be formed in a season, when all that is necessary to do is yearly to prune it in, and when fairly started, shake away some of the old soil, replace with fresh, and place in a warm moist atmosphere for a time.

The plants above enumerated are those of the sweetest nature, which are the most easily grown. By their means one may command perfume the whole year through. There are, of course, many other sweet-scented plants, amongst which may be cited the Hyacinth, the Rose, and many of the Cyclamen persicum. The Lilac, the common Thorn, and the Sweet Brier may all be potted and started early into growth, where there is convenience to do so. The Gardenias, or Cape Jessamine, are remarkable for their perfume, but they demand an accommodation and manipulation which prevents their being so generally grown as they otherwise would be.—"Field."

NOTES AND QUESTIONS ON THE INDOOR GARDEN.

Yucca filamentosa variegata.—This is the kind of plant one needs for conservatory or corridor decoration, for while it combines all the beauty of a variegated Pine and similar tender subjects, it flourishes in the temperature at which such places are kept during the greater part of the year. A good sponging and syringing overhead occasionally removes accumulations of dust to which plants are subject in such situations.—J. GAOON.

Musa Livingstoniana.—Some years ago (Linnean Society's Journal, 1865, p. 123) Dr. Kirk dedicated what he regarded as a new species of *Musa* to Dr. Livingstone. Seeds of this *Musa Livingstoniana*, we learn from a German contemporary, are offered for sale by Thierrard, of Alexandria. To preserve the germinative power of the seeds they have been dipped in honey and then rolled in coal-dust. No doubt many persons would like to possess this plant on account of the interest attached to its name; but we may remind our readers, in order to prevent disappointment, that it is very much like *Musa Ensete*. Indeed Dr. Kirk says himself that in habit *M. Livingstoniana* is undistinguishable from *M. Ensete*. It is 18 ft. high, with a thick conical stem, bulged at the base, where it is of a purple colour. The leaf is nearly sessile, the midrib thick, and the blade broad, as in *M. Ensete*; but the seed is very different, and this is the only difference yet known, as the fruit has not been described. Dr. Kirk describes the seeds as small, tuberculated on the surface, rounded, with flattened facets, a deep hilum at one extremity, and a disk-shaped elevation. The testa is black, but not glossy, as in *M. Ensete*, and hard and brittle.—"Gardeners' Chronicle."

THE LIBRARY.

GUIDE TO THE ROYAL BOTANIC GARDENS, KEW.*

THIS new edition of a popular guide book is just what is wanted by the general run of visitors, who desire some little information on the more striking and curious plants cultivated in our national garden. Containing many woodcuts and concise accounts of the uses, &c., of the plants spoken of, it is made still more interesting by the very numerous quotations from all sorts of books—paragraphs describing the beauty of the trees and plants in their native habitats and the impressions they gave the writers. In the present edition new matter has been introduced and information culled from various sources previously unavailable; e.g., several newly-published books are quoted from, or at any rate books published since the date of last edition, such as Flückiger's and Hanbury's "Pharmacographia," and Belt's "Naturalist in Nicaragua." From the former work the following extract is given: "The Fig is said to have been introduced to England by Cardinal Pole, where they still exist in the garden of Lambeth Palace. But it had certainly been in cultivation at a much earlier period. There is record of its cultivation in the thirteenth century." A plan of the pleasure grounds is given in this edition, by means of which many of the collections of forest trees and shrubs can be easily found. Altogether, care seems to have been taken to bring the "Guide" up to date and to render it as useful as possible. It, however, is by no means perfect, for there are many errors which certainly ought never to have been allowed to creep into it; for instance, *Retinispora* for *Retinospora*, *Callitris* for *Callitris*, *Notochlaena* for *Nothochlaena*, *Alcacia* *Lowei* for *A. Lowi* (a mistake, by the way, continued from previous editions). Again, we are told specially to note many plants which a careful search in the spots indicated fails to discover. *Amorpha fruticosa* is not to be seen on lawn D, and the *Opuntia* with the cochineal insects feeding on it only exists—at any rate, the insects only exist—in the printer's ink. *Cheirostemon platanoides*, the Hand-plant of Mexico, has long disappeared from its bed in the winter garden, although the paragraph concerning it remains in the present "Guide." After mentioning *Fuchsia excorticata*, a New Zealand species, it is stated "that, with this and another exception, the large genus *Fuchsia* is exclusively South American;" this, however, is not the case, as there are several Mexican species, and at least another New Zealand one in addition to *F. excorticata*. Now that carnivorous plants are attracting so much attention, the compartment in which they are grown, recently built at the end of the Orchard house, might profitably have been given in the plan and much worry both to inquirers and to those inquired of would thus have been saved. With regard to the great Palm stove, we are now told that the interior is heated by six boilers (of which three or four are usually all that are required in winter), with which a system of over 19,500 ft. of hot-water piping, 4 in. in diameter, is connected; the last edition estimated the length of 4½-in. pipes at about 24,000 ft.

HOLMES' BOTANICAL NOTE-BOOK.†

If students of botany will follow strictly the lines laid down for them in this little work they cannot fail to acquire a good foundation on which to erect a thorough superstructure. The author is perfectly correct in saying that too often the names of plants merely are learned, while a corresponding knowledge of their structure and of the reasons why they are placed in certain Natural Orders is not obtained. No doubt this state of affairs is owing to the numerous exceptions to given rules met with by students, and also to the great number of technical terms found in so many text-books. In the present work only the terms most frequently found in floras, &c., are given, and these are thoroughly and succinctly explained in a glossary. Two charts of the Natural Orders are given, and in these the diagnostic characters are reduced to a minimum as far as possible, those which are most easily observed having been chosen in preference to the more minute, whilst all the exceptions have been indicated in an appendix. With this help it becomes a comparatively easy task to find out the Order of any plant belonging to the more important Natural Orders and of all plants indigenous to Britain. Three diagrams are given—Scarlet Geranium, Daisy and Dandelion, and Narcissus. All the parts of the plant and flower are given in detail, and each part has its name printed near it. The plants purposely chosen for illustration are very easily obtained. The Daisy shows both ray and disc florets, but as it has no pappus, the Dandelion is figured, which has. Explicit directions are given for examining

plants, microscopically and otherwise, chapters on how to describe a plant in the schedules contained in the book, how to use the charts, &c.; also a floral calendar or list of plants with their periods of flowering. Although this book will be specially welcomed by medical and pharmaceutical students, we can heartily recommend it to all who are commencing the study of botany.

The *Album Van Eeden* No. 1., 1878, just received contains coloured plates of a single early Tulip with variegated leaves called Yellow Prince; *Sprekelia* (*Amaryllis*) *formosissima*, a well known crimson kind; a group of *Calochorti*, of various colours; *Lilium Thunbergianum aureum maculatum*; a group consisting of charming varieties of the beautiful *Spargax* *tricolor*; and two varieties of *Glaucolus floribundus*. These are well drawn and beautifully coloured. Their only fault is the ground colour, which is too dark.

The *Official Handbook of the National Training School for Cookery*.*—A useful clearly written book, and a decided improvement on the usual cookery book, being so explicit in the case of small details, which in themselves are necessary to produce a good result in cooking. The portion of the book devoted to vegetables is the least instructive. Very few receipts are given, and these are of the most ordinary kind. Hardly any mention is made of fruits, a strange omission, seeing that the work is compiled for the use of the National Training School for Cookery.

TREES AND SHRUBS.

IMPORTANCE OF THE CATALPA TREE FOR ECONOMIC PLANTING.

By C. S. Sargent, Director of the Arboretum of Harvard University.

The *Catalpa* (*Catalpa bignonioides*), long known and generally planted as an ornamental tree, has of late years begun to attract considerable attention as offering peculiar advantages for economic planting. The wonderful durability of the wood of this tree, long ago pointed out by General Harrison, but until lately imperfectly understood; its rapid growth in good soil, and freedom from the attacks of insects, make the *Catalpa* a most promising subject for general planting in rich, strong soil, in any portion of the United States south of the 42nd parallel. Farther north it often suffers in severe winters, especially when young; and in the New England States, except in exceptional situations, the soil is not rich enough to make the planting of this tree as profitable as that of many others better suited to reach maturity in that section of the country.

The wood of the *Catalpa* is soft, light, close-grained, and unselective of a good polish. In general appearance it closely resembles Chestnut, but, unlike that wood, it is easily "filled," and shows none of the tendency to warp or start which renders Chestnut unfit for the best cabinet work. Should the wood of the *Catalpa* ever reach the market in quantity, it will rank with Butternut for cabinet and architectural work, and will make a valuable addition to the hard woods now so freely employed in interior decoration. It is, however, for railway ties, fence and telegraph posts, Hop and Vineyard poles, and such purposes that the wood of the *Catalpa* is particularly adapted, and it is for these and similar employments, where a wood capable of resisting decay when exposed to the soil and weather is required, that *Catalpa* will probably be more profitably employed than the wood of any other tree suitable for cultivation over so large an area of the United States.

Why the soft wood of this fast-growing tree, which is traversed with large open ducts, nearly as broad as those of Red Oak—a wood which notoriously rots very quickly—should resist decay longer than almost any other of which we have any knowledge, is not clear. And this fact presents a problem for which a chemist may perhaps be able to find a solution. The fact, however, is undeniable. Samples of *Catalpa* wood are before me, taken from the top and bottom ends of posts which are known to have stood in the ground in Indiana for seventy-five years, and which are still perfectly sound; and many other similar instances of its power to resist decay are recorded. Another peculiarity of the *Catalpa* is its small amount of sap-wood or living tissue, so that, unlike the Red Cedar and most exogenous trees, in which the soft and worthless sap-wood turns by death into durable heart-wood only at the end of many years of growth the *Catalpa* produces heart-wood when the stem is scarcely 1 in. in diameter. For this reason the *Catalpa* has not an equal for fence posts and different sorts of small stakes, for which, if other woods are used, many years of growth must be sacrificed in order to avoid the rotting away of the outer and living layers, which have no power to resist decay.

* "Guide to the Royal Botanic Gardens and Pleasure Grounds, Kew." By Daniel Oliver, F.R.S., F.L.S. 28th edition. London: Macmillan & Co. 1878.

† "Botanical Note-book, or Practical Guide to a Knowledge of Botany." By E. M. Holmes, F.L.S. London: Christy & Co. 1878.

* London: Chapman & Hall.

The few experiments which have been made with Catalpa wood for railway ties seem to promise that it will be of great value for this purpose, although such experiments are neither frequent enough nor of sufficiently long duration to be entirely conclusive; and it is evident that a longer test than it has yet been subjected to is necessary to demonstrate that this wood has the power to resist the crushing of the rails and to hold spikes equally well or better than Chestnut or White Oak, which, all things considered, are the best North American woods yet extensively employed for this purpose. It is but fair to say, however, that many practical railway men of excellent judgment, who are carefully watching in the West the Catalpa ties, speak with great confidence of their value, and already very large experimental plantations of this tree are being made in Eastern Kansas by railroad directors of that State,

with a view of raising their own ties in the future. The Catalpa would seem, then, to be one of the most valuable trees which our cultivators, suitably situated, can plant. It grows readily and rapidly from seed, and can be very easily transplanted either in the spring or autumn. If planted thickly—say 4 ft. between the plants each way—they will run up with tall, straight stems, and make trees very different in appearance from the short-stemmed, round-headed, and rather distorted-looking specimens which are generally met with in ornamental grounds, especially in the Northern States. The thinnings of a grove of Catalpa, if planted in good soil, will in a few years be large enough for Vineyard stakes; in a dozen years the alternate plants will each make two or three fence posts, and the remainder will each, in twenty-five or thirty years from the time they were planted, probably be large enough to be cut into five or six railway ties. Cultivators to whom the annual expenditure for posts, fencing, or stakes is very considerable, will do wisely to plant every year a few hundred or thousand Catalpas, according to their circumstances, and thus insure for themselves an abundant supply of home-grown material. Should the objection be raised that the planter of trees must wait too long for his returns, it must be borne in mind that the money value of land will be largely increased if it has upon it a thrifty growing grove of Catalpas, or other valuable trees, whatever their age may be, and that purchasers of land in the near future are going to look with considerably more attention than in the past at the size and nature of the wood-lots.

A well-marked variety of the Catalpa is recognised in cultivation in some of the Western States, flowering two weeks earlier than the ordinary form, which it is said to greatly excel in hardiness, with larger white flowers and more upright, rapid growth. This variety, which reproduces itself from seed, is the more desirable to plant. Seeds of it can be procured through Mr. E. E. Barney, of Dayton, Ohio, who has long taken an active interest in the Catalpa tree, and has done much to make its merits more generally known. He has lately published a pamphlet on the subject ("Facts and Information in relation to the Catalpa Tree"), which should be read by all, and their number should be legion, who intend planting this tree.

Mr. Barney has favoured me with several large and instructive sets of wood specimens of the Catalpa, with which I have been able to enrich the principal museums of economic botany in this country and Europe.—"New York Tribune."

THE CLUSTER PINE.

(PINUS PINASTER.)

This well-known Conifer was first introduced to Britain by Gerard about 1596; the original trees, it is said, were planted in the garden of Bishop Compton, at Fulham, and probably some of them are still in existence. The Pinaster is a native of

France, Spain, Portugal, and other parts of Continental Europe, where it is extensively grown, mostly near the sea-coast, in light, sandy soils, it being naturally adapted for maritime situations. There are now many varieties in cultivation more or less distinct, some with peculiarities of habit and growth, others that differ from the species in the development of cones, some of which are borne in clusters of twenty or more in a whorl. The variety *Lemoniana* bears single cones on the ends of the leading shoots, so much do the varieties vary as to coning; the cones of the type are large and ornamental, of a bright brown colour, and are chiefly grown in whorls of four or five in number, but sometimes more. This Pine is invaluable for planting on sandy stretches along the sea-coast where shelter belts are needed. As a proof how vigorous and healthy it grows close to the sea, it may be seen at Hastings, on an exposed hill adjoining the shore, thriving beautifully where no other Pine succeeds so well. On the coasts of the Bristol Channel and many other parts of the west, examples of the Pinaster may often be noticed standing out boldly where but few

other trees can exist, bearing the brunt of terrific western gales without injury. Indeed, it is essentially the Pine above all others for planting on the sea-shore for shelter or ornamental effect, but it should not be crowded together when planted in belts or masses, but should be thinned out regularly and gradually, so as to allow its wide-spreading branches room for full development. It has a peculiar habit of growing crooked in the stem, and often in a leaning direction, as if threatening to uproot, but in reality rarely doing so, for it is a comparatively deep-rooting Conifer. As an ornamental tree, when well grown and fully matured, it ranks amongst the quaint, picturesque type, and its foliage is of a deep green colour. The timber is coarse and of no great value compared with that of other kinds of Coniferous trees.

G. B.

Leaves and Cone of Pinus Pinaster.

ANSWERS TO CORRESPONDENTS.

Pink Hawthorns.—I want to know the proper time and how to strike cuttings of the Pink Thorn, so as to have some pots for the conservatory.—H. S. [The Pink Thorn, or any other variety of Thorn is most easily propagated by budding on the common Hawthorn in July or August, according to the condition of the stock and bud. The quickest way of having Thorns in pots for the conservatory would be to procure young plants from a nursery and pot them.—O.]

Plants for Exhibition.—*Aberian.*—To your first question we say "Yes," unless the schedule states that fine-foliaged stove or greenhouse plants are required. 2. You can show all the Ferns you name as exotic Ferns, but not as stove Ferns. 3. See separate article on this subject. 4. All the plants named are well adapted for the purpose you mention.

Leaf-mining Insects.—Can you tell me what grub it is I send you within *Cineraria* leaves. My plants last year, although constantly hand-picked, were destroyed by it, and, unless you can suggest a remedy, I fear the same result this year. Would some solution of paraffin added be of any use.—T. W. H. [The mines in question I believe to be executed by the larvæ of a small moth, about which I hope to give more information shortly, as many of the larvæ are in the chrysalis state, and will, I expect, soon make their final change. The only way of hindering the spread of the insects is to pick off the affected leaves and burn them. When first observed, a gentle pressure of the leaves between the thumb and finger at the spot where the larva is working will destroy it, and prevent further disfigurement of the leaf.—W. W. S.]

Names of Plants.—Correspondents wishing plants to be named will oblige by complying with the following rules: To send the specimens as complete as possible, i.e., both stem, leaves, and flowers, and fruit, when possible. We cannot attempt to name plants from single leaves. To carefully pack them in gutta-percha tissue, or other impervious material which will prevent evaporation. Not to send varieties of popular flowers, such as *Fuchsias* or *Pansies*, which are best named by experienced growers of such plants, who have the means of comparison at hand. Not to send more than four plants or flowers at a time. Always to send, in addition to whatever pseudonyms or initials they may desire to use in the paper, their full name and address. To pre-pay all packages containing plants or flowers.—C. M. O.—1. *Omphalodes linifolia*. 2. *Phlox Listoniana*. 3. *Hieracium aurantiacum*. 4. *Polystichum vestitum* (syns.—*Aspidium vestitum*, *Polypodium vestitum*). Native of New Zealand. *H. D. H.*—*Otontoglossum cristatum*. *Mrs. M.* The Rose is a fine form of *Rosa pimpinellifolia*. The other plant is *Myrtus Kranesi*. *J. E.*—1. *Matricaria Chamomilla*. 2. *Polygala calcarea*. 3. *Prunella vulgaris*. 4. *Medicago lupulina*. *A. A.*—The Ground Ivy (*Glechoma hederacea*) *G. T.*—*Cibotium princeps* is a Tree Fern. The *Begonia* looks like one which was raised some time ago at Chiswick, the name of which we do not at the moment recollect.

Thinning Lilies.—I have some large clumps of the commoner kinds of Lilies which I want to reduce in number from twelve or twenty to about six. I want to know which to leave. I have read carefully the valuable information in THE GARDEN on the root-life of Lilies by "Dunedin" and others, but I am not clear as to whether each bulb will always grow on from year to year until it flowers. If this be so, in dividing a clump I should leave those bulbs which have not flowered this year, as they should do so next year. I suppose the best plan is to make such a change soon after the plants have flowered, taking care to keep the roots moist.—F. CLOWES, *Windsor-merc.* [I would recommend Mr. Clowes to replant in each clump five or six of those bulbs that have flowered this year. From the manner in which he puts his question, it appears to me that he has not yet noticed that within all bulbs that flower one year are the successional bulbs which will flower next year, and their successional bulbs will do the same the following year, and so on. He is right, according to my doctrine, in supposing that the best plan is to make such a change very soon after each class of plants have flowered. This plan I can recommend, with the greatest confidence, as being the means of causing the plants to flower stronger and longer.—"Dunedin."]

Trees Killed by Field Mice.—If "R. F." (see Vol. XIII, p. 629) will try the following plan, he will, I believe, keep mice from injuring his young trees. Some years ago there was a young plantation here of Ash and Oaks, and amongst them a quantity of young Holly bushes. Many of these trees and Hollies showed one summer that they were in a dying state; and, on examining them, all were found to have been denuded of their bark at the surface of the ground by field mice. The long Grass hid them till the injury to the trees became apparent. A mode of destroying the mice was therefore tried by sinking glazed earthen pots or "panshons," as they are called here, into the ground, their tops being left level with its surface, and half filling them with water, with a little Scotch oatmeal dusted over it. Hundreds of mice were found drowned in these traps in a short time, and their numbers were so reduced, that the destruction of the trees was stayed. Large garden flower-pots, I have to doubt, would answer the same purpose if the hole in the bottom be well plugged, so as to hold water.—WILLIAM TILLERY, *Welbeck.*

Questions.

Weeds in Ponds.—How can I best get rid of weeds in a large piece of water?—E. C. S.

Preserving Rose Leaves.—What is the best way of preserving Rose leaves for keeping in a room for the sake of their perfume?—*Sonscaibna, Belfast.*

Sudden Failure in Raspberries.—Can any of your readers inform me of the cause of a sudden failure in the growth of my Raspberry plants? Up to this time I have been most successful in growing Raspberries, being careful in choosing the best varieties. The last renewal was about five years ago. Every autumn, at the time of removing the old wood, I apply to the surface of the ground over the whole plantation a full top-dressing of farmyard manure. This year the plants are gradually withering away without any prospect of fruit, and the young canes for the next year's supply are scanty and wanting in vigour. I have hitherto trained in a semi-circular fashion, bending the head of each plant, consisting of four or five canes, to that of its neighbour; I have, however, never found any bad result from this method of training. Can any remedy be suggested? or is it best to renew the whole plantation?—EDWARD THOMAS, *Welfield, Bulth.*

DESTROYING SLUGS.

TWENTY years ago my house, in the suburbs of Bristol, was practically in the country, being surrounded by small dairy farms and nursery grounds. Birds of all kinds were abundant, and the locality was so open, that one of my neighbours, about 250 yds. off, once found a covey of partridges in his kitchen garden. Since then the speculative builder has had a glorious time of it, and from my windows I can now see houses containing more than 3000 persons where, fifteen years ago, there was not a population of more than two or three families. As a natural consequence, the birds, save the inevitable sparrow and jackdaw, have disappeared. It is only in this way that I can account for my inability of late years to grow any tender seedlings. Last summer, after repeated efforts, I found all my labour and expense thrown away, and I came to the conclusion that my concealed enemy—for there was nothing to be seen—was the slug. At Michaelmas I resolved on a campaign, and, by the help of a few greased Cabbage leaves and an extemporised lantern, I made the following victims:—

Week ending	Sept. 29	.	.	.	1750
"	Oct. 6	.	.	.	1480
"	Oct. 13	.	.	.	1017
"	Oct. 20	.	.	.	690
					4937

Here let me stop for one moment to show the danger of arguing upon too narrow foundations. Looking over the above figures, I made certain that I had broken the back of the enemy, and that another week or two would clear my dominions. Imagine, then, my horror as the results came out, which I shall now set down:—

Week ending	Oct. 27	.	.	.	1997
"	Nov. 3	.	.	.	1792
"	Nov. 10	.	.	.	1894
"	Nov. 17	.	.	.	1215
"	Nov. 24	.	.	.	432
					12,267

Cold weather had now set in, and the work became, literally as well as metaphorically, not worth the candle. With the return of spring, however, I renewed the campaign, and the following is a summary of the results:—

February	825
March	326
April	1490
May	1329
June	1484
					5454

You will perceive that since the latter end of September I have caught over 17,700 slugs (including a few hundred snails). Perhaps you may suppose, however, that my ground is of considerable extent. In point of fact, a gardener would not call it a garden at all; it is but a strip about 30 yds. long and 10 yds. wide. Sapping it to be about 300 square yds., I have got, on the average, about sixty slugs upon each square yard. I have, unhappily, no reason to believe that my work is even half accomplished. This evening (July 1) a fresh attack on my enemies has brought me in only two or three short of 150 with which to commence the labours of another month, that is, if I continue the task, which seems utterly endless and hopeless.

AN AMATEUR.

SOCIETIES AND EXHIBITIONS.

ROYAL BOTANIC SOCIETY'S EVENING FETE.

JUNE 27.

THE floral decorations, which formed part of the entertainment on this occasion, were of a very interesting character, and visitors repeatedly stopped to admire the banks of beautiful annuals furnished by Messrs. Carter & Co., of Hulborn, and which are still on view. The best floral decorations were shown by Messrs. E. G. Henderson, of the Pine-apple Nurseries. They consisted of fire-place arrangements, so skilfully ornamented as to elicit general admiration. The one which obtained the first prize had a mantel-shelf covered with groups of Mosses and Ferns, out of which grew fine-leaved Caladiums. A plant of *Dendrobium thrysiflorum* graced one corner, and *Odontoglossum Alexandræ* the other. The first-place itself contained a well-grown specimen of *Eulalie japonica zebrina*, surrounded by brightly-flowered *Masdevallias* and a few Ferns. At each corner was a grand plant of *Todea superba*, and all vacant spaces were filled with Club Mosses. A light, creeping *Selaginella*, trained up the marble supports, gave the whole a light and elegant appearance. The other arrangement, not in competition, was highly commended; it was in every way equal to the one just described. The best dinner-table arrangement was contributed by Mr. Soder, gardener to O. Hanbury, Esq., Weald Hall, Brentford. The centre piece consisted of a graceful Palm (*Cocco*) set amidst blooms of white Water Lilies, crimson Cacti, *Anthuriums*, and *Cattleyas*, the stem of the Palm being partly encircled by a spike of flowers of *Odontoglossum Alexandræ*. At each end were trumpet-shaped vases, the cancers of which were filled with white *Gladioli*, *Dendrobium Bensoniæ*, double pink *Pelargoniums*, and pink *Cornflowers*. The trumpets contained Grasses, amongst which were a few blooms of *Odontoglossum gloriosum* and blue *Cornflowers*. A dozen small glasses, placed round the table, contained blush *Rose-buds* and Ferns, and the effect as a whole was charming. The best ball-room bouquet came from Mr. Green, Victoria Street, Belgravia. It was wholly devoid of that formal and stiff appearance so frequently seen in bouquets, and was of a very appropriate size. It consisted chiefly of white flowers, such as those of *Stephanotis*, *Bonvardias*, *Tuberoses*, *Hoyabells*, sprays of white *Spiræas*, and Ferns. To these were added a few flowers of a pink *Bouvardia* and of *Aerides odoratum*, just to give a little colour. Several good head-dresses were shown, and, as a rule, the whole arrangements were excellent.

NATIONAL ROSE SOCIETY.

JUNE 29.

THIS, the second great show of this Society, took place last Saturday at the Crystal Palace; though a good one, it was not equal in some respects to that of last year, and the arrangements were somewhat unsatisfactory. In the first places, there were many vacant places on some of the stages, which might easily have been avoided. This was caused, we learn, through many exhibitors who brought their Roses keeping them under the benches instead of staging them, a practice neither creditable to the exhibitors nor fair to the Society. In the next place, no provision had been made for allowing representatives of the horticultural press to visit the show until it was opened to the public, an oversight which caused much unnecessary trouble and inconvenience, for when the crowd of visitors arrived it was impossible to take more than a passing glance at the Roses. In the third place, the tickets announcing the prize collections, instead of being associated with the exhibitors' cards, were in most cases stuck carelessly on to the sides of the boxes, causing considerable trouble in finding them. No sooner, too, had the judges finished their work than large placards, bearing the names of the growers, were placed on their productions, thus greatly impairing the effect of the exhibition.

The Roses, on the whole, were exceedingly good, and a large and fine collection from Messrs. Wm. Paul & Son added greatly to the effect of the show. The classes for blooms of one variety were well filled, and the nurserymen's classes were all that could be desired. The collection of old Roses from Mr. Stadden was exceedingly interesting, and, with the exception of the few mistakes just alluded to, the show, we think, may be fairly pronounced to have been a success.

Nurserymen's Classes.—In the premier class for seventy-two distinct trees there was a fair amount of competition, five collections being shown. Messrs. Cranston & Co., Hereford, had magnificent blooms of *Madame Lacharme*, the brilliant rosy-crimson *Horace*

Vernet, very large and exquisitely-formed examples of *Madame Eugénie Verdier*, the white *Niphotos*, and *La Havre*, an elegantly-formed flower of a bright vermilion colour; with these were effectively associated brilliant blooms of *Xavier Olibo*, *Reynolds Hole*, the beautiful pink *Annie Laxton* and *Madame Etienne Levet*, and the flesh-coloured *Duchesse de Vallombrosa* and *Captain Christy*. Mr. Cant, Colchester, had the next best collection, the principal kinds in which were medium-sized, but beautifully-coloured, examples of *Reynolds Hole*, *Star of Waltham*, the brilliant *Charles Lefebvre*, and the clear pink *François Michelson*. The white *Souvenir de Elise* and the creamy *Devoniensis* formed a striking contrast to the velvety-crimson *Duke of Edinburgh* and the bright red *Horace Vernet*. In the same class Messrs. Paul & Son had fine examples of *Jean Liabaud*, *La Duchesse de Morny*, *Baron Rothschild*, and *Souvenir de Elise*. In other collections the best blooms were *Captain Lamure*, *Souvenir d'un Ami*, *Maréchal Vaillant*, and *Madame Hippolyte Jamain*. In the class for forty-eight Roses, three blooms of each, Messrs. Cranston & Co., Hereford, had good examples of the pink *Edward Morren*, finely-formed flowers of *Marie Banman*, the brilliant *La Havre*, *Madame de St. Amand*, the brilliant scarlet *Exposition de Brie*, and the bright rosy-pink *Madame C. Wood*. The next collection in point of merit came from Messrs. Keynes & Co., in which were elegant blooms of *Souvenir de Elise*, *Madame Marie Rudy*, and *Niphotos*. In the class for thirty-six single blooms there were nine exhibitors, the most successful one being Mr. Turner, Slough, who had *Souvenir de Elise*, finely-coloured *Maréchal Niel*, the rosy-magenta *Madame Ferdinand Jamain*, and *Paul Neron*. These were shown off to good advantage among fine blooms of *Xavier Olibo*, maroon-crimson *Louis Van Hontte*, *La Rosiere*, and the beautiful rus-coloured *Madame George Paul*. In the same class Messrs. Curtis had beautiful fresh blooms of *Duke of Wellington*, *Marquise de Castellane*, the bright *Avocat Duvier*, and *Star of Waltham*. The other collections were grand blooms of *Paul Neron*, *Captain Christy*, and fine examples of *Marie Banmann*, whilst the pure rose *Antoine Dacher* and the maroon-crimson-tipped *Reynolds Hole* were probably never shown better. *Horace Vernet* and *Miss Hassard* were also excellent. The best twenty-four Roses, three blooms of each, came from Mr. Cant. Amongst them were *Xavier Olibo*, the delicate pink *Baroness de Rothschild*, the rich cream-coloured *Devoniensis*, and the golden-centred *La Boule d'Or*. *Fisher Holmes* was excellent in colour, and associated effectively with the bright rosy-magenta *Ville de Lyons* and the deep rose *Marie Rady*. Messrs. Keynes had very fine ivory-white blooms of *Souvenir de Elise*, the magenta *Docteur Andry* associated with *Reynolds Hole*, and the pink-dusted *Catherine Mermet*. In other collections the best blooms were the *Countess of Oxford*, *La Havre*, and *Horace Vernet*. Mr. Turner had the best twenty-four single blooms, among which were even medium-sized examples of *Marguerite Brassac*, the bright crimson *Lord Macaulay*, and *Charles Lefebvre*. From Messrs. Curtis, Sanford & Co. came good blooms of *Madame Charles Wood*, *General Jacqueminot*, the cream-coloured *Rubens*, and *Countess of Oxford*. In other collections were good blooms of *Annie Laxton*, *Marie Rady*, *Fisher Holmes*, *Horace Vernet*, the rosy-pink *Camille Bernardin*, and the deep crimson *Abel Carrière*. Messrs. Mitchell & Sons had the best twelve *Tea* or *Noisette* Roses, among which *Souvenir de Elise Vardon* was probably never seen more perfect; *Devoniensis* was beautiful; also the white *Julie Mansais*, and *Madame Margottin*. Mr. Cant had the blush *Souvenir d'un Ami*, the creamy-white *Madame Villermoz*, and *Niphotos* in fine condition; and in other collections we noticed admirable blooms of *Souvenir de Elise* and *Madame Hippolyte Jamain*.

Open Classes.—The best twelve new Roses, not in commerce, came from Messrs. Paul & Son, Cheshunt, consisting of finely-formed, smooth-petalled flowers of the fiery maroon-crimson *Jean Souper*, the clear pink *Annie Laxton*, the brilliant *Duke of Connaught*, and *Sultan of Zanzibar*. Mr. Turner, of Slough, had *John Stuart Mill*, rosy-scarlet; *Marguerite Brassac*, deep rose; *Rev. J. B. Camm*, lively pink; and *Henry Bennet*, bright crimson, in good condition. The best twelve blooms of *Etienne Levet* came from Messrs. Paul & Son; they were of a fine carmine colour, large, and full. Messrs. Keynes & Co. had smaller and darker-coloured blooms of the same variety. *François Michelson* was poorly represented; the best blooms of it came from Messrs. Keynes & Co. Messrs. Cranston & Co. had twelve fine even blooms of *Jean Liabaud*, as did also Messrs. Paul & Son. Mr. Turner had the best twelve blooms of *Maréchal Niel*, and Messrs. Paul & Son the best *Marguerite de St. Amand*. In the class for twelve blooms of any dark-coloured Hybrid Perpetual, not named in the schedule, Messrs. Paul & Son were awarded a first prize for fine examples of *Marie Baumann*. Mr. Cant had good blooms of *Horace Vernet*, and Mr. Laing also showed *Marie Baumann*. The best light kind was *Captain Christy* from Messrs. Paul & Son, the blooms of which were very large and of a fine flesh colour. M. Ridout, gardener to J. B. Haywood, Esq., Reigate, had very large

and even blooms of the delicate silky-pink Baroness Rothschild, and the next best kind was the beautiful white Madame Lacharme.

In the class for twelve Tea Roses of any kind, not named in the schedule, Mr. Cant won the first prize with remarkable blooms of Bonle d'Or, a beautiful golden-coloured Rose with petals of great substance. This was one of the finest stands of Roses in the exhibition. Messrs. Keynes & Co. had good blooms of Souvenir de Elise, and Mr. Pinne had Jean Ducher in good condition.

The best new seedling Rose came from Messrs. Wm. Paul & Son, Waltham Cross, and consisted of a bright red kind named Duchess of Bedford.

In the class for old Roses in commerce previous to 1840 there was only one exhibitor, viz., Mr. Julius Stadden, Chipping Norton, who showed over fifty kinds. To many this collection was a highly interesting one; it afforded an opportunity of selecting certain kinds suitable for the wild garden, and served to show the improvements that had taken place in Roses since that date. It contained the single striped York and Lancaster, the white Globe Hip (so fine for small bouquets), Lamarque, yellow Provence (a fine Rose, but one which does not often open well), the creamy-yellow Eliza Sauvage, Chenedole (a Rose shown in every collection about twenty years ago), the common Moss and old Cabbage, the former said to be a sport from the latter, and a host of sorts the names of which were unknown.

The best twelve Roses in the amateurs' classes, three trusses of each, came from Mr. John Quennell, Brentwood, and contained good blooms of the crimson Xavier Olibo, Marie Baumann, La France, and Paul Verdier. In the same class Madame Lacharme and François Fontaine were well represented. Mr. Soames, Freeman Park, had the best twelve single trusses, among which the best were Captain Christy, the brilliant scarlet-purple-shaded Dr. Andry, and the pink Mons. Norman. Professor Adams, the Observatory, Cambridge, had good examples of Xavier Olibo and Madame Bravy. The best blooms in the class for six trusses were those of Maréchal Niel, Reynolds Hole, Marquise de Castellane, Lord Macanlay, Devonensis, Captain Christy, and Duke of Edinburgh, and the best examples of suburban-grown Roses were those of Charles Lefebvre. The best twelve blooms of Tea or Noisette Roses came from Mr. Waterlow, Reigate, and included good examples of Jean Ducher, Louise de Savoie, and Madame Berard. In other collections Cheshunt Hybrid, Catherine Mermet, the yellow Madame Margottin, and Madame Villermoz were the best blooms. In the class for eighteen Roses, six varieties, three trusses of each, Mr. Hollingworth, Turkey Court, Maidstone, sent good blooms of Maréchal Niel, Madame Villermoz, and Souvenir d'un Ami.

Miscellaneous.—Amongst Messrs. William Paul & Son's extensive collection of Roses, the most striking were Duke of Edinburgh, Fisher Holmes, the white Madame Lacharme, the rosy-magenta Alfred Colomb, Countess of Oxford, and Victor Verdier. The same firm also showed stands of new Roses, including the brilliant deep rosy-magenta-shaded May Quennell (one of the best new Roses that has been raised for some years), the scarlet Duchess of Bedford, Duke of Connaught, Madame Prosper Sangier, and a golden-yellow Tea Rose named Madame Lazarine Pixean, fine in a bud state for bouquets. Mr. Corp, Oxford, sent a large collection of Tea Rose buds cultivated on the seedling Brier. Mr. Rumsey, Waltham, also sent a good collection of Tea Rose buds, as did also Mr. Mayo, Oxford.

ROYAL HORTICULTURAL SOCIETY.

JULY 3.

THE exhibits on this occasion, though but few, were of an interesting description. New Roses from the Cheshunt, Waltham, and Slough nurseries, a group of new Lilies from the Colchester Bulb Company, and a fine display of Verbenas from Mr. Cannell, Swanley, formed the chief features.

First-class Certificates were awarded to the following new flowers, plants, and fruits:—

Rose Penelops Mayo (Turner).—A Hybrid Perpetual of English origin, and one which promises to become a most useful kind for exhibition purposes. Its flowers, which are a brilliant carmine-red, are large and finely formed.

Rose Dr. Sewell (Turner).—Without doubt one of the most beautiful English-raised Roses ever shown. It resembles Xavier Olibo, and is somewhat in the way of General Jacqueminot, but is deeper in colour. It is said to be a good grower, and no good collection of Roses will probably be long without it.

Rose Duchess of Bedford (Paul & Son).—An excellent Rose, previously described in THE GARDEN, and shown better on this occasion than hitherto.

Pelargonium Elfrida (V. Lemoine).—An Ivy-leaved kind having large trusses of clear rosy-violet-coloured well-formed double blossoms. A variety of great value for decorative purposes.

Pelargonium A. F. Barron.—An Ivy-leaved kind of bushy growth having double flowers, the colour of which is a pinkish-rose.

Pelargonium Lucie Lemoine (V. Lemoine).—A kind with dark glossy green Ivy-like foliage, bearing abundance of large, delicate purple-shaded, whitish blossoms. A useful and attractive variety.

Freesia refracta alba.—A white-flowered kind, beautifully scented, and well worth culture.

Melon Dells's Hybrid (Dell).—A green-fleshed variety with yellow, netted skin and of fine flavour.

Melon Netted Victory (Gilbert).—A coarsely-netted, green-fleshed kind, remarkably juicy and of excellent flavour.

Miscellaneous Plants.—Messrs. Veitch & Sons sent a pretty Oncidium, named *O. prætextum*, and several hybrid Lilies, which attracted much notice. Messrs. Chautriar Bros., Montefontaine, Oise, France, contributed a fine specimen of Croton Baronne James de Rothschild. It is a stately-growing plant, with leaves as large as those of *Magnolia grandiflora*, and of a beautiful dark bronzy-green colour, marked with bright crimson and orange veins. Mr. J. R. Pearson, Chilwell, showed Pelargoniums raised from seed of *P. echinatum*; they were named Beauty, Ariel, hybridum, and Prizie, all of good habit and bearing large trusses of varied shades of rose-coloured blossoms. Mr. C. Paohe, Birmingham, sent a double scarlet-flowered, golden-leaved Pelargonium named Golden Jewel. A large collection of Lilliums and Freezias came from the Colchester Bulb Company, including *L. Browni*, *L. Hansoni*, *L. parvum*, and other interesting kinds; also *Triteleia laxa grandiflora*, a beautiful blue-flowered kind from California, and several finely-coloured Calceolarias. Messrs. Carter & Co. furnished a basket of flowering plants of their *Eschscholtzia Mandarin*, figured in THE GARDEN (see Vol. XII., p. 568); also examples of a beautifully striped Phlox, named *P. Drummondii viridis laciniata stellata*. Messrs. Laing & Co., Forest Hill, sent the speckled *Gloxinia Papillon*, which was much admired. Mr. Barron showed, on behalf of Mons. V. Lemoine, Rue de l'Étang, Nancy, France, new Ivy-leaved Pelargoniums of a meritorious description; the best were Elfrida and Lucie Lemoine, already described, the double pink-flowered König Albert, and Madame Emilie Gallé, white with purple-striped centre. From the Society's gardens, at Chiswick, came finely-flowered, bushy plants of the beautiful blue *Torenia Fournieri* growing in pots, showing it to be one of the most useful and effective of decorative plants when well grown. Mr. G. Smith, Tollington Road Nursery, showed a collection of striped *Petunias*, which were highly commended on account of the fine dwarf habit of the plants, and the large size and varied colours of the blossoms.

Cut Flowers.—Stands of new Roses were shown by several of the leading growers. Mr. Turner, Slough, had grand examples of Harrison Weir, a blood-red Rose, double, and of fine substance; also Congress, Dean of Windsor, Dr. Sewell, and Penelope Mayo, to which latter two we have already alluded. Mr. Wm. Paul had a collection of English-raised Hybrid Perpetual Roses, among which were some promising kinds. Those which had been named were R. Dudley Baxter, rosy-crimson; Masterpiece, bright scarlet, very double; and Duchess of Bedford. The same exhibitor also showed a box of the beautiful pink May Quennell, one of the best new Hybrid Perpetual Roses in cultivation. Messrs. Paul & Son, Cheshunt, also sent several promising new Roses, among which may be mentioned Countess of Darley, a remarkably double flower when fully expanded and of a rich rose colour; Duke of Teck, very bright crimson; and Charles Darwin. Mr. Candwell, Wantage, contributed a box of good Rose blooms. Mr. G. F. Wilson sent blooms of *Lilium californicum*, *paralinum*, *Robinsoni*, and *Kramerii*, from large and small bulbs to show the different shades of colour. Mr. Noble, Sunningdale, sent blooms of Rose Queen of Bedders; also a new seedling Rose. Mr. R. Dean, Ealing, showed a collection of flowers of his improved strain of Sweet Williams, most of which were light coloured, but fine in shape and smooth and sound in the petals. Several of the kinds were striped and pretty, and some had Auricula-like flowers of a beautiful mauve colour with white edges. Mr. Candwell, Wantage, also sent an extensive collection of Sweet Williams, among which were some remarkably fine flowers, both light and dark. The same exhibitor also sent blooms of *Antirrhinum*, which were noteworthy on account of their large spikes and well diversified colours. Mr. Cannell, Swanley, had a large collection of cut blooms of Verbenas, which embraced every shade of colour, from brilliant scarlet, blue, and purple, to the most delicate white, pink, and mauve. A large and interesting collection of cut blooms of *Dianthus Heddeewigi* came from the Society's

gardens; the flowers were large and fine, and remarkably bright and varied in colour. Mr. Dean sent several promising seedling Carnations and Picotees, and Mr. Noble had cut spikes of *Spiraea palmata* of a highly meritorious description. Mr. Parker showed a double-flowered Martagon Lily, also *Chotbera Youngi*, one of the best of the Evening Primroses for border decoration.

A cultural commendation was awarded to Mr. Heims for a well-grown plant of *Cattleya gigas*, which bore a dozen very large, gorgeously-coloured blossoms.

Fruits and Vegetables.—Mr. Monro, Potter's Bar, sent a dozen Melons named Monro's Bismarck, a green-fleshed, deeply-ribbed kind; also a scarlet-fleshed Melon called Lord Salisbury. Mr. H. Mann, gardener to Mrs. Hornsby, St. Vincent's, Grantam, also showed seedling Melons. Mr. Gilbert, Burghley, exhibited several large Peas; and Mr. Turner, Slough, sent a beautiful Kidney Potato named Early Bird, a kind which was highly spoken of at the Potato exhibition in 1877. Mr. H. J. Hardy, Stour Valley Seed Grounds, showed plants of a new Pea called Sequel. It is said to be a heavy cropper, and each pod contains not less than ten medium-sized, round Peas. Mr. Cowburn, Sunbury Park, sent a Cos Lettuce named Sunbury Park, which appears to be a good kind.

SCOTTISH PANSY SOCIETY.

UNDOUBTEDLY the best and largest display ever made by this Society during its existence of thirty-four summers was on 21st ult., on the occasion of the annual show held at Edinburgh. Not only were the entries larger by half than is usual, but exhibitors were represented from a very wide radius, showing that the Society is attracting to itself an interest over the length and breadth of Scotland; while the quality of the exhibits must be pronounced exceptionally good, evincing a growing attention to the culture of this pretty border flower. In the nurserymen's class for twenty-four blooms of Show Pansies, Mr. Paul, Paisley, for the third consecutive year was awarded first prize and the Society's silver medal, with fine specimens of J. P. Barbour, Michael Saunders, Alex. Watt, Mauve Queen, John Rowatt, Robert Black, dark self; Jeannie Grieve, Mary Paul, Mrs. Eylee, Mrs. Arthur, Mrs. Henderson, Minnie, Mrs. Owen, the Duchess, Annie Wood Paul, white grounds; Clonard, Dr. Livingstone, James Orr, Miss Hope, Miss Rogers, R. Pollock, George Steedman, yellow grounds; May Queen, white self; and Mrs. Horeburgh, yellow self. Messrs. Dicksons & Co., Edinburgh, 2nd; Messrs. J. Cocker & Sons, Aberdeen, 3rd. For twenty-four fancy Pansies, Messrs. Downie & Laird, Edinburgh, received 1st and silver medal. The following are the varieties, and they were unquestionably the finest blooms for size and quality in the exhibition, viz., F. W. Leland, Mrs. S. Plommer, Mrs. J. Watt, James Grieve, Mrs. L. T. Fleming, Angus McLeod (seedling), W. Postlewhaite, Miss M. Methven (seedling), Mrs. E. H. Wood, Mrs. Jamieson, Honourable Mrs. Beatson, Isa McMeeking, Lady Falmonth, George Wood, Miss Talbot (seedling), Miss McNut, Mrs. Longfield (seedling), Lady Clerk (seedling), and six seedlings unnamed. Messrs. Dicksons & Co., 2nd; Cocker & Sons, 3rd. In the open class, Mr. Paul, Paisley, carried off 1st for eighteen show Pansies, with Luna, Darkness, Mauve Queen, Captain Knowles, dark self; Janet Lees, Miss E. Cochran, Delicata, Minnie, Mary Robertson, Mrs. Henderson, Jeannie Grieve, white grounds; Defoe, James Orr, Oracle, Mrs. Russell, Clonard, yellow grounds; May Queen, white self; and Citron, yellow self. Twelve seedling fancy Pansies: 1st, Downie & Laird; 2nd, Dicksons & Co. Six seedling show Pansies and six seedling fancy Pansies were shown in excellent condition by W. Paul, who was 1st. Twenty-four bedding Violas: 1st, Downie & Laird; 2nd, Dicksons & Co.; 3rd, W. Paul. Messrs. Downie & Laird's stand contained flowers possessing qualities in colour and substance to an eminent degree, and we are sorry we could not get a list of the varieties, as they were far ahead of what one generally sees in the Viola as exhibited at previous shows. Twenty-four bedding Pansies: 1st, Dicksons & Co.; 2nd, William Paul. Twenty-four self Pansies, viz., four blue, six white, six yellow, and eight dark: 1st, Mr. W. Paul, with Sunnypark Rival, Royal Blue, Chieftain, Crossfat Rival, blue; May Queen, Parity, Bessie Peacock, Snowdrop, Mrs. Todd, Miss Ransay, white; Mrs. Horeburgh, Dr. Masters, Citron, Cloth of Gold, Nugget, Zama, Yellow Boy, yellow; J. P. Barbour, M. Saunders, Darkness, John Rowatt, Mauve Queen, Luna, Rev. J. Morriean, Alex. Watt, Jas. Dalziel, dark; 2nd, Mr. L. T. Fleming, Berwick. It is unnecessary to give the other prizes in detail. In the gardeners' class Mr. Borrowman, Beeslack, Edinburgh, carried all before him with very fine flowers of the leading varieties in cultivation, and also secured some prizes in the open class; while Mr. Fleming, Berwick, was the most successful competitor in the amateurs' class, and gained the silver medal for most prizes. The amateurs' class was also well represented by Mr. Rose, Laurence Kirk; J. S. Ritchie, Denny; and

W. Barr, Paisley. For the prizes for the best flowers in the various classes, to be selected from any stands in the exhibition, the following flowers were chosen: Best white ground, Jeannie Fleming (seedling); best yellow ground, Charles Turner (seedling); best dark self, Crosshill Gem; best white self, Jenny Anderson; best yellow self, Mrs. Horeburgh; best blue self, Sunnypark Rival; best flower in the exhibition, Jeannie Fleming. A prize was also offered for the best crimson self, and Pilrig Beauty, a variety sent out this year as a show Pansy, and described as a "crimson-lake self, a fine round flower of great substance," was the candidate, but the judges unanimously refused it. First-class certificates were awarded to Mr. Borrowman for fancy Pansy J. H. Borrowman; to Dicksons & Co. for fancy Pansy Memento; to Mr. Rose, Laurence Kirk, for fancy Pansy Jas. Douglas; and to Mr. Robertson Mauro, Edinburgh, for bedding Viola Pink Perfection. J. G. P.

Scottish Horticultural Association (July 2).—Mr. A. D. Mackenzie read on this occasion a paper on "Heating." He described two methods of heating by water—the one by means of high pressure with small malleable iron pipes, and the other by low pressure with cast iron pipes and boilers. He then gave his experience of the various boilers which were used, giving preference to the saddle boiler. All who took part in the discussion agreed that the saddle boiler was the best. Mr. James Grieve read a paper on "Campanulas" in which he enumerated the different kinds, the places from which they had been first brought to this country, and then gave a general idea of the mode of cultivation. Rare specimens of the Iris, *Tropeolum polyphyllum*, and *Astromeria chilensis* were exhibited by Mr. Dow, twenty-four new seedling fancy Pansies came from Messrs. Downie & Laird, beautiful flowers of *Hoya carnea* from Mr. R. Robertson, and large spikes of Stocks from Mr. Wm. Black.

Rainfall at Kylemore Castle, Co. Galway:—

June	June	June
1 —	11 '65	21 '08
2 —	12 —	22 '49
3 '66	13 —	23 '43
4 '23	14 '03	24 1'07
5 '48	15 '33	25 '42
6 1'24	16 —	26 '13
7 '66	17 '33	27 '77
8 '01	18 '19	28 '04
9 '35	19 '63	29 —
10 '22	20 '64	30 '35

11'32

This amount of rainfall is unprecedented, even in this wet locality, and is, perhaps, the largest on record. It will be observed that there were only six dry days during the whole of the month; the sky was dull and leaden, and the wind north and cold.—JAMES GARNIER.

OBITUARY.

COLONEL THE RIGHT HON. W. F. TIGHE died at Woodstock Park, Ireland, on June 11, in the eighty-fifth year of his age. To gardening and arboriculture the death of Colonel Tighe is a great loss; for more than sixty years he devoted a large portion of his time to his gardens and extensive woods, and for fifty-three years of that time he was zealously assisted by Lady Louisa Tighe in every work that has made Woodstock so beautiful and interesting. Colonel Tighe's first work was to plant Mont Alto, now so picturesque, but then a naked barren sear; and so well has ornamental planting been kept up, that Woodstock Park may now be said to be a vast arborium. Rare trees and shrubs now extend continuously from the house to what is termed the upper glen, some two miles distant, and the last work of Colonel Tighe was to plant an avenue of *Picea nobilis* on the upper drive to the glen. Colonel Tighe looked upon every new hardy tree as a treasure. Of the *Araucaria imbricata* he formed a high opinion, and when it was most expensive he planted some 200 trees of it; only one, however, of these has grown up to be a fine tree, and that owing to its having been planted on a suitable soil. The public can still see and appreciate the rare beauties of Woodstock Park, but only those who had the pleasure of living near or serving Colonel Tighe can fully estimate the loss which his death has occasioned. He trusted his servants with a dignified confidence, and when any plan of operations was once settled on, he never interfered with the details of the work. To the gardening public it will be interesting to know that Woodstock Park will continue the residence of Lady Louisa Tighe.—CHARLES McDONALD, *Stokesley, Yorks.* [All who know Irish gardens, and all who have seen the beautiful trees at Woodstock, will share the regrets of our correspondent and sympathise with Lady Tighe in her loss.]

WE have also to record the death, on the 29th ult., of Mr. William Holmes, Florist, Hackney, at the comparatively early age of fifty-seven. Mr. Holmes was well known and much respected, and by his death horticulture, especially that branch of it in which he was more particularly engaged, has lost an energetic supporter.

"This is an art
Which does mend Nature: change it rather; but
THE ART ITSELF IS NATURE."—*Shakespeare.*

BRITISH ORCHIDS FOR THE GARDEN.

In last week's GARDEN I observe (see p. 7) a short article from Mr. C. W. Dod in which he calls attention to *Orchis latifolia* as being worthy of more frequent cultivation than it has hitherto been subjected to in British gardens; and he further asks whether "*Orchis latifolia* is specifically distinct from *O. maculata*." In my opinion, Mr. Dod's observations deserve attention, especially his assertion that *Orchis latifolia* ought to be made more of a garden plant than it is at present. I would supplement his recommendation by stating that, in my opinion, all our British Orchids might be more extensively cultivated than they are, and that with much advantage and effect in modern flower gardening. It is only where they are seen in masses that their beauty and effectiveness can be realised. As a general rule, they grow singly, scattered through our meadows, which is probably one of the causes why they are so little noticed. I had an instance lately of the grand effect produced by *Orchis latifolia* as it grew in quantity together while on a botanical excursion to the extreme south-west of Ireland. On passing over a strip of country lying between Dingle and Ventry, Co. Kerry, I came on the corner of a moist field which was quite purple with the flowers of *O. latifolia*. The plants covered a surface of some three-fourths of an acre, and were nearly as close together as they could grow. The moist, warm atmosphere of that portion of Ireland which lies along the sides of Dingle Bay seemed very favourable to this Orchid, each plant averaging 1 ft. or more in height. I may here add another instance of the fine effect produced by a different species when growing together in large quantities, viz., *Orchis pyramidalis*. This grows naturally in the Glasnevin Gardens and in all the neighbouring meadows. I had last week occasion to look over a field which has lately been purchased by Government for the extension of the Glasnevin Arboretum, and in doing so I observed a dry bank on a portion of the field where many hundreds of this Orchid were in bloom and nearly close together. No one who is only accustomed to see the plant growing singly could form an adequate idea of its beauty in this instance where so many were under the eye at a glance. I had a quantity of it dug up and removed to the Orchid department in the garden; and even ordinary visitors were so attracted by the effect which it produced, that they left the gravel walks and went to examine what the brilliant flowers were which seemed new to them. The query having reference to the specific distinctness of *Orchis latifolia* and *O. maculata* seems to me not so easy to answer satisfactorily as would at first sight appear. I believe there are not many British botanists who would not say, offhand, that they are truly distinct species, which is also my own opinion in so far as the generally received idea of a species is concerned. It must, however, be conceded by those who have seen these plants growing extensively under very varied circumstances that forms do occur, especially on the side of *O. latifolia*, which are very intermediate. The longer spur, more deeply three-lobed lip, with the three sepals of the flowers spreading, and the solid stem are pretty constant marks for distinguishing *O. maculata* from *O. latifolia*, though I have seen forms where all these marks did not hold good. None of our British Orchids sport so much into varieties as *O. latifolia*, some of which are very superior to the ordinary form, but I have never seen any with flowers nearly equal in size to those mentioned by Mr. Dod, who says he has met "with flower-heads fully 1 ft. long, and closely set with blossoms." An inflorescence covering a rachis of from 2 in. to 4 in. long is what I have seen in the case of this plant.

D. MOORE.

Glasnevin.

TABLE PLANTS.

In the remarks which I forwarded to you upon this subject (see p. 1) I purposely confined myself to the consideration of plants which one can see over, and of plants which one can see under, when placed upon tables of the usual height, which is generally 2 ft. 5 in. from the ground. But there is a third group of table plants to which I did not then allude, because their height is of very little consequence. To this group belong all those plants which one can see through. Under this heading may be mentioned a few Palms of the character of *Cocos Weddelliana* and *Geonoma gracilis*, a few flowering plants, such as *Thyracanthus rutilans* and *Russelia juncea*, and a host of elegant Grasses. I do not mean to assert that any and every specimen of the plants which I have enumerated is a good table plant, but rather to say that from amongst plants of this general habit, when well cultivated and when not possessing too dense a growth, may be picked some of the most elegant and useful decorations for the table. When, therefore, prizes are offered for table plants, the schedule ought to state whether they are for plants which one can see through, see over, or see under. In all cases the size of the pot in which the plant is grown ought to be limited. In the case of plants which one can see through, nothing need be said about height. In the case of plants which one can see over, the height should be restricted to 15 in. or to 27 in. from the bottom of the pot. While in the case of plants that one can see under, it is not necessary to limit the height, but the schedule must explain that there is to be a clear stem up to 20 in., or up to 32 in., from the bottom of the pot.

W. T. T.

TABLE DECORATIONS.

We have heard much on this subject from time to time: what sort of plants to use—their height, colour, and habit; the way to make the dining-room table so as to accommodate as many plants and flowers as possible without inconveniencing the diners, &c. Now, the notion I have to support is that dining-room-table decoration is an incongruity, is indefensible, unnecessary, and a deprivation of luxury. I base my argument on the same grounds as the landscape gardener did who said that flower-beds in the middle of a Potato quarter or a bed of Horseradish would be an outrage, not only on good taste, but on common sense. I maintain that no plea whatever can be set up for the use of flowers or plants on a dining-room table—they are an utter incongruity. Roses, Ferns, and other flowers or graceful plants do not and never can associate with roast beef or turtle soup. I knew a lady once who complained to her gardener about introducing scented Thyme into her flower vases. She said "that was for the kitchen—not for her vases," and so far she was right; and we venture to assert that flowers and plants are for the drawing-room, the library, and the boudoir, and not for the dining-room. There the cook, the confectioner, and the fruiterer should reign supreme, and they possess the art and everything else to render a dining-table as attractive as it can be made. What man or woman with a healthy appetite cares one farthing for the flowers on the table? it is only when they have done dining that, as a matter of fact, they deign to glance at them, and by that time they should retire to the drawing-room or the conservatory, where they may legitimately turn their attention to Flora's treasures. We have had not a little to do with this table decoration business, and we more than fancy that there are not a few ladies and gentlemen who share our opinions—who regard a dining-room table strewed with flowers till it resembles a flower bed as one of the most objectionable arrangements ever introduced. We have known more than one sturdy old English gentleman quietly protest against the table being encumbered with flowers and flower vases by first pushing them as far out of his way as possible preliminary to making a meal. One old veteran, pretty well known "in the service," and who is a perfectly cultivated and courteous gentleman withal, regularly "clears the deck" in this fashion before making the attack, and no one calls in question his "ways." The real truth of the matter is, table decoration is a fashion which is now extending downwards, even to high life "below stairs," "school teas," and such like festivals, and we shall probably soon see it going

out of fashion in the upper grades of society in consequence—and the sooner the better.

J. S. W.

LILIUM HANSONI.

PERMIT me to reply to Mr. Wilson's remarks (see p. 8) in regard to this Lily, that nothing could be further from my intention in my previous remarks than to insinuate that the plant which he exhibited was obtained either directly or indirectly from me or my firm. I simply stated that the Lily was in my possession unnamed in 1869-70. We identify it, now we have seen the flower, to be the early yellow-flowering Martagon then obtained for us from Japan, and grown on for years without a flower being obtained. It was named *Hansonii* at quite a recent date. I have now before me a catalogue of a sale at Messrs. Stevens of "New and Rare Japanese Lilies, collected by Mr. Kramer in Japan," dated December 23, 1871. This sale was a remarkable one, for seed of *Primula japonica* fetched the astonishingly high figure of £84 for a quantity under 3 oz., and likewise for its being the first occasion on which *Lilium Krameri* was introduced by me and subsequently named in honour of its collector—Mr. Kramer. Lots 163, 164, and 165 are headed *Lilium colubicum*—see drawing. The drawing was a Japanese one of *L. Hansonii*, and the three bulbs offered were some of a batch sent over to me, of which the others grew and were Martagons, but did not bloom. These three lots were bought by Mr. Ball, Mr. Barr, and Mr. Wilson, as I have stated. What became of the bulbs I do not know; but I know that *L. Hansonii* was that year in my possession and sold by me, and entered in my catalogue without name. Of *L. Szovitzianum* Mr. Wilson writes: "To see this Lily in perfection a visit should be paid to Edinburgh to Mr. M'Nab." I hope that Mr. Wilson will allow that perfection may be obtained nearer London. We have had here 1500 spikes of bloom from 4 ft. to 6 ft. high, with from four to twenty bells of flower on each spike, some of them 6 in. across, most beautifully coloured, and likewise no two alike. Add 2000 more smaller plants, with smaller blooms, and you have our bed. It was a grand sight. Without wishing to detract from any credit due to Mr. M'Nab, we also claim that the word perfection should be applied to our bed.

A. WALLACE.

Colchester.

Roses at Boxhill.—A fine display of Roses may now be seen in Mr. Appleby's nursery at Boxhill. It consists of some 3000 plants arranged as an avenue on each side of a long walk. Planting in straight lines is, as a rule, objectionable, but when the colours are judiciously blended, as they were in this case, and backed on each side with Conifers and other trees and shrubs, the effect is all that could be desired. The soil here is a deep yellow loam, with a subsoil of fullers'-earth, and in this Roses appear to succeed remarkably well, plants which have only been budded two years having made fine bushy heads loaded with large blossoms. Among kinds unusually well flowered we noted Paul Neron, bearing large and well-formed blossoms, the delicately-tinted *Baroness de Rothschild*, and the pure white *Boule de Neige*. Half-standards of *Princess Louise Victoria*, with compact bushy heads, bore more than twenty fully expanded, delicate, blush-coloured blossoms, and *Maréchal Niel*, grown as a standard, does better here than we have seen it anywhere else, its blooms being fine in colour and produced in profusion. The cream-coloured *Belle Lyonnaise*, considered to be a great improvement on *Gloire de Dijon*, bears large flowers of great substance, and *Mlle. de Tartars*, a Tea-scented Rose of a pinkish-rose tint not often seen, and fine in the bud state for bouquets, does unusually well here; as does also *Cheshunt Hybrid*.—S.

Town Roses.—It is right that I should speak a good word for the success that has attended the growth of Roses since I left Kensington, about ten years ago. One reason that I had for leaving town for the country was, that I could not grow Roses and Conifers. The fuliginous "smogs" of the atmosphere not only checking their growth, but destroying them altogether. A few days ago I was at a garden party on Campden Hill, and was surprised and delighted to see the choicest varieties of Roses grown with the utmost beauty and luxuriance. Not so the Conifers, the sulphur in the air being fatal to them.—E. W. C., *Glen Andred*.

Old Roses.—The names of the old Roses shown at the Crystal Palace last week were, so far as known, as follows: Old China, Scotch White, *Felicité Perpétuelle*, *Aimée Vibert*, Old Monthly, White Bath, *Bourbon Queen*, Old Cabbage, Common Moss, *Madame Legras*, *Chenédulé*, *Fairy*, *Eliza Savage*, Yellow Provence, *Crimson Damask*, Old *Damask*, *Pactols*, *Ruga*, *Globe Hip*, *Rosa Manetti*, *Comtesse de Lacépède*, *Rosa Mundi*, *York* and *Lancaster*, *Village Maid*, *Rose de Meaux*, *Compe de Hebe*, *Adam*, *Crested Moss*, *York White*, and *Comte de Paris*.

NOTES FROM KEW.

HARDY SHRUBS.—Undoubtedly one of the most handsome of hardy climbers is the Chilean *Berberidopsis corallina*; the clusters of drooping, coral-like blossoms are, as well as the flower-stalks themselves, a beautiful deep red. For the rafters of the cool conservatory few plants surpass this in loveliness. *Myrtus americana* makes a pretty wall plant; the leaves are smaller than those of the common Myrtle, and the almost white, waxy flowers are borne on longer stalks. *Veronica kermesina* is a very desirable kind for a dwarf wall, the long spikes of mauve-coloured flowers being both graceful and pretty. *Clematis acuminata*, a Himalayan species and a very free bloomer, has flowers of a blue-purple colour; altogether, this is a charming plant, and one worth a place in any garden.

HARDY HERBACEOUS PLANTS.—The large and beautiful genus *Veronica* contains few species which are more distinct and at the same time combine so much elegance and beauty as *V. virginica* var. *japonica*. This new claimant for garden favour has the leaves in whorls just like the common Martagon Lily; the stem attains a height of about 18 in., and is surmounted by a long spike of blue flowers with yellow stamens. Another new plant, perhaps less beautiful but not less interesting, is *Villarsia capitata*, a miniature aquatic from Australia; in colour the small flowers are similar to those of *V. nymphaoides*, a rather rare British plant found in still waters in some of the southern counties. In Australia it grows in wet sand, and, under cultivation, it makes a small cushion of bright green leaves, thickly studded with its pretty yellow flowers. A South European form of *Orchis pyramidalis* merits special mention; it is extremely handsome, and so far superior in size and beauty to our British plant that most people would never suspect the two to be botanically identical; the Kew plants were imported from Portugal. *Abronia arenaria*, a Californian perennial, is a pretty trailer with clusters of bright yellow flowers. *Hypericum orientale* grows about 15 in. high, and produces a profusion of pale yellow blossoms. For growing in small chinks in rock-work the little *Mazus Pumilio* is very suitable; its purple flowers are borne on short stalks which just overtop the foliage; this, perhaps the most interesting of the genus, is a native of Van Diemen's Land. *Thladiantha dubia*, a Chinese member of the Gourd family, has heart-shaped leaves and showy, bell-shaped, yellow flowers; this hardy perennial would furnish a beautiful partial summer covering for small arbours, &c., and for such purposes can be strongly recommended. *Neja gracilis*, a neat bushy Composite from Mexico, has needle-shaped leaves and heads of bright yellow blossoms; it grows about 1 ft. high, and is a most charming plant for dry sunny spots of the rockery or open border. Two *Grindelia*s, *G. robusta* and *G. angustifolia*, are very fine just now; both have large heads of golden-yellow flowers and grow about the same height (2 ft.); the latter, as its name would imply, has narrower leaves than *G. robusta*. *Erigeron speciosus*, a Californian perennial, has broad leaves and mauve-coloured blossoms, whilst *E. multiradiatum* has narrower leaves and flowers a shade deeper in colour than those of *E. speciosus*; both grow from 2 ft. to 3 ft. high. As a single specimen or for making a bold and effective mass, *Telekia cordifolia* comes in well; it has large, heart-shaped leaves and golden-yellow heads about 4 in. across; the flower-stems grow as high as 4 ft. *Campanula lactea* is a beautiful, tall-growing Bell-flower with innumerable, upright, pale porcelain-blue blossoms; *C. Van Houttei* is a much dwarfer grower, with long, drooping, purple flowers. The North American *Lysimachia ciliata* is a tall perennial with flowers of a pale yellow colour.

GREENHOUSE PLANTS.—*Mesembryanthemum violaceum* and *M. coccineum* are handsome plants, very easily grown, and most useful for cool house decoration; both are of similar shrubby habit. *M. violaceum* has purple flowers, whilst the colour of those of *M. coccineum* is reddish. *Crassula pallida* has precisely the habit of the old *Rochea falcata*, or, as it is now called, *Crassula falcata*, but the flowers are whitish instead of bright red. *Bomarea Carderi*, when planted out as at Kew, makes a most attractive and uncommon-looking object; the drooping flowers are pink, spotted with purple.

ORCHIDS.—*Odontoglossum Lindleyanum*, from New Granada, is a compact plant with narrow leaves; the sepals and petals

are pale yellow and brown, the column and the horns at the base of the lip white. This is not a mere botanical plant, but is worth growing from a garden point of view. *Palumbina candida*, a native of Guatemala, has small narrow pseudo-bulbs each bearing a single leaf; the flowers are white, tinged with rose. *Dendrobium dixanthum* is a pleasing species with good-sized yellow flowers, and *D. secundum*, a smaller-growing one, with spikes of smaller blossoms, is a rosy-purple, with the exception of the little lip which is deep orange-red. A Mexican *Epidendrum*, *E. radiatum*, is a free-flowering fragrant species with the general habit of *E. cochleatum*; the sepals and petals are greenish-white, and the large, shell-shaped lip is marked with radiating purple lines.—†

BROUSSA AND MOUNT OLYMPUS.

FROM SYRA I went on to Constantinople by Austrian Lloyd's steamer, passing between the islands of Andros and Tenos, and by Mytilene, Tenedos, and the Plains of Troy, and finding a steamer in the Golden Horn just starting for the port of Broussa, I got on board without landing, re-crossed the Sea of Marmora to Modania, and drove to Broussa, 20 miles through a lovely country, reaching my destination the same afternoon. The culture of silk is the prevailing industry of this part of Asia Minor, and the road out of Modania passes for several miles through a succession of Mulberry plantations bright and green in their spring leafage. Long strings of camels passing to and from the interior give a novelty to the scene. The roadsides are rich with several species of *Salvias* and boraginaceous plants, including a white *Symphytum* and *Onosma taurica*. The sprigs of the latter are gathered for the silkworms to spin in. The aspect of the country is most fruitful; Quinces, Plums, Peaches, White Mulberry, and the Olive luxuriate. Rice is cultivated here and there on the low-lying ground, and we pass fine groves of a handsome deciduous Oak, but the general cultivation is poor in the extreme, not a fourth of the surface being under tillage, and there is a pervading aspect of thriftlessness too general throughout Turkey. A railway was constructed a few years ago from the port of Modania to Broussa, with the intention of ultimately connecting it with a general system throughout Asia Minor, including the line from Soutari to Ismid, but the earthwork was so wretchedly planned and executed, that the line would have to be completely remodelled before a train could pass over it; when the rolling stock arrived it would not fit the rails, and the railway pier at Modania is already toppling over. The aspect of the Bithynian Olympus as it is approached from the coast is truly grand. A finely moulded ridge of 5000 ft., capped with a peaky snow-covered summit, rising another 2000 ft. out of the dark pine-fringed edge of the main plateau. As Broussa is approached the ditches are all steaming from the hot springs which burst up from the north-west flank of the mountain, and supply the baths—some of which are very ancient—with water at a temperature of 140°.

Broussa is, without exception, the most beautiful place I have ever seen, with a situation reminding one of Great Malvern. It covers an immense area on a sloping plateau, at from 550 ft. to 700 ft. above the sea level, at the foot of Olympus. It contains fifty-two mosques, with their bubble-like domes and white minarets, and other fine buildings, interspersed with Mulberry orchards and luxuriant gardens. The mountain, with its well-marked zones of vegetation, which, however, interlace and overlap, consisting of—first, Chestnut; second, deciduous Oaks and Hazel; third, Beech; fourth, Pines of two species; fifth, Junipers; sixth, snowy summit, rising up from the city, which is partly built up its lower slope. Broussa contains several excellent hotels; horses and attendants are remarkably cheap and good, only two francs a day. I went twice up Olympus, but not to the final summit, which was covered with snow. My Turkish attendants, though they could not converse with me in any language common to us, were really capital fellows, though savage to behold, with their picturesque costume, and belts full of rude arms. They fell into botanical pursuit with good fellowship and will, and did as much work as any professed botanical guide in the Alps, often finding and pointing out species that would otherwise have escaped my notice.

Contrasted with the Greek Archipelago, evergreen Oaks were almost entirely absent, and replaced by several deciduous species; indeed, there are few evergreen shrubs on Olympus. The common Laurel and *Daphne pontica*, the Eastern form of *Daphne Laureola*, were the main exceptions. Bulbous plants were remarkably abundant. *Fritillaria pontica* in profusion almost everywhere, with a range of altitude of nearly 4000 ft. I obtained also seven or eight species of *Ornithogalum*, a *Galanthus* out of flower, and six or seven species of Crocus. I was just in time to see Crocus aëris in full beauty, at a height of from 4000 ft. to 5000 ft., the flowers at its highest limit appearing amongst the melting snow, and lower

down under the Pine trees, intermixed with Crocus gargaricus, a charming little yellow species. At a height of from 3500 ft. to 4000 ft. the floral display was like a garden. The purple *Anubrieta deltoidea*, with a yellow Alyesam on the rocks, and the yellow and blue Crocuses, intermixed with *Hypericum calycinum*, a handsome *Doronicum*, and large tufts of a handsome purple *Primula*, varying with white flowers, identical with a plant in cultivation under the name of *Primula altaica*, but closely allied to our common Primrose. Two or three species of *Gagea*, and the lovely glaucous low-growing *Hypericum olympicum*, were also conspicuous, intermixed with a blue *Muscari*. The summit of the plateau, at a height of about 5500 ft., the limit of the Pines, was comparatively barren, and afforded nothing but tufts of a *Juniperus*, a sort of "Savin," a small *Potentilla*, *Crocus aëris* and a little *Gagea* among the snow patches; but it was evidently too early on April the 16th for the higher region of Olympus, which in June would probably afford a further set of species. *Vaccinium Arctostaphylos* is an abundant shrub on the flanks of Olympus; the leaves are collected and used in lieu of tea. They are gathered in spring, and after being laid in the shade on a straw mat, are rolled in the hands and dried by a slow fire in an oven. It is only within the last few years that the *Vaccinium* leaves have been thus employed, but they have now become a regular article of commerce, sold under the name of "Broussa Tea" at from 30 to 60 piastres the oke of 2½ lb., and I am assured make a very palatable beverage. To give anything like a complete list of the plants of Olympus would be beyond the scope of this paper; the number of species named after the mountain expresses the extreme richness of the flora. In addition to those already named I found a *Dentaria* closely allied to *bulbifera*, *Viola olympica*, a handsome species coming between the Alpine *calcarrata* and *tricolor*. *Cistus lanrifolius* and *C. salviaefolius*, *Anemone blanda*, the eastern representative of *A. apennina*, *Ruscus aculeatus*, and *R. Hypophyllum*, a *Sedum* allied to *Telephium*, a *Gentiana* allied to *Asclepiadea*, *Saxifraga rotundifolia*, a handsome *Lanium* allied to *L. longiflorum*, a number of conspicuous species of *Lathyrus* and *Orobanch*, including one with yellow flowers. Boraginaceous plants are extremely abundant, including several *Symphytums*, a *Borago*, and *Lithospermum purpureocœruleum*; also a *Digitalis* not yet in flower, *Campagna perisicifolia*, an Alpine *Myosotis*, a *Corydalis*, a *Geranium*, a *Convallaria*, and *Asphodelus luteus*.

Amongst the shrubs were *Ligustrum vulgare*, *Cercis Siliquastrum*, gorgeous with its rich rosy-crimson flowers, intermixed with a handsome white-flowered *Fraxinus*, which was very conspicuous above Broussa; also *Juniperus oxycedrus*, *Jasminum fruticosum*, and *Viscum album* on the Chestnut.

Ferns were tolerably abundant, but I observed none but the following British species: *Scolopendrium vulgare*, *Asplenium Adiantum-nigrum*, *A. acutum*, *A. Trichomanes*, *Cystopteris fragilis*, *Polystichum angulare*, *Pteris aquilina*, and *Athyrium Filix-femina*. The fauna of Olympus is also rich. Roe-deer and wild boar are very abundant; red-deer are also found, together with foxes, jackals, and wolves. Eagles, of more than one species, were constantly in sight. Vultures are occasionally met with, and the red-legged partridge, quail, and woodcock are abundant. The view from near the summit embraces one of the most superb panoramas I ever beheld. The ridge of Olympus is isolated, and commands a wide range of vision all over the Sea of Marmora to Constantinople, and far inland, to the mountains of Asia Minor, with the rich plain of Broussa and the lakes of Maniysa and Abullonia as a near foreground. On the day following, my second ascent of Olympus, I made an excursion across the plain of Broussa to the hills south of Gemlik, and found an annulate Crocus said to have yellow flowers in midwinter, probably *chrysanthus*; also a second species of Crocus, along with *Lavandula Stœchas*, *Paliurus aculeatus*, a cream-coloured *Onosma*, and *Jasminum fruticosum*.—G. MAW, in "Transactions of the Botanical Society of Edinburgh."

Spiræa Ulmaria fl.-pl.—This dwarf-growing variety now forms a charming feature in some of the London nurseries. It is planted generally on the borders of shrubberies and in masses, and in either way, where the soil is good and sandy, the plants spread freely and throw up strong plumes of cream-coloured flowers in abundance.—S.

Zephyranthes carinata.—This lovely Mexican Zephyr flower is now flowering freely in the hardy bulb collection at Kew. It is a very fine variety with blossoms 3 in. across and of a deep rose colour. It appears to be thriving admirably on a sunny border in company with the well-known white-flowered *Z. Atamasco*. Many other fine bulbous plants are also in flower at present, including the twin-flowering *Bravoa* (*B. gemminiflora*), with its bright, scarlet, tubular flowers borne on stems 18 in. high, and *Watsonia fulgens* with blossoms of the same brilliant colour, but very much larger. The white variety of *Gladiolus Colvillei* also forms an interesting object.—A.

NOTES OF THE WEEK.

The Fruit Crops.—Our reports of these, furnished by many of the best growers throughout the country, are published in part this week, but many are left over owing to want of space. These reports will be found valuable, not only as such, but from the information that is given incidentally as to the kinds that do best in many different localities. Next week we hope to publish the Scotch, Irish, and supplemental English reports.

Periploca græca.—This curious and graceful creeping shrub, usually crucified on walls in the usual manner, forms a vigorous mass on an old tree in the Cambridge Botanic Garden, and now has many flowers. *Celastrus scandens* also grows vigorously as a shrub in the same garden.

Campanula nobilis.—Though cut spikes of this *Campanula* are largely used in Covent Garden, they do not last long in good condition, but on the plant they produce a fine effect for many weeks. We lately saw some fine plants of it in Messrs. Veitch's nursery, where they grew in front of some rockwork, and were one mass of blue blossoms. In shrubberies, sides of woodland walks, or in the wild garden this is a most effective plant.—S.

Striped-leaved Dracænas.—Few *Dracænas*, handsome though they be, are more ornamental than one named *Hendersoni tricolor*. It is a robust grower, its leaves arch gracefully, and they are beautifully striped with different shades of rosy-scarlet, orange, and green. We lately saw some good plants of it in Messrs. Lee's nursery at Hammersmith.

Lady's Bedstraws (Galium).—These are full of flower just now, and well deserve to be brought more into general cultivation. The whites and pale yellows intermingled are beautiful in point of colour, and the odour, it need hardly be said, is delightful. They seem to delight in the sun, and all flower very freely. Of course they will do admirably for the wild garden among shrubs placed thickly, or on banks where many other things would not grow.

Triteleia laxa.—This is one of the best blue flowering hardy plants now in bloom. Grows in good deep sandy loam, the spikes of flower are large and strong, and the flowers of a deep blue colour. Cut blooms of it were shown well at South Kensington the other day from Colchester.

The Cotton Thistles (Onopordone).—These noble plants, usually left to the botanic gardener, are now in flower, and no hardy plants are more valuable for their stately port, while their flowers are very large and showy. One now in the Cambridge Botanic Garden (*O. græcum*) has very large showy flowers of a deep rosy-purple. They thrive as well in exposed places as in sheltered ones among shrubs, and they may be effectively used in a variety of ways. Temperance in their use is, however, desirable, as in some situations they are apt to seed so freely, that they require to be kept down judiciously.

Geranium sylvaticum fl.-pl.—This double-flowered form of a well-known hardy plant does not appear to be grown very extensively either in nurseries or gardens. It yields abundance of double mauve-coloured blossoms, which are almost equal in appearance to those of a double Primrose. It would be well worth growing if only to supply cut blooms.—S.

Plants in Flower at Colchester.—In our Orchid houses *Dendrobium transparens* and *D. formosum giganteum* have opened fine flowers; likewise a very pretty form of *Oncidium intermedium* between *O. pubes* and *O. earodes*, with barred yellow flowers, about 120 on a branched spike about 1½ ft. high, gracefully pendulous. *Maxillaria grandiflora* and *Thunia alba* are just opening, and the not too well-known *Oncidium Harrisonianum* is throwing up flower-spikes; likewise *Catasetum tridentatum*. *Thelymitra caucalicata*, from Australia, is just disclosing its spike of flowers, and, from the same country, *Dictyopogon hamilis* has opened its lilac-tinted flowers, perfumed like the *Heliotrope*, on a branched spike 1½ ft. high. In the open ground it is also showing flower; also *Bulbine bulbosa* (yellow); from the Cape, *Hypoxis Rooperi* has opened its spike of yellow star-shaped flowers; and the three *Freesias*, *Leichtlini*, *refracta*, and *refracta alba*, are still in bloom, and perfume the air around. *Rosecoea purpurea*, from the Himalayas, has opened a quaint purple flower, and *Cummingia trimaculata* is just out. *Hyacinthus candicans* promises to be very fine this year. *Romneya Coulteri* is now 6 ft. high, and 3 ft. through, and just showing flower-buds. Among the Calceolites, *C. luteus venustus* and *macrocarpus* are fully out. Of the Lilies, our bud of *L. dalmaticum* is fine in five varieties, differing from dark blood-red to a light puce, with about 500 stems of bloom. *L. Hansonii* and *ocridion* are just over. *L. japonicum* Colchesteri is now out, and a few late blooms of *L. Brownii*, *L. polyphyllum*, *L.*

superbum, *L. canadense*, *L. pardalinum*, *L. Humboldtii* and its ocellated variety are now in bloom. Amongst the *Thunbergianoms* the new *citrinum*, *Van Houttei*, *marmoratum*, and *T. fl.-pl.* are out, while the forms of *longiflorum*, *exceolum*, *Kramerii*, the showy *philadelphicum*, *candidum flore-striata*, and *callosum* are not behind; but the dry weather is very trying; and the early blooms of *aratum* are opening. *Triteleia laxa grandiflora* forms a bright mass of Tyrian blue. *Brodiaea congesta alba fl.-pl.* is still out (it began six weeks ago), and *B. grandiflora* (in two forms, one very dwarf), is exceedingly floriferous. *Iris iberica* has surprised us by opening a fine very late bloom. The *Gladioli* have begun with *Colvillei*, *Colvillei albus* (most beautiful), *ramosus*, and *Prince of Wales*. *Phædranassa chloracra*, and *Amaryllis sulica* are also now opening.—A. WALLACE.

Lilium auratum virginialis.—We are indebted to Mr. F. Miles for the sight of some fine specimens of this nearly white variety of *auratum*, which is perhaps the most beautiful variety of that Lily.

Primula capitata.—An exceedingly fine variety of this beautiful Himalayan Primrose is now in flower on a rockery at Kew; indeed, it is the finest we have as yet seen. The heads of blossoms are nearly 2 in. across and of an intensely deep purple colour, which is shown up more fully by the white mealy substance which thickly covers the stem and head.—W.

Sweet Williams and Antirrhinums.—Examples of these have been sent to us by Mr. Cadwell, of Wantage. Amongst both were some handsome kinds, the result of many years' selection. The *Antirrhinums* comprised one or two good yellow ones, and amongst the *Sweet Williams* were some charming light-coloured ones, striped and spotted with different shades of crimson and lilac.

Cymbidium Parishii.—This beautiful *Cymbidium* is now in flower in the Victoria Nurseries, Holloway, being the first time in which it has flowered, we believe, in Europe. The blossoms, which are large, are agreeably scented and pure white, with the exception, of the labellum, which is marked with purple streaks and blotches and has, in addition, an orange-coloured base.

Orange Lilies in Hyde Park.—We have lately noticed a very brilliant effect afforded by a few groups of tall Orange Lilies in Hyde Park, near the Victoria Gate. The Lilies are in partial shade under trees. Such effects are worth taking the trouble to secure, and we trust they may be multiplied. But to secure them it will be necessary to give up the old system of rough digging the whole surface and mutilating root and branch every year. This system is only navy's work. The true gardener should know every inch of his ground and all the life that it bears, whether of bulb, roots of herbaceous plants, or shrubs. What we must have in the future is a system of weeding and dressing, only digging with vigour when preparing well before planting.—R.

Lobelia littoralis.—There are but few prettier subjects for the rock garden than this New Zealand *Lobelia*. It creeps over the surface of the soil after the manner of the fruiting Duck-weed (*Nertera depressa*). The flowers, which are about 1 in. in height, are borne very profusely, and are of a pure white colour, and of a size larger than those of the kinds used for bedding purposes. In autumn they are replaced by numerous violet-coloured berries about the size of large Peas. Therefore the plant may be said to be beautiful from May till October. It is stated in the "Flora of New Zealand" to be found in damp, shady places, but I find that under those conditions in cultivation it does not flower. If placed on an exposed part of the rockery, with ample room for it to spread, an abundance of blossoms will be the result. It appears to be very little known in gardens at present, although it has been introduced some years.—A.

Ellacombe's Plant Lore and Garden Craft of Shakespeare.*—We have just received the first copy of this book, which will be welcome to many readers of THE GARDEN as being a reprint of the many interesting papers contributed to our columns by Mr. Ellacombe. In this work every passage is quoted in which Shakespeare names any tree, plant, flower, or vegetable production. A short account of each is given, identifying Shakespeare's plants with their modern representatives, with illustrations from contemporary writers, and with notices of any points of literary, botanical, and gardening interest connected with the plants named. Under the circumstances, our only duty is to announce the appearance of the book.

Moss Pink Delicatae.—This is an improvement on the ordinary kind as regards colour. It is, I believe, a cross between a laced Pink and a Sweet William.—W. PAUL, Paisley.

* "The Plant Lore and Garden Craft of Shakespeare." By Rev. Henry N. Ellacombe, M.A., Vicar of Bitton, Gloucestershire. Printed for the Author by William Pollard, Exeter.

DYE PLANTS.

ALTHOUGH the ancients knew little or nothing of the principles of chemistry as a science, they, nevertheless, managed to

Fig. 1.—*Rhamnus utilis*.

practise it as an art with a certain amount of success, more especially in the way of extracting beautiful dye stuffs from

Fig. 2.—*Rhamnus chlorophorum*.

various animal and vegetable substances. The Phœnicians, Indians, Persians, Chinese, and Egyptians were the first to

discover that, by proper treatment, certain plants and animals were capable of yielding brilliant dyes, and they no doubt taught the art to the Greeks and Romans. Amongst the dye plants used in former days, the forms which are figured herewith may be taken as typical specimens, and there is but little doubt that Joseph's coat owed some at least of its rainbow tints to the juices of the Buckthorn, Polygonum, and the Indigo plant.

Rhamnus utilis and *R. chlorophorum* (figs. 1 & 2) are used to the present day by the Chinese and Japanese for the extraction of a peculiar dye called *Lokao* or *vert lumière*. Unlike any other vegetable green dye, it is just as brilliant by candle-light as by daylight. It was much used in France at one time, but the discovery of a still more brilliant dye obtained from coal tar, which was just as unchangeable at night, put it completely out of favour. The *Rhamnus Frangula*, from which Persian or Turkish yellow berries are obtained, is closely allied to those figured above.

The uses of the *Indigofera tinctoria* (fig. 3) and its congeners dates from the earliest ages. Like the *Polygonum tinctorium* (fig. 4), which is much used in China for dyeing fabrics blue, the juice of this plant is quite colourless, and it is not until it is exposed to the action of the air

Fig. 3.—*Indigofera tinctoria*.

Fig. 4.—*Polygonum tinctorium*.

that it becomes blue. The process for dyeing fabrics blue by means of these plants is the same in principle in all parts of the world, whether carried on in some peasant dyer's hut in India and China, or in the scientifically ordered dyeing establishments of France and England. To the mixture of the prepared indigo in the requisite amount of water a certain amount of lime water and other alkali is added. The liquor immediately becomes clear and colourless. The cloth to be dyed is then passed through the liquor several times, wrung out, and exposed to the air. As it dries the oxygen of the air acts on the colourless liquid contained in the pores of the cloth and turns it blue. When dried the cloth is again passed through the dye vat, and the process is repeated until the desired tint is obtained. There are many other plants besides those which have just been enumerated, such as the *Isatis tinctoria*, the *Althæa rosea*, *Wrightia tinctoria*, and the *Hibiscus rosa sinensis*, which also yields a blue dye under similar circumstances.

The *Isatis tinctoria*, or Woad, it will be remembered, was used by the ancient Britons instead of broadcloth. There are several specimens of mummy cloth in the British and other museums, which chemical analysis proves to have been dyed with indigo.

C. W. QUIN.

THE INDOOR GARDEN.

SPECIMEN SCHIZANTHUSES.

As greenhouse annuals the Schizanthuses are unsurpassed in beauty, and they are, moreover, within the reach of every one who has the least ambition for plant growing. It is not many weeks ago since there were some fine examples of them shown at the summer exhibition of the Liverpool Horticultural Society, where they created quite a sensation, and not a few people were heard to exclaim that they were the prettiest flowers which they had ever seen. What noble specimens they are, too! said more than one admirer. What a time they must take to attain such a state of perfection! Judging from these and similar remarks, it is clear that the cultivation of some of our most useful plants is not generally understood; indeed, is not even known amongst that class to which flowers that are easily cultivated are so great a boon. Half-a-dozen Schizanthuses or so in a greenhouse or conservatory from April onwards are about as pleasing objects as anyone could wish to possess; the only difficulty (and it is one easily overcome) is in being able to procure seeds true to name and selected with care from superior varieties. The seeds should, therefore, in all cases be got from a trustworthy source. From the beginning to the end of August is the best time during which to sow; or, what would be still better, to aim at a succession by making one sowing at the beginning and another at the end of that month. The seeds may be sown either in pots or pans, keeping each variety distinctly named, so that the requisite number of each may be potted when they are fit to be handled. Drain the pots or pans slightly, and cover the drainage with some rough material; then fill up to within $\frac{1}{2}$ in. of the surface with any ordinary soil nearest at hand, and run a surface sprinkling through a fine sieve; press all moderately firm, and on this scatter the seeds thinly, and cover slightly with the sifted mould. If the soil be moist when used, and the seed-pans be placed in a frame which is kept syringed and shaded, no watering will be necessary before the seeds germinate—a process that soon takes place under favourable conditions. Gradually inure the young seedlings to the light, and keep them close up to the glass to induce a sturdy habit of growth. These, like other rapid growing plants, require most attention when young; for instance, if they are kept unnecessarily shaded for a few hours, or are kept too far from the light, or are neglected in the seed-pans till they become lanky or are debilitated for want of light and air, it is next to impossible to resuscitate them. When the seedlings are fit to be handled, prick them off into pans filled with soil composed of equal parts of loam and leaf-mould with a sprinkling of river sand, and keep them on the shelf of a cold greenhouse till such time as they are strong enough to be potted. When this period has arrived, the selection of soil in which to pot them will have to be considered as well as the form which the plants are intended to assume. A compost in which Chrysanthemums or Fuchsias will grow will answer admirably, only it might be used a little poorer for the winter potting in order to induce a hardier and firmer texture of growth. Pots 6 in. in diameter need not be exceeded for winter use and the plants should have a cool airy position with as little water as possible during the winter months. Previous to entering into other details, the form of training should be determined, in order that future operations may be directed towards the fulfilment of the object in view. Taking the habit of the plant into consideration, the bush form is the best mode of training that can be adopted, that of the pyramid or cone being the next most likely form to please those who have a leaning towards formality. Assuming, then, that the plants are established in 6-in. pots, and are placed in favourable winter quarters, those that are intended to be grown into handsome bushes should have their points pinched out when they are from 9 in. to 12 in. high; and, coiled round the rim of the pot and pegged down, little growth will of course take place during the winter—the less the better—till after the turn of the year, when they may be potted on into 9-in. pots, using a compost consisting of loam, leaf-mould, and rotten manure in such a condition that it can be rubbed to pieces with the fingers and incorporated with the soil. The young shoots will now have

grown a few inches in height, and an upright stake painted green should be placed to each. It is not necessary at starting to train each shoot in a perpendicular direction, for whilst the shoot is fastened to the stake at its base, its point should be inclined either in an oblique or downward direction, so that each shoot may in turn produce a number of other shoots to furnish a handsome specimen. This can be done as soon as shoots enough have been formed upon which to operate. For specimens of any size, the final shift need not exceed a pot 12 in. in diameter, and if the soil be rich and open and ordinary attention be given, every stake will be covered by the end of April, and any training attempted later would detract from the natural form of the plant, except just tying in a stray or straggling shoot. Other forms of training are managed on a similar principle, the only difference being in the shape alone. Willows inserted at the sides of the pot, pulled together in the shape of a balloon, and fastened about the middle to a wire hoop, in order to keep them in shape, make a good foundation, provided the after-training is not overdone. The one thing to be kept in view throughout in the cultivation of these plants is to pay strict attention to minute matters, to keep them always while growing close to the glass, with abundance of air, but sheltered from draughts or cutting winds. As regards varieties, selected forms of *retusus* and *retusus albus* are not easily surpassed; they make excellent plants for hanging baskets.

W. HINDS.

NOTES AND QUESTIONS ON THE INDOOR GARDEN.

Tropæolum tricolorum Deeply Potted.—“A. D.” says that “the tubers of this *Tropæolum* increase but slowly.” This is doubtless true when they are potted, as they frequently are, so that a great part of the tuber is exposed; but if they are potted as deeply as one would pot a Potato it will soon be found that they increase in size rapidly; not only so, but from the same tuber one may readily get the long-shaped tubers of *Jarratti* and the round ones of *tricolorum*. At any rate, such is my experience in growing them for many years, and nearly always in houses under Vines.—S. GARLAND, *Castle Street, Salisbury.*

Begonias as Basket Plants.—The improved kinds of tuberous-rooted Begonias, now everywhere so abundant, make excellent basket plants. In this way their large, brilliantly-coloured blossoms, which are naturally of a drooping character, can be seen to advantage, and if grown in good soil and kept well supplied with water in a moderately cool, dry house, they will produce a charming display for months in succession. On rockwork, too, in any corner of a conservatory or greenhouse, or even out-of-doors in a warm corner, they grow and flower freely and are exceedingly effective. To tall, light-leaved, sub-tropical plants, in a warm, sheltered situation, they would add variety of colour and be much more satisfactory than plants of other kinds often used for such purposes.—S.

Filmy Ferns and their Culture.—Any one interested in these most beautiful of Ferns may grow them successfully without covering them with bell-glasses or keeping them in warm houses. In confirmation of this we may refer to a houseful of them in the Boxhill Nursery. It is of small dimensions and sunk in the ground, so that the eaves of the roof, which is of octagon shape, are only just above the surface. It is entered by means of rustic steps through a narrow span-roofed house, in which hardy British Ferns are growing amongst virgin cork. The inside of the Filmy Fern house is lined in the first place with old railway sleepers, placed in an upright position, and which support the roof. These are covered with virgin cork, on which are growing various kinds of Ferns. The Filmy varieties, consisting of fine specimens of *Trichomanes radicans*, *Todea superba*, *T. pelucida*, and others, are growing in pots or pans placed on a bank, raised 3 ft. or so above the ground floor and extending all round the house, excepting at the doorway. The side walls are built with rough stones, among which grow Club Mosses and small Ferns. A canvas shading under the roof is left there summer and winter, but no means are provided for heating the house artificially. Inside it is easily kept damp and close, and under such conditions Filmy Ferns grow remarkably well both in summer and winter.—S.

Pelargonium John Watson.—This is a strong-growing zonal, which produces very large trusses of scarlet flowers in the greenhouse all the year round. I cut a truss from it this week which measured upwards of 5½ in. through, and contained over 120 pipes and blooms. It is well worth the attention of amateurs, as it forms a conspicuous feature for the back of the stage in a conservatory.—W. A. SMITH, *Higher Broughton.*

THE CHUSAN PALM IN NEW ENGLAND.

SOME two or three years ago I sent you a short notice of the flowering and fruiting of the Chusan Palm (*Chamærops Forsteri*); that was, I think, in the spring of 1874. The two plants are now coming into bloom again, and in a week or more will make a grand display. The male plant is really beautiful. The bunches of flowers are from 2 ft. to 3 ft. long, and the countless number of golden stamens, of which the flowers are comprised, present a bunch of the richest golden hue, intermingled with massive fronds of the deepest green. The female plant is not so showy, but the clusters of blossoms are the same length and bunched in the same manner. There are four spikes on the latter and three on the former. The plants are in tubs and have not been shifted for five years; they are about 9 ft. high. In the winter of 1873-4 they were wintered in a cool house, where the temperature fell as low as 15° occasionally. The three succeeding winters they were put into the greenhouse, on account of the room being wanted for other plants, and they showed no signs of blooming either year. Last autumn we left them outdoors until ready (January 1), or until the temperature fell as low as 13°, when we removed them to the packing shed, digging a hole in the ground to let down the tubs from want of head-room. Here the temperature ranged from 32° to 12°. They were placed outdoors again early in April, and are now (June 15) nearly ready to flower, the flower-stems first making their appearance two weeks ago. Some cultivators may think there is beauty enough in a Palm without the blossoms, as is the case with most kinds, but the Chusan Palm is an exception. Not only are the huge clusters of golden flowers remarkably showy, but the great bunches of berries which succeed, covered with the azure bloom of the richest Plum when ripe, and going through all the changes from green to that tint, are quite as attractive as the flowers. Aside from these merits, it comes so near being hardy in our severe climate, that it is as yet the only Palm that can be used as a decorative object for the lawn early and late in the season, or that can be wintered without a greenhouse. It may be safely wintered in any stable, shed, or cellar where the temperature does not fall below 10°, protecting the roots by a good covering of leaves. We have now hundreds of young Palms raised from the seeds of the previous fruiting, and, though we have not been much of a believer in the acclimatation of even half-hardy plants, it may be that these seedlings will prove quite hardy, just as the imported Douglas Firs are tender, while the seedlings from trees raised in our climate are hardy. As a hardy Palm for the climate of England, it must possess a value which does not appear to be generally appreciated.

C. M. HOVEY.

Boston, Mass.

Leptopermum bullatum Hardy in Valencia.—I see (Vol. XIII., p. 613) allusion made to this growing out-of-doors for three winters in Kent. If this is a matter of any interest, I may as well say

that I have had it out now for nearly twenty years without its having received any special protection or care, and I have recently, say for one or two winters, had other New Zealand plants out without any protection, except a few branches to save them from storms, and they are thriving admirably—for instance, the *Pitcairnia tenuifolia*, *Corinocarpus laevigatus*, *Suttonia australis*, *Dyaxylon spectabile*; and though it is too soon to speak with absolute certainty of their hardiness, I have little doubt of their suitability to our climate here. I may as well mention that I have the Madeira *Clathra arbores*, which has now been out-of-doors for about nineteen years without having received any protection, except that of surrounding shrubs. It is now 16 ft. or thereabouts in height, with most glorious foliage, and covered with formed, but as yet unopened, blossoms. It is certainly one of the finest shrubs that it is possible to see.—K. K.

JAPANESE MAPLES.

AMONGST the many importations from Japan—both as regards flowering and fine-foliaged plants—that we have had during the last few years, few promise more useful results than the several varieties of Maple. The delicate, Fern-like character of the foliage of some, and the beautiful variegation and bright colours of others render them beautiful objects for masses in contrast with each other, or as single specimens on Grass, and in the sub-tropical garden they are also highly effective, the older variety, *Acer Negundo variegatum*, being well known for the beautiful effect which it makes in the form of dwarf standards rising above a groundwork of *Colera* or of plants with similar foliage. I lately saw some fine examples of them in the Coombe Wood Nursery, where they have stood fully exposed in quite open positions during several winters. They would doubtless grow rapidly sheltered by large trees or in such positions as are usually selected in gardens for fine-foliaged plants. In table decorations, on a white cloth, the elegantly cut leaves of such varieties as *Acer polymorphum dissectum* or *A. p. palmatifidum* would be shown off to excellent advantage. Even as pot plants for conservatory decoration they are highly effective, forming, as they do, quite a distinct feature, and contrasting well with the abundance of flowers usually found in such structures during the early part of the year. Being of moderate growth, they might be kept of a serviceable size for decoration in pots for many years by simply shaking them out and re-potting them in the same sized pots; and when turned out of doors the pots should be plunged in leaves or ashes, as the roots of even the hardest plants are more liable to injury from extremes of temperature or drought than the top growth.

J. GROOM.

The Golden *Retinospora* as a Hardy Evergreen.—I should like to tender my testimony in favour of this beautiful little golden evergreen on one special account, namely, that of hardiness. It is a well-known fact among all who have attempted to grow evergreens on the bleaker points of the New England shore, such as the

A Reach of Park Water.

cliffs at Newport, &c., that generally they are not capable of resisting the effect of severe ocean winds laden with salt spray. The Norway Spruce is soon rendered thin and meagre and the Hemlock utterly destroyed. *Arbor-vitæ*, Junipers of certain varieties, and Yews shrivel up and die, and even Scotch and Austrian Pines, in most cases perfectly ragged, will in peculiar localities lose the lower limbs, and become naked and bare. These last-named evergreens may, however, be termed fairly hardy, and classed in this respect with the White Spruce, Creeping Juniper, &c. Indeed, so few evergreens thrive in full exposure to the vicissitudes of such situations, that the use of deciduous shrubbery and trees is to be specially commended for the main and most exposed plantations of these localities. Strange to say, however, a Conifer that has been occasionally, with seeming injustice, called tender, exhibits in the worst exposures a vigour and endurance that are really astonishing. The Golden Retinospora, the Conifer I mean, has something in its nature that adapts it to more situations, more pruning, more transplanting, than almost any evergreen that can be named. I do not propose to dwell on the other notable virtues of this Retinospora, but simply to point out this particular quality, tested now for years, that must always entitle it to a high place in the list of the landscape gardener's material.—"Rural New Yorker."

THE KITCHEN GARDEN.

WINTER CUCUMBERS.

THE fact that Cucumbers are sold at from 1s. to 2s., and sometimes 3s. apiece, during the winter—even in the provincial towns—is sufficient to show that they are not plentiful. Notwithstanding the high price which they fetch, we believe that market gardeners do not find winter Cucumbers to pay as a rule, but prefer to cater for the market between April and November, when a crop is sure. In private establishments they do not pay the expense of labour and fuel in one case in twenty, judging from the examples of culture one sees. Cucumbers can be grown successfully, however, and, we think, remuneratively, throughout the winter and early spring months by those who understand their culture—for winter culture and summer culture are two very different matters. Something, perhaps a good deal, depends upon soil, &c., but most depends upon management. The best winter Cucumber grower we have ever known was Mr. Dick, now of Phoenix Park, Dublin; and it cannot be said that he was favoured by circumstances—unless it was in the variety he cultivated, about which more anon—for he was alike successful at Wynyard in the murky climate of Durham, and in the pure air and genial climate of Dorset, within sight of the Isle of Wight. For many years, to our knowledge, he did not cease to cut fine fruit every day in the year for home consumption, besides sending large quantities to the market at good prices. He grew his plants in a low house, about 40 ft. long, and their roots were confined to a narrow pit of soil about 1 ft. wide and the same depth. He attributed his constant success to restriction at the root, moderate temperature, and last, but not least, to beginning in good time and getting the plants up in a hardy condition against the coming winter. He informed us that the bottom-heat was sometimes as low as 65°, but that he aimed at keeping it at 70° or thereabouts; and that the top-heat fluctuated between 65° and 70°, with a little rise in the sunny weather, but that in severe weather he had a difficulty in keeping these figures up. In addition to this, he pinched and trained methodically, and stuck to that good old variety known as Lord Kenyon's Favourite, the seed of which he had saved himself for many years. This variety, which can hardly be superseded for general excellence and as a winter forcer, is not easily procured true—scarcely at all from the trade, we believe, but it is still in existence, and there is one grower for the markets in the midlands who sends some of the finest samples for sale, and has it true, though he keeps silent about it apparently. We dropped casually on a hamperful of it in the market one day, and were informed by the fruiterer it was the most saleable Cucumber that came to his shop, and he took all of it the grower could send him. These remarks are by the way, however, and to proceed to cultural matters we had better begin with the—

SHAPE AND SIZE OF HOUSE FOR WINTER CULTURE.—The Cucumber house should be a lean-to, sloped at an angle of 45°,

and ventilated at the lowest and highest points, back and front, in the usual way. Above all, the heating surface should be ample—sufficient to sustain the temperature at 75°, if necessary, in the coldest weather, and without making the pipes too hot. To do this—and supposing the structure to be 7 ft. or 8 ft. wide, and proportionately high—five rows of 4-in. pipes will be required at least. The extra piping makes it more expensive at the first, but the difference will soon be saved in coal; for in a house where the piping is deficient the stoker is continually stirring the fire, and adding fuel quite needlessly in his anxiety to keep up the temperature. This is where the waste is effected in such cases, for, of course, it takes no more fuel to heat one row of piping violently than it does to heat two rows moderately; it is in the frequent mending of the fire that the coal is consumed. But, in addition to this, very hot pipes in proximity to the leaves of Cucumbers are a fertile source of injury; in fact, there is no greater evil, for everything depends on getting up good foliage and preserving it, and currents from over-heated pipes are very destructive agents. As to the capacity of the house, it should be from 30 ft. to 40 ft. long, where there is much demand for Cucumbers. A house 50 ft. long can be fired with proportionally less fuel than one half that length. Winter Cucumbers do not grow at a quarter of the pace that summer Cucumbers do, and the fruit is long in coming to a usable size; consequently it is necessary to have a much greater quantity of Cucumbers swelling at a time in order to keep up the supply. A house 50 ft. long might all be planted with Cucumbers for the winter; but after the days have turned fairly, and the plants begin to grow a bit, one-half of the house may be cleared out and planted with early Melons, and thus turned to better account. A winter Cucumber house is well adapted for that purpose, and it is a good plan to combine the two together, clearing out the Cucumbers in one half of the house in March, for the Melons sown early in February and forwarded in pots, and the other half some time later, and after the spring-sown Cucumbers come into bearing in the frames. In our winter Cucumber house an early crop of Melons is ripened off early in June in one division, and another crop in July and August in the second division, after which it is again all cleared and planted with Cucumbers for the winter.

SOWING AND PLANTING OUT.—Winter Cucumbers should be sown some time between the beginning and middle of August. They will do later than this, but it is desirable to have the trellis covered, or nearly so, by the plants in November, and ready to break into a general bearing condition; and to have them thus far advanced it is not too soon to sow early in August. For plants to come into bearing in February and March, we have sown in September and October; but for the whole winter supply the August-sown batch is the best, as they have more vigour than in plants sown later. We have known such plants bear without intermission the whole year round. The seed should be sown in a bottom-heat of 75° or 80° in a pot of light rich soil, and the plants potted off as soon as they can be freely handled and have made their first rough leaves, and afterwards grown on with plenty of light and air, in a temperature never exceeding the above at any time. Moderately strong growth and small rather than large leaves of flabby texture are most to be desired; an over-luxuriant growth augurs ill for the plants getting through the winter. That kind of growth which the Cucumber produces out of doors in situations where it grows is the most likely to keep green and healthy during the dull and trying winter months, and a moderate temperature and not over-rich soil are the very conditions likely to secure such a growth.

PREPARING THE BED AND PLANTING OUT.—A bed of soil 9 in. or 12 in. deep and 18 in. wide is quite sufficient to sustain the plants in health and fruitfulness for nearly twelve months, with occasional top-dressings, which should be applied to Cucumbers under any circumstances, and plenty of liquid manure. The best soil is a light, turfy, and rather sandy loam, without any additions in the way of manure or leaf-soil; but should the loam be heavy, it must be reduced, according to its texture, with leaf-mould and sand. Cucumbers prefer a light to a heavy soil; indeed, they will not thrive in a heavy loam either in summer or winter. The plants should be planted in the bed as soon as they are fairly established, but not much

later than the beginning of September. They may be put out 2 ft. apart, and the main shoots trained half-way up the roof, when they should be stopped for the first time.

TEMPERATURE, WATERING, AND GENERAL TREATMENT.—Throughout the whole winter the top-heat should range from 65° to 80°, night and day respectively, and always with more or less air; the ventilators should never be entirely closed, even in the severest weather. In cold nights the temperature may drop to the minimum figure (65°) towards the morning, but the more it is kept at 70° the better. By day, and as early in the morning as possible, it should rise to 75°, even in the coldest weather, and to 80° with sunshine. At lower temperatures than these the Cucumber almost stands still, and if higher it is unduly excited, and the growth is weak and poor. As to the bottom-heat, it should on no account exceed 75°, and there is no fear if it stands very frequently at 70°, which is a safer figure than anything above 75°. Very much depends on making good use of fine days. When the weather is mild and fine for the season, it should be taken advantage of to raise the temperature to the maximum point by the aid of fire-heat, and closing early in the afternoon; one good day is worth a week of bad weather in the winter time. In watering and damping some judgment must be used. There is little demand upon the leaves in a house necessarily kept so close as a winter Cucumber house always is, and it is very necessary to keep the bed moist, taking care, however, that it does not get dry in the bottom through being over cautious. Through this cause we have sometimes found the sods in the bottom as dry as dust when examined. It must always be borne in mind that there are hot pipes underneath. Damping and sprinkling should be done only on fine afternoons, and the evaporating troughs may always be kept filled. With the roots in a proper condition as regards moisture, this will be enough; but vigorous syringings may occasionally be given to keep down insects.

In the training of the shoots any methodical system may be adopted that is likely to cover the trellis with wood soonest. Should the plants grow vigorously, they may be pinched at any second shoot or so; but towards mid-winter they usually make little progress, and it is then better to let the shoots extend without pinching. The plants, when they do well, come into full bearing in November, and by the end of that month, or later, the cultivator should aim at having a quantity of fruit set and swelling. This will insure a supply during the most critical period, and until the days are fairly turned, when the plants will begin to grow again. Should there be more fruit hanging than is needed, it should be cut and stored in a cold room, setting each Cucumber on end in a little water; in this way they will keep perfectly fresh for two or three weeks, and the plants will be all the better for being relieved of the fruit.

S.

GOOD ENDIVE.

THE middle of June is, in most situations, as early as this crop can be profitably sown; and if the sowings are repeated fortnightly till the end of August, there will always be fresh relays of young plants put out, and this is the best way of ensuring a good supply of well-grown Endive. There must, of course, in addition, be a well-manured, deeply-stirred soil; for Endive, like Lettuces, to be crisp and good, must be grown quickly, and on poor shallow land this would be impossible. A liberal supply of moisture in dry weather is also essential, accompanied by frequent stirring of the surface. Liquid manure, when available, will be very beneficial. This will be best given immediately after a watering of plain water, as by so doing its presence will be longer felt than by pouring it on a dry, parched soil. Always sow the seeds thinly, and when they come up single them out, so that no two plants absolutely touch each other. No matter how good the parentage of the stock of seeds may have been, there will always be some weakly plants, and these latter should, on thinning, be taken out. The first sowing should at any rate be made in drills, as if a few plants are left undisturbed from 12 in. to 15 in. apart, they will be less likely to halt prematurely. Later sowings, if the land is scarce, may be made broadcast, but the plants must

be transplanted immediately they are large enough, and not be allowed to remain to draw each other up weak and spindling. On the whole, however, sowing in shallow drills will be found the most satisfactory plan, as it facilitates earth-stirring, which, in many ways, is so beneficial to the young plants. There is some advantage in putting a few plants out in different aspects. The main crops should occupy some good open situation, but a few plants of the early sowings, to meet exceptional seasons, might be planted on the north side of a fence or wall. Endive also generally does well on the ridges between the rows of late Celery. The greater depth of soil gives increased development, and in a damp season the elevated site secures freedom from damp. All the later plantings should be made on raised beds or borders if possible, as otherwise, especially if the soil be of a retentive nature, the crop will decay before it can be used. A good breadth from the last July and August sowing should be put out on a south border for late autumn and winter use, to be lifted and planted in frames, or protected in some other way when frost makes its appearance. Endive that is blanched where grown should be allowed plenty of space; 15 in. between the rows, and 12 in. from plant to plant, is not too much. After the plants are tied up, the surface soil from the 15-in. space between the rows may be drawn up round the base of the plants with a hoe, and then, if a flower-pot saucer be turned over the top of each plant, the blanching will be quickly done without any deterioration of flavour, as there is nothing so cleanly as dry earth. The plants, of course, must be dry when this tying and earthing up is done, or they will rapidly decay. Blanching in winter may be quickly done by taking the plants when full grown or nearly so, a few at a time, into a Mushroom house, or any other dark, warm structure, and, as they make abundance of fibry roots that hold the soil together, they may be easily lifted with balls, and taken anywhere. In this respect they are much more manageable than Lettuces. As regards varieties, Earley's Digswell Prize is a very good variety of the green curled section, and the white Lettuce-leaved Batavian will be useful in autumn.—"Field."

NOTES AND QUESTIONS ON THE KITCHEN GARDEN.

Early Cauliflowers.—These form an important crop in many of the London market gardens, and the excellent way in which they are cultivated can only be reached by those who fully realise the fact that even the smallest detail connected therewith if worth doing at all is worth doing well. In the neighbourhood of Fulham might lately have been seen several acres fit for cutting and in process of being packed for market, and it would be no exaggeration to say that not 1 per cent. could be selected from them that fell below the average of really good heads. This amount of perfection is the result of certain growers making a speciality of certain crops, and devoting their whole energy to obtaining first-class produce. This is the only way in which good prices can be got at all seasons. As a rule, market growers save their own seed, and, by constant selection from the very best, they have produced strains that combine a dwarf sturdy habit with a large head, heart, or flower, as the case may be. These growers, from the abundance of manure which they readily obtain, are enabled to get two or three crops without digging the ground; but when they perform that operation it is done thoroughly, and in the case of any crops that are planted at so wide distances apart as Cauliflowers, an intermediate crop, such as Lettuce, is planted between them. I may also remark that particular dates on which to sow such crops as the Cauliflower are more rigidly adhered to in market gardens than in private ones, as the high manuring renders the land almost like a hotbed, and the growth of such crops in favourable seasons is exceedingly rapid and luxuriant.—J. Groom.

Peas from Old Seed.—Some of the finest rows of Peas which we have seen this year are growing in Mr. Appleby's nursery at Boxhill, and consist of Bedman's Imperial Old Marrow, a Pea of great excellence, but one not now grown so much as formerly. They were the produce of four-year-old seed, the rows were 5 ft. through, and the crop an extra heavy one.—S.

Roots and Potatoes.—Those who are troubled with roots unearthing young Potatoes at this season would do well to adopt the following preventive measures, which have been found to be thoroughly effectual: Get several sheets of brown paper, wet them, and sprinkle dry gunpowder over them; then tie them to the tops of stakes placed here and there among the Potatoes, and set light to them; the paper being wet will not burn, but will retain the smell of powder for a long time, and the roots will not come near whilst that lasts.—S. J.

GARDEN BOTANY.

(Continued from p. 10.)

The Calyx.

The calyx is polysepalous when the sepals are free to the base and fall away separately, as in the Poppy or Buttercup, or can be detached separately, as in Geranium (fig. 296); and

Fig. 296.—Polysepalous calyx of *Geranium roseum*, having five equal sepals. Fig. 297.—Gamosepalous 5-partite calyx of *Corrigiola littoralis*.

gamosepalous when the sepals are more or less united, as in *Corrigiola littoralis* (fig. 297) and *Primula* (fig. 298).* The terms entire, toothed, fid, partite, &c., are applied in the same way to calyxes and corollas as they are to leaves. The gamosepalous calyx is either free from the ovary, as in *Agrostemma* (fig. 299)

Fig. 298.—Gamosepalous toothed calyx of *Primula sinensis*. Fig. 299.—*Agrostemma Gitnago*, showing 5-fid calyx. Fig. 300.—*Mesembryanthemum*, calyx adherent to the middle of the ovary.

and the Primrose, or adherent to it, as in *Fuchsia*. The part of the calyx that is free above the ovary (future seed vessel) is the limb, which is sometimes very small or almost obsolete, or it is more or less distinctly lobed. In *Mesembryanthemum* (fig. 300) the calyx is adherent to about the middle of the

Fig. 301.—Calyx and fruit of *Gaillardia picta*. Fig. 302.—Fruit of *Valeriana*, crowned with a feathery calyx limb.

ovary, and it has a distinctly four-lobed limb. The calyx of *Fuchsia* is adherent to the ovary, and produced above it in a long tube and deeply four-lobed at the top; it is also noteworthy as being one of the not very numerous examples of a coloured (not green) calyx. In the *Compositæ* the calyx limb is usually

* When the parts of the same whorl, as the sepals, are united, the union is termed cohesion, and adhesion when the parts of different whorls, as calyx and seed vessel, are confluent.

reduced to a number of plumes, as in the Dandelion and the Thistles, and it is stalked in the former and sessile in the latter. The calyx limb of the *Compositæ* has received the

Fig. 303.—Calyx of *Scabiosa atropurpurea*, the investing involucre cut and spread open. Fig. 304.—A flower of *Pezænum harmala*, the sepals of which are deeply cut.

special name of pappus, and it presents a great variety of modifications useful in classification. The pappus of *Chicory*

Fig. 305.—Wallflower; two of the sepals gibbous at the base. Fig. 306.—Flower of *Aconite*; one of the sepals the shape of a helmet.

consists of short scales; in *Zinnia* it consists of two bristles; in *Gaillardia* (fig. 301) it is not unlike the ordinary calyx limb

Fig. 307.—Flower of *Lavender*; one of the sepals spurred. Fig. 308.—Flower-bud of *Balsam*; posterior sepal spurred. Fig. 309.—Flower-bud of *Callisthene minor*, showing the spurred sepal.

of other natural orders. In some *Compositæ* it is cup-shaped, or reduced to a narrow rim, or quite obsolete, as in the *Nipple-*

Fig. 310.—A flower of the Canary creeper, *Tropæolum adnatum*, the posterior sepal spurred. Fig. 311.—Longitudinal section of a flower of *Pelargonium*, showing that there is a cavity answering to the free spur of *Tropæolum*. Reduced.

wort and Daisy. *Valerianacæ* (*Valeriana*—fig. 302) and *Dipsacæ* (*Scabiosa*—fig. 303), small natural orders allied to the *Compositæ*, have a similar calyx limb. Both polysepalous

and gamosepalous calyces have regular and irregular modifications. (See foregoing paragraph on regular and irregular flowers.) The calyx of *Geranium* (fig. 296) is polysepalous and regular, and the sepals are entire, whilst in *Peganum* (fig. 287) they are deeply divided into narrow segments. There are several very singular irregular calyces belonging to quite

which the two genera possess in common. In *Pelargonium*, as in *Tropæolum*, one of the sepals is spurred; in the latter the spur is free, as shown in fig. 310, whilst in the former the spur is adnate to the pedicel (see figs. 311 to 314). Except when spurred, the sepals are usually produced only above the point of attachment to the receptacle, as fig. 315, but in the *Violet* (fig. 317) they are produced below the point of attach-

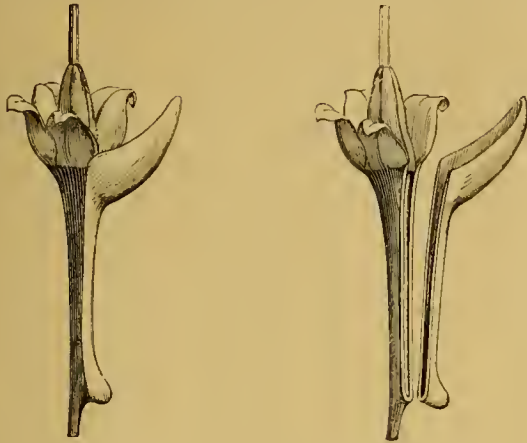

Fig. 312.—Calyx of *Pelargonium*. Fig. 313.—Calyx of *Pelargonium*; the spurred sepal detached.

familiar flowers. Two of the sepals are gibbous, or saccate, at the base in the *Wallflower* (fig. 305); one of the sepals in the flowers of *Aconite* is helmet-shaped and larger than the rest

Fig. 320.—Irregular gamosepalous calyx of a *Labiate*. Fig. 321.—Irregular gamosepalous calyx of *Lavandula epica*.

ment. The space between the two anterior sepals is where the spur of the corolla protrudes. All the sepals of *Myosurus* (fig. 318) are spurred below. Fig. 319 represents an example of a regular gamosepalous (monosepalous of some books) calyx, and figs. 320 and 321, varieties of the irregular type.

DURATION OF THE CALYX.—In the *Poppy* and most of the plants belonging to the same natural order the sepals fall away

Fig. 314.—Transverse section of the pedicel of *Pelargonium*, showing the cavity formed by the adnate spurred sepal. Fig. 315.—A flower of *Helleborus foetidus*, which is apetalous, and whose sepals are entire. Fig. 316.—A detached sepal from the flower of *Helleborus foetidus*.

(fig. 306); and in the *Larkspur* (fig. 307) one of the sepals is produced below in the form of a hollow spur. Compare the flower of *Aquilegia* with the last; it has all the petals spurred.

Fig. 322.—Reduced inflorescence of *Hydrangea*, in which the outer flowers present a very greatly enlarged calyx.

before the petals expand, and the petals drop the same day that they become fully expanded. Sepals which fall so early are termed caducous, and if they remain attached during what may be termed the flowering period and then fall, they are deciduous. Frequently, however, the calyx, whether free to the base or adherent to the ovary, does not fall before the fruit,

Fig. 317.—Calyx of a flower of a *Violet*. Fig. 318.—A flower of *Myosurus*; all the sepals produced below the point of insertion in minute spurs. Fig. 319.—Flower of *Asperula odorata*, showing the regular four-lobed calyx.

Other examples of spurred calyces are the *Balsam* (fig. 308), *Callisthene* (fig. 309), and the *Canary Creeper* (fig. 310). In the latter the sepals cohere, forming a gamosepalous calyx. At first sight one would not take the genus *Pelargonium* to be closely allied to *Tropæolum* (*Canary Creeper*, *Nasturtium*), but a cursory examination will reveal some unexpected characters

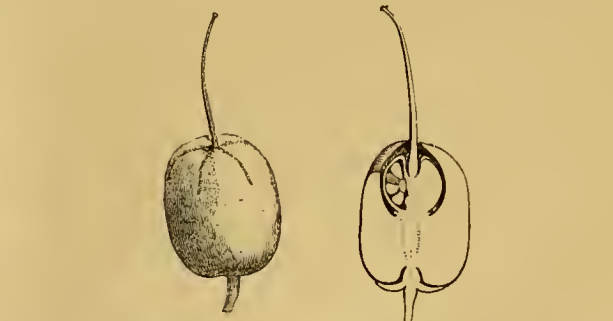

Fig. 323.—Fleshy calyx of *Gaultheria*, enveloping the fruit. Fig. 324.—Section of the same, showing the seed-vessel.

and it is termed persistent. The remains of the calyx lobes of the adherent calyx of *Gooseberry*, *Currant*, *Apple*, &c., may be seen at the apex of the ripe fruit, and in the *Raspberry*, *Strawberry*, &c., there is the green, free calyx at the base of the ripe fruit. In many instances the calyx is not only persistent, but it grows out (is accrescent) during the ripening of the fruit. We have already alluded to the enlarged calyx of the barren

flowers of *Hydrangea* (fig. 322). The calyx of *Gaultheria* (figs. 323 and 324) becomes quite fleshy, and the lobes converge at the tips and enclose the seed vessel. Among ornamental accrescent calyxes those of *Howardia caracasana*, *Mussaenda frondosa*, and numerous other species, and two species of *Calycophyllum* are the most remarkable. One of the lobes of the gamosepalous calyx grows out like a stalked leaf, 1 in. to 6 in. in length, according to the species, and is of a pure white or some brilliant colour. It may be mentioned, too, that there is a natural order of large timber trees, chiefly natives of tropical Asia, called the *Dipterocarpeæ*, characterised by having two or more of the sepals grown out and forming wing-like appendages to the fruit, giving it somewhat the appearance of a shuttlecock. The gamosepalous calyx is usually persistent, even to the limb, whilst the contrary commonly obtains with the polysepalous calyx.

W. B. HEMSLEY.

GARDENING FOR THE WEEK.

Indoor Plant Department.

Odontoglossums.—Where the different varieties of these are grown in quantity, especially the *O. crispum*, or more generally understood *O. Alexandræ*, section, of which there are so many forms, with the newer *O. cirrhosum*, which also differs very much in size of flower and marking, some or other will be in bloom through a considerable portion of the season. Those that flowered early will now be making their growth, and should be encouraged to push on by placing them at the warmest end of the house and keeping them a little closer, except during that portion of the day when air is freely admitted. They are water-loving plants, yet it is possible to keep them too wet, the result of which is that the leaves become diseased and spotted. This is almost inevitable if there be any stagnant water about them through the plants having been allowed to remain in the same material until it has got into a decomposed soapy condition, in which case whatever stage of growth they are in they should be at once turned out and replaced in fresh soil. Where a large collection is grown it is always necessary to keep an eye to this, for, although the time for general potting is undoubtedly at the period just before growth has commenced, yet it invariably happens that there are a number of plants, either through having made late growth or other causes, do not admit of being operated upon at the time when the majority receive attention in this way. For this reason it may be said that the potting season in the case of any considerable collection of Orchids is, to some extent, continuous. Another cause by which the soil in which these plants are grown gets into an unsuitable state is through the pots being allowed to stand on a smooth surface, such as slate shelving, kept generally moist. The water from the sates is regularly soaked up, thus keeping the roots almost as wet as if the pots were set in saucers. This plan of setting the plants on smooth surfaces is easily avoided by having the stages covered with small pebbles, which will allow water to be applied without the base of the pots being in absolute contact with it. *Odontoglossums* that succeed with warmer treatment than that just named, such as *O. bictonense*, the different forms of *O. grande*, *O. coronarium*, *O. citrosimum*, *O. Phalenopsis*, *O. Rossi*, *O. maculatum*, *O. basilabium*, *O. vexillarium*, and *O. Roezli*, that are now making growth, should be kept a little warmer—in such a temperature, indeed, as that usually given to the generality of *Cattleyas*—keeping up sufficient moisture in the atmosphere with the requisite quantity of water to the roots and enough air through the middle of the day. Perfect cleanliness, as regards insects, should be aimed at. Greenfly is difficult to eradicate, from the fact that the plants dislike fumigating in amount sufficient to destroy it; but if the use of a sponge, with a little Tobacco water, not so strong as to leave a dirty sediment on the leaves, be persevered in, it can be exterminated. The little yellow thrip must be in like manner sought after. This, from its small size, frequently escapes detection until a good deal of mischief is done, as, unlike the aphides, that attack the outside of the unfolding leaves, it takes up a position where it is not so easily got at—right down in the inside of the young growth. Where sufficient light and air are given to the plants, to impart the requisite solidity, most *Odontoglossums* will bear syringing slightly overhead early enough for the water to get dried up before evening, which will have the effect of banishing thrips, as they cannot exist on the surface of leaves that are moist, even for a few hours in the day.

Epidendrums.—*E. vitellinum*, so desirable for the bright orange-scarlet colour of its flowers, will, in most cases, now have done blooming; and where potting is required (though it does not need very much root room) that should have attention, and the plant forthwith encouraged to make growth. It will generally be found to do the best amongst cool-growing plants, as will also *E. erubescens*, *E. sceptrum*, and *E. pterocarpum*.

Cool Oncidiums.—Amongst the many *Oncidiums* worth growing, there are a few that succeed best in a cool house, such as *O. serratum*, *O. superbiens*, *O. Weltoni*, *O. Roezliannum*, *O. nebulosum*, *O. macranthum*, and the different forms of *O. leucochilum*. At the same time, they will generally do better with a little more warmth and with less water at the

roots than the coolest *Odontoglossums* and *Masdevallias*, &c., but where this cannot be afforded them, a slight compromise should be made by putting them at the warmest end of the *Odontoglossum* house, admitting less air near them, or they may be set at the coolest end of the intermediate house, where they will be still further accommodated by giving the most air near where they are placed; and in most cases the latter arrangement may be found preferable, as the somewhat collective drier conditions under which *Cattleyas*, *Lælias*, and kindred plants are grown will suit *Oncidiums* better.

Intermediate Oncidiums.—There are a few of the older, somewhat despised *Oncidiums* that for providing cut flowers and for general effect are amongst the most useful that can be grown. For instance, there is nothing in the whole range of yellow-coloured flowers that equals *Oncidium flexuosum*, either for bouquets, button-holes, or vases of cut flowers. It is an easily-grown plant, providing it be kept quite clear from white scale, and so placed that cockroaches, woodlice, or slugs cannot get admittance to the pots or baskets (the latter much the most suitable) in which it is grown, as, from its natural erect habit of growth and the way in which it throws its roots out as it progresses upwards, they are directly exposed to the attacks of everything that will prey upon them; for this reason it is much the best suspended from the roof, in which position it will attain the most strength and bloom proportionately. If, after the first flowers produced in the season are over, the heads of the bloom-stems are cut off just below where they branched out, leaving the lower portion of the stem, these will push out and flower a second time, which is so much gained over the usual method of cutting the whole of the flower-stems away. It likes plenty of water and does well syringed overhead every day; it requires a cool intermediate house temperature. Amongst the best of the *Oncidiums* also wanting intermediate house treatment may be named *O. ampliatum* and its larger form *O. ampliatum majus*, *O. crispum*, several forms including the fine-flowered *O. Marshalli*, *O. Cavendishi*, *O. bicallosum*, *O. orniithorrhynchum*, *O. Wentworthianum*, *O. Rogersi*, *O. Barkeri*, *O. cornigerum*, *O. sarcodes*, and *O. Krameri*. These are worth a place in any collection, succeeding well in an intermediate house, but should have more water at the roots than *Cattleyas*. With these the best use ought to be made of the sunny weather that may be looked for during the next two months by closing the house with a moderate amount of sun-heat in the afternoons. The warmth thus obtained is vastly more conducive to the well-being of the plants than fire-heat. The intermediate house plants collectively will be benefited now for a couple of months by thus closing the house earlier, for even should the temperature rise by the action of the sun for a few hours some degrees above that which is usually considered sufficient for these subjects, now, whilst there is a maximum of light, no harm will be done, and increased size and strength of growth will be the result.—T. BAINE.

Stoves.—More air will now be required by plants in the stoves than earlier in the season, when the growth was young and tender, and liable to injury if much external air came in contact with the partially developed foliage; but, in its admission, always be guided more by the state of the weather than the time of the year. In our changeable climate we often, even in the height of summer, experience cold days, when, if a considerable volume of air be admitted, it reduces the temperature and checks growth. Even when the weather is hot and air can be given in abundance it should be taken off sufficiently early in the afternoon, while the sun has yet power on the glass. By this means the temperature of the house rises very considerably and the growth of the plants be kept up until the wood is well matured. The numerous insects to which stove plants are subject, such as mealy-bug, scale, and thrips, at this season increase apace. Those who are so unfortunate as to have mealy-bug to contend with have an unceasing task before them so long as a trace of the pest exists upon their plants. Later in the autumn, when growth is completed in most things, is the best time to make a determined onslaught on the insect. Its destruction will be rendered much easier if it be kept well down during the summer, for if once it be allowed to get such a head as is sometimes seen, where it not only half smothers the plants, but gets into crevices in the wood and brickwork, it is difficult to deal with. There are so many prescriptions for the destruction of this and similar insects, all in their turn by some pronounced infallible, that it is a wonder any are left alive. Many of the insecticides are recommended to be laid on with a camel's-hair brush or a sponge; this might answer if only an odd plant or two were affected, or if there was an unlimited amount of time at disposal for this kind of work; but this is seldom the case, and some readier means must therefore be resorted to, the best of which will be found to wash the plants with Fowler's insecticide for scale; at this time in the season hard-wooded plants will bear it at a strength of 5 oz. to the gallon, syringing it on at a temperature of 90°, so as to reach every part. For bug, which is harder to kill than brown scale, Abyssinian mixture is the best, using it at from 5 oz. to 6 oz. to the gallon, according to the nature of the leaves of the subjects upon which it is used. Where this insect is kept under during the summer months, an attempt in the autumn to completely destroy it is much more likely to be successful. Such kinds of *Gloxinias* as are considered desirable to increase should now be propagated. The leaves being fully matured, are now in a much better condition to form roots than earlier in the season when they were soft. In varieties of which there are a sufficient number of leaves the stalks of those used should be shortened to about 1 in. below the leaf; three or four of these should be placed round the sides of a 6-in. pot, sufficiently drained and filled with a mixture of two parts of loam to one of sand, the cuttings being put in so deep as to cover the stalk and about $\frac{1}{2}$ in. of the base of the leaf. Where leaves for propagation of any particular sort

are scarce, several roots may be had from a single leaf by laying them down on the surface of the soil in a seed-pan filled with the compost, as above. The mid-rib of the leaf must be cut through in five or six places and laid with the underside downwards, a small stone, just large enough to keep the severed part of the mid-rib at the point where cut touching the soil, being put over each place where it is thus cut. In this way bulbs will be formed, but these will not, individually, be near so large as when the stalks are inserted, and each leaf employed to make a single root. Old plants of Poinsettias should now be encouraged to make strong sturdy growth. Another useful winter-blooming plant is *Begonia dipetala*. If small plants of this are now at hand and grown on freely they will furnish quantities of bloom in the winter. *Allamandas*, *Clerodendron splendens*, and *Dipladenias* showing flower freely should now be trained round their trellises, but not too closely, as that gives them too stiff an appearance, and also has a tendency to cause premature decay in the leaves, which turn yellow and decay; this has also a tendency to weaken the plants and reduce their blooming capabilities. Expose them to all the light possible, using just sufficient shading material to break the direct rays of the sun; by this means the flowers will be produced much stouter, and will stand in a cut state, if required, much longer than when treated more tenderly. Autumn-struck cuttings of hard-wooded stove plants, such as *Ixora*, *Allamandas*, *Gardenias*, &c., which have been potted during the winter, will by this time require a further shift. The aim of the cultivator ought to be to get the plants up to the required size as quickly as possible; if such plants are allowed to become stunted through being pot-bound, it takes a long time afterwards to get them to move; in fact, it is better to commence with a cutting than to grow a plant on that has been allowed to get into such a condition. It would seem that the increased demand for cut flowers at the present day is illimitable; it therefore behoves gardeners to make provision to meet it. In most establishments, large or small, there will be some things held in greater esteem than others. Therefore it is impossible to name any plants in particular that would be held in general estimation. Yet during this and the next two months flowers from stove plants will be largely used for mixing with *Roses* and other outdoor productions. There is a great charm in variety; yet the old system of growing collections of plants where the object was to include the greatest number possible, both of species and varieties, is anything but calculated to meet the requirements of the present day; it is much better to confine to a reasonable extent the number of varieties of plants grown to such as are the most attractive, last the longest, and are held in the greatest estimation. If there is one plant more than another that is more generally useful as a decorative stove or intermediate house plant, and capable of producing quantities of cut flowers for eight or ten months in the year, it is *Ixora coccinea*. Now is a good time to either strike cuttings or procure plants of it; and if kept clear from insects, and grown under the same conditions as to temperature and atmospheric moisture, summer and winter, that will suit Cucumbers, it will amply repay for the trouble bestowed upon it. Its flowers will stand in water for a week, and it can be cut with impunity without injuring the plants.

Ferns.—In the tropical Ferneries fire-heat can now be almost dispensed with; the temperature, however, should not sink too low. Maintain a moist atmosphere; water growing plants abundantly, dew them gently overhead with tepid water, but refrain from damping the fronds of *Gymnogrammas*, *Chelidanthes*, *Maiden-hair*, and other such Ferns, and re-pot any that have well filled their pots with roots and that are not already in large pots. Seedling Ferns must be pricked out after they have germinated and can be transferred without difficulty from the seed-pans. Spores should always be sown as soon as they are ripe, and young plants growing on *Asplenium bulbiferum* and *viviparum*, *Woodwardia orientalis*, and others should be separated and treated as ordinary plants, or the fronds containing them may be taken off and layered like *Begonias*. Keep a sharp watch over insects of all kinds, remove decaying fronds, and everywhere preserve neatness and order.

Pelargoniums.—The beauty of large-flowered kinds that have been the first to bloom will now be over, and it is not desirable to allow them to push a second growth and flower again, which they will if not interfered with, as this prevents their being cut down and making growth that will bloom early next spring. If there be a scarcity of plants to take their place, and flowers be required, a portion may be allowed to go on blooming for a time. Move at once the plants that flowered first into the open air, so as to get the wood ripened before they are cut back; if maturity be not effected before cutting back takes place, they will not break either evenly or freely. Place them in the full sun in an open situation, but do not all at once withhold water, as that course stops further growth; no harm will, however, be done by letting the soil get dry enough to cause them to flag for a few hours; then give water, and when again dry let them go a little longer before applying any, and in this way, by degrees effect the ripening process of the wood, which in a few weeks will assume a hard brown colour, after which the shoots must be removed to within from three to half-a-dozen eyes of where they were headed back to the preceding year, according to the size of the specimens, allowing the greatest length of shoot to remain in the case of young plants which it is desirable to increase in size. Do not let them get saturated with wet during thunder-storms or continued rains. When there is an appearance of such occurrences lay them down on their sides. Plants that are wanted to be in flower some weeks longer should be well supplied with manure water, particularly if in small pots, and these very full of roots. What are called fancy kinds push their flowers almost all together, and after the general head of bloom is over they should be cut back; they must not, however, be cut in nearly so close or into the hard wood as the

large flowering sorts, or the result will most likely be the loss of the plants; neither will it be well to expose them in the open air in the manner advised for the other kinds; a pit or cold frame after flowering will be the most suitable place for them, never subjecting them to such extreme drought as the large-flowered ones will bear. They are equally impatient of too much wet, which is generally the cause of their dying suddenly in a way which they often do.

Indoor Fruit Department.

Vines.—Look over lately inarched Vines and see that the ties are not interfering with the expansion of the wood; do not remove the matting entirely, although the union may seem complete, as the slightest pressure will cause a separation. It is a safe plan to put a single round of matting above and below the jointing, and let it remain all the season. Where *Lady Downes* are stoning and show the slightest indication to scald keep the interior of the Vinery in which they are as cool as at all times as a greenhouse until the stoning process is over, and not 3 per cent. of the berries will be injured. This scalding, as it is termed, consists in the most prominent berries becoming soft and brown on one side, as if they had been burnt with a hot iron; sometimes a single berry here and there throughout the bunch is affected, and in more severe cases the whole side of the bunch is destroyed. Many a bunch which promised well to begin with has through this been reduced to almost nothing in a short time. A burning sunshine is the chief cause of the disease, for in dull sunless weather nothing of the kind takes place. When sufficient air cannot be admitted a temporary shading is often placed over the glass outside to keep down the temperature inside. Midsummer Grapes are colouring fast now, and an inch or two more opening may be left on the ventilators all night with advantage; on mild, wet, dull days the front ventilators should not be kept entirely shut. Be careful to keep the Vines from which all the fruit has been cut perfectly clean from every form of insect. The best eyes from which to raise next year's Vines are those selected from the earliest-ripened wood, and this fact in itself should be sufficient inducement to ensure attention.

Pits and Frames.—Cucumbers that have been bearing from the commencement of the season, and are now falling off a little, should have some of their shoots thinned out and a little fresh soil added to the surface of the bed. In this the shoots will strike root from the joints, where required, by pegging them down. If the plants be clear from insects thus treated, they will again push out growth and fruit freely.

Melons.—The late-planted crops will now be growing fast, and must receive every attention in thinning out superfluous shoots, stopping those retained as soon as they reach the sides of the frame; this will cause them to throw out bearing wood. Keep up the necessary warmth in the beds by slight linings; these will not require now to be so heavy as earlier in the season when the weather was cooler, but with late Melons in frames the beds must not be allowed to get cold, or the plants make little progress and the summer is too far advanced before the crop comes to maturity. As the preceding crops gradually ripen withhold water so as to impart the requisite flavour to the fruit, but do not let the soil become so dry as is sometimes done, and thus stop the full development of the fruit. Endeavour by the use of the syringe on such as are swelling off the crop to keep the foliage free from insects, for where the leaves are scanty and injured by red spider or other pests the fruit, as a natural consequence, will be small and deficient in flavour. Woodlice are a great nuisance where they exist in large numbers in Melon pits or frames, and before the fruit begins to ripen measures should be taken for their destruction. They are not at all particular as to their food, slices of raw or boiled Potatoes, or pieces of Apple placed in the bottom of a few small pots and covered with hay or Moss, will attract them in numbers, while by looking over them every morning and destroying they can be kept down so as to little inconvenience. It is only where such precautions are neglected during the advancing stages of the crop that woodlice exist in such numbers as to do serious mischief.

Kitchen Garden.

Late Peas.—As a means of retarding, in some measure, the last sowings of late Peas, so as to have them far on in the autumn, the points of the shoots may be nipped out at the spot where they show the first flower; this will induce them to throw out growths at the joints lower down, and it also makes them more bushy, as they will, thus treated, push two or three shoots in the place of one, and will delay their cropping from a fortnight to three weeks. As to the quantity produced by Peas so treated, it does not appear to have any influence either one way or the other. The greatest enemy late Peas have is mildew, for if this once makes its appearance their cropping powers are soon over. If, as advised at the time of sowing, the most open airy situations were selected for these late crops, and the rows were placed far apart, the chief measures for avoiding this troublesome parasite have been taken; but if they are ever allowed to want water, mildew is certain to follow. If, therefore, the weather be dry, give a copious watering once a week, so as thoroughly to soak their roots, and mulch the ground with half-rotten manure for 2 ft. on either side of the rows.

Turnips.—A good breadth of Turnips should now be sown, as, after this time, the beetle is not usually so destructive as earlier in the season. Ground that has been cleared of early Potatoes, Peas, or other crops will now be available for these. It will not be necessary to dig it previous to putting in the seed, unless it be of a very strong adhesive nature, nothing

being gained by doing so; in fact, when the land is light it does absolute harm by inducing the growth of leaves rather than that of the bulb. Previous to sowing, hoe the ground 2 in. deep, rake off and remove any weeds that may exist, and sow the seeds in rows 1 ft. apart, putting in enough to allow for loss from the depredations of birds or the fly. Before sowing dress the seed with red lead; if this be properly done, according to the directions already given, it will secure them from molestation from all birds except the greenfinch, which seems to defy any dressing that can be given to seeds of the collective family of Brassicas. It is a well-known fact that seed-bearing severely taxes the energies of any plant, although all are not alike affected by it, but it is simply a waste of strength to allow anything to seed when the seed is useless or not required. For this reason *Asparagus* in private gardens should have the seeds stripped off as soon as they are large enough to take hold of. At first this may appear a tedious process, but a little practice will enable any one to clear a good breadth in a few hours. Do not allow them to get large or full grown before they are taken off, for, in that case, the injury they do is almost complete. Go over the beds frequently to remove all weeds, which, if allowed to grow so much, impoverish the soil, and this crop, more than most others, cannot bear this.

Planting Cottager's Kale.—A good space should now be planted with the useful Cottager's Kale, as this is a most excellent vegetable, and so hardy that it will stand even on severest winters. It is much better to have a good breadth of it than to grow several varieties of similar winter greens that are not equal to it in any way. Give the plants 20 in. space in the rows, and allow as much between each row.

Vegetable Marrows and Endive.—Thin out Vegetable Marrows sufficiently, not allowing them to get too much crowded, and if the situation be at all exposed, secure the shoots so that they will not be blown about by the wind. See that they are well supplied with water. Wanting this, the plants will not bear to the end of the season. Making a sowing of the Batavian Endive, and also of the Green Curled; these will come in as an autumn supply, as the plants from this sowing will not be so liable to run to seed as those sown earlier. Do not put the seed in too thickly, as nearly all of them vegetate and are not so liable as many to suffer from the ravages of birds or insects.

Extracts from my Diary.

July 15.—Sowing Snowball and American Strap-leaf Turnips. Potting in cuttings of Carnations and Pinks under hand-lights. Planting out Wheeler's Imperial and Carters' Heartwell Early Marrow Cabbages for autumn use. Layering Strawberry runners, three in a bunch, on pieces of turf 6 in. square, for making new plantations. Stopping and nailing in Tomatoes. Looking over Cucumbers and Melons, stopping them, and earthing them up a little where required. Mulching late Peas and Beans with well-rotted manure.

July 16.—Sowing a little Chervil for autumn and winter use; also Mustard and Cress. Taking up and dividing a quantity of old Polyanthuses. Planting out Celery in trenches. Getting up early Potatoes and storing them away for seed. Dutch-hoeing among Gooseberries and Currants, and all other growing crops. Gathering Apricots for bottling. Giving Scarlet Runner Beans a good soaking of manure water. Taking the nets off Strawberries and putting them over Morello Cherries.

July 17.—Sowing Green Curled and Frazer's Broad-leaved Endive. Pricking off herbaceous Calceolarias; also *Cinerarias* and *Primulas*. Planting out the last rows of Cardoons. Picking off the dead flowers and nailing and tying in Roses on walls. Giving Peach and Nectarine trees a good soaking of water. Cutting herbs and placing them in an open shed to dry. Gathering Raspberries and Red Currants for preserving. Renovating the linings round Melon and Cucumber frames, and giving all Pear trees, where heavily laden with fruit, a good watering.

July 18.—Sowing Red and White Turnip Radishes. Putting in cuttings of different sorts of *Pelargoniums*. Clearing off a large piece of Peas; manuring the ground, and getting it dug up ready for other crops. Training out and pegging down bedding plants, and staking and tying in plants on borders. Stopping and nailing in the leading shoots of Peaches, Nectarines, and other wall fruit. Sticking Peas, and getting them earthed up. Watering the Pines all through, and putting stakes to any that require it.

July 19.—Sowing Canadian Wonder dwarf French Beans. Potting on *Begonias*, Palms, and *Dracaenas* for table plants. Earthing up early Celery when the soil is dry and in workable condition. Clearing off a piece of Broad Beans, manuring the ground, and digging it in ridges on which to sow Winter Spinach. Stopping and pegging down Vegetable Marrows, and giving them a good soaking of manure water. Looking over *Vinerias*, stopping laterals, and giving all late houses a good soaking with guano water.

July 20.—Sowing Spinach. Tying out and picking blooms off *Fuchsias* intended for exhibition. Thinning Turnips. Turning over manure for making new Mushroom beds. Watering Cauliflower, Celery, Lettuce, Endive, and Tomatoes. Drawing drills for Spinach, and well watering them previous to sowing. Giving Peaches and Nectarines a good washing every evening with the garden engine to keep down insects. Mowing and cleaning in the pleasure grounds, and rolling down all gravel and turf that require it. Fruit in use for dessert: Pines, Grapes, Melons, Peaches, Nectarines, Figs, Strawberries, Raspberries, and Cherries.—W. G. P., Dorset.

PLATE CXXXVI.

THE STUARTIAS.

(WITH A COLOURED FIGURE OF *S. VIRGINICA*.)

Drawn by MRS. DUFFIELD.

CONSIDERING how few ornamental shrubs there are that produce their flowers in summer, it is not a little remarkable that any really good hardy species should be neglected. Yet how many gardeners or amateurs have heard of a *Stuartia*? much less seen a fine specimen in its full beauty, although two species were introduced during the last century. Like many other North American plants, they were not very generally dispersed in British gardens when first introduced; and during the last thirty years or more deciduous shrubs and trees have not received their due share of attention, in consequence of the great demand for evergreens. There are still, however, some gardens where the precious introductions of former owners are prized and carefully preserved. Notable amongst these is Syon House garden. The present duke is a great lover of trees and shrubs, and his gardener, Mr. Woodbridge,

Flower-bud of *Stuartia virginica*.

is very proud of the historical collection under his charge. At Syon one may see a *Stuartia* amongst the numerous rare species in the arboretum. About a year ago Mr. Woodbridge exhibited flowering specimens at South Kensington, and every one who saw them admired them. Now there is one species, at least, which deserves a place in every garden, no matter how unpretending its design. The genus *Stuartia* comprises four known species, two native of the Eastern States of North America and two of Japan. Only the American species have hitherto been introduced into Europe, but, judging from the dried specimens, one of the Japanese species is equally handsome as the North American. They are all deciduous shrubs with simple leaves, much like those of some species of *Cerasus*, and the flowers resemble those of a good single *Camellia*; in fact, there is more than an outward resemblance, for *Stuartia* and *Camellia* belong to the same Natural Order. The two North American species have been confused by some writers, but it is important to distinguish them, since one is rather hardier than the other. *S. pentagyna* (syn.—*Malachodendron ovatum*) is perhaps the hardier of the two. There is a coloured figure of it in Sir James Smith's "Exotic

AN AMERICAN SHRUB (STUARTIA VIRGINICA)

Botany," t. 110, which was prepared from a specimen grown at Kew. Smith says: "It has long been cultivated at Kew, where the late Mr. Aiton gave me specimens in 1785 from an old full-grown shrub." He also speaks of it as being exceedingly rare. It differs from its congener *S. virginica* in its larger, less hairy leaves, larger cream-coloured flowers, and especially in having five distinct styles in the flower, instead of only one, or rather of five consolidated into one. Its flowers, which are solitary in the axils of the leaves, are 3 in. or 4 in. across, and they are produced in great profusion during the months of July and August. The petals are cream-coloured inside, and tinged with red on the outside, and more or less jagged on the margin. This species is at home in the mountains of North Carolina and Tennessee, and thrives in any good garden soil. *S. virginica*, on the contrary, inhabits swamps and shady woods from the coast to near the foot of the mountains in the South-Eastern States, including Florida and Louisiana. I have seen no specimens from so far north as the State of Virginia. The flowers of this species are also very showy, the petals being pure white and the stamens purple; but it does not flower so freely as the other. It is figured in Andrews' "Botanists' Repository," t. 397, under the name of *Stewartia marilandica*.

W. B. HEMSLEY.

[The specimens from which our plate was prepared were supplied from the gardens at Syon House.]

PROPAGATING.

PERENNIAL PHLOXES.—There are several ways by which these may be increased, viz., by division, cuttings, and roots. For

Fig. 1.

Fig. 2.

spring propagation the plants must be got into an intermediate house, the temperature of which is about 55° in February, when they will soon begin to grow and produce fine, soft cuttings. Take well-drained pots, fill them with fine soil, consisting of loam, leaf-mould, and sand, putting $\frac{1}{2}$ in. of sand on the top; give a sprinkling of water, and make the cuttings as shown in fig. 1 or fig. 2, cutting off the bottom leaves and leaving the buds; insert the cuttings up to the leaves, water them, and place them in a gentle bottom-heat; they will, however, do equally well in the box in the propagating house, or in a bed of fermenting material, taking care to let off all excess of moisture by opening the glasses every morning; if on a manure bed, a little air given at the back part of the frame will be beneficial. Cuttings may also be taken off in autumn; the best way is to put them in single pots on a spent manure bed; they will emit roots in three weeks or so, when they may be put on a shelf in a cold greenhouse to winter; they may lose their tops, but they must not be thrown away, as in spring they will shoot up from the bottom and make early strong plants. In order to increase them by means of division and roots, take

up the plants intended for that purpose in September, cut off all the roots that are not wanted (there are a great many more in the case of some varieties than in that of others), cut up the plants according to their strength, pot them, and place them in a cool, close frame. The roots must be cut up into pieces about $1\frac{1}{2}$ in. long, and laid in rows flat in pots or pans well drained and filled with rather sandy soil, with $\frac{1}{2}$ in. of covering of the same over the top; give a good watering, and place them on a shelf near the light. After they begin to grow, which some sorts will do quickly, they should be carefully watered during winter, and should be potted off in February and afterwards kept in the greenhouse a short time till they have become established. H. H.

THE FRUIT CROPS.

METROPOLITAN AND SOUTH-EASTERN DIVISION.

Southgate.—Peaches and Nectarines on open walls in this neighbourhood are generally bearing good crops where they received ordinary protection whilst they were in bloom, although just in the midst of their flowering we had two or three nights with from 12° to 14° of frost. Apricots also in most places are a full crop. Apples set freely, but a great many have fallen off, and they will not be near so plentiful as at one time seemed likely; the most constant-bearing kinds, such as Lord Suffield, Keswick Codlin, Hawthornden, New and Old, King of the Pippins, Blenheim Pippin, Wellington, Manks Codlin, and Cox's Orange Pippin, are carrying the best crops. Pears are in most places below the average. Plums abundant generally. Strawberries plentiful. Cherries fair, but not heavy. Raspberries and Currants a full crop. Gooseberries mostly very thin. Nuts, both Cobs and Filberts, next to none. Walnuts the same.—T. BAINES.

Syon House, Brentford.—Apricots in the gardens here are a good crop. They were covered with frigi-domo in spring, but in some places there is an equally good crop where they had no covering whatever. Peaches and Nectarines a good crop where protected with double net in the spring. Cherries at one time were most promising, but many dropped at stoning time, and since then all the tender-fleshed kinds, such as Governor Wood, have suffered severely from the scorching heat of the sun; Bigarreaus have withstood the sun heat best. Apples and Pears are very thin; the former were very promising at one time, but a great many dropped just as they began to swell. Plums are also rather thin, although in some places about here there are good crops. Red, White, and Black Currants, and also Raspberries, are abundant; but Gooseberries are very scarce, except where they are grown in sheltered situations. Strawberries are very abundant, especially Keen's Seedling, Garibaldi, or Vicomtesse Héricart de Thury, President, Sir J. Faxton, Sir Harry, Oxonian, and Elton Pine.—J. WOODBRIDGE.

Gunnersbury Park, Acton.—Apples in our own orchard, sheltered from the north and north-east by a belt of trees, are a good crop, but on trees fully exposed the crop is light. The most trustworthy kinds in the market gardens in this district are King of the Pippins, Stone Pippin, Lord Suffield, and Duchess of Oldenburg. The trees have suffered much from blight. Pears are a light crop. The most fruitful are Hessele, Comte de Lamy, and Hacon's Incomparable. Our soil, a good loam resting on light clay, is favourable to the growth of Apples and Pears. Stone fruits in general are a failure. Of Apricots we grow none. Peaches and Nectarines, protected with frigi-domo, are a light crop. Much of the fruit fall through imperfect setting, caused by the long continuance of wet, unless weather in spring. Plums, with the exception of Victoria, are a complete failure. Cherries are a moderate crop; Elton on an east wall and Morello on standards are good. Bush fruit is a fair crop; the lightest are Gooseberries and Raspberries. Amongst Strawberries I have seen heavy crops of fine fruit in this neighbourhood, but, like all other kinds of fruit ripened up to the present time, they are deficient in flavour.—J. ROBERTS.

High Grove, Pinner.—Fruit crops in this district have suffered greatly from the heavy rainfall and want of sun. The soil of this neighbourhood consists of deep loam on the London clay, the high lands being gravel and sand. Apples and Plums grow very luxuriantly with us. Apricots are scarce. Apples in many places are almost a failure, though we had the finest show of fruit this season which I have seen for years. Pears are plentiful, most varieties fruiting this season, and free in most places from blight. Peaches and Nectarines are a fair crop in most places. Plums partial; good on walls; the Victoria, Prince of Wales, and Orleans are the best general croppers.

Gooseberries are very scarce. Currants are a fair crop. Strawberries good, but enfeebled greatly from too much rain. Orchards hereabouts are generally planted with Plums and Apples, small fruits not being largely grown. Raspberries are, however, plentiful, and Fastoff is one of the best for bearing heavy crops. The best Apples in this neighbourhood are Golden Pippin, Court Pendu Plat, Cox's Orange Pippin, Lord Suffield, Yorkshire Greening, and Freuch Crab; the sorts generally grown in orchards are Wellington and Blenheim. Of Pears we grow the Crassane, Marie Louise (on standards and walls), Easter Beurré, Glou Morceau, Williams' Bon Chrétien, and Jargonelle; but the two latter do not fruit freely with us. I may add that Potatoes as yet show no sign of disease.—G. BRUSH.

Weirton House, Maidstone.—In this neighbourhood, as in many others, the fruit crop is very unsatisfactory, and must come very short of what was expected. The trees, which were, while in blossom, objects of great beauty, are now much disfigured by maggot and other insects. Many young trees, which were healthy last year, are looking half dead; some plantations are better, but few are in a healthy condition. Cherries of all kinds are very thin. Pears the same. Plums are better, but still a light crop; some of the principal kinds in bearing are Early Orleans, Prince of Wales, Royal Dauphine, Damsons, and La Delicieuse; the last, a fine old late market Plum for kitchen purposes, deserves to be more grown than it is. Apples are unhealthy, and the crop will be a short one. Currants are thin, except Reds, which are a fair crop. Gooseberries are fewer than they have been for many years past. In the garden here we have plenty of Peaches and Nectarines where coping boards and netting are used, but on other walls only protected by evergreens they are very thin. Gooseberries are not a quarter of a crop, the best bearers being the large Lancashire kinds. Strawberries of all kinds are abundant. We are well sheltered by timber trees, and the garden slope to the south, the soil being a sharp loam on the Kentish ragstone. On the night of July 3 the thermometer fell to 37°, the highest point the next day being 68°, with a scorching sun.—W. DIVERS.

The Deepdene, Dorking.—Fruit crops here this year are very varied; as regards quantity we have very heavy crops, others very light ones. Apricots, Plums, and Cherries are most abundant; also Currants and Raspberries; but Apples and Pears are thin. There is not one well-cropped Apple tree in the garden, though the bloom was very abundant, but we had a fine crop last year, and we can scarcely expect much this. Marie Louise Pear and Beurré d'Amanlis are the only two varieties that are carrying a crop. We had very little bloom, owing to the very cold, wet season last year. Peaches and Nectarines are very thin, but the trees look healthy. Gooseberries are a medium crop; a large number dropped off from the effects of sharp frosts which we had in the end of March. Strawberries are a fair crop, but have been hitherto very deficient in flavour. Figs in some places round here are a most abundant crop. Nuts, both Cobs and Walnuts, are very scarce as far as I have seen. Hardy Grapes on walls are showing well for a crop, but mildew has been very troublesome during the past two seasons. Our Apricots were in full bloom during the very severe frost which occurred in the end of March, but they were well protected with a good thick canvas, and the result is a very plentiful crop. I have never found herring nets to be of the slightest use when the frost was more than 6° or 7°.—JOHN BURNETT.

Tunstall, Sittingbourne.—This year commenced with great promise as to fruit, but the result has proved disappointing with almost every kind. Plums stand first as to crop, but I understand this only applies to certain districts; the Victoria and Prince of Wales are both bearing heavily hereabouts. Cherries have suffered much from late spring frosts and are not above a quarter of a crop; the Bigsreen and English have done the best. There are a few common sorts of Pears, but all the best sorts are again very short. Apples are a very partial crop, bearing fairly at some places, but at others very short. All kinds of bush fruits are short and scarce, except Red Currants, which are good. Wall fruit is again very thin; indeed, almost a failure.—G. WEBB.

Sulhamstead, Reading.—On looking over my orchards and gardens I find I am not equal in quantity of fruit to what I was last year, though in regard to Apples I have got the lion's share, and the "tittle of the whole" in this district will not amount to more than one-fourth of a crop, and Pears less. I have read various theories for this deficiency after so favourable an exemption from spring frosts. I think that the severe north-east winds, late frosts, and blight of last spring (viz., of 1877), which so thoroughly emaciated the first foliage, so weakened the buds that sufficient stamina was not attained to perfect the blossom-buds for this year. My trees blossomed profusely, but they looked pale and delicate, and the stalks were more slender than I ever remember to have seen them before. Of the Plum tribe I have plenty, though too frequently as I go about I see

trees fruitless. Two-thirds of a crop will be about the result. Upon walls that I have seen Plums are a full crop, particularly where protection was given. Pears, Apricots, Peaches, and Nectarines may be considered as a good sprinkling, and that is all. Figs are scarce, Quinces good, and Malberries abundant. I fear much complaining will result as regards the paucity of Filberts, and even common Nuts. My Walnut trees will produce me about half a crop, and ten trees of my neighbour's, about a mile off, will produce two Walnuts, according to my scrutiny. Walnuts and Filberts are certainly scarce. Of the smaller fruits, Gooseberries are partial, Currants plentiful, Raspberries enormous, and Strawberries beautiful, though not rich as regards flavour. I hear complainings about the Potato disease, chiefly in gardens, amongst the American sorts, which, from their exuberant foliage, are invariably planted too thickly, and in a dripping time are the first to suffer in consequence. I have the usual curl amongst the American varieties, but in my rather extensive plantations of English sorts I am glad to say I have no complaint of either curl or Peronospora at present.—ROBERT FENN.

Heckfield, Hants.—Apples set their fruit apparently vigorously and then disappeared, but through what cause I am quite in the dark; there may, perhaps, be a quarter of a crop; on some few trees half a crop, the best being Hawthornden, Keswick Codlin, Blenheim Pippin, Lord Suffield, and Northern Greening. Pears may average half a crop; on walls they are very good, the most prolific being Seckle, Marie Louise, Duchesse de Angoulême, Beurré Hardy, Ne Plus Meuris, Althorp Crassane, and Glou Morceau. Peaches and Nectarines are a heavy crop, and the trees are growing vigorously. They were all protected with scrim canvas. On several nights when they were in bloom we registered 6° and 8° degrees of frost, and the wind was continuously blowing from the north-east, thus creating a dry atmosphere and saving the blossoms from frost. Apricots are also a very full crop, and promise to be large; they were protected similarly to the Peaches; indeed, such is the severity of our spring seasons that it is now quite useless to expect fruit without artificial protection. Gooseberries suffered terribly through frost when in flower, and are very thin—scarcely a third of a crop. Morello Cherries blossomed after the sharpest frosts were over, and are a full average crop; the earlier kinds are scarce. Plums are partial; some kinds are bearing prodigiously, notably Diamond, Victoria, Jefferson, Orleans, and Belgian Purple; other sorts are thin. None were protected. Currants and Raspberries are a fair average crop, and Strawberries very heavy; I never before saw them so good; the favourite sorts are Vicomtesse Héricart de Thury and President. Potatoes are very fine, and as yet there are no signs of disease. The soil of this district is sandy loam, the substratum being gravel and sand.—W. WILDSMITH.

Eaglehurst, Fawley, South Hants.—Apples in this district are a very light crop. Although there was a good show of bloom, the young fruits dropped after setting. Blenheim Orange, Beauty of Kent, Ribston Pippin, King of the Pippins, Newtown Pippin, Profit, Hawthornden, and Alfriston are the best bearers. Of Apricots we have scarcely any, except a few on the Moorpark and Hemskirk. Cherries are a thin crop with the exception of Morellos, which are very good. Of Pears we have scarcely any. Beurré d'Amanlis, Beurré Diel, Jargonelles, William's Bon Chrétien, Glou Morceau, and Louise Bonne are bearing a few scattered fruits. Of Peaches we have none, but Nectarines are a fair crop, the Elruge and Violet Hâtive being the best. Plums are abundant, but the trees very much blighted. Jefferson, Victoria, White Magnum Bonum, Early Orleans, Reine Claude de Bayar are the best. Figs, both on walls and standards, are a heavy crop. Raspberries a full crop and fine in quality. Bush fruits abundant and clear of blight. Strawberries are a very heavy crop, but deficient in flavour, owing, doubtless, to the wet, dull, and sunless weather which we have had. Our soil is of a light, black character, from 2 ft. to 4 ft. deep, resting on a gravelly sub-soil, and requiring in the summer time a good shower of rain every week to keep crops growing. I may mention that the Potato crop is good, but the disease is very prevalent in this quarter.—W. WATSON.

Welford Park, Newbury.—Fruit crops in this neighbourhood are not going to turn out so well as was expected earlier in the season. Apples will not be so plentiful as they were last year; there was abundance of bloom, and most of the sorts set pretty well, but more than three-fourths of the fruit have dropped off; many of the trees, both young and old, look as if they had been scorched, and some of the branches are quite dead. A few sorts are bearing an average crop and the trees are healthy, viz., Keswick Codlin, Eeklinville, Northern Greening, Lewis's Incomparable, Sturmer Pippin, and Cornish Aromatic. Of Pears we have but one-third of a crop; the best are Josephine de Malines, Marie Louise, and Beurré Rancé. Cherries are an average crop; May Dukes are most abundant, but many of the Morellos have dropped, and the result will be a light

crop. Plums an average on walls, but very few on standards. Apricots are quite a failure. Figs a light crop, but likely to be good in quality. Peaches and Nectarines will be about half a crop; none of the trees have had any protection this year. Strawberries are abundant and good. Currants, Gooseberries, and Raspberries are fair average crops.—CHARLES ROSS.

Royal Gardens, Windsor.—The fruit crop here and in this neighbourhood is a very good one, more especially Apricots, Peaches, Nectarines, and Plums. These are plentiful, and promise to be excellent in quality. The trees were covered with canvas every cold night from the end of January to the beginning of June. Cherries are above the average both on walls and standards; Morellos especially are most abundant. Strawberries are a good average crop; some varieties, such as Late Pine, Aromatic, Vicomtesse Héricart de Thury, Mr. Radclyffe, La Grosse Sacrée, and Fairy Queen, are bearing heavily; but other varieties, such as Keen's Seedling, Sir Joseph Paxton, Unser Fritz, and Cockcomb, are thin, and many of the plants "blind." Pears are below the average; the trees generally were thin of bloom; the fruit, however, promises to be excellent in quality, and at present free from spots. Walnuts are about an average crop; but Filberts are thin. Plums on standard trees are everywhere most plentiful; also all kinds of bush fruits. Taking the Apple crop as a whole, I may say that it is about an average one here. Blenheims are thin; also the Wellingtons; but Rosemary Russet, Scarlet Russet, Downton Nonpareil, Cox's Pomona, King of the Pippin, Cockle Pippin, Frogmore Prolific, and others are bearing heavy crops. Near here Apples in places are very thin, a circumstance probably owing to the cold, damp, and shady weather which we experienced towards the end of May and beginning of June. From May 21 to May 26 the day temperature ranged from 34° to 40° with a cold north and east wind. All Apples set well, and the dropping of the fruit I attribute to the above-named cause.—T. JONES.

SOUTH MIDLAND DIVISION.

Wycombe Abbey.—Apricots are a full average crop, and appear as if they would be early in ripening and good. Apples an average crop. Cherries under the average, and white kinds, which have not been protected from the effects of rain, are cracking. Morellos much above the average, and promise to be fine. Currants of all kinds a full average crop. Gooseberries very much below the average, all the earliest being cut off by frost. Nuts below the average. Plums a full average crop and fine. Pears under the average. Peaches and Nectarines average. Raspberries full average. Strawberries over the average and very fine. Walnuts under the average. Cherries abound in this neighbourhood, but some varieties of these are but partial crops, and such is the case with Apples. In some places Pears are remarkably scarce. Amongst Plums, Victorias are bearing the greatest crop, and Gooseberries are plentiful on the higher land.—G. T. MILES.

Dropmore, Maidenhead.—The soil about here is mostly gravelly, and, in most cases, pretty much sheltered by hedgerow timber, such as Elm and Beech, where orchards are formed. There was a fine show of blossom of almost every kind of fruit, but the heavy rainfall and the continuance of an easterly cutting wind caused it to fall off after one might have thought it to be quite safe. Wall fruits fell very much. Apricots set well with me under a covering of Russian mats, and a good crop is the result; but a great many fell off when about the size of marbles, and I hear that this shedding of fruit has occurred in other localities.—PHILIP FROST.

Burnham, Bucks.—Apples here are a fair crop. Pears very thin. Plums and Cherries middling. Strawberries and Raspberries a good crop. Currants a fair crop. Gooseberries very thin. Walnuts middling. Peaches and Nectarines pretty good. Apricots a fair crop. Nuts and Damsons, thin.—J. CLIVARD.

Great Tew, Enstone.—Owing to the cold rains which we have had Apples are very scarce, Pears are about half a crop, Plums and Cherries about two-thirds. Of Apricots, Peaches, and Nectarines we have very few. Gooseberries are about two-thirds of a crop. Raspberries, and Black, Red, and White Currants are full crops, and the same may be said of Strawberries. The orchard house is our only reliable place for crops of Apricots, Peaches, and Nectarines, and here, as usual, they are most satisfactory. This is now the eleventh summer of its existence, and every year has been the same—no disappointment; and, as regards the trees in pots, they are as fruitful and healthy as at first.—A. MACFARLANE.

Blenheim, Woodstock.—We had a profusion of bloom on all our fruit trees; but, nevertheless, with a few exceptions, we have not more than the title of a crop. There are scarcely any Apricots, the only exception being where the trees were thoroughly well pro-

tected. Apples are but little better; the most certain bearer is Stirling Castle, young pyramidal trees of which carry good crops, whilst standards of Blenheim Pippin and Wellington (the best of all cooking Apples) have scarcely a fruit on them this year. Pears also are very partial, Marie Louise, Louise Bonne, and Beurré Rance being the best bearers. I attribute our failure to the buds being frozen through in their embryo state, the unusually mild weather previous to April 1 having brought them to such a forward and tender condition as to be quite unable to repeatedly withstand 15° and 16° of frost. To this must be added the late immature growth of last season. Cherries and Plums of all kinds are good, especially Damsons, which threaten to break down the trees with the weight of the fruit. Strawberries are also a very heavy crop and good in quality, Sir Joseph Paxton being one of the best for main outdoor purposes, and gradually ousting President. British Queen and Sir C. Napier do not do so well on our limestone. Bush fruits, with the exception of Raspberries, are up to the average. Walnuts are a fair crop. Filberts and Cobs thin. The Potato disease is making its appearance.—WILLIAM CRUMP.

Castle Ashby.—The fruit crops in this neighbourhood are very unsatisfactory generally. Here we have a few dozen Apricots, and a small crop of Peaches, Nectarines, and Pears. Upon wall trees a medium crop of Plums and Morellos; on standards a small crop of Plums. Very few Apples or Pears; on pyramidal-trained Pear trees very few; on horizontally-trained Apple trees the same. Strawberries are plentiful, but the flavour is inferior; too much rain for them in the early part of the season. Raspberries are a medium crop, but late in ripening, a remark which applies to all kinds of outdoor fruit, judging by the appearance of what has to ripen and what we have now harvested. Red Currants are a moderate crop, bunches small, having been injured by rain and wind. Of Gooseberries we have very few; I never remember less. Black Currants plentiful and good. Very few Walnuts; a few Cob and Filberts. Mulberries promise to be good.—G. BEECH.

Ramsey Abbey, Hunts.—In this immediate neighbourhood there will, I think, taking all things together, be an average crop of fruit. Apples are good, so are Plums, Cherries, and Peaches. Pears and Apricots, with a few exceptions, are rather thin. Strawberries and Raspberries are fine. Gooseberries are thinner than usual, but the size of the fruit is much above the average. Currants (Black, Red, and White) are good crops. Figs and Grapes are promising; the latter quite free from mildew. Nuts of all kinds are very thin indeed. Our soil is a rather heavy loam on Oxford clay, interspersed with occasional beds of gravel. It is adhesive in winter, but dries rapidly in summer, and often cracks into deep fissures. We are well sheltered from the east, but much exposed to north and west winds, the latter being often violent. The following are the names of some of the best kinds of fruits in this district: Apples—Wellington, Lord Suffield, all the Codlins, King of the Pippins, Blenheim Orange, Juneating (Red and White), Royal Pearmain, Red Quarrenden, Scarlet Pearmain, Old Royal Russet, Bess Pool, Ribston Pippin, Waltham Abbey Seedling, Fearn's Pippin, Hawthornden, Sturmer Pippin, Yellow Ingestre, Scarlet Nonpareil. Pears—Autumn Bergamot, Glou Morceau, Beurré Boe, B. de Capiamont, B. Diel, B. Rance, B. Superfin, B. d'Arnhemberg, Duchesse d'Angoulême, Jar-gonelle, Bon Chrétien (Williams'), Louise Bonne of Jersey, Marie Louise, Winter Nells, Swan's Egg, Seckle, Heasel, Passe Colmar, Ne Plus Meuris, Vicar of Winkfield, and Easter Beurré. Plums—Victoria, Diamond, Early Prolific, Goliath, Pond's Seedling, Prince of Wales, Damson Green Gage, Transparent Gage, Kirke's, Coe's Golden Drop, Jefferson, Reine Claude de Bavay, and Washington. Peaches—Noblesse, Grosse Mignonne, Royal George, Prince of Wales, Barrington, and Walbrton Admirable. Nectarines—Downton, Elruge, Pine-apple, and Pitmaston Orange. Apricots—Moorpark and Hens-kirk. Strawberries—Keen's Seedling, Vicomtesse Héricart de Thury, British Queen, Dr. Hogg, President, Sir C. Napier, Elton Pine, and Red Alpine.—E. HOBDAV.

WEST MIDLAND DISTRICT.

Madresfield Court, Great Malvern.—Fruit generally, though much more abundant than last year, is extremely partial. In some orchards crops are heavy, while in others, more especially in the case of Apples, they are suffering severely from blight, and much of the fruit, where set, has fallen off. In fact, more fruit falls this season than has been the case for some years. This is, I think, principally owing to the heavy rains and sunless days which occurred during May and the first half of June. Here espalier and pyramidal Apples are producing fine crops. Amongst the best bearers are Lord Suffield, Golden Spire, Hawthornden, Stirling Castle, Golden Noble, Warner's King, Cox's Pomona, and Lord Grosvenor. The latter will be a great

favourite when better known, being an enormous bearer and similar in growth and appearance to Lord Suffield. Pears are generally a light crop, many of the trees producing but little bloom. Plums are generally good, the hardier kinds on standards and pyramids being heavily laden; choicer kinds on walls are only a moderate crop. Apricots in some places, and especially against dwelling houses, are a good crop, but they suffered so severely on cold walls last season that many of the trees, where not killed, were seriously injured, and are this season barren. The same remarks apply to Peaches and Nectarines; here we had a full crop of fine fruit last year, and the crop is equally satisfactory this season. Of Peaches, our best varieties are Crawford's Early, Violette Hâtive, Barrington, Bellegarde, Late Admirable, and Walburton Admirable. Of Nectarines, Elruga, Oldenburg, Downton, Murray, Pitmaston Orange, and Victoria. These afford a good succession in the order in which they are named. Where climate and soil are suitable, Walburton Admirable Peach and Victoria Nectarine are especially valuable, prolonging the season of gathering well into October. Of bush fruits, Currants and Raspberries are a fair crop. Gooseberries are a heavy crop here, but not generally. Strawberries bloomed well, but we have had too much dull wet weather for some kinds; the best this season are Sir Charles Napier, La Constante, Sir Joseph Paxton, British Queen, and Oxonian; the latter we grow extensively, finding it most valuable for late use, as, by trussing up and netting, it can be had until the middle of August. Potatoes are at present looking remarkably well; some few instances of disease have occurred, but the present fine hot weather will, I trust, keep it in check.—WILLIAM COX.

Witley Court, near Stourport.—Fruit crops in this district are again most unsatisfactory, and in some respects inferior to those of last season. Plums and Apples in some instances carry heavy crops, but this is by no means general. The great profusion of blossom gave every prospect of an abundant fruit crop, which was somewhat remarkable, as the autumn was sunless, wet, and cold, and by no means congenial to the maturing of the wood. The failure this year is doubtless attributable to the severe frosts which we experienced in April and May. Apricots are a failure generally. Plums partial; under average; we have a famous crop upon walls where protected. Cherries very partial—half a crop—and of inferior quality; trees much blighted; Morellos and Kentish heavily cropped. Peaches and Nectarines half a crop; trees healthy, protected by two folds of 1-in. mesh netting. Apples generally scarce; in low-lying situations they appear to have suffered most; trees much blighted. Amongst varieties bearing generally full crops may be named King of the Pippins, Lord Suffield, Keswick Codlin, that excellent kitchen Apple Ecklinville Seedling, Dutch Mignonne, Normanton Wonder, Yorkshire Greening, and Tower of Glamis; Striped Beefing, one of the most certain and best of our cooking Apples, is also bearing a good crop, as are also Hawthornden (new), Northern Greening, Golden Winter Pearmain, and Sturmer Pippin. Cider fruits are also partial and scarce. Of Pears we have very few upon walls or standards; small fruits are of inferior quality, and the trees are much blighted. Gooseberries are a very light crop. Black Currants an average crop—fruit small. Currants are light, and Raspberries are under the average. Filberts are very thin, and Walnuts are a failure. Mulberries abundant. Strawberries are under an average, and inferior both in size and quality; on President there is the best crop; Vicomtesse Héricart de Thury and Dr. Hogg are bearing moderate crops. Potatoes in several instances show signs of disease; otherwise the crops are promising.—G. WESTLAND.

Westwood Park, Droitwich.—As far as the gardens here are concerned the account I have to give is satisfactory. Gooseberries are a fair crop. Currants very fine. Strawberries excellent, President and Carolina superba being very fine, Garibaldi and La Grosse Sucrée not quite so good; Kest's Seedlings are a good crop, but after the first gathering the fruit is small. Plums are a heavy crop, though some say that during the past week one-half has withered and fallen off. We have well-laden trees of Early Favourite, Victoria, Kirke's, Green Gage, Peach, Jefferson, and Golden Drop. Morello Cherries are a full crop. Of Pears most of the trees here are bearing a good crop; a large tree of Duchesse d'Angoulême bloomed and set well, but every one fell off in the first week after setting. On the Jargonelle there is a good crop, on Bon Chrétien an extra good one. We have fine fruit on young trees of Pitmaston Duchesse Souvenir du Congrès, Beurré Superfin, Knight's Monarch, and Glou Moreceau; on walls Beurré de Capiaumont, Glou Moreceau, Beurré Diel, Swan's Egg, Brown Beurré, Beurré Rance, and Crassane are thick; on large bushes Gansel's Bergamot, Albertine, and Goubalt are a good crop; on espaliers Marie Louise, St. Germain, Louise Bonne of Jersey, and Vicar of Winkfield are carrying good crops. Apricots are a fair crop under glass coverings, those unprotected being destitute of fruit. Most of the Peach trees that were worth it have had a cheap glass roof

erected over them 11 ft. wide, with trees planted in the front, and a flow and return pipe added. In this way we have secured a good crop, and the trees will soon pay for it by bearing crops annually. Another lot of trees has been grabbed up and twenty new ones planted in a new border; these will be covered with an inexpensive wide glass coping. As to Apples, Cellini never has been without a crop anywhere that I have seen it, and here we have grand crops of it. It is a variety which every one should grow. A small tree of Worcester Pearmain is bearing a good crop; Red Astrachan is loaded with fruit, also Prince's Pippin, Emperor Alexander, Lord Suffield, Stirling Castle, Keswick Codlin, and Blenheim Orange. In the orchards round here Plums and Damsons are good crops, but Pears are partial. A neighbour with large orchards has only a few Apple trees bearing anything like a crop, and they are Tom Patt. There is a local kind grown here called Chulley Kernel, and by some Chulley Pippin, a great favourite. It is a medium-sized, handsome, high-coloured variety, and bears a full crop almost everywhere. Cider fruit is but partial; in some places next to none.—JOHN GOUGH.

Ashton Court, Bristol.—Apples and Pears here are under the average, both in orchards and gardens. The following kinds are bearing the best crops: Apples—Lord Burghley, Lord Suffield, Cellini, Dutch Mignonne, Hawthornden, Fearn's Pippin, Bedfordshire Foundling, Golden Winter Pearmain. Pears—Beurré Diel, Althorp Crassane, Hayshe's Victoria, Beurré Sterckmans, Thompson's, Williams' Duchesse de Angoulême. Of Peaches and Nectarines, there are good crops, whilst Apricots, Plums, and Cherries are much under the average. Strawberries are plentiful; so are also bush fruits, with the exception of Gooseberries. Nuts of all kinds are very thin. I attribute the generally light crops of fruit more to the effect of the cold drenching rains which we experienced throughout the greater part of the spring than to the influence of frost.—JOHN AUSTEN.

Alton Towers, Cheshire, Stoke-on-Trent.—Fruit crops in general here are very good. Strawberries, Gooseberries, and Currants are plentiful, but small. Damsons, Plums, and Apples are all excellent. Pears are not very good, and Apricots are a poor crop. Peaches are an average crop. The Potato crop is excellent, and I have seen no disease yet. We have suffered very much from rain on heavy soils thus far north.—T. RABONE.

Drayton Manor, Tamworth.—Speaking generally, I am sorry to report that the fruit crops in this district are very light indeed. Pears are under half a crop, but the following are bearing fair crops on walls, viz.—Barronne de Mello, Beurré d'Amanlis, Beurré Diel, Brown Beurré, and Glou Moreceau; on espaliers and pyramids—Beurré Clairgeau, Aston Town, Seckle, and Williams' Bon Chrétien. Apples are about half a crop, excepting the following, which are bearing heavily, viz.—Lord Suffield, Keswick Codlin, Manks Codlin, Hawthornden (new and old), Cat's-head, and Cellini; the following are bearing medium crops, viz.—King of the Pippins, Ribston Pippin, Cox's Orange Pippin, Red Astrachan, Blenheim Orange, and Court Penda Plat. Apricots are under half a crop; the Royal is the surest cropper with us—these were well protected in spring. Damsons are quite a failure. Danyer's Victoria Plums are bearing heavy crops; as standards, and the following are fair on walls, viz., Cox's Golden Drop, Kirk's, and Reins Claude de Bayay. Plums generally are light. Raspberries are very good. Of Strawberries we never had better crops, especially from forced plants planted out last July; our best varieties are President, Sir Charles Napier, Keen's Seedling, Vicomtesse Héricart de Thury, and Dr. Hogg; for cropping and general excellence I consider President the best Strawberry grown. Gooseberries are a light crop; so also are Black Currants. Red and White Currants are good crops. Apricots are the only trees protected with us. Our soil here is light, resting on gravel, and, being situated rather low, and surrounded by water, we are very subject to spring frosts; but, in my opinion, frosts have not had much to do with the fruit failure this year; it is rather to be attributed mainly to last year's wood being imperfectly ripened, in consequence of the wretchedly wet and sunless season which we had. There were plenty of blossoms on all trees this spring (excepting Pears), with a promise of abundant crops, but no sooner had the fruit formed than most of it dropped; especially was this the case with Apples and Pears. I observe that many of the bush and pyramid trees are bearing heavier crops on the south and south-west sides this year than usual, which seems to me to point to the same fact, namely, better-ripened wood on the south side.—OWEN THOMAS.

Tortworth Court, Gloucester.—The Apple and Pear crops in this district is much below the average. Although the bloom was very abundant and at one time very promising, it set badly and dropped off. Late fruits are by far the best. Peach and Nectarine crops, protected only with old fishing nets, are abundant. Of Apricots we have very few. Plums on walls and standards are abundant. Of Cherries we have a full crop. Gooseberries and Currants are also

good. Strawberries excellent. Nut trees here produced but few catkins, and the crop will be a light one.—THOS. SHINGLES.

Eastnor Castle, Ledbury.—After last year's failure, a dry, mild winter seemed to favour all kinds of fruit trees, which, Pears excepted, were laden with blossom-buds, but the severe frosts which we had in May greatly injured stone fruits, and the incessant down-pour of rain damaged the Apple blossoms. The consequence is we have in this district what may be termed a partial fruit year. Apricots are a fair half crop; the trees very free from grub. Apples in favoured situations are plentiful and promising, while in low, cold soils they are in many cases a complete failure. Hawthorn, Keswick Codlin, and a kind known here as Izard's Kernel are fruiting well. The finer kinds, such as Ribston, Cox's Blenheim, and other Pippins, are very shy. Pears on walls, where there was blossom, seem to have set well. Marie Louise, Pitmaston Duchess, Knight's Monarch, Beurré d'Amanlis, and Duchesse d'Angoulême are carrying good crops. Cherries set well, but most of them fell off the trees. Bigarreau, Napoleon, Governor Wood, and May Duke are fairly good. Morellos on north walls are unsatisfactory. Plums are more plentiful than was at one time anticipated. Gisborne's Early Prolific, White Magnum Bonum, and Victoria are plentiful on bushes and standards. Coe's Golden Drop and Green Gage, a complete failure last year, are this season bearing good crops on walls. Damsons with us are plentiful. Peaches and Nectarines, where protected from the May frosts, are a full crop, in many cases requiring much thinning; trees clean, healthy, and promising. Bellegarde, Grosse Mignonne, Prince of Wales, Barrington, two of the very best late Peaches, are bearing good crops. Nectarines of all kinds have stood well. Lord Napier should be grown extensively on west as well as south walls. Albert Victor, Stanwick, and Elruge are very fine, but, like Victoria, they require a thoroughly good position and warm soil. Currants, Gooseberries, and Raspberries are abundant, clean, and fine. Strawberries on our cool soil are an immense crop, and the fruit is large and bright, the intense heat of the past week having just suited them. Walnuts promise to be abundant. Filberts light.—W. COLEMAN.

NORTH MIDLAND DISTRICT.

Radcliffe-on-Trent.—We are situated in the valley of the Trent, six miles east of Nottingham. We rise from the edge of the river up to the peculiar rounded uplands so characteristic of Nottinghamshire, our soil—sandy, with gravelly bottom in the valley generally, with variations of it up to the stiff clay of the higher lands—having a skerry bottom, which, I suppose, is a sort of bastard lia. The cliffs which overhang the Trent on the north side break the force of the winds from that quarter, as do also the highlands on the eastern side, which finish at the head of Belvoir. The centre and lowest part of the valley, lying, as it does, in the hollow between these two elevations, is, however, swept by the north-east winds, and so in their course they do us deadly damage when spring frosts occur. Apples are a very good crop, and the trees are in moderately good health. The cold wet of May rather caused the early foliage to become stunted and blackened, but the new growths, since the hot weather set in, are all that could be desired. Keswick Codlin, Blenheim Orange, Bess Pool, Northern Greening, Maltster, Caldwell, Barton's Free Bearer, and in some cases Ribston Pippin, are much grown. Apricots are a poor crop generally; where the trees were sheltered by glass copings they are, however, abundant. The cottagers here grow many trees on their house walls; on these it is only the late blooms that are set; the frosts of the last week in March entirely destroyed the first and best blooms. Pears are a fair crop. Early Catherine and Welbeck Bergamot are two largely-grown market Pears. Jargonelle, Williams' Bon Chrétien, Beurré d'Amanlis, Louise Bonne of Jersey, and Winter Nelis are very generally grown in gardens. Plums, taken as a whole, are a heavy crop. Mrs. Gisborne, Early Prolific, and Victoria are the heaviest croppers and the sorts chiefly grown. Damsons are a fair and even crop. Strawberries a good crop. Vicomtesse Héricart de Thury, Keen's Seedling, President (A 1), British Queen, Sir Charles Napier, and Frogmore Late Pine are sorts much grown. Amongst Raspberries, Fastolf and Fillbasket are the most grown; they are bearing good crops. Currants—Black, Red, and White—are also good crops, Black especially so. Black Naples, Red and White Grape, and Raby Castle are the sorts mostly grown. Gooseberries are a middling crop. Brown Bob, Lancashire Lad, Warrington London, Antagonist, and Red Champagne are all grown, besides others, the first-named varieties being the most common. Altogether, our fruit crops are not so bad as they are in some districts.—N. H. POWNALL.

Chilwell.—I can give but a poor account of the fruit crops in this vicinity. We had an abundant show of bloom on almost everything, but little fruit will be the result. Our main crop of Apples is

very poor; many of the trees are bearing no fruit at all, and the best are but thin. Perhaps Keswick Codlin, Northern Greening, and Court Pendu Plat are amongst the best. Pears are very scarce; there are a few Early Crawford, Grey Beurré, and Beurré de Capiau-mont, but many sorts are quite bare; on the walls I see Doyenné d'Été and Marie Louise d'Uccle bearing well. Victoria Plums and Damsons are about half a crop. Apricots are very scarce. Cherries are plentiful, as are also Strawberries. Gooseberries and Currants are thin crops, and the Currant trees much blighted.—A. H. PEARSON.

Thoresby Park, Ollerton.—When trees were in bloom heavy crops were anticipated, but many of the flowers never set, and many that did set dropped off when the fruit should have begun to swell. This applies to Apricots, Apples, Pears, Plums, and Gooseberries, of which we shall have about half a crop; while Cherries, Currants, Raspberries, and Strawberries are abundant, and promise to be fine, especially Strawberries. As regards Peaches, Hale's Early is one of the best grown, being both early and large in size, with a fine colour when exposed to the sun. We have gathered a fruit of it off a young tree last week, grown in a late house, while fruits of Royal George, Grosse Mignonne, and others are not half swelled yet.—A. HENDERSON.

Welbeck, North Notts.—Fruit crops promised to be abundant this year early in spring. In May, however, the weather turned out excessively rainy, with a low temperature, and some of the varieties were attacked with aphides and blights, and the young fruit, especially Apples and Pears, dropped off. In general these fruits will therefore be only partial crops, but nothing like a scarcity as there was last year. "A. D." (Vol. XIII., p. 630) gives an excellent list of Apples, growing in the bush form with him, that have borne freely this year, namely, Hawthorn, Lord Suffield, Mother Apple, Cellini, King of the Pippins, Sturmer Pippin, and to these varieties I have to add Irish Peach, Margil, Scarlet Nonpariel, Cox's Pomona, and Rosemary Russet, all grown here on the Paradise stock. The Sturmer Pippin I set down as one of the most valuable Apples grown, for it is a sure bearer and keeps well all the year round in a good fruit room. If these better and free-bearing varieties of Apples were planted in quantities along with late keepers, such as Blenheim Orange, Orange Pippin, Reinette du Canada, Damelow's Seedling, Dutch Mignonne, and French Crab, in bad seasons there never would be a lack of Apples. On the strong soil of the kitchen garden here I find that Apples grown as bush fruit do best on the surface-rooting stocks, such as the Paradise and Doucin, and the Pears on the Quince stock. By adding litter or rich mould to the surface in dry seasons the trees are always kept fruitful. Pears on walls are only partially cropping this year, the best bearers being Beurre Bosc, Jargonelle (double-grafted), Beurré Giffard, Marie Louise, Louise Bonne of Jersey, Winter Nelis, and Hacon's Incomparable. On iron trellis the following kinds are bearing well, viz., Seckle, Bezi d'Heri, and Catillac (stewing Pears), Beurré Clairgean, and B. Diel, Noveau Poiteau, Bon Chrétien (Williams'), Beurré Bosc, Louis Bonne, and Marie Louise. The Apples on the same trellis are Small's Admirable, Court Pendu Plat, Alfriston, Pomme d'Api, Fearn's Pippin, and Mannington's Pearmain. Of Plums, Victoria, Cox's Emperor, Prince Englebert, Diamond, Imperial de Milan, and Kirk's are bearing best. Cherries are only thinly cropped, except Morellos on walls and the Kentish on standards. Small bush fruits, such as Gooseberries, Raspberries, and Currants (Black and Red) are plentiful crops here, but the aphides have sadly destroyed the foliage and injured the fruit. Strawberries showed abundance of bloom, but the wet, cold weather in May made many of the flowers "blind."—WILLIAM TILLEAY.

Chatsworth, Chesterfield.—Spring here was unfavourable. We had upwards of 10 in. of rain in May and during the first ten days of June; consequently, vegetation made no progress, not even the weeds. Since then the weather has been better. Of Peaches, Nectarines, Apricots, and Figs, we grow none out-of-doors; we have to depend on indoor fruit chiefly the year round. Apples are a very thin crop. Plums none. Cherries good; May Duke, Elton, and Morello do best with us. Gooseberries are about half a crop; Warrington, Whitesmith, and Crown Bob are the best. Strawberries Vicomtesse Héricart de Thury, Underhill's Sir Harry (true), and Harry Veitch are our best. Currants are fine crops; White, Red, and Black, and Lee's Perpetual are excellent. Raspberries good; the best is Cutbush's Prince of Wales. Pears Jargonelle, Marie Louise, and Louise Bonne of Jersey are the best. Of Filberts we have none.—T. SPEED.

Bloxholm Hall, Steaford.—Fruit crops early in the season looked most promising, but the result has not fulfilled our expectations. This is not to be wondered at when it is remembered that we had an open, wet winter. In fact, we had no winter weather till the middle of March, when sharp frosts set in and continued up to the end of April; Apricots, Peaches, Pears, and Gooseberries were then

in full bloom, and were very much out, except where well protected. Apples, Cherries, and Plums were not in bloom till after the sharp frosts were over. Apple blossoms opened apparently very well, and in many cases the fruit was partly formed; but, being injured by frost, much of it dropped off; and the same may be said of Cherries and Plums. Apricots are a fair crop where well protected, but where not protected they are a failure. Apples are a very poor crop, although we had an excellent show of blossom. Of Pears we have an average crop of some varieties, but generally they are deficient, both in quantity and quality. Plums on standards are a failure, but a fair crop on walls where protected from frost and birds. Peaches and Nectarines are a fair crop where well protected. Cherries were most promising, but three parts of them fell off before swelling, leaving a very poor crop; black fly has been very troublesome on Cherry trees this season. Strawberries are most abundant and fine—in fact, I never witnessed such a crop; Garibaldi is the kind chiefly grown here, and, in my opinion, it is the most useful Strawberry in cultivation. Figs out-of-doors are a fair crop, as are also Gooseberries, though a little injured by frost and very much so by bullfinches. Raspberries are a very fair crop, and the fruit is good. Red Currants are under the average, and the bunches are smaller than usual, the severe frost nipping them when in bloom. Both White and Black Currants are fair crops. Walnuts and Filberts are a partial failure.—DAVID LUMSDEN.

Waterdale, St. Helen's.—Where gardens are well sheltered, fruit generally hereabouts is plentiful, but in exposed situations the crops are thin. Kitchen Apples are plentiful, but choice sorts are thin. Pears in sheltered situations are bearing good crops, but where exposed they are light, both on walls and standards. Cherries of all sorts are good, especially the Morellos. Plums are only moderate, and amongst them there is a good deal of blight, with the exception of Damsons, which are mostly good. Where Gooseberries are well sheltered the trees are loaded to the ground, but where exposed they are almost fruitless, with the exception of the Red Warrington, which stands cold the best. Black and Red Currants are both well loaded. Raspberry bloom is plentiful, but looks poor and starved, as well as the foliage, even under favourable weather. Many fruits will be deformed, and the same may be said of Strawberries, although bloom is plentiful on all sorts and the foliage looks well.—JAMES SMITH.

Coleorton Hall, Ashby-de-la-Zouch.—Apples are thin crops in this neighbourhood. Apricots thin generally about here. Pears very poor. Plums of most sorts are a good crop. Peaches and Nectarines are very abundant, requiring much thinning. Cherries of all kinds a good crop. Strawberries showed abundantly, but did not set well, on account of the long continued wet weather. Figs are a good full crop. Gooseberries are thin. All other bush fruits plentiful, but much blighted. Filberts are an average crop. Of Walnuts we have scarcely any.—MONTGOMERY HENDERSON.

SOUTH-WESTERN DISTRICT.

Clevedons, Lyme Regis.—The Apple crop in this neighbourhood is almost a total failure. Pears also are very scarce; although the trees flowered freely, very few fruit set. Apricots are not grown much in this locality. Cherries are scarce. Peaches and Nectarines in some cases are a fair crop; in others there are none. Strawberries are a fair crop. Plums a partial crop. Gooseberries, Black and Red Currants, and Raspberries are plentiful. As a whole, the fruit crops in this neighbourhood are much below the average.—HENRY MUNRO.

Sherborne Castle.—Fruit crops in this neighbourhood are anything but good this season. All kinds, with the exception of Pears, bloomed well but weak, a circumstance which I attribute to the wood not being properly ripened last season, and to fertilisation not being able to take place owing to so much wet weather at the time when they were in bloom. Apricots are very thin. Apples about two-thirds of a crop, and the trees are very much blighted. Cherries do not do well in this vicinity, with the exception of Morellos, and of those we have a moderate crop. Pears are a failure, with the exception of the following kinds, of which we have a few on the walls, viz., Easter Beurré, Passe Colmar, Glou Morceau, Ne Ploc Meuris, Beurré de Capismont, Jargonelle, and Marie Louise. Plums are very poor, and Peaches and Nectarines are a long way under the average. Nuts of all kinds will be scarce. Of Currants, Gooseberries, and Raspberries there is a very fair crop, and Strawberries are the best we have had for many years past both as regards size and quantity. Keene's Seedling, President, Vicomtesse Héricart de Thury, and Sir Charles Napier are the sorts that I find do best here. I am sorry to say that the Potatoes are getting very badly diseased; it made its appearance here quite three weeks earlier than usual. The soil in

this neighbourhood is heavy, and is what is commonly called stone-brash; our sub-soil in low places is of a gravelly nature, but is generally, especially on the hilly grounds, very rocky.—W. G. PRAG-NELL.

Wilton House, Salisbury.—Apples hereabouts are a very bad crop. The early blossoms were destroyed by the severe frosts and wet weather which occurred in April, and the continuous rain which prevailed throughout the month of May was equally destructive to the late varieties. Of Apricots we have a fair crop; they were protected by means of three thicknesses of $\frac{3}{4}$ -in. bird netting. Cherries are a fair crop. Currants medium. Figs not an average. Gooseberries scarce. Peaches and Nectarines, protected by canvas blinds, are good crops. Nuts and Filberts are scarce. Pears are a moderate crop. Plums good on walls only. Raspberries are a great crop. Strawberries abundant and fine, but indifferent in flavour. Walnuts very scarce.—THOMAS CHALLIS.

Carclew, Cornwall.—Apples will average half a crop; they are best where sheltered from southerly gales, from which exposed trees suffered very much last spring. Soil light loam, very shallow, soon dries and cracks. Some local but second-rate sorts do well. The following answer best with us, viz., King of the Pippins, Oslin, Braddick's Nonpareil, York Pippin, Bleaheim Oranges, Golden Harvey, Boston Russet, Adams' Pearmain, Keswick Codlin, and Hawthornden. Of Pears we have scarcely any. Soil very unsuitable, and the fruit liable to crack. We get occasionally good specimens, but very second-rate as to quality. Beurré Clairgean is our best cropper, but generally has to be used in the kitchen; Marie Louise, Ganeel's Bergamot, Beurré Diel, and Duchesse d'Angoulême are most satisfactory on the whole. Apricots are not grown out-of-doors here. Peaches are a good crop, but the trees were much affected with swollen curl in spring, and we seldom get the wood ripened sufficiently. We cover with netting during the blooming period, but suffer from the east winds, the garden eloping sharply in that direction, so much so that the east wall affords no protection to the trees on the south wall. Nectarines do not succeed so well as Peaches. Of Plums we have one-third of a crop. The earliest ones do best; late ones often do not finish properly, and the same remark applies to Damsons. Of Early Cherries we have none; Morellos half a crop. Figs generally do well, but this year they are scarce. Gooseberries are a good crop and the fruit is fine in quality. Strawberries are a good crop, but not so heavy as might have been expected; Sir Chas. Napier is by a long way the best all-round Strawberry which we grow here. Of Raspberries we have a good crop of very fine fruit. We grow them on a north border; they do not succeed in open quarters. Of Red and White Currants we have two-thirds of a crop. Curiously enough, the bushes cast their foliage very early; they will be quite bare by the end of this month or first week in next, but I do not find that they suffer from this circumstance. Black Currants are a very good crop. For crops to succeed well in the garden here rain would be requisite every other day in summer, as mines—not worked in living memory—are in close proximity; in fact, they are under the kitchen garden, which, consequently, is drained too freely. The soil is about 1 ft. deep, and the sub-soil useless for bringing to the surface. There are great complaints of the failure of the Apple crop in the surrounding neighbourhood, also of Pears in gardens. Apple orchards in this county are generally planted in low sheltered situations to guard against damage from winds, one, if not the chief, enemy to them here both when in blossom and fruit.—G. PALMER.

NORTH-WESTERN DIVISION.

Worsley Hall, Manchester.—Fruit crops in this district generally are about the average. Stone fruits are never good here; our soil does not suit them. The garden is situated on the border of Chat Moss; a good part of it is pure Moss; the rest has been heavily dressed with loam and clay. Though the trees grow fairly well, still they have never borne good crops. Apples will be a fair crop, especially Lord Suffield and Keswick Codlin, which sorts do as well as any. Irish Peach always bears well, but the fruit is undersized and inferior. Pears are a good crop; Beurré Diel and Easter Beurré are the only exceptions. Marie Louise promised well, but the blooms suffered in spring. Morello Cherries are heavily laden, and will help to take the place of Plums, which are deficient. Many of the earliest, and of course the best, blooms of Strawberries were destroyed; still we have fair crops of rather small fruit. Vicomtesse Héricart de Thury and President are the best. La Grosse Sucrée promises well, and we are increasing our stock of it. Gooseberries are under the average, but good. Currants are a capital crop, except Black kinds, which are greatly injured by a mite which defies all attempts to eradicate it. Raspberries promise well, though the unusually dry weather seems to be affecting their swelling. Peaches

barely exist even on a south wall; all ours are under cover.—W. B. URBORN.

Abney Hall, Cheadle.—This, upon the whole, promises to be a fair fruit year with us. Of Strawberries, we have gathered a good crop of Black Prince for preserving; the other two sorts which we mainly grow, Lucas and President, are now swelling satisfactorily. The protecting material which we put on our Vine borders for the winter is used in spring for putting between the rows of Strawberries, and this, we find, acts as a manure, and at the same time keeps the fruit clean. Red Currants are a plentiful crop. Black ones an average crop. Raspberries are an average crop. Gooseberries a good crop. Apples are very abundant on some of the trees here, and when in blossom they were a fine sight. Pears are not nearly so abundant as Apples; there is, however, a good crop on Williams' Bon Chrétien, Beurré d'Arenburg, and a few others. Plums are a fair crop, the Victoria being overloaded. Cherries are an average crop. Peaches, Nectarines, and Apricots are not much grown out-of-doors in this district.—ROBERT MACKELLAR.

Crewe Hall.—Apples are scarcely up to the average hereabouts, and the same may be said of Pears. Plums are very plentiful, much more abundant than they have been during these last few years. Apricots and Peaches are under the average. Gooseberries the same. Currants are an average crop. Strawberries a very abundant crop, and the fruit large and good. Raspberries are also plentiful and good. Owing, I have no doubt, to the absence of sunlight and the low temperature during the greater part of last summer and autumn, the fruit-bearing wood of many trees was imperfectly ripened and showed but little bloom, and in many cases much of that fell off without setting. This was especially the case with Peaches, Nectarines, Pears, and Apples. Our soil is light and friable, and well suited for fruit trees, but rather too much shaded. We protect Peaches, Nectarines, Apricots, and some Pears on the walls with canvas covers, which generally secure good crops; but this spring protection was not much needed, except in the case of Apricots, as we had no late frosts. Damsons are much grown in this district, and this season they are a very good crop. The sorts of fruit upon which I rely for our principal supply are chiefly Moorpark Apricots; Early Louise, Royal George, Noblesse, Early Alfred, Dymond, and Walbrton Admirable Peaches; Elruge, Rivers' Early Orange, Pina-apple, and Victoria Nectarines; Green Gage, Coe's Golden Drop, Jefferson, Kirke's, Victoria, and White Magnum Bonum Plums; Jargonelle, Williams' Bon Chrétien, Louis Bonne, Marie Louise, Winter Nelis, Glox Morecan, and Easter Beurré Pears; Keswick Codlin, Hawthornden, Lord Suffield, Minohall Crab, Cat's-head, and Norfolk Beefog kitchen Apples; Irish Peach, Margil, Ribston and Wormsley Pippins Coat Pendu Plat, and Nonpareil dessert Apples; President, James Veitch, and President Delacour Strawberries; and for forcing, Keen's Seedling, Vicomtesse Héricart de Thury, La Grosse Sacrée, and President.—Wm. WHITAKER.

Eaton Hall, Chester.—The fruit crop, with the exception of Strawberries, Cherries, and Plums, will be very much below the average in this neighbourhood. Apples and Pears bloomed well, but the crop is light. Apricots are scarce. Plums, both standards and on walls, are a fair crop. Gooseberries are very scarce indeed. Currants better. Strawberries are unusually plentiful and fine; on our stiff, heavy soil we find no Strawberry succeeds so well as Sir Harry.—THOS. SELWOOD.

Belvoir Castle, Grantham.—The present season has taught us that there exist circumstances of weather as antagonistic to the well-doing of fruit trees as absolute frost. During part of April and May, the period when fruit trees were generally in bloom, no frost occurred, and the promise of Apples and Pears was very great; but a blight fell upon fruit trees in June, the leaves curled and became blotched and disfigured by dead patches, and the fruit fell from many trees. Thus the crop of orchard fruit will be much less than was anticipated. It will be useful to record the kinds of Apples that are likely to bear satisfactory crops this season, and thus show constitutional hardiness. The record of rainfall during May, and a chilled soil submerged with wet from $4\frac{1}{2}$ in. of rain, was unquestionably one of the potent causes of the state of things I have described. The following Apples, situated in three large orchards and all in heavy soil resting on lias clay, show a satisfactory amount of fruit, viz., Hawthornden, Eve Apple, Downton Pippin, Cox's Orange, Pomona, Blenheim Orange, Beauty of Kent, Golden Noble, Northern Greening (a constant bearer), Golden Russet, Bess Pool, Lincoln Pippin, Caldwell, Ribston Pippin, Sturmer Pippin, Margil, Herefordshire Pearmain (very constant), King of Pippins (very prolific), Yorkshire Greening, and Frogmore Prolific (unfailing). Pears are not so badly blighted, but the fruit fell from standard trees in the same way as the Apples. The following kinds, trained on south-east and west walls, show well for fruit, viz., Old Crassane, Autumn Bergamot, Bergamotte

d'Esperen; Soldat d'Esperen, Marie Louise, William's Bon Chrétien, Orpheline d'Enghein, Bonne d'Anjou, Triomphe de Jodoigne, Knight's Monarch, Doyenne d'Éts, Citron des Carmes, Beurré Diel, Benra Clairgean, and Josephine de Malines. Peaches moderate under Rendle's coping. Apricots thin. Plums are excessively abundant, Victoria, Golden Drop, and Jefferson being too much loaded. The Cherry crop is also very abundant, especially Kentish. Strawberries are a large crop. Currants good. Gooseberries thin.—W. INGRAM.

Otterspool, Liverpool.—Fruit crops in this neighbourhood are, generally speaking, good, except Peaches and Damsons, which are almost failures. The Apple crop here is fairly good; but there are many cases just the reverse, and I hear many complaints of whole crops of Apples and Pears falling entirely off where the subsoil is at all heavy or wet. With a light soil and a fairly good situation, we are more fortunate here. All the old varieties of Apples and Pears are carrying full crops; Marie Louise, Louise Bonne of Jersey, Beurré Diel, Passe Colmar, Glox Morecan, and Winter Nelis are bearing excellent crops, many of which have had to be thinned more than once. Lord Suffield is the Apple for this climate, and, indeed, is good everywhere. Cherries are a moderate crop. Strawberries are quite a full crop, the best being those that were forced in pots last season; old plantations are fast disappearing before the hot weather where the soil is light; Vicomtesse Héricart de Thury and Sir Charles Napier are the most certain croppers. Gooseberries, Raspberries, and Currants are a full crop, and quite up to the ordinary standard in point of size. Potatoes are a fine crop; I have noticed but one or two attacked with disease as yet.—W. HINDS.

Haigh Hall, Wigan.—In this locality the Apple crop is under the average; Lord Suffield and Cellini have done best. Pears are a very thin crop. Plums above an average, especially Victorias. Cherries blossomed abundantly, but failed to set, and are not half a crop. Strawberries are fine and abundant. Gooseberries good. Red and Black Currants plentiful. Raspberries a very fine crop. The gardens here are very much exposed to east winds, which are every year more or less destructive to the fruit crops.—A. JAMIESON.

EASTERN DISTRICT.

Culford Hall, Bury St. Edmunds.—At this place, and as far as I can ascertain in this neighbourhood, the Apricot and the Peach crops may be said to be failures. Both looked at one time as promising as could have been desired, but 17° of frost on the morning of April 1 proved too much for them even under a glass covering extending 6 ft. from the wall. The same low temperature proved in a great measure fatal to the Apple and Pear crops. As regards the latter grown as standards, nearly all are failures, except such hardy sorts as Swan's Egg, Green Pear of Yare, and Williams' Bon Chrétien, while very few Apple trees are bearing so much as half a crop. Plums on east and west walls are plentiful, but the trees are not in good condition, and can with difficulty be freed from aphides. Damson and other sorts grown as standards are failures. Morello Cherries on north aspects are looking promising and carrying good crops. Figs on open walls as well as under glass will be a light crop. Walnuts, Nuts, and Filberts will all be very light and partial, many trees being without a fruit upon them. The Gooseberry crop is very light, the severe weather experienced during the first week of April having caused the blooms to fall off in great numbers. Raspberries will be a moderately good crop, but the fruit appears to be smaller than usual. Currants of all sorts will be plentiful, and Strawberries are abundant and remarkably fine. I may add that some old trees here of the various kinds of dessert Apples trained to a low wall with a west aspect are producing good crops, and the trees are looking more healthy than usually. Medlars are a fair crop, but Quinces are a failure. Taken altogether, this season hereabouts will be distinguished by the paucity of the fruit crops generally. The soil here is light and dry upon chalky formation.—P. GRIEVE.

Hardwicke House, Bury St. Edmunds.—In the garden here Peaches and Nectarines are a fair crop. Apricots the same, where heavily protected with glass copings, nets, boughs, and canes; absolutely none under glass copings alone. Pears very meagre in blossom and thin in fruit. Apples promising when in blossom, which remained, however, too long on the trees; it was also wanting in colour, indifferent as regards setting, and much of the fruit fell off. The trees seem to be blighted with something much like mildew. Cherries about half a crop; Morellos plentiful. Plums a fair crop, especially the Victoria and Violette Hâtive on walls. As to exceptionally good crops, I can find none among Pears. Among Apples, the Keswick Codlin, Kerry Pippin, Warner's King, and New Hawthornden are the best; Cellini, which has mostly set freely, is almost bare of fruit, unless in an exceptional case now to be noticed. A

length of diamond cordon Apples, stretching the whole length of the garden, and heavily protected with shrub branches, has hardly a barren tree in it, while the same varieties as pyramids are without fruit. Gooseberries, Currants of all sorts, and Raspberries plentiful. Strawberries in these gardens a full crop of fine fruit. As to the district, it is very bare of fruit. The walls, unless where heavily protected, are almost bare. Pears have not been so thin for years. Plums are also scarce, and Cherries, unless here and there. The Apples that have set are falling in shoals, pierced by a maggot, weakened by blight, or through imperfect setting. Gooseberries scarce; immense quantities totally destroyed in flower or in a young state. Currants generally a fair crop. Raspberries scarce. Strawberries very varied; the crop promised well generally, but was wrecked in many gardens by the continuous rains and wet cold weather that continued up to June 20. Outdoor Figs are also thinner than usual. Never, perhaps, has fruit dropping been so prevalent as this season. It extends to all fruit, including Figs. At one period the latter showed well; but the fruit has been falling fast for weeks, and comparatively few are left. The fruit prospects of the year are by no means bright. Fortunately, glass and artificial heat render us independent of the seasons to a great extent. The qualification is inserted advisedly, as I have heard this season of stone fruits and Grapes not being up to the usual mark. It may be added, for the comfort of those who find consolation in having many companions in adversity, that the fruit crops of France seem but little brighter than our own. Cherries and Strawberries are a fine crop across the Channel, but beyond these the prospects are anything but brilliant, and Peaches and Pears, unless in exceptional localities, seem little better than in England.—D. T. FISH.

Guntton Park, Norwich.—Peaches and Nectarines here are thin crops, though protected with frigid-domo; Violette Hâtive and Barrington Peaches withstand the cold, east winds here best. Apricots, protected with three thicknesses of fish nets, flowered well and set a heavy crop, but it was nearly all destroyed by the frosts which occurred on March 24 and 27 and on April 1 (when we had here 8°). Apples are a heavy crop on some trees, while on others there are none. All flowered well, but in the case of many of the trees the blossoms were entirely destroyed by the heavy, cold rains that we had daily when the major part of the trees were in flower; the trees promised so well that at one time I feared the crop might be too heavy. The kinds on which we have most fruit in this neighbourhood are Lord Saffield, Keswick Codlin, Nelson's Glory, Tower of Glamis, Ribston Pippin, and Red Astrachan. Pears are a very thin crop; some of the trees promised well, but a very light crop is the result. The best crops are on Williams' Bon Chrétien, Comte de Lamy, Josephine de Malines, Beurré Bosc, Jersey Gratioli, and Beurré Clairgeau. Strawberries are a fine crop; the heaviest cropping kinds on our sandy loam are President, Sir C. Napier, Vicomtesse Héricart de Thury, Sir Harry, Sir Joseph Paxton, James Veitch, Lucas, and Crimson Queen. Of dessert Cherries we have a fair crop of Bigarreau and Napoleon; Morello Cherries are very light. Currants a heavy crop. Gooseberries medium. Filberts on pruned bushes a fair crop. Figs very thin.—W. ALLAN.

Woolverstone Park, Ipswich.—The condition of the fruit crops in these gardens and around this district is most unsatisfactory, for although there was a good set of most of the hardier kinds such as Apples, Plums, Pears, and Cherries, the embryo fruit was evidently much injured during the severe frosts that prevailed towards the end of March, as the greater portion has since fallen off, and those that remain are swelling very irregularly and appear as if they would never attain their proper form or size. This is more particularly the case with Plums on walls, and Cherries were nearly as bad, the stones of many of which were only just covered with skin, and these hung on the trees till quite recently, but the Plums we have had to thin. Gooseberries are nearly bare, many of the bushes being entirely so, and the bunches of Currants are very gappy, especially the Red and White kinds, but Raspberries are bearing fair crops. Strawberries gave promise of being unusually abundant and would have been so had the pollen a chance of ripening, but unfortunately the flowers were nearly always wet, which prevented the fruit from setting in the free manner it otherwise would. The British Queens have suffered most and Eltons next, while Keen's Seedling and other kinds withstood the damp better, probably from being a little more forward and the weather a trifle better just at the critical time they were in bloom. Figs, which, owing to the favourable autumn and mild winter, were full of fruit here, since they came into leaf and the cold and wet set in, shed nearly the whole of them, so that the season for these will be one of the worst we have had for a long time past. Apricots are very thin, but what there are are swelling fast, and promise to be unusually fine. Peaches and Nectarines, where heavily protected

by branches of evergreen and other coverings, in addition to wood copings, have fair crops, but in all other cases the frost that occurred on the night of April 1 proved too much for them, and did a great amount of damage to the trees, from which they are only just now recovering. The Apple crop about here will be a very poor one, and in many places the trees are badly blighted, the leaves being discoloured and curled in such a manner as to look like having been burned or scorched by hot air, so shrivelled do many of them appear. The sorts bearing best are Cox's Orange Pippin and Keswick Codlin, the former an Apple that should be largely planted, as it seldom fails, and is one of the most satisfactory for both ordinary and dessert purposes that can be grown. Pears are very thin on walls, but better on pyramids, and the trees, favoured by the heavy rains, are looking well and making plenty of wood. Passe Colmar is generally good with us in our light warm soil, as are also Glou Morceau, Marie Louise, Louis Bonne, Josephine de Malines, and Bergamotte d'Esperen, the latter two the only really late Pears that are worth growing, and even these require good aspects to get them well up.—J. SHEPPARD.

Audley End, Saffron Walden.—The gardens here lie very low and close to a river, consequently, we suffer very much from spring frosts; the soil is rich and pretty deep, resting on a gravelly sub-soil. Most kinds of Pears do pretty well on the Quince stock. On some varieties we have a good sprinkling of fruit, but many trees had no bloom on them. A few of the earliest kinds were injured here by frost on April 1, but in the higher districts they escaped. Apples do well generally in this neighbourhood, but in the gardens here they often ripen prematurely in dry seasons; this year there is not half a crop. Apricots set well, but the frosts in April, even where covered with thick canvas, with but few exceptions killed the young fruit. This is the only kind of fruit tree to which we give any protection. Cherries are a fair crop, especially Morellos, which do remarkably well here. Currants of all kinds are abundant, with the exception of some of the newer varieties of the Red, which show the bloom before the leaves. These were very much injured by frost. Figs are promising; the Brown Turkey is the only variety which we grow. Gooseberries were nearly all killed on April 1. Peaches and Nectarines might be put down as almost a total failure, excepting in the higher districts, where there are fair crops. Here the last few bad seasons have nearly killed the trees. Of Nuts we have a sprinkling, with the exception of Walnuts, of which we have scarcely any, but in higher places they are better. Of Plums we have a very fair crop; most varieties do pretty well here. Raspberries are a fair crop. Strawberries are abundant and very fine; our best varieties on this light soil are Sir J. Paxton, President, Keen's Seedling, and Black Prince for the earliest, and which do well if fresh planted every year. We also grow Trollope's Victoria, Elton Pine, and British Queen. Other varieties we have tried, but the above are the best. None of them do well, however, more than two years.—J. BRYAN.

YORKSHIRE.

Wortley Hall, Sheffield.—The crops of Apples and Pears here will not be so good as they promised to be when the trees were in flower. Two or three cold days, with occasional showers of sleet and hail, after a week or two of almost forcing weather, just when the fruit was setting, did considerable injury to the blossom; still there will be a good sprinkling of fruit. Cherries are good, Plums poor generally, and Apricots scarce. Small fruits are a light crop, except Strawberries, which are plentiful, but late, Black Prince not yet (July 3) having yielded a gathering in the gardens here. Potatoes were rather diseased-looking a fortnight ago, but the late warm weather has restored them, and they now promise well. No body in this district remembers such a plague of slugs as has been this season; crops have only been saved after frequent sowings and much trouble. The rainfall during the latter part of May and the beginning of June was over 8 in.—J. SIMPSON.

Ribston Hall, Wetherby.—Fruit crops this season are unusually light. Apricots, though on a south wall and protected with old nets, are a very thin crop. Peaches and Nectarines are very partial; some have to be thinned, others are almost destitute of fruit. Gregory's Late, Barrington, and Walburton's Admirable Peaches have set well. Plums on walls have set well; Coe's Golden Drop, Victoria, Kirke's, Jefferson's, and Reine Claude de Bavay are good. All standard and bush Plums are almost a failure. Pears are also very partial. The lower leaves are much affected with spot, caused, no doubt, by the late rains; and Apple trees have suffered in the same way. The ground under the trees is covered with dead leaves. On Beurré Diel, Winter Nellis, and Beurre d'Arenburg there are good crops. Of Marie Louise we have but few. Apples are unusually thin and the trees look miserable. Keswick Codlin and Manks Codlin are

the best. Ribston Pippin, which has not failed for twenty years to produce as many as we required for dessert, I should have no difficulty in counting this year. Gooseberries are thinner than I have known them for years, Ashtons especially, and yet in the case of some of the Lancashire show sorts we have had to use props to keep the fruit from the ground, so heavily are they laden; they were in bloom early, and got out of danger before the frost of April 1. Strawberries and Raspberries are fair crops. Cherries are not worth netting, except Morellos. If crops of fruit were like the crop of eluge, we should have no reason to complain.—THOS. JONES.

Bretton Park, Wakefield.—The state of the fruit crops in this neighbourhood is far below what was at one time expected. Since the end of April to the beginning of last week we had not one sunny day, the weather being wet, damp, and cold, and even occasionally frosty at night; consequently, the trees have become infested with mildew and fly. Peaches, Apricots, Plums, and Pears on walls are almost a failure; standards of the two last-mentioned are fruitless. Apples are scarce; many trees have not a fruit on them. The only kinds that are bearing full crops are Lord Nelson, Hawthornden, and Ribston Pippin. Strawberries, Raspberries, and Currants are abundant. Gooseberries about one-third of a crop; in many gardens near here there is not a single berry. Cherries have dropped while stoning. May Duke has proved the best. Morellos are a poor crop. The soil in this neighbourhood is generally of a heavy stiff character, with a clayey subsoil.—GEO. CLIFTON.

Thorpe Perrow, Bedale.—Fruit crops in this part of the North Riding of Yorkshire are anything but good generally. Apples are almost a failure. At this place the early autumn sorts are pretty good, but late sorts were killed on May 19 by hail and snow, followed on the same night by 7° of frost. Apricots are a very moderate crop. Kentish Cherries are very abundant; other sorts not so good. Pears are good generally, especially Marie Louise, Beurré Diel, Winter Nelis, and Glou Moresau. Peaches, too, are good. Plums on many trees required considerable thinning. All kinds of bush fruits are very abundant. Strawberries are plentiful and fine. Apple trees have suffered very much from the cold, wet spring, and the leaves are falling from the spurs as if it were autumn.—WILLIAM CULVERWELL.

Grimston Park, Tadcaster.—Apples hereabouts are, on the whole, a light crop; Cox's Orange Pippin, Lord Suffield, Warner's King, and a local variety called Ceckpit, are our most regular croppers. Apricots are thin; Moorpark is the variety mostly grown in this part of Yorkshire. Peaches and Nectarines are also scarce; Royal George, Bellegarde, Early York, and Walburton Admirable are our best Peaches, and Violette Hâtive the best Nectarine. Plums are thin on standards, but fair crops on walls; Victoria, Jefferson, and Green Gage are the best croppers. Winesaps are very much grown as standards; Sberbarne, some few miles from this, is quite noted for them. One grower there can usually dispose of his fruit at about 10s. per peck of 13 lb. Cherries are thin, even Morellos, which nearly always produce heavy crops. Pears are partial; on Jargonelle and Marie Louise, which are our best cropping sorts, there are fair sprinklings. Small fruits are abundant and promise to be fine, with the exception of Gooseberries, which were much damaged by the severe frosts and snow which we had about the middle of April. These frosts are blamed for the generally thin crops which we have hereabouts, but, in my opinion, they are not the true cause of the failure. For my own part I never expected good crops of choice fruit this year, at all events in the north. Could good crops (excluding small fruits) the year after such a cold, wet, unless summer as we had last year be expected? We had plenty of bloom on all kinds of fruit, but it was weak, and in many cases very imperfectly developed. Our soil here is a stiff leamy one, resting on magnesian limestone.—H. J. CLAYTON.

NORTHERN DIVISION.

Raby Castle.—Apples are almost a failure, although there was plenty of bloom and at one time apparently a good portion of it had set, but there was unquestionably debility both as regards bud and flower, arising no doubt from the want of sunshine last year. Trees that I have trained against walls, such as Ribstons, are bringing forward good healthy crops; a few other trees in very sheltered situations are producing good half crops and are in good health, but trees more exposed have a wretched, stunted appearance, the tops of the shoots being all scorched as if by fire. Pears are a light crop, but the trees are remarkably clean and healthy. Of Apricots we have plenty, if quality be preferred to quantity, and the trees are making strong growth, but canker is still making sad havoc where not immediately cut out. Branches which are diseased should in all cases be cut off just below the cankered part. Every particle of canker

should be cut out, leaving nothing but what is perfectly sound and healthy. Healing the wounds would be greatly facilitated by plastering them over with fresh cow manure and clay well mixed together. In this way air is excluded and a little moisture is retained about the wound, which greatly assists the healing process. I have always observed that what are termed "rider" Apricots are less susceptible to canker than dwarf trained ones. We have here a rider trained between two dwarfs, and both the latter are dead. Canker, I imagine, originates at the point of union between the graft and stock, which probably is the most sensitive part of the tree. These unions in the case of dwarfs are made so close to the ground, that they are constantly exposed to extreme variations; therefore nursery-men should provide us with trees having stems 3 ft. high instead of as many inches. Peaches and Nectarines are not grown here on open walls. Cherries of the dessert class are good; of Morellos we have very few. Plums are a good crop; of Victoria and some of the free setting kinds we have abundance; but no Damsons. Of Gooseberries we have only a few; the bushes, like Apple trees, are very much blighted. Currants, Black and White, are abundant, of Red there is about half a crop. Raspberries are plentiful, but stunted. Of Strawberries, plenty set, but only a few are swelling, and these are small.—R. WESTCOTT.

Lambton Castle.—Fruit crops in Durham suffered severely from late frost, more especially from that which occurred on May 21, which caused most of the early fruit to drop. Apples here are best on pyramids, eight years' planted, in a heavy soil. All bloomed freely, and showed signs at one time of great abundances; but now those which have most fruit on them are the following, viz., Ribston Pippin, Mannington Pearmain, Scarlet Nonpareil, Boston Russet, Rusetta da Canada, Magnum Bonum, Keswick Codlin, Rymer, Lord Suffield, Cellini, Bleaheim Orange, Cockle Pippin, Claygate Pearmain, King of the Pippins, and Manks Codlin. Pears suffered in the same way as Apples. The following are bearing most fruit, viz., Easter Bonrre, Jargonelle, Incomparable Bonrre, Hessele, Green Yair, Louise Bonne of Jersey, Althrop Crassane, Beurré de Capianmont, Vicar of Winkfield, Beurré Superfin, Passe Colmar, and Comte de Lamy. Apricots are a failure, and the same may be said of Peaches and Nectarines, except in favoured spots where protection has been given them. Cherries are a good average crop and fine in quality. Pines are also well cropped and, to all appearance, going to be good. Gooseberries suffered sadly from late frosts, very few fruits being retained on the bushes, which are healthy. Strawberries are good, both in crop and quality. Currants of different kinds are fairly represented; also Raspberries. Lambton Garden lie on the banks of the River Wear, about seven miles from Sanderland, and so near the level of the sea, that the river rises some 6 ft. or 10 ft., so influenced is it by the tide, causing vegetation to suffer much from early and late frosts.—J. HUNTER.

Seaham Hall, Sunderland.—The gardens here are about 1800 ft. from the sea, and we are therefore subject to easterly winds and a constant change of temperature. They slope towards the south and are surrounded by trees. The soil consists of two kinds—one light and sandy, the other a stiff clay, which becomes hard and had to work, except in wet weather; in fact, we can do with a shower daily, as the garden lies on limestone rocks. The locality produces little fruit, except common sorts. Apples are scarce in this district; Hawthornden, Ribston Pippin, and a small Pippin supposed to be Downton, are the only sorts that are bearing a crop; these are rather exposed to the wind, and therefore were in blossom later than the others; there was abundance of bloom, but at that date we had cold wet weather. Pears are very scarce; on common sorts there are a few, but good sorts will not ripen. Plums will not set their fruit being too near the sea. Peaches and Nectarines have set a fair crop on walls, but they are never worth the trouble of culture out-of-doors. Raspberries are always a sure crop, and they look very promising this season. Strawberries are also always a good crop, but they require a wet season; at present they look promising. Gooseberries of all sorts do well; the only risk they run is from late spring frosts and east winds. Since I left off pruning the bushes I get double the quantity of fruit, owing to the branches protecting the blossoms, and in a few seasons they require no pruning, as they make no wood. Of Currants, Black and Red, we are always sure of a crop, as they flower ten days later than the Gooseberries. Potatoes look well; they have plenty of foliage and no signs of disease. Slugs and weeds have been very troublesome this season.—R. DRAPER.

Alnwick Castle.—Fruit crops in this neighbourhood are not very satisfactory. With us Apples are almost a failure, with the exception of late sorts. Apricots are rather thin, but what fruit is left is looking well, and the trees are clean and healthy. Early Cherries are a fair crop; Morellos very thin. Currants and Gooseberries, with few exceptions, are tolerably good. Raspberries and Strawberry.

ries are abundant. Pears are a good crop, except where much exposed; most sorts do well here. Green Gage Plums are thin. Of others sorts we have good crops. Golden Gage is one of the best Plums with which I am acquainted, and a sure cropper if properly managed. Peaches and Nectarines on a south wall, well sheltered, are a good crop; on another south wall, more exposed, they are very thin, but the trees are all healthy and making good wood; Prince of Wales, Dr. Hogg, Royal George, Barrington, and Bellegarde Peaches; Pine-apple, Pitmaston Orange, Elruge, and Hardwick Seedling Nectarines, are most to be depended on in such seasons as those we have had of late. We seldom suffer from late frosts here, as the soil is light and dry, at an elevation of nearly 200 ft. above sea level. What we suffered most from, both this year and last, is the long continuance of cold wet weather during the flowering and setting period. We protect stone fruits on walls in spring with double herring nets, stretched tightly on poles, 4 ft. apart and 2 ft. from the wall at the ground, their tops being under the coping. I have tried many kinds of covering for trees, but I have found nothing to equal herring net if properly put up. Its cost is not much, and the trouble attending its application very little. It affords great protection to the trees, and does not obstruct light and air.—A. INGRAM.

Shawdon Hall, Alnwick.—The Apple crop in this district is again all but a failure. Notwithstanding the sunless year of 1877, the trees were loaded with blossom and great hopes were entertained of an abundant crop, but this has not been realised. The fine weather in March was followed by heavy rains during the latter part of April and May; the temperature of the nights hardly ever rose above 35°; and the result is, that most valuable and indispensable of out-door fruits, the Apple, has again failed, and not only is the fruit a failure, but the foliage of the trees in many places is blighted and falling to the ground as if it were early autumn. Small fruits vary much in different places. Gooseberries have failed in some quarters, while in others they are a fair crop. The same holds good regarding the different sorts of Currants. Strawberries are exceptionally fine this year; they are late, but likely to prove an abundant crop. Raspberries have suffered from the same cause as the Apple trees, and their foliage is blighted and falling off. Wall fruits have become such a precarious crop in our northern district, that no correct statement respecting them can be given. The Peach only comes to full perfection in exceptional situations, but under glass both it and the Nectarine attain a quality equal to that obtained in any district in England. This year there is a fair crop in places even where no protection has been used; in others where different kinds of material have been kept on the trees the fruit is a failure. It therefore becomes a question worth consideration whether or not in wet springs covering fruit trees with netting of various kinds does not do more harm than good. I have seen nets in some places kept over the trees even during the day. Apricots are an average crop in most places; unlike Peaches, they are healthy and clean in the foliage. Moorpark is the standard kind in the north of England, other varieties are only grown for succession. Plums are seldom taken into account in many parts of this district; the old sorts are still the only kinds to be seen in many of our best gardens. This is to be regretted, as they form a valuable addition to the dessert table. River's Early Prolific is a most useful early variety; nevertheless, it was so little known in this district, that the first time I showed it in a collection of fruit few people would believe that it was a Plum ripened in the open air in the early part of August. This fine early Plum can be followed up by other sorts in succession till October. The Cherry crop is very meagre; the fruit did not stone, and consequently have dropped. Altogether, the fruit crop in Northumberland is below the average both in quantity and quality. This last defect is owing to the blighted state of the foliage, caused by an extremely low temperature.—J. THOMSON.

Figs in Pots.—At Messrs. Veitch's Fruit Tree Nursery I recently saw several ranges of houses exclusively devoted to Figs in pots, and most useful they are where forced Figs are in request. The old Brown Turkey kind still appears to maintain its popularity, and, amongst new sorts, Negro Largo seems to be held in high estimation, while some other kinds not yet in commerce appear likely to eclipse all their predecessors as regards fruitfulness. The merits of Figs of the newer kinds are only just beginning to be recognised, and for the future better places must be found for Figs planted out than the back walls of Vineries and similarly shaded houses. No wonder that a plant which revels in sunshine in much hotter countries than this could not ripen its wood or the fruit attain its maximum flavour under such circumstances; but keep the roots under control in pots or in brick compartments, and give the tops all the light and air possible, and the Fig will now, as of old, maintain its proverbial character for fertility.—J. GROOM.

ANSWERS TO CORRESPONDENTS.

Orange Nectarium.—Will this Nectarine stand forcing? This season it is a failure with me, although every attention has been paid to it, such as watering and setting the bloom.—E. S. [The Orange Nectarine is not a good forcer; at least, such is our experience. We prefer the following for that purpose, viz., Elruge, Pitmaston Orange, and Violette Hative.—W. W.]

Weeds on Lawns.—Is there anything that will weed on lawns, such as Daisies, Buttercups, &c.—*Subscissa*. [Try Watson's lawn sand.]

Sudden Failure in Raspberries.—The Raspberry plantation alluded to in last week's *GARDEN* (p. 21) will require renewing. The treatment could not have been better, and we can only account for their sudden failure by a want of vigour to enable them to withstand the extreme heat of the last ten days of June. Raspberries prefer a moist situation; it cannot be too moist; provided the drainage is effective.—W. W. H.

Tropæolum azureum.—In answer to "D.," I may state that I have employed both the balloon and flat trellises, and with care in training the plants may be made to cover them from the pot upwards. I have found them, however, to grow stronger when allowed to ramble in a more natural and unrestrained manner, as on a trellis near the roof. The manner of training, as well as the situation, which "D." has described as having suited Jarrist will do equally well for this species.—J. COANHILL.

Names of Plants.—Correspondents wishing plants to be named will oblige by complying with the following rules: To send the specimens as complete as possible, i.e., both stem, leaves, and flowers, and fruit, when possible. We cannot attempt to name plants from single leaves. To carefully pack them in gutta-percha tissue, or other impervious material which will prevent evaporation. Not to send varieties of popular flowers, such as *Fuchsias* or *Pansies*, which are best named by experienced growers of such plants, who have the means of comparison at hand. Not to send more than four plants or flowers at a time. Always to send, in addition to whatever pseudonyms or initials they may desire to use in the paper, their full name and address. To pre-pay all packages containing plants or flowers.—C. M. W.—1. *Cereus serpentinus*. 2. *Echinopsis Eyriesi*. 3. *Opuntia cylindrica*. 4. *Pereekia aculeata*. F. E.—*Adenocalymna comosa*. Mrs. M. A.—Roses should be sent to some Rose grower, who has the means of comparison at hand. C. F.—*Teucrium fruticans*. J. E.—1. *Pastinaca sativa*. 2. *Scabiosa arvensis*. 3. *Carduus arvensis*. 4. *Centaurea nigra*. Bentham's Handbook of the British Flora. W. C.—The orange-flowered shrub appears to be a *Caesia*. The other—not in flower—is indeterminate. *Sub.*—The Welsh Poppy (*Meconopsis cambrica*).

Amaryllids and their Treatment.—What is the proper treatment, at this season of the year, of *Amaryllis Belladonna*, *vittata*, and the *Nerines*. Will you kindly ask someone when they should be dried off? and for how long? and when started again? Should they be kept without any water, like the other kinds of *Amaryllis*? By proper attention to growing and resting, can they be made to bloom every year, like *Amaryllis Prince of Orange* or *Regina*? I have no greenhouse, only cold frames and hot beds.—JAS. R. TOWNSEND, Cedar Street, New York. [*Amaryllis Belladonna* for flowering in pots should be treated somewhat the same as *Vallota purpurea*. After flowering it should have plenty of water, and should be nearly shut up in a close frame until it has made good flowering bulbs for the next season; then it should be gradually dried off. It does best out-of-doors, but to grow and flower it well the bulbs should be planted about 6 in. deep in a good rich border in the full sun, where they may remain for years without being transplanted, and will produce an abundance of flowers. *Amaryllis vittata* should be treated precisely the same as other *Amaryllis*. *Nerines* also require much the same treatment as *Amaryllis*; they flower chiefly in autumn, and if properly dried off the flowers are thrown up before the foliage. As soon as the flowering is over, the plants should be placed in a close frame and kept well syringed, so as to make good flowering bulbs for the following season.—B. S. W.]

Questions.

Stamp the World Peach.—Do any of your correspondents know any thing of this Peach? Grown in the same house, it exceeds Royal George and Violette Hative. We find it to be a very free bearer, and the fruit to be large and handsome and a good traveller.—A. HARRISON, *Thoresby Park, Ollerton*.

Cure for Rats.—Will Baron Von Baekhoven (see p. 16) inform us what is meant by common Squills? Is it *Scilla nutans*? or *Ornithogalum Squilla* (the Official Squill), which is said to be poisonous to several animals? Information on this point is required.—P. BARR.

Roses in Bouquets.—At a recent horticultural show I was an exhibitor in a class headed in the schedule as follows: "For the best Bouquet of Greenhouse Flowers." Would the judges be considered justified in disqualifying a bouquet on the ground that it contained a Rose or Roses?—CONSERVATOR READER.

Viola Ardwell Gem.—This is a clear yellow variety, which is exceedingly dwarf; indeed, it literally creeps along the ground, and the flowers, which are produced in profusion, are thrown well up above the foliage. For bedding purposes it is all that could be desired.—W. PAUL, *Paisley*.

THE ROOKS AND ROOKERIES OF LONDON.

By Edward Hamilton, M.D., F.L.S.

WITH the exception of the ubiquitous house sparrow, no birds frequenting our London parks and trees are so familiar to us as our black-coated friends the rooks, or, as they are commonly but erroneously called, crows. Winter and spring, summer and autumn, they may be seen stalking about searching for food, confident in their security, claiming friendship with man, yet wary withal, for they never allow too near an approach. Never disturbed by crow-boy or gun, their progeny protected, and allowed to gain maturity, no rook-shooting parties to molest them, they are happy in the dust and turmoil of this overgrown city.

The rook, indeed, is to the citizen what the nightingale is to the countryman—the harbinger of spring; and there are few pleasanter sounds in Nature than the harmonious cawing from the lofty Elm which greets the ear at Eastertide. We never pass beneath a rookery in early spring, or listen to the distinct voices of our sable friends without being reminded of Longfellow's lines in "The Birds of Killingworth":—

Do you ne'er think what wondrous beings these?
Do you ne'er think who made them and who taught
The dialect they speak, where melodies
Alone are the interpreters of thought?
Whose household words are songs in many keys
Sweeter than instrument of man e'er caught!
Whose habitations in the tree-tops even
Are half-way houses on the road to heaven!

Alas! the rooks and rookeries so pleasant to old Londoners are gradually diminishing and disappearing, and the London rook, to our grandchildren, will be a bird of the past. The cause is not far to seek. The extension of buildings limits their feeding ground, and they have farther and farther to go to seek sustenance for themselves and their young. The parks are now so cut up with walks and so frequented, that the birds can find but little repose and but scanty subsistence. When the writer first came to London the Elms in Hyde Park and Kensington Gardens were in the finest condition. Herds of fallow deer frequented the glades, and there was only one walk across Hyde Park from where the Marble Arch now stands to the Wellington Statue. All the rest was luxuriant Grass, affording abundant food for birds and beasts. "Tempora mutantur!"

Beginning westward, the first rookery to notice is that in the grounds of Holland House, one of the most ancient in the land. The trees bordering the high road were formerly covered with nests; now there are only four, and thirteen more in the avenue. In the days when Addison wrote, and in later days, when Sheridan, Jeffery, Byron, Brongham, Lyndhurst, Tom Moore, Macaulay, and a host of other wits and celebrities passed under that grand avenue to the splendid hospitality of that glorious mansion, the rookery was in its prime. Those great names are reminiscences of a great time in England's history, and are now of the past, and so soon will be the rooks and the rookery.

A colony of rooks has existed for many years in the high trees in the north part of Kensington Gardens. This rookery, in 1836, extended from the Broad Walk near the Palace to the Serpentine, where it commences in the Gardens, and there must have been very nearly one hundred nests. The rooks were very busy and their voices very merry when our present gracious Queen first saw the light in the south-east apartments of Kensington Palace, on May 24, 1819; and their descendants were as merry and as busy when her Majesty held her first Council on her Accession, in that same Palace, on June 28, 1837. Even now the younger scions of our royal family can hear the "caws" of the old and the feeble cries of the young rooks, descendants of the old colony, now, alas! reduced to thirty-one nests, and confined to a few of the upper trees skirting the Broad Walk near the North Gate.

A few years ago a pair of rooks took possession of the Plane tree in the grounds of the Deputy Ranger of Hyde Park. The colony increased, and numbered ten nests in 1870; dwindled again to two in 1874; increased to seven in 1877; and again diminished to two in 1878. Some new buildings have been erected close by; this may be the cause of the diminution at the present time.

A rookery formerly existed in the Green Park, in the Elm trees at the end of the garden belonging to the Green Park Lodge, the residence (if my memory serves me) of the late Princess Amelia. When the lodge was pulled down some of the trees were also destroyed and the rooks all left. The rookery in Chesterfield Gardens then existed, but I think about this time the nests in Wharnclyffe Gardens were commenced, and (as I suspect) by the rooks from the Green Park which migrated from those trees.

If the great Lord Chesterfield could revisit the scene of his greatness here on earth, what would he see? His house remains, it is true, but in what desolation! The garden, described by Beckford as

the finest private garden in London, entirely destroyed and covered with modern mansions; the stately Elms, with their sable inhabitants all gone; the beautiful colonnade in the courtyard demolished; nothing but the mansion left, despoiled of all its beauty and significance! In those old Elms above that old bulging wall in Curzon Street there were, in 1816, close upon fifty nests, and two in Lord Wharnclyffe's garden. Now the trees are all gone and the rooks too. The colony in Wharnclyffe Gardens has increased from two to ten nests, which are at present confined to three or four Plane trees behind the mansion. A year or two ago there were a few in the trees in the outer garden.

In 1875 a rook's nest was built and the young hatched in a tree at the back of Hereford Square, Brompton. The following year the birds returned with others, and ten nests were built in the fine Elm and Plane trees there, thus establishing a fine colony.

A rookery formerly existed in the trees in the gardens of Carlton House; but this was destroyed in 1827, when the trees were cut down and the old house demolished, when the rooks emigrated to a plantation at the back of New Street, Spring Gardens.

In the gardens of Brunswick House, in the New Road, opposite Devonshire Place, a colony of rooks has been established for some years. I find from my notes that in 1840 there were twenty nests in the Plane trees of Brunswick House, and five in the trees overhanging the New Road. In 1858 (an extraordinary mild season), on January 23, rooks were building, in the Plane trees of Brunswick House, fifteen nests. In 1876 I counted seventeen nests. This year, on April 15, fifteen nests, which now occupy only three of the Plane trees nearest the Regent's Park. The tree overhanging the New Road is untenanted, although in 1875 it contained a single nest.

In some Plane trees in a garden on the east side of Gower Street are three rooks' nests, and two others in a Plane tree in the garden of No. 5, Gordon Place, Gordon Square.

There was formerly a considerable rookery in the Temple Gardens, in the Elms in the King's Bench Walk. When they ceased to build there I cannot ascertain exactly. One of the porters tells me that he has been in the Temple, man and boy, between forty and fifty years, and he cannot remember any rooks or nests there. In Goldsmith's time it was a flourishing colony. In his "Animated Nature," printed in 1774, he says:—

The rook, as is well known, builds in woods and forests in the neighbourhood of man, and sometimes makes choice of groves in the very midst of cities for the place of its retreat and security; in these it establishes a bond of legal constitutions, by which all intruders are excluded from coming to live among them, and none suffered to build but acknowledged natives of the place. I have often amused myself with observing their plan of policy from my window in the Temple that looks upon a grove where they have made a colony in the midst of the city. At the commencement of spring, the rookery, which during the continuance of winter seemed to have been deserted or only guarded by about five or six, like old soldiers in a garrison, now begins to be once more frequented; and in a short time all the bustle and hurry of business is fairly commenced; where these numbers resided during the winter is not easy to guess, perhaps in the trees and hedgerows to be nearer their food. In spring, however, they cultivate their native trees; and in the places where they were themselves hatched they prepare to propagate a future progeny.

The birds whose habits are thus so graphically described must have been in the height of happiness, and in the bustle of their business, when poor Goldsmith was on his deathbed, and their voices may have been his funeral requiem when he was placed in his grave in the Temple burial-ground, on the evening of Saturday, April 9, 1774, almost overshadowed by those Elm trees—

Where the bat circled, and the rooks reposed,
Their wars suspended and their councils closed.

Twenty-five years ago the rookery in College Gardens, Doctor's Commons, still existed. Hone, writing of it in April, 1826, in his "Every Day Book" (vol. i., p. 494), has the following anecdote concerning it:—

Amongst the deliramenta of the learned, which have amused mankind, the following instance merits a particular rank. Some years ago there were several large Elm trees in the College Garden behind the Ecclesiastical Court, Doctor's Commons, in which a number of rooks had taken up their abode, forming in appearance a sort of convocation of aerial ecclesiastics. A young gentleman who lodged in an attic, and was their close neighbour, frequently entertained himself with thinning this covey of black game by means of a crossbow. On the opposite side lived a curious old civilian, who, observing from his study that the rooks often dropped senseless from their perches, or as it may be said, without using a figure, "hopp'd the twig," making no sign, nor any sign being made to his vision to account for the phenomenon, set his wits to work to consider the cause. It was probably during a profitless time of peace, and the doctor, having plenty of leisure, weighed the matter over and over, till he was at length fully satisfied that he had made a great ornithological discovery, that its promulgation would give wings to his fame, and that he was fated, by means of these rooks, to say, *Volito vivus per crura verum*. His goosequill

and foolscap were quickly in requisition, and he actually wrote a treatise stating circumstantially what he had himself seen, and in conclusion giving it as the settled conviction of his mind that rooks were subject to the "falling sicknesses."

Few people, save lawyers and their clients, ever visit one of the quietest precincts in the city of London, viz., Gray's Inn. Turning out of noisy Holborn or Gray's Inn Lane, the most perfect stillness suddenly prevails; another city seems to have arisen; quiet alleys and paved courts shut out the noise of the busy world; a solitary footstep—made still more solitary by its echo—breaks upon the ear. Can this be in the midst of London? Even so, and in that great square the chief noise is the "caw" of the rooks.

In the gardens of Gray's Inn may still be seen the largest rookery in London. How long it has been established I have not been able to ascertain. The Elm trees were planted by Lord Bacon. It was probably coeval with that of the Temple, and probably increased when the Temple rookery was abandoned. Six years ago there were thirty-eight nests. Two years later some of the trees were blown down, others were cut down, and the rookery was nearly annihilated; a few nests only remained on some Plane trees. The gardens having been kept very quiet, and all noisy children excluded, the rooks are returning, and this year, on April 28, there were twenty-eight full nests with birds sitting, and four unfinished. On going round the garden I was informed that every morning one of the residents feeds the rooks, and that often as many as eighty birds have been counted. Now as twenty-eight nests will only give fifty-six birds, the rest must come from a distance—probably the birds of a former year. Let us hope, from the care taken, that this rookery will long flourish and increase. The gardens are beautifully clean, and the birds as glossy as if they had made their nests 100 miles from this smoky city.

For some years a pair of rooks built their nest in the Plane tree at the corner of Wood Street, Cheapside. I have notes of this in 1835, 1836, 1837, and 1838. Yarrell says that they did not use the nest after 1836, but this is a mistake. Probably these birds were the same who built their nest previously on the Dragon of Bow Church spire. Mr. Harting, in his "Birds of Middlesex," states that in 1845 there were two nests in this tree. I have no record of this circumstance. The same author states that in 1838, a pair of rooks made their nest on the crown which surmounted the vane of St. Olave's Church, Crutched Friars.

I know of no rookeries farther east in London—that is, London proper—for we must exclude the outlying districts from our limits.

There used to be some rooks' nests in the burial ground of St. Dunstan's in the East, in Tower Street; and in 1876 a pair of rooks took up their quarters and built their nest in Bermondsey Church-yard.—"Zoologist."

Large Peach Tree.—A Peach tree at Sunbury Park measures 22 ft. by 22 ft., equal to 484 square ft. Suppose we allow an average of eight fruit to a square foot, the result would be 3872, or 322 doz. Peaches. An Elrnge Nectarine in the same house covers 225 square ft., and carries 150 doz. splendid fruit. The trees are about fourteen years old, and perfect specimens of good cultivation. In the same range there are two large Vineries, the crops in which are equally good.—J. F.

A Double Edelweiss.—The allusion to the Edelweiss in THE GARDEN (Vol. XIII., p. 588) reminds me of a very interesting novelty cultivated (only a few plants) in the Imperial Botanic Garden at Innsbruck, viz., a double Edelweiss. I have seen a flower of it; it is very beautiful, and, as the single flower is so much prized (it is the club mark of the German "Alpenverein"), the double form will be of great interest. I am astonished to see from the remarks in THE GARDEN that the Edelweiss is rather difficult to grow in England. Here it is of the easiest culture; indeed, almost a weed.—T. FÖRSTER, Augsburg, Bavaria.

Table Decorations at Tunbridge Wells.—At a recent show held here, table decorations formed a prominent feature. They exhibited much taste as regards arrangement, and the wild flowers with which some of the centre pieces were filled had a better appearance than if the most costly stove plants had been employed. This is a point worthy of special notice, as the flowers used are within the reach of all, and the result is an increase of what may be called a more refined taste. Hand bouquets were also shown in profusion, and prettily made up many of them were. Matters such as these well deserve encouragement.—G. BRUSH.

OBITUARY.

LEWIS SOLOMON, one of the best known of Covent Garden fruit merchants, died at Folkestone on the 2nd inst., at the age of sixty-three. His knowledge of fruit was most extensive and accurate, and in times gone by he often filled the office of judge at fruit shows both at Chiswick and at the Crystal Palace. He was well known and much respected.

SOCIETIES AND EXHIBITIONS.

ROYAL BOTANIC SOCIETY.

JUNE 10.

ALTHOUGH some think there are too many flower shows now-a-days, we are pleased that the Botanic Society have this year returned to their old plan of having a third summer show, at which fruit is an important feature. This course is desirable, not only because such a society ought to fairly represent fruit among its exhibitions, but also for the sake of prolonging the season of these very pleasant meetings in a garden universally admitted to be so well suited for them. Roses and other cut flowers and fruit formed the main attractions this time; and although the large plants were absent, there was a very good meeting and many excellent Roses shown, the chief prizes falling to Mr. George Paul, whose immense baskets of Roses were much admired. Any plan that gets away from the ordinary straight box-way of showing the fairest of flowers is welcome. Mr. Paul's way in this case was to fill an ordinary circular packing basket, about 5 ft. across and 1 ft. deep, with Moss or other light material, and then plant it all over with superb cut Roses, sometimes one huge basket of a kind, sometimes a variety of kinds in groups. Mr. George Paul also had a very interesting collection of climbing Roses. We believe that the beauty of climbing Roses has never (owing to the general practice of mutilation under the name of pruning) been fairly represented in our gardens; and though they can be only very poorly represented at a flower show, they nevertheless deserve to be more often seen at shows. Their heads of abundant blossoms are welcome after the single blooms of the show kinds. Among new large-flowered Roses which have become standard kinds, we may mention M. Liabaud and M. E. Y. Teas. These will stand the test time which is so fatal to many new Roses. Messrs. Cranston showed many Roses of great size and beauty. Mr. Turner's two new and beautiful Roses, Harrison Weir and Penelope Mayo, were there and much admired. Mr. Turner had also a very interesting group of yellow Carnations, of which too rare and delicate race a fine vigorous batch has recently been raised at Slough.

Among the cut flowers, those of British plants were, as usual, a failure, owing to stiff arrangement and similarity in the groups. In the interest of the flora of a country, it is not desirable to offer prizes for the greatest variety of wild flowers, because this tends to the extermination of the rare kinds; it is equally injudicious as regards effect. It would be better to give prizes for effective and simple arrangement of the more beautiful and graceful of the easily-obtained native flowers and Ferns. Then we might get away from the "besoms" now so often seen. There is more beauty in a single wreath of wild Rose than in scores of those crammed bunches. There was some improvement in exotic cut flowers, but in this case also stiff bad arrangement was the rule—a striking exception being the collection of cut flowers shown by Mr. Morse, of the Original Nursery, Epsom.

The unusual calls on our space this week prevent us saying more of the fruit than that it was in many cases excellent, and that a detailed list of the prize-winners will be found in our outer sheet. Mr. Douglas showed a fine basket of a quite smooth Tomato (Vick's Criterion), which is as smooth as a Nectarine, but whether the fruit will be any better in consequence we cannot say.

ROYAL HORTICULTURAL SOCIETY.

PROVINCIAL SHOW AT PRESTON, JULY 10, 11, 12, & 13.

THIS great show opened on Wednesday last under favourable circumstances as regards weather. A more suitable place to hold a flower show could hardly have been selected than the Preston Nursery and Pleasure Gardens, for, in addition to being attractive in themselves, the surrounding country, with its beautiful scenery, added much to the enjoyment of visitors. The principal tent consisted of three spans, and covered a large space of ground, thrown into a series of banks and undulations. A miniature lake occupied the centre, in which were

placed Tree Ferns, and on a series of round plots of turf on each side were placed groups of Orchids, *Dracænas*, and Ferns alternately, which had a good effect. The banks round the tent were occupied by stove and greenhouse and fine-foliaged plants. Groups of specimen zonal Pelargoniums gave colour to the show. The arrangement of the plants as regards general effect was in every way satisfactory—a remark, however, that does not apply to many of the minor details. Lord Aberdare, in opening the show, hoped that it would be a success, not only from a financial point of view, but from that of diffusing a wider taste for the cultivation of flowers amongst people generally.

FLOWERING & FINE-FOLIAGED PLANTS.—On entering the tent, on the left was a fine bank of these from Messrs. Veitch & Sons. Amongst these were noticeable the new hybrid *Zygopetalum Sedeni* (with rich chocolate-petaled flowers and bright purple-spotted lip), the pretty Cinnamon-flowered *Saccolabium curvifolium*, and several fine varieties of *Aerides odoratum*. Specimens of the bright-flowered *Masdevallia Harryana*, furnished with upwards of fifty blossoms, imparted colour to the group. *Rhododendron Maiden's Blush* was well flowered, and R. Duchess of Edinburgh was conspicuous for its brilliant orange-scarlet, waxy blossoms. At each corner of the collection was a fine group of *Begonias*, the flowers of which were exceedingly bright. These were surrounded by such fine-leaved plants as *Croton Hanburyanum*, *Dracæna speciosa*, and the beautiful *Phyllanthus roseo-pictus*. The bold-looking *Anthurium Veitchi* was remarkable for its deep green and bronze deep ribbed leaves, some of which measured nearly 3 ft. long. A plant of the variegated hardy Grass (*Eulalie japonica*) in this group was very effective; and Pitcher Plants, furnished with large pitchers of various shapes, together with numerous bronze, crimson, and green-leaved *Sarracenias* and similar plants, made up a collection of great interest. *Sonchila Hendersoni marmorata*, a garden hybrid from the same firm, was remarkable for its silver-coloured foliage and dwarf, compact habit. *Adiantum speciosum*, from Peru, had large branching fronds and bold pinnæ; and the new *A. cyclosorum*, from New Granada, looked like masses of silvery bronze. *Asparagus virgatus*, as a pot plant, was much admired, on account of its light feathery appearance and deep green colour. This collection contained, moreover, bright-flowered *Gloxinias*, among which were *Vesuvius*, brilliant velvety crimson; *Patrie*, a white-flowered kind with rich purple throat; and *l'Univers*, an unusually large, upright-flowered sort, beautifully speckled with blue, purple, and white. *Disa grandiflora* was here shown off to the best advantage against the white waxy-flowered *Thunia Marshalli* and the fine-leaved *Acalypha Macfeeana*. A stand of small fine-foliaged plants, covered with a bell-glass, attracted much attention. It contained miniature plants of the golden-veined *Anæctochilus setaceus cordatus* (one of the most beautiful of this class of Orchids), *Bertolonia Van Houttei*, *Liparis elegantiissima*, and small-leaved *Marantas*.

Opposite this group was one from Mr. Williams, of Holloway, consisting of fine-foliaged and choice-flowering plants; amongst them were finely-flowered plants of *Dipladenia amabilis* on a balloon-shaped trellis; *Odontoglossum Alexandræ*, furnished with massive spikes of beautifully-spotted crisp blossoms; *Dendrobium devonianum*, and some fine Lilies. The new *Croton Prince of Wales* was shown better in this group than we have hitherto seen it, its long, gracefully drooping, twisted leaves being very bright. The narrow, bronze-leaved *Dracæna lentiginosa* was noticed as being one of the best of plants for table-decoration; and the bright, rosy, purple-flowered *Dendrobium Goldiei*, hitherto known under the name of *D. superbiens*, was much admired, as was also a well-flowered specimen of *D. suavissimum*, and the elegant *Adiantum palmatum*. A panful of the lilac-flowered *Lobelia Lilac Queen* was very pretty, also *Torenia Fournieri*; and the variegated Vine, the white-leaved *Habrothamnus elegans argenteus*, and some new *Dracænas* were very showy.

Near this was one from Messrs. Rollisson & Sons, Tooting, consisting of finely-flowered *Ericas*, such as the white *E. Aitoniana Turnbulli*, *E. venosa*, and *E. Dennisoniana*; also large boxes filled with small, but profusely-flowered plants of *E. Massoni major* and *E. tricolor profusa*. Associated with

these were *Cattleya Leopoldi*, the lemon-yellow *Oncidium sessile*, *Aerides odoratum* loaded with blossom, *Lady's Slippers*, and fine-leaved *Dracænas*.

In a miscellaneous group of plants from the Preston Nursery Company were good examples of *Gymnogramma decomposita*, the white-leaved *Phyllanthus nivosus*, the yellow *Croton volutum*, *C. Queen Victoria*, *Adiantum scutum* and *A. Farleyense*, *Lomaria gibba*, with a stem 4 ft. long, and finely-grown plants of *Cocos Weddelliana*.

NEW PLANTS.—Of these Mr. Bull had a collection, among which the most striking were *Dieffenbachia Shuttleworthi*, a plant of excellent habit with glossy green, pointed leaves, and a band of silvery-white down the mid-rib; *Lomaria discolor bipinnatifida*, a beautifully crested kind; a red-veined *Alocasia* named *A. Johnstoni*; a pretty cut-leaved *Artocarpus* named *exculpta*; and the lace-like *Davallia fijiensis*. Associated with these were also *Philodendron Carderi*, *Dracæna Bijou*, *Croton formosum*, *Anthurium insigne*, *Zamia princeps*, *Dieffenbachia Leopoldi*, *Adiantum princeps*, *Dracæna Goldieana*, *Bowenia spectabilis serrulata*, and *Ixora regina*.

Messrs. Rollisson showed in this class *Dracæna vivicans*, a narrow-leaved variety, bright bronze and rosy-crimson in colour; *D. Smithiana*, a bold looking plant with broad, glossy green leaves; the graceful *Grevillea filicifolia*; a pretty little Tree Fern called *Alsophila Imrayana*, *Anthurium Warocqueanum*, and a new Stag's-horn Fern.

Mr. Williams had *Croton Queen Victoria*, the fine table plant *Pauax laciniatus*, the new *Dracæna Goldieana* and *Berkeleyi*, *Croton Prince of Wales*, and *Dendrobium suavissimum*.

Among new plants exhibited for Mr. Bull's cups, the most striking were the black-leaved *Artocarpus Cannoni*, the fine Fern named *Anemidctyon Phyllitidis tessellatum*, a brilliantly-coloured *Croton* called *C. princeps*, a distinct *Acalypha marginata* with green and bronze leaves edged with deep rose, the double yellow-flowered *Hibiscus rosa-sinensis Colei*, a fine *Aralia* named *filicifolia*, evidently very suitable for dinner-table decoration, *Panax laciniatus*, and *Brahea filamentosa*.

STOVE AND GREENHOUSE PLANTS.—Mr. T. M. Shuttleworth, Preston, furnished probably the most extensive and best grown collection of these ever before exhibited by an amateur grower. It consisted of nearly seventy gigantic specimens of flowering plants. It contained *Allamanda nobilis*, *Ixora Crosseana*, the white-flowered *I. Colei* covered with blossoms, and the brilliantly-coloured *I. coccinea superba*. *Statie profusa* and *S. imbricata* were probably never seen so well flowered as they were in this collection. It also contained a fine specimen of *Lapageria alba* covered with blossoms. The brilliant *Dipladenia Brearleyana* was very conspicuous, and the blue *Plumbago capensis* could be seen from every part of the tent. Among fine-foliaged plants were massive specimens of *Davallia elegans*, *D. Tyermani*, *D. Mooreana*, and fine balloon-shaped plants of *Paullinia thalictrifolia*. *Gleichenia Speluncæ* was represented by a specimen fully 9 ft. through, the fronds being remarkably strong, and the leaves beautifully green, without spot or blemish. *G. rupestris* and *G. microphylla* represented massive mounds of elegant foliage. These were associated with vigorous plants of *Cordalino indivisa*, the fan-leaved *Pritchardia pacifica*, *Cycas revoluta*, the fine basket Fern, *Nephrolepis davallioides*, fine-leaved *Crotons*, *Aralias*, and *Cocos Weddelliana*. The background consisted of grand specimens of the Weeping Tree Fern, *Cibotium Stebboldi*, *Cyathea Burkei*, *Cycas circinalis*, and similar plants.

Of twelve stove and greenhouse plants, an excellent collection came from Messrs. Cole & Son. It contained good plants of *Erica tricolor Wilsoni superba*, *E. retorta major*, and the white *E. Shaunoni*; the white *Ixora Colei*, a finely-flowered *Stephanotis*, *Allamanda cathartica*, and *A. nobilis*. In other collections were finely-flowered plants of *Franciscea calycina major*, the scarlet-spathed *Anthurium Scherzerianum*, the orange and cinnamon-coloured *Ixora amboynensis*, and a specimen of *Dipladenia amabilis* bearing scores of brilliant rosy-pink flowers and buds.

In a group of miscellaneous plants from Messrs. F. & A. Dickson, of Chester, we noticed fine examples of the broad, bronze-leaved *Dracæna Taylori*, variegated Pines, and fine-leaved *Crotons*.

In open classes for sixteen stove and greenhouse plants, in or out of flower, there was considerable competition, and by the flowering plants being mixed up with those distinguished for fine foliage, a better effect was produced than when the two classes of plants are arranged separately. The best group contained a large specimen of *Allamanda grandiflora* completely covered with blossom, which was shown off to advantage between a finely-grown plant of *Gleichenia hecistophylla* and the rosy-flowered *Erica Parmentieri rosea*. A specimen *Anthurium Scherzerianum* was furnished with upwards of thirty large brilliant spathes, and *Clerodendron Balfourii* was a mass of blossom.

FINE-FOLIAGED PLANTS AND FERNS were but sparingly shown. Among them were several fine specimens of *Cycas revoluta*, the white-veined showy-leaved *Anthurium crystallinum*, and the elegant feathery-leaved *Lomatia silaifolia*.

Ferns, which occupied a large sloping bank, were numerous. Amongst them were fine plants of *Gleichenia rupestris*, *G. Mendelli*, the fine lace-like *Pteris scaberula*, golden *Gymnogrammas*, fine plants of *Davallia Mooreana* and *Stag's-horn Ferns*; also the Australian Bird's-nest Fern. We noticed that many of the plants were grown in shallow tubs with handles attached to them, a way in which they are more easily moved from place to place than when in pots.

ORCHIDS.—The best came from the London nurserymen. Mr. B. S. Williams, Holloway, showed finely-flowered specimens of *Cattleya Mendelli* and *C. Leopoldi*, *Cypripedium barbatum speciosum*, the beautiful white *C. niveum*, and the brilliant *Epidendrum vitellinum majus*. A plant of *Dendrobium formosum giganteum* was well furnished with flowers, and *D. Bensonii* was a mass of bloom.

Messrs. Rollisson & Sons had finely-flowered plants of *Cypripedium Parishii*, the curious *Odontoglossum hastilabium*, a fine variety of the showy *Oncidium macranthum*, and a large panful of *Cypripedium niveum*.

In the amateurs' collections were grand plants of *Dendrobium nobile*, *Cattleya Warneri*, and the yellow and cream-coloured *Dendrobium Schroederi*; and several good *Lady's-slippers* were also shown; and we likewise noticed a finely-flowered plant of *Aerides Lobbi Ainsworthianum*, the colour of which was unusually bright and attractive.

Of *Begonias* the best came from Messrs. Laing & Co., Forest Hill, who had well-grown plants of *F. M. Dos Santos Viana*, a bright cinnamon-yellow-flowered sort, with dark velvety-bronze leaves of the *Pearcei* type; *Corail Rose*, a fine rose-coloured flower of fine form; *Gloire de Nancy*, dwarf in habit and completely loaded with bright scarlet flowers as double as those of a *Hollyhock*; *La Baronne Hruby*, rosy-crimson; and *John Laing*, salmon.

Dracaenas were shown in good numbers; they were arranged in isolated groups with excellent effect. Among the best kinds were *D. Baptisti*, a robust sort with rich bronze leaves edged with bright salmon and rose; *D. Gladstonei*, a variety with dark, broad, recurved leaves; and *D. regina*, green and yellow. Messrs. Rollisson & Son, who had the best group in the exhibition, showed *D. amabilis*, *D. Goldiana*, *D. Guilfoylei*, *D. terminalis alba*, *D. Gladstonei*, *D. Salmouea*, and other fine kinds.

Cut flowers were shown in large numbers, especially in the shape of bouquets, none of which, however, were worthy of special remark. Pansies from Messrs. Downie & Laird attracted much attention on account of their bright and varied colours.

Roses were beautifully fresh and fine, and there was the best display, as regards colour, size, and quality of bloom, which we have seen this season. Among good kinds in the first prize collection were *Marguerite de St. Amand*, *Baroness Rothschild*, *Annie Wood*, grand blooms of *Mdlle. Marie Rady* and *Prince Camille de Rohan*. *Charles Lefebvre* was probably never shown finer than it was on this occasion. Messrs. Cranston, Hereford, who had an extensive collection, showed boxes of *Louis Van Houtte*, which were highly commended on account of the size, and rich crimson-scarlet colour of the blossom. It is one of the best dark Roses we have seen this year. *Marie Baumann* was in equally good condition.

In the whole of the collection, which consisted of more than twenty stands, there was scarcely a bad bloom, and more

attention was directed to this part of the show than to any other. The blooms were arranged for effect, and this was gained by giving them room, and by their having plenty of foliage surrounding them. They were awarded a silver medal. Mr. Prince, Oxford, showed *Roses* grown on the seedling *Brier*, fine both in form and colour.

Of *Crotons* there were several fine collections, and being arranged on sloping banks they formed a striking feature. Among those of the *C. angustifolium* type, the most remarkable were *C. Johannis*, *C. majesticum*, and *C. interruptum*. Among those of the pictum and variegatum types, the best were *C. undulatum*, *C. Wiesmanni*, and *C. Queen Victoria*. The curious *C. pecturatum*, with its pendent leaves, attracted much notice; those with tri-lobed leaves were well coloured and distinct.

Of *Heaths* there were only two collections, the best plants in which were *Erica ampullacea*, *E. Aitoniana Trnbulii*, *E. obbata*, and *E. Williamsi*, white kinds; *E. ferruginea*, *E. Paxton*, and *E. Massoni major*, reds; and the yellow *E. Cavendishi*.

FRUIT occupied a large tent specially provided for it. In the competition for Messrs. Veitch's prizes offered for collections of ten varieties of fruit, Mr. Coleman was first with fine examples of *Black Hamburgh Grapes*, large both in bunch and berry, and finely-coloured, beautiful clean examples of *Muscat of Alexandria*, which, however, were hardly ripe; large *Royal George Peaches*, *Black Circassian* and *Bigarreau Cherries*, *Eastnor Castle Melon*, and very fine fruit of *Oxonian Strawberries*, *brown Turkey Figs*, and a *Queen Pine-apple*. In the competition for six kinds Mr. Bannerman, gardener to Lord Bagot, had good *Elruge Nectarines*, *Royal George Peaches*, a finely netted *Reed's hybrid Melon*, and *Muscat of Alexandria Grapes*. The same exhibitor had also the best *Muscat of Alexandria Grapes*, which, though shown in good numbers, were, as a rule, unripe. *Nectarines* and *Peaches* were well shown and in good numbers; the best dish of the former was *Elruge* and the best *Peaches* *Bellegarde*. *Black Grapes* were of average quality, but in many cases they were wanting in colour. The best three bunches (each of which weighed some 2 lb. or 3 lb.) were of fine form, and the berries were large and black and covered with a beautiful bloom. *Pine-apples* consisted chiefly of *Queens* of medium size and well ripened. *Melons* were numerous and good; the best was a green-fleshed *Golden Queen*, the next *Conqueror of Europe* and *Eastnor Castle*. *Strawberries* made a fine display, being large and clean, but they appeared to have suffered from wet. The kinds which won the first prizes were *British Queen*, *Oxonian*, *Frogmore Late*, *President*, *Cockscomb*, and *Dr. Hogg*.

VEGETABLES.—These were shown largely. Mr. Miles had the best collection, consisting of *Stamfordian Tomato*, *Canadian Wonder Bean*, *Culverwell's Telegraph Pea*, *Bayley's Selected Cauliflower*, and *Excelsior Potato*. The best *Cauliflower* was *Rarly London*; the best *Bean*, *Seville Longpod*; and the best *Tomato*, *Stamfordian*. *Peas* made a good display; the finest looking kinds were *Culverwell's Telegraph*, *Laxton's Superlative*, *Laxton's Supreme*, and *Ne Plus Ultra*. *Potatoes* were well shown; the best *Kidneys* were *Mona's Pride*, *Veitch's Ashleaf*, and *Snowflake*; and the best rounds, *Porter's Excelsior*, *Rector of Woodstock*, and *Schoolmaster*. Classes were provided for *Tomatoes* and *Cucumbers*, which brought forth a fine display. *Salads* were comparatively poor.

MISCELLANEOUS EXHIBITS.—Messrs. Little & Ballantyne showed a weeping *Wellingtonia*, which seems likely to prove a valuable addition to choice Conifers. Mr. Pearson showed a collection of *Pelargoniums* of the *Echinatum* type, and first-class certificates were awarded to the following kinds, viz., *Beauty*, *Ariel*, and *Pixie*. Messrs. Cowan contributed remarkably fine examples of *pot Vines* grown from eyes this season.

A list of prizes awarded on the occasion will be found in our advertisement columns.

Table Decorations.—In the report of the fête given the other evening in the Royal Botanic Society's Garden we omitted to state that Messrs. John Mortlock & Co., of Oxford Street, secured two first, one second, and a special prize for table decorations, viz., one first prize for buffet decorations, one first for an epergne dressed with fruit, &c., and one second for a fireplace; also a special prize for three very pretty stands for fruit, &c. Other decorations were also highly commended.

"This is an art
Which does meet Nature: change it rather: but
THE ART ITSELF IS NATURE."—*Shakespeare.*

DINNER TABLE DECORATION.

I do not agree with "J. S. W." on this subject. I do not see how one can compare two so entirely different things as flowers and roast beef; one might just as well compare a butcher's shop with a drawing-room. It is not now the fashion to put any dishes on the table at dinner, everything being helped from the sideboards; and, in spite of what "J. S. W." says about the lady and the Thyme, I venture to assert that flowers are just as suitable for the dining-room as they are for the drawing-room or boudoir. And as for people not "deigning" to notice the flowers and plants on the table until they have finished their dinner, generally almost the first remark that people (especially the fair sex) make when they sit down to dinner is, "How beautiful the flowers are!" or words to that effect. People who do not care about flowers on the table are generally those who care for nothing but eating and drinking, and who at dinner never find time to speak a word to anybody, or give a look at anything beside their own plate, and, I presume, would prefer a table only decorated with plates, knives, and forks to one adorned with Nature in one of her most beautiful forms. I don't see why the fashion of table decoration should go out of the "upper grades of society" because it happens to be made use of at school teas and among the lower grades. It is getting quite common among the lower classes of society for every one to keep a piano, but I should fancy that "J. S. W." would very much object to give up his own on that account. I am sure that if there were to be no table decoration it would be a great loss to the ladies, as one of the pleasures of a dinner party is the exercising of their ingenuity and good taste in arranging the table and decorating it with flowers and plants in the way that will look best. I suppose that, as "J. S. W." prefers a table only covered with eatables and drinkables, he will regret that he is obliged to leave uneaten the plates, &c.; and that as he dislikes anything to distract his attention from eating, he would rather use a perfectly plain white dinner service than one of the beautifully painted sets that are made now-a-days.

F. R. H. S.

— It certainly speaks volumes for your candour and impartiality to allow a diatribe against the use of flowers on the dinner-table to appear in THE GARDEN; but I regret to see it nevertheless, as I cannot but regard such a letter as a retrograde movement in civilization. Why should dining-room table decoration be an incongruity? be indefensible, unnecessary, or a deprivation of luxury? Does your correspondent assert that it is so because it tends to divert the mind from the all-important business of dining? If that be so, it would be no great stretch of his argument to assert that all dining-room decoration should also be annihilated, and that all pictures, plate, and ornaments of every kind should be banished, and the room be made as naked and uncomfortable as possible. One's mind recoils from such an idea. Just fancy a room with a carpet (even if the argument would allow a carpet), but no pattern thereon, equally plain walls, and a table with only the necessary number of plates, knives, and forks. What would become of the designs in the damask tablecloth and napkins? Surely they are also an incongruity, and could not be allowed, and the glass would be destitute of ornament to match—nothing whatever to impede the dinner! The "sturdy old English gentleman" would have a fine time of it, and his dinner could proceed without any "protest" at all. But I maintain that, unless very much overdone, the use of flowers at meals is no incongruity, but a very material help to rendering the meal agreeable and healthful—as giving pleasure to the eye and the higher senses, affording a charming subject for conversation, and so, I verily believe, assisting a healthy digestion. A well-laid dinner-table will have no flowers on it that will incommode the guests; but why the use of flowers is to go out of fashion and be vulgar, because the vulgarity of some people makes them overload their tables, is more than I can see; and it would be no more absurd to prevent your son from learning to read or wear a hat or shoes because the lower orders did so than it would be to banish flowers from the dinner-table because they were in vogue in the servants' hall or were used at school treats.—J. L.

— I have read with much interest "J. S. W.'s" remarks (see p. 25) on this subject, and I feel very strongly that those who entertain his views are much to be pitied, since the fashion of the present day shows so little consideration for their feelings. It is beside the mark

to talk of artistic taste when a steaming, savoury sucking pig stands before us. No doubt there is nothing in its way to compare, for effect on a dinner-table, with a silver soup tureen, balanced at the other end by a grand cover which hides a fine bit of fish; and then four flat, covered, silver, quadrangular basins, containing made dishes of cooked-up meats, and surrounding an iced plum cake covered with the flags of all nations. It is under such circumstances alone that the worthy entertainer can say, "You see your dinner." It is only under such circumstances that one has any chance of seeing the beautiful designs on the table-cloth, or that a clever waiter has an opportunity of so spilling the gravy as to make a map of Australia or of some other recognisable island. What are a few paltry flowers which any one could stick into a bowl compared with such a display as this? I can tell "J. S. W." how he can quickly put an end, as far as he is concerned, to all "this table decoration business," this "depravation of luxury," this "indefensible, unnecessary incongruity." Let him use in his table vases several blooms of *Lilium auratum* and *Arum Draconculus*, with some elegant *Aristolochias* (in flower) hanging over and twining round the glass stems of the vases; and let his flat decorations consist of *Stapelias*, their lovely chocolate and black blossoms being set off by close proximity to the delicate white cellular tissue of *Phallus impudicus*, garnished with the leaves of crisped *Tansy* slightly bruised. If this does not release him from all trouble in the matter of floral table decoration, at once and for the future, I'll eat him.—W. T. T.

— The remark (see p. 3) that table decorations do not seem to be improving is calculated to give us hope that they will be done away with altogether. This would be the best improvement that could be effected. I have certainly had very little to do with dinner table decoration, but I think that flowers used so much on dinner tables is a vulgar practice which will very soon go out of fashion. If people will have decoration let it be on sideboards or in vases. I used to have to decorate a dining room in Paris where nothing was used but fruiting plants, and if we had none in fruit no other plants were used; but there is such a variety of fruiting plants in the way of Oranges, Pines, and even commoner plants, that something fruiting may be had all the year round. In winter hardy berried plants might be used on the candelabra.—H. K.

MESEMBRYANTHEMUM EDULE HARDY.

THIS is one of the noblest of the almost innumerable family of Fig Marigolds. The merits of the *Mesembryanthemum* for the summer decoration of rockwork have been long recognised, and justly; for what with their endless diversity of form, power of resisting the most intense drought, and the metallic lustre of their gorgeous flowers—white, orange, rose, pink, crimson—they have few equals for that purpose. Nevertheless, Fig Marigolds are too little appreciated. They are children of the sun; and a rockery devoted solely to a collection of them, in an open, sunny spot, is a sight worth seeing, and one which can only be compared to a pyrotechnic display of variously coloured fire. A situation where the soil consists of little else than sand and gravel suits them perfectly. The species with which I have headed these remarks is, perhaps, one of the holdest-looking and most striking of the whole family. Its massive, prostrate stems and large, fat-looking leaves ramble about in all directions, something after the manner of the New Zealand Spinach (*Tetragona expansa*)—just the plant to ramble and sprawl amongst blocks of stone, where a Nettle or a Thistle could not possibly live; and, owing to the very great weight of its succulent leaves and branches, it would be just the plant for a vase in a windy, exposed situation. It is perfectly hardy; indeed, it is scarcely known how very many of this almost innumerable family are truly hardy—perhaps upwards of a hundred would be found to survive our winters. Amongst the limited number which I have grown, the following are hardy, viz, *M. cuceifolium*, edule, Taylori, acutangulum, glaucum, foliosum, and others. Those who possess a large collection should turn the whole out on banks or rockwork, and leave them there, taking cuttings off them yearly for next season's supply. They attain characters out-of-doors never seen in pots. The foliage of the whole family is singular and diversified, and I should say, as a massing plant, the deeply glaucous, almost silvery *M. deltoides* would be most valuable.

THOMAS WILLIAMS.

Ormskirck.

[One of the most valuable and suggestive communications we have had respecting hardy plants. The beauty of the

creeping Mesembryanthemums in countries a little warmer than our own has often surprised and delighted us, but we did not know that so many were hardy in England. What a lovely drapery for the sunny sides of old walls!—Ed.]

HARDY WATER LILIES.

EVERYONE knows and appreciates that queen of native wild flowers, the common white Water Lily; but my object now is to bring into notice other less common kinds, which, from their diversity of form and colour, are equally valuable. Their culture is of the simplest kind, for, if properly planted at first, they seldom give any further trouble. Where it is convenient to drain off the water, the best mode of planting the larger kinds is to make a hillock of a compost consisting of good loam and a small quantity of well-decomposed manure and river sand; on the surface of this place some large stones to prevent the soil from being removed by the water. In this hillock place the plant so that the depth from its crown to the surface of the water may not exceed 2 ft. If there be no means of lowering the water, the best substitute is to put the plants into large baskets and to sink them to the proper depth. If the bottom be of a gravelly nature the plants will not spread much, but if otherwise they should be kept within bounds, or they will soon grow into a mass which tends to considerably mar the effect, as shown in the form of isolated patches. In the case of young plants and the small-growing kinds enumerated below it is advisable to keep them in small baskets and in shallow water. There are about eighteen half-hardy Water Lilies in cultivation at the present time. The majority belong to the genus *Nymphæa*, and the remainder to the genus *Nuphar*. Of the native kinds, which need no description, there are three varieties, which are very distinct. The minor form is very interesting on account of its small size, the blossoms being but $1\frac{1}{2}$ in. to 2 in. across, with the leaves small in proportion. The variety *candida* is a form intermediate in size between the two preceding. The rose-coloured variety (*N. alba* var. *rosea*) is a plant which has excited much interest ever since it first expanded its lovely blossoms, a short time ago in the open air at Kew, being the first time of flowering in this country. It is said to have originated in a solitary lake in Sweden, from whence it was taken to one of the Swedish botanic gardens, which is doubtless the source of the Kew plants. It is destined to become as common as the white one, and, in company with it and other aquatics, it will produce a charming effect. The North American species, *N. odorata*, is a very near ally to *N. alba*, but the most perceptible distinction between them is the larger blossoms, which measure from 6 in. to 9 in. across, and which are very sweet-scented. The veins on the under sides of the leaves are also much more raised above the surface. The flowers of this kind, too, have a decided tendency to assume a red colour, and the full development of this is admirably shown in the rose-coloured variety (*N. odorata* var. *rosea*, or *N. odorata* var. *minor* of some), as the flowers are much smaller than those of the type. It is a source of much pleasure to hear that living plants of this beautiful variety have recently been imported into this country from the North American lakes. The variety *maxima* differs from the type only in having larger flowers. The variety *reniformis* has the lobes of the leaf much rounded, so as to assume a kidney shape, but there is no difference in the flower. The type of the sweet-scented Water Lily was introduced into this country in 1786, but it is not so common now as it deserves to be. It requires precisely the same treatment as *N. alba*, and will be found to be quite as hardy in the southern counties. The tuberous-rooted *Nymphæa* (*N. tuberosa*) is also a native of North America, and much resembles our native kind, but differs from it principally in having tubers developed on the roots which spontaneously detach themselves from the plant, and so afford a ready means of propagation. The shining-leaved Water Lily (*N. nitida*) is also a near relative of *N. alba*, but has very shining leaves, and blossoms not so large and scentless. It inhabits the lakes and still waters of Siberia, and also the River Lena. This kind, and also the preceding, can be obtained from nurseries in which hardy plants are made

a speciality. The pigmy Water Lily (*N. pygmaea*) is a native of China and some parts of Siberia. It is the smallest of all, having leaves not more than 2 in. across and very small flowers. It is very rare in cultivation, but I noticed it at Kew in company with other kinds. The most interesting of all the *Nymphæas* is, perhaps, the yellow-flowered kind *N. flava*, on account of its colour, as in no other sort, either tropical or temperate, is it found. I have not seen the flowers, but I am pleased to hear that living plants have just been imported into this country from *N. America*. The common yellow Water Lily belongs to the genus *Nuphar*, of which we have one species, *N. lutea*, which inhabits many of our lakes and slow-running rivers in abundance, and, therefore, is too well known to need description. It has a very interesting miniature variety called *pumila* or *minima*, which is found wild in some of the Highland lakes of Scotland. It is considerably smaller in all its parts than the type, and also possesses the same vinous perfume. The stranger or three-coloured *Nuphar* (*N. advena*) is the North American representative of our yellow Water Lily; it nearly approaches it in general aspect, but it may be at once distinguished by its larger size and the leaves standing erect out of the water if it be shallow. The blossoms are larger and the same in colour outside, but the cone of stamens in the centre is of a brighter red. It was introduced in 1772, and is rather common in cultivation now. *N. Kalmiana*, also a North American kind, much resembles the small variety of *N. lutea*, and is a very interesting plant to grow in company with it. There is another kind, the arrow-leaved *Nuphar* (*N. sagittifolia*), but I doubt if the true plant is at present in cultivation in this country.

W.

Campanula nobilis.—In last week's issue of THE GARDEN (see p. 28) mention is made of a plant with the above name, which must be an error. The plant which "S." had in view when writing his note appears to have been *Campanula grandis*, not *nobilis*. The latter has no spike, but a few large drooping bells of a dull, indescribable colour, something between dull mauve and dirty violet, and is more singular than handsome, the beauty of the flowers (what little they have) being the spotted interior of the bells. Like the *Rapunculus* tribe, it is weedy; what is known as *C. punctata* appears to be a white variety of it, and *C. Van Houttei* is probably an hybrid. *C. grandis*, the plant passing as *nobilis*, is totally different, and has a habit like that of *C. pyramidalis*; it bears a profusion of large, blue, salver-shaped flowers, and, when well managed, is even superior to *C. pyramidalis*, owing to its certainty of flowering. Lift the old plants in August, select the strongest, grow them on well till winter, and pot them in rich earth for conservatory decoration, and plant the remainder out in the borders. Owing to its very dense mode of growth, if not often lifted and separated, it is seldom satisfactory. A well-grown potful of this fine plant is most effective.—T. WILLIAMS, Ormskirk.

The Preston Show of the Royal Horticultural Society.—This is said to have been a disastrous failure financially. What else could have been expected from the selection of such a place for a national show in presence of the fact that some really great centres, where horticulture is very popular, were open to the Society? Correspondents complain to us of being charged from four to six times the usual prices for rooms in the inns, a fact which speaks sufficiently of the character of the place. In such towns as Birmingham, when similar shows were held, no such extortion was practised. The selection of such a place may have benefited a few private individuals, but not horticulture.

The American Star Grass (*Aletris farinosa*).—This rare and pretty hardy dwarf perennial may now be seen in flower in the Kew collection. Although not very showy, it is, nevertheless, very interesting. The leaves are lance-shaped and ribbed, and form numerous tufts, from the centre of which spring the flower-stems. The latter are from 15 in. to 18 in. high, on which are densely arranged the pure white, bell-shaped flowers, which are about $\frac{1}{2}$ in. in length. The outside of the blossom is very much wrinkled, which gives it a mealy appearance; hence its specific name. It is also interesting on account of its being the only hardy plant belonging to the Blood-root family (*Hæmodoracææ*). A cool and deep peat soil with partial shade seems to suit its requirements.—A.

Mr. ENXOWS, of Little Bridge, has recently built a series of excellent spanned houses for Mr. W. Ball in his new nursery at Chelsea. It consists of eighteen houses, and although the building commenced not more than nine months ago, the work was so well and promptly done that the houses are already well stocked with new plants.

NOTES OF THE WEEK.

Florists' Flowers in London.—We have been surprised and pleased during the week at seeing the superb collection of Carnations and Picotees blooming in Mr. Dodwell's garden at Clapham Rise, in a crowded part of the town, and with a busy railway running by. Mr. Dodwell is perhaps the best known of any amateur florist to readers of gardening literature; he has grown his flowers with great success in various parts of the country, but never more so than in his small garden at Clapham Rise. Of course, the choicer Carnations and Picotees are bloomed in glass structures, in which, however, they are reached by the "blacks;" but a great number of seedling plants bloom in the open air in the beds in which they passed the winter. In days when success with vigorous and very ordinary shrubs in London is thought worthy of record, it may encourage many to know what one of the acknowledged leaders among florists has done with flowers known to require good culture and much care to bring them to the standard of perfection recognised by florists.

Lord Napier Nectarine.—This large and handsome fruit has recently been in fine condition in Messrs. Rivers' orchard houses at Sawbridgeworth. It is one of the most valuable of the recent gains in new fruits.

Centaurea macrocephala.—This plant is now in full flower here, in the form of large masses 3 ft. or 10 ft. wide and 4 ft. high, crowned with great golden ball-like flower-heads, which are very ornamental. It would make a good plant for the wild garden.—T. SMITH, *Newry*.

Delphinium George Taylor.—This Larkspur is one of the many handsome ones now in Mr. Ware's collection. These plants, above all other hardy ones, need no praise; but they deserve to be more grown than they are, owing to their incomparable shades of blue and purple—a wondrous gift of colour, which only the humming birds share with them.

A Black Panay.—The St. Osyth Black Pansy is a very valuable plant, and is a very rich black with a small yellow eye. It is a most useful and distinct variety, and the more particularly so from the fact that Messrs. Carter have, by careful selection for a number of years, succeeded in establishing it as a race coming true from seed. Those who know the way in which Pansies sport from seed will know how to value this quality.

Salvia gigantea.—This is one of the handsomest hardy plants in flower here. It has large, rugose leaves and partially drooping terminal spikes of pale mauve-coloured bracts, very much resembling the inflorescence of some *Bougainvillea*. It grows about 4 ft. high, and nearly half of that height is floriferous, making it altogether a most distinct and striking plant.—T. SMITH, *Newry*. [Is it not a variety of *S. Sclarea*?—Ed.]

Hardy Red Water Lily.—The Red Water Lily (*Nymphaea alba rosea*) is in the hands of Messrs. Fröbel & Co., nurserymen, Neumünster, Zurich, Switzerland, but whether they have as yet sent it out is more than we can say with certainty. Fröbel's plants are planted out in a lake, and they speak in the highest terms of their beauty. They say that it is worth going to Switzerland to see them. Since writing the above we see that Messrs. E. G. Henderson offer plants of it for sale.

Lobelia Omen.—This is a pretty *Lobelia* of the *pumila* type; it is a kind that does well in good soil, and, if kept moist, it will continue in flower much longer than some kinds. Its flowers are purplish-pink, a colour which contrasts well with blue-flowered sorts. Many of these, as well as that first named, may now be seen in fine condition in the Royal Exotic Nursery, Chelsea.

Dendrobium barbatulum grandiflorum.—This pretty white-flowered Dendrobe is now in flower in Mr. Bull's nursery, Chelsea. Grown on small, flat pieces of wood, its slender flower-spikes droop gracefully from the pseudo-bulbs, and its silky, white, transparent blossoms rank amongst those of the choicest of Orchids now in bloom.

A New Dendrobe.—Under the name of *D. d'Albertisi* we find a pretty little Dendrobe in the Holloway Nurseries. It is a native of New Guinea, and is one of four species which form a rare and distinct group of Orchids. The pseudo-bulbs at the base are round, afterwards thickening, and becoming four-sided or square, and finally tapering to a sharp point. It is a profuse bloomer, the long slender flower-stalks being emitted all the way up well-ripened bulbs. The flowers, which are small, are interesting and distinct. The petals are pure white and waxy, and the lip is striped with claret and purple, forming a pleasing contrast to the pair of narrow horn-like, green sepals with which each flower is furnished. Though by no means a showy variety, it is well worth adding to good collections of Orchids.

A Sky-blue Daisy.—*Bellis rotundifolia cœrulea*, now in flower, really deserves the above English name, the colour of the ray reminding one of the much admired sky-blue variety of the Wood Anemone. This Daisy is a very delicate and pretty rock plant and grows freely from seed, which is offered, we believe, in some of the catalogues.

Compass Plants.—One of these now in flower (*Silphium conatum*) is a very showy, Sunflower-like plant with a stately and large habit of growth. No border of the mixed type could contain such a giant, which, however, is one of those plants which first suggested the idea of the "wild garden," in which it will be found at home among the most vigorous plants. It thrives and flowers freely on the worst clay soils known to the writer.

Spiræa callosa alba.—This is a white-flowered variety of this the best of all shrubby *Spiræas*. Its flowers are larger than those of the type, and they last even longer in good condition. Like *S. callosa*, it can doubtless be readily raised from seed. It is a rapid grower, and plants of it from 3 ft. to 5 ft. through when laden with masses of white blossoms are very ornamental in shrubbery borders. We lately saw fine plants of it in Messrs. Veitch's Coombe Wood Nursery.

The White-flowered Oleander.—This is largely grown by Mr. Wills for decorative purposes. The plants, which are chiefly imported ones, are grown in a moist, warm temperature near the glass, and thus treated they make handsome bushy plants loaded with large trusses of snowy blossoms. This white variety appears to flower more freely than the rose-coloured kind, and its blossoms in a hot state are much more valuable.

Pitcher-plants at Chelsea.—The house devoted to Pitcher-plants in Messrs. Veitch's nursery will shortly be worth a visit. It contains hundreds of plants of such *Nepenthes* as *N. Rafflesiana*, *Hookeri*, *Sedeni*, *intermedia*, and a few of the new kind called *Courti*. These are laden with pitchers, now increasing in size rapidly.

A Continuous-flowering Orchid.—A well-flowered specimen of the brilliant orange-scarlet-flowered *Epidendrum vitellinum majus*, in the Holloway Nurseries, serves to illustrate the great value and lasting qualities of this Orchid. The plant in question was in bloom in May, and, after having been exhibited at Regent's Park, South Kensington, Manchester, Preston, and other shows, it still remains in good condition, and will, to all appearance, last for several weeks yet. Such plants as this can scarcely be too highly valued.

Ceanothus Arnoldi.—This is just now remarkably showy on a wall in Messrs. Veitch's nursery at Coombe Wood. It grows freely and yields in abundance large trusses of delicate pink blossoms. Either as a wall plant or as a bush it is one of the finest of the *Ceanothuses*, and might be cultivated largely with advantage.

Croton Prince of Wales.—Amongst new *Crotouns* raised of late years few are so ornamental as this one. Its leaves, which are prettily curled and from 1½ ft. to 2 ft. long, assume a gracefully drooping habit, and are marked with the richest golden, crimson, green, and rose colours. As a dinner-table plant this *Croton* will, no doubt, soon become popular.

Carnations and Picotees.—A collection consisting of some of the best of these is now in flower in a greenhouse in Messrs. Veitch's nursery, Chelsea. It comprises many kinds not often seen, and all of them are of fine form and colour. A large bed out-of-doors, too, is very attractive, many of the newer as well as the older kinds being represented. The value of Carnations for border decoration is not so well understood as it ought to be, and there are now many kinds which succeed best in this way, and which, at this season of the year, produce a fine effect, as well as furnish choice flowers for cutting.—S.

Weigela amabilis aurea.—This beautiful golden-leaved form of a well-known flowering shrub is destined to play an important part in ornamental shrubberies. Its flowers are similar to those of the type, and are as freely produced, but in its golden leafage lies its chief value. For planting in large, rough shrubberies it will not be found so suitable as the golden-leaved Elder, but for introducing into small clumps of shrubs on lawns it is one of the best plants which we have seen for some time. It would also make a capital pot plant for the cool conservatory.

Spiræa palmata in Masses.—The fine effect produced by planting this *Spiræa* in masses is fully realised in the form of large beds of it growing under trees in Messrs. Veitch's nursery at Coombe Wood. It is in full flower, and when seen from elevated parts of the grounds is very effective. Its branching plumes of deep rose-coloured blossoms are large and fine, owing to its being planted in deep, rich, moist sandy soil. *S. venusta* grows rather taller than *S. palmata*. Its blossoms are, however, not nearly so bright in colour, but they last longer than those of *palmata*.

NOTES FROM KEW.

Hardy Herbaceous Plants.—Two of the most distinct and obarming of the perennial Larkspurs are *Delphinium cardinale* and *D. nudicaule*; the former grows 4 ft. or more in height, and the latter about half that size, while the flowers of both are scarlet, though brightest and deepest in *D. cardinale*. *Cimicifuga racemosa*, a stately perennial from the United States, has white flowers, and attains a height of more than 6 ft.; *C. Serpentaria*, with greenish-white flowers, has more finely-cut leaves, and is nearly as tall as its congener. *Hypericum Coris* has Heath-like leaves and a profusion of yellow flowers, and is one of the prettiest of the smaller-growing St. John's-worts. *Arenaria gypsophylloides viscosa*—if we mistake not, one of the recent introductions from Central Asia, which we owe to the zeal and industry of the Russian naturalists—is an elegant plant about 15 in. high; the white flowers are borne in rather flat, branching panicles, and the long, pointed, narrow leaves are a greyish-green. *Galaga persica*, an eastern member of the Pea family, is a fine plant with pinnate leaves, and grows 6 ft. or 7 ft. high; the profusion of upright racemes of pure white blossoms renders it a very interesting kind. A Continental form of the common purple Loosestrife of our river banks and marshes (*Lythrum Salicaria grandiflorum*) is very striking on account of the much longer spikes of larger and more deeply-coloured flowers than are possessed by any of our indigenous varieties. In *L. virgatum* is combined much elegance and beauty; it grows between 2 ft. and 3 ft. high, and has narrow leaves and red flowers. One of the European Willow-herbs (*Epilobium Dodonæi*) is a neat, compact kind about 2 ft. high; it has leaves much like those of Rosemary, and from that peculiarity its now generally accepted name, *E. rosmarinifolium*, has been given. With the Rosemary-like foliage are associated deep rose-coloured flowers. *Pentstemon heterophyllus*, 1 ft. high, produces abundantly its showy blossoms, which are purplish, with deep blue blotches on the outside of the tube. *P. spectabilis*, double the height of last-named, has broad leaves and long, narrow-tubed, scarlet flowers. *P. Richardsonianus*, with deeply-cut leaves and purple blossoms, is a good, free-flowering kind growing from 2 ft. to 3 ft. high. *Campanula macrostyla*, for figure of which see THE GARDEN of September 1, 1877, is not less curious than beautiful; its large, upright, bell-shaped, dark purplish-netted flowers are very attractive, and the whole plant differs much from any other member of the genus we have seen in cultivation. A Texas perennial (*Echinacea angustifolia*) has foliage much like that of the narrow-leaved Rib Grass, and large, handsome flower-heads, 3 in. in diameter, borne singly on stems rather more than 1 ft. high, the long ray florets being of a deep rose colour, and those of the disc a dark blood-red. One of the finest of the *Hedysarums* is *H. Mackenzii*, a fine American species, and a recent and charming addition to British gardens; it grows about 18 in. high, and has pinnate leaves and long upright racemes of purple-pink flowers. This is a very desirable perennial worthy of a place in the most select collections of herbaceous plants. A prettier and more uncommon kind than its European relative is the American *Gratiola quadridentata*, a neat little plant about 6 in. high, with narrow leaves and an abundance of white flowers. *Lysimachia atropurpurea*, with its dark purple blossoms, is a fine sort worth growing for itself, though scarcely so beautiful as some of the other species of the genus which have already been noted. *Stobæa purpurea*, a handsome Composite from the Cape of Good Hope, has Thistle-like, spiny leaves, and winged, spiny stems 3 ft. in height; the flower-heads, 3 in. across, are light purple, changing to white.

Stove Plants.—*Cassia glauca*, an East Indian shrub, with doubly pinnate, Fern-like leaves and stalked, globular heads of white flowers, is a handsome kind and an easily-managed and useful one for the decoration of the stove or warm greenhouse. A South African bush, *Bauhinia natalensis*, has conspicuous flowers, pure white with the exception of a crimson vein in the centre of each of the three upper petals; this makes a pretty and compact pot plant, and does not at all resemble some of the other members of the genus, which are huge, large-leaved climbers that reach the tops of high trees in the Tropics.—†

Hardy Plant Gardens.—You must have felt great pleasure, as I have, when visiting the nurseries round London where hardy plants are made a speciality, in finding how many beautiful new species have been introduced and how many old treasures recovered. I occasionally get a hurried run through the Tooting Nurseries, Mr. Parker's, Mr. Barr's, and Messrs. Rollissons', and see interesting and beautiful plants new to me, and find that the freemasonry which happily exists among all classes of growers of hardy plants leads to an amount of attention which, as only a small customer, I could not otherwise expect. Last week, for the first time for some years, I found myself at Tottenham. It was a day to be marked with a white

stoue; all went well. Having a genial companion full of information, a dusty half-hour's walk from the station only prepared us for more fully enjoying what was to come—a hospitable reception at the house of a relative with one of those beautiful picturesque gardens of old days which are one by one disappearing before the advance of bricks and mortar. We were then taken to an amateur's collection of Orchids, which, by the size and health of the plants, reminded me of Mr. Ruoker's collection in old days—rare Orchids, not in single plants, but by dozens. Some beautiful species were in bloom; in the full flowering season the sight must be splendid. We then went to Mr. Ware's, and, under the guidance of Mr. Perry, had a real treat. He certainly has, to say the least, no advantage of situation, but makes the plants under his charge grow beautifully. I was especially struck with the Cape and Californian plants. Many of the tall herbaceous plants were very fine, and one plant of *Sparaxis pulcherrima* was a picture. The Lilies were very good; *L. pardalinum*, *L. californicum*, *L. longiflorum* in its different varieties, and *L. Szovitzianum* were over, but the tall, stout stems and large seed-pods reminded me of those grown in Edinburgh. Altogether, the garden is a most interesting one.—G. F. WILSON, *Heatherbank, Weybridge.*

A GARDEN COVERED WAY.

The illustration on the opposite page shows a very successful covered way in Mr. Noble's garden at Park Place, Henley-on-Thames. The gardener's house is placed between two ranges of glass. The covered way connects the two, and leaves a space in front of the house protected. Beneath the glass roof of this and clustering round the pillars are various plants which thrive

with such protection better than in the open garden. The effect from the garden is very good, and the plan is in all ways so successful that it would seem worth adopting in other situations besides the one now illustrated. The above cut shows the covered way in relation to the glasshouses on each side. The whole is very tastefully garlanded with plants by Mr. Stanton.

Begonias Planted Out.—Tuberous-rooted Begonias may with little protection be left in the ground all winter, and in that case they throw up shoots early in the season, and are effective sooner than those planted in the spring. By the latter method, however, if the soil be deep, moist, and rich, and in a warm, sunny spot, under a south wall or sheltered by trees and shrubs, a good display may be had from July to October. Mulching during hot weather greatly facilitates growth, and consequently bloom; and if planted alternately with blue, white, or yellow Violas, the result is most satisfactory.—S.

Climbing Roses and Holly.—A very pretty effect is produced in a small garden near London by a large specimen Holly being over-run with Roses. The Holly still retains a profusion of berries, part of last year's crop, and the Roses, which consist of the common white-clustered Damask, form a striking contrast with the red and green of the fruit and leaves. Although the practice of overrunning trees and shrubs with climbers may not in every case be advisable, yet, in this instance, neither Roses or Holly trees appear to be injured by the union. A silver-variegated Holly, near the one alluded to, over-run with striped York and Lancaster Roses, is also an effective object.—C. S.

Muhlenbeckias.—For covering trellis work or for isolated specimens on stumps, &c., these graceful and free-growing evergreen trailers are invaluable; in fact, they present an appearance not obtainable in any other class of hardy plants. The kinds in cultivation are all natives of New Zealand. The best known is *M. complexa*, which is a very rapid grower, with long, wiry, and entangled branches bearing minute oval-shaped leaves. The flowers are rather inconspicuous, being white and of a waxy substance, about ½ in. across. *M. adpressa* is larger in all its parts than the preceding, bearing heart-shaped leaves and long racemes of whitish flowers. *M. varia* is a small-growing kind, with fiddle-shaped leaves and very distinct from either of the above. They are very indifferent as to quality of the soil, but grow best in a rich compost.—A.

ROSES.

HAPPY HOURS.

THEY who love the beautiful, and who live in London or near it, may have a large happiness at a small cost if they will betake themselves to the station in Liverpool Street, and purchase a return ticket (price, for second class carriages, half-a-crown) to Waltham. Arriving, they will pass at once from the platform into the very interesting and extensive grounds belonging to Mr. William Paul, and will find themselves suddenly surrounded by a manifold and delightful variety of "things pleasant to the eye." Walking up a broad way of level, close-cut sward, they will see to the right and left not only Roses in abundance, old and new (from *the* Madame Plantier, before which Sir Joseph Paxton sat himself down that he might admire her beauty in a long and leisurely enjoyment, to the last belle of the season), but also the "pictorial trees," trees grown for the purpose of diversifying and lighting up our sombre shrubberies—golden Oaks, Chestnuts, Sycamores, Elders, Ashes, Acacias, Yews; silvery Maples, Poplars, Osmanthus, Hollies; trees beautiful for their foliage, and trees beautiful for their flowers; evergreen and deciduous, high and low. There you may learn, if you please, for Mr. Paul, or his son, or one of his staff, will tell and show you all; how old favourites among the Roses are multiplied out-of-doors by the acre in the budding grounds, and indoors, that is, under glass, by the thousand (you may see that number of Niphetos and Maréchal Niel together, and in the perfection of cleanly health), and also how new favourites are obtained; and of the latter

A Garden Covered Way (see p. 56).

I would advise you not to forget May Quennel, a grand acquisition (the best seedling Rose I have seen this year), and the Countess of Rosebery. And then you must go on, some mile and a half, on wheels or feet, as you prefer, to Cheshunt, and there Mr. George Paul will dazzle your eyes and bewilder your brain with beauty. He will show you that which has been your ideal and dream, but which, in all probability, you have never seen, the Rose in her complete, unblemished prime. You may have met with her very lovely at the shows, but there something of the freshness is always wanting. Here, in her first home and beauty, you see the Rose. And why? I know the answer which the inexperienced make. "Oh!" they say, "on this fertile plain of rich alluvial soil, sheltered but not overshadowed, you must have Roses. Dip a walking-stick in Rose-water, and plant it here, and it will produce you beautiful flowers." No doubt the soil is genial, no doubt the position is propitious, but you must have something more. The walking-stick reminds me of a story, how a clergyman borrowed a sermon which had much impressed him and the congregation to whom it was addressed, preached it, and returned it to the author with the remark that it had not interested his people more than one of his own discourses.

To which the reply was sent—"Dear Sir, I lent you my fiddle, but I could not send you the stick." You must have the mind, the man, to do anything excellent; and whoever hears George Paul speak about Roses, or sees the reverent love with which he handles them, knows at once the source of the success. And this success is, perhaps, most strikingly demonstrated in the glorious Roses born and bred at Cheshunt. Nothing can exceed in rich, glowing brilliancy the Duke of Edinburgh, Reynolds Hole, Sultan of Zanzibar, and others as seen in the Rose fields of Cheshunt when the sun is westering to its close, or when morn in the bright wake of the morning star comes furrowing all the Orient into gold. I thought, as I came back to London with a brother rosarian well pleased as I, how much more happily and healthfully to body and spirit an evening might be spent (as ours had been) than in hot dining-rooms or gas-tainted theatres, and carrying away bright Roses and yet brighter, because more lasting, memories. I pitied the poor folks who were fuming and fanning in the crowded tents of Vanity Fair, vainly striving to suppress those persistent yawns, which say, as plainly as Mariana's words, "I am a-weary, a-weary; I wish I was in bed." S. REYNOLDS HOLE.

CUTTINGS OF ROSES.

THERE can be but little question that for most purposes, and with far the greater number of the varieties of Roses in cultivation, they are much better grown on their own roots than either budded or grafted. The fact that comparatively so few Roses are met with on their own roots may be attributed to two causes, the first of which is that by budding and grafting many more plants may be made of a scarce new variety than can

be done by cuttings, and also that the plants when on suitable stocks can be sooner had, not only in a condition to bloom, but in a shorter time attain a size to produce flowers freely. In the cutting-striking of Roses, in the manner often practised at this time of the year from half-ripened shoots, there is a good deal of uncertainty, a considerable portion turning brown and dying off instead of forming roots. The method frequently pursued is to take a number of the half-matured shoots reduce them to a couple of eyes, insert them in cutting pots, and at once place them in bottom-heat. To the latter cause is attributable many of the cuttings failing to grow, as, unlike plants of a softer nature, in this way they are too much hurried. If, instead of at once putting them in bottom-heat, the pots containing the cuttings were placed for about three weeks in a cold frame on a bed of ashes, so as to exclude worms, and kept closely shut up, they would do better. When the sun is very powerful the frame should be shaded with a mat and a little air should be given, but not so much as to make the leaves flag. As a further preventive of this, too, the soil in the pots should be kept moist by syringing overhead daily in hot weather, and the surface on which they stand should also be well moistened. Treated in this way, in the course of the

time stated almost every cutting will be found to have formed a callus at the base; and when this exists they may be at once put in a moderate heat, when very few will fail to strike directly. When fairly rooted give more air, gradually dispense with the shading, and pot them off singly, but they must be kept for some time sufficiently warm to further the development of as great an amount of roots as possible before winter, for on this, in a great measure, depends the size and strength which the plants will be able to attain the ensuing summer. For propagating in this manner, cuttings should be put in without delay, otherwise the season gets so far advanced that there is not enough time for them to become established singly in pots, and that necessitates their being kept in cutting pans through the winter; consequently, their being potted singly is deferred until spring, when the disturbance of the roots interferes with their progress. Another matter that has a great deal to do with the plants attaining a useful size in the least possible time, and which, with many, is a matter of the greatest importance, is that the cuttings be had as large as they can be got consistent with the requisite condition of the wood. As I have said, it should consist of shoots in a half-ripened state, but instead of reducing them to small bits with a couple of eyes each, if they can be had 6 in. or 7 in. long all the better. Insert them at least 2 in. deep in the pots, in which way they are less likely to get disturbed than when they have not so much hold of the soil. Stout Rose cuttings such as these will make plants in half the time that small weakly bits will, just in the same way that the strong mature shoots taken off plants late in the autumn and made into cuttings 8 in. or 10 in. long, and inserted well in the ground in cold frames or other slight protection, make plants so much sooner than cuttings not more than half the size. The pots must be sufficiently drained, and the soil should consist of about one-half finely-sifted loam to an equal quantity of sand well incorporated. Before putting in the cuttings see that they are quite clear from mildew and aphides, as, should either of these exist, they attack the young growth as soon as it is formed, and prevent any satisfactory progress being made. A little Tobacco water, sufficiently strong to kill the aphides, with Gishurst at the rate of 2 oz. to the gallon added, will exterminate the mildew. Dip the cuttings in clean water before placing them in the pots, as I have found that Tobacco water or any similar mixture in which cuttings are immersed sometimes affects their striking.

PLANTING OUT ROSES FROM POTS—Where any alteration has to be made in the planting of Roses against walls, rustic fences, pillars, or in beds, by the substitution of better for inferior varieties, this may at once be effected where strong plants of the required kinds in pots are available, which they often are in private establishments where Roses for growing in pots are yearly propagated. When there is a surplus of such over the requirements for forcing, or in the case of any that are getting larger than wanted, they may with advantage be utilised in positions like the above; this applies more particularly to the best free-growing 'lea varieties, which it is well to have on walls or other places where they will receive some protection. If planted on different aspects they will yield a regular supply of flowers through the summer and autumn, which is a matter well worth consideration where Roses are required largely for cutting; for although variety is desirable, yet Roses, if to be had in sufficient quantities, and in their various shades and colours, go far to satisfy most people. In fact, it is a question whether a vase or stand of any description tastefully filled with Roses, relieved by their own foliage, and perhaps a few Ferns, can be much improved by the addition of any other flowers. Plants such as described, by being turned out now, will commence rooting at once, and make better growth and yield more flowers, especially during the latter part of next summer, than they will if not planted until the autumn or winter. Where either Roses that have to be discarded, or anything else has been grown calculated to exhaust the soil, it will be better to remove part of it and replace it with good loam enriched with rotten manure.

T. BAINES.

Cutting Roses.—In cutting Roses many think that they are injuring the bush, especially if a wood length of wood be taken with the bloom; but that is not so. We cut hundreds of blooms during the season, and, although about 1 ft. or more of wood is removed with each bloom, we never had Roses more numerous or finer than they are this season.—CAMBRIAN.

THE FLOWER GARDEN.

OPEN-AIR VEGETATION IN JUNE.*

JUNE has been mild and agreeable, although somewhat hot towards the end of the month, when a severe thunderstorm was experienced, accompanied by heavy rain and hail, the latter damaging the leaves of many herbaceous plants, such as *Rumex officinale*, Vegetable Marrows, and other large foliaged plants. Easterly winds were prevalent, with occasional showers, somewhat resembling the June months of old. Arborescent vegetation, although earlier than last year, is still about ten days behind, comparatively few trees being seen with their full complement of leaves thoroughly developed. Perhaps at this time the most copious display of foliage is to be observed on the Sycamore or Plane trees, Limes, Elms, Service trees, Horse Chestnuts, and Thorns, all being kinds already noticed as remarkable for their scarcity of flowers. Although Lime trees are not yet in bloom, and although there is little appearance of their flowering profusely, owing to the points and leaves on that part of the trees being much destroyed by caterpillars, the bulk of the leaves away from the points are all thoroughly developed and, as yet, free from caterpillars. The prevalence of easterly winds has been very destructive to the blossoms of many fruit-bearing trees, and fruit in consequence is scarce in comparison with the mass of blossom which each tree originally showed. During the early part of May the young leaves of many trees got scorched by lightning, and large portions of Beech, Elm, Oak, and others seem very much browsed on one side in various parts of the country. In my notes on open-air vegetation for May I stated that certain trees and shrubs had produced few or no flowers. I have to add that the blossoms of many other later flowering kinds have also been exceedingly limited. A large tree of the Flowering Ash (*Fraxinus Ornus*) standing in the centre of the garden here, and which is generally observed to bloom freely, came into flower on June 18, while the 28th was the day on which the first flower opened last year. Instead, however, of 400 or 500 heads being expanded at one time, not more than 80 could be counted altogether, and these unusually small and of short duration. Many Service trees which fruited last season have very few flowers on them now. A large *Sorbus domestica*, annually noticed for its systematic flowering, still exhibits the same peculiarity, but in a less degree. The top of the tree in question is divided into two leading heads, which flower alternately each successive year. Last summer the western half was loaded with flower and ultimately fruit. This year, although only three or four dozen heads were visible, they were on the eastern half. On *Sorbus torminalis*, which was remarkable during 1877 for the abundance and brilliancy of its fruit, not a vestige of flower is to be seen. The foliage on all the Service trees is now in perfect health. Walnut trees look as if they would be barren. Their foliage in general is poor; many of the young leaves fell off early, quite black. The Elder, which is by no means overladen with blossoms, opened its first flower-head on the 15th, although the first blossom on the same plant was not opened last year till the 27th. The Portugal Laurel and the Bay, which are often in full bloom at this time, have no flowers on them, and scarcely any buds. Holly, on which there was last winter such a show of fruit, and which ought to be in full flower now, has very few as yet visible, while numerous clusters of berries of last year's crop are still adhering to many plants. Yew berries were also particularly abundant during the autumn of 1877, but very few are now to be seen, even in a young green condition. Ghent Azaleas have been very full of blossom, and so were the varieties of the beautiful Alpine Rose (*Rhododendron hirsutum* and *ferrugineum*), which are, perhaps, finer than they have been for many years. Of the *Kalmia latifolia*, although not less than 150 plants are cultivated in the garden, not one is in flower, notwithstanding the specimens are all in the most perfect health, and vary from 2 ft. to 36 ft. in circumference. Some large plants of *Wistaria sinensis*, which are generally covered with flowers, are this year bloomless, although the plants are all in vigorous condition. The scarcity of bloom on the various examples alluded to is in a great measure due to the unripened state of the wood from want of sun during the last two summers. As far as this season has yet gone, and judging from the more matured state of the wood, we may fairly look for a copious display of bloom, and probably fruit, next season. In those instances, in which the bloom has been stated as very plentiful such as in the case of Ghent Azaleas and Alpine *Rhododendrons*, the flowering growths were observed to be unusually short. As this season has the appearance of being very favourable for the formation of leaf-wood growth, it may not be so advantageous in every instance for the formation of flowering wood.

On the rock garden 360 species and varieties of plants were

* Read by Mr. James M'Nab before the Botanical Society of Edinburgh, July 11, 1878.

counted in flower on June 30. Perhaps the most striking were the varieties of *Orehis foliosa* and *O. maculata superba*. These plants are usually cultivated in dampish soils. Here they are flowering freely in comparatively dry stone compartments. Many of the plants originally put in with single roots are now tufty, each with many heads of flowers, and annually increasing. The *Orehis maculata superba* has heads of flowers 5 in. long and 5½ in. in circumference. The varieties of Alpine Poppies are also very beautiful, being crosses between *Papaver alpinum*, *P. nudicaule*, and others. They are white, yellow, and orange, and vary also in size and depth of colouring. The *Orobanchae rubra* (Red Broom Rape) which flowered last year, producing eight spikes, has this year forty-two flowering-heads coming forward on the same plant. It is growing on the roots of the White Thyme, on which it is a parasite. This tuft of *Orobanchae* is about 16 in. square. Besides soil, a portion of the Thyme is growing on stone and a part on a walk made with ashes; some flowers of *Orobanchae* are to be seen on each place.

Calculating the night temperatures above the freezing point during the month of June, I find that the aggregate is 493°, while the corresponding month of 1877 indicated 485°, showing a difference of 8° above last year. The six lowest night temperatures were on the 4th, 5th, 6th, 11th, 13th, and 14th, when 36°, 38°, 42°, 41°, 39°, and 40° were indicated; while the six highest were on the 20th, 23rd, 26th, 27th, 28th, and 30th, when 54°, 55°, 57°, 56°, 58°, and 54° were indicated. The six lowest night temperatures above 32° amount to 236°, while the six lowest last year were 241°. The aggregate of the six highest this year was 334°, while 325° is the amount recorded last year.

The following is a list of some of the most conspicuous plants now in bloom on the rock garden (June 30):—

Allium McNabianum	Helonias apodeloides
oreophyllum	Iris filifolia
Androsace lanuginosa	Linnaea borealis (American)
Arnebia echinoides	" " (Scotch)
Arenaria laricifolia	Meconopsis nepalensis
Aster alpinus albus	" " Walliichi
Astragalus alpinus	Menziesia polifolia versicolor
" vaginalis	Nierembergia rivularis
Campanula turbinata and varieties	Orehis foliosa
" Van Houttei	" maculata superba
Chrysobactron Hookeri	Oxytropis cyaneus
Cypripedium spectabile	Papaver alpinum arantiacum
Delphinium Belladonna	Potentilla alchemilloides
" casherianum	Primula capitata
Dianthus alpinus	" luteola
" neglectus	" scotica
Dracocephalum grandiflorum	" sikkimensis
" speciosum	Rosa pyrenaica
Epilobium obovatum	Saponaria caespitosa
Eriogonum aureum	Saxifraga (many sorts)
Eriophorum alpinum	Sedum
Erodium Manescavi	Sempervivum "
Fragaria lucida	Silene alpestris
Galax aphylla	Vernonia rupestris
Gentiana gelida	Watsonia splendens

Mr. McNab placed on the table about sixty species of hardy Alpine and herbaceous plants in pots, including the following:—

Astragalus alpinus	Papaver alpinum album
Campanula macrostyla	" " aurantiacum
" Raineri	Primula capitata
Cyananthus lobatus	Saxifraga aizoides
Dianthus alpinus	" mutata
" " hybridus	" flagellaris
" " deltoides	Sedum brevifolium
" " dentosus	" " Pottsi
" " neglectus	Sibthorpia europæa variegata
Diss. grandiflora	Silene Elizabethæ
Epilobium obovatum	Spraguea umbellata
Erpetium reniforme	Swertia perennis
Gentiana ornata	Triteleia Murrayana
Orobanchae rubra	

Half-hardy Salvias.—The finest of these in flower at the present time is undoubtedly the Mexican *S. porphyranthera*. The brilliancy of colour and size of the flowers far exceed those of any of the cultivated scarlet-flowered kinds. It is also very floriferous. *S. farinacea*, a beautiful kind, was figured in THE GARDEN last year; it apparently varies greatly in colour, as in the specimen under notice the blossoms are of a light lavender with a white lip, quite different from that of the figure just referred to. The flower-spike is covered with a very short, dense pubescence, which gives it a mealy appearance. *S. interrupta*, a species introduced a few years ago from Morocco by Mr. Maw, is also very fine, with large light blue and white flowers. *S. Grahmi*, another very old Mexican kind, has

a very distinct habit and blossoms of a bright carmine colour. Although the above are classed amongst half-hardy kinds, yet they are quite hardy enough to survive an ordinary winter in a light, warm soil in the southern counties.—W.

HARDY CYPRIPEDIUMS.

To lovers of flowers Orchids have always a special interest; the generality of them, however, are natives of tropical climates; but, fortunately, during the last few years some hardy species of *Cypripediums* have been discovered and largely imported into this country, one at least of which will vie with any of those that are grown in hothouses. The most lovely of the hardy kinds is *C. spectabile*, which throws up stems from 12 in. to 18 in. high that bear during June or early in July from one to three flowers at their apices; the sepals of this species are pure white, and the lip or slipper part suffused with bright rose, the two delicate colours blending most beautifully together. This pretty *Cypripedium* is a native of the United States and North America, from whence large quantities are annually imported during the winter; and as strong tufts of these can be purchased at from three to five shillings each, their price brings them within reach of most people who are fond of their gardens. *C. japonicum*, a more recent introduction from Japan, is another charming variety that forms an admirable companion plant to the above, and, like it, is perfectly hardy in any sheltered positions where it can have the protection of shrubs or rock, or receive a slight mulching of Moss or partly-decomposed leaves just over the crown. *C. Calceolus*, as its specific name implies, somewhat resembles the *Calceolaria* in the form and colour of the flower, the lip being of a bright golden-yellow, which contrasts well with the dark sepals, by which it is backed. Although this variety is a native of Britain, it is very rare indeed that plants of it are now found, and those in commerce are from imported plants, or are obtained by propagation, which is done by dividing the crowns, a rather slow process, as they do not spread very rapidly. There are several others of these hardy *Cypripediums*, all more or less interesting, but the three just named are the most distinct and showy, and an additional recommendation is that they are the easiest to cultivate. Those who have seen the fresh imported tufts of *C. spectabile*, will, on examining them, soon be able to arrive at a pretty safe conclusion as to the treatment they require, for the roots are found embedded in layers of flaky peat and Moss, intermixed with other decomposing vegetable matter, such as is only found in shady damp places. To succeed with them, therefore, they must not only have similar material afforded them to grow in, but a position where they can enjoy the same or similar conditions of root moisture they formerly had, and any one having such a spot, or a cool shady corner where they can keep them well watered and duly attended to, will find these Lady's Slippers among the most beautiful plants they can have. Although they may be grown in pots with tolerable success, they do not succeed near so well as when planted in a bed in a situation such as that above described, as there they are not so restricted for root room, or subjected to sudden transitions in regard to moisture, a uniform state of which is essential to their welfare. If kept in pots or pans they should be placed along the front wall of any damp, cold frame, where they can receive the constant shade of the brickwork and have the full benefit of the moist atmosphere there generally is in such structures during the early spring months, a time when *Cypripediums* are making their growth. In order to get them to bloom freely, the principal thing is to induce a free, healthy development of foliage, for without this it is impossible to get full, plump crowns by the autumn, and it is only such that have sufficient strength to produce flowers the following year. The leaves should, therefore, be preserved as long as possible in a fresh, green state, and allowed only to die away naturally when their functions are performed. It should be borne in mind that, although these *Cypripediums* come from extreme northern latitudes, they are protected by fallen leaves or other covering during the winter, and to render them safe at that season it is necessary to afford them similar shelter and to plant where they will not be affected by cold-cutting winds, which nip the tender growth in the spring. *S. D.*

FROM THE BIRTH TO THE DEATH OF THE LILY.

In my paper of April 27 (Vol. XIII., p. 385) I endeavoured to explain as clearly as I could the existence of the Lily from its birth until the seed-bud was six months old, that is, the existence of the germ until it had vegetated and was large enough to be seen by the naked eye, and then on, as the seed-bud, until, at the end of the six months, it was about to enter another phase of its growth, entitling it to be called a bulbule, or small undeveloped bulb. In order to bring up the history of the Lily in a connected form I must now turn back to the first step in life, but it will be on this occasion not in connection with the hereditary succession or reproduction of the Lily by central seed-buds, but in connection with its propagation by offsets. Mr. J. G. Baker, of Kew Gardens, has laid Lily growers under a debt of gratitude by placing in their hands a new synopsis of all the known Lilies. Having done so much, he can well afford to allow me, an amateur of some little experience, to make a few remarks in connection with the underground growth of the plants. In Vol. XI., p. 112, of THE GARDEN, he is there represented as saying: "A new bulb, whether grown from seed or from bulblets developed in the axils of the aboveground leaves of the floriferous stem, or produced in the axil of one of the bulb-scales, takes not less than three years, under the most favourable circumstances, before it develops a flower-bearing stem." The same writer who quotes the above adds at p. 116: "Raising seedling Lilies is a long process, as one must wait from three to ten years ere they bloom." All this may be admitted, but this is not the point. Mr. Baker is further represented as adding: "The first season we get an ovoid mass, perhaps $\frac{1}{4}$ in. in thickness, composed of half-a-dozen tightly imbricated scales, which sends out three or four slender radicular fibres from its base. At the end of next summer we have a bulb as large as a Hazel nut, with a copious development of strong radicular fibres from its under side, and the half-dozen scales prolonged above the soil into a rosette of oblanceolate leaves. Next year, if circumstances be favourable, the flower-bearing stem is developed, and then, if nothing untoward happen, the bulb goes on living for an indefinite period, sending out each year a flower-stem from its centre and shredding off old scales with buds in their axils—more copiously in some kinds, less in others—from the circumference all around." In this statement it will be seen that there is no allusion whatever to the interior action of the bulb. The very existence of a central seed-bud is ignored entirely, though facts prove that to it, and to it alone, we are indebted for the annual bloom.

The above remarks have been quoted and requoted in this and other periodicals, with such variations as the fancies of the different writers have induced them to make, until at last the result is that there is not one in every fifty Lily growers who do not believe but that the same identical offset goes on year after year growing larger and larger until it becomes capable of developing a flower-bearing stem. Now, this is entirely erroneous, and clearly contrary to facts; for experimental researches have proved beyond a doubt that there is no such thing as a two or a three-year-old offset, the existence of an offset being comprised within the first season of its growth, after which it decays and dies, having thus fulfilled what Nature had destined to be its office. In the meanwhile, however, a successor is growing up within the original offset in the same manner as the legitimate seed-bud or bulbule is growing up within a fully developed adult bulb, with this exception, that every season Nature clothes the successional offset bulbule with new and more numerous scales, the original offset not having had a covering of more than some six or eight scales, according to the class of Lily to which it belonged. The first appearance from the offset above the ground is not a stem, but is generally one or two leaves attached to a long slender stalk or petiole. If lifted out of the ground, the offset will be found to be possessed of slender rootlets, these having been protruded from the base of the offset before the leaf and its stalk began to rise, or, indeed, before there was the slightest appearance of their rising. The next season we see in a bed that has been originally planted with genuine offsets a very slight stem shooting up, furnished with a few leaves. This is a sign that a germ in the centre of the original offset has vegetated into a seed-bud; for without the presence of a

seed-bud there can be no real stem. The next season the stems will appear larger and more fully developed, and the bulbules, if dug up, will be found to be also larger, with more scales, and with new and more numerous roots—the site of the decayed stems and roots of the previous season being on all the bulbules distinctly visible. This process goes on year after year until the bulbule, which may now be called a fully developed bulb, produces a flower-bearing stem. All this is, to the Lily grower, worthy of the most attentive study, as the first thing that must strike the reflecting mind is the harmony that exists in what we are permitted to contemplate in the Lily, namely, the singular similarity in the organisation of all the kinds that are really true Lilies. Yet there are some writers who assert, without the vestige of a single experimental fact to support themselves, "that the different ways of reproduction are so marked, that it affords subject-matter for endless controversy." A distinguished Lily grower has also said in THE GARDEN lately: "Lilies of various sorts form their bulbs very differently; therefore, no general theory can be applied to every species." It is a fact, and I regret to say it, that visionary theories have created a great deal of confusion in the minds of amateurs and Lily growers in general, as it is impossible for them to reconcile the various and contradictory opinions that are floating about. For myself, I must say that I deal with facts, where no inconsistencies can arise, and I place it within the power of any one to prove, by facts, whether I am right or wrong. With respect to the little bulbs, while only small offsets, they have by some been called side-buds by way of contradistinction, and have also been called the principal reproducers of their class. Now, some of them may be called side-buds, though more properly small offsets, but they all differ widely from the true legitimate reproducers—the central seed-buds. The central or legitimate seed-buds are growing up, not at the side, but in the very centre of the parent bulbs, and will, most certainly, without changing their identity, flower the season after the parent bulbs have bloomed, unless something unforeseen should happen to them; that is, they will germinate, grow up, bloom, decay, and die, all within two years; while the side-buds or little offsets, which have no fixed place for their appearance at any time, will change their identity, by being transformed by a new creation every year, and will not take less than three or four years before they can, through their transformed successors, develop flower-bearing stems. These side-buds or little offsets are the means which Nature has placed in our hands for the purpose of propagating and multiplying the species, but not for the purpose of reproducing that which is lost, namely, the parent bulb, or the bulb of the previous season. The reproduction of that bulb is due alone to the central seed-bud; for this bud, the instant it has germinated, is provided with all the organs of vegetation that the full-grown Lily possesses, and is, in fact, a miniature resemblance of an adult bulb. This should teach us that if we desire to ascertain whether a plant is a true Lily or not, we should carefully examine the organic interior structure of the bulb, as well as the flower itself. These side buds, though they have been made a great deal of by some writers, cannot be placed under any other category than that of "adventitious buds," for they present themselves without any order, and the exact spot where they may present themselves cannot be foreseen. It will, therefore, be seen that those who deal with the propagation of the Lily by seed, bulbules, or buds in the axils of the old scales entirely overlook the marvellous organ and its functions which Nature has provided for carrying on the hereditary reproduction of the plant, for the central seed-bud alone is all-sufficient to continue to reproduce annually the Lily and its bloom, if seeds, bulbules, and all sorts of adventitious buds were never to have any existence. In fact, we every year see this result in our gardens, though we never dream of searching or looking for the cause.

As a practical, and almost tangible, illustration of the truth of what I have said, I send herewith a photographic representation of the interior and reproductive organs of offsets, bulbules of one, two, and three years' growth and fully developed bulbs, collected during the first two weeks in May last from clumps of a dozen or more distinct species of *Lilium* proper; I also send the originals, so that there can be no room for a doubt on a question of so much importance to Lily

REPRODUCTION OF LILY BULBS.

growers at the present time. There are three specimens of the offset in its first and only year; eighteen specimens of offset bulbules in their second, third, and fourth years; and twelve specimens of fully developed or flowering bulbs. It is impossible to look at these thirty-three specimens without seeing that they have all been growing up from the base and close to the parent stem, the same organisation and structural formation being distinctly apparent in all.

I would wish particularly to draw the attention of Mr. Harvey, Mr. Groom, and some others who are interested, to the specimen No. 31 low down on the right hand side. This Lily was one of the same clump as that which is represented in Vol. XIII., p. 143. That bulb was lifted out of the ground on January 1; this one in the beginning of May. The difference in the seed-bud of the former specimen (which was six months old when lifted) from the almost fully-developed bulb of the present specimen shows with what rapidity (according to an increasing ratio) the interior parts grow, with the additional aid of their own roots and favourable weather during the second six months of their existence, as noticed and calculated by me in a former paper. I have also to direct attention to the roots of this specimen. They are new, for I carefully removed the parent roots to make the new ones more apparent. They were, as they are now seen in the drawing, nearly 2 in. long in the beginning of May. By the time the parent bulb would be in bloom, namely, about the end of June, they would be much longer if they had been left in the ground, drawing a large and independent amount of nourishment from the soil, as I explained in my reply to Mr. Groom (Vol. XII., p. 451). Turning over now to p. 48, we find Mr. Groom saying: "In reply to Mr. Hovey, 'Dunedin' reiterates the advantage of early planting, and states that no harm resulted from lifting the bulbs in full bloom on June 30 and exposing them to the atmosphere during six of the hottest weeks of the year." Now, if Mr. Groom will kindly refer again to my reply to Mr. Hovey, he cannot but see that I have said no such thing; in fact, in all my writings I have always spoken strongly against exposing Lily bulbs to the damaging influences of the air. As to the advantages of early transplanting, according to the class of Lily and time of flowering, to which Mr. Groom objects, it will yet be found that these cannot be overrated, for as soon as the parent plant has bloomed, the new bulb will be in the very best condition for the change, without the risk of any check to its progress; and the warmth of the atmosphere at the time will also be much in its favour. It is a remarkable circumstance that the advocates of later transplanting cannot produce a single fact in support of their system. One gives one reason, another gives another, and when investigated, they turn out to be mere fancies; and those who talk about the propriety of Lily bulbs being permitted to remain some years in the ground without being disturbed, really do talk as if Lily bulbs were perennials, overlooking or not knowing the fact that the true Lily blooms only once and then dies.

DUNEDIN.

NOTES AND QUESTIONS ON THE FLOWER GARDEN.

Spiræa palmata elegans.—This has given as much disappointment here as at Newry (see p. 2). It is simply good for nothing, and the least ornamental of all *Spiræas*. It bears rather a close resemblance to *S. palmata* in foliage, but in colour, boldness, and mass of flowers it in no way resembles nor can be compared with *palmata*, which is one of its alleged parents. With its other alleged parent it has no affinity whatever. I quite agree with Mr. Smith that we have been imposed upon in this matter, but think we have imposed on ourselves in the first instance by adopting and using the name *Spiræa* for *Hoteia* without any authority, so far as I am aware. By doing so we lift *Hoteia japonica* out of the Natural Order Saxifragaceæ and place it in Rosaceæ, to which *Spiræa* belongs, but we do not succeed thereby in establishing that identity of structure and natural affinity which is essential to the production of a hybrid. Practically, I presume, it would be as reasonable to expect to obtain hybrid offspring from an attempt to cross a Peach and a Saxifrage as from *Hoteia* and *Spiræa*, even though mere superficial resemblance favours the notion that such a thing might be remotely possible in the case of the two latter. By adopting this erroneous name and using it in the universal way in which it has been used since the so-

called *Spiræa japonica* became a popular forcing plant, it appears to me that if we do not invite imposition we at least spread erroneous ideas, which are certain to return upon us with one vexatious result or another.—W. SUTHERLAND, *Aigburth Nursery, Liverpool*.

Lilium excelsum.—Four years ago one bulb of this Lily was planted in an ordinary border and has since then remained perfectly undisturbed; it has bloomed well every year, and this year has produced four spikes, the tallest of which is over 6 ft., and at the present moment there are just twenty-four fully expanded blooms on it. Szovitzianum has also done remarkably well under the same conditions, and every year increases in strength, yielding this year a profusion of its handsome flowers. The soil is a very heavy one, but neither of these Lilies has had the slightest protection. Under the same treatment *L. auratum* has entirely disappeared.—A. K., *Eastcott Cottage, Pinner*.

Saxifraga nepalensis.—"A. D." says (see Vol. XIII., p. 536) that this Saxifrage is far from being a free bloomer, an assertion contrary to my experience. I have grown it by hundreds for years, and so great was the demand for it that it was almost an impossibility to keep a stock of flowering plants of it on hand. My mode of treatment was as follows: In the spring and autumn of each year I secured all the offsets possible and inserted them in sand under a handlight, where they soon formed roots; I then potted them in 3-in. pots, and grew them on in a frame, taking care to keep them at all times free from offsets, which would have greatly impeded their progress. I always found that cuttings inserted in spring could be made to flower in spring two years afterwards, that is to say, if they had been put in last spring they will flower in the spring in 1880. I have flowered plants of it in twelve months, but only in cases where strong rosettes were obtainable.—E. JENKINS, 16, *Canterbury Terrace, Maida Vale*.

Forget-me-nots in Marshes.—Beautiful as beds of Forget-me-nots are in the flower garden in spring, I doubt if any of the cultivated kinds, including *Myosotis dissidua*, certainly the finest for beds, can rival the masses of the common *M. palustris*, with which one meets at this season in water meadows and marsh ditches, where large breadths of lovely blue are only broken here and there into irregular outlines by some more stately form of vegetation, such as Reeds, Rushes, and other plants that delight in abundance of moisture. I may add, too, that at this period of the year, positions in which Forget-me-nots abound are also very rich as regards other flowering British plants that flourish under semi-aquatic conditions, and to those who are interested in beauty of form, I know of no more interesting spots than the native haunts of the wild Forget-me-not.—J. G.

Libertia formosa.—Mr. Miles (see p. 12) has done good service by directing attention to this lovely plant. I myself pointed out the value of *Libertias* as hardy plants in THE GARDEN some time ago. *L. formosa* is beautiful at all seasons, even in the depth of winter, owing to its persistent dark green foliage, which is as green as that of the Holly, and it produces spikes of flowers of snowy whiteness more like those of some delicate Orchid than of an outdoor plant. Amongst all the hardy plants which I grow it is, when in flower, the gem of the garden. There are about four species of these charming plants, amongst which there is some confusion as to nomenclature, *formosa*, *palohella*, and *ixioides* often doing duty for each other. But *formosa* is in every way the handsomest of the group, as far as I have seen them; it is neat, dwarf, and compact, and has flowers twice the size of those of the others lying close together on the stem, and reminding one of the old, nearly extinct, double white Rocket.—THOS. WILLIAMS, *Ormskirk*.

Oenothera Youngi.—This is the best of the Evening Primroses for borders. Whether planted in masses and allowed to grow at will, or pegged down in front of low shrubs, it is equally effective; and in either case, if the soil be deep and moist, it will continue to flower for months.—V.

Aralia Sieboldi.—Fine plants of this *Aralia* have withstood the past winter near London without the least injury, and, where a little shelter has been afforded them by neighbouring trees and shrubs they are now growing vigorously. Were such ornamental plants as this left in some of the beds and borders in the London parks, and surrounded by spring flowers, they would not have such a desolate appearance during the dull days as they now have.—R.

Ferula glauca and *communis*.—These make charming fine-foliaged hardy plants, but need to get fully established before their full beauty is apparent. Plants of them grown in pots under glass are frequently discarded, as when the foliage gets drawn in too much heat it droops, and soon becomes anything but ornamental. But planted out of doors, with space in which to fully develop themselves, they are truly noble objects.—J. G.

The *Pigmy Iris* (*I. ruthenica*).—This is one of the smallest as well as one of the rarest *Iris*es in cultivation. Its flowers, which are about 2 in. across and of a richest lilac-purple colour with a white lip, are borne on stems about 1 in. above the surface, and nestle snugly among the bright green slender foliage. It is also the latest to flower amongst *Iris*es. Siberia and adjacent countries is its native habitat.—W.

THE LIBRARY.

FLOWERS: THEIR ORIGIN, SHAPES, PERFUMES, AND COLOURS.*

THE critic of any work must regard it from two points of view: its aim and its execution. Readable as are the works of Dr. Darwin and Sir John Lubbock, even for the unbotanical, there was undoubtedly room for some one handy volume which should sketch the whole of the new philosophy of flowers in the manner of the indefatigable and apparently omniscient Dr. Taylor. Any fears suggested by a proverb about numerous avocations were soon put at rest by evidence of knowledge of a most thorough order, and we were agreeably surprised to find, in lieu of a second-hand compilation, a work often highly suggestive to the working botanist. Nevertheless, as might be expected, Dr. Taylor appears to the greatest advantage in his chapters on the geological antiquity and geographical distribution of flowers where he competes least directly with the Master. Two of the concluding sentences of the first of these are noticeable: "We have seen that the appearance in geological time of the most beautiful or sweetly perfumed flowers is also that of the insects which now habitually frequent flowers. . . . We have, therefore, a peculiar aspect of evolution here presented, not necessarily towards higher organisation (as some people think is imperative in evolution), but in the direction of special adaptation to each other's necessities and well-being, on the part of two groups of organisms having no other connection with each other." No doubt, as the author says,

The Chicory, or Succory (*Cichorium Intybus*).

some excuse must be made for naturalists feeling irritated at the dogmatism of half-educated theologians; but, perhaps, it would have been better to leave the Church of Rome, Copernicus, and Dr. McCosh out of a work of this character. The book is fortunately well bound and on excellent paper. Its numerous woodcuts are mostly good old friends, and far better than the coloured plates. For whom do publishers insert these latter expensive atrocities? We have little doubt we shall speedily hear of a second edition, and hope then to see numerous "misprints" corrected. For instance, what does the following sentence mean: "There are more than 300 species of plants common to the Southern States of America and Japan than to Europe?" Fig. 91 is described as "Wood Sorrel (*Anemone nemoralis*) with 'monstrous' petal formed instead of true leaf," whilst it represents a Wood Anemone with such a petal in addition to the normal three leafy bracts on the flower-stalk. Such slips, however, are small matters, and we welcome the appearance of the work with all its imperfections on its head; for has it not a good index—that cop to the critical Cerberus—and would it not be valuable if only for teaching the *dilettante* that the inflorescence of Chicory and such Composites (e.g., Daisy, Dandelion, Thistle, Dahlia, Chrysanthemum, and Cineraria) is not one flower, but a "social" colony, recognising even the great principles of self-sacrifice and the division of labour? G. S. BOULGER.

STREET PAVING IN PARIS.

THE following statement was prepared by the Chief Engineer of Roads and Bridges, Paris, for the information of the Paddington Vestry:—

Granite paving does not exist in Paris, and that in porphyry is being abolished. The stone almost exclusively adopted is a hard sandstone, which is used in the form of a rectangular parallelepiped (cubes) of 6½ in. long, 6½ in. deep, and 4 in. broad, the depth of the sand on which the stones are placed being 7½ in. below the level of the street. The materials which compose a macadamised road vary according to traffic. The foundations of streets subjected to excessive traffic, such as the Boulevards, are formed of two beds of stone of small dimensions (2½ in. at the most on the surface of each stone); the first or upper bed is in porphyry of a thickness of 6 in., and the lower bed consists of a kind of gravel of the same thickness. These rest directly on the ground, and are bordered by the channelling. In order to facilitate foot traffic, crossings are constructed at certain points, especially where streets intersect each other. These crossings are made generally of asphalt.

For a long time past mastic asphalt, or pitch, or bitumen has been discontinued. Natural rock asphalt, compressed by heat, is the only material now used. With some exceptions the asphalt has been laid upon a bed of mortar of hydraulic lime of 4 in. in thickness, but it has been found that Portland cement is far preferable. The thickness of the asphalt after being compressed is 2 in., but in the less frequented streets a thickness of 1½ in. is sufficient.

Of wood pavements, of which trials have been made on a large scale, that of Norris or the Improved Wood Company has answered the best. The blocks are composed of Pitch Pine, and are placed on a double flooring of the same material. Consequently in this statement, the following four modes of paving will be dealt with, viz:—

1. Paving in hard sandstone of small pieces.
2. Macadam, composed of porphyry and gravelly pebbles.
3. Compressed natural asphalt.
4. Improved wood paving.

Observations Relating to Street Paving.

The cost of constructing a square yard of paving is as follows, viz:—

	s.	d.
For sandstone procured from l'Yetta	14	0
For porphyry and pebble gravel	6	0
For compressed asphalt of 2 in. in thickness.	13	0
For the improved wood paving	20	0

It is impossible to state accurately the cost of cleansing, but in general asphalt costs less than wood, and wood less than the ordinary pavement, and the latter is cheaper as regards cleansing than porphyry and pebble gravel.

The yearly cost of maintenance, including payment of first cost by instalments, is as follows:—

	s.	d.
For ordinary pavements	0	10
For porphyry and pebbles	6	0
For asphalt	1	0 for streets.
" " " " " " " " " " " " " " " "	1	8 " crossings.
For wood	2	6

As regards the last-mentioned pavement, it must be observed that Mr. Norris (Improved Wood Paving Company), in entering into the last contracts with the city of Paris, has undertaken to maintain such paving at the rate of 1s. 3d., that is to say, at much below half the actual cost, as proved by experience.

The wear depends upon the nature of the traffic, state of the weather, the gradient of the street, &c. In a level road the resisting power or traction averages:—

40 lb.	per ton	on ordinary paving.
60 "	"	on porphyry pebbles.
20 "	"	on asphalt.
12 "	"	on wood.

If the road be not level, a kilogramme or 2 lb. must be added or deducted for each millimetre of inclination.

The ordinary pavement lasts about twenty years. In each arrangement one or two gangs of workmen are always occupied in keeping the same in repair. Important repairs, such as re-laying and re-dressing, are done by the contractors to the city of Paris. The roads much frequented require repairing nearly every six years. The paving in porphyry requires constant supervision, and the workmen belonging to the administration take care twice in each year to have all holes properly filled in; by the adoption of this plan

* "Flowers: Their Origin, Shapes, Perfumes, and Colours." By J. E. Taylor, Ph.D., F.L.S., F.G.S., &c. Hardwicke & Bogue.

great durability is secured. For the price which is paid to the contractors for asphalt paving they must make good all defects; in other words, they have to renew once in each year about two-fifteenths of the whole paving. The greater number of streets do not require repairing to the extent of one-fifteenth and a-half, or a tenth; in the much frequented thoroughfares, repairs to the extent of two-fifteenths and a-half are scarcely sufficient. Wood paving does not last more than five years.

The snow and frozen rain tend to make the sandstone and the Macadam pavements almost equally slippery, but the asphalt is rendered more so. In dry weather the Macadam is much less slippery than asphalt, and the latter a little less slippery than the sandstone. Wood paving seldom becomes slippery, not even during wet weather, as then the moisture penetrates into the wood, but does not render the surface thereof slippery. Accidents arise solely from slipperiness, but they are generally not so serious on wood pavement. On asphalt they are more serious, and on porphyry, pebble gravel, and sandstone pavement still more so.

There is less mud on asphalt than on wood, and less on the latter than on ordinary sandstone pavement; porphyry and gravel produce the most mud of all. Wood produces less dust than asphalt, and asphalt less than ordinary pavement; porphyry and pebble gravel produce the most. Asphalt is impermeable, and the ordinary pavement absorbs less than the porphyry; as to wood pavement, notwithstanding any defects therein, no complaint has ever been addressed to the administration touching its insanitary condition.

Porphyry pavement never decomposes, neither does the sandstone. Gas escaping from underground pipes renders asphalt soft and spongy, and moisture under its surface injures it. Wood suffers to a greater extent from these causes, and is also liable to rot away, especially in small by-streets where there is but little current of air. Water evaporates pretty quickly on asphalt, not so much on sandstone, and still less on porphyry. Wood absorbs moisture readily, and is preserved thereby.

Wood deadens the sound most. Macadam and asphalt are both noiseless to an extent. Sandstone pavement produces more noise than any other kind of pavement. From the foregoing remarks, it must be obvious that the noisiest pavement is the most injurious to health.

Wood and asphalt produce but little vibration; granite causes vibration, especially during the winter months, when under the influence of moisture, the mud accumulation being soft, the stones rub against each other and pulverise. The vibration of ordinary pavement is such as to shake the houses abutting upon the road, and it is only owing to the incompressibility of the sand that the stones disturbed by passing vehicles are not shaken out of position.

There is but little wear and tear on asphalt; very little on granite; a great deal on ordinary pavement, owing to the jolting it causes to the carriages; there is very little wear and tear on wood. Horses are subjected to most strain on asphalt, on account of there being no foothold. They are subjected to much less strain on the ordinary pavement than they are on the granite; the dust on the latter pavement is prejudicial to health; there is very little wear and tear on the wood. Persons travel with more comfort on asphalt than on wood, and with more comfort on wood than on granite, and much easier on granite than on ordinary cube pavement.

Under the head of safety, the granite occupies the first place, then the ordinary cube pavement, then the wood, and lastly the asphalt. In order to prevent accidents on the last-named pavements, sand should be spread over them; in cases of steep inclination, the ordinary cube pavement and the granite require sand to be spread over the surface.

A good paving should possess the following advantages: It should be impermeable; strong, but elastic; easy to repair and cleanse; smooth, without being slippery; exempt from dust and mud; noiseless. The most efficient and economical system of cleansing is by water; hand-sweeping is dearer than machine-sweeping; scraping by india-rubber apparatus is very advantageous as far as asphalt is concerned.

Watering by hose is the most economical; it can be done at half the cost of cart watering. By the hose system, the men in charge of the same can see exactly what portions of the roads require watering. Watering by hose is adopted in Paris in all the important thoroughfares.

There are no tramways in Paris on wood pavement. Where tramways are laid on the granite pavement, the macadam is removed, and between the rails cubes are substituted for macadam. If tramways be laid on asphalt the cubes are laid down on either side of the rails, and a strip of asphalt is left between the rails; the band of asphalt in question keeps the stones in a firm position.

PLATE CXXXVII.

FANCY PELARGONIUMS.

Drawn by MARIAN CHASE.

THESE constitute the prettiest and freest flowering section of Pelargoniums; and, although they are not so showy as the large-flowered section usually called show Pelargoniums, they are, nevertheless, very useful decorative subjects for the greenhouse or conservatory, and as cut flowers for small glasses they are charming. Small plants of them in 5-in. or 6-in. pots are the most useful for ordinary purposes, but plants of very large size may be grown in pots 8½ in. across, and these are usually trained purposely for public exhibition. It has been found best to graft the fancy varieties on stocks of the more robust large-flowered sorts, and the strongest-growing kinds of these, such as lilacinum, Charles Turner, Admiration, and others should be selected for the purpose. For ordinary purposes, however, it is easiest to raise plants from cuttings, which are usually put in when the plants are cut down in July or August, but I have found the month of May a good time to take cuttings. When the plants are raised at this time they make good specimens by the end of the year, and produce abundance of fine flowers the following season. My plan is this: I take the cuttings from a part of the plant where they are not missed, then cut across the stem just under a leaf; the leaf is then removed close to the stem; I then insert each cutting singly in the centre of a thumb-pot, using a soil composed of equal parts loam, leaf-mould, and sand. I plunge the pots in a hotbed with very little bottom-heat, just enough to afford a little warmth. When the roots have grown a little round the sides of the pots, I re-pot into 3-in. pots, using more loam in the compost than hitherto. The best place for the plants when potted is on a shelf near the glass in a greenhouse. Before potting the plants, see that they are quite moist at the roots, and then it will not be necessary to water them for three or four days after potting, and when water is applied it ought to be in sufficient quantity to thoroughly saturate all the soil in the pots. As fancy Pelargoniums grow at a rapid rate, they soon require to be potted a second time. The pots used must bear some proportion to the size and vigour of the plants; 5-in. or 6-in. pots will be found the most suitable. The soil for this and all other pottings for established plants should consist of six parts loam, two parts leaf-mould, and one of rotten cow manure, and to each barrow-load of this compost use three pints of crushed bones, a little pounded charcoal, and sufficient silver sand to keep the compost open. Drain the pots well, and over the drainage place the fibrous portion of the turf from which the earthy particles have been sifted. The compost should be pressed in firmly by the hand, but not with wooden or other rammers, as is sometimes done. During all stages of growth the plants ought to be kept rather close to the glass, and they require considerable attention in order to keep them in a healthy condition. Green fly should be destroyed by fumigation on its first appearance, and if the plants suffer from lack of sufficient moisture at the roots at any time, the result will be a number of yellow leaves a few days after. The leaves are sometimes affected with a disease called spot, which sadly disfigures them. I fancy this is caused by chilling the roots with cold, hard water applied in winter and in too large quantities. Fancy Pelargoniums are not nearly so hardy as the large-flowered sorts; they require a lighter compost, and should be kept rather warmer during winter. Their most desperate enemy is green fly, and this must be destroyed on its first appearance. Should any of this pest remain on the plants just before the flowers open, the house should be fumigated until every one is destroyed. Tobacco smoke applied after the flowers open causes the petals to drop. In order to retain the flowers as long as possible some shading should be placed over the glass during sunshine. A few of the finest varieties are Miss Goddard, Mrs. Pope, Mrs. Phipps, and Thomas King; these are new varieties sent out by Mr. Charles Turner, Slough; all of them have received first-class certificates; indeed, we are indebted to Mr. Turner for most of the improvements that have been made in regard to this class of plants. Of older sorts may be named Ann

PRIMULA (P. sp.)

Page, Countess of Dudley, East Lynn, Ellen Beck, Fanny Gair, Henry Bailey, Leotard, Mrs. Baker, Mrs. Dorling, Mrs. Hart, Mrs. Mendel, Princess Teck, Roi des Fantaisies, The Shah, Undine, and Vivandière.
J. DOUGLAS.

PROPAGATING.

GLOXINIAS.—The best mode of increasing these is to take a pan with a hole in the bottom of it; put one crock over the hole and a little coarse peat in the bottom; then fill up with fine sandy peat soil, on which put $\frac{1}{4}$ in. of clean silver sand; take some of the largest and fleshiest leaves and cut them through just below the ribs, as shown in the annexed woodcut; make a small trench in the sand across the pan with the handle of the propagating knife, and place the pieces, rib part downwards, in the sand; draw the latter up close and level; then go on with the next row till the pan is full; sprinkle them over with water, and place them in a close, moist, bottom-heat, opening the glasses or lights every morning. They will soon form little bulbs and throw up young growths, when they may be potted off and be kept growing in a warm place. If a large quantity be required, and if the leaves are large, they may be cut up into smaller pieces, always taking care to cut just below the ribs or veins.

H. H.

PROPAGATING PRIMULAS.

A REMARK recently made by Mr. Anderson-Henry respecting an apparent difficulty in propagating certain kinds of Primulas, by which *P. denticulata* was specially mentioned, might lead to the conclusion that this and similar kinds were doubtful propagators. *Primula denticulata* and its ally *P. purpurea* grow here in the open ground like weeds, and may be propagated freely. A single crown breaks into two, three, or four crowns the succeeding year, and these split up make from twelve to fifteen the next year, and so on; whilst plants that remain in the ground untouched will produce from six to twelve crowns in a couple of years. These Primulas will sometimes seed freely, especially under glass. I have now probably 500 plants in a seed-pan, the produce of a single truss of bloom of *Primula purpurea*, so that propagation is found to be rapid enough. To get the full beauty of these grand Himalayan Primulas, the plants should be lifted into large pots in the autumn and be put into a cold frame until the flowers are showing, and then be taken into the greenhouse; in this way they are glorious spring-flowering plants. *Primula japonica* can be propagated with great rapidity by seed, as this variety seeds freely, as also does the fine East Indian *sikkimensis*, which comes true in that way. I have endeavoured to secure a cross between these two kinds, using pollen of *japonica*, which is a thrum-eyed flower, on the styles of the flowers of *P. sikkimensis*, a pin-eyed variety. Seed-pods are set and ripening, but I cannot assert that the desired cross has been effected. *Primula cortusoides amœna* and its varieties seed but sparingly, as, although some of the pods make a great show of seeding, they are generally found barren, but then the plant makes amends by reason of its free root propagation, as a seedling will in the second year produce several roots and crowns, and in the fourth year about 100 crowns, and in a few more years multitudes. The most indifferent propagators, perhaps, are of the *nivalis* or *viscosa* section; these are allied to the *Auricula* group, and, like that popular florists' flower, can only be propagated by the slow process of division or the taking off of offshoots. These seed sparingly; indeed, it is rare that seed is found, and, therefore, they can never be abundant, especially as being somewhat miffy during the hot weather they now and then collapse. Keep the plants cool during the summer, and when the offshoots are strong enough, take them off with a sharp knife, fix them in a pan of sandy soil, and place them in a cold frame. In the case of old plants it is well to shake them quite free of soil and cut away all the old stock roots, leaving only the newest ones; then,

potted up in fresh soil and in smaller pots, the plants will start afresh and with renewed health and vigour. Most of the farinosa section will seed freely, and it is well to keep a few seedlings always coming in, as the old plants will suddenly decay and disappear. Blooming, as most of the hardy Primulas do, early in the spring, it is more probable that seed will be got from plants flowering sheltered under glass than from those exposed to heavy rains and late frosts. If seed, therefore, be needed, the precaution of growing some in pots should not be neglected.
A. D.

Cascades and Fountains in Pleasure Grounds.—Perhaps no feature in connection with the laying out of pleasure grounds and flower gardens requires nicer management than these. Everything depends upon the judgment of the operator and the choice of a situation whether the result will be a success or a failure. The passion for fountains and cascades in flower gardens has in many instances led to their being found in situations where they are nothing but an incongruity. A jet of water has itself a refreshing and pleasing effect almost anywhere on a warm summer day; but the "fountains" which so frequently form the central figures of our geometrical flower gardens have usually a rather depressing effect. Built of solid masonry, and standing in the midst of a dreary waste of gravel walks, or at best in the centre of a group of geometrical-shaped flower beds—and in ninety-nine cases in a hundred unable to play for want of water—they are almost meaningless objects, wholly out of place. Naiads, mermaids, dolphins, and other mythical figures and fishes, bleaching in the sun among a lot of scarlet Geraniums and Calceolarias, &c., is surely as absurd an incongruity as could possibly be conceived. The first essential in a fountain or a cascade is water, and this is just what is usually wanting. We are acquainted with numbers of flower gardens containing fountains where there is hardly sufficient water to play them for one week in the year, and there the nude figures stand, blistering in the sun and blackened with soot, a melancholy testimony of the incompetency and stupidity of the designer. And quite as often, when the fountain is playing, its noblest effort is a disappointing squirt, which might be easily surpassed by a garden engine or a common brass syringe.—J. S.

Cool Treatment of Lobelias for Bedding.—Where anything like exactness of outline is necessary, Lobelias should always be raised from cuttings, as seedlings cannot be relied upon to produce a compact mass without pinching or cutting. Our annual stock is from 4000 to 5000, and, except for keeping the stock plants through the winter, we do not now use either pots or boxes, but simply dibble the cuttings into very slight hotbeds made up a few days before the cuttings are ready. The hotbeds are generally composed of lawn mowings, mixed with a few leaves or other rubbish to keep down and steady the heat. As regards the stock plants, about six or eight dozen of the latest outtings are potted in small pots in spring, plunged in the open ground, and have the flowers pinched off during summer. About August they are shifted into 4½-in. pots and are wintered on a back shelf in a cool house just under the ventilators, where in fine weather they have full exposure. In this position the growth made is wonderfully robust, and when the outtings are taken off in March and April, a very small amount of bottom-heat will suffice to root them quickly. It is always a good plan to have a stock to work from in proportion to the number of plants required; as, although it is possible to work off a wonderful number from a few plants, it is not wise to do so, for over-propagation is an evil, and leads to deterioration in vigour; indeed, I have no doubt many of the cases of plants dying off in summer, and leaving an unsightly blank in the beds, may be traced to this cause of forcing and over-production. We strike *Alternantheras*, *Coleus*, &c., in the same way, and produce far better plants, with less than one-tenth of the labour, than by potting; and the plants, being close to the glass, assume a brighter colour, and are stronger, hardier, and better enabled to resist vicissitudes of weather and climate. Plants grown in this way may be planted out ten days earlier than when they have been grown in close, warm houses.—E. H.

Smilax maculata.—For covering low walls in a warm position this is one of the best of plants. It grows freely, its tendrils cling firmly to the wall, and its dense masses of narrow, pointed, glistening bronze and white-spotted leaves have a pleasing effect.—V.

Delphinium cardinale.—This very distinct Larkspur is, I consider, even more beautiful than its dwarf congener, *D. nudicaule*, as it is much more robust in habit, forming a pyramid from 4 ft. to 6 ft. in height. The flowers are larger and of a more brilliant scarlet, and they last a long while in good condition. A place should be found for it in even the most select collections of hardy plants.—A.

GARDENING FOR THE WEEK.

Flower Garden.

THE staking and tying up of climbers and the pegging down of dwarf-growing plants are operations which will require constant attention. Fine-foliated, or what are known as sub-tropical, plants should, when necessary, be supplied with abundance of water, and the surface of the beds should be well mulched with good rich manure to check evaporation and assist in the production of a fine, healthy, luxuriant leafage, which constitutes the principal beauty and attraction of such plants. The unsightliness of the manure may be easily concealed by the mowings of lawns, and the margins of the beds should be neatly covered with green Moss, which the occasional waterings will keep in good condition. Wherever carpet bedding is practised this must also have constant attention in the way of pinching in and regulating the growth of the various plants employed for that purpose so as to preserve the outlines and patterns of the beds. All flowering shrubs, as soon as they go out of bloom, should have dead and decaying flowers removed, and when necessary the plants should be cut back. Box edgings may also now be trimmed, and wherever divisional lines are formed by means of Sweet Brier or the common evergreen Privet they should also now be cut. Few plants are better suited for forming low ornamental hedges than the Privet, but, being of free growth, it requires to be clipped several times during the season. The common Yew is also an excellent hedge plant, but it is of slow growth. There are, however, several other hardy Coniferous trees to which this objection does not apply, such as *Cupressus Lawsouiana*, *Tunja Lobbi*, *Thuja borealis*, &c., all of which are well suited for ornamental hedges or screens. Where such already exist the present is the most suitable time for cutting or rather clipping them; but when such hedges or screens consist of large-leaved plants, such as the common or Portugal Laurel, it is then advisable to prune with the knife, in order to avoid, as much as possible, the mutilation of the leaves. Dwarf Coniferous trees and ornamental shrubs of various sorts are frequently used in the embellishment of Italian and geometrical gardens, and, where that is the case, it is generally necessary to preserve a certain amount of uniformity as regards shape and size; and the present is a suitable time to attend to the cutting or trimming of such specimens. Among plants well suited for this purpose are the Sweet Bay, the Portugal Laurel, the *Laurastinus*, &c., trained in the form of standards or otherwise, together with various sorts of *Cypresses* and *Junipers*, and other plants of a drooping habit of growth; also the *Irish Yew* (*Taxus fastigiata*), generally trained in the form of pyramids, and on which are sometimes grafted the gold and silver-striped varieties of the *Taxus baccata* or common Yew, a union which produces a very striking effect, as do also trained specimens of the fine-leafed *Acer Negundo variegatum*, which, although deciduous, produces, nevertheless, during the summer months, a very pleasing contrast when associated with sombre or dark-foliated plants. Continue to extract Plantains and other broad-leaved plants from lawns, and occasionally take an opportunity, after a considerable rainfall, to well roll all dressed ground. This will, however, seldom be necessary where a heavy horse machine is used, and where that is employed avoid by all means a too close approach to fine specimen Coniferous or other trees upon the lawn. Whatever portion of surface the mowing machine may not have reached should be neatly cut with the scythe on the following morning; at the same time the margins of walks and clumps should be trimmed or clipped with the Grass-edging shears, an operation quite indispensable to neatness and high keeping.

Phloxes.—These beautiful summer-flowering occupants of the herbaceous border, if grown in a situation where the roots of deciduous trees or evergreens can interfere with them, require plenty of water at and about the time of their opening their flowers. They are strong-rooted plants, and need a good deal of sustenance. If allowed to become dry they are sure to suffer from the attacks of black thrips, which get into and spoil the flowers as soon as they open. Any plant, either flowering or fruit-bearing, grown in the open air that is attacked with thrips, black or yellow, can only be relieved from them by continuous use of the syringe or garden engine, for they will not remain where there is much moisture. Plants that are allowed to flag through want of water at the root appear most liable to their attacks.

Gladioli and Marigolds.—A slight mulching of an inch or so of rotten manure over the surface of Gladioli beds will benefit them, and will help to keep the soil moist and the roots cool, which has a considerable influence in preventing the disease. Tie the plants up before they get so large as to be acted upon by the wind, using for this purpose a neat stick, such as a stout dry Willow or Hazel, the thickness of one's finger; and be careful, when inserting it, not to thrust it down so near the roots as to injure them. There are few more handsome and continuous border flowers than the French Marigold, blooming, as it does, from the present time until it is cut down by frost. Those who happen to have a good strain of striped or edged kinds, should now, as the plants come into flower, remove all that are single or semi double. This not only greatly improves the appearance of what are left, but is also necessary in saving seed, which is deteriorated by the presence of poor flowers. No seed should be saved except from the best double blooms. If the strain is too dark, or does not possess a sufficient number of the rich yellow-striped forms, or is deficient in size, a few plants of the African Yellow should be grown near, or amongst, them. These will cross with and improve the French varieties both in colour and size; but this must not be repeated every year, or they will become too yellow.

Astere.—Do not allow these to grow too thickly, or the flowers will be small, and the plants soon become exhausted. If they show signs of weakness, through the ground not being rich enough, assist them with manure water. There is no plant less able than *Asters* to bear the effect of aphides, whose presence is easily detected by the leaves curling up. A good washing with Tobacco water is the best remedy, and this should be applied as soon as the insects are detected, or the plants will be irreparably spoiled. The tall-growing kinds if at all in an exposed situation, will require a small stick and tie to each plant.

Hardy Fernery.—Ferns, unless well looked to and properly supplied with water, will soon present a shabby appearance, as thrips are sure to attack them. Moisture-loving kinds, such as the different varieties of *Athyriums* and the majestic-looking *Struthiopteris* will be the first to suffer, and therefore, where these have not a cool damp soil afforded them to grow in, frequent and copious waterings will be necessary to keep them in health. These should be applied overhead, so as to thoroughly wet the fronds, or where that cannot conveniently be done the garden engine or syringe may be advantageously employed to give them a thorough wetting; if this can be done every night it will considerably prolong their freshness and beauty. Where bulbous plants and others of a semi-wild character are grown in suitable portions of the hardy Fernery, as they always should be, the less interference they receive in the way of trimming or removal of leaves the greater will be their strength and capacity for blooming next year. It is a great mistake, for the sake of appearances, to denude such plants of their foliage, as is frequently the case long before it has died off and ceased to be useful, the effect being to stop the maturation of the bulb or crown of the plant, as the case may be, and prevent the formation of flowers.

Indoor Plant Department.

Conservatories.—The numerous choice stove plants available at this season for decorating both greenhouses and conservatories will afford more richness and variety, both in foliage and flower, than is attainable in these comparatively cool houses at any other season of the year; and as it will not be safe to allow choice specimens of these to remain in such structures for any lengthened period, it will be well to use them as extensively as possible during the next month or two, in order that the pleasure to be derived from them may be enjoyed without having to go into the strong moist heat of the stove to view them. By means of frequent changes and occasional re-arrangement much interest may be imparted and fresh effects produced in such houses; and, in addition to all this, the plants will be benefited by being turned and changed about, so as to expose a fresh side to the light. Were this more attended to, less training and tying would be requisite, and the use of objectionable stakes puncturing the ball might then in a great measure be dispensed with. Before placing choice specimens of stove plants in the conservatory, however, see that they are properly hardened, and select for them the best positions for showing them off to advantage, taking care at the same time that they are out of the way of cold draughts. To ensure their safety, keep them as dry at the root as the plants will bear without flagging or shedding their flowers; thus treated, they will endure the change much better than if they were freely supplied with water, wet and cold, at the same time, having a paralyzing effect on them. Keep roof-climbers properly thinned and regulated, otherwise, owing to the rapid growth which they are now making, they will soon become entangled. It is rare that conservatory borders are of sufficient depth or extent to keep in health such fast-growing, free-flowering plants as *Begonias*, *Tacsonias*, &c.; and where any of these plants are at all pinched for root-room, the deficiency in soil must be made up by giving an abundant supply of water, or red spider will soon make its appearance, and when once this pest becomes established, its removal is a work of some difficulty.

Camellias.—Most *Camellias* have their wood and flower-buds by this time sufficiently developed to necessitate removal to cooler quarters, so as to get their wood well ripened. Examine spring grafted and inarched plants, and unfasten all ligatures from such as have united and are growing, but still keep them in rather close quarters. Do not entirely head back the stocks to the scions until the latter have fairly started into growth, but shorten any too vigorous growth on the part of the stock. The end of this month, and for six weeks afterwards, is a good time for grafting *Camellias*; therefore have good, healthy, and well-established stocks in readiness, also a close pit or frame inside a cool house for the reception of the "worked" plants. They require dense shading for a time, and any that are too tall may be laid on their sides or in a sloping direction.

Daphne indica should, if possible, be kept on growing in a pit where a little closer atmosphere than that of an ordinary greenhouse is maintained, or it may be placed on the front shelf of a late Vinery, as the warm, moist atmosphere produced by syringing and closing the house early in the afternoon will completely answer its requirements; so treated it will make double the amount of growth that it would in a greenhouse, which is so far an advantage that it admits of more of the flowers being cut than when the plant makes less progress, although, under no conditions should too many shoots be removed when in bloom. This plant ought never to be exposed to the open air, as it suffers if the soil becomes too wet by exposure to rains. As generally seen, it is of medium growth, and even by those whose glass accommodation is limited half-a-dozen plants will not be too many to grow, and by keeping a portion through the winter a little warmer than others a long succession of flowers may be secured. It is essential never to overpot or overwater it.

Pleroma elegans.—This easily-grown and showy plant strikes as freely as a *Verbena* from the half-ripened shoots put in about the present time. They are best struck singly in small pots, drained and filled with a mixture of sifted loam, peat, and sand. Kept moist, covered with a bell-glass, shaded, and placed on an ordinary hotbed, they will root in a few weeks; after that they may be fully exposed, the points of the shoots pinched out to induce them to break, and subjected to greenhouse treatment for a couple of years. In the second summer they should be placed out-of-doors in the open air at the shady side of a tree or wall that will prevent the sun in the middle of the day shining upon their leaves, which are somewhat impatient of its direct influence. As they require more room move them on into 8-in. or 10-in. pots. So treated, they will bloom from almost every shoot, producing flowers which in colour are not equalled by anything in cultivation.

Pits and Frames.—Where pot plants are grown in pits they must be kept well up to the glass or they are apt to become drawn. Plants in such structures are more liable to get neglected as regards water than in houses, where they can be more readily examined. Under such circumstances, too, insects are more likely to escape observation than in more open quarters, and therefore must be looked after more closely. In addition to supplying pot plants with sufficient water at the roots, it is also requisite, while active growth is progressing, to keep the floors of the pits or frames on which they stand well and regularly moistened, for if this be not attended to the atmosphere during hot sunny weather becomes so dry that healthy growth is out of the question.

Hardy Fruit.

Strawberries.—Old Strawberry beds that have become exhausted should be dug over as soon as the fruit is gathered. The best method is to cut them off with the spade just below the collar and bury them as the work goes on, opening a trench for the purpose sufficiently wide at the commencement. The old tops thus dug under will benefit the ground, especially if it be of a heavy character. There is no better crop to follow Strawberries, when dug up at this time of the year, than Turnips, which should be sown as soon as rain falls after the ground is prepared.

Pears and Plums on walls should have their summer shoots removed as soon as they have ceased to grow, a state at which the trees will arrive sooner or later, according to the earliness or lateness of the locality in which they are grown. The object in taking these summer shoots off is to give the tree a better opportunity to form fruit-buds for the ensuing year, and to expose these to the ripening influence of sun and air; but if such shoots be removed too soon, *i.e.*, whilst there is a considerable flow of sap in the trees, more harm than good will be done, as the trees will start again into growth. The usual way is to break the breast-wood (for that is the term usually applied to these summer shoots) off with the thumb laid across the blade of the pruning-knife, or a stout pair of ordinary nippers may be used for the purpose, severing the shoots at about $\frac{1}{2}$ in. or $\frac{3}{4}$ in. above the point from which they spring.

Kitchen Garden.

Sowing Cabbages.—Those who have not had an opportunity of observing the marked influence which the difference of a few days in sowing the seeds of some vegetables exercises over the future crop are apt to smile at the fixed dates at which the last generation of gardeners used to have for sowing in spring and autumn. A little reflection will convince any one that the difference of a single day or two in committing the seed to the ground cannot be of vital importance; yet it is well not to treat old customs too lightly. The object which those who have preceded as had in view in fixing arbitrary dates was simply to prevent either too early or too late sowing, and thus ensure punctuality. For instance, in sowing Cabbage seed during the present month for the early spring supply, a difference of ten days has an important influence upon the time when the crop will be ready, and also affects the varieties grown. In the northern parts of the kingdom, where hardy sorts, such as the Esfield Market, stand the winter best, the seeds of these should be sown as soon as the 20th of the present month is passed; delay beyond this will cause the crop to be fit for use later in the spring. If sown sooner many of the plants will run to seed instead of hearing at the proper time. Where early varieties, such as the York, are grown, they must not be sown until eight or ten days later, or the plants will bolt. In the southern parts of the kingdom Cabbages should be sown a week later than the above dates, the later kinds being put in first and the earliest last. Where these directions are followed, the disappointment of seeding instead of hearing will not be experienced. Select an open situation where the plants, from the time they are up, will get plenty of light and air, for the drawn and weakly plants sown near trees or high walls are not calculated to stand a severe winter.

Celery and Scarlet Runners.—Where the seeds of Celery were sown early and the plants prepared as directed, with a view to obtaining an early supply, they will now be growing fast. Where the ground was well enriched there will not have been any necessity for watering; but where there has been a deficiency of manure, weakly applications of manure water will be required. Should Celery become at all affected with green fly, to which it is very subject if grown near anything else that is troubled with the insect, its presence will be indicated by the leaves curling up and an unhealthy, stunted appearance of the plants. So soon as any aphides are found give a good washing with soapy water from the wash-house, applying it with the syringe. To be effectual, like all other applications of a similar nature, it must reach every part of the plants above ground, for, even upon such portions of the leaves as harbour no

living insects, it is more than likely that there are eggs which will quickly come to life. Should the fly not be killed by one dressing, give a second within a few days. Scarlet Runners grown without sticks should have their shoots repeatedly nipped out as they push up; this will induce them to break afresh and continue flowering.

Extracts from my Diary.

July 22.—Sowing black-seeded Brown Cos Lettuce for winter use. Potting on small Cinerarias. Planting out Lettuces and Endive. Earthing up Cardoons. Lifting pickling Onions and spreading them out to dry. Sticking Peas and getting them earthed up, and topping those which are growing above the sticks. Picking Laxton's Unique and William I. Peas for seed. Getting large rough frames ready for sowing late Peas and late dwarf French Beans so as to protect them from the early autumn frosts. Nailing and tying in Roses on walls and picking off all dead flowers. Hoeing and weeding amongst Strawberries, and cutting away all runners that are not required for planting.

July 23.—Sowing Laxton's Omega and Unique Peas. Budding Roses, and giving them a good mulching with rotten manure. Hoeing and weeding herbaceous borders and giving them a general clean up. Watering Celery; also Leeks, Parsley, Turnips, &c. Gathering Black Currants for preserving. Clearing out Mushroom house and getting it white-washed. Giving the Peach trees in early house a good watering night and morning with the garden engine to keep down red spider and other insects. Lifting early sorts of Potatoes and spreading them out in the sun to ripen them well for seed next season.

July 24.—Putting in Pink and Carnation pipings under hand-lights. Gathering Apricots for preserving. Earthing up Celery when the soil is dry and in workable condition. Weeding and picking over carpet bedding borders. Making up new Mushroom bed in the open ground. Looking over Marrows and Gherkins, and closely stopping them all. Digging up, manuring, and watering borders previous to sowing with Wheeler's Imperial Cabbage, and stopping and nailing in the shoots of Tomatoes on walls. Nailing in all the leading shoots of Peaches, Nectarines, Apricots and Cherries. Looking over Cucumbers and Melons, watering them and stopping them where required, and renovating the hangings round all manure frames.

July 25.—Potting on Celosias, Celenses, and Begonias. Picking off early blooms and pegging down the branches of exhibition Balsams. Stopping the laterals through all Vineries and giving late houses a good soaking with guano water inside and out. Staking and tying in plants on borders. Training out and pegging down bedding plants and clearing away decaying leaves and flowers. Thinning out Turnips, Carrots, and Spinach. Cutting back Laurels in pleasure grounds where overgrowing walks. Watering Lettuce and Endive beds, and hoeing amongst all growing crops.

July 26.—Putting in Phlox and Pelargonium cuttings. Tying out and picking the early blooms off exhibition Fuchsias. Weeding, hoeing, and afterwards mulching Aster beds. Stopping and tying out Dahlias and thinning out the blooms where required for exhibition. Cutting back Ivy on walls where overgrowing windows. Clearing off Peas and manuring and digging the ground ready for autumn Cabbages. Getting new mould into cold pits and pricking them out with Parsley roots for winter use. Cutting back the breastwood and nailing in the leaders of Plums and Pears. Gathering Raspberries and Red and White Currants for preserving.

July 27.—Pricking off a late batch of Primulas and Cinerarias. Transplanting Silences and Forget-me-nots from seed beds; also seeding Violas. Watering the Pines all through and putting sticks in any that require it. Cleaning up mould yards. Planting out a large breadth of Saveys for small heads; also Coleworts. Mulching late Peas with rotten manure. Getting all Pine pots washed and getting in the soil ready for potting. Giving Scarlet Runner Beans a good soaking of manure water. Weeding and cleaning Box edgings in garden walks. Watering Celery, Cardoons, Cauliflowers, and Tomatoes. Mowing and cleaning up the pleasure grounds and rolling down all gravel and turf that require it. Fruit in use for dessert: Pines, Grapes, Melons, Figs, Peaches, Nectarines, Strawberries, Cherries, Raspberries, Gooseberries, and Currants.—W. G. P., Dorset.

Wild Flowers for Table Decoration.—At the Woodbridge Horticultural Society's show, held on July 11, amongst centre pieces for table decoration were some pretty arrangements of wild flowers. Of flowers and froits combined I also noticed some good examples, but it is to the wild flowers I wish to direct attention. Amongst these Water Lilies, Corn-flowers, and Forget-me-nots are now abundant, and there is also an endless variety of foliage that almost possesses the fairy-like lightness of our native Grasses. With such materials one can scarcely avoid producing a graceful effect. Water bouquets were also largely represented, and for this purpose Water Lilies, Forget-me-nots, and other aquatic flowers looked far more at home than such subjects as Gloxinias and stove Ferns, which are frequently employed for that purpose. However beautiful exotic or even native flowers may be in themselves, their beauty may be greatly enhanced by having some regard to natural position and surroundings. A Water Lily should evidently be in a situation where it can be looked down on, while a climbing plant—like a *Tecoma*—can only be seen to advantage when viewed from below.—J. GROOM.

GARDEN BOTANY.

(Continued from p. 36.)

NUMBER OF SEPALS.—It has already been mentioned that the parts of the flower of dicotyledons are usually in fours or fives, or multiples of these numbers, and this, of course, would apply to the calyx as well as the corolla, and stamens and carpels. Perhaps as many as 80 per cent. or even 90 per cent. of dicotyledons have a pentamerous (five-parted) calyx. The number of sepals forming the gamosepalous calyx can usually be determined by the number of lobes. The *Fuchsia* and most of the members of the same order have a tetramerous, or four-parted, calyx, but the *Enchanter's Nightshade*, also belonging to the same family, has only two sepals, two petals, &c. Then there

Fig. 325.—Diagram of the flower of *Circea luteiana*; the two sepals lateral, and the two petals anterior and posterior.

Fig. 326.—Diagram of the flower of *Dicytra formosa*; one of the sepals anterior and the other posterior.

Fig. 327.—Diagram of the flower of *Plantago major*; neither of the four sepals with its median line anterior or posterior.

is the small family, the *Portulacæ* (*Portulaca* and *Calandrinia*), which is characterised by having a calyx of only two sepals. The flowers of *Calycanthus* and *Chimonanthus* exhibit a gradual transition from bracts to sepals, and sepals to petals, so that it is impossible to know where one ceases and the other begins.

POSITION OF THE SEPALS.—The accompanying floral diagrams illustrate some of the variations in the relative position of the sepals. When the calyx consists of only two sepals, they are either lateral, one on either side to the right and left, as in *Circea luteiana* (*Enchanter's Nightshade*—fig. 325), or one posterior, that is, next the mother axis, and the other anterior, as in *Dicytra formosa* (fig. 326). When there are four sepals, they are commonly arranged—one posterior, one anterior, and two lateral; but in *Plantago* (fig. 327) the centre of neither of the petals is in the same vertical plane as the centre of the

Fig. 328.—Diagram of the flower of *Phaseolus*, showing the odd sepal is anterior.

Fig. 329.—Diagram of the flower of *Linum*, showing the odd sepal is posterior, or next to the axis.

axis, two of them being to the right of it, and two to the left. When the calyx is composed of five sepals, the odd one is almost always posterior, or next to the axis, as in *Linum* (fig. 329), though in the *Leguminosæ* the odd one is anterior (fig. 328).

The Corolla.

Almost all that has been said respecting the calyx applies equally to the corolla, that is to say, there are regular and irregular polypetalous and gamopetalous corollas, and the position of the petals with respect to the axis is equally variable, as well as their number. But the cohesion and absence of cohesion of the petals are characters of more importance in systematic botany, as dicotyledons, having a distinct calyx and corolla, are divided into two groups, the polypetalæ and gamopetalæ (monopetalæ of some botanists). The natural orders belonging to the former are characterised by having, with few exceptions, the petals free to the base, whilst those of the latter group are almost invariably more or less united. There is, moreover, a greater variety in the shape of the corolla than

there is of the calyx, or at least the variations are more striking. There are several leading types of polypetalous corollas which we will briefly describe. One of the most striking is the papilionaceous type (figs. 330 and 331), and it is characteristic of a larger number of species than any other polypetalous corolla. It is irregular, and the upper or posterior petal is usually larger than the others, which it overlaps in the

Fig. 330.—Papilionaceous corolla.

Fig. 331.—Irregular polypetalous (papilionaceous) corolla spread open; the upper petal is termed the "standard," the lateral "wings," and the two lower more or less combined form the keel.

bud, both of its edges being outside of the others. The upper petal of a papilionaceous corolla is the standard, the two lateral ones the wings, and the two lower, which cohere more or less, form the keel. It is important to remember this distinction of the petals, because it is from various modifications in the shape and the relative sizes of the petals that some of the

Fig. 332.—Flower of Wallflower, showing the cruciform type of corolla.

Fig. 333.—Flower of *Silene pendula*.

generic characters are drawn. It is almost superfluous to give examples of this type, as they abound in the field and in the garden. The Furze, Broom, Pea, Bean, Wistaria, Clover, Lupin, &c., are of this type. Another type of polypetalous corolla characteristic of a large number of familiar plants is the cruciform (fig. 332). This has four petals, commonly consisting of

Fig. 334.—Flower of *Hypericum erythraicum*; corolla polypetalous and regular.

Fig. 335.—Flower of *Gann*, showing the rosaceous type of corolla.

an erect, stalk-like part (the claw) and a spreading limb. Cabbage, Candytuft, Stock, Wallflower, Arabis, &c., have a cruciform corolla. The polypetalous corolla of the Pink family (fig. 333) is similar to the cruciform, but it has five petals. All three of the types described have the petals more or less distinctly clawed. The Rosaceous type (fig. 335) has sessile petals, which spread from the base; this type is represented in many natural orders, and is not peculiar to members of the

Rosaceæ. The corolla of Aconite consists of two singularly shaped petals enclosed in the hood-shaped petaloid sepal (see fig. 336, where the sepal is removed to show the petals). In *Polygala* two of the sepals are much larger than the others and coloured like petals, and there are only three petals, and they adhere to the stamens. The two larger sepals are called the wings, just as the two lateral petals are of a papilionaceous

Fig. 336.—A flower of Aconite, with the sepals detached.

Fig. 337.—Flower of *Salvia bicolor*, with two-lipped corolla.

corolla, and they persist and enclose the seed vessel. Gamopetalous corollas offer a great diversity of shapes, but there are some very distinct types. The corolla of the Labiatæ (*Salvia* family) is usually two-lipped (bilabiate)—fig. 337—as it is also in many Acanthaceæ (*Justicia*), Scrophulariaceæ (*Pedicularis*),

Fig. 338.—Ligulate corolla of the Compositæ.

Fig. 339.—Flower of Tobacco, with an infundibuliform, or funnel-shaped corolla.

and Verbenaceæ; but there is every degree, from a nearly regular shape to the very decidedly two-lipped corolla of *Salvia bicolor* (fig. 337). When the two lips meet and enclose the stamens (*Antirrhinum*, for example), the corolla is persouate. The ligulate corolla (fig. 338) is characteristic of the Com-

Fig. 340.—Flower of *Hyoscyamus albus*; corolla gamopetalous and regular.

Fig. 341.—Flower of *Symphytum officinale*, with a tubular corolla.

Fig. 342.—Flowers of *Cestrum*; corolla gamopetalous and regular.

positæ (see paragraph on the capitulum); in the Dandelion all the flowers of the head are ligulate; in the Daisy only the outer ones, the others being tubular. Honeysuckles have an irregular corolla something of the same shape. Among regular gamopetalous corollas are the campanulate (bell-shaped), as of

many Campanulas, *Convolvulus*, &c.; the infundibuliform (funnel-shaped), fig. 339; the tubular (fig. 341); the vase-shaped (fig. 342); the salver-shaped (fig. 343); the urceolate (fig. 344); and the rotate (fig. 345). There is no very precise meaning attached to these terms, and campanulate corollas are as variable in form, or perhaps more so than bells.

APPENDAGES OF PETALS.—The petals of the Ragged Robin, *Campion*, and many of the same family (*Caryophyllaceæ*) are furnished with a scale at the base of the limb; and most of the Boraginaceæ (*Myosotis*, *Borago*, *Symphytum*) have the throat of the tube of the corolla closed by scales. *Cardiospermum* (fig. 346) has the petals provided with a crested scale; the famous Coca tree has the petals furnished with two lateral crested scales (fig. 347); and the petals of the *Buttercup* (fig. 348) have a small glandular body at the base.

Fig. 343.—Flower of Lilac, with hypocrateriform or salver-shaped corolla.

Fig. 344.—Flower of *Arbutum Unedo*, with an urceolate or urn-shaped corolla.

Fig. 345.—Flower of *Lysimachia*, with a rotate corolla.

INSERTION OF PETALS.—When the calyx is adherent to the top of the ovary, the petals appear to spring from the base of the limb of the calyx, and are what is termed epigynous; when the petals are attached to a free calyx, or a calyx that is not adherent to the top of the ovary, they are perigynous; and when they spring from the enlarged floral axis itself, free from the calyx and below the gynoecium, they are hypogynous. The same terms apply to the insertion of stamens, though in both cases it may be the result of adhesion commencing in a very early stage of development.

ABSENCE AND SUPPRESSION OF PETALS.—When a species of a

Fig. 346.—Petal of *Cardiospermum Halicacabum*, furnished with a central crested scale.

Fig. 347.—Petal of *Erythroxylon coca*, furnished with two lateral crested scales.

Fig. 348.—Petal of *Ranunculus*, furnished with a gland at the base.

genus normally having petals is destitute of them it is said to be apetalous. Most of the species of *Fuchsia*, for example, are provided with petals, but there are about six apetalous species. In *Amorpha fruticosa*, a shrub belonging to the Leguminosæ (sub-order, Papilionaceæ), only the upper petal or standard is developed, all the others being suppressed. *Clematis* and *Anemone* are referred to the Ranunculaceæ, although they are apetalous, because in all other essential characters they agree with *Ranunculus*, &c. In these genera the sepals simulate petals.

The Perianth.

A general definition of the perianth, as the term is employed in descriptive botany, is given in a previous paragraph, and we need only repeat here that in practice it is applied to the floral envelope when it is in one whorl or series, or if in more than one whorl the parts of both whorls are similar in shape and

colouring. The perianth is free and polyphyllous or gamophyllous, or it is adherent to the ovary, and it is either regular

Fig. 349.—Female flower of Stinging Nettle, having a four-leaved perianth.

Fig. 350.—Female flower of Rhubarb, with a six-leaved perianth.

or irregular in form. The perianth of the Cupuliferæ (see also preceding paragraph on the involucre of this family) specially

Fig. 351.—Fleshy perianth of Muhlenbeckia surrounding the fruit.

Fig. 352.—Irregular gamophyllous perianth of *Aristolochia clematitis*.

deserves our notice, as its real nature is likely to be misunderstood. In the Oak and Beech the perianth is adherent to the

Fig. 353.—Perianth of *Aristolochia tricusdata*.

ovary, but though this is not very apparent in the mature Acorn or Beech Mast, it can be traced by beginning at the

flowering stage. Several dicotyledonous orders have a single perianth, as the Thymelacææ (*Daphne* and *Pimelea*); Proteacææ (*Banksia* and *Grevillea*), with the stamens superposed on (opposite to) the leaves of the perianth; the Urticacææ (*Stinging Nettle*—fig. 349); and the Polygonacææ (*Rhubarb*—fig. 350). The free perianth is either deciduous or persistent; in *Muhlenbeckia* (fig. 351) it is persistent, and becomes fleshy. The Aristolochiacææ (*Aristolochia*, *Asarum*) have an irregular gamophyllous adherent perianth of very variable shape (figs. 352 and 353). There are two principal types of perianth in

Fig. 354.—Perianth of an Orchid.

monocotyledons: the petaloid (*Tulip*, *Hyacinth*, *Crocus*, &c.) and the glumaceous (*Grasses* and *Sedges*). The former is usually of some other colour than green, and often very brilliantly coloured; and one of the principal things to note is, whether it is free from the ovary, as in *Lilies* and *Tulips*, or adherent to it, as in *Iris*, *Snowdrop*, and *Narcissus*.

The Perianth of Orchids.

The perianth of Orchids presents a most wonderful diversity of singular forms; all belonging, however, to one type almost peculiar to the family. It is almost invariably irregular, and consists of six pieces in two series. The three outer ones are

usually uniform in size and shape, and are generally called sepals; and of the three inner parts, the two lateral (petals) are alike, and the other of a very different shape (fig. 354). The latter is called the labellum or lip, and it is this that varies so much in size and shape and colour, being usually of a different colour or differently marked from the others. Oftentimes it is produced below in the form of a spur, which attains a length of $1\frac{1}{2}$ ft. in *Angraecum sesquipedale*, of which fig. 354 is a reduced representation. It is always adherent to the ovary, and almost always the posterior part becomes anterior through a half twist of the ovary.

W. B. HEMSLEY.

THE FRUIT CROPS.

SCOTLAND.

Floors Castle, Kelso.—Apples are a complete failure hereabouts. Apricots are a partial crop on most trees, Moorpark being the best sort. Plums are plentiful, and we never had so many Green Gages for these last eight years as we have this season. Cherries are a failure, and the Morello crop was never so bad; but I attribute this to a severe north-east blast which smote the trees on May 20, while Apricots and Plums on an opposite aspect were more sheltered. In a case of this kind walls are invaluable. We have very few Pears, and this I attribute to the occurrence of a cold north-west wind at the time of flowering, although they were protected by a 3-ply net. Our Pear wall has the disadvantage of not having a natural protection from a plantation, which is not half established; but in a few years this plantation will give the desired protection. My opinion is that cold winds do more harm than frost, for we can protect from frosts, but we cannot protect from cold winds. Strawberries are an excellent crop. Gooseberries poor. Currants are good, and so are Raspberries.—HENRY KNIGHT.

Tynninghame, East Lothian.—Apricots are a fair crop here and throughout the neighbourhood. Apples poor, except some of the earlier sorts; the blossoms wanted stamens. Pears on some trees good, on others only middling. Plums generally a heavy crop. Cherries a full crop. Strawberries, Black and Red Currants, and Raspberries extra heavy throughout the district. Gooseberries in general next to or entirely a failure; in our own case a very heavy crop. The trees generally were damaged some two months ago, but they are now making clean healthy growths, and bid fair to ensure a good promise for next season, provided the weather proves at all propitious. The remarks as to varieties remain the same as in previous years. A new Strawberry, named Moffatt's Duke of Edinburgh, is being largely grown for market purposes. It is a heavy cropper and very large, but deficient in flavour. Mr. Sinclair, of Prestonkirk, grows it largely for market, and it is certainly worthy of a trial in other districts.—R. P. BROTHERTON.

Culzean Castle, Ayrshire.—Fruit crops hereabouts this season are in general good. Strawberries have been very plentiful, especially Keen's Seedling, which does best in this district. Gooseberry bushes are quite loaded, but in some gardens near here they are scarce. Currants, both Red and Black, are a medium crop, although they promised well when in flower. Raspberries are a good crop, but the fruit is small. Apples are very plentiful, and the same may be said of Pears, especially those on walls. Cherries, Figs, and Plums are also good crops. Our most fruitful Apples here are Lord Suffield, Ecklinville, Royal Russet, Early Margaret, Keswick Codlin, King of the Pippins, Wormald's Pippin, and Cambusnethan Pippin. Pears Williams' Bon Chrétien, Knight's Monarch, Marie Louise, Passe Colmar, and Ne Plus Meuris. Plums Victoria, Kirke's, Jefferson, Coe's Golden Drop, and Rivers' Early Prolific. Our kitchen garden is well sheltered from the north and east winds, and the soil is of a heavy, stiff character, resting on a hard red clay.—D. MURRAY.

Eglinton Castle, Ayrshire.—Fruit crops hereabouts this season are very variable, a circumstance attributable to last season being exceptionally wet and cold, so that neither wood nor buds were matured; hence, though the blossom was abundant and the spring more favourable than that of the average of seasons, the blooms fell off without setting. There are, however, some exceptions, in which a fair average crop will be secured, arising from the situation being better sheltered and the soil more suitable than ours. Apples will be very scarce—generally speaking, very few, if any. Of Pears the blossom was less abundant than that of Apples, but the crops are heavier. Plums are more abundant than they have been for some years. Cherries are a fair crop. Currants heavy, as far as I have seen and heard. Gooseberries very partial; in some gardens they

are a heavy crop, but, on the whole, they are scarce. Raspberries ure a fair average crop, and the same may be said of Strawberries. Our garden here lies very low and damp, being only a few feet above the bed of the river Lugton, and also a very few feet above the sea level. The soil is generally heavy, and very unamiable for good fruit returns. The following are the names of fruits that seem to do best with us, viz., Apples—Lord Suffield, Ecklinville, and Stirling Castle. Pears—Beurré de Capiauimout, Williams' Bon Chrétien, Hessel, Jargonelle (on walls), and Marie Louise. Strawberries—President, Garibaldi, Keen's Seedling, and Elton.—J. GRAY.

Bothwell Castle, Lanark.—I may state generally that Strawberries, Raspberries, and Cherries, more especially Morellos, are fully average crops; other sorts of fruit are rather below the average; that is the case here, and I understand that it applies to the Clyde orchards generally. Gooseberries are grown more largely than other sorts of fruit in this locality for the Glasgow markets, and the annual public sale which took place recently realised much less than in average seasons. The soil in the parish of Bothwell is very variable, but a stiff soil with a clayey sub-soil predominates.—ANDREW TURNBULL.

Munches, Dalbeattie.—Small fruits are generally a good crop, except Gooseberries, which are decidedly defective. Apples, Pears, and Plums are in most places a short crop, although not quite so bad as last year. We have had a variable spring, but no frost to do any injury, from which inert blossoms generally suffer seriously. I may mention that we never now have the crops of large fruit which we used to have forty or fifty years ago either from standards or from walls. Probably this may to a small extent arise in the case of Pears, at least on the walls, from our trying to introduce too tender or early blooming kinds.—W. H. M.

Dumfriesshire.—A most abundant crop of blossoms on both Apples and Pears disappeared without leaving scarcely any fruit behind. Last year's growth has been very much affected with canker and dying back. No doubt these results have been brought about by the dull wet summer and autumn of last season having left the wood in a very immature condition. Plums in some gardens are a good crop. Gooseberries are about half a crop, and the bushes are not looking well. Raspberries, Currants, and Strawberries are plentiful. There has been less frost here in May than for the last ten years, and, so far, the summer has been a great improvement on that of last year. Potatoes are looking exceedingly well, and, should the autumn be fine, there is the prospect of a fine crop.—D. THOMSON.

Blythwood, Renfrewshire.—Fruit prospects, and even the condition of the trees this year in this neighbourhood being so infested with caterpillars, are very discouraging. The trees bloomed well, but did not set. Apricots and Peaches on walls are quite a failure, the wood of neither being at all well set. Plums and Pears are a thin crop. Morellos about an average. Apples poor, but some sorts, such as Brabant Bellefleur, Cox's Pomona, Cellini, Ecklinville, Lord Suffield, and Stirling Castle, have more or less of fruit on them. Gooseberries are rather under the average; in some gardens nearly all had failed; in others there is a good crop. The bushes have been badly infested with black aphid. Black Currants are plentiful and fine, and Red and White ones are also abundant. Strawberries are heavily cropped, especially Garibaldi, Baum's Seedling, and Dr. Hogg. Raspberries also promise to be a good crop. The soil here is stiff and heavy, with no lack of atmospheric moisture.—JOHN METHVEN.

Dupplin Castle, Perthshire.—The Apple crop in this district is all but a failure. Apricots the same. Plums are a heavy crop; Green Gage and Victoria being particularly fine this season. Pears are not half a crop. Strawberries are a good average crop. Gooseberries and Raspberries are an average crop. Owing to the cold, wet summer last year trees on walls did not ripen their wood sufficiently, consequently any blossom that was on them did not set.—JOHN BROWNING.

Ardrara Castle, Ross-shire.—Our fruit prospects this season are not good. Pears, Apples, Plums, and Peaches are all deficient; the cold, wet, and useless autumn of last year did not ripen the wood sufficiently. Peaches in orchard houses here (which are unheated) had the leaves hanging quite green at Christmas. Gooseberries and Currants are a moderate crop. Strawberries and Raspberries look promising. Our soil is a heavy loam resting on a cold, damp bottom. Only hardy and early sorts of fruits succeed here, even in favourable seasons.—ROBERT MASSIE.

Gordon Castle, Fochabers.—Peaches and Apricots are a light crop, early set fruit and expanded blossom being killed by frost, accompanied by a high wind in the last week of March. Pears are generally a light crop on walls; those on espaliers and standards are better. Apples are generally light; though they blossomed abun-

dantly, they set badly. Plums are a good crop both on walls and standards. Cherries good. Strawberries are a light crop here, but they are good in the neighbourhood. Raspberries, Currants, and Gooseberries are all abundant.—J. WEBSTER.

Glamis Castle, Forfarshire.—Most of the hardy fruit crops are under average in this quarter. Standard Apples are almost a total failure, and Pears are the same, except on walls in favourable situations. The following Plums on walls are a fair average crop, viz., Coe's Golden Drop, Green Gage, Goliath, Jefferson, Orleans, Prince of Wales, and Victoria. Peaches in the open air are almost a blank, and Apricots are not half a crop. Strawberries are plentiful and of fine quality; our favourites are Eclipse, Vicomtesse Héricart de Thury, Sir Joseph Paxton, Keen's Seedling, Duke of Edinburgh, and Elton Pine, all of which are very fine here. Cherries, with the exception of Morellos, are under average. Raspberries are an average crop. Gooseberries half a crop, and Currants are much the same. Most blossoms looked weakly in the spring, a circumstance owing to the cold and wet summer of 1877. This season is, however, very different, and if it continues we may look out for better results next season.—GEO. JOHNSTON.

Cawdor Castle, Nairn.—Small fruits, such as Gooseberries, Raspberries, Currants, and Strawberries, are abundant. Apples very unequal; Lord Suffield, Stirling Castle, and others need thinning, while on some there are none; others are carrying half a crop. Our soil is light, mostly on a gravelly sub-soil. Pears are a scanty crop generally; an old Jargonelle here is bearing a good crop and early; on others on walls there are none. Of Plums we have a sprinkling, but in a garden in the neighbourhood they are in clusters. Cherries mostly dropped when stoning. Apricots are an average crop; I protected with canvas, but a neighbour who used no protection has crops as good as mine. Of Peaches we have none; the old leaves were on them when we pruned in April. This season is in striking contrast to that of last year, fruits being a month in advance of last season. Gooseberries look large. Our best Strawberries are Garibaldi, President, and Elton Pine. Plums—Victoria, Jefferson, and Early Orleans.—JAMES MAITLAND.

WALES.

Margam Park, Glamorganshire.—Excepting Strawberries, Raspberries, Currants, Gooseberries, and Plums, none of our fruit crops are heavy this season, but there is a very fair sprinkling of fruit on many of the Apple, Pear, Cherry, Peach, Nectarine, and Apricot trees, and no kind of crop is an entire failure. Keswick Codlin, Lord Suffield, and Hawthornden are three of our best kitchen Apples. Of these the first never misses a good crop, and this is its general character in Wales. King of the Pippins, Blenheim Orange, and Golden Pippin are amongst our best dessert sorts. The Victoria Plum is bearing heavily, as it always does, and Kirke's, Jefferson's, and Coe's Golden Drop are not far behind it. Moorpark Apricot is the only one that can be relied on in this neighbourhood; it only fruits, however, in certain seasons; but this is not a first-class Apricot district. Royal George, Noblesse, Lste Admirable, and Salway Peaches are bearing fairly well on a south wall, and these and the Elruge and Victoria Nectarines succeed much better than Apricots. May Duke Cherries have been moderately plentiful, and on some trees Morellos are abundant. Medlars are a fair crop, and Raspberries and Gooseberries are very plentiful. Currants—Red, Black, and White—are abundant. Keen's Seedling and Black Prince Strawberries are the two which succeed best here, and they have produced an excellent crop; on Sir Charles Napier and President we have hardly any. We do not protect any fruit trees much in spring; they are well sheltered, by means of plantations, from the north and west, but the east winds frequently do much injury both to the bloom, tender fruit, and foliage.—J. MUIR.

Downton Castle, Ludlow.—Fruit crops hereabouts vary a great deal. In my own case Apples will not be half a crop; those that have set best are Codlins and Devonshire Reds. In other localities they are a total failure, with the exception of older Apples, which, generally speaking, bloom late. Currants are a fair crop. Gooseberries middling; generally speaking, the Warringtons and Rough Reds are carrying the heaviest crops. Sweet Cherries are poor, but Morellos are a fair crop. Apricots a middling crop. Peaches and Nectarines fair; the latter were protected with frigidome and Fir branches, and so were Apricots, but the trees have not altogether escaped without blistered leaves, which so badly affected them last year. Plums here are a fair crop, and in other parts they are a heavy crop. Damsons the same. Walnuts are very thin, and so are Filberts. Raspberries are a fair crop. Strawberries plentiful and good, especially President, Keen's Seedling, and Sir Charles Napier. Figs not grown. The soil here is generally stiff clay rest-

ing on a shaly rock. Trees appear to live a long time in such soil, but do not improve with age. Pears are a failure; they showed a fair quantity of bloom, but it dropped off. At the time when several of the above were in bloom we had a very deep snowstorm, with from 4° to 10° of frost, which killed quantities of bloom. The best crops of fruit are where the trees are protected from the east and north-east winds, but the rainfall has been excessive this spring. During the whole of May and early part of June we scarcely had a fine day, which partly accounts for the failure of the Apple crop.—N. F. FULLER.

Bodorgan, Anglesea.—Apples here are much below the average. Pears are a light crop; Marie Louise, Beurré Rance, and Beurré Diel promise best. Plums are almost a failure, with the exception of Green Gages, which are a moderate crop. Cherries good, especially Morellos. Peaches, Nectarines, Apricots, and Figs do not succeed in the open air here. Gooseberries and Currants are average crops. Strawberries very good, both in crop and quality. Aphides have been unusually troublesome on Plums and Cherries. Our soil is a moderate loam resting on a substratum of rough, hard, stony clay. The climate is mild, particularly in winter, from 14° to 16° of frost being very unusual. The great drawback to outdoor fruit growing about here is exposure more or less to the prevailing winds blowing from St. George's Channel, often charged with moisture and very saline. All trees in a greater or less degree in a few years become covered with Moss and lose vigour. Of hardy fruits that succeed best with me I may mention Apples for autumn and early use—Early Oslin, Keswick Codlin, Lord Suffield, and Hawthornden; later sorts—Cox's Orange Pippin (the best of all dessert Apples), Ribeton Pippin, Damelow's Seedling, Alfriston, Blenheim Orange, Reinette du Canada, Count of Wick, Golden Noble, Norfolk Beefing, and Dutch Mignonne; these are our most reliable sorts. Of Pears, Louise Bonne of Jersey, Marie Louise, Beurré Diel, Passe Colmar, Crassane, and Glon Morceau do best. Of Plums few succeed, except Green Gages. Cherries do fairly well against walls, especially Morellos. Amongst Strawberries the best are President, Sir Charles Napier, Keen's Seedling, and Dr. Hogg. Vicomtesse Héricart de Thury is very good this year, but has always failed before. I shall discard it, as not being so reliable as the sorts first mentioned. I have tried many sorts, but none do so well as the three first named.—J. ELLAM.

Cardiff Castle.—Of Apples we have not more than half a crop; the fruit is small and the leaves very much browned by the storms which we had in May. Pears are partial in places, and, on the whole, scarce; and of Figs we have none. The trees promised well for a crop, but the slight frost which we had in May killed the young fruit. Stone fruits are scarce, and the leaves are very much injured by green fly. Plums scarce, with the exception of Victoria, which bears well in most seasons. Peaches are a fair crop in some places, but in others there are none. Nectarines partial, and Apricots a half crop. Vines on the castle wall here and at the Vineyard, Castle Coch, promise well for a good crop, notwithstanding the severe storm which occurred on Sunday, May 19, which broke off a great many of the tender fruit-bearing shoots and leaves. The plants are strong and healthy, and although the crop will not be heavy, owing to the damage done by the storm, the bunches will be larger and finer than they were last year. Storms of wind are more to be dreaded in the Vineyard here, as well as in the Vineyards of France, than frosts. Strawberries and Raspberries are heavy crops and the fruit is of good quality. Gooseberries and Red, White, and Black Currants are plentiful here, but scarce in more exposed places in the district.—A. PETTIGREW.

Castle Malgwyn, Boncath, S. Wales.—Fruit crops, as a whole, are not very good this year. Pears are nearly up to the average. Apples much under the average, but there is a pretty good crop on an espalier and dwarf-trained trees both here and in the neighbourhood; on orchard trees, however, there are scarcely any, though there was a good show of bloom. Cherries are good. Peaches (outdoor) an average crop. Figs and Plums the same. Apricots do not succeed here, nor in the neighbourhood. Nuts are under the average. Of Gooseberries we have very few. Red, White, and Black Currants are average crops. Strawberries plentiful and large; some we had measured from 5 in. to 6 in. in circumference. The soil here is naturally stiff clay, but in the garden under my care, which is about five acres in extent, it has been removed to about 2 ft. in depth, and replaced, as far as possible, with better soil; still we have, however, the cold wet sub-soil which makes vegetation very late, but we are improving it by means of burnt clay and lime. Vegetables do remarkably well in it, but it requires great care to make fruit trees succeed. The system which I am adopting with these is to open a hole 4 ft. square, bottom it with flagstones or slate, with smaller stones on the top to prevent water from standing about the roots; I then get some good loam and plant the trees in it, root-pruning them

afterwards if too vigorous or adding fresh soil if too weak. Unless something of this sort be done it is impossible to get good fruit. Some of the soil in this neighbourhood is very shallow, being situated on the slate rock, and fruit trees generally canker on it.—HY. HOWARD.

IRELAND.

Headfort, County Meath.—I have a fair share of Apples and Pears, but they are not, as a rule, good crops. Strawberries are very good; also Black, White, and Red Currants. Gooseberries fairly good. Raspberries very poor with me. I have left Peaches and Nectarines to the last, for with me they are the least. Owing to continual rains last year and a wet, cold, clayey subsoil, the wood did not ripen, so we could not expect fruit, although we are well sheltered from the north and east winds. I also hear had accounts of the Apple and Pear crops from other gardens. In some there are no Gooseberries. In one garden here Plums are a good crop, but the same cannot be said of anything else.—JOHN CLEWS.

Birr Castle, Parsonstown.—Apples set an abundant crop hereabouts, but three-parts of them have dropped off, the ground being literally strowed with them; some trees have even cast the whole of their fruit. Cherries are an average crop, but small. Figs are an average, but very late. Plums are pretty good. Pears an average both on trained and orchard trees. Peaches on open walls have set well where they were protected during cold nights whilst they were in blossom, but I fear they will not ripen unless we have a very fine autumn. Strawberries are an abundant crop of fine fruit; the heavy rains which we experienced in spring seem to have suited them admirably. Gooseberries are thinner than usual, but fine. Currants are very good. Raspberries are abundant and good. Nuts are very promising. The soil here is of a heavy, clayey nature, but we are pretty free from frosts.—T. J. HART.

Powerscourt, Wicklow.—With few exceptions, stone fruits are not so good as usual in this district. The great amount of rain which we had in the spring prevented the fruit from setting. Apples and Pears are also very thinly set. Amongst Apples the old Keswick Codlin and Lord Suffield are bearing well in our light land lying on gravel. Another good bearing sort of Apple is King of the Pippins, on which there is a fair crop. Strawberries and Gooseberries are particularly good, as are also other small fruits.—C. PENFORD.

SUPPLEMENTARY ENGLISH REPORTS.

West Middlesex.—Living in the midst of market gardens and fruit orchards, I have excellent opportunities both for ascertaining and observing the general character of the crops in the district, and I find that the great main fruit crop—that of Apples—is so light as to be regarded as about one-third of that produced in a good season. When the trees were in bloom all looked rosy enough, but in a week or two it was seen that the fruit germs had fallen wholesale, and that the promise of a good fruit year was greatly reduced. Since then there has been another great thinning during what may be called the seed-setting season, and now the crop shows itself in all its full nakedness. A good sprinkling here is far more than compensated by a miserable crop there, some kinds being fairly good, others bearing none; and others again, say, a third of a crop. An orchard that in a good season has produced 1000 bushels this year will not give more than 300. If the 1000 bushels produced at 5s. per bushel £250, the 300 at the enhanced price of 8s. per bushel gives a total only of £120. Pears are a poor crop; so few indeed are they, that it is rare a tree is seen having enough fruit upon it to render it noticeable. The most favoured market Pears are Willisms' and Hazel. As a rule these are the most certain bearers; therefore, when they have a thin crop it is not likely that other kinds are worth looking at. The Plum crop is fairly good, although not so heavy nor the fruit so large as it was three years ago. To get two good Plum crops within that short interval is unusual, as such results rarely follow oftener than once in five years, but we welcome the Plum crop this year as some recompense for the losses incidental to other fruits. It is, however, a very temporary crop, in and gone in a few weeks; and, if not marketed ere ripe, is often irremediably spoiled. Prince of Wales, Victoria, Diamond, and Goldee Drop are the most favoured market sorts. Of Cherries, the crop of dessert kinds was only about one-half what it should have been, and the fruit not so fine as could have been desired. Morellos, grown largely here as standards, have about two-thirds of a crop, but these rank among the more regular of fruit producers. Raspberries, now nearly over, have been fairly good, better than Red Currants, of which there has been but a moderate crop, and that thin in the bunch. Black Currants in some gardens are a fine crop, in others a very thin one; thus it is difficult to estimate the general bulk. The selling price, however, shows that there are much fewer than usual. Gooseberries were so thin that

nearly all were gathered to sell green, such a good price accruing; whilst Strawberries, the only other large market fruit, have been abundant and generally good.—A. D.

Bearwood, Wokingham.—Fruit crops in this neighbourhood are mostly thin, not at all what was expected early in the season, although they escaped spring frosts. The continuous fall of rain and little sunshine seem to have been equally disastrous. Of Apples we have here next to none. Pears are, however, a fair crop both on walls and standards. Peaches and Nectarines are very good, and that without any protection whatever. Apricots are thin, and our trees have suffered much from last year's wet, being on clayey soil. Plums are an average crop both on walls and standards. Of Cherries we have good crops. Strawberries on our heavy soil have also been good; the sorts which I find best this season are Keen's Seedling, Sir Charles Napier, and British Queen, the last very fine. Bush fruits are good, but of Nuts we have none. I may add that our early Potatoes turned out well; they consisted of Veitch's Ashleaf and Hammersmith Kidneys. In looking over later kinds I find that the disease has made its appearance. Cottage gardens seem to be suffering most from it.—J. TEGG.

Strathfieldsaye, Winchfield.—I am glad to be able to report favourably concerning the fruit crops here, with the exception of Apples and Pears. The former bloomed more sparingly than usual, but still I shall have a good half crop. Pears showed well for bloom, but though the flowers were not open, most of the buds were killed by the severe frosts which occurred between March 22 and April 10. Plums, both on walls and standards, are a heavy crop. Cherries a moderate one. Peaches are a fine crop, but insects have been troublesome ever since the young leaves began to unfold; by taking them in hand at once, however, the trees are now in a healthy condition. Apricots are a very fine crop; I protect both them and Peaches with coverings of stout Flax sheeting. I have repeatedly proved this to be a perfect safeguard against 12° of frost. It, of course, requires to be carefully fitted. It is rather expensive in the first instance, costing with fittings about 1s. 1d. per square yard; but I have some of it that has been in use for thirteen years. Therefore it is cheaper in the end than scrim canvas or, I believe, any other covering. Strawberries are abundant and remarkably fine this season. The same may also be said of Raspberries. Many of the Gooseberry buds dropped, but there is still a fair crop. I have for some years allowed the bushes to be very thick of wood, which I find affords protection from frost.—JAMES BELL.

Hanbury Hall, Droitwich.—Fruit crops here, with the exception of Apples, are very good this season compared with what they were last year. From Strawberries, such as President, British Queen, James Veitch, and Alice Mand, we had excellent first gatherings, but now, in consequence of the drought, they have ceased to bear. Gooseberries are a fair crop. Currants, Red and White, good; Black an excellent crop, the bushes being literally laden with fruit. Peaches are scarce. Apricots where protected with tiffany are a fair crop. Figs thin this season; last year we had an abundant crop of them. Plums on pyramids are a good crop, especially on such sorts as Denyer's Victoria, Orleans, Belgian Purple, and Prince Eglebert; on standards Blue Impératrice, White Magnum Bonum, Golden Drop, and Smith's Orleans are all good. Pears on pyramids are very satisfactory, the most prolific being Beurré Duhaume, Doyenné d'Été, Thompson's, Bergamotte d'Espereon, White Doyenné, Prince Albert, Beurré Giffard, Hscon's Incomprable, Knight's Monarch, and Easter Beurré; on walls the following are good, viz., Autumn Bergamot, Marie Louise, Louise Bonne of Jersey, Williams' Bon Chrétien, and Gansel's Bergamot. Cherries, such as White Hearts on standards, are very good; likewise Morellos on walls. Apples, excepting Keswick Codlin, Blenheim Orange, and Ribston, are a failure here this season. Filberts and Walnuts are also very thin; last season we had the best crop that had been gathered for years.—T. W. SANDERS.

Moreton, Dorchester.—Strawberries, Raspberries, Gooseberries, and Currants are all good crops with us. Apples are a very poor crop; on some espalier trees there is a fair crop, but on standards there are scarcely any, and the trees look badly. Our old tree of Tom Patt is bearing a good crop; this is a good hardy sort, and one which seldom fails. It ought to be more grown than it is, being a thoroughly good kitchen Apple, and one not to be despised for table use, and it keeps good until the end of December. Pears are a poor crop generally; Williams' Bon Chrétien, Louise Bonne of Jersey, Bergamotte d'Espereon, and Beurré de Capiaumont are the best. Plums are very poor indeed; Orleans and Victoria are the best. Morello Cherries are pretty good, but of other sorts we have scarcely any. Figs nearly all dropped. Peaches and Nectarines out-of-doors are very thin, and the trees suffered from cold in spring; but in orchard houses they are a good crop. In one garden in this neighbourhood there is a fair crop of Plums under glass, while out-of-doors

in the same garden there are next to none. Another garden furnishes a convincing proof of the need of protection; there a piece of thatch overhangs a small portion of a Winter Nellis Pear tree. Under the thatch the fruit is clean and good, and required thinning, while on the exposed part there are none. The Potato disease appeared earlier than usual in this neighbourhood. We have not much in our garden, but some patches in cottage gardens are much affected, both in haulm and tuber.—D. UPSHILL.

Killerton, Exeter.—Peaches, Nectarines, and Apricots are abundant, and the trees are healthy. Of Pears we have a moderate crop on walls, but on pyramids they are scarce. Apples in orchards moderate; they have fallen off very much during the last few weeks. Of Cherries we have very good crops. Plums are scarce. Figs moderate. Gooseberries a heavy crop. Black Currants only moderate; Red and White good crops. Strawberries are very fine and abundant, and of Filberts we have good crops. Potatoes of the earliest sorts both in frames and on borders are much diseased; late sorts very promising.—JOHN GARLAND.

Shrubland Park, Ipswich.—Hereabouts Apricots are a failure. Peaches on walls scarce; under glass plentiful. Pears and Apples are a partial crop and the trees are badly blighted. The sorts of Apples on which there are fair crops and that generally bear best are King of the Pippins, Nonanch, Cellini, Lord Suffield, Beauty of Kent, and Nonpareil. In a few orchards that are sheltered from the east winds there are average crops. The soil in this neighbourhood is variable, but chalk subsoil prevails. Among Pears, Louise Bonne of Jersey, Williams' Bon Chrétien, Althrop Crassane, and Beurré Rance on walls are the most regular bearers. Plums of all sorts are a light crop outside, but in orchard houses they are abundant. Strawberries are fine in size and quality, but only half a crop. Raspberries are plentiful. Gooseberries are a failure. Black Currants are a full crop and good. Red and White are under the average. We have had no rain here for the last three weeks.—THOMAS BLAIR.

Cossey Park, Norwich.—Of Apricots we have but few, and Peaches and Nectarines are a short crop, but the trees are healthy. Plums, both on walls and standards, are scarce, but in some quarters they are abundant. Apples are a good crop, but lately they have fallen so much that most of them are on the ground under the trees. Of Pears we have but few. Gooseberries are a fair crop. Currants are short and bad in quality. Of Strawberries we have an average crop. Walnuts and Filberts are not up to the average. The Potato disease appeared very early, but made little progress, owing to the drought. I never observed it so early as the middle of June before.—J. WIGHTON.

Priory Gardens, Warwick.—Fruit crops in this locality are, with a few exceptions, good. Peaches, Nectarines, and Apricots are scarce, except on trees which were well protected. Plums, consisting of Victoria, Kirke's, Magom Bonum, Orleans, Green Gage, and Damsons, are a fair average crop. Of Pears on walls and pyramids the following are carrying good crops, viz., Thompson's, Beurré d'Amanlis, Williams' Bon Chrétien, Marie Louise, Napoleon, Beurré Rance, Easter Beurré, Louise Bonne of Jersey, Beurré d'Arenberg, and Jargonelle. Apples are likewise heavy crops; those which are fruiting most freely are Lord Suffield, Cellini, Keswick Codlin, Normanton Wonder, Hawthornden, Newtown, Rieston, Forfar, and Cox's Orange Pippins, King of the Pippins, Blenheim Orange, Fairy, Emperor Alexander, and Early Nonpareil. Of Cherries we have an average crop of White Hearts, May Duke, Bedfordshire Prolific, and Morellos. Amongst bush fruits, Red, White, and Black Currants are heavy crops, and fine in quality. Gooseberries are, with a few exceptions, light—not half a crop. Raspberries plentiful and fine, and Strawberries abundant and extra fine in quality, though their season will be short, as the last two weeks of warm, dry, sunny weather have ripened them all at once. Walnuts are about half a crop. Filberts are scarce. Potatoes are turning out very good, and as yet free from disease. Our soil is light and poor, situated as we are on the sandstone rock; therefore a wet season suits us remarkably well.—ROBERT GREENFIELD.

Osmaston Manor, Derbyshire.—Apples, Pears, Apricots, Plums, and Damsons are medium crops. Strawberries and Raspberries good. Gooseberries half a crop. Red, White, and Black Currants good. Peaches, Nectarines, and Figs grown indoors and Cherries half a crop. Filberts and hedge nuts good. The soil here is almost all gravel, and in order to grow fruit well clay should be used with it. The following are the best fruits for this district: Marie Louise, Louise Bonne of Jersey, Williams' Bon Chrétien, Gansel's Bergamot, Comte de Lamy, Beurré de Arenberg, Easter Beurré, Winter Nellis, Glou Morceau, Passe Colmar, and Jargonelle Pears. Court Pendu Plat, Cox's Orange Pippin, Gravenstein, Ribston, Sturmer, and

Fearn's Pippins, and others amongst dessert Apples; and amongst kitchen sorts Blenheim Pippin, Cox's Pomona, Hawthornden, both old and new, Keswick Codlin, Manks Codlin, Northern Greening, Damelow's Seedling, Warner's King, Waltham Abbey, Lord Suffield, Minchall Crab, and others. Our best Cherries are Elton, May Duke, Black Tartarian, Black Eagle, Bigarreau, Napoleon, and others. Plums—Blue Gage, Green Gage, Cox's Golden Drop, Dove Bank, Kirke's, Jefferson's, Victoria, and Washington. Black Currants—Naples. Red Currants—Warner's Grape and Victoria; and Gooseberries—Warrington and Crown Bob.—JOHN BOOTH.

Huntroyde Park, Burnley.—Apples here are a complete failure; the trees were covered with healthy bloom, but it was destroyed by frost, a continuance of cold wet weather, east wind, and low temperature. Pears on walls with southern aspects are a fair crop; on east and west walls very thin. Marie Louise, Glou Morceau, Duchesse d'Arenberg, Beurré Diel, Autumn Bergamot, and Passe Colmar are amongst the best Pears for this neighbourhood. Plums on walls are a heavy crop; Jefferson, Rivers' Early Prolific, Angelina Brdett, Yellow Impératrice, and Victoria are some of the heaviest croppers with us, especially the last-named variety. Cherries are a fair crop on walls. Morellos, however, are light, both on walls and standards. Strawberries are not so heavy this year as we usually have them, and the fruit is smaller, owing to the hot dry weather which occurred while they were swelling. Gooseberries are a fair crop. Black Currants heavy. Red not so good. No Peaches or Apricots are grown hereabouts outside. We consider the season a fortnight earlier than we have known it to be for the last ten years. Our gardens are on the blue clay, very tenacious, and lying upon the coal measures in a valley running east and west. In the spring we have cutting east winds from March until the middle of June, and we occasionally suffer from south-west winds, especially late in summer. A dry season suits us best. Potatoes are turning up clean and good in quality.—H. L.

Latimers, Bucks.—Apples here are under the average, but on King of the Pippins there is a heavy crop. Our best sorts are Cellini, Cox's Orange Pippin, King of the Pippins, Lord Suffield, Blenheim Orange, Golden Noble, and Court of Wick. Plums are an average crop; the most prolific are Jefferson's, Victoria, Golden Drop, and Prince of Wales. Pears are a light crop, and so are Nuts. Cherries an average crop, but smaller than usual. Of Peaches and Nectarines we have very few. Strawberries are plentiful; the best sorts here are President, Vicomtesse Hélicart de Thury, Sir Joseph Paxton, Lucas, Oxonian, and Eleanor; also the old Hautbois. All sorts of Currants are plentiful, and so are Raspberries. Our soil principally consists of stiff clay; in some parts chalk. Potato disease hereabouts is very bad; the worst affected are the Early Rose and other American varieties.—A. DONALDSON.

MELONS AT CARDIFF CASTLE.

ON my way back from Bristol the other day I took the opportunity of making a hurried visit to Cardiff Castle, expressly to see the Melons growing there. I had heard much about the way in which they were managed, and I now wish to state that, although I have seen Melons grown in many ways and in many places, I never saw them cultivated so well as at Cardiff Castle. One side of a large span-roofed house is filled with them. The bed in which they are planted is about 4 ft. wide, and heated underneath with hot-water pipes; the plants stand about 6 ft. apart, and the material in which they are growing is a mixture of loam and manure. From the surface of the soil to the first wire of the trellis is about 4 ft., and each plant has a clean stem of that length as thick as a stout walking-stick. The leading shoot reaches the top of the trellis, which is a distance of some 6 ft., and from this the side shoots are trained horizontally. Not one of them encroaches on its neighbour; on the contrary, every one of them has its own place, like the shoots of a carefully-trained Peach tree, and not one of the leaves, which are very large, overlaps or shades one another. Five, six, and seven fruits were hanging on each plant, but their numbers were nothing to their size, plumpness, shape, and netting. Reid's Hybrid is a kind largely grown here, and, though by no means a large Melon, one of this variety which I saw weighed 5 lb., and it was not the largest; therefore 7 lb. would not be too much to guess them at. The 5 lb. one was quite ripe. The plant from which it was cut was growing in soil quite wet, yet there was no indication of splitting or deterioration in flavour, and every leaf was as fresh and green as when the plants were six weeks old. The Melons in frames were in all respects equally good; some plants put in for late crops looked most promising, although they were planted in the same soil in which early crops had been produced. CAMBERIAN.

ANSWERS TO CORRESPONDENTS.

Increasing Rhododendrons.—I possess a very fine species of Rhododendron, and I wish to obtain several plants of it by slips or otherwise. What are the best means of increasing it?—F. B. [The best way is to graft it upon the common *R. ponticum*. Cuttings taken off and inserted firmly in pots singly and kept close in a frame or under a handglass will also soon emit roots.—H. H.]

Ferns.—I wish to show Ferns at our forthcoming exhibition. The schedule says, "Six exotic Ferns, in pots, different species." Now I want to know if I may show more than one *Adiantum*, or *Pteris*, as the case may be, without being disqualified?—J. R. [As many genera as possible would doubtless be desirable, but obviously you may show more than one species in each genus and not be liable to be disqualified.—M.]

Jerusalem Artichokes.—Should these be thinned out now?—J. M. [They should have been thinned out when the plants were young; but if very thick you might even now cut out some of the stems.]

Vine Leaves.—*W. H. M.*—They are attacked by red spider, which you may see by putting them under a magnifier. Your only remedy is to keep the roots well supplied with water and the house moist, and if the Grapes be not colouring syringe the leaves, avoiding wetting the berries as much as possible. Painting the hot-water pipes or flues with thick guano water when the house is closed at night imparts vigour to the leaves and kills many insects.—S.

Names of Plants.—Correspondents wishing plants to be named will oblige by complying with the following rules: To send the specimens as complete as possible, i.e., both stem, leaves, and flowers, and fruit, when possible. We cannot attempt to name plants from single leaves. To carefully pack them in gutta-percha tissue, or other imperious material which will prevent evaporation. Not to send varieties of popular flowers, such as *Fuchsias* or *Pansies*, which are best named by experienced growers of such plants, who have the means of comparison at hand. Not to send more than four plants or flowers at a time. Always to send, in addition to whatever pseudonyms or initials they may desire to use in the paper, their full name and address. To pre-pay all packages containing plants or flowers.—*H. F.*—*Astrantia* major. *J. H. F.*—1. *Blechnum occidentale*. 2. *Gymnogramma Martensi*. 3. *Doodia lunulata*. 4. *Adiantum pubescens*. *P. M.*—Withered up; but looks like a double variety of *Gesnerium sylvaticum*. *C. M. A.*—*Encomis*, probably punctata, grown in shade. *C. W.*—1. *Caladium Meybeer*. 2. *Bethoven*. 3. *Decandolle*. *C. R.*—Your Aroid is *Saurumatum guttatum*, an East Indian plant. *H. M. E.*—The little rock plant is *Mentha Requienii*, a native of Corsica. *F. F.*—A promising Rose of the purple-shaded bright-crimson class; not large, but very double. *C. M. O.*—1 and 2. *Gentiana gelida*: 3. Probably *Semprevivum ciliatum*; but if leaves had also been sent it could have been named with certainty.

Begoniae Shedding their Flowers.—Many *Begonias* have a vicious habit of shedding their male flowers unexpanded. I observe this to occur in plants of different species in different greenhouses, and in some plants out of a number potted and treated alike. Can any of your correspondents assign a reason and suggest a remedy for a habit which detracts so seriously from the successful cultivation of this beautiful family of plants?—P. [*Begonias* shed their male flowers when not sufficiently watered, or when their roots are destroyed by too much moisture. Some varieties, however, always drop their male blossoms, and such sorts should be thrown away; others drop their male blooms when planted out-of-doors, but retain them when cultivated under glass.—L.]

Roses in Bouquets.—"Constant Reader" inquires (see p. 48) if a judge would be justified in disqualifying a bouquet containing one or more Roses which was competing for "the best bouquet of greenhouse flowers." I should understand a schedule so worded to mean that stove and hardy flowers are not to be used. If the competition took place at a season of the year when any flowers in the bouquet are in bloom out-of-doors, that bouquet ought to be disqualified, even if the exhibitor were able to prove that he gathered every flower from within a greenhouse. If a bouquet of hardy flowers were shown at a period of the year when none of the flowers could be gathered out-of-doors, I should regard that as a bouquet of greenhouse flowers. The white Japan *Spirea* must be regarded as a stove plant when in bloom at Christmas, a greenhouse plant in the spring, and a hardy plant in summer.—*W. T. T.*

Yellow Carnations and Insects.—Is there any cure for Carnations attacked by insects like the enclosed samples? I have a number of Carnation plants in my garden, but none are attacked as the beautiful yellow one is. I cannot make out if the mischief is done by earwigs or small snails. The bud, when large, is sometimes completely eaten out; at other times cut across, and the stem completely bared. Is there any remedy?—*C. F. C.* [It is not earwigs that have eaten the stalks of your Carnations; they, however, eat the lower parts of the petals. I have taken hold of flowers that did not seem much damaged, and have found nearly all the petals eaten clean through at the base. They can be best destroyed by picking them off with the aid of a lamp at night. Nor do I think that slugs are the depredators, as they mostly look for a softer substance on which to feed; if it is, you will find them at work at

dusk. In all such cases look for the culprit at night; you will find him feeding between 8 and 10 p.m.—*J. D.*]

Roses for Exhibition.—What is the quickest and best method of growing pot Roses for exhibition? and I shall also be grateful for any hints you may give me as to pruning and shaping them. My plants are young and vigorous.—*J. M.* [There is no quick road to making specimen Roses. Your young, vigorous plants should be kept growing healthily and steadily under glass during the next month, air being freely admitted and the plants syringed and shut up early in the evening. Then have them placed on slates to exclude the worms out in an airy, sunny position, and let them be taken under shelter before the winter rains set in, say by October 1. Water them occasionally during winter.—*Geo. Paul.*]

Anemones from Seed.—I will be much obliged for full directions as to the culture of Anemones. When to sow the seed? if in open ground, or in pans to transplant? what aspect? to be kept moist or dry? what soil? whether best left from year to year, or taken up and re-planted? in short, all information possible.—*G.* [Taking Anemones as they are understood in the seed shops, viz., the varieties of *coronaria*, of *fulgens*, and of *hortensis* or *stellata*, they are most successfully cultivated from roots. Of the forms of *coronaria*, double and single, they range from pure white through all the shades of lilac and purple to the richest glowing magenta; of *fulgens*, from the colour of a soldier's coat to bright crimson, including the double Peacock Anemone of the south of France, and *stellata* with its beautiful starry flowers. These all prefer a loamy, well-drained soil with partial shade, and if planted in succession will yield flowers for at least six months of the year. We have had a bed of *coronaria* varieties in bloom throughout June, and but for the hot sunshine and the absence of shade they would have continued a good way throughout July on soil moderately drained and somewhat inclined in summer to be harsh. These roots were planted in April. Plants of *fulgens* were in bloom from Christmas, along with the various single forms of *coronaria*. If you must have seed, it should be sown in March or April on a bed of well-prepared soil, moderately moist and in partial shade, and the seedlings should not be transplanted until the second year. On soil where these Anemones succeed, and where slugs do not prey upon them, they will flower earlier and continue longer in bloom if they are left undisturbed; on wet soils they are better lifted and re-planted late in autumn, and in such soils the roots are better surrounded by sand.—*P. Baur.*]

DYE PLANTS.

With reference to the article on "Dye Plants" (see p. 29), I may perhaps be allowed to point out that the Lo-Kao or green dye of the Chinese is obtained from the barks of *Rhamnus utilis* and *R. chlorophorus*. Its use in France was chiefly in the silk-producing districts for dyeing silk, but what is said with regard to its now being rejected, in consequence of the more general use of the coal-tar dyes, applies equally at the present time to nearly all the vegetable dyes. *Rhamnus Frangula* is described as yielding "Persian or Turkish yellow berries." *R. Frangula* is, however, the Alder Buckthorn, from the unripe fruits of which a green dye has been obtained; but the chief value of this plant lies in its wood, which is used almost exclusively for making charcoal in the preparation of the best rifle gunpowder, and is known to gunpowder makers as dog-wood. The little round fruits, known in commerce as Persian berries, yellow berries, French berries, or grains d'Avignon, are generally attributed to *Rhamnus infectorius*, but are probably furnished not alone by this species, but also by *R. amygdalinus*, and perhaps other species. *R. catharticus* (the Purging Buckthorn), which, like *R. Frangula*, is an indigenous British species, produces a green colouring matter from its fresh fruits, which, when properly prepared, constitutes the pigment known as sap green. The colouring matter from *Hibiscus rosa sinensis* is, unlike most other dyes, obtained from the flowers; these are either yellow, white, dark purple, red, or variegated. Upon bruising the petals they turn either black or purple, the black being so intense as to be used for blacking boots; hence the plant is sometimes called the Shoebuck Plant. Besides the Woad (*Isatis tinctoria*), *I. indigotica* is grown largely in the north of China for the sake of the dark blue dye afforded by it. JOHN R. JACKSON.

Museum, Kew.

Old Roses.—I notice that among the old Roses shown at the Crystal Palace was the old Yellow Provence. Perhaps some of the readers of THE GARDEN who succeed in growing this remarkably beautiful old Rose well will be so good as to describe their mode of culture or treatment in THE GARDEN. I possessed it twice, but could do no good with it on either occasion—only keeping it alive a few years, and cutting a few flowers of indifferent quality. I have only seen it good once, and that was in Devonshire. Has any one succeeded with it on the Manetti or the Brier?—*D. T. Fiss.*

DROUGHT IN THE EASTERN COUNTIES.

This has now become serious. We have had no rain since about June 20, and this long continuance of drought includes a week or more of real tropical weather from that date, when the thermometer reached 90° in the shade as its maximum and remained for nearly a week hovering between 75° and 85°. This intense heat coming on the back of a long period of dull weather tried vegetation to the uttermost. A few showers would have proved invaluable, but none have fallen. The indications of rain up to and about St. Swithin's were most tantalising, and since the 15th the weather seems to have cleared off for a new and more intense spell of drought. Vegetables flag, languish, and run to seed with provoking despatch, and the Apples continue to drop until it almost seems as if few would be left on those trees that did set a fair crop. Peaches and Plums seem rather to enjoy the drought. Roses on strong soils droop and flag, and the ground cracks into huge fissures. Potatoes are ripening fast. The early ones had better be lifted before the rains come, or the cresses are they will be ruined by the disease. The later Potatoes, unable to swell, have sent out feelers in the form of long white runners from the small tubers to see if moisture is within reach to enable them to form a secondary crop. The first crop is thus being ruined, and the second, if any, is not likely to prove of much account. No doubt the unusual heat has a good deal to do with this provoking development; perhaps as much, or more, than the drought. Potatoes do not bear tropical temperatures well. The heat and the drought have been all that could be desired for the hay, Corn, and Mangold crops. The first is now safely stacked; the Wheat and Barley are rapidly setting, and on warm soils also changing colour, and harvest, should this weather last, will be general by the end of July; this is much earlier than was anticipated. The Mangold luxuriates in the heat and the drought, in this respect presenting a striking contrast to Swedes, Cabbages, and Turnips, which are assuming a blue tint, as are Broccoli, Cauliflowers, &c. The greatest want of these eastern counties is more water in the gardens. Our waterings, to say the least of them, are a mere mockery. We want, as the farmer expressed it about his Turnips, to have a river over our fruit and kitchen gardens for twenty-four hours. I once saw this done on a Vine border at Belvoir. I believe that it is in the more liberal use of water that the French growers are enabled to beat us in the growth of summer salading. Labour must be cheap in France, judging by the amount of it expended in the cultivation of vegetables and salads, and the really moderate prices of the same in the Parisian shops and markets after being taxed with the duty at the barriers.

D. T. FISH.

Conifers at the Preston Show.—Amongst outside exhibits at this show none was more interesting than the collection of Conifers from the Borrowash Nurseries. They consisted of large and healthy specimens of the short-leaved Japanese Yew (*Taxus adpressa*), the Hoon Pine (*Dacrydium Franklinoi*), one of the most irregular-habited of Conifers, and one suitable for rockwork or elevated positions; and a distinct new hardy Conifer named *Retinospora tetragona aurea*, a variety having a free, upright growth and of a soft golden colour. With these also came a gigantic plant of the golden Dovaston Yew (*Taxus Dovastonii variegata*), a kind with a gracefully drooping habit, and one of the best of the Yews as far as single specimens on lawns are concerned; the true Japanese Hemlock Spruce (*Abies Sieboldiana*) furnished with drooping masses of deep green leafage; and the drooping, column-shaped *Podocarpus alpina*.—S.

Japanese Plants at the International Exhibition.—Some time since in speaking in the "Revue Horticole" of the interesting groups of plants exhibited by the Japanese at the Universal Exhibition, and on the special subject of Pæonies, M. Carrière remarked that the herbaceous varieties would not flower, which was much to be regretted, but that the shrubby Pæonies promised to bloom abundantly. In the number of the "Revue Horticole" for July 1, M. Carrière informs us that at the end of May a large number were in full bloom, the flowers being remarkable for the beauty and, in many cases, for the novelty of their colours. None of the varieties show very large or full flowers, but this is easily accounted for by their having to be re-potted on their arrival in Paris, an operation which would be quite sufficient to diminish the size of the flowers, and above all to lessen the number of their petals. M. Carrière does not give us the names of the most interesting varieties in consequence of their being tinketed in Japanese.—C. W. QUINN.

Carpet Bedding with Hardy Plants.—A carpet bed near the entrance to Messrs. Veitch's Coombe Wood Nursery is well worth notice, showing, as it does, what excellent effects may be obtained by the use of dwarf-growing hardy shrubs in what is called pattern gardening. The plants employed in this case are silver and golden-

leaved *Retinosporas*, *Euonymus alba-variegatus*, and *Mahonia*, the whole being edged with a band of *Erica herbacea carnosa*. Such beds give little or no trouble when once planted; they are equally beautiful in winter and in summer, and, although it might not be advisable to carry this style of gardening to an unlimited extent, yet a few such beds introduced into flower gardens where a series of pattern beds exist would go far to relieve the monotonous blaze of colour usually found in such places, and thereby greatly enhance the general effect.—S.

What is a Crop of Peaches?—A Peach tree at Sunbury Park is said (see p. 50) to cover 22 ft. by 22 ft. The estimated crop is 322 dozen fruits, or eight to the square foot. It would be interesting to know if that is a fair average of what the tree in question annually produces, or whether it is exceptionally heavy. One of the greatest mistakes to which we cultivators are liable is not thinning Peaches or other fruits sufficiently during their early stages of growth. Every one conversant with Peach culture is aware that a moderate crop of good fruit is of far more value, both commercially and for dessert purposes, than an unlimited number of inferior fruit; even at the lowest computation the crop at Sunbury Park on one tree would weigh considerably over $\frac{3}{4}$ of a ton. That the best examples of culture in every branch of horticulture should receive due recognition is only right, but too glowing reports often make inexperienced people dissatisfied with the results which they obtain. I must confess that a crop of Peaches averaging eight fruits to the square foot for every foot of trellis covered is a feat the like of which I never expect to see realised.—JAMES GROOM.

— I notice "J. F.'s" remarks (see p. 50) about the Peach tree at Sunbury Park. Several years personal acquaintance enables me not only fully to confirm all that he says, but to add that the Peach and Nectarine trees there have borne equally heavy crops for several successive years; so much so that many of his neighbours have remarked to Mr. Cowburn (the gardener) that he would ruin the trees by overloading them. He, however, appeared to be of a different opinion, which has certainly proved a correct one. The fruit is not only quite as numerous as stated by "J. F.," but is large and even in size and of first-rate quality. The same remarks may apply to the Vines, which never fail to produce an abundant supply of fine Grapes. Such successive crops can only be the result of good cultivation.—ROBERT OSBORN, *Fulham*.

"Brief."—Messrs. Wymon have issued the first volume of this well-edited and well-arranged weekly journal, which is likely to be useful for reference. Attention is invited to the index, which presents the following features: 1. The headings of the articles have been re-cast, in order that the references may precisely indicate the nature of the matter to which reference is made. 2. The references to occurrences under each heading are in chronological order, thus indicating the progress of any given event, as well as the current opinion regarding it. 3. To most of the principal events of the period the date of occurrence is appended; thus an index to the files of all the daily and weekly press is presented. 4. Much care has been taken in compiling the obituary, as well as the list of wills and bequests, which are alphabetically arranged. It is bound in a very neat and simple cover.

Othonna crassifolia for Baskets.—This pretty Mesembryanthemum-like plant when curved with its bright yellow flowers, is very valuable for baskets or similar purposes. It was lately shown by Mr. Boller, of South Kensington, who had a rustic flower stand ornamented with it, in order to show its value for basket adornment.—S.

The Potato Crops in Ireland.—With us the Potato crops look very promising; the haulm is very green, and as yet there are no signs of disease, though after the very heavy thunderstorms which we had on the 26th and 27th of June, I fully expected to see some. One thing in our favour is, it is very cold for the time of year. Yesterday, July 8, was a summer's day, but to-day it is cold again, and the barometer is falling. Very few early Potatoes are grown here, and what are grown are Flounders, there being very few Ashleaves. Of late Potatoes, we have seldom any before November, and I have seen them later.—JOHN CLAWS.

THE QUEEN, accompanied by Princess Beatrice, honoured the Royal Nursery at Slough with a visit the other evening. In one of the houses was arranged for her inspection a large collection of cut Roses, which were much admired, Her Majesty personally selecting some, which she took away with her. The Royal visitors were much struck with the Carnations—especially a houseful of yellow ones, seedlings from Princes of Orange—and also with the *Ficoides* and specimen Roses.

FOURMOST amongst the decorations at Charing Cross on the occasion of Lord Beaconsfield's return from Berlin were the plant ornamentations provided by Mr. Wills. These consisted of over 10,000 plants, many of them 20 ft. high and amongst the cut flowers were some 3000 Roses.

"This is an art
Which does mend Nature: change it rather: but
THE ART ITSELF IS NATURE."—*Shakespeare.*

A FINE KENTUCKY COFFEE TREE.

(GYMNOCLADUS CANADENSIS.)

I SEND you a photographic illustration of a tree of this that grows on an estate in this neighbourhood. It is a tree which is not so much planted as it should be, even here, and one which I do not remember to have seen used as an ornamental tree in England. The specimen in question was planted in 1825, and its present height (1878) is $87\frac{1}{2}$ ft.; the circumference of the branches is 180 ft., and that of the stem at 4 ft. from the ground, 10 ft. This species of tree is found in the western part of the State of New York, as far north as Montreal, in Canada, but its greatest perfection is in the fertile bottoms of Kentucky and Tennessee. About 60 ft. is the usual height of the Coffee tree in these soils, but the growth of the tree, a photograph of which I send, exceeds this by over 20 ft. When in full foliage (which this specimen was not when taken) it is a very beautiful tree. The leaf, doubly compounded and composed of a great number of bluish-green leaflets, is generally 3 ft. long and of two-thirds that width on thrifty trees. The whole foliage hangs in a well-rounded mass that would look almost too heavy were it not lightened in effect by the loose tufted appearance of each individual leaf. The flowers, which are white, are borne in loose spikes in the beginning of summer, and are succeeded by ample brown pods, flat and somewhat curved, which contain six or seven large grey seeds imbedded in a sweet pulpy substance. As the genus is dioecious it is necessary that both sexes of this tree should be growing near each other to produce seeds. When Kentucky was first settled by adventurous pioneers from the Atlantic States, who commenced their career almost without the necessaries of life, except what was produced by the fertile soil, they fancied they had discovered a substitute for Coffee in the seeds of this tree, and accordingly the name of Coffee tree was bestowed upon it. But when a communication was established with the seaports they gladly relinquished their Kentucky beverage for the more grateful flavour of the Indian plant, and no use is at present made of it in that manner. It has, however, a fine compact wood, very useful in building and cabinet work. The Kentucky Coffee tree is well entitled to a place in every garden. In summer its charming foliage and agreeable flowers render it highly beautiful as a lawn tree, and in winter it is certainly one of the most novel trees in appearance in our whole native sylvia. Like the Ailantus, it is entirely destitute of small spray, but it also adds to this the additional singularity of thick, blunt, terminal branches without any perceptible buds. Altogether, it more resembles a dry, dead, and withered combination of sticks than a living and thrifty tree. This would be monotonous were it the common appearance of our deciduous trees in winter, but it is not so; on the contrary, it is a rare and unique exception, and it is highly interesting to place such a tree in the neighbourhood of other full-sprayed species. The seeds vegetate freely, and the tree is usually propagated in that manner. It prefers a rich, strong soil, like most trees from the Western States. There are some very fine specimens of it on the lawn at Hyde Park, on the Hudson, the seat of Mr. Walter Langdon, about twenty miles above here, which have fruited during a number of years.

HENRY WINTHROP SARGENT.

Wodeneth, Fishkill-on-Hudson, New York.

[The photograph, for which we are indebted to Mr. Sargent, shows a very fine tree, reminding one somewhat of an old Planera in the upward tendency of its main branches. Little of the character of the tree, however, can be seen in a small photograph. We should like to see it done by Vernon Heath, and then it might be possible to make a fine engraving of it. We have also to thank Mr. Sargent for a series of views in his

garden on the Hudson—a fair and well-stored garden in a lovely country, and of which all who have visited it will have pleasant recollections.—Ed.]

TREES WITH COLOURED LEAVES.

ACERS.—Several very favourable allusions have been lately made to *Acer platanoides Schwedleri* in the various horticultural papers, wherein, as I think, its merits as a new coloured tree are overestimated. Its peculiar characteristic, viz., its colour, should be as constant as possible; whereas, in this case, the bronzy hue of its new leaves lasts only for a very short time. It usually makes its growth in the spring very rapidly. When the leaves first unfold their colour is deepest and brightest, but this quickly passes away, and they gradually acquire a dusky, unpleasant brown hue, and finally a dirty green, and, besides, the leaves are rarely perfect, often having broken edges, a peculiarity for which I can scarcely account. I think we are often much too prone to neglect old friends for new ones. Now I wish to direct attention to an *Acer* that I consider much superior to *Schwedleri*, viz., *colchicum rubrum*. The colour of the new leaves of this is much deeper than that of *Schwedleri*; young leaves are always being formed which afterwards gradually change to bright green, and they have a distinct shape of their own with clearly-cut outlines. The tree is a very fast grower. Another good and desirable *Acer* is the Sugar Maple (*A. saccharinum*). It is a tree of moderate growth, but its growing points are of various shades of rose and crimson, and the leaves are elegantly cut and very pretty. A virginianum is also a free-growing tree, with very elegant foliage; the young leaves appear as though coated with powdered bronze. *A. spicatum* is a species of moderate growth, whose distinct foliage in a young state is creamy-white. I must not by any means leave out the really fine *A. Leopoldi*, whose young foliage presents such beautiful combinations of rose, crimson, white, and green, and afterwards becomes beautifully white and green. It is very remarkable that, notwithstanding the great wealth of good pictorial trees now to be had, but few are often seen; taking the *Acers* as a case in point, the common *Sycamore* is the one most frequently met with.

QUERCUS PALUSTRIS.—I should not omit to mention as a coloured tree this Oak, whose young foliage possesses such beautiful shades of orange and red, and this quite apart from the very rich tints assumed by it in the autumn.

PTELIA TRIFOLIATA VARIEGATA.—This is one of the handsomest of golden variegated trees, and its variegation is much more enduring than that of the Golden Oak, which speedily burns in the sun. It is also much brighter than the Golden Elder; in fact, in the distance it appears to be covered with rich golden flowers. Nevertheless, it is a tree which is seldom seen. Why is this? for it is not new. [We fancy the variegated form is rare. The specimens sent by Mr. Smith fully bear out what he says of it. It will probably prove more attractive than the green normal form to many people.]

WEIGELA LOOYMANSI AUREA.—This pretty dwarf shrub ought to become common. It grows freely, and has a rich golden colour peculiar to itself. The yellow is laid on with such an unsparring hand, as to leave nothing to be desired in that respect.

Newry.

T. SMITH.

The Golden-leaved Chestnut (*Castanea chrysophylla*).—Of all the fine trees and shrubs that have yet been introduced from the New World this is perhaps the handsomest, and the fact that it has withstood with impunity our English climate much enhances its value. There is a specimen of it against one of the walls at Kew, which, although small, is now in fruit. The leaves are dark green above, and covered with a golden-yellow powder beneath; thus the contrast between the upper and lower surfaces produces an effect rarely seen in this class of plants, rendering this Chestnut most useful as a decorative shrub. It inhabits California and Oregon, where it grows in great abundance, and usually forms low shrubs, flowering and fruiting freely when not more than 3 ft. high. In the Cascade Mountains of Oregon, however, it attains a height of from 30 ft. to 60 ft., forming a large spreading forest tree. Doubtless it is quite hardy in the more favoured parts of this country and elsewhere if under the protection

of a wall, in which case it should have an eastern or western aspect, as much exposure to direct sunlight produces an injurious effect upon it. It is procurable in most nurseries in which trees and shrubs are made a speciality, but it is far from being commonly cultivated, which it certainly deserves.—W.

NOTES OF THE WEEK.

Eulalia japonica.—For shrobberry planting, or for pot culture for the conservatory, few variegated Grasses equal this. It is perfectly hardy, grows about 5 ft. or 6 ft. high, and its leaves, which are gracefully arching, are beautifully striped with green and white and tinted with rose. We lately saw some fine specimens of it in Messrs. Veitch's Coombs Wood Nursery, where, associated with choice Conifers, it had a charming effect. For isolated positions on lawns it is an excellent plant, or it might be used in the wild garden with advantage.

Strawberries in Middlesex.—In some recent statements about Strawberry culture for the London market which have been going the round of the press no mention of their culture in Middlesex is made. It will be apparent that this is an important omission when we state that more good Strawberries are sent to the London market by growers in Middlesex than from all the other home counties together.

The Greater Bindweed (Convolvulaseppium).—This, although generally a great pest in gardens, may nevertheless be rendered a most useful and beautiful auxiliary in spots where it would not stand a chance of becoming a nuisance. In a cottager's garden near Kew an arbour, roughly constructed of sticks, is partially covered with the bines of the Hop, and these again are almost hidden by the large, snow-white, trumpet-shaped flowers of this Bindweed, the whole forming a picture of surpassing loveliness, and putting altogether into the shade many much more ambitious attempts in that direction.—G.

The Coral-bearing Barberry (Berberidopsis corallina).—Whether in a greenhouse or against an outside wall this charming climbing shrub forms at this season a very striking object. The blossoms present the appearance of being carved in coral both in colour and substance, and they are borne abundantly in gracefully-drooping racemes. It is a native of Chili, whence it was introduced by Messrs. Veitch a few years ago. Specimens of it may be seen in flower at Kew in the greenhouse, and also against the walls outside. The fact of its being hardy much enhances its value.—W.

Shading Heaths.—Those who place Heaths when out-of-doors under the shade of trees, or in similar situations, can have little idea of the way in which both Heaths and Epacris are brought to such perfection by London growers. At Messrs. Low's, Clapton, Heaths represent just now a miniature field of green healthy plants. There they get no shade whatever; on the contrary, they are fully exposed to the sun, receive abundance of water at the roots, and under these conditions they grow sturdily, hardy, and bushy, and eventually flower profusely.

A Few Good Fancy Pansies.—Among new seedling fancy Pansies exhibited by Messrs. Downie & Laird at Preston the other day we noted the following as being well worth attention, viz., Sunny Park Rival, deep blue with a dark centre; J. Douglas, claret with white edges; George Wood, velvety orange-crimson; and Mrs. Jamieson, black with well-defined, bright yellow margin. John Alloway, Mrs. Plommer, and David Evan were also excellent kinds.

Lapageria alba as a Pot Plant.—The rose-coloured Lapageria, though often grown on balloon-shaped trellises for exhibition, seldom makes an attractive plant, and it is therefore seldom seen at shows. The white-flowered variety, however, will make one of the finest exhibition plants in cultivation. Mr. Shuttleworth had a large specimen of it in his collection the other day at Preston loaded with blossoms, which, contrasted with the deep green foliage, had a fine effect. It was, without doubt, the finest plant of white Lapageria that has ever been grown in a pot.—S.

Plants in Flower at Colchester.—Out-of-doors *Lilium auratum* has opened its flowers; *L. chalcedonicum*, *superbum*, and *pardalinum* are in full force; *L. Humboldtii* and its congeners *ocellatum* are fully out; likewise the pretty *Thunbergianum venustum*, *L. Leichtlini*, and *longiflorum eximium*; *L. Wallacei*, quite a distinct new form, and *L. Wilsoni* promise to be open next week. *Romneya Coulteri* is showing a fair supply of blooms, which may expand at the end of the week. *Freesia refracta alba* has a few late blooms on it still, and *Calochortus venustus*, *luteus*, *citrinus*, and *flavus* (the old *Cyclobothra flava*) are now to the fore. *Tolbaghia violacea*, a small flower, but of a beautiful tint, is out. *Hyacinthus candicans* has fine spikes just coming into

bloom. In our frames *Watsonia plantaginea* and *humilis*, *Hypoxis Ruperi*, *Hesperantha cinnamomea*, *Rosecoea purpurea*, *Rigidella immaculata*, *Cucurghamia triunculata*, *Lapeyrousia corymbosa*, *Gladiolus Colvillei albus*, *G. purpureus amatus*, and *Habeuarua psychodes* show flower; and *Brodiaea congesta* alba fl.-pl. is still out. Amongst the Alliums, *carinatum*, *flavum*, *angulosum*, and *sphaerocephalum* show flower-heads.—W.

Phyllanthus nivosus.—Associated with flowering stove and greenhouse plants, this is one of the most effective of plants. Large specimens of it furnish abundance of long shoots clothed with snowy-white and light green leaves. It is a plant which possesses a compact habit of growth; it requires neither staking nor tying, and it is devoid of that formal character too often found in stove and greenhouse plants. It has a fine effect when grouped with *Dracæna* or *Croton*s. *P. roseo-pictus* is a good plant, but not so showy or effective as the one just alluded to. We lately saw both kinds in good condition in Mr. Bull's nursery.

The Dell at the end of the Serpentine is well planted this year—not such a confusing wreath of tropical plants—and those used are more tastefully grouped than hitherto, with some space for open turf left between them.

Hardy Red Water Lily.—We learn that Messrs. E. G. Henderson, Pine-apple Nursery, have been fortunate enough to obtain a quantity of this fine Water Lily—large roots—some of them in bud. It is said by those who have seen it in its native lakes that it is the lovely white Water Lily in everything but colour, which is a clear Rose.

Double-flowered Agapanthus.—This is now in bloom in the Victoria Nurseries, Holloway. It is equally as floriferous as the type, and its blossoms, which are of a deep sky-blue colour, are found to be exceedingly useful in bouquets. Eventually this will doubtless become a favourite greenhouse plant.

Plumbago capensis as an Exhibition Plant.—Few specimens stove and greenhouse plants exhibited at Preston were more admired than this *Plumbago*, which from every part of the show was a conspicuous object. Its sky-blue flowers supplied a colour which no other plant can furnish at this season of the year, and, considering how easily they can be produced, it is surprising that it is not oftener seen at shows than it is. A vigorous young plant of it grown in good soil could be made to form a good-sized specimen in a couple of years or so, and, although its individual flowers do not last long, they are produced in such quantities in succession that little fear need be entertained that it will not be in bloom when required. It is best of all, however, trained on a high back wall or pillar in a cool house. If grown in this way, and the shoots allowed to hang carelessly down, it is the fairest of all greenhouse, wall, or pillar plants that flower late in summer and autumn.

Plants in Flower at Tottenham.—Amongst many interesting plants in Mr. Ware's collection we noticed the white American *Leymachia clethroides*, a good perennial; the large white *Ornithogalum thyrsoides*; *Stokesia purpurea*, a large Composite flower with pale lavender rays and a purplish centre; the pretty little blue *Lapeyrousia corymbosa*; the lilac *Mimulus alatus*, one of the kinds of little importance for gardens; a fine series of varieties of the common Everlasting Pea, among which the delicate rose-pink appears to us to be very desirable for general cultivation; several of the less conspicuous, but not the least beautiful, *Gladioli*; the white-flowered *Brodiaea congesta*; the handsome spotted *Lilium Leichtlini*; several good varieties of the American Swamp Lily, which appears to us to be one of the very finest of the American Lilies, although not so much talked of now-a-days as some of the Californian ones; *Freesia odorata*; *Hyacinthus candicans*; some of the rarer *Alstroemerias*; and the curious *Pelargonium melananthum*.

Hardy and Half-hardy Salvias.—Has not "W." (see p. 59) made a mistake about *S. farinacea*? From his description I should say that the plant he mentions is not *S. farinacea* at all, but *S. leucantha*. His praise of *S. porphyranthera* is just and well merited. He should grow the true *S. tricolor*. I shall be happy to send him cuttings if he can send me *S. interrupta*, which I have lost. *S. gigantea*, as sent to me by Messrs. Smith, Newry, is what I have grown for years as *S. bracteata*. It is a very handsome plant, though rather coarse and straggling. I should be very glad to possess the true *S. farinacea*. A plant, which I cannot distinguish from *S. taraxifolia*, came up last year among some Indian seeds collected nearly forty years ago and kept in a dry warm place.—H. HARPUR CREWE, Drayton-Beauchamp Rectory, Tring.

Abnormal Lily Stem.—Dr. Armstrong has sent us a fasciated stem of *Lilium auratum* which seems to have produced an unusually large number of blooms. The plant had another stalk besides the one sent, and on that there were thirty blooms. The bulb in question was planted three years ago in a Rhododendron bed, where it has ever since remained undisturbed.

WATER IN PARK AND GARDEN SCENERY.

The introduction of water into park and garden scenery lends a charm thereto unobtainable by other means. In many places water exists naturally either in the form of small lakes, ponds, or running brooks; but this is more the exception than the rule, and water effects have oftener to be secured by artificial means. Where water naturally exists there is but little difficulty, as we have but to fill in the outline which Nature has sketched to obtain a variety of pleasing and natural pictures. In the case of artificial lakes and canals there is a vast difference. In natural formations the surroundings are pretty sure to be in harmony; Nature seldom voluntarily assumes formal shapes or regular outlines, and it is more particularly in this respect that we should do well to follow the example which she invariably gives us. The more correct taste of the present time has happily banished from our gardens those monstrosities in the shape of clipped shrubs in which our ancestors delighted. It must be admitted that the planting and grouping of trees and shrubs has made great strides within these last few years; it is, therefore, the more surprising that the formation of lakes and similar pieces of water should still, as a rule, be conducted with such a disregard of the first principles which Nature has so plainly laid down for our guidance. Let me take as illustrations two examples which have come under my notice. The one is a sheet of water some acres in extent. It is of natural formation, and the margins and surroundings have, with but one slight exception, never been altered by the hand of man. On one side, where I should suppose the dwelling would be placed (the locality I am describing is quite wild and unenclosed), the margin of the lake is quite devoid of trees, and the eye rests upon a clear expanse of water. There is no bridge, no boat-house, no building of any kind to mar or obstruct the view. The opposite shore, if I may be allowed the term, is broken up into irregular miniature

Broken Margins to Artificial Water.

creeks, the margins of which are lined with Flags, Sedges, and other moisture-loving plants. The ground then gradually rises up to a plantation of Firs, the intervening space being studded with irregular masses of low-growing shrubs, Brambles, and Heath. On the right, in the foreground, is a small island, on which grow a solitary Willow and a few minor shrubs. On the left, the shore is broken up by masses of trees and shrubs, evergreen and deciduous, until it reaches two large islands, which have been planted with Rhododendrons and other shrubs, and between which the water is seen gleaming beyond. The *coup d'œil* is, as may be imagined, charming. The utter absence of methodical arrangement, the breadth of water, and the contrast afforded by the vegetation which fringes it, cannot fail to please even the most casual observer. Let us now describe that which is in all respects a perfect, but not by any means a pleasing, contrast to the foregoing. It is also a lake, but formed artificially, and one which has had no expense spared upon its construction. In shape it nearly approaches an oval, and about in the centre is an island which is almost circular. The banks and margins are turfed and well kept, and, with the exception of the privileged Willow, not a plant of any kind breaks their monotony.

A neatly-built little summer-house stands out conspicuously, and at intervals there are some beds of flowering plants and clumps of shrubs. All this is pretty enough, but it can hardly be said to realise in any way our ideas of natural scenery. This is but a type of what exists in many places. In artificial creations it is not always possible to wholly obliterate the traces of mechanical agency; there must always be a certain amount of keeping which will in some degree induce formality. Still, much may be done to promote an appearance of natural beauty in such situations, and if the planting be done in an intelligent manner time will produce those free, graceful effects which no mere grouping can ever give us. It is just as easy to form broken, irregular outlines as it is to produce regular, unbroken curves and straight lines, and a little judicious planting, with subjects which will not only live but extend themselves, will speedily obliterate all traces of man's handiwork. The formation of islands in artificial pieces of water appears to me to be in many cases a mistake. The main purpose which islands serve is to break the monotony of a considerable expanse of water; but in the case of lakes of small dimensions they cannot be needed for that purpose, as

in such instances we desire to get as large a surface as possible under our eye. Islands, in fact, should in any case be but sparingly introduced, and even then should not come immediately before the eye. They should lie away from the main points of view, so that they might not obscure the vegetation and outline of the opposite banks, and should not be crowded with a mass of foliage. A single tree of an appropriate character, with some low-growing shrubs and sub-aquatic plants, will sufficiently indicate the object without occupying a too prominent position. Nothing can be more charming than the presence of a natural stream of running water in garden scenery, and where this occurs there is little difficulty in securing graceful and natural effects. In arti-

ficial canals and streams the same fault would often appear to be committed as occurs with respect to lakes and ponds—Nature is subordinated to art. If we follow but a short distance the course of a stream or small river, what do we see? We find the banks in some places worn into hollows and cavernous recesses; we see in the summer time, when the river is low, the traces of winter floods, which wear away the soil here and there, gradually encroaching upon the land which borders it, while in other places it deposits a mass of earth and *débris* which becomes a nucleus for the formation of groups of such plants as delight in moisture. In some places we see the banks high and far above the water level, in others the water at times overspreads them. These diversities of formation and the attendant variability of the vegetation may always be introduced more or less into all kinds of water scenery, whether large or small. Whether it be a lake acres in extent, or a mere fishpond, there is always scope for realising natural effects; but it is by no means necessary to employ a mass of vegetation for this purpose. Close and indiscriminate planting, indeed, often defeats the end in view. A single tree, with a few smaller subjects around it, and a clump or two of Flags or other water plants in the foreground,

will tend more to give a notion of natural formation than the most elaborate grouping could do. It is not so much the quantity of subjects as their variety and the knowledge of placing them so that they are in harmony with the situation in which they are put that is required.

J. CORNHILL.

Byfleet.

THE FRUIT GARDEN.

GRAPES ON OPEN WALLS.

THE Grape may even yet be called a neglected fruit as regards open-air culture, for, although no fruit is grown so largely or so well under glass, I question if the merits of any have been so systematically ignored on open walls. The best examples are usually found on cottages, where, on warm gable-ends, in many cases protected by an overhanging thatched roof, fine crops are produced year after year; and in favourable autumns the luscious sweetness of this fruit forms one of the greatest delicacies obtainable at rural desserts, and even in bad seasons a really good wine is made from the produce, though in a partially ripened condition. Much, however, might be done in the way of pruning and training to assist the earlier maturation of the fruit. In the first place, if a favourable wall be at command, viz., one that gets a maximum of sunshine, or an aspect facing between south-west and south-east, the soil should be well broken up by deep trenching early in autumn, and, if poor, some decayed manure, or, in preference, some loads of fresh turfy loam, should be added; as a rule, however, soil that has been in cultivation will be found to be quite rich enough for open-air Vines, as success depends more on getting moderately strong growths well matured than in producing an unnaturally luxuriant growth. If the Vines are in pots, they may be planted out at almost any season of the year, but the roots should be thoroughly separated. If in leaf, shading for a few days will be advantageous, and they should have a damping overhead, which will quickly start them into active growth. But as they may safely be planted any time during what is called the dormant season, the best plan would be to perform that operation as soon after the fall of the leaf as possible. If a good-named variety be not available, the best plan is to get a layer that is well rooted from a Vine that produces good crops in the neighbourhood. Young, ripened shoots of one year's growth, if brought down from the wall and partially buried in the earth, will make good rooted plants the following season. As regards sorts, the Sweetwater and Muscadine for white or rather yellow Grapes, and the Esperione and Miller's Burgundy for black, will succeed in ordinary situations; Black Prince also always colours well and produces fine bunches.

As regards training, the principal point is to keep the main shoots a good distance apart, so that when they produce fruiting spurs they may have room to fully develop their foliage without the shade becoming so dense as to entirely darken the wall, as it is the latent heat that is absorbed by the wall during sunshine, and that is again given off when the atmosphere gets colder than the temperature of the wall, that is of benefit to the Vines. The leading shoots should be nailed or tied to strong supports in the wall as they progress in growth, as, being brittle, they are easily broken off by rough winds. The bearing shoots should be stopped at one joint beyond the bunch, and only one bunch should be left on a shoot. Some varieties, especially the Sweetwater, are so prolific, that they produce three times as many bunches as they can bring to perfection, and not only the bunches but the berries in them need thinning if good fruit be desired. All lateral weakly growths should be kept pinched off, as they only shade the principal foliage. A very common notion prevails that removing the foliage in dull, sunless summers will promote the ripening of the fruit; but this is a mistake, and when carried to excess not only spoils the crop, but quite paralyses the Vine, checking the ripening of the wood on which future crops depend.

I do not wish to advocate the wall culture of Vines in any sense as superseding that under glass; nor would I recommend any one to make an open-air Vineyard, except in exceptionally favourable sites, but I look on the wall fruit tree culture of small gardens as about the weakest point as regards

their management. I have seen hundreds of good flower, vegetable, and mixed fruit gardens managed by amateurs, but, as a rule, their walls have presented an unprofitable aspect. The reason of this is that usually the best positions are assigned to Peaches, Apricots, and Cherries, which, if carried safely through the flowering period, are still liable to have their foliage more or less destroyed by insect pests, to the attacks of which they at length either wholly or partially succumb, while if the same amount of labour were expended on that portion of the wall space devoted to Vines, far more fruit fit for dessert would be the result. Nothing repays a little extra care better than the Grape Vine; even in seasons when all who allowed their wall Vines to take their usual haphazard course have been complaining of the inclemency of our autumns and the non-ripening of their fruit, others, who really paid attention to Grape culture, have had satisfactory results. I have seen very good examples of Black Hamburgs grown by amateurs who made a speciality of their Vines. In large gardens it might be worth while to devote a small portion of a good aspect to Vines, in order to see what could be realised by means of glass copings that are in many cases lying idle during the autumn months.

Out-of-door Vines enjoy comparative immunity from insect pests, and they are less afflicted by disease than most fruit-bearing trees, while as respects longevity, as they root readily from any portion of the ripened wood, it is quite possible to keep a wall furnished with fresh bearing wood on its roots by layering shoots in succession at the base of the parent Vine; in fact, one of the most important points in Vine culture is to keep a succession of young bearing wood from base to summit, for although the class of Vines suitable for open walls are of such a fruitful nature as to produce plenty of bunches under the most primitive kind of pruning and training, the most casual observer will note that the finest fruit is on the previous year's wood. Therefore, at the winter pruning, some of the oldest rods should be annually taken out to allow space for an equal number of young rods to be trained in. Perhaps the greatest enemy open-air Vines have is mildew, from which, in some seasons, they suffer severely; but sulphur carefully dusted amongst the leaves on the first sign of its appearance will generally be found efficacious in checking it. I feel confident that even those who have small gardens would do well to turn their attention to outdoor Grape culture, which would yield good returns for the labour expended on it during, at least, average English summers.

J. GROOM.

WATERING FRUIT TREES.

SUDDEN changes from extreme humidity to parching drought must greatly affect the vital forces of all fruit trees, but especially those carrying heavy crops of fruit. The drooping foliage and prematurely falling fruit sufficiently testify to the truth of this assertion. I believe, too, that the ill effects of ungenial atmospheric influences in summer are more permanent in character than is generally supposed. We are too apt to lose sight of this and to ascribe all our troubles in fruit culture to the prevalence of spring frosts. No doubt the latter are destructive, but no one can observe the sufferings of fruit trees during sudden and severe periods of heat and drought without being convinced that a good supply of water and some ready economical means of applying it would have a wonderful effect in keeping the trees healthy, and consequently more fruitful. In some measure the tendency of cultivation is to alter the character, habit, and perhaps in some degree the constitution of fruit trees, slowly, it may be, but none the less surely; indeed, one of the professed aims of modern cultivators is to induce surface rooting, and to this end various expedients (such as grafting on particular stocks, root pruning, &c.) are adopted, which, though they bring the trees more under the cultivator's control, and, so far, are a benefit, yet at the same time add to his responsibilities by making them more dependent upon his care. I cannot help thinking that if the importance of this matter had been more fully recognised, more adequate means would have been ere this provided to supply their wants during times of trial. Surface mulching, of course, will do much, but this ought to be supplemented occasionally with a thorough soaking of water; but if the water

has to be carried by hand some distance the chances are that the watering will not be effectually done, even if orders are given to that effect. Few kitchen or fruit gardens are so well supplied with water as they ought to be. In some cases that have come under my notice, where the flower-beds have been well cared for the vegetables and fruits have had to depend mainly upon what has fallen from the clouds, and I need not say that in dry seasons inferior produce is the result. During the last forty years the drainage of the country has undergone a gradual, but at the same time a great, change, and in discussing this question this should not be lost sight of, as it appears to me to render more urgent the adoption of improved appliances for successfully coping with severe drought. If watering is to be effectually done, some cheaper and more efficient means than manual labour must be resorted to; indeed, when one thinks over the matter there is cause for wonder that on this matter of watering the same methods and the same implements are in use now in most country gardens as were common a century ago, when surrounding circumstances were so different. The mowing machine has, by banishing the scythe from the lawn, economised labour as well as effected an improvement in its appearance, and I have no doubt that the same result would follow the introduction of some simple, but efficient, system of hydraulics for the application of water to fruit trees and vegetables at a time like the present. Fruits of all kinds contain a considerable amount of water, and if the supply of that fluid be cut off when they are in the midst of their growth, both the crop and the individual fruits must be small. In difficult times all trees of any considerable age generally contrive to get rid of a good portion of their crop, and it is no uncommon occurrence now to see almost as many Apples lying under the trees as there are remaining on them. A mulching and one thorough soaking with water every week or so would have saved them, and, where plenty of water is available, it benefits the trees greatly to give them a good washing overhead occasionally. I noticed the other day a neighbour with horses and water-carts watering the trees in his orchard, and no doubt the plan was a wise one, but how few gardeners can call in the aid of extra help at such a time. It is, in many cases, the first outlay for pipes and pumping gear that stops the way, but I am convinced that the investment would, in most cases, be a profitable one. In our climate we never have too much sunshine, and it is only where irrigation is neglected or altogether disregarded that a long continuance of bright weather does harm to growing crops. E. HOBDAV.

CLASSIFICATION OF APPLES.

By Prof. W. J. BEAL, of Lansing, Mich.

A NATURAL classification would be one in which every distinguishing feature of the plant was considered, giving each character its due weight. This would include the peculiar features of the young embryo as it began to germinate, following on with every step in its growth to a mature plant bearing fruit. In such a classification nothing must escape notice. The twigs, buds, leaves, all parts of the flowers, fruit and seeds—every point must have its due weight in determining the relations of each variety to all the others. The varieties of Apples have become so numerous, that each should be more completely described than has generally been customary. In defining wild plants, the botanist places great stress on the peculiarities of the flowers. I believe these characters are of great value in describing our Apples. I will briefly describe and compare the flowers of a few of the varieties first examined. The petal of the Red Astrachan is ovate, and, on the average of many specimens, is $1\frac{1}{4}$ in. long by $\frac{3}{4}$ in. broad in the widest place. The petal of a Talman's Sweet is elliptical, twelve-sixteenths by seven-sixteenths, just about long enough to reach across the widest part of a petal of the Red Astrachan. The petal of the Porter is nearly orbicular, cordate at the base, with a very short claw or stem. It is twelve-sixteenths by thirteen-sixteenths of an inch in breadth and length. The petal of a Sweet Bough is broadly ovate, or elliptical ovate, measuring fourteen-sixteenths in. across the surface, having a distinct claw. This is enough to show something of the great value of the petals in describing Apples. On the Red Astrachan the styles are seven-

twelfths of an in. long, united for one-third in. to two-fifths in., and then diverging. They are slightly pubescent where they begin to separate; above and below they are smooth. In the Talman's Sweet the styles are five-sixteenths of an in. long. The upper half of the five styles is closely covered and matted together by a dense woolly substance. In the flowers of the Jersey Sweet the styles are short, stout, and twice the diameter of those in the Seek-no-further. The "Journal of Horticulture," 1876, p. 185, gives something of a new classification of Apples by Dr. Hogg. The only new points used are those based on the shape of the calyx-tube and the position of the stamens in the tube. The calyx-tube varies in form from conical to funnel-shaped, and is seen between the eye and the core on making a longitudinal section of an Apple through the centre. The stamens form a bristle-like fringe round the inner surface of the calyx-tube. Some form a fringe immediately under the base of the segments, and are called marginal; others are medium; others situated near the base are called basal. To test the value of these new characters of Dr. Hogg, I have examined a large number of our Apples. In the first forty-eight varieties examined, seven had the stamens marginal, twenty-four medium, three basal, eight between marginal and medium, six between medium and basal. As we should expect in any character, it is sometimes very decisive and of much value, while in other cases it varies or is so near midway between two forms that we can make little use of it. An artificial classification is based on some one point or a few points of difference, ignoring all other points, any of which may be important. As an illustration, we may call all Apples sweet or sour, large or small, striped or not striped. So in botany, the best artificial keys in our text-books require the student to divide only one, two, or three points at a time. This one divided, he leaves it for the next, and so on until the specimen is separated from all others. Mr. A. J. Downing believed the classification of Apples to be impracticable, and arranged his fruits in alphabetical order. Mr. Thomas Barry, Dr. Warder, and some others, have arranged the varieties in a way to assist a person in finding the name of an unknown fruit. Many of us would like still more aid to make it easier to trace out an Apple. If an Apple is of such a size as to make it doubtful whether to call it large or medium, place it in both classes in the key. So with other points which are likely to be misunderstood as to shape, time of maturing, &c. Many fruits are still very imperfectly described. To make use of the new characters of the flower, it will be necessary to go again over all the work of others in examining fresh specimens when in flower and in fruit. In the classification which I have adopted, I first decide whether the Apple is sweet or sour; second, is it ripe in summer, autumn or winter; third, is it striped with red, not striped nor russet; fourth is it flat, round, conical, or oblong. These four points can be expressed in a key on two pages of a book facing each other. At the end of each line in the key I give the page on which to continue the investigation. After making use of those four classes, I do not pursue any definite order, but make use of just those points which seem to me most characteristic. In some it may be the basin; in some this may not be a marked feature. I seize whatever is the most striking point for contrast between any two Apples or lot of Apples in hand.—"American Pomological Society's Proceedings."

PERMANENT STRAWBERRY PLANTATIONS.

IN making Strawberry plantations anything in the way of early returns and fine crops depends upon the preparation of the plants and of the ground. Plants put out of pots—that is, old forced plants—do not root deeply; hence they bear well for only one or two years, and are then useless. But young plants from runners, put out in a good soil, will send their roots down 2 ft. or 3 ft. Ground for a plantation should therefore be trenched two or three spades deep, or at least be deeply dug. In either case it should be well manured with stable-yard or cow manure, crushed bones, fresh loam, or any good manures, which should not, however be buried in the bottom of the trench, but be turned in with the spade in the digging. This renders it accessible to the roots at once. It is a good plan, indeed, when the ground is trenched, to trench in the rough manure, and then dig or fork the ground over afterwards, just one spit deep, turning in at the same time another dressing of manure of a more

rotten description for the benefit of the young plants, as, when the manure is all put in at the trenching and deeply buried, the plants hardly get the benefit of it till the second year. In gardens where the soil is thin, trenching cannot be advantageously practised; but the want of trenching may be made up for by manuring with the more retentive manures, of which that of the cow is best, and mulching during the summer season. Mulching, indeed, should always be practised on thin and poor soils. Short stable litter is about the best material that can be employed for the purpose, and the more horse manure there is amongst it the better. It then acts both as a mulching and a manure; the rains wash the strength of it down to the roots just when the fruit is swelling and the plants are needing support. No time should now be lost in securing runners. If stock has to be procured from a nursery, there is little chance of a crop the year following, for nursery plants are seldom strong. But if they can be propagated at home or in a friend's garden, a good crop this time twelvemonth is a certainty. No plants bear so abundantly for their size, or have such fine berries, as young plants propagated and planted the year before. The late Mr. M'Ewen, who wrote on the Strawberry, has stated the number of berries he gathered from one stool planted the August previous; we forget what the quantity was, but it was enormous. It was usually from his young plants that he gathered his finest fruit for exhibition, and he was successful everywhere he went. It is no advantage whatever to layer the plants in pots. The best and most expeditious plan is to prepare a heap of good soil, loam principally, mix it with half-decayed horse manure or old Mushroom manure—or, failing these, Standen's manure, which well repays its use—and lay the same in a flat ridge, 4 in. deep, between the rows of Strawberries. On this ridge the runners should be laid, with a stone a few ounces in weight behind them to keep them in their places. Afterwards they will need attention in pinching, for it is necessary that all the strength be concentrated in the layered runners, and to see that no fresh runners are produced beyond. A look over once a week or ten days will be enough for this, and, with watering occasionally in dry weather, the plants will be broad and strong by the end of July or beginning of August, when they must be planted. The ground having been prepared as before directed, the plants should be taken up with a trowel with good balls to each, which can easily be secured with a little care, and planted up to their collars 2½ ft. from row to row, and 18 in. between the plants. Some cultivators plant three plants together in a triangular patch, which is a good plan, but the patches should in that case be 2 ft. apart. The work of making a plantation is finished with the getting in of the plants, which want little or no attention till next spring, when the ground may be stirred over with the hoe between the rows, and mulched with short Grass or manure, and the result waited for in the shape of a fine crop of fruit. After the crop is gathered some remove one or two of the three plants of each patch, as, if they were all left, they would get too thick on the ground. A good deal, however, depends upon soil, and, as we should have stated, upon the variety. In some strong soils we have seen such sorts as Keen's Seedling, British Queen, and Sir Charles Napier have little enough room at 2½ ft. between the rows, considering the importance of letting the air and sunshine in among the fruit in wet weather to dry it; but dwarfier sorts, like Black Prince, will do well in moist soils at 18 in. between the plants and between the rows. Thinning out the plants, therefore, at the end of the year must depend upon these circumstances. If they grow very rank, thin to one plant; and if moderate growth only is expected, leave them as they are. S.

Poisoning by Peach Stones.—A fatal case of poisoning by Peach stones, which has just occurred in Paris, may serve as a warning to families in which children are allowed to look after themselves for hours together. It may be assumed that very few children under the age, say of ten or twelve, have any idea that Peach stones are dangerous. They have been shown the deadly Nightshade, and probably the wild Hemlock, and have a dread of them, but the dangerous character of Peach stones has never been pointed out to them. The victim of the recent accident in Paris secreted the stones of a number of Peaches, and, possessing himself of a hammer, when left alone broke them open industriously and eat them, the result being that he was poisoned by prussic or hydrocyanic acid. It is as well, now that the season for wall fruit has arrived, to explain what extent of poisoning properties is possessed by the Peach stone. Writers on toxicology state that 1 oz. of the kernels contains about one grain of pure hydrocyanic acid, and it is known that one grain of that poison will almost to a certainty kill any adult person. Two-thirds of a grain has very often been fatal, and, indeed, may be regarded as a fatal dose for a child.

Peach Prince of Wales.—This is an excellent midseason Peach, large, high-coloured, and of good flavour; and the tree has a good constitution. A market grower told me the other day that it always fetches the best price in Covent Garden.—E. HOBDAK.

GARDEN BOTANY.

(Continued from p. 71.)

Flowers of Grasses.

The flowers of Grasses are arranged in spikelets, which bear one or more flowers and are loosely disposed, as in the Oat, or densely, as in the Wheat. They are enclosed in the chaffy bracts (glumes), and what is generally regarded as representing the perianth of other plants is quite rudimentary, and in some species there are no traces of it. A spikelet, whether it contains one or more flowers, is, with few exceptions, enclosed in two outer glumes (fig. 357), and each flower is subtended by two scales. One of these is similar to the outer glumes, having

Fig. 355.—A single flower of Wheat, removed from the spikelet; the two small scales at the base represent the perianth.

Fig. 356.—Spikelet of Wheat. Enlarged.

a central rib or keel, is often furnished with a bristle (awn), and usually embraces the other in the bud: this is the flowering glume. The inner has two lateral ribs and no midrib, and is designated the pale (fig. 357). Fig. 355 represents a flower of Wheat removed from the spikelet and divested of its glumes. At the base are two lodicules, forming the perianth. In Phleum (fig. 358) the outer glumes are awned. During the flowering period the glumes and pales spread out and afterwards close

Fig. 357.—Expanded epikelet from the inflorescence of the Oat; G, outer or empty glumes; Pe, flowering glume; A, awn; P, pale; F, S, sterile flower.

over the grain, and the pale and flowering glume adhere to the ripe grain. The grain, it may be added, consists of a single seed and the adherent pericarp. The pericarp, it should be explained, consists of the wall of the ovary alone, as in Wheat and Rye, or of the wall of the ovary and adherent pale, or pale and flowering glume, as in Barley.

Æstivation.

Sepals and petals, and the lobes of a gamosepalous calyx or gamopetalous corolla, are variously folded or arranged in the bud. The manner in which they are folded is constant in a species, and the same type of folding usually prevails throughout a genus, and, in some instances, throughout a natural order. This folding is termed the æstivation, of which there are two distinct types. When the edges of the petals or sepals meet at the margins only, and do not overlap each other at all, they are valvate in æstivation. The petals of the Grape Vine

(figs. 359 and 360) are valvate in æstivation, and the sepals of the Mallows and Hollyhock, and indeed of all the Malvaceæ, are valvate. When there is any overlapping of the margins of petals or sepals, the æstivation is imbricate (fig. 361, &c.). The valvate type of æstivation obviously cannot vary much, but there

Glumes open.

Glumes closed.

Fig. 359.—Flower-bud of Grapa Vine, showing valvate æstivation of corolla.

is a wide scope for diversities in the overlapping of petals, &c., in imbricate æstivation. Valvate petals may have in the bud their margins directed towards the centre of the flower, so that parts of the outer surfaces of contiguous petals lie face to face; or the margins may be directed outwards, so that the inner surfaces of contiguous petals are applied to each other. Names have been given to these variations of the valvate type of æstivation, and also to many variations of the imbricate type,

Fig. 360.—Diagram showing the plan of valvate æstivation.

Fig. 332.—Diagram of a corolla of Pedicularis palustris; both margins of the anterior petal outside of the lateral petals.

but very few of them are in general use. Some of the variations of the latter are, however, worth distinguishing. When one edge of each petal is inside and the other outside, as in figs. 363 and 364, the æstivation is twisted or contorted. All the Malvaceæ have contorted petals. The æstivation is decussate when the petals are in opposite pairs and the outer or lower pair overlaps the next, as in the Holly (figs. 365 and 366). Another variation of the imbricate type is common to all the

Fig. 363.—Flower-bud of Hermannia denudata, æstivation contorted.

Fig. 364.—Diagram of contorted æstivation.

members of the large sub-order Papilionaceæ of the Leguminosæ. Here the upper petal, the standard, is always outside along both edges, and often quite enfolds all the others in the bud (figs. 367 and 368). The reverse obtains in the Cæsalpineæ, also a sub-order of the Leguminosæ. Cercis siliquastrum, the Judas tree (figs. 369 and 370), is a familiar example, both edges

of the upper or posterior petal being overlapped by the lateral petals. Verbascum Thapsus (figs. 371 and 372) has the anterior petal with both edges covered in the bud, and one of the others wholly outside. Some botanists would restrict the term

imbricate to the kind of æstivation characteristic of Atropa Belladonna (figs. 373 and 374), where two petals of five are inside and two outside, and the other with one edge overlapped and the other overlapping. A very unusual condition of the

petals in the bud occurs in the Poppies, where they are intricately crumpled.

The Androecium (Stamens).

GENERAL OBSERVATIONS.—We have now to review the prin-

Fig. 371.—Flower-bud of Verbascum Thapsus, showing the æstivation of the corolla.

cipal types of modification exhibited by the androecium and gynoecium. There are flowers destitute of perianth of any

Fig. 374.—Flower-bud of Atropa Belladonna.

Fig. 375.—White Water Lily (Nymphaea alba); gradual transition from petals to stamens.

kind, but a fertile flower, a flower that is to fulfil the function of a flower, must contain, or consist of, either a gynoecium or androecium or both, as these are the organs of reproduction.

Androecium is the name given to the stamens collectively whatever their number or arrangement. With rare exceptions, the stamens are very differently formed bodies from the petals; in the white Water Lily (fig. 375), however, there is a gradual transition from perfect petals to perfect stamens. The innermost stamen, or that on the extreme right in the figure, has all the parts of the most highly organised condition of that

Fig. 376.—A perfect stamen; a, anther; f, filament.

Fig. 377.—Stamen with two-celled anther.

organ. A perfect stamen consists of two distinct parts, a filament and an anther (fig. 376). When the filament is exceedingly short, as in Verbena, or quite obsolete, as in Orchids, the anthers are sessile. The anther is the essential part of a stamen. It is a hollow body, having usually two compartments or cells—seldom one or more than two. The cells are usually

parallel, as in fig. 377, and that part of the anther which bears or connects the cells is the connective. Within the anther cells the male element necessary in fecundation originates, and it receives the name of pollen.

VARIETIES OF POLLEN.—The ordinary condition in which the

Fig. 381.—A pollen-mass of *Orchis maculata*; c, caudicle; r, gland.

Fig. 382.—A pollen-mass of *Habenaria chlorantha*; c, caudicle; r, gland (retinaculum).

Fig. 383.—Powdery pollen-mass of *Listera Nidus-avis*.

pollen issues from the anthers is in separate minute one-celled yellow granules, forming a powder, which is very copious in some plants, especially in many of the Coniferae. When the anthers are discharging their pollen it disperses in quite dense clouds. The separate granules of pollen are of diverse shapes, and the surface is often beautifully marked or pitted or otherwise embellished. In the Buttercup (fig. 378) the granules

are spherical; and in *Basella* (fig. 380), of the form of cubes. The pollen is simple when each granule consists of a single cell, and compound when more than one-celled. In Heaths and Epacris, many Mimoseae (*Acacia*, &c.) and Coniferae, &c., the pollen grains are several-celled. In *Pinus*, for example (fig. 379), each grain is three-celled, the end cells being opaque and the middle one transparent. Perhaps it is more correct to say that compound pollen grains consist of a number of granules in a state of cohesion. The pollen granules of most Orchids are variously combined together by viscid elastic threads, and each agglomeration is a pollen mass or pollinium. From one to four pollen masses are developed in each cell of the anther, and they are either sessile or stalked, that is to say, the mass is borne on a slender stalk (caudicle). At the base of the caudicle is a viscid expansion termed the gland (figs. 381 and 382). The pollen masses of *Listera Nidus-avis* (*Bird's-nest Orchis*—fig. 383) are less compact than those of *Orchis maculata* and *Habenaria chlorantha*, and unprovided with a caudicle. Another family, the Asclepiadeae (*Hoya*, *Stapelia*, *Asclepias*), has the pollen cohering in masses, often in pairs (fig. 384).

VARIATIONS OF THE CONNECTIVE.—Commonly the cells of an anther are contiguous and either parallel or end to end, and the connective simply serves to unite them; but the Melastomaceae (*Medinilla*, *Pleroma*, *Heeria*, &c.) are remarkable in having the connective furnished with spur-like or thick, fleshy appendages, and the connective of the Violet is produced above the anthers;

Fig. 384.—Pair of pollen-masses of *Aclepias floribunda* united by their glands.

Fig. 385.—A stamen of the Hornbeam (*Carpinus Betulus*), the cells on separate branches.

Fig. 386.—Flower of Sage cut open to show the stamens in which the cells of the anther are separated by a long connective, and the lower cell is abortive.

those of the two anterior stamens have also a filiform appendage which protrudes into the spur of the petal. In the Hornbeam (fig. 385) it is branched, so that the cells are separated, and each branch terminates in a tuft of hairs. A still greater isolation of the cells occurs in *Salvia* (fig. 384), and the lower cell of each stamen is abortive. Finally, the connective is either continuous with the filament, as in fig. 377, when the anther is adnate and immovable, or the attachment is above the base of the connective, often about the middle, when it is versatile and oscillates freely (fig. 387). Grasses, Lilies, &c., have versatile anthers.

W. B. HEMSLEY.

Dipladenias at Holloway.—These form a striking feature just now in Mr. Williams' nursery. The plants, which represent all the best kinds, are, for the most part, grown in pots, their main shoots being trained round balloon-shaped trellises, whilst the flowering branches are allowed to entwine themselves on strings strained along the roof, a good plan, inasmuch as a fine display can be made in the house in which they are growing, and, should the plants be required for exhibition purposes, the strings can be cut with the shoots attached to them, and be twined, with little trouble, round the trellises. With all trailing plants which are required to flower well it is highly necessary that the wood should be well ripened, and this can be best realised by training them on strings under the roof close to the glass. Wires are sometimes used, but they are more troublesome than strings, as the shoots must not be allowed to twine round them, as, if they do, much labour is involved in unwinding them, an operation, too, which is far from being beneficial to the plant. The best way, therefore, is to tie strings to the trellis and then attach them to the roof, allowing all young shoots to grow round them that seem inclined to do so. When wanted for exhibition, string shoots and all can be tied round the trellis, and when done flowering they can again be unwound and tied up to the roof to ripen.—S.

NOTES ON COLLECTING PLANTS.

A COLLECTOR'S OUTFIT. — Before entering on a botanical ramble let us see what we shall need to take with us on the trip. On an ordinary excursion it is well to be provided with both portfolio and botanical box. The former is preferable in most cases, for with plenty of specimens in it its capacity is quite unlimited, and, besides, there are many occasions in which plants of a delicate texture, or having ephemeral floral parts, as many of the aquatics, the *Helianthemums*, the *Tradescantias*, and others, would be greatly impaired by carrying home first before putting in press. Plants of this class should be put into portfolio or press immediately after being gathered. On the other hand, a box is very essential to carry plants which we wish to examine fresh, and also plants having thick roots, large fruits, &c. When the collector's time is limited, and we wish to explore as large a territory as possible in the period at our disposal, for instance, while a train or boat is delayed, or having only a leisure hour's run in the fields and woods, then necessarily the box becomes the favourite. Also on a windy day it is perhaps preferable; for there is little that is more vexatious or calculated to call out the "Old Adam" of our nature than endeavouring to put specimens into the portfolio when a lively breeze is playing among our papers and specimens, and no place handy to seek shelter from its airy and sportive caresses. For home excursions, if the portfolio be well stocked with paper, the box need be quite small. The one I have used with much satisfaction is of oval-cylindrical shape, 17 in. long, 4 in. deep, by 6 in. wide. It is light and convenient to carry, provided with a light strap to throw over the shoulder, and so attached to box near front narrow side as to have the lid open from the person when hung on the shoulder. The lid opens nearly the whole length of one of the flat sides—15 in. by $4\frac{1}{2}$ in., with $\frac{1}{4}$ in. lap—made to fit as tight as possible, and fastens with a simple spring catch, effective and convenient, a great improvement over the old way of fastening, which has to be held in place with peg or key. I have seen and used a number of different boxes, but I give my preference decidedly to the one described above. For extended trips, I formerly used a much larger box with a lunch compartment at one end. It is 21 in. by 9 in. and 6 in. But it is much too heavy to carry with the portfolio, and in fact too heavy, even when used alone, for mountain rambling. For long trips when the collector wishes to bring home a large number of fresh plants, I should prefer, instead of such a large cylindrical box, one made something like an old-fashioned trunk with a wooden handle in the lid to carry it by. It should be large, say 21 in. long, 12 in. wide, and 12 in. high to the top of the lid, which opens like that of a trunk, and is very convex. It is to be left in some central place, or where we make our headquarters for the night, and made a kind of depository, while the small box is used for collecting. Of course this plan is feasible only where we expect to radiate around one or more central points during the trip, yet I have made many extended excursions and always found it practicable. The chest is portable and not so heavy as a large box of usual pattern, and in travelling, if desirable, the small box can generally be carried inside the chest. Such a tin chest keeps plants fresh and handsome a long time, and permits a better arrangement and easier handling of the contents.

The Portfolio,

the usual size of which is 18 in. by 12 in., is subject to some variation in its arrangement. Some collectors prefer simply two pieces of binder's boards covered with enamel cloth and merely fastened together with a strong cord or strap. This filled with specimen paper is ready for the excursion. Simple and well-adapted to field-work, is the verdict in its favour. After several years' use I have found one made after the following pattern at all times give excellent satisfaction, and it has some advantages not found in the other, though costing a trifle more. It is made of two rather thick pieces of binder's board, covered like the first, each having a handle like a carpet bag for carrying. One of the sides has a stiffish bottom interior apron to keep the papers from slipping, and both of the sides are fastened together at bottom with two or three small buckle straps that can be let out when the portfolio

is filling up. Similar straps are in front and one on each side, but these are seldom used, and instead there are a couple of straps attached which go around the whole portfolio, so that small or heavy pressure can be given as desired. By using more driers and changing, I can preserve plants very finely in the portfolio when travelling, but this is a secondary consideration, the main use of the portfolio being to collect for home press, and for this purpose not much pressure is required, merely sufficient being demanded to hold the specimens snug and not allow undue shrivelling. The portfolio should be stocked with a sufficient quantity of thin unsized paper—folded sheets; tea-paper will answer, but it is not very good economy to use sheets so much smaller than portfolio, for of small plants a sheet will not hold so many specimens, and besides such small sheets finally bring the plants too much in the middle of the pile when pressing, making it too rounding to press evenly and well. It is better to have specimen (I will call them by that name) sheets of nearly the size of the portfolio, and driers 18 in. by 12 in. I prefer a poorer quality of printing paper. The folded sheets are 11 in. by 17 in., and this allows for shoving a little, and keeps the edges from getting curled and torn. 11 in. by 16 in. is a good size. It costs 9s. 6d. to 10s. 6d. a ream, according to quality, at any paper warehouse, and usually comes double the size required, but it is easily cut and folded, each ream giving 960 folded sheets. This is as cheap, notwithstanding the difference in size, as tea-paper which costs about 3s. a ream—a ream of this having only 320 sheets. I have used also rather largely for specimen sheets thin manilla paper. It is excellent for coarse, rough plants, as it is stronger than white paper, lasts longer, and gives very nearly as good results. I insist strongly upon the importance of using specimen paper in pressing. Do not attempt to get along without it. Many plants, as *Caulophyllum*, the *Dentarias*, many of the *Cruciferae* and *Leguminosae*, and others outside of these Orders, are so delicate and sensitive, that they will not bear the least handling, unless enclosed in sheets, without curling and shrivelling; an attempt to transfer them from one drier to another, unless enclosed, only resolves them into tangled confusion. The specimens should be left in these papers through all changes of driers until thoroughly cured, and it is a good plan to let them remain in these sheets even afterwards until wanted for mounting or for exchanging. The specimens, by so remaining, are kept in much finer condition than by taking them out and huddling together in other papers. Besides, it saves time in transferring, an important item during a busy collecting season.

In getting ready for a tramp it is a good idea to put several driers into the portfolio with specimen paper. It is not necessary to have a drier between every paper as some young collectors think—in fact, for a trip of a day, or two or three days even, the plants keep fresher by having sheets with specimens next each other than with driers interposed. Only a few driers are desirable, interposed to keep thick and stubborn plants from making the pile too uneven when putting into the portfolio.

Digging.

For digging up roots, bulbs, &c., I have used nothing better than a small triangular trowel. Its blade is about 5 in. or 6 in. long, sharp-pointed, and known, I believe, as the masons' smaller pointing trowel. Be careful to select one strong and stiff. Perhaps one fully as good, if not better, is the one known as the Webb botanical trowel. It is made from a large triangular file, to which a curvature of nearly 1 in. of point part can be given by a blacksmith. The teeth should be ground off, and a handle fitted. A leather case to carry either of the foregoing trowels would be found convenient and probably save from annoying losses. Always carry a knife. Part of one edge of the first trowel can be ground sharp for cutting, but it is much better to have a strong pocket-knife with you. It is well to be provided with a good lens on an excursion. It will be found very useful, if not necessary, in collecting specimens of many of the more difficult and recondite families, where the distinctive characteristics of the species are minute and often obscure, as in the *Sedges*, *Grasses*, *Mosses*, &c. The *Excelsior*, *Gray's*, or *Coddington Lens* all answer a very good

purpose for field work. Last, but not least, be sure to take a note-book with you on the excursion. This I regard as one of the most important requisites of the trip. Habitats of rare plants, with many valuable observations, may be noted down in the field, which may be afterwards of deep personal, and, possibly, public interest, and which would be often entirely lost if left to unreliable memory.

Whether it be a good plan on an ordinary occasion to cumber himself with a descriptive botanical work, I leave to the collector to determine. Some botanists always carry one. In new or remote regions there are times when it might prove serviceable; but on an ordinary trip it hardly pays. It adds too much unnecessary weight, while a good botanist will probably recognise all the plants he encounters, even if there be some new to him. When it is desirable to take a luncheon along, and not convenient to carry it in the small box, it is better to provide a small haversack made of light enamelled cloth and carried on the back. It weighs only 2 oz. or 3 oz., comes handy for various purposes, and is preferable to adding an extra compartment to the box, as this addition, I have found, adds more in weight than utility. A good, stout, easy-fitting pair of boots or shoes should be worn on a long tramp. They should have thick, broad soles, broader than the feet, and low, wide heels, for easy walking. Good walking shoes are excellent for fields and mountain climbing, but as many of our rarest plants are to be found in swamps, marshes, and low, wet grounds, boots, perhaps, on the whole, are preferable to shoes for botanising, unless one is willing to follow the example of an enthusiastic botanical friend, who, in traversing some deep miry swamps, in company with the writer, would deliberately pull off his shoes as he came to each swamp, and explore the batrachian wilderness barefooted. Rubber boots, except for a limited period in marshes or swamps, should not be worn; they soon become unendurable to the wearer, and early put him out of order. Light, loose-fitting clothes will be found most comfortable. For a trip of several days or longer flannel shirts are to be recommended—blue or grey is preferable. For alpine botanising, where the air is often exceedingly chilly, a warmer dress is necessary. Finally, ere concluding these notes on the outfit, let the young collector be cautioned against carrying too heavy a burden on setting out on an expedition. It is a temptation into which young botanists are inclined to fall. In the morning, in his freshness and vigour, the load will probably not seem over heavy, but after some hours' tramping through tangled swamps, sinking morasses, and over dipping bogs, its oppressive weight will be painfully recognised. Rather than carry a very heavy box all day, it is better to bring in the surplus specimens wrapped in Osmundas and the bundle tied with Grasses. I have frequently done this; the bundle being slightly moistened, the most delicate plants can be kept as fresh as in the box.—"Bulletin of Torrey Club."

LANDSCAPE GARDENING.

THE following questions given to students of landscape gardening are a fitting illustration of the ideas on landscape gardening that have hitherto obtained. With such, no wonder gardens are everywhere spoiled instead of improved by so-called designs.

What are picturesque objects, and where are they appropriate on a place?

How can you show originality without avoiding good taste?

Where are suitable places on a lawn for single trees or for groups?

Define richness and polish.

What is gradation? appropriation?

With such meaningless drivel on the part of examiners, what can we expect from the unfortunate students? or any of them who made a straightforward effort to get at the bottom of these problems? We are told that madhouses are growing larger, and really it is not to be wondered at in the face of the questions asked of young men new-a-days.

R.

Adiantum caudatum.—This is one of the best of Ferns for baskets. Its fronds, which grow in a gracefully drooping manner to a length of 2 ft. or 3 ft., emit young-rooted plants, which also produce long fronds. In baskets or in pots, or planted to cover walls of stoves or in any warm greenhouse, this *Adiantum* will, when well known, be highly prized. It is not yet sent out, but Mr. Willis has a large stock of it in his Fulham nurseries.—S.

PLATE CXXXVIII.

PERENNIAL LARKSPURS.

Drawn by MARIAN CHASE.

Few families of hardy plants have undergone so great a change as the Delphiniums or Larkspurs. Our forefathers cultivated a number of them, some of which are still appreciated and eagerly sought after by lovers of hardy plants, but the greater number of old kinds are useless for decorative purposes, being wholly eclipsed by the lovely varieties recently obtained by means of hybridisation. For decorative purposes these stand pre-eminent, their bold, stately spikes and ample foliage rendering them conspicuous even at a distance. For mixed borders they are indispensable, and some of them are almost perpetual flowerers. It may not be generally known that Delphiniums can be made to bloom for several months by continually cutting off the spikes immediately they have done flowering. If the central spike be removed the lateral shoots will flower, and by thus persevering in cutting off the old flowers fresh shoots will issue from the base and keep up a succession of bloom. Another plan is to let the shoots remain intact until all have nearly done flowering, and then cut the entire plant down to the ground, when in about three weeks or so there will be a fresh display. In order, however, to keep the plants from becoming exhausted they must have a heavy dressing of manure or a liberal supply of manure water. Top-dressings are necessary not only in the case of Delphiniums, but in that of all plants of like character, such as Phloxes, Hollyhocks, Chrysanthemums, and the tall-growing Lobelias. They keep the soil cool and moist, give the plants a healthier appearance, and wonderfully increase the quantity and improve the quality of the flowers. Larkspurs thrive in almost any situation or soil; they are easily increased, and are quite hardy. A good friable loam, enriched with rotten manure, is their favourite compost, but the character of the soil apparently is of but little importance, as I have seen them growing luxuriantly in hot, sandy soil, which was, however, heavily manured and watered, whereas loam requires less attention in that way. Every three or four years they should be re-planted, dividing them at the same time. This operation may be performed in spring, just as they are started into growth, or in summer; if done in summer, cut the plants down that are intended for division, and let them remain for a week or ten days until they start afresh; then carefully divide and re-plant, shading and watering until they have become established. I dislike late autumn division in the case of Larkspurs.

Some of the best varieties are Delphinium cashmerianum and its white variety, a kind dwarf in habit and free flowering; *D. laxiflorum* is somewhat similar; *D. grandiflorum* and its double form (once common, but now scarcely ever seen) are both excellent; *D. chinense*, the Chinese form of *D. grandiflorum*, is a little-known plant, but one that I can strongly recommend; it is exceedingly free flowering, the blooms are large and of every shade of white and blue; in habit it is dwarf and neat, and it lasts in good condition for a considerable time. *D. cardinale* and *D. nudicaule*, two Californian species with scarlet flowers, are too well known to need description, and the same remark applies to *D. elatum*, *elegans*, and *formosum*, all good sorts. The following small selection will, I think, be sure to please everybody:—

SINGLE VARIETIES.—Belladonna, sky blue; Hendersoni, dark sky blue; Cambridge, sky blue with black centre; Granville, flowers large, deep indigo blue with brownish centre; Gloire de St. Maude, light blue with a brown and black centre; Barlowi versicolor, semi-double, deep Prussian blue tinted with red, centre brown, habit dwarf; Coronet, dark blue, centre purple and yellow, very profuse flowering; magnificum, gentian blue, centre white; Lavender, light blue; pulchrum, silvery grey, very free flowering, a fine bedding variety; formosum lilacinum, lavender tipped with pink, centre white; Celestial, ultramarine blue, centre brown, extra fine.

DOUBLE VARIETIES.—Madame E. Geny, rosy purple tipped with blue, centre white; Madame Henri Jacotot, bright azure blue, shaded with rosy pink; Madame Richalet, rich cobalt blue tipped and striped with violet; Pompon Brilliant, deep violet

TWO DELPHINIUMS

blue, centre reddish; Roi Leopold, blue and violet, centre white and yellow; Hermann Stenger, bright violet-blue, centre rosy purple; Claire Courant, azure blue; George Taylor, bright blue, centre purple; ranunculoides, rosy lilac, margin of petals deep cobalt blue, very double; Roncevaux, rich cobalt blue, with a metallic lustre, centre white; Le XIXe. Siècle, violet and sky blue, very double; Keteleeri, rich lavender blue tinted with reddish lilac, centre white; Prince of Wales, bright azure blue, centre white; General Ulrich, dark glossy blue, each petal having a central stripe of rich lilac; Arc en Ciel, silvery grey suffused with blue, centre white.

[The specimens from which our plate was prepared were supplied from the Hale Farm Nurseries, Tottenham.]

PROPAGATING.

EUPATORIUMS.—These are readily increased by means of cuttings, either in the shape of young tops on eyes as shown

Fig. 1.—Eupatorium riparium.

in [fig. 1 (*E. riparium*), or as seen in fig. 2 (*E. gracile*). The plants for stock must be got into an intermediate house in order to induce them to make shoots fit for cuttings. They should be inserted in pots filled with sandy soil, consisting of

Fig. 2.—Eupatorium gracile.

peat and loam, and the pots should be plunged in a gentle bottom-heat in the cutting box, where they will emit roots in about ten days. They should be occasionally sprinkled with a fine-rosed pot, and the glasses that cover them should be taken off for an hour every morning. The best month in which to propagate them is April, as they will then make fine plants for early winter flowering.

H. H.

Selaginella apoda.—This is the most compact growing of all the Selaginellas, but it is one which is not so easily grown in perfection as some other sorts. An essential point as regards its culture is plenty of heat, for although too much moisture can scarcely be given it, yet directly the temperature becomes low the plants damp off. It does best in a partly-shaded place, and, if grown in well-drained pans filled with turfy loam, peat, leaf-mould, and silver sand, fine compact, cushion-like plants will be obtained.—S.

Fragrostis elegans in Pots.—In addition to the many uses to which this beautiful light feathery Grass may be put in a cut state, I find that it is now largely employed in Covent Garden as a decorative plant in 4½-in. pots. When sown and treated in the same way as Mignonette it has a very pretty effect amongst flowering and fine-foliaged plants, and during the summer months, when Ferns suffer from the exposure to which they are often subjected, such plants as these are very useful.—J. GROOM.

GARDENING FOR THE WEEK.

Indoor Plant Department.

Cattleya crispata.—The different varieties of this *Cattleya*, which are essentially late summer-flowering plants, do not find so much favour with Orchid growers generally as they deserve, principally, I believe, through their being comparatively shy bloomers. This is, however, in most cases traceable to their receiving treatment not in accordance with their wants. I have seen large specimens of these that have been grown on for a number of years without their showing any inclination to flower, through being placed, whilst making their growth, in a position where they had insufficient light and too little air; and although the bulbs and leaves so produced were large enough, they lacked the sturdy, robust character which the plant assumes when treated as it requires. Such plants when subjected for a single season to more light and air will usually flower freely from every growth which they make. The contrast between the chaste white ground colour of the sepals and petals, and the dark chocolate, blotched, crisp-edged lip, combines to give them a charm unsurpassed by any other species of this grand family of Orchids. After being rested through the spring and early part of summer, the flower-spikes of the different varieties of this *Cattleya* will now be pushing up inside their capacious sheaths. They will last considerably longer in bloom if, during this stage of their development, they are placed in a late Vinery or in any similar structure where a little more warmth exists than that of an ordinary greenhouse, but with more air and less moisture in the atmosphere than is given to any Orchid house. *C. crispata* and its varieties will stand more water at the roots than most *Cattleyas*, and just as much root-moisture should be given as will help the pseudo-bulbs to become plump after the slight shrivelling that will have occurred during the long drying process that this *Cattleya* needs through the spring to prevent its keeping growing both summer and winter, and enable it to flower.

Autumn and winter-flowering *Cattleyas*, such as the old true *C. labiata*, and the paler-coloured forms of this fine species, the hybrid *C. exoniensis*, and also the numerous varieties of *C. Trianae*, will now have made considerable progress in their growth, and through the whole of the next month the house in which they are grown should be kept at the maximum temperature which these plants will endure. If the weather comes dull and cold, as is frequently the case during our changeable summers, the requisite temperature ought to be kept up by the use of fire-heat, for it must be borne in mind that our summers being comparatively short there should be no loss of time, such as occurs through the occasional low temperatures we experience during the summer months, and which have a corresponding influence upon the internal temperatures of all glass structures, necessitating the deficiency being made up by fire-heat, without which, during these cool intervals, little progress is made; and the evil is not confined to the loss of time alone; on the contrary, when the heat falls too low, the plants receive a check that has a material influence in preventing their growths attaining the size which they would do where a regular temperature is maintained. Some growers of the cooler section of general stove plants allow the fires for some weeks in the middle of summer to go out altogether; but that I regard as a mistake, especially in the case of Orchids that need either a cool or high stove temperature. The later flowering *Cattleyas*, including the many forms of *C. Mossiae*, *C. Warneri*, *C. intermedia*, *C. amethystina*, *C. Skinneri*, and *C. albosa*, though not so far advanced as the preceding, will now be making active growth, and should be encouraged by sufficient warmth and as much water at the roots as it is safe to give them; but even during this their most active season the material in which their roots are placed must never be kept so moist as is required by the majority of Orchids. There is no exaggeration in saying that four-fifths of the evils connected with the growth of *Cattleyas* arise from too much root moisture. Wherever *Cattleyas* are met with in better than ordinary condition it will be found that the plants increase rapidly in size by double breaks, and if examined it will invariably be apparent that they possess an abundance of roots; but although the family collectively may be said to be much more impatient of water than any other Orchids, except the nearly allied *Laelias*, their ability to bear and benefit by its freer application will almost always be found to be governed by the stout sturdy character of the growths consequent upon being grown with plenty of light. This is clearly shown by plants suspended near the roof, which flourish with double the amount of water applied that a similar example is able to take when in a position where less light will reach it, both plants being potted in material equally porous and the drainage alike efficient.

Laelias.—These need the same treatment as *Cattleyas*. The different handsome forms of *L. elegans*, *L. purpurata*, and *L. Perrini* are particularly like *Cattleyas* in their general requirements, the last named beautiful autumn-flowering species, both the large and smaller variety, well deserving a place in any collection, for though not so much esteemed as many of the more fashionable varieties of Orchids, yet their distinct, handsome, finely-coloured flowers and their time of blooming which is late in autumn when comparatively few Orchids are in flower, make them worthy of cultivation by all who value the general character of a plant more than mere fashion. *L. Perrini* will now be fast plumping up its bulbs, but there must be no attempt at reducing the limited quantity of root moisture which it needs. A good light position, especially in this stage of the growth, enables the plants to flower freely. Stout, strong, well-matured bulbs will produce three, four, or even five flowers to a single growth in place of the more usually seen couple of blooms from a scape. The late autumn-blooming *L. anceps* with its several

beautiful varieties and *Lælia autumnalis* will now be in the midst of their growth, which should be encouraged by furnishing requisite heat and moisture. These more than most Orchids require a good light position; they do well on blocks hung up near the roof, and where grown in pots one of the lightest situations in the house should be given them. Grown under conditions that impart to the leaves an elongated, soft, flabby character, the plants, especially *L. anceps*, will not be likely to flower.—**T. BAINES.**

Pelargoniums that were placed in the open air to ripen their wood, as recently recommended, will now be in a fit state for heading down, an operation which should be done at once, as their ability to flower early next spring depends much upon the time at which they are cut down. No plant with its roots confined in a pot should ever have its head removed without first allowing the soil to get as dry as it will bear without injury; for when the leaves, which are its evaporating surface, are removed, it has not the power to throw off the moisture absorbed by the roots, a circumstance considerably aggravated if the soil be wet at the time when the plant is headed down, a condition which causes the roots inevitably to perish. Hence the necessity for allowing the soil to become dry, more or less, according to the nature of the plant to be operated upon before removing its top. It is necessary to be more careful in this matter in the case of *Pelargoniums* than in that of most plants, as they are more impatient of their roots being in soil that is too wet than the generality of plants in cultivation. After they are headed down place them in a cold pit or ordinary garden frame in a sunny situation, put the lights on, but tilt them in the daytime in order to admit air, closing them in the afternoon whilst the sun is on the glass, syringing them freely overhead at the same time, which will be all the water they will require until they have broken into growth afresh.

Fuchsias.—A portion of the plants that flowered earliest may now with advantage be placed for ten days or so in the open air, during which time they should receive only just enough water to prevent them from flagging. If after this their side branches are cut in to four or five joints, the leading shoot being shortened proportionately, and they are then put in a house or pit, where the atmosphere can be kept a little close and moist by freely damping the floor, closing the lights in good time in the afternoon, and syringing overhead, they will quickly throw out fresh shoots that will bloom freely through the autumn; and to assist them to do that they should have weak manure water applied once or twice a week.

Cassia corymbosa is a plant that is easily managed, and will keep on producing its yellow blossoms from August to October. Young plants if it potted in spring, and well attended to since that time, will now be setting their flowers, and as these are produced from the extremities of the shoots, there must be no further stopping, except in the case of any that it is deemed more desirable to grow on than to permit to bloom. Keep them well up to the glass, so as to promote a bushy, compact growth.

Petunias.—These make excellent pot plants and are very showy, especially the flaked varieties, both single and double. To have them stocky and short jointed they should be grown out-of-doors, fully exposed to the sun, and be stopped frequently to induce them to break back freely and form bushy plants. When grown under glass the stems become drawn, which they likewise do in the greenhouse while producing their blooms. To obviate this as much as possible they should be placed in light airy positions, where they only get a small amount of shade, if any at all. By cutting back any that have become straggling and drawn, and replacing them out in the open air, they soon break again and flower with great freedom, so that a constant supply may be kept up by growing a few plants and treating them in this way. While out-of-doors the pots should be plunged so as to prevent the sun from drying the roots.

Celosias.—The brilliant and feathery plumes of these and the length of time during which they may be had in bloom render them very desirable plants to cultivate, either for the purpose of supplying out flowers or for greenhouse or conservatory decoration, where for effect they have no equal among soft-wooded plants. Unfortunately, however, they are very subject to red spider, and, unless kept well syringed while growing and freely supplied with water at all times, they become so much injured as to lose their foliage entirely long before the flowers become shabby.

Double Zinnias.—There is generally a paucity of gay-blooming plants late in the autumn; and although *Zinnias* are not generally cultivated in pots, they are most valuable for that purpose, their gay colours and fine large globular flowers making quite a display indoors long after they cease blooming in open beds, where damp nights and heavy rains generally cut short their beauty. Any left over from planting should have their flower-buds nipped out and be potted up at once, after which set them in the shade for a few days till they get hold of the soil, and then out in an open situation. A few seeds sown now will not be too late, as they grow rapidly at this season and soon come into bloom.

Late-flowering Lilies of the lancifolium section will now have formed their flowers, and have filled their pots with roots. Where there are many bulbs in a pot the soil naturally becomes exhausted, and unless from this time onwards they are regularly supplied with manure water, the bottom leaves will turn yellow, and fall off long before the flowering is over, a circumstance which gives them an unsightly appearance. Where a number of these useful decorative plants are grown, their season of blooming may be much prolonged by placing a portion at the north side

of a wall now, where they will not receive much sun. When the flowers are visible this will not have any effect upon drawing them up weakly, provided they are set where they will get plenty of light; keep them well tied out so as to admit light to the inside leaves. If aphides make their appearance upon them they should be immediately thoroughly syringed with Tobacco or Quassia water, laying them down on their sides for the purpose, for if the aphides be allowed to remain on them, they will destroy the leaves in a very short time. One of the first essentials of successful Lily culture is to maintain the leaves in a healthy state as long as possible. The number of flowers produced by pot Lilies is generally not more than half the quantity which they would bear were the treatment such as they require.

Flower Garden.

At this season of the year trees and shrubs grow so rapidly that the more common and robust kinds are likely to encroach upon their weaker, although sometimes more valuable, neighbours; and this very often causes serious injury before it is observed. Strong shoots are also sometimes produced by the stocks upon which choice varieties have been budded or grafted, and these should be removed at once. It sometimes happens that trees and shrubs produce abnormal growths, or sports of various kinds, such as variegated shoots, flowers of a distinct or different colour, &c.; and these, if they are considered sufficiently valuable, may be perpetuated by being budded upon other representatives of the family. Where alterations in grounds and gardens are contemplated the present is the most suitable time for making notes and observations having reference to these changes, as all trees, &c., have now attained to a mature condition, as regards the hue or colour of their foliage, their habit of growth, &c.; and such notes made now will probably be found to be very useful at a later period of the season, when such alterations are being carried out. In selecting trees and shrubs it is necessary to take into consideration their habit of growth and the form they are likely to assume when they are fully developed, and whether they will be of an upright or drooping habit, or of a round-headed or pyramidal form &c.; and, with a view to secure the desired effect in grouping or arrangement, the hue and form of leaf should also have attention given them. There is also another very important point which should not be lost sight of, viz., that of selecting plants that are likely to thrive in the soil and situation where it is intended they should be planted. In the case of newly introduced species this can only be ascertained by experiment, and this will generally be upon a somewhat limited scale. But it would, doubtless, be unwise to form extensive plantations of *Rhododendrons* and other American plants upon a soil resting upon a chalk formation, or to plant freely such Coniferous trees as the *Abies canadensis*, *Menziesii*, and *Douglasi*, upon a light dry soil. Attend to the usual routine operations of mowing, sweeping, rolling, weeding, &c., the frequent falls of rain having been exceedingly favourable to the growth of weeds of all kinds. Attend also to staking and tying up tall-growing plants, as well as to training and regulating dwarf or trailing species.

Many annual flowers, such as *Nemophilas*, *Clarkias*, and many other species, although exceedingly beautiful while in bloom, are yet of short duration, even during favourable seasons, and, of course, more so during such seasons as the present. They should (if the seed is not required) be cleared off as soon as their beauty is over, and be immediately replaced by some other species of plants from the reserve garden. Attend to the various sorts of plants in the flower-beds, as regards training, pegging down, watering, &c., and regulate the growth of standard and pyramidal specimens of *Fuchsias*, *Pelargoniums*, *Tropæolums*, *Clematises*, &c., while drooping plants in baskets and vases will also require to be occasionally regulated and trained, so as to be made to depend gracefully over the sides, and around the margins of the same. Plants suitable for this purpose are the various sorts of Ivy-leaved *Pelargoniums*, *Clematises*, *Convolvulus*, *Maurandias*, *Lophospermums*, and many others. Biennials and perennials raised from seed sown during the spring must on no account be allowed to stand too close on the beds, for if crowded they whole get drawn up weakly, and a season is so far lost that they flower only meagrely the ensuing spring and summer. In preparing nursery beds for those that do not absolutely require a shaded situation select an open position where they will make close compact growth, which will enable them to stand the winter and produce double the quantity of flowers that can be obtained from weakly-grown examples. Those that do not like full exposure to the sun, as, for instance, *Primroses* and *Polyanthuses*, should have a place at the north side of a wall, not, as they are often seen, crammed away under the shade of trees that not only darken them too much, but impoverish the soil to an extent that prevents them attaining anything like the necessary strength and vigour. In the herbaceous borders stake and tie everything that requires it before it is broken down by the wind, especially tall-growing subjects like *Hollyhocks*. These fine plants are often thrust at the extreme back of a border close up to shrubs or trees where there is no possibility of their ever being more than mere shadows of what they would grow to if justice were done to them; in such places the bottom leaves are usually all destroyed by red spider before their flowering is half over. Mulching with 3 in. of rotten manure over the roots will greatly assist them, and a free use of the syringe with clean water twice a week, taking care to moisten the roots as well, will much improve their health and appearance. Remove all dead and decaying tops from plants that have flowered early in order to reduce to a minimum the greatest drawback to herbaceous plants; but for the sake of mere appearance never remove the healthy tops from any plant, or the never-failing result of such treatment will be to weaken it seriously, and perhaps irrecoverably.

Indoor Fruit Department.

Vines.—Late varieties will now require to have their young growths pinched frequently, as it is better to go over them often than allow the wood to grow for a number of feet and then remove it. Gros Colman, after being stopped the first time, never afterwards makes many young growths. The leaves of this variety are very liable to become shrivelled in autumn before the fruit is quite ripe; therefore, in order to have the foliage fresh as long as possible, the lateral growths should be left three or four leaves in length. Every opportunity must now be taken to encourage the development of late Grapes, as one month of bright summer weather, properly utilised, is of more benefit than two later in the season. Grapes being now frequently transferred from one place to another, packing ought to receive careful attention. Grapes are, however, not so easily injured by travelling as some fruits, but the bloom is apt to get rubbed, and without bloom the appearance of the fruit is deteriorated. Single bunches or a few pounds should be wrapped up in tissue paper and placed in a box made of $\frac{3}{4}$ -in. deal, as near the size of the quantity it is destined to contain as possible. A layer of paper shavings should be laid along the bottom, and, as each bunch is placed in the box, a small quantity of the shavings should be placed between it and the next bunch, enough of the same material being laid over the top of the whole before putting on the lid as will prevent any of the bunches from getting displaced. Screws should be used for fastening down the lid, as they can be put in and taken out without shaking the box or splitting the wood. Baskets with close-shutting lids may be, and often are, used; but they are not so secure as the wooden boxes. When large quantities are being packed no wrapping or stuffing between the bunches is necessary. If a lining of paper shavings be placed round the box or basket, and the bunches are laid closely against each other, they will travel a long distance and stand much knocking about without being in any way injured. This is the safest, easiest, and cheapest way of packing large quantities of Grapes.

Pines.—Large suckers, which were rooted a month or two ago may now be shifted into their fruiting pots. They will make considerable growth before the end of the season, and, at the latest, will be in fruit by this time next year. Treat them as plants with no roots for a week or two after potting. As plants from which the fruit has been cut are thrown away, space will be made to admit of thinning out and re-arranging the young stock of fruiting Queens. The best plants generally are those which are grown far enough apart to prevent leaves from intertwining. Continue to pot suckers as they become fit for separation from the parent plants.

Hardy Fruit.

Peaches and Nectarines.—These should be gone over as often as they require it, removing all superabundant and ill-placed shoots. Take care, however, to destroy none that will be required for bearing next year. Want of observation and forethought in this matter is the cause of so many of these trees being deficient in the way of bearing wood in the centre, the fruit being borne almost exclusively near the extremities of the branches, instead of being evenly distributed over the whole surface. Such shoots as are to be retained should now be all laid in close to the wall, an operation especially necessary in late localities, where there is a difficulty in getting the wood ripened over each tree; moreover, now and then, to see that the fruit is fully exposed to the sun, and where any symptoms of mildew, either on the leaves or fruit, show themselves dust the tree, or at all events the affected parts, with flowers of sulphur, by means of the old-fashioned sulphur-puff, a contrivance as yet unsurpassed for the purpose. It is so simple in its construction that it cannot get out of order, and by its use the sulphur can be directed to any part where necessary, both to the upper and under surfaces of the leaves. Let the sulphur remain undisturbed four or five days before it is syringed off. Mildew is making its appearance upon Peaches later than usual. Be assiduous in regularly syringing with water, and also in giving a copious supply to the roots; this is not only necessary to enable the fruit to attain its full size, but also to prepare good wood for another season. Where, in the early part of summer, trees are allowed to suffer from want of water the growth gets stopped before its time, and when copious rains come during August these have the effect of causing them to push fresh growth, for the ripening of which there is neither sun nor time. I have no hesitation in saying that half the failures that occur in the cultivation of Peaches and Nectarines, particularly in small gardens, are due to the trees not receiving sufficient attention. With the exception of pruning and nailing, they are, comparatively speaking, often left to take their chance, or they are subjected to a course of alternate care and neglect, which results in a crop of fruit being obtained in such seasons as it is to be met with everywhere, but none at other times. There is also an immense difference in the size and quality of fruit borne by trees that receive the requisite attention as compared with that produced by those existing under neglected conditions.

Apricots.—These should also have sufficient young shoots nailed or tied in close to the wall to supply bearing wood evenly over the whole surface. These young shoots, when in absolute contact with the wall, will frequently set a crop of fruit when that upon spurs, which stand further away, is destroyed by spring frosts. The difference that 2 in. make in such matters would scarcely be credited by those who have not had an opportunity or taken the trouble to compare the results.

Kitchen Garden.

Drying Herbs.—Herbs should be gathered as soon as they begin to open their flowers. In drying them two methods are employed. One is

to tie them into bunches as soon as cut and hang them up in a room or shed; the other is to first lay them out in the sun to dry. By both these methods the quality is deteriorated. If fermentation takes place sufficient to discolor the leaves—such as occurs, more or less, when herbs are tied up in bunches whilst green and sappy—their best properties are destroyed. In confirmation of this it is only necessary to point to the extreme care taken by the growers of Lavender, Mint, &c., for distilling; for such purposes they are not allowed to lie together, even for a few hours. If, on the other hand, herbs be exposed to the sun, much of their strength is dissipated; they become quite brown, and that fresh green appearance which they possess when the drying is well managed is destroyed. But when herbs have been improperly treated, loss of strength is not the worst result; there is always imparted to them a disagreeable flavour. In drying herbs an open shed or room, where plenty of air can be given, is necessary. Stretch out a piece of netting, such as is used for protecting fruit from birds, wire netting if at hand will do; on this lay the herbs (which should be cut when quite dry) thinly. Thus treated, air acts upon them from all sides and they dry quickly, which is the primary object, without losing their best properties. When perfectly dry put them loosely in white paper bags, tie them up, and hang them where they will be free from damp or they will become mouldy. Herbs treated in this way will be found to be but little inferior to such as are fresh cut. Sage should now be propagated by slips, taking off middling-sized branches and inserting them moderately deep in the ground in rows where they are to be grown. If the weather becomes dry give them plenty of water until they are rooted. The advantage of growing Sage from slips or cuttings is that plants so produced have not such a disposition to flower as those raised from seed.

Tomatoes on Open Walls.—The naturally vigorous habit of these plants is such that they usually grow too rank if they receive over much moisture at the roots, but in exceedingly dry weather they must be regularly supplied with water, or the fruit will neither swell to the requisite size, nor will the plants continue growing. Do not allow them to get too much crowded with superabundant shoots or to hang loosely from the wall, or the progress will be slow. If they be kept regularly and evenly trained so that the sun, of which they are so fond, can reach every part, our summers are not too long for the successful cultivation of Tomatoes, particularly in late seasons, and if ever they suffer through inattention they lose time that cannot be regained.

Extracts from my Diary.

July 29.—Sowing Wheeler's Imperial and Carters' Heartwell Early Marrow Cabbage; also Frazer's Broad-leaved and Green Curled Endive on a border previously well watered. Planting out the last rows of Celery in trenches, in which has been put a good supply of well-rotted manure, to which had previously been added soot and salt at the rate of 25 lb. of the former, and 1 bushel of the latter to the load. Preparing three-light frames and planting them with Cucumbers. Putting Jargonelle Pears in gauze bags to protect them from wasps, &c. Nailing and tying in leading shoots of Peaches and Nectarines. Tying out and picking blooms off Fuchsias intended for exhibition at the end of August. Picking over borders of carpet bedding. Taking lights off early Peach house and well watering the borders. Layering Strawberry runners in pieces of turf 4 in. square which have previously been soaked in manure water.

July 30.—Sowing Black-seeded Brown Cos, and All the Year Round Lettuce, Red and White Turnip Radish, and a large border of Early Horn Carrots for autumn use. Potting a large batch of Primulas and Cinerarias for supplying cut flowers. Taking up and storing away Shallots and Garlic in a cool shed. Earthing up Celery whilst it is perfectly dry. Turning a large heap of manure for Mushroom bed. Stopping laterals through all Vinerias where the fruit is ripening. Hoeing, cleaning, and watering amongst late Peas. Taking up a border of Early Ashleaf Kidney Potatoes and laying them in the sun to get green for seed. Watering Celery and Cauliflowers. Commenced summer pruning of Apples and Pears.

July 31.—Sowing Tarnips. Putting in a few Pelargonium cuttings. Staking Chrysanthemums. Tying out Tricolor Pelargoniums for exhibition. Pruning and nailing Plum trees. Clearing off a large piece of Peas and digging the ground for other crops. Pulling up pickling Onions and laying them out to dry. Stopping and nailing the shoots of Tomatoes on walls. Giving the late Vinerias a good soaking of guano water. Watering the Pines all through; also Celery, Broccoli, Lettuce, and Endive.

August 1.—Sowing Mignonette in pots; also Telegraph Cucumbers. Planting two three-light pits with Parsley for winter use. Renovating linings round all Melon and Cucumber frames. Digging large pieces of ground (previously occupied by Peas) for Cabbages. Gathering Apricots and Gooseberries for preserving. Earthing up Cardoons and Celery. Dutch hoeing amongst Gooseberries and Currants. Giving carpet bedding and other borders a good soaking of water.

Aug. 2.—Sowing large piece of Spinach; also in a pit Osborn's Early Forcing Bean to succeed the outdoor crops. Planting out Wheeler's Imperial and Carters' Heartwell Early Marrow Cabbage on ground previously occupied by Peas, and well watering them. Re-potting batch of Ferns and Dracenas for dinner-table. Cutting last few bunches of Black Hamburg Grapes, and putting their stalks in bottles of water so that the house may be thrown open in order to ripen the wood. Spawning Mushroom bed at a declining temperature of 80°. Earthing up Leeks, thinning Turnips and Spinach, gathering Tomatoes from plants grown in

pots in Pine houses. Watering outdoor Tomatoes, late-planted Celery, Carrots, and Radishes.

Aug. 3.—Sowing a bed of Early White Naples Onions for use in spring. Pulling up one portion of spring-sown Onions to dry. Weeding and clearing Box edging in kitchen garden. Rolling gravel walks after rain. Gathering Gherkins, Cucumbers, Cauliflower, Onions, &c., for mixed pickles. Clearing off large pieces of Raspberry canes; also a piece of Broad and Dwarf Beans. Putting together six cartloads of manure, adding 20 lb. of salt and one bushel of soot to the load, and giving the whole a good turning for Celery trenches. Watering Peach house; also Cabbage plants, Lettuce, Endive, and Scarlet Runner Beans. Fruit in use for dessert: Pines, Melons, Grapes, Peaches, Nectarines, Apricots, Figs, Plums, Gooseberries, and Currants.—W. G. P., *Dorset*.

THE FLOWER GARDEN.

FORMAL FLOWER GARDENING.

Is it true, as some professed authorities would have us believe, that certain formal styles of mansion architecture commit us to a formal style of gardening also? Does a square and evenly-balanced, castellated structure, for example, with its stairs and terraces, commit one to a geometrically-shaped flower garden in front of it, in which all the beds are laid out with geometrical order and balance, and planted in the same way? or does a Grecian frontage entail a classical style of garden and formality as well, with the usual fountains, vases, and other adjuncts? Would it be an incongruity to place a mansion, in any style of architecture, down at once upon a Grassy lawn among trees, shrubs, and flowers, laid out without the least regard to formality, but becoming and natural? Would such an arrangement offend good taste? or would it violate any rule or principle in landscape gardening? and would it be incompatible with any particular style of architecture? I ask these questions because it has been not unfrequently stated that the style of the mansion determines, to a great extent, the style and character of the flower garden, and there are not a few who believe as much, as is testified by many a garden in England, to see how much landscape gardeners are fettered by such rules we have only to read their treatises on the subject. One of the most recent writers on landscape gardening, who has published a book on the subject, cannot apparently conceive a garden in front of a mansion in any direction without geometrical parterres in front of the windows, and his diagrams, which are furnished to show the "application of the principle of unity and breadth to garden compositions," betray the same rigid artificialism. Examples of this unity and breadth are represented by a proportionately balanced structure (a square two-storey house) with a square plot of Grass in front, bounded by straight walks and straight lines of trees on each side, and a variation of this design consists of a larger, or rather a longer, house with the same plot of Grass in front and the same straight lines of walks and trees, except that the Grass plot is divided into four plots with the inevitable fountain in the centre surrounded by a gravel walk. Nowhere is the "principle of unity and breadth" exemplified by a free and natural style of embellishment, and the impression left on the mind by the author's statements is, that unity without geometrical uniformity is an impossibility. Fortunately, we are not left to books alone for lessons in landscape gardening. Here and there a venturesome mind has broken loose from leading-strings and stepped out in an independent path of its own. As an example of what may be called the natural style we may mention Wentworth House, the princely seat of Earl Fitzwilliam, in Yorkshire. The house is a magnificent Grecian mansion, consisting of a centre and two wings extending above 600 ft. in length. The front of the mansion faces one of the finest park scenes in England. This consists of a wide expanse of open park with undulating masses of woodland to the right, left, and beyond, and distant glimpses here and there between. Deer are abundant, and stroll about familiarly close to the windows of the mansion, which we have seen them approach to take crumbs from the hands of the domestics. On the pleasure ground front the style is nearly the same, except that the grounds are kept in perfect order. There is first a roomy gravel space in front of the house, and beyond a wide and open extent of smooth lawn with one or two clumps of shrubs and trees, but not many,

and ending in the natural wood beyond. Near the house, at the edge of the gravel, there are two or three narrow flower beds and a good vase or two, but there are no pretensions to a flower garden whatever. A carriage drive runs straight from the entrance for some distance, and has on each side a broad margin of lawn overhung by noble Beeches and other trees, but not planted in formal lines. They form just the edge of the wood, and there is also a kind of wild garden on each side of the drive. The general aspect of the scene is free and natural, and without a single formal line anywhere, except it be the drive. There is no lack of either unity, or breadth, or repose. We do not say that a flower garden might not have been made in the same situation, or that it would have been a mistake, for we are not condemning flower gardens, but the example as it stands shows us, as well as anything could do, that a geometrically laid out flower garden is not a necessary adjunct to a mansion, let the style of the latter be what it may.

J. S. W.

HERBACEOUS PLANTS AT HUNTINGDON.

I KNOW of nothing so well calculated to excite enthusiasm on behalf of hardy herbaceous plants as an occasional visit to a good nursery where this department is well cared for. Those whose knowledge of flowers is mainly confined to the common run of bedding plants have no idea what a mine of floral wealth there is carefully stored up and cherished in some of the old-established country nurseries in hardy plants alone, and what facilities such plants offer for the supply of cut flowers. One may be in the possession of an acre of flowers bedded out and yet be unable to fill a vase tastefully and well from a sheer lack of materials. Can anything be more lovely for cutting for vases at this season than the Delphiniums? and what a striking effect they produce in the borders when growing! A variety called Cambridge—from its shade of colour being just the Cambridge University tint—is especially striking; so also is the double variety *rannunculifolium* and the dwarf scarlet kind *nudicaule*. It cannot be known how very effective these plants are, or we should see them in every garden. Pyrethrums have been good, but are now nearly over, so far, at least, as regards the principal bloom; but, like Roses, with a good collection there will nearly always in summer and autumn be a few flowers. The early Phloxes are just showing colour; and what an interesting sight is a good collection of Carnations, Picotees, and Pinks! One need not be a skilled florist to enjoy such flowers, and they are eminently suited for town gardens, being pretty well proof against smoke; at least, I have seen prize stands cut from a crowded city garden. Depend upon it, if we really wish to find pleasure in the culture of flowers we must seek for it among those families of plants that have been too long comparatively neglected. How lovely are the Ranunculus flowers where they do well! but how disappointing they often are. The double Potentillas are now very showy; they have been much improved of late years and make excellent border plants, throwing up a succession of flowers for a long time. Among miscellaneous plants that are now in flower may be named *Plagiograndiflora*, a North African plant, quite hardy, bearing large, striking yellow flowers on solitary stalks. A bed of the old scarlet *Lychnis* is wonderfully bright and even more effective than the double-flowered form. *Scabiosa speciosa* is pretty, and so are *Gladiolus Colvillei rubra* and *albus* and the yellow-flowered Siberian Poppy (*Papaver nudicaule*). A bed of the white *Dianthus Marie Pare* is now very effective, and, as is the case with all good collections of herbaceous plants, some are going off flower while others are coming on; therefore, the interest never flags.

E. HOBDAV.

Ramsey Abbey.

Dwarf Lilies for Flower Beds.—A quantity of plants of the White Trumpet Lily (*Lilium eximium*) now flowering in Mr. Bull's nursery at Chelea suggests the idea that where it is desirable to keep flower-beds gay throughout the year such plants might be made to play an important part. Single bulbs placed in small pots filled with good sandy loam and rotted cow manure, and plunged in a cold frame or in a sheltered position out-of-doors, could easily be moved into flower-beds when coming into bloom. They would be effective either in masses by themselves or plunged 12 in. or 18 in. apart in beds of *Viola* or other plants in flower in June and July. The plants alluded to in Mr. Bull's nursery have stems from 6 in. to 8 in. high, each surmounted by a large, pure white, trumpet-shaped Lily. *L. longifolium*, which is so largely grown for market, and which, at the present time, may be seen in such profusion in the flower shops in the Central Avenue, Covent Garden, differs little from *L. eximium*, but it grows rather taller and its flowers assume a more upright character.—S.

THE MICROSPERMAS.

ONLY two species of this genus are known, both being annuals and natives of Mexico. *M. bartonioides* is a very distinct and beautiful plant, which flowers freely through the summer months; it grows about 1 ft. high, and has rough, hairy stems and jagged leaves. Either for the open border, or for the decoration of the greenhouse or cool conservatory, it is certainly worth growing, the large sulphur-yellow petals, and the very numerous, long, slender filaments of the same colour making a fine show. It succeeds best as a pot plant because, when grown in open ground, the rather succulent stems are apt

Microperma bartonioides.

to suffer damage from wind or heavy rain. In any case it requires to be treated as a tender annual, that is, to be raised in bottom-heat and gradually hardened off. *M. lobata* is a much less beautiful plant with smaller flowers. N.

Hardy Plants Costly.—Now, when something like an earnest attempt is being made to introduce a class of plants into our gardens which when once planted will be able to take care of themselves, it is to be hoped that their commercial value will not get above that of plants that have to be coddled under glass nearly all the year round. At present, as far as expense is concerned, one might furnish

a large bed with *Pelargoniums*, *Calceolarias*, and similar soft-wooded plants at at least half the expense that would be needed for hardy *Anemones*, *Aquilegias*, *Delphiniums*, &c. That an increased demand will soon remedy the evil, by making the cultivation of hardy plants more general in nurseries, I have no doubt, but just now it is a considerable drawback to the extended culture of such plants that for only the very smallest piece with a root, that can by any stretch of imagination be called a plant, the same price is charged in the market that would procure a well-grown *Pelargonium* or other tender bedding plant.—JAMES GROOM.

FROM THE BIRTH TO THE DEATH OF THE LILY.

In my last paper (see p. 60) I brought the history of the Lily up to near the end of its first twelve months of existence, or to within a month of the flowering period of some of its species. On the 15th inst. I lifted and transplanted several clumps of *L. bulbiferum*, *candidum*, *croceum*, and *Martagou*, and in doing so I took occasion to dissect some of the bulbs. I first washed them thoroughly in a pail of water, divesting them of every particle of soil, so as to enable any one to distinguish distinctly between the scales of the old bulb and the scales of the new one, and also between the old and the new roots. I then took a bulb of *L. candidum*, and, as I knew that the new bulb would be found sitting close beside the stem of the present year in a nidus or nest composed of the old scales, which were discoloured in various parts, I carefully picked off the scales until I uncovered the new bulb. On submitting the old scales to the microscope, it was clearly seen that the discolouration was caused by their already beginning to decay; the new bulb itself being, on the contrary, clear, white, and smooth, like a piece of polished ivory, with its scales firmly packed upon one another. I picked off twenty-five old scales before I cleared all away from the new bulb; the new roots, the core, and the old stem being alone left with it. This ought to teach those who are interested in settling this question not to judge by outward appearances, by mistaking the old bulb for the new bulb within it. When cleared of the old scales the new bulb measured 2 in. in diameter, and 2½ in. from base to apex—more than double the size of specimen No. 33 (see p. 61). I next cut down through the bulb near its centre, and thus laid open the central growth or rudiments of the new or next year's stem and leaves, which were clearly observable by using a common garden magnifier. The new roots at this time measured from 3 in. to 5 in. in length; and, in cutting down the bulb through the old core, I laid open the connection of these roots with the new bulb, so that they could be seen passing through the core in the clearest manner. I have been induced to be thus particular in my description, in order that those interested may be enabled in like manner to dissect any number of bulbs for their own satisfaction, this being the best time of the year for doing so. There are many readers, I am aware, who differ from me in opinion, but they are simply opinions, as I know well that, experiment as they may, they cannot prove by facts that I am wrong. If they will look at the specimens (see p. 61) they will see that, in every case, the new bulb is springing up from the very side of the old flower-stem, and as it grows larger and larger it pushes the old flower-stem on one side (this is an experimental fact), and, as it rises, it "shoots up from (almost) the precise centre of the bulb as previously." These are the words of one of my opponents, and he is quite correct so far, but he has not yet discovered that it is the new bulb that shoots up, and not anything connected with the decaying old bulb.

WHEN TO RE-PLANT LILIES.—One who has written various works on horticulture tells us how the Lily should be cultivated; but though he gives us a list of all the known Lilies he only treats on a few of the most common kinds. With respect to the first, namely, *L. candidum* (or the White Lily), he says: "When the stools of bulbs have become large, they will have exhausted the soil, and it will be advisable to take them up, divide them, then dig holes, taking away the old exhausted soil, and put at the bottom of each hole a shovelful of rotten manure; fill up with fresh earth, and plant immediately three strong bulbs in each hole, covering them about 3 in. deep. The best time to do this is in September, and the

reason for planting immediately is because these bulbs will not bear exposure to the air without injury. By this treatment they will flower well the next season, but much finer the second." Now this is a mixture of good and bad advice; and although the bad predominates, it is, unfortunately for amateurs, to be found in almost every work on Lily culture. It is said, "by this treatment they will flower well the next season, but much finer the second." Why, the writer does not tell us; and this is the way with almost every one who writes on the Lily. They give us the result, because it is forced on their attention. They cannot give us the cause, for they do not know. In the first place bulbs are recommended to be lifted and re-planted in September. Now this is just two months after that operation should be done to be in the highest degree successful. The White Lily has done blooming early in July. In September its roots are in the most vigorous action. I have proved by facts that, in the beginning of May, the roots of the new bulb are 2 in. long; and now (July 15) they are from 3 in. to 5 in. long. What, then, must they be in length and quantity two months later? The removal of the bulbs in September destroys the vital and most useful parts of the roots by wrenching off the hair-like fibres, and the sap extracted from the bulbs for the formation of new rootlets would have served to increase the size of other parts. Besides, until the new root fibres are in full action, the bulb would be left without its natural support, and subject to a loss of strength. Then how is it possible that the first year after re-planting the bloom should be what it ought to be? Had the bulbs been lifted and re-planted soon after the parents had done blooming, this would not have happened. It may be said this is mere assertion. I grant that it looks so, but as my doctrine does not depend on anything like assertion, let me, as usual, explain. The roots increase their growth at their extremities only; these extremities are always fresh, and always furnished with permeable and soft cellular tissue. It is in the neighbourhood of these tender extremities that the absorption takes place of the liquid matters which are destined to penetrate into the interior of the plant. This absorption is facilitated and increased by means of fine elongated hair-like fibres attached to the younger portions of the roots; these root-hairs, as they are called, though sometimes discernible by the naked eye, may almost always be plainly shown by a moderate magnifying power, while a higher power distinctly reveals their nature, as prolongations of some of the superficial cells from a certain point into slender tubes, thus largely increasing the absorbing surface. Hence the danger—as I have said in my last paper—of disturbing the active roots during the season of growth. Lifting and re-planting is, in fact, even at the earliest period, work only for a very careful man. Then, what must it be two months later in the season? Not work, certainly, for a man who, from the manner in which he treats the roots, knows not whether a Lily has got root-hairs or even rootlets. It is agreed by writers on Lily culture that, as they are great feeders, the soil becomes exhausted in three or four years. It stands to reason, then, that in half that time the soil will be greatly deteriorated. And, further, it requires very little science to tell us that the first season is the only one that the Lily can have a sufficiency of fresh and sweet food; for though mulchings and liquid manure are excellent in their way, they cannot equal, by many degrees, good imitations of the Lily's native soil, supplied annually and early, that is, at the very time when the roots are beginning to feed freely. Mr. Groom has said that he agrees with me as regards the importance of transplanting Lilies annually; and he has further said that I would confer a boon on many cultivators if I would illustrate that neither directly nor indirectly is the succeeding year's flower-stem affected by cutting down the leaves while they are yet green. I venture to think that I have done so by bringing forward every proof that I could think of. And, in so doing, I trust I have given the very best reasons in favour of early lifting and re-planting. Last year I had some examples of *L. testaceum* left in the ground that had been doing very poorly; early in the season I took away from the clump two bulbs and planted them in a separate place, with a sufficiency of good food. This year they flowered ten days earlier and the flowers were really twice the size of those that had not been disturbed. Besides this, bulbs that are left in the ground for some years

are very apt to produce deformed flowers, just as if they had not sufficient strength to open them fully and freely; and that is the truth. It is the same with offsets. If we desire to cultivate a progeny of offsets at the expense of the bloom, by all means leave the bulbs in the ground for some years undisturbed. Every offset on the side of a bulb is drawing the sap from that bulb which would otherwise have gone up the stem for the good of the flowers. And every offset on the roots, like little brigands, intercept and rob the best of the sap as it passes from the delicate rootlets up to the bulbs; and, moreover, the longer these offsets are allowed to grow and multiply undisturbed, the worse will it be for the main bulbs and the bloom. In such cases some people say, "My Lilies are doing very well, and I do not intend to disturb them." This is the old story—"letting well alone" until it is well no longer. The following is a case in point: "A. K.," of Eastcott Cottage, Pinner (see p. 62), informs us that four years ago he planted bulbs of *L. excelsum* and *L. auratum*, and that under the same treatment which he gave to *L. excelsum*—that is, allowing it to remain in an ordinary border perfectly undisturbed during the four years—*L. auratum* has entirely disappeared. This need surprise no one. *L. excelsum* (synonym—*testaceum*) is a Lily that will grow well treated the same as the white Lily, but both it and the white Lily will grow and bloom much better if lifted and re-planted early every year in well manured fresh soil. This is also a preventive to the leaves withering and dropping off, as they are apt to do before the plant has done blooming. As regards *L. auratum*, it is altogether different. "A. K." appears to have fallen into the error out of which hundreds of Lily fanciers will not, or cannot, move a single step, so much are they bound down by traditional theories. They leave the bulbs too long in the ground without attending to their requirements. Besides what we see in the season, we have Mr. Baker's authority for saying that the flowers of *L. testaceum* are from one to six, but sometimes up to a dozen. "A. K.," alluding to the bulb which he planted four years ago, says, "It has bloomed well every year, and this year has produced four spikes, the tallest of which is over 6 ft., and at the present moment there are just twenty-four fully-expanded blooms on it." This is not an uncommon way for some writers to state the case, but it is very much calculated to mislead the uninitiated; for, though in some instances, we have twin bulbs, and even triplets, if "A. K." were to lift his bulbs he would find that the four spikes (or more properly, stems) have sprung from four separate bulbs; for during the four years' undisturbed stay in the ground, the original bulb had time enough to propagate and multiply itself into more than four distinct flowering bulbs. If "A. K." had lifted and re-planted his bulbs of *L. auratum* annually, soon after flowering, giving them appropriate and fresh food, the successional bulbs would now, in all probability, have been in full and fine bloom. If I were lifting and re-planting Lily bulbs, I would pick off none of the old scales, unless they were loose; nor would I touch the old roots, as this might damage the new ones. Both old scales and old roots will decay and dry up in due course of time without interfering in the slightest degree with the growth of the new bulbs.

DUNEDIN.

THE RUNNERS OF *ERYTHRONIUM AMERICANUM*.

THE botanist or amateur flower collector who wanders at this season of the year (early in May) along the woodland stream or loamy hill-side, can hardly fail to observe numerous colourless stems, forming, as it were, little loops 3 in. or 4 in. in length, on or near the ground, both ends being buried beneath the surface. If his curiosity should lead to a closer examination, he will find that while one end is firmly rooted, the other yields readily to his effort to withdraw it, and proves to be, not a root, as he may have at first supposed, but a stem, smooth and of uniform diameter, excepting at the end, where it enlarges into an oval knob, which, later in the season, is further developed as a true bulb, and ultimately planted by the growth force of this slender stem at the depth of 3 in. or 4 in. in the loose wood-mould. If he should trace the same stem backward, carefully loosening the earth to avoid breaking it, he would find that it had its origin, with two or three others, in the lower extremity of a similar bulb, pear-shaped, somewhat flattened, perhaps $\frac{1}{2}$ in. long by $\frac{1}{4}$ in. in thickness, to the upper end of which may still cling a single withered leaf. Should he visit the same locality a few weeks later, he will find that leaf

and stems have both disappeared, and that the little bulb he saw in the process of being planted by such a deft and delicate finger has thrown out a radiating group of roots from near the lower end and, showing no other signs of growth, has evidently settled itself to await the developments of another spring time.

A whole year is a long time for our botanist to wait the solution of his problem as to genus and species; so we will anticipate the result of his observations next year. The April sun will hardly have begun to warm the south fronting hillsides ere our sleeping bulb will waken and reach up into the moist spring air a single glossy leaf, spotted or blotched all over with spaces of darker shade, which he will then recognise, or any child could tell him, is the sterile condition of his misnamed, though favourite Dog's-tooth Violet (*Erythronium americanum*). Soon after the leaf is fully developed spreading forth its rich juices to the influence of sun and air, three or four stolons or runners, such as already described, will protrude at the lower extremity of the bulb, and, promptly turning upwards, will be seen bursting through the surface of the ground, reaching up 1 in. or 2 in. into the air and then in a wavering, uncertain way burying themselves again in the earth to plant the bulb that shall repeat the same process next year. As is well known, in its single leaf condition this plant never blooms. In this second year of its existence, therefore, the bulb cannot have fulfilled its whole mission; if, and we admit it to be an assumption not proven, the law of Nature would give to every individual at least the chance to reproduce itself by means of perfected seed. By the third year, then, we presume the bulb will have attained the strength necessary to enable it to seed up two leaves and a flower-stalk and become what it should have been called, a Lily indeed, with its pendulous golden bell.

In the Lily family, propagation by means of lateral or axillary bulbs (as a compensation, perhaps, for the frequent failure to perfect their seeds) is familiar to every one; but I cannot find that these partially aerial runners of the *Erythronium*, by which it projects its bulbs sometimes to the distance of 1 ft. from the parent plant, have been previously noticed. It may be well to add that these observations refer especially to one locality in what is known as Sweet Briar Glen, Fairmount Park, Philadelphia; that the mode of propagation described is the universal habit of the plant the writer is not prepared to assert.—American Naturalist."

NEGLECTED PLANTS.

I AM pleased to see that one of your correspondents has so just an appreciation of good old hardy plants, which, unfortunately, have been so much neglected. At the same time it is a matter of congratulation to find that he does not indulge in a fling at the carpet hedging system, as some of the writers in THE GARDEN have done, denouncing it in no very mild terms. The mixed border and carpet bedding each have their merits, and must not be viewed from the same point. Nothing can be more striking than well-arranged carpet beds, and nothing more beautiful and interesting than mixed borders of annuals, biennials, and perennials. Individually, the latter must claim precedence; but, *en masse*, the carpet system stands out just as a richly-toned painting commands one's attention among a hundred less conspicuous, but equally meritorious specimens. In their proper place and on a grand scale carpet beds are wonderfully pretty. Where, however, they are undertaken, as is too often the case, in small gardens intermixed with trees and shrubs, rustic baskets, small rockwork, &c., they are as much out of place as a magnificent tapestry amid the cheap furniture and ordinary surroundings of a common room. Unless there be plenty of space and a favourable position, carpet beds had better be omitted. I am reminded of the old plants just now as the stately Foxgloves, the masses of Sweet Williams, the profusion of Canterbury Bells, and the coral-like spikes of the Larkspur are making such a fine display, quite taking away all the glory of the beds of our finest Pansies, which a few days ago were the great attraction. And so it is the season through; the masses of Verbenas and beds of Alternantheras and Golden Feathers are beautiful, but the Gladioli, the Tritomas, and the Phloxes soon tower up and eclipse their more humble companions. Let us have not only mixed borders and wild gardens, but carpet beds also, and while we appreciate and value novelties, if they really have merit, let us not throw aside or neglect the grand old specimens which "our forefathers loved to cultivate," and which are to-day among the most beautiful and valuable of garden plants. C. M. HOVEY.

Boston, Mass.

[The geometrical arrangement and clipping of dwarf plants known as "carpet bedding" is simply a modification of "bedding out." There is a true kind of carpet gardening, however, which is worthy of much more attention than it receives, and that is the growth of carpets of a great variety of dwarf hardy plants beneath tall bulbous flowers, herbaceous plants, shrubs, and low trees.—Ed.]

NOTES AND QUESTIONS ON THE FLOWER GARDEN:

Roses Pegged Down.—The increased amount of bloom which can be obtained by pegging down the strong branches of dwarf Roses is astonishing, yet it is a plan not so frequently adopted as one would imagine it would be, for if grown on a sloping bank, and the colours are judiciously blended, a much better effect can be produced than by Roses grown in any other way. The chief objection to pegging down Roses is that the ground cannot be readily cleared of weeds; but if a mulching of half-rotted manure or Cocoanut fibre refuse be applied in spring, the Roses will be greatly benefited and few weeds will make their appearance.—S.

Nymphæa sphærocarpa.—The supposed existence of a very hardy *Nymphæa* bearing red flowers was announced in the "Revue Horticole" last year by M. Carrière, who took occasion to express his doubts as to the truth of the story. In the number of that journal for July 1 M. Carrière states that there need no longer be any uncertainty in the matter, for he has received a number of plants of this interesting species from M. Otto Fröbel, the well-known horticulturist of Zurich, which have flowered abundantly in the open air in the tanks of the Jardin des Plantes, where they have been flourishing for some time past. M. Carrière promises to return to this subject, and supply us with a full description and figure of this new addition to our present somewhat meagre stock of water plants. Caspary has named this species *Nymphæa sphærocarpa*, and it is considered by some to be a variety of *Nymphæa alba*.—C. W. Q.

Hardiness of New Zealand Plants.—The following remarks are extracted from a paper read by Dr. Lander-Lindsay before the Botanical Society of Edinburgh at its June meeting. They relate to the hardiness of the following plants. *Clinanthus puniceus elegans* has stood three winters on a west wall, where it flowered splendidly last spring. It has more shining leaves and seems a more rapid grower than the type, which also stands out in mild winters in some places. *Cookia Cotonaster* has stood the last two winters at the base of a wall with a northerly exposure. *Craspedias*—two herbaceous species, one large and the other small—have been grown in gardens about Edinburgh for the last twenty-four years. They were sent originally from Van Diemen's Land. *Myosotidium nobile* stood three years since in a cool glass-house with a northerly exposure, unharmed, with a temperature about 20°. A *Veronica*, unknown to Dr. Hooker, with remarkably narrow Rosemary-like leaves, stood out the two last winters at West Shandon, on the Gareloch. *Fagus antarctica*, or an allied evergreen species from South America, stood the winter of 1860—61 at Prestonhall, when the temperature there fell to about zero; but several plants were killed down to the snow-line about Edinburgh when it fell 5° to 6° lower. *Arundo conspicua*, an elegant Grass, is very hardy; its leaves remained fresh and green when exposed to the late severe frost.

New Annuals.—If colour in flowers is to be the test of premiership, I give the preference to the new carmine Candytuft, which is most certainly a fine variety, and has a new and very pleasing hue of colour. The dwarf white is an exact duplicate of the carmine kind, except in colour. These Candytufts are marked by a robust branching habit, a compact growth, and trusses of flowers of great size and excellent form. Beds of either would indeed be charming features in any garden. *Godetia Lady Albemarle* is better known, but it is a fine annual, and introduces a rich and beautiful hue into our gardens. Its true colour is a deep, rosy magenta; and, although the plants do not even yet all show that even compact habit which marks the best forms, yet the colour is the same all through. It is charming in pots, in beds, in lines. The new *Eschscholtzia Mandarin* is a fine plant, and the combination of reddish crimson on the outside of the petals with a rich orange within renders it singularly attractive in the mass. Exception is sometimes taken to flowers that close up when the glory of the sun has departed, but it has little force, inasmuch as flowers are thus better preserved from rains and winds. The *Eschscholtzia*s are so hardy, that in open soil they stand the winter well; and those who have the Mandarin flowering for the first time this summer will see its glory in full next spring from old plants. I commend all these hardy annuals heartily as real gains, and veritable improvements in all their respective sections.—V.

Seedling Carnations.—A bed of these just now in full bloom affords such a supply of flowers, that it is difficult to write in terms too appreciative of these useful plants. Seed from any good double strain invariably gives a large proportion of double flowers. Some will, of course, be single, as the finest strain of any double flowers always produces some that are either inferior or single; but even these are useful to use in nosegays. The variety that can be obtained from a packet of seed is remarkable. I gathered a few days since from a bed of seedlings a bouquet of flowers, everyone distinct, and

examples of all the various sections into which Carnations and Picotees are divided by florists. The nearer the plants produce flowers allied to the florist's kinds the less freely do they produce seed; but the varied and in many cases singularly marked Continental kinds are free seeders. Few of these, however, would do for exhibition, as the edges of the petals are serrated, whilst the florist's flower must have broad even petals, with smooth rounded edges. Seed should be sown in pans or boxes in a cold frame or greenhouse in the spring; the young seedlings planted out in any out-of-the-way place for the summer; and then they may be lifted with nice balls of earth, and be planted up either in a bed, or widely distributed in a border, as may be desired. Florists divide Carnations into Sells, of which there are several hues, white, yellow, rose, purple, crimson, scarlet, &c.; Flakes, of scarlet, purple, crimson, rose, &c.; and Bizarres, that is, two colours on a diverse ground, of which there are several forms. Picotees are more or less deeply edged, and are divided into rose, purple, crimson edges, &c.—"Field."

Hardy Water Lilies.—I have been a grower of nearly all the Lilies enumerated by "W." (see p. 54) for forty years. They were first most kindly given to me by my friend the late Mr. Kent, of Bath. He grew them in a pond—many in pots or boxes. I adopted the same plan at Bitton, but when I was transplanted hither, having no convenience for a pond, I have grown them ever since most luxuriantly in tubs, hogsheads, or old claret casks cut in two, and placed within an easy distance of a pump. Here are Lilies now in full bloom, with lofty Typhas, two Pontederias, and several Sagittarias—one, *S. latifolia* fl.-pl., a great beauty—altogether forty tubs, including Equisetums and other aquatics—in all, about sixty species. They are all of easy culture, and many being ready to burst the tubs, it would be a pleasure to me to distribute them to any lover of such plants rather than throw them away. I am too old to lift, label, and pack them, but I shall be pleased to give them to any one who will favour me with a visit and take them away with him. There is one feature peculiar to *Nymphaea odorata* which is not noticed by "W.," nor have I observed it in any botanical work. I allude to the beautiful deep purple colour of the undersides of the leaves.—H. T. ELLA-COMBE, *Clyst St. George, Devon.*

Violet Queen Sweet Pea.—This remarkably distinct and valuable variety is dwarfier in habit than any of the other varieties which I have grown. Indeed, the seed itself is so different from that of other kinds as to suggest the idea of its being a distinct species, which is not, however, the case. The colour of the flowers is such as to be, as has been stated, suggestive of the beautiful *Bougainvilleas*; consequently, they are exceedingly useful for the purpose of cutting for bouquets or for furnishing vases, as they are equally highly perfumed as the other varieties, while the plant itself, whether grown in lines or in patches, is exceedingly ornamental, its dwarf habit of growth being greatly in its favour.—P. GRIEVE, *Culford.*

Eulalia japonica.—This plant, which was sold some years ago as a novelty, is not a new species, but only a variety with variegated leaves. This fact is now proved beyond a doubt. Some seeds of this plant gathered in France were given to M. Emil, the well-known horticulturist, of the Rue Sibuet, Paris, which produced seedlings with only green leaves. It is very possible that this is also the case with *Eulalia zebрина*. Here, then, are two instances in which plants, after having been described and figured as species by learned botanists, are obliged to descend from their lofty position and rank in the category of varieties. In any case, what has happened with *Eulalia japonica* need in no way surprise us, seeing that such events, so far from being exceptional, are more constantly the rule. If this multiplication of species continues, the word will lose its true scientific significance.—C. W. Q.

Campanula pumila alba.—This makes a good carpet either for beds or borders. It grows close to the ground and yields a profusion of white bell-shaped flowers. Beds of it, associated with a few standard bronze-leaved Japanese Acers, or other dark foliaged plants, have a fine effect. It is also an excellent plant for covering banks on rockwork, or it may be grown in pots, pans, or baskets, with good results.—S.

The Notch-lipped Slipperwort (*Calceolaria crenatiflora*).—This old, but little known, Chilean plant has much to recommend it. Its flowers are large and of a bright yellow colour with a peculiarly notched lip, and are borne very profusely on slender stems about 1 ft. high. It seems strange that such a distinct plant should have so long escaped general cultivation, as it has been introduced for nearly fifty years.—W.

Fuchsia microphylla.—I always make a point of growing a few species of Fuchsias, and I like to have in contrast the bold and massive *F. fulgens* and the diminutive *F. microphylla*. There is another reputed species known as *F. thymifolia*, which, though greatly resembling *F. microphylla*, is said to have larger leaves, and to have flowers a trifle larger, and it possesses a greater depth of colour. Both make very pretty pot plants, and would do well as an edging to a bed of taller-growing Fuchsias.—D.

GARDEN DESTROYERS.

THE WHITE CABBAGE BUTTERFLY.

(*PIERIS BRASSICÆ.*)

WHITE Cabbage butterflies are common all over Great Britain from May to October, and are in no way injurious to vegetation, as they feed entirely on the nectar of flowers. The caterpillars, however, commit sad havoc among all kinds of Cabbages, Radishes, Horseradishes, and Turnips, and are a great source of trouble and annoyance to kitchen gardeners.

In both sexes of this insect the wings are white, more or less finely sprinkled with black at the base. In the upper wings the front margin and a somewhat crescent-shaped spot at the

White Cabbage Butterfly.

tip are black. In the lower wings there is a blackish spot near the upper margin. On the upper wings of the female there are also two round black dots, one above the other, about two-thirds the length of the wings from the base, and a black splash near the middle of the lower margin. The undersides of the wings in both sexes are alike, the upper wings being

Caterpillar and Chrysalis of the White Cabbage Butterfly.

white with yellowish tips and with two black spots near the centre of each wing; the lower wings are pale yellow. The head, thorax, and body are blackish above and pale grey below. The antennæ are long and slender, with a small club at the end; they are black with the tip and underside of the club yellow. The males are rather smaller than the females; the former measure across the wings when expanded $2\frac{1}{2}$ in.; the former about 3 in. The eggs are bright yellow in colour, somewhat cone-shaped, deeply furrowed lengthways; they are laid twenty or thirty in a cluster on the undersides of the leaves of Cabbages and other cruciferous plants. The first eggs are laid about the end of May, and early in June the first larvæ or caterpillars are hatched; but there are a succession of broods during summer and autumn. The caterpillars have thirteen joints, not including the head. The first three of these each bear a pair of legs, on the next two the legs are wanting, the following four have each a pair, the next three have none, and there is a pair on the last. The caterpillars when full grown are about $1\frac{1}{2}$ in. long, pale blue or green above and yellow beneath. They have a yellow stripe

with a row of black spots on either side of it down the middle of the back, a row of large black spots down each side, and various black specks and fine hairs scattered over the body. Soon after attaining its full size, the caterpillar seeks some sheltered place, such as the trunk of a tree or a paling, and assumes the chrysalis or pupa state. The chrysalis is pale green, spotted with black, and with three yellowish stripes; the butterfly emerges from it in about a fortnight. The chrysalides of the last brood, however, remain alive during the winter, and the butterflies do not make their appearance until the following spring.

This insect when in the caterpillar state fortunately has many enemies. Among those most fatal to them are the ichneumons (four-winged insects with long, slender bodies), of which there are several kinds; these insects are armed with long ovipositors with which they pierce the skin of the caterpillar and deposit their eggs in its body. The eggs soon hatch into grubs, which in time kill the caterpillar, but not until it is nearly ready to assume the chrysalis state. Other small insects, nearly allied to the ichneumons, lay their eggs on the chrysalis, and the grubs when hatched eat their way into it and eventually destroy it. Several kinds of birds devour the caterpillars, and wet weather at times causes great mortality among them. There does not seem to be any way of ridding a garden from this insect, except by encouraging its natural enemies, and destroying it whenever practicable in whatever state it may be found. S. G. S.

NOTES FROM KEW.

Hardy Shrubs.—One of the handsomest and most distinct of all the Brambles is a new species—*Rubus pœnicolasius*—which we first saw in the Paris Jardin des Plantes, and which has been recently found its way into English gardens. The Kew specimen, planted out in one of the borders of the Winter Garden, is at present one of the most striking objects of which Kew can boast. As we have seen it do well as a wall plant we class it amongst hardy shrubs. The large leaves are uniformly composed of three leaflets, and the stems and leaf-stalks are densely clothed with small needle-like prickles and long, gland-tipped hairs; the beautiful coral-like fruit is a bright scarlet and the under surfaces of the leaves is nearly snowy-white. The young stems and leaf-stalks, too, are of a decided reddish tint at first, but as they become old they assume a deep brown colour. *Spiræa Pallasi*, evidently a near relation of the Himalayan *S. Lindleyana*, has larger flowers of a purer white than that species; both are fine shrubs, and worthy a place in any shrubbery, if only for their elegant pinnate leaves. *Viburnum macrocephalum* is a charming shrub of dwarf habit and bears large heads of white, showy flowers in profusion.

Hardy Aquatics.—A North American Marsh Marigold, *Caltha leptosepsis*, although not so showy as the common *C. palustris* of our marshes and ditch banks, has the merit of novelty to recommend it, being quite new. It has smaller leaves than the British plant, and flowers about the size and colour of those of the white-flowered Lesser Celandine (*Ranunculus Ficaria*); it has, however, hardly had a fair trial as yet, and may much improve in beauty ere long. *Samolus littoralis*, a New Zealand representative of our Brook-weed (*S. Valerandi*), is very much superior in every respect to that species; it grows about 1 ft. high, and bears clusters of showy flowers, white tinged with rose. A beautiful and elegant plant is the North American *Pontederia cordata*; it grows about 3 ft. high, has deep green leaves and numerous spikes of blue flowers; in every select collection of aquatics this should find a place. *Justicia pedunculata*, a native of the same country as the last, attains a height of from 2 ft. to 3 ft., and forms a pleasing mass of stems with narrow leaves, from the axils of which spring long-stalked spikes of white and purple flowers.

Hardy Herbaceous Plants.—*Solanum Torreyanum*, a new species, deserves special mention. It grows about 15 in. or 18 in. high, and the blue flowers, which are borne in large clusters, are 2 in. in diameter; the conspicuous yellow anthers lend additional beauty to this charming perennial. Another new plant, and a very lovely one, is *Eurotia sinuata* var. *maxima*, a native of Texas, and one of Mr. W. Thompson's recent introductions. It grows from 2½ ft. to 3 ft. high, but flowers freely at 1 ft.; is of erect, branching habit, without the coarseness of many of the other species of Evening Primrose, and the bright yellow flowers are nearly 3 in. in diameter. *C. speciosa*, 2 ft. high, is a very free bloomer; the large blossoms are white with a yellow centre. *Statice spicata* is a neat little plant only about 3 in. high; the spikes of pale rose-coloured flowers spring from a little rosette of deeply-crent leaves. *Specularia pentagona*, a

very showy annual, has flowers more than twice the size of those of *S. hybrida*. *Campanula strigosa*, another desirable plant, is a very free-flowering kind, and grows about 6 in. high; the colour of the flowers is blue. *Mulgedium macrophyllum*, a United States Composite, is a striking plant, and a very ornamental one; the large root leaves are heart-shaped, and the flower-stem, which reaches 3 ft. or more in height, bears numerous large, delicate purple flower-heads. *Kniphofia Rooperi*, one of the smaller-growing kinds, has a flower-stem about 2 ft. high, the curved flowers being scarlet and deep orange-red. *Milla grandiflora*, from 6 in. to 1 ft. high, is a lovely bulb, with umbels of fine blue-purple flowers. *Mesembryanthemum tricolor* and *M. tricolor album* are two extremely handsome kinds, the former having brilliant rosy-crimson blossoms. Few plants—if we except some of the Fig Marigolds—make a more charming show when seen in sunshine than the beautiful little Caps succulent *Grammathees gentianoides*. It has small fleshy leaves, and forms dense tufts (about 3 in. high) covered with star-like, yellow or orange-red flowers; it should have a sunny spot and open sandy soil in which to grow. *Calochortus luteus* is a very attractive sort; the flowers are bright sulphur-yellow, each petal being spotted with brown, and bearing a blotch of deep orange-coloured hairs near its base. One of the most stately of the Teasel-worts is *Cephalaria tartarica*, a native of Russia and Siberia; it reaches a height of 9 ft., and bears numerous heads of straw-coloured Scabious-like flowers. This species and *C. procera*, which is even taller than *C. tartarica*, are well adapted for planting in masses where bold and striking effect is desired. A near relation of these two, but one totally different in habit, is the pretty little Grecian Scabious (*Scabiosa Parnassi*). It forms a dense, cushion-like mass not more than 1 ft. in height, and is covered with a profusion of light purple flowers. *Lotus hirsutus*, a shrubby plant with rose-coloured flowers, has woolly leaves and stems, and is a distinct and striking plant. *Phygellus capensis*, as a wall plant in a sunny spot, makes a splendid show; the leaves and stems much resemble those of the common Figwort of our river banks, but the drooping flowers, which are of a brilliant red colour, are very conspicuous, and are produced in great abundance.—†

Kew Gardens.—I was surprised to see in one of your late issues an article about Kew Gardens so at variance with the facts, that I must ask you to correct it. The residents seldom use the Gardens. I and my family, and many other families here, do not trouble them with our presence for weeks together sometimes, and should not do so even if open at sunrise. In the interest of the public only have we agitated this matter, seeing as we do daily the numbers of disappointed people who arrive from all parts at ten or twelve unable to gain admission. I am day by day a witness of this fact, and have known many go away, as they had arranged to spend the afternoon elsewhere. Last week some Americans accosted me, and expressed great disgust at the want of freedom in this country, closing for the best part of the day gardens which, they said, in the States would be public property, being paid for by the nation. Bear in mind also that we are only acting in accord with Richmond select vestry, the Corporation of Kingston, the Chiswick and Hounslow Local Board, the vestries of Chelsea, Kensington, and Paddington, besides many other localities. I think, therefore, that we, the inhabitants, do not deserve the censure your article places on us. As to the students, it is well known they are nearly all *nil*, and I can assert that many of them come after 4 p.m. I can name several well-known men who do so, and who laugh at the idea put forth that the Gardens should be kept closed for their supposed benefit. The compromise you speak of is none at all, for it has the effect of being misunderstood by the general public, who flock here as early as ten expecting to be admitted. To-day nearly 100 people were seeking admittance before eleven; many accosted me and expressed annoyance at having to wait till one. Several went back, others asked where they could get refreshment to fill up the time. Who fills the public-houses, may I ask? I think in this case the obstructives at Kew, is the answer.—JOHN E. RICHARD, F.R.S.A.S., in "Gardeners' Magazine."

The Meadow Rue-leaved Dicentra (D. thalictroides).—This is a charming hardy climber. It much resembles *Adlumia cirrhosa*, but is far more robust in habit, and the leaflets are larger; moreover, it is a perennial. It bears small, yellowish blossoms, which are not very conspicuous. It is a native of Nepal and parts of the Himalayas, and has been known in gardens for about forty years, generally under the generic term of *Dactylocaenos*. Its culture is very simple. Seeds may be either sown in pots in the ordinary way in spring, and the seedlings planted out under the shade of a hedge, trellis, wall, &c., or it may be sown a little later in the season in the place in which it is intended to remain. A mixture of loam and peat, with the addition of a little sand, will suit its requirements.—A.

SOCIETIES AND EXHIBITIONS.

ROYAL HORTICULTURAL SOCIETY.

JULY 23.

On this occasion the National Carnation and Picotee Society held its Southern Section annual exhibition in conjunction with the Floral and Fruit Committee meeting of the Royal Horticultural Society. The principal exhibits belonging to the Horticultural Society consisted of collections of Abutilons and double Zonal Pelargoniums from the Society's garden at Chiswick, groups of Balsams from Messrs. F. & A. Smith, of Dalwich, and Stocks grown in pots from Mr. Wills' nursery at Anerley.

First-class Certificates were awarded as follows:—

Rose Harrison Weir (Turner).—A very double flower of rare substance and of a brilliant crimson-magenta colour, shaded with bright purple. It is of the Duke of Edinburgh type, large and full, and deliciously scented. It has a vigorous constitution, and succeeds perfectly on the Mauetti stock and as a standard on the Brier.

Pelargoniums Beauty, Pixie, and Ariel (Pearson), all belonging to the Echinatum breed, and well worth growing; their prevailing colour is rose of various shades, and they are all effectively spotted with black.

Orchids.—Sir William Marriott showed three panels of *Disa grandiflora* antherba, all remarkable examples of good culture. Collectively, the plants bore nearly thirty strong flower-spikes, each of which was surmounted by a pair of brilliantly-coloured blossoms. Mr. Speed, Chatsworth, also sent a plant of *Disa grandiflora* bearing an unusually strong flower-spike furnished with nine large buds and blossoms. Mr. James, Castle Nursery, Lower Norwood, showed a fine variety of *Oncidium prætextum* named *superbum*. It bore a branching spike of rich chocolate blossoms, the lip being blotched with bright yellow.

Abutilons from the Society's gardens were represented by twenty-one kinds, the best of which were the white *Boule de Nègre*, the lemon-yellow *Reine d'Or*, the drooping variegated *vexillarium*, so useful for clothing walls or rafters in conservatories, or for grafting on strong kinds and growing in the form of standards for table decoration. Others consisted of *Louis Marignac*, a pale pink-flowered very distinct variety; and the variegated-leaved *Darwini* and *tesselatum* formed a striking contrast with the green-leaved kinds.

Balsams shown by Messrs. F. & A. Smith were remarkable for their dwarf habit of growth and the size of their blossoms, many of which were almost as large as those of a *Camellia* and equally double. Their colours varied from pure white, salmon, and cream colour to the brightest rose, purple, and brilliant scarlet, and there were, moreover, several beautifully striped and spotted kinds. These constituted one of the finest strains of Balsams that has been exhibited for some time.

Mr. G. F. Wilson, Weybridge, contributed a plant of the *Swamp Lily* of North America (*Lilium superbum*) furnished with two strong stems 8 ft. long, each surmounted by from twelve to fifteen orange-scarlet, beautifully-spotted blossoms. It was exhibited for the purpose of showing to what perfection this kind can be grown in pots.

Messrs. Veitch & Sons exhibited examples of *Celosia pyramidalis*, an admirable pot plant for the conservatory. Its habit is pyramidal, and it bears large magenta-coloured plumes from the point of every shoot. The same firm also showed the new yellow-flowered *Torenia*, which, when well grown, is likely to be as good as *T. Fourcieri*. Lady Dorothy Nevill exhibited a variety of *Cockscombs*, all of which were very pretty, and for which a vote of thanks was awarded.

Mr. Brown, The Nurseries, Truro, contributed three small-growing *Thujae*. One having a pyramidal habit and gold-tinted foliage was named *T. aurea erecta*; the other two were of bushy growth, with compact, round heads. One named *Thuja aurea Browni* was of a bright gold colour; the other, *T. sulphurea nana compacta*, was of a silvery-green suffused with pale yellow. These little Conifers seemed well adapted for pots or small vases, or for planting in select positions. Mr. G. Alett, The Gardens, Warren Wood, sent a silver variegated *Myrtle* in flower. It was named *Myrtus latifolius argenteus*, and seemed to be well adapted for pot culture.

Messrs. Veitch & Sons exhibited a basket of plants of *Olearia Haasti*, a hardy shrub, literally covered with whitish, sweet-scented blossoms.

Mr. Wills' Ten-week Stocks were shown in 5-in. pots. They were remarkably dwarf and bushy in habit, and their colours consisted of rose, purple, salmon, yellow, mauve, violet, blue, and white. The trusses were large and the flowers very double and well-formed; altogether, a fine strain for pot culture or for planting in small beds.

Among the best double Pelargoniums from Chiswick were *Emily de Girardin*, pink; *Ernest Louth*, dark scarlet; *Madame Thibaut*,

rosy-pink; *La Constitution*, salmon; *Jewel*, very double, scarlet. There were also some very attractive seedlings in this collection, including several white-flowered kinds. Mr. Barron again sent from Chiswick finely-grown plants of *Torenia Fournieri*, showing that under good treatment it will continue in flower for a great length of time.

Cut Flowers.—Messrs. Paul & Son, Cheahant, exhibited several new Roses. They consisted of Mrs. Laxton, bright rose; *Marquis* of Salisbury, magenta, shaded with purple; and *Duke of Teck*, bright velvety scarlet.

Mr. Turner, Slough, sent a boxful of blooms of a new Rose named *Harrison Weir*, which attracted much attention.

Mr. Cannell, Swanley, sent boxfuls of cut blooms of *Verbenas*, which were much admired. The trusses were large, and the flowers, individually, almost equal in size and form to those of *Phlox Drummondii*. Among the most attractive were *Isa Branton*, magenta-purple, with a white eye; *General Picton*, dark crimson; *La Lovie*, violet, agreeably scented; *Edwin Day*, lively scarlet; *George Branning*, velvety-maroon, shaded with purple, and having a clear white eye; and *Lady of Lorne*, white, shaded with pink. There were also several beautifully striped varieties.

Mr. Parker, Tooting, sent cut sprays of a double pink-flowered *Blackberry* profusely laden with round button-shaped blossoms.

Mr. G. Smith, Caledonian Nurseries, Guernsey, exhibited cut spikes of *Sparaxis pulcherrima* 6 ft. in length, crowded with bright, rose-coloured, bell-shaped blossoms.

Some *Glove Carnations* came from Chiswick. Blooms of *Dianthus* of the *Heddwigi* type and *Phloxes* from the same place were also much admired.

Fruit.—A fine collection of Melons was shown by Mr. Clark, Melton Constable, and Mr. A. Donaldson, Stoodleigh, had several dishes of Peaches and Nectarines, the best of the latter being *Pine-apple*, and the best Peaches, *Early Louise* and *Early York*. A few Apples and Pines were also shown.

CARNATION AND PICOTEE SOCIETY.

In point of numbers this show was not so good as that of last year; it was held too late for the southern growers, but, notwithstanding that, excellent blooms were shown in all classes. They were, backed up as usual by cards, an objectionable practice, at least, in the case of plants in pots.

First-class Certificates were awarded as follows:—

Picotee Royal Visit (Turner).—A fine smooth-petalled flower with heavy pink edge.

P. Henry Tait (Turner).—A seedling from *Prince of Orange*, with a fine yellow ground and bright crimson edges.

P. Eleanor.—A fine double flower from the same source as the above, of a sulphur colour, slightly tinted with pink.

P. Alice (Turner).—Another seedling from *Prince of Orange*, of free growth and remarkably floriferous. Its blossoms are very large; the petals are beautifully incut and of a bright lemon colour, heavily edged with bright crimson.

P. Ophir (Turner).—A fine double flower of a pure sulphur colour. A very distinct and attractive kind.

P. Lord Beaconsfield.—This is also a seedling from *Prince of Orange*. Its ground colour is of a rich creamy-yellow, and it is heavily edged and striped with bright orange-crimson.

P. Lothair (Turner).—A large and finely-formed flower heavily edged with dark crimson.

Carnations.—The best twenty-four blooms of these came from Mr. Douglas, gardener to F. Whitbourne, Esq., Loxford Hall, Ilford. Amongst them we noticed fine blooms of *Eccentric Jack*, pink and purple Bizarre; *James Cheatham*, scarlet flake; *Captain Stott*, purple and rose Bizarre; *Squire Meynell*, purple flake; and *Dreadnought*, crimson Bizarre. Mr. Turner, Slough, had fine, large, smooth-petalled blooms. Amongst his Bizarres the best were *Albert Chancellor*, purple and pink; the *Lamplighter*, purple and rose; and *Jenny Lind*. The best pink flakes were *Goardeman*, *Maid of Athens*, *Rosabella*, and *Misa Napier*; and the best crimson flakes were *William IV.* and *Superb*. In other collections the best Bizarres were *Sir J. Paxton*, scarlet and dark crimson, very smooth and well formed; *Admiral Curzon*, *Mars*, and *Graceless Tom*, pink and violet; *Unexpected*, pink and claret; *Garibaldi* and *Mercury*. Among scarlet flakes the best were *Annihilator*, *Sarah Payne*, *Sportman*, and *Clipper*; and of rose flakes the best were *John Keat*, *Mrs. Dodwell*, and *Sybil*; the best purple flakes were Mr. Douglas, *Ajax*, *Earl Stamford*, *James Taylor*, and *Squire Meynell*.

Single Specimen Carnations.—The best amongst Bizarres were: *Scarlets*—*True Briton*, *Garibaldi*, and *Curzon*; *crimson*—*Jenny Lind*, *John Simonite*, and *Captain Stott*; *pink*—*Jas. Taylor*, *Sarah Payne*, and *Eccentric Jack*. Of purple flakes as single specimens the best were: *J. Douglas*, *Ajax*, and *Squire Meynell*; *scarlet*

flakes—Annihilator, Clipper, John Bailey, and Sportsman; rose flakes—Sybil, John Keat, Mrs. Green, and Rose of Stapleford.

Picotees.—These were much superior to the Carnations both in numbers and quality of bloom. The best in the large collections which came from Mr. Turner and Mr. Douglas were, amongst heavy-edged kinds—Lathair, elsewhere described; Brunette, dark crimson; John Smith, red; J. B. Bryant, crimson, large and fine; Selina, violet; Royal Visit, pink; Medina, purple; Mrs. Fuller, bright crimson; and Norfolk Beauty, violet-purple. Of light-edged kinds there were excellent blooms of Minnie, purple; Mary, purple; Seedling, crimson; Mrs. Payne, pink; Mrs. Langtry, purple; Rev. F. D. Horner, rose; Alliance, violet; Miss Lee, red; and Ethel, pink.

Single Specimen Picotees.—The best of these were heavy-edged kinds: Reds—John Smith, Princess of Wales, and Dr. Abercrombie; purple—Mrs. Albert Chancellor, Zerlina, and Mrs. Niven; rose or scarlet—Mrs. Payne, Juliana, and Mrs. Horner. Amongst light-edged, rose or scarlet, the best were Victoria, Miss Wood, and Lucy; purple—Mary, Alice, and Mrs. Douglas; red—Thomas Williams and Violet Douglas. The best yellow ground Picotees were Hon. Mary Lascelles, Prince of Orange, and Alice Waite.

Plants in Pots.—These were shown in small numbers. Mr. Turner's collection of seedlings from the Prince of Orange were much admired on account of their free growth and abundance of bloom. Mr. Douglas had a good collection, and Mr. Ware sent Picotee Lady Armstrong, a sort with a pyramidal habit and flowers having a yellow ground edged with scarlet. Sulphur Pink, from the same exhibitor, bore beautiful fringed-edged flowers of a pale yellow colour and very attractive.

The list of prizes awarded on the occasion will be found in our advertising columns.

PATENT SLOT THROTTLE VALVE.

IN the management of greenhouses it frequently happens that a valve fails to properly regulate the flow of the hot water through the pipes being set fast with rust and dirt, or through some carelessness in turning the handle by which the valve spindle has been strained.

A smith is sent for, and he shows the impossibility of repairing the mischief without cutting the valve entirely from the pipes, and as valves are often placed under floors and surrounded by brickwork, a heavy bricklayer's bill follows that of the smith, and the interior of the greenhouse is completely upset. The patent throttle valve, manufactured by Foster & Pearson, horticultural builders, is said to remove all danger of these annoyances. The following illustration will explain the principle of the valve. On the top of the valve is a longitudinal slot large enough to allow the valve wing being passed through it. This slot is covered by the cap B, which is secured by two screws, and the joint between the valve and cap is made sound by an india-rubber ring C. By this arrangement the working parts can be removed for repair without disturbing the body of the valve and the cap will not be set fast, as is the case when lead paint is used to make the joint. As the two screws are in the top of the valve they can always easily be taken out in any position in which the valve handle can be reached. One more point worthy of notice is that these valves can never be spoilt in the way that so many are, namely, by having the handle turned the wrong way; this is obviated by inserting a small pin in the cap, which works in the collar of the brass spindle, and renders it impossible to turn it past the centre when opening the valve. By the use of these valves in a hot-water apparatus much after trouble will be saved.

DINNER-TABLE DECORATIONS.

I CANNOT allow "J. S. W." to stand alone in his sensible condemnation of one of the most senseless innovations of modern times. We have been taught to believe that there is a place for everything, and assuredly there are many places for flowers, comparatively few of which are yet filled with such taste as they might be; but I never could see that the dinner table was a fit place for such ornate decorations as have been placed upon it. The decorations are inconvenient and incongruous. Almost everything could be found or seen on the table but the dinner. Old fashioned ladies, as well as gentlemen, never took kindly to the dinner-table decoration mania. Only a year or two ago a lady, high in rank and social influence, drove home from a grand dinner at a neighbour's house and ordered mutton chops, as she had not dined, and could not, as both Lady L.'s flower garden and conservatory seemed crushed on to the table. The old plan of an epergne and centre-piece was much more sensible. The dinner and dessert were still the chief objects on the table; the guests dined in comfort with abundance of good talk to aid digestion. But now there are rocks, lakes, streams, waterfalls, ponds, fish, glaciers, dense masses of foliage and flowers, banks of Moss, zinc tins and glass dishes innumerable—all piled on the table to swamp the dinner with the most heterogenous assemblage of incongruous accompaniments, and prevent the diners often from seeing either each other, or their dinner, or, indeed, anything save the decorations. Now, not only are such decorations incongruous, but untrue to facts and incompatible with convenience. "J. S. W.'s" old dinner-out, who regularly cleared his table space for dining as a commander might the deck of his ship for action before a storm or a battle, was far more sensible than those who had fettered his freedom with their crowded, cumbersome decorations. Decorate as we may, no one can convert a dinner table into a conservatory, a flower garden, or a bit of charming landscape. And were it possible, to what good would it tend? Comfort, plenty, good society constitute the substantial charms of the dinner table. By sweeping nine-tenths of the decorations of the day off our dinner tables, the comfort of the diners would be vastly enhanced. It is time to affirm that mere mass of materials is no proof of taste; and that display for its own sake, whether on the dinner table or elsewhere, is one of the surest symptoms of vulgarity.

D. T. F.

I hope your correspondents would not object to a few good flowers arranged in a graceful and simple manner. I can hardly understand anybody objecting to that. It is no doubt the elaborate and paining display seen at London shows that he objects to. I have myself never happily seen these away from the said shows, but no doubt many persons are led to worry themselves in imitating them. I believe all arrangements piled up in the middle of the table, however well done, are wrong, so far as the ordinary dinner-table is concerned. A good Rose or a few buds beside each guest in a small glass, or a few flowers gathered shortly before the dinner, and arranged in a few minutes by any person caring about flowers, is what seems to us most desirable in the matter of table decorations. It is clearly wrong to make the men and women round the table subsidiary to the floral display; they must be so in the case of many of the "compositions" we have all seen. Apart from appearance and comfort, there is another reason why dinner-table decorations should be simple and unpretending, and that is, the shortness of the time in which the flowers are seen on the dinner table.

E. D.

I have just a few words more to say on this subject and then I will leave the discussion to others. I shall have done some little service if my remarks do no more than call attention to a practice which is being carried to such an absurd length. I speak of the custom as we find it. Were table decorations confined to a plant or two, or a bouquet of flowers—something simple and chaste—there would be no reason to say much about it; but it is not so. I am perfectly familiar with table decoration as it is carried out in West End mansions and in country houses, and I know that while in many of the most distinguished houses it has never been pushed to an extravagant extent, in others the custom is ridiculously overdone. The table is completely littered over with plants and flowers to its very margin, and sometimes the table

cloth is first covered with Moss before the flowers are put on. I was perfectly well aware that some of your correspondents might combat me with my own weapons by attempting to turn the argument against me in reference to the furniture and decorations of the dining-room, the pictures, carpets, &c., but that is begging the question. I do not mean to deny the ordinary accessories to a comfortable dining-room; but people do not go into a dining-room to have their attention distracted by the pattern of the carpet, and as for the pictures and other essential decoration of the walls, the diners, as a rule, turn their backs upon them when they sit down to table; but the flowers are set before them, interrupt conversation, and impede the diner's general freedom of action. As to the prettily painted dinner services to which "F. R. H. S." refers, I have no particular objection, but could do just as well without them. As dinners are conducted now-a-days, the diner has hardly any opportunity of admiring the patterns on the bottoms of the plates. Although I wrote against the use of flowers for the table, I did not condemn table decoration of every description. I only said that it might safely be left to "the cook, the confectioner, and the fruiterer, who possess the art and everything else to render a dinner-table as attractive as it can be made," and I repeat that statement. Personally, I have no occasion to seek release from the practice, as "W. T. T."—whom, I guess, has rather a craze on the subject—insinuates; but I can express an opinion, entertained by others besides myself, on a custom which indicates a rather effeminate kind of "civilisation." A man may have cultivated tastes, and may be an ardent admirer of flowers without caring to have them thrust upon his notice in season and out of season; and such a man will be able to dine like any other rational being, and find topics of conversation without having his other senses regaled at the same time with the sight and odour of flowers.

J. S. W.

[We have received other letters from gardeners complaining, not only of the time taken up in dinner-table decoration which might be otherwise more profitably employed, but also of the way in which both flowers and plants are cut to pieces to serve a purpose which lasts for so short a time. Some of them complain, too, that more is expected of them in this way than their means at command will afford.]

ANSWERS TO CORRESPONDENTS.

Tea Roses.—I shall feel much obliged by your giving me the names of a few good Tea Roses of rather recent introduction.—M. [The best comparatively new Tea Roses are—Anna Olivier, Catherine Mermet, Comtesse de Nadaillac, Jean Pernet, La Boule d'Or, and Marie Van Houtte.—S. R. H.]

Fuchsias—Will you be kind enough to inform me which of the following Fuchsias were sent out first: Purit, Dr. Jepson, or Venus Victrix?—G. F. F. [Venus Victrix. It was sent out before Dr. Jepson.]

Clipping Yew Hedges—When should this be done?—A. Z. [Yew hedges should be trimmed at midsummer and toward the end of autumn. When not in a healthy and vigorous state of growth once a year is sufficient, and that may be done any time between autumn and spring.—G. B.]

Nozzles for Garden Fountains.—Can any one tell me the best place in London to get these, for a large jet, to throw the water in different patterns?—L. A. [Try Tyler & Sons, Newgate Street; or Warner & Sons, Jewin Crescent, Aldersgate Street.]

Wiring Walls.—I have a new wall, with eyes put in for galvanised wire 3 in. apart and $\frac{1}{2}$ in. from the wall, and 6 ft. apart lengthways. Is that a proper distance to have the wires? or should they be further apart? I am anxious to know, as there has been a good deal said of late about galvanised wire attracting electricity, but I think myself that it is too tight tying the branches that causes the injury to the bark complained of.—A. A. [6 in. apart will be a good distance for most fruit trees, but for Peas they should be 9 in. asunder. Your wires will be too far away from the wall; there should only be just room between them and the wall to pass the ties through.—S.]

Woodlice in Cucumber Frames.—How can I destroy woodlice in a cucumber frame? They have eaten more than half the Cucumbers, and I have tried several ways to destroy them, but without effect.—H. B. [In order to clear frames from woodlice, remove the heating materials as soon as the crop is cleared out, then fill up all the crevices with mortar and thoroughly drench any portions of the pit or frame, where any have found shelter, with boiling water. The best traps for woodlice are ordinary flower-pots half filled with dry hay and baited with Potatoes. They will congregate in these, and, if emptied out every day into a pot of scalding water, their numbers may soon be reduced to reasonable limits.—J. G. S.]

Names of Plants.—J. M.—The tree with red berries (from near Cairo) is a species of *Rhus*; further than that it is impossible to say without much better material to work upon. Z.—1. *Spiraea Douglasii* concolor. 2. *Douglasii*. 3.

Reevesii. 4. *canadensis*. H. L. & Son.—The tall plants appear to be varieties of the common single Rocket; the composite is the orange-flowered Mouse-ear Hieracium (*H. aurantiacum*). Rosz.—From the very dry specimen sent, we cannot be sure of the name of your Rose, but it looks like the Old Musk. M. J. S.—Next week.

Drying Everlastings.—How can I dry the blooms of such plants as *Catananche cœrulea* and similar Everlastings? All mine shrivel up into the seed vessel when dried.—I. [Gather them when fresh and young, i.e., not too much open, place them on shelves in a dark store-room, and they will dry perfectly.—W. R.]

Ants in Grass.—How can I get rid of ants in a Grass lawn? It is an old piece of turf which has now become coarse from want of cutting, the ants preventing the use of either scythe or machine.—W. E. W. [Now that the ants have got established you will scarcely be able to dislodge them or make a turf fit for a lawn without adopting radical measures, such as trenching up the whole plot and keeping it well cultivated during the ensuing winter. Early in spring the surface may be carefully levelled and re-sown with a good lawn Grass mixture, and afterwards kept frequently rolled. Paraffin oil or gnaon will dislodge ants or drive them to seek fresh quarters; but if the whole plot be in the rough state described, the only way to produce a satisfactory result would be to adopt the first recommendation.—J. G.]

Figs.—Are Bourjassotte Blanc and White Marseilles sufficiently hardy to be planted out in an orchard?—S. H. F. J. [These Figs are sufficiently hardy to withstand any ordinary winter without protection if the wood be thoroughly ripened; but an orchard where they would be shaded during summer by taller trees would be about the worst position to select for them. In fact, it is only in the most favoured counties that the Fig ripens its fruit on open standards. If a warm aspect on a wall be not available, select the most sheltered position possible with full exposure to sunshine, confine the roots in order to check over luxuriant growth, and press the soil very firmly about them. As standards or bushes Figs require very little pruning. Black Bourjassotte and Bourjassotte Grise are of medium size and excellent quality, and would probably prove better adapted for this mode of culture than larger varieties.—J. G.]

Culture of Raspberries and Strawberries.—Could you inform me on the following points, viz.:—1. What kind of land is best suited for the cultivation of Raspberries and Strawberries? 2. What is the best aspect? 3. What should be about the cost per acre respectively of Strawberries and of Raspberries, the latter to be trained on wire runners? 4. What would be the best sorts, the place being the counties of Forfar, Fife, and Perth.—J. E. S. [1. The best kind of land for Raspberries and Strawberries is a deep friable loam or alluvial deposit, where drought (the greatest enemy of these crops) is not likely to affect them. 2. The best aspect is an open one with shelter from the north and east, a valley with high ground to the north or woodlands. 3. The cost per acre cannot be given with any kind of accuracy; if done at ordinary catalogue prices, viz., Strawberries 3s. per 100 and Raspberries 2s. or 3s. per dozen, the cost per acre might prove a formidable affair; but large quantities can generally be procured at lower rates. Training Raspberries to wires with a row or two of Strawberries between them is about the best method to adopt. 4. As to varieties of Raspberries, Reds may consist of Pastoff, Red Antwerp, Semper Fidelis, and McLaren's Prolific; yellows of Antwerp and Yellow Magnum Bonum. Of Strawberries the best are Vicomtesse Héricart de Thury, Sir C. Napier, Keen's Seedling, President, Sir J. Paxton, Sir Harry, Oscar, and British Queen.—G.]

Early Louise Peach.—This useful early Peach was ripe here this year on a south wall out-of-doors on July 18. In a cold Peach house facing east, the same variety was fit for use on July 2. This Peach will be found invaluable for early forcing.—H. HASAAS, *Denne Park, Horsham*.

Prolific Peach Tree at Sunbury Park.—Although I regret that Mr. Groom should doubt the accuracy of "J. F.'s" report (see p. 50), yet I am pleased to see his remarks, and I quite agree with him that it is necessary that all such reports should be verified. In my case parties far and near, who have seen for themselves, can confirm "J. F.'s" statement, and I am sorry that Mr. Groom has not himself seen the tree in question, as it would have agreeably surprised him. I am now gathering from it daily Peaches that weigh from 6 oz. to 8 oz. each, and of first-class quality.—TROS. COWPAR.

Re-planting Lilies.—"Dunedin" says (see p. 62) that I am opposed to early re-planting or potting as the case may be, but in this he is mistaken. I am so thoroughly convinced of the advantage of early re-planting, as any one can be. In my reference to autumn-blooming varieties, I by no means suggested that the best season for re-potting them was the best in the case of early-flowering kinds.—J. GARDNER.

A COMMUNICATION has been received from Thorncliffe, Dukinfield, without the name of the writer, so we are unable to forward as requested.

"This is an art
Which does mend Nature: change it rather: but
THE ART ITSELF IS NATURE."—*Shakespeare.*

SUMMER-FLOWERING CHRYSANTHEMUMS.

THESE are flowering much later than usual this season, owing doubtless to the comparative absence of bright sunshine. Last season they were three weeks earlier, but even now they are sufficiently attractive to entitle them to a foremost place in every collection of perennials, and a few of them might even be planted in the smallest border in which plants are grown. This section of Chrysanthemums is as yet little known; therefore, a few notes respecting them may be useful. Their propagation and cultivation are the same as in the case of the ordinary varieties, and they may be used for the same purposes; but they flower from June to November, thereby producing a display long before the ordinary varieties have begun to open their blossoms. *C. indicum nanum* is one of the best of the group; it is exceedingly dwarf and compact, and forms a handsome, well-feathered bush from top to bottom. In hot weather many varieties become what is termed leggy and miserable-looking, but in the case of this variety, even during the brightest weather, one can scarcely ever find a yellow leaf, owing to the branches closely covering the soil, and keeping it cool and moist. In this respect it is distinct from all others belonging to this group, as they partake more or less of the upright growth of the ordinary Chrysanthemum. The flowers, which are of a delicate cream colour, deepening towards the centre into yellow, are of medium size, the petals being broad, good in substance, and recurved. *Precocité*, another good kind erect in habit, has flowers of medium size, and of a bright golden-yellow, with flat, incurved petals. In *Bois Duval* the petals are also incurved, and the prevailing colour is purplish-rose striped with white. The flowers are smaller than those of the preceding, but they are so numerous as to render it conspicuous even when looked at from a distance. In *Scarlet Gem*, another of these summer-blooming Chrysanthemums, the flowers are of a bright brick red, of medium size, and well formed. In habit it is dwarf, and later in the season the colour gets brighter, but it never becomes what one would call scarlet. Of *Jardin des Plantes* there are both white and yellow varieties, and both are similar in character, very dwarf and compact. The flowers of these are large, well-formed, and produced in profusion. For cutting purposes the white variety should be grown extensively. A kind bearing the name of *Delphine Caboche* has small flowers, of a rosy-purple colour, with petals flat and blistered, which gives them a peculiar appearance. It is a neat, dwarf, very free-flowering variety. These are the best at present in flower in a collection consisting of some thirty varieties. P.

CULTURE OF DISA GRANDIFLORA.

SELDOM is this fine terrestrial Orchid seen in cultivation in anything like perfection, a fact doubtless owing to attempting to grow it under unnatural conditions. The prevalent fault is growing it in too much heat, for, seeing that it inhabits lofty elevations of the Table Mountain at the Cape, it will withstand quite as low a temperature as any cool climate Orchid. The finest specimens of it that I have seen were growing, in company with *Sarracénias* and other North American bog plants, in a house with a northern aspect, shaded from too much sunshine and well ventilated all the year, with the temperature in winter frequently falling to 40°. Such a house I think best adapted for its successful culture. The compost I use for potting consists of equal parts of good fibry peat and chopped live Sphagnum Moss, with the addition of a small quantity of sharp white sand and broken charcoal. Some cultivators mix manure with the compost, but, as it invariably contains worms or their germs, I prefer using weak liquid manure when the plants are in vigorous health. The pots should be thoroughly drained and a layer of live Moss

chopped fine should be laid on the surface of the soil, as when growing it absorbs moisture plentifully and gives it off when necessary to the plant. Small plants of this *Disa* may readily be procured, and should not at first be over-potted, but as the roots show themselves at the outside of the ball a liberal shift should be given, as it is through allowing the plants to become pot-bound or lack moisture that they prematurely throw up flower-spikes, which are, in most cases, very small. In the course of the season offshoots will be formed at the top of the tuber, which, when rooted, should be taken off and grown on. Good single specimens should be in 12-in. pots, with spikes 3 ft. high, and with from six to twelve large flowers on each spike. In the case of imported plants, they should, when first received, be potted in the above-named compost, kept rather dry, and gradually inured to moisture, and the rooted offshoots should be taken off, leaving one only. This Orchid is very subject to thrips, which especially attack the axils of the leaves; but they must be kept down by the free use of some insecticide. Established plants commence to make growth about October, from which time until the end of the flowering season, which is from May to July, they should have a copious supply of water, but I find that setting the pots in pans of water is injurious to them. Frequent syringings should also be given in warm weather, to keep the atmosphere cool and damp, as in their native habitat they are subject to dense mists, &c. After flowering they should have a short rest by withholding water for about two months, but must not be allowed to become very dry. There are several varieties, which differ from the type either in size of the blossoms or in the intensity of colour. The variety *superba* is considered the best. The variety *Barrelli* is a very fine form with the colours much more defined and brighter than the type, but it is, I fear, now extremely rare in cultivation. It was introduced a few years since by Mr. Bull. *Disas* may be raised from seeds, and many fine varieties have thus been obtained; but though this may be carried out in a shorter time than with the majority of Orchids, it is, nevertheless, a very slow process.

W.

ROSES AT SLOUGH.

THE weather in this neighbourhood this year has been anything but favourable for Roses, at least, as far as the blooms are concerned, and Mr. Turner has hitherto been unable to cut Roses in quantity for exhibition this season. The plants themselves, however, appear to have been benefited by the weather, for their growth is remarkably strong, and a good autumn bloom may be expected. Roses on the *Manetti* stock are unusually late this season, being just now arriving at their best. Dwarf Roses on the seedling *Brier* do not succeed here so well as on the *Manetti*; at least it is more difficult to get them to take. They make admirable, compact, and bushy plants for pot culture, but Roses on this stock will always probably be more expensive than those on other stocks. Mr. Turner has this year a rich collection of new Roses, many of which have yet to be tried another year before their merits can be decided. *Harrison Weir*, which is doing well both as standards and dwarf plants, is considered to be one of the best kinds ever raised at Slough. *Penelope Mayo* is also in good bloom, and the same may be said of *Dr. Sewell* and *Mrs. Harry Turner*, together with many other very promising kinds. Reds, whites, pinks, and other colours among seedlings are all kept in separate groups. Such as are likely to prove good are kept, and others are destroyed or disposed of in mixed collections for the decoration of semi-wild places. *Maréchal Niel* on walls has not done so well this season as in previous years, owing to its blossoms having been nipped in spring, but good blooms will no doubt be produced in autumn. *Star of Waltham* does well here in hot summers, but in cold ones its blooms do not open well. *François Michelin* in long rows is well furnished with bright pink blossoms, and *La France*, in the shape of dwarf plants, was, when we saw it, a mass of flowers. *Dean of Windsor*, a good new garden Rose, has flowers of a bright red colour, and borne in profusion; indeed, at the time of our visit, the plants were bearing a second crop, the result of cutting off the early blooms and part of the shoots. When the present flowers are over the plants will be again cut back in order to induce them to bloom in the autumn. S.

Scented-leaved *Pelargoniums*.—Being a lover of this species of *Pelargoniums*, and remembering the interest which I used to feel in Mr. Saunders' fine collection of them at Reigate, I naturally feel

afraid that the rage for colour and showy flowers will drive my old favourites out of cultivation. They, however, deserve a place in all gardens, if not on account of their flowers, for their various and pleasant odours, a quality almost lost in the plants which attract the attention of the Pelargonium Society. Some of the Cape Pelargoniums rank amongst the best of scented plants, and for that reason they are most useful in bouquets. *P. Radula*, mis-called the Oak-leaf, is now and then used for this purpose, but it is not the best scented form. The following are some of the best, viz., the lemon-scented *P. crispum*, an erect-growing, compact kind; *P. odoratissimum*, a very strong, pleasantly-scented plant, dwarf and trailing; *P. fragrans*, nutmeg-scented, dwarf and glaucous; *P. tomentosum*, peppermint-scented, very strong and pleasant as regards odour; *P. scabrum*, lemon-scented, a good shrubby plant; *P. citriodorum*, a strongly lemon-scented sort, and a compact grower. We have also *P. glutinosum*, as good a fly-catcher as any *Dionæa*, but I always noticed that it did best when deprived of such luxuries. As bracket plants, for those who care for variety, I would select *P. flavum*, which has foliage finely cut, like that of a Fern, and pendent; and *P. filipendulifolium*, also a good kind for such a purpose. For those who are fond of studying varieties of foliage, I know of no genus more interesting in that respect than the Pelargonium. Some of its species also have tuberous stems or roots, like those of the Carrot, while others are clothed with spines almost like a *Cereus*; others, again, have foliage resembling that of the False Acacia, Vine, Oak, Fern, Nasturtium, Celery, and Oxalis. Variation of foliage is a subject not, in my opinion, sufficiently studied; flowers alone appear to absorb the attention of most people. It is an ascertained fact that we get the worst flowers from the most ragged and undefined foliage plants, at least, in the case of the Pelargonium, as, for instance, in *P. triste*; but if we go to *P. tricolor* or *P. alatum*, we get neat foliage and good flowers.—J. CROUCHER, *Sudbury House, Hammersmith.*

LIFTING AND RE-PLANTING LILIES.

IN "Dunedin's" criticism (see page 92) of my communication (see p. 62) on the good growth, in a heavy soil, of *Lilium excelsum* and others, he states that "*L. excelsum* is a Lily that will grow well treated the same as the white Lily." It was my wish to make this fact more generally known to amateurs like myself that induced me to write on the subject. "Dunedin," however, goes on to say, "But both it and the white Lily will grow and bloom much better if lifted and replanted early every year in well manured fresh soil. This is also a preventive to the leaves withering and dropping off, as they are apt to do before the plant has done blooming;" also, "the flowers of *L. excelsum* are from one to six, but sometimes up to a dozen." How can the former part of this statement be proved? So far as my case is concerned, instead of *L. excelsum* only giving "from one to six, but sometimes up to a dozen" blooms, the four stems show now the remains of 37 flowers, and besides this several had been cut for decorative purposes. The strongest stem yielded fourteen flowers, and the leaves are still perfectly fresh and green. From Chislehurst, where the soil is light sandy loam, comes the same good account of *L. auratum* without removal for certainly three years. Do not these facts go to prove that we ought to select the kinds of Lilies which will do really well in certain localities and soils, and, by avoiding those that disappear, render the annual removal of the bulbs, described by "Dunedin" as "work only for a very careful man," quite unnecessary? I of course agree with "Dunedin" that the four stems of *L. excelsum* have sprung from four separate bulbs, and I am content to leave them where they are until the four have become forty. "Dunedin" ought to bear in mind that the annual removal of the bulbs, though possible where Lilies are grown by themselves, becomes almost impossible where the clumps are in the mixed borders or shrubberies. For myself, as long as the result is so satisfactory, I prefer to be guilty of what is in "Dunedin's" eyes such a heinous offence, viz., "Letting well alone." A. K.

Eastcott Cottage, Pinner.

Billiardiera longiflora Hardy.—Few shrubs are more effective, for the greenhouse or against an outside wall, than this beautiful evergreen trailer. It has long, slender branches thickly clothed with small dark green, lance-shaped leaves. In spring it is profusely studded with long, blue, bell-shaped flowers, which are succeeded by as many indigo-blue berries, about the size of Hazel nuts, which hang on all the winter. It is a native of Van Diemen's Land. It seems strange that it is not more frequently seen in gardens than it is, as it has been introduced a long time, is of easy propagation, and is perfectly hardy in the neighbourhood of London if planted against a wall.—A.

NOTES OF THE WEEK.

Edelweiss.—A good deal of mystery is made of this plant in the newspapers, and even some horticultural contemporaries announce its flowering, as if that were rare. But anyone who knows anything of the hardy plant collections in the country, past or present, knows its flowering is not rare, and its culture not difficult in any way, even as a border plant on sandy soils.

Tuberous Begonias as Basket Plants.—A number of the new race of tuberous Begonias have peculiar value as basket plants, or for growing in any way, so that their stems and blossoms may hang down gracefully, as is their natural habit. We noticed some baskets of them in Mr. Laing's collection in the Stanstead Park Nurseries, Forest Hill, with the branches drooping for quite 18 in., and laden with huge Fuchsia-like blooms. Specially grown and selected, the results would be more remarkable. Nothing could exceed the beauty of these plants—the foliage, picturesque drooping habit of the stems, and brilliant flowers being each in their way admirable.

Clematises and Ivy.—Ivy-clad rocks, roots, or mounds are much improved by having some of the stronger growing Clematises of the Jackmanni type planted sufficiently near them to allow them to ramble at will over the Ivy. In summer the Clematises make a fine show, whilst in winter the Ivy, which is left green and uninjured, in some measure protects the buds of the Clematis from cold, wind, and frost. The light-flowered kinds are the most effective, blue flowers not showing themselves off to such advantage on a green background, but such colours may be introduced among the lighter ones with advantage.

Torenia Bailloni.—We notice that this remarkable species has been passed over by the Floral Committee at South Kensington. Had it been the one hundred and seventeenth recorded form of a common Fern it would of course have received a first-class certificate.

Veronica Hendersoni.—We have received from Messrs. E. G. Henderson a handsome herbaceous Speedwell bearing this name, and furnished with long spikes of flowers of an intense purplish-blue. It is said to be a native of Japan.

The Sea Heath (*Frankenia laevis*).—I saw the other day, at Kew, a patch nearly 6 ft. square of this beautiful British seashore plant, profusely studded with tiny pink blossoms amongst the Heath-like foliage. It is growing in one of the driest parts of the Gardens, and therefore for an exposed part of the rock garden it is well adapted.—A.

Dicentra eximia.—This plant is little grown in private gardens, and even in nurseries it is not so common as it might be. It looks well isolated in the herbaceous border or as an edging to shrubberies. It flowers from May till September, or even longer, and its finely-out foliage may be used effectively among out flowers.

Ceanothus Gloire de Versailles.—A large plant of this *Ceanothus* covers a wall in Mr. Turner's nursery at Slough, and is one of the most attractive objects in the way of wall plants which we have seen for a long time. Its branchlets are allowed to droop loosely from the main shoots, and each is furnished with large branching trusses of beautiful mauve-coloured blossoms, almost equal in size and appearance to those of a Lilac. This *Ceanothus* is a strong grower, and if its shoots are cut back after the flowers drop they will push fresh spray, which will soon bear another crop of blossoms. Such wall shrubs as this might be planted more largely than they are with advantage.

The Rosy Snowflake (*Leucocjum roseum*).—The prettiest hardy bulb in flower in the Kew collection at the present time is this rare little gem. Its blossoms, which are about the size of Snowdrops, are unaccompanied by leaves, and are borne on slender stalks about 4 in. high, in the same nodding way as in the case of Snowdrops. The name *roseum* is probably taken from the flower-stalk and the membranous leaf on it, which are of a red colour, but it does not affect the snowy whiteness of the flower, except at the point of attachment to the stalk. Like most of its congeners, this Snowflake is a native of South Europe, and delights in a sunny border in a light soil.—A.

Hardy Plants at Tooting.—A fine effect in the way of hardy flowers may now be seen in Mr. Parker's nursery. A piece of ground is parted off into sections, some of which are planted as follows:—First, there is a line of white Phlox *The Queen*, supported on each side by the brilliant scarlet spikes of *Gladiolus Breuchleyensis*; on either side of these are two lines of a lilac Phlox named *Madame Billy*; next comes a line of a dwarf deep rosy-crimson Phlox *coccinea*, the whole being edged with a broad band of blue *Violas*. Another fine effect is made with dwarf plants of the white-leaved *Aoers*, among which are planted alternately *Delphinium formosum*

and *Belladonna*, edged with purple *Violas*. Lines of *Yuccas* in full flower, alternating with plants of the *Globe Thistle*, supported on each side with thick lines of *Lythrum Salicaria roseum superbum*, have also a fine effect. Planting in lines is, of course, sometimes necessary in nurseries, but in private gardens such forms of planting are but in few cases advisable. Such arrangements, however, as those just alluded to serve to show what grand effects may be made in our flower gardens without having recourse to tender subjects, which require endless labour and care all through the winter, and even in summer their beauty is but short-lived.

Berry-bearing Plants.—Two of the handsomest of these just now are *Actæa spicata* (the common Baneberry) and *A. spicata rubra*, an American variety of it. Our plants of the latter, though small, are covered with large bunches of coral-like berries, which are very conspicuous.—P., *Hale Farm Nurseries, Tottenham*.

Pentstemon heterophyllus.—This blue-flowered *Pentstemon* is now in bloom in Messrs. Rollisson's nursery, Tooting. Many seedling *Pentstemons* of an attractive character have of late years been raised, but none of them possess the colour of this species. For hybridising purposes one would think it would be invaluable.

Alocasia Jenningsi.—This, which by many is called *Caladium Jenningsi*, is one of the best of plants for table-decoration. Its leaves are round, green, and conspicuously blotched with black. A good plant of it can be accommodated in a 6-in. pot, and it is a kind well worth growing for the purpose just alluded to.

Gladiolus Saundersi.—This is one of the brightest and best of the dwarf *Gladioli*, and good groups of it may now be found finely in flower at Mr. Parker's. It was figured in *THE GARDEN*, Vol. XII., p. 64.

Oenothera speciosa.—This is a white-flowered species and one of the best of the Evening *Primroses*. It grows to the height of 2 ft., and bears an abundance of large showy blossoms.

Exotic Bulbous Plants at Tooting.—A fine collection of the white-flowered *Nægelia amabilis* and other coloured varieties, together with *Tydæas*, *Achimenes*, and *Gesneras*, is now in flower in Messrs. Rollisson's nursery. *Achimenes* and *Gesneras* most people grow, but the other plants just alluded to are comparatively little grown, although they are so easy to cultivate and so attractive when in bloom.

Calandrinia nitida.—This is very brilliant in the open ground at Tottenham just now. Its flowers are bright rosy-purple and produced in profusion.—P.

Buddlea globosa.—This is grown in pots in the Pine-apple Nursery, and in spring they are plunged in the ground where it is desired the plants should bloom. Thus treated, we saw plants of it in this nursery a short time ago covered with golden-yellow button-like blossoms. It is a common shrub in many districts, but not in or near London.

Crinum Mackenni.—The finest plant of this *Crinum* (hitherto known under the name of *C. ornatum africanum*) which we have ever seen is now in flower in the large conservatory at Pine-apple Place. Its bulb close to the soil measures 26 in. in circumference, and it is furnished with a massive stem and handsome leaves. The flower-spike at the base measures 4½ in. round and is 3 ft. long, surmounted by no fewer than eighteen large pink blossoms and unexpanded buds.

Cattleya Leopoldi.—A specimen of this *Orchid* in Mr. Williams' nursery at Holloway is an attractive object. It bears nearly fifty large blossoms with chocolate and green-spotted petals which contrast strikingly with the brilliant purple lip. As a rule, this *Orchid* is not so great a favourite as some others, but when seen in such fine condition as the plant just alluded to it is both attractive and distinct, and lasts in bloom for a long time.

Clematis lanuginosa.—This, one of the oldest of the hardy large-flowering *Clematisses*, and the origin of numbers of valuable hybrids, is still one of the best for covering walls or pillars. We lately saw a fine plant of it in the Slough nurseries. It was growing in a soil not much better than gravel, and was trained between two glass houses, and its masses of large, mauve-coloured blossoms could be seen a long distance off. It has been in flower for several weeks past, and will, in all probability, keep in that state until late in the autumn.

Seedling Picotees at Slough.—These have been lately very attractive. Out of 250 plants raised by Mr. Turner only a few bad flowers occurred amongst them. They are throughout robust in growth and very floriferous, and are well adapted either for conservatory-decoration or for open border culture. They vary in colour from almost pure white through several shades of yellow, and some are edged with bright orange-scarlet. The names of some of the

best of them were given in our report (see p. 96) of the National Carnation and *Picotee Society's* show. They are grown in 7-in. or 8-in. pots, and at the time of our visit many of them bore from eighteen to twenty large and showy blossoms.

Tuberous Begonias.—The principal feature of next Tuesday's meeting at South Kensington will be a fine display of tuberous *Begonias* from Chiswick, and also from some of the leading nursery-men.

Cianthus Dampieri in the Open Ground.—That the chief reason why people do not succeed in growing this plant satisfactorily is that they treat it too kindly and give it too much heat there can be no doubt. We lately saw a plant of it in the Pine-apple Nursery which, whilst grown indoors, was anything but healthy, but which, when plunged in a half-shady place out-of-doors in June, began to grow freely, and is now bearing several trusses of flowers.

The Kew Gardens Defence Association contemplate asking Parliament to sanction the formation of a public School of Botany at Kew, so as to make Kew a teaching centre for botany and its allied sciences. Lectures open to all, somewhat after the fashion of those in the Garden of Plants, Paris, is, we apprehend, what they contemplate.

French Bouquets.—Mr. Fish devotes a long article to denouncing the Paris way of making bouquets, and prays "that Covent Garden artistes," as he calls them, may be sent over to deliver the French from the ugliness of their nose-gays. Admitting at once the vast superiority of Covent Garden in the matter of bouquets, we confess, however, we prefer to see a little variety, and think we should be none the worse if each country had a different way of arranging flowers. In like manner we think it is a great evil that so many countries try to imitate French cookery instead of making the best of their own.

Lythrum Salicaria roseum superbum.—This fine hardy plant is now in flower in the herbaceous collections near London. Grown in deep, moist soil, its flower-spikes are from 2 ft. to 3 ft. long, and of a bright rose colour. It is well worth growing by the sides of lakes or in marshy land. It is easily and rapidly increased by means of cuttings, which soon make good flowering specimens. Isolated plants of it in good soil make well-shaped bushes 3 ft. or 4 ft. high and as much through, a way in which they look better than when planted closely in rows.

Seedling Begonias.—These, like *Cinerarias* and *Primulas*, are now becoming so good, and the varieties from which seed is saved so superior to those in existence a few years ago, that few people will require to purchase named sorts. A packet of seeds will produce hundreds of plants, which will bloom in six or eight months from the time of sowing, and yield kinds in many instances equal to named varieties. We lately saw a large batch of seedlings in the open air in Messrs. Lee's nursery, Isleworth, yielding abundance of varied and brilliantly-coloured blossoms.

Hyacinthus candicans.—This is now in full flower in our nursery, and is the admiration of all who see it. We have a large bed of it bordered with *Gladiolus Branchleyensis*, and the pure white of the numerous flowers of the *Hyacinth*, gracefully arranged on stems 3 ft. and more in height, contrasts strikingly with the intense red of the *Gladiolus*, which is just the proper height to make a good edging for the taller *Hyacinth*. This is an arrangement which we can recommend; and both plants rank amongst the best for the summer-decoration of our gardens.—E. H. KRELAGE & SON, *Haarlem*.

Professor Asa Gray.—We are pleased to learn that at the last meeting of the French Academy of Science, held on July 29, Prof. Asa Gray, the well-known American botanist, was elected corresponding member of the botanical section of that learned body by thirty-two votes out of forty. Mr. Charles Darwin, who was the other candidate, only polled five votes. Although, of course, we should have been glad if the honour had fallen on our own countryman, we most cordially congratulate Professor Asa Gray on the well-earned distinction conferred on him, a sentiment in which we are perfectly sure that his unsuccessful rival will join most heartily. It will be seen by this that if one wants to consider the feelings of all, and particularly those of M. Decaisne and the gentlemen who compose the French Academy of Science, it is not well to do too much. Professor Gray, however, is also an indefatigable worker in the cause of science.—C. W. QUIN.

The Royal Horticultural Society has fixed its meetings for 1879 as follows: January 14, February 11, March 11 and 25, April 8 and 22, May 13 and 27, June 10 and 24, July 8 and 22, August 12 and 26, September 16, October 14, November 18, and December 16. The great summer show will be held on May 27, 28, 29, and 30; and the Rose show and the show of the *Pelargonium Society* on June 24.

NOTES FROM KEW.

Hardy Shrubs.—In dry, warm spots *Bækia virgata* makes a lovely wall plant, and will succeed well, even without any protection, during the winter months. This charming shrub has small, glossy leaves, and its graceful sprays, covered with small, white, Myrtle-like flowers, are very elegant. Another member of the Myrtle family, and, like the last-named, a native of New Holland, is *Myrtus tenuifolia*. Under the same conditions as *Bækia virgata*, it makes a pretty object, the drooping branchlets bearing an abundance of pale rose-tinted blossoms. *Hypericum patulum*, a fine Japanese kind (a coloured plate of which was issued with THE GARDEN of Sept. 22, 1877) is at present very showy, and proves itself to be one of the best of the St. John's-worts.

Hardy Aquatics.—*Villarsia ovata*, from the Cape of Good Hope, is much smaller than, and totally different in habit from, *V. nymphæoides*; the flowers are orange-yellow, and are fringed inside somewhat like those of the Bog Bean (*Menyanthes trifoliata*) of our English ponds. The double Arrow-head (*Sagittaria sagittifolia* fl.-pl.) is a desirable water plant, and for general decorative purposes superior to the single form. One of the most elegant of aquatics is *Thalia dealbata*, from South Carolina; associated with stately, Canna-like, glaucous foliage, are tall, graceful panicles of purple flowers. Provided the root-stalk of this beautiful plant be kept far enough under water, so as never to be actually frozen, it will pass through our winters uninjured.

Hardy Herbaceous Plants.—A recent introduction from Australia, *Lobelia tenior*, is a lovely plant; it grows about 6 in. high, and the bright blue, white-throated blossoms are $\frac{3}{4}$ in. in diameter. For crossing with smaller-flowered kinds this will prove very useful; altogether, it is a useful addition to our flower garden favourites. A Cape bulb, *Montbretia laxifolia*, with salmon-coloured flowers on stems 1 ft. or more in height, is very pretty, though not so showy as some of the other members of the genus; it is a rare plant in cultivation. Perhaps still rarer is *Arnebia echinoides*, from the Alps of Caucasus and Armenia; the large, bright, golden-yellow flowers have five deep purple spots at the throat. This very distinct and attractive Borage-wort, though generally believed to be difficult to cultivate, does very well on a piece of rockwork in a rather shaded position at Kew. *Centaurea leucophæa*, a kind recently distributed under the name of *C. rufifolia*, has pure white flowers; the leaves somewhat resemble those of *C. ragasina*, and, like it, the young plants of *C. leucophæa* would probably do well for bedding purposes. *Campanula peregrina*, a new ally of, but more beautiful than, the rare Primrose-leaved Bell-flower (*C. primulaefolia*), grows 2 ft. high, and bears a large number of almost saucer-shaped blue blossoms, each with a central ring of black-purple. The Cape of Good Hope is, according to Paxton, the native country of *C. peregrina*, whilst *C. primulaefolia* is said to come from Portugal. *C. Waldsteiniana*, a little rock plant about 3 in. high, has small grey-green leaves and nearly flat blue flowers. Two kinds of *Gladiolus*, *G. aureo-purpureus* and *G. Saundersi*, are very desirable bulbs; the first has yellow blossoms, the lower portions being conspicuously marked with deep red-purple; *G. Saundersi* has spikes of deep scarlet flowers—a coloured plate of this magnificent Irid appeared with THE GARDEN of July 21, 1877. *Hyacinthus candicans* is a noble Cape bulb, which has proved perfectly hardy in the open border; the Kew specimens, which are only medium-sized ones, are between 3 ft. and 4 ft. high; the numerous large, drooping, white, bell-shaped blossoms are very handsome. Two of the most distinct and striking of the various sorts of *Asclepias* now to be seen at Kew are *A. Douglasi* and *A. speciosa*; both have the same large umbels of pinkish flowers, but the first, which comes from the western side of the Rocky Mountains, has hairy leaves and grows 2 ft. high, whilst *A. speciosa* attains double that height, and has glossy green leaves. *Gentiana septemfida*, about the same size, has heads of bright sky-blue, white-throated blossoms, and is extremely handsome. *Dracopcephalum canescens*, one of the finest of all the Labiates at present in bloom, grows little more than 1 ft. high, and is one mass of purple flowers. *Calsimntha glabella*, a lovely little plant from the United States, grows only about 2 in. or 3 in. high, and forms a compact patch covered with reddish-pink blossoms; the whole plant is highly fragrant. *Nisandra physaloides*, a pretty annual with light green leaves and pale blue, white-throated, trumpet-shaped flowers, is an easily cultivated and desirable plant, growing about 1½ ft. high. *Hypericum tomentosum*, an oriental species with small woolly leaves and bright yellow flowers, is a distinct and very attractive St. John's-wort about 1 ft. in height. *Malvastrum grossulariaefolium* is a lovely Mallow, of prostrate habit, with reddish-orange flowers, which are freely produced. *M. capensis*, a more upright, branched, shrubby kind, has small leaves and rose-coloured blossoms, bearing a crimson blotch at the base of each petal.

Greenhouse Plants.—*Mesembryanthemum falciforme* is a neat-habited, shrubby kind with large rose-coloured flowers; *M. ænemon* is a half-shrubby sort with large blossoms nearly the same colour as those of the last named; and *M. lepidum*, a larger-growing kind of shrubby habit, has white flowers. *Virgilia capensis*, a native of the Cape of Good Hope, is a fine conservatory bush; it has elegant pinnate leaves and long-stalked racemes of light rose-coloured blossoms. A very charming Sea Lavender is *Statice rhytidolepis*, a shrub 3 ft. or 4 ft. high, with small tongue-shaped leaves and numerous bright rosy-red flowers.—†.

Ornithogalum revolutum.—In general appearance this resembles *O. thyrsoides*, but it differs from it in coming later into flower, in having longer foliage, in being generally more robust, and in the individual flowers being larger. The spike or thyrsæ, too, is larger and not so compact. At Tottenham it is now beautifully in flower in pots. On some of the spikes I counted eighteen fully-expanded flowers and as many more in a bud state. The flowers are of a glistening white colour with a conspicuous yellowish-brown centre. The spikes are erect, about 15 in. in height, and when two or three bulbs are potted together they form very attractive objects.—P.

Paris Universal Exhibition.—During the last fortnight M. Jules Vallerand, nurseryman, Bois de Colombes, Asnières, near Paris, has kept in one of the houses, not far from Mr. Wills' exhibition, a beautiful collection of Gloxinias, consisting of 250 plants and comprising 200 varieties. All the old good and well-known plants belonging to this genus were to be seen in this assemblage, and also a considerable number of seedlings, some not yet named. Amongst them the following were the best, viz., G. Prince de Galles, Madame Hubert, Charmé de Lutèce, No. 367 (not named yet), and Bergmani, the largest-flowered kind. The same house likewise contained a large number of double Pelargoniums staged by M. Poirier.—B.

Androsace sarmentosa.—Like many other woolly-leaved Alpines, this beautiful Himalayan species is very difficult to keep alive through our cold and damp winters. For the last two winters I have taken the precaution to place a piece of glass in a slanting position about 6 in. above the plant, and I find that this effectually preserves it. Care should also be taken to put finely broken sandstone immediately under the rosettes of leaves and over the surface of the soil to keep every part of the plant, except the roots, from being in contact with the soil. I find this plan much better than that of lifting the plants in autumn, as it invariably injures them, or using bell-glasses, which too much confine them. The plants that I treated in the above manner are now in the most robust health, and have flowered profusely.—W.

Two Santolinas.—I am much charmed with *Santolina incana*. I do not know what is going on in our public parks, but this is a plant which ought to be conspicuous in all town gardens, for it will thrive under conditions the most unfavourable to growth. It is a truly beautiful plant, silvery-white, dense, and compact, perfectly hardy, and, perhaps, too easily propagated. It may be clipped into any shape easier than Box. As a white bedding plant it is certain to supersede many already used for that purpose, as it may be kept from 3 in. to 1 ft. in height. It makes fine blocks or masses of white in bold patterns, and would give a tone and character to any garden. It is well adapted for subduing a blaze of high colour, such as that produced by scarlet Pelargoniums, and as an edging it would give a finish to masses or beds of *Rhododendrons* or *Azaleas*. *Santolina alpina*, a totally different plant, is very unlike a *Santolina*; it grows flat on the ground (as if it had been rolled every day), scarcely exceeding 1 in. in height, and is of a silvery-grey colour; no plant could be better adapted for carpeting or as a groundwork to higher-coloured plants. It would also make excellent beds or divisional lines in geometric gardening, and it might in many cases be substituted for Grass edgings, as it would never require mowing. It is a true hardy perennial, and all that would be required when used for any of the above purposes would be to clip off the globalar flower-heads. It is known in some nurseries as *Artemisia alpina*, an error with which, I believe, I have had something to do.—THOS. WILLIAMS, Ormskirck.

The Single Dahlias.—A correspondent of ours, who is growing and collecting the species of *Dahlia*, will be greatly obliged for information as to new or rare species sent to him through THE GARDEN.

Botanical Discovery.—Country papers, at a loss for something new, in the absence of the big Gooseberry or the gigantic Mushroom, announce that Mr. Murray, head gardener at Peniarth, and an under gardener, found, the other day, a plant of *Platycerium alaicorum*, growing upon the Cadar Idris mountain chain. Some years since persons from the gardens at Penrhyn Castle are said to have found the same Fern at Llyn Idwal.

TREES AND SHRUBS.

ESCALLONIA PHILLIPIANA.

THIS is a very distinct species, reminding one more of a *Leptospermum* than an *Escallonia*, the flowers being white and the petals sessile. It is one of Pearce's introductions for Messrs. Veitch, and is a native of Valdivia, South America. Phillipi first described it under the name of *angustifolia*, but that name being previously occupied in the genus, it became necessary to substitute another in its place. It is a very free flowering shrub, growing from 2 ft. to 6 ft. high in its native country. It thrives in a sandy soil, and it is said to be hardy in the neighbourhood of London.

GOLDEN CONIFERS.

THESE constitute a valuable class of trees for the adornment

growth; its foliage is peculiarly neat and pretty. It was planted out in the nurseries here last autumn, and stood the winter without the slightest injury; the late scorching hot weather has put it severely to the test, and it has come through the ordeal, I may almost say, without injury, for the little that is burnt is hardly perceptible. This, no doubt, when it has become cheaper and more plentiful, will be in great demand.

CUPRESSUS LAWSONIANA LUTEA.—This is by far the best of the golden varieties of Lawson Cypress. It is a free grower, with good form and graceful habit. Its colour is deep golden, which becomes deeper and more intensified as the summer advances, and it is an established fact that its foliage never becomes singed from the effects of a scorching sun. It is, in short, an invaluable ornamental plant.

JUNIPERUS CHINENSIS AUREA.—Amongst Junipers this is undoubtedly a great acquisition; its colour is soft golden-yellow. It is very hardy, and has stood the test of a burning

Branchlet of *Escallonia Phillipiana*.

of woods, pleasure grounds, and lawns, and even for the flower garden they may be made to play a prominent part, particularly in winter and spring. The following are the best varieties in cultivation:—

RETINOSPORA OBTUSA AUREA.—This is a free-growing tree with a drooping, graceful habit; the colour of its foliage is deep golden. It is hardly possible to conceive a more beautiful object than a well-grown specimen of this growing on a Grassy bank or lawn. I have never known it to suffer in any way from the extremes of severe frost or burning sun.

R. PLUMOSA AUREA.—This forms a striking contrast to the preceding, having a somewhat pyramidal and upright habit of growth, clothed with pale golden, soft, feathery foliage. It is quite hardy, and can endure a burning sun without being scorched, but no doubt it will succeed best in a cool and rather shady situation.

R. TETRAGONA AUREA.—This is comparatively a new variety, rich golden in colour, with apparently an upright habit of

sun this summer without being singed in the least degree.

BIOTA ORIENTALIS AUREA.—This is an old and well-known variety. Its young shoots when in a growing state are of a beautiful golden colour, changing in autumn and winter to bright green. It forms a globular bush, dense and compact in habit.

B. O. SEMPERAURESCENS.—This is an improvement on the last-mentioned variety, on account of its retaining a beautiful bright golden colour throughout the year. Its habit is different from that of *B. o. aurea*, having more of the oblong form.

B. o. ELEGANTISSIMA.—This is a bright gem amongst Conifers, and unsurpassed for elegant beauty. It forms a lovely golden-yellow pyramidal dwarf tree, which is hardy, pretty, neat, and distinct.

THUJA OCCIDENTALIS AUREA.—This is a good rich golden variety of the common *Arbor-vitæ*, and one well worth cultivating. It is of recent introduction, and only small plants of it can therefore be had in the trade.

CHAMÆCYPARIS SPHEROIDEA AUREA.—The young shoots on the current season's growth of this neat and elegant Conifer are bright golden in autumn and winter. It is quite hardy.

ARTHROTAXIS SELAGINOIDES (Donniana).—The young shoots of this singular-looking Tasmanian tree are tipped with yellow when growing in spring and summer, changing in autumn and winter to green. It is but a slow grower.

PINUS SYLVESTRIS AUREA.—This is a unique variety; the colour of its foliage in winter is rich golden, changing in spring to dark green, the colour of the type, which it retains until the latter end of autumn, when it begins to assume its golden hue. It need hardly be said that it is perfectly hardy.

JUNIPERUS CHINENSIS AUREA.—Amongst Junipers this is a real acquisition; its colour is pale golden, and it has stood the test of burning summers without harm. This is a very distinct and beautiful variety, and well deserves a place in every collection.

TAXUS BACCATA AUREA.—This golden variety of the common Yew is too well known to need description; suffice it to say that it is always brilliant and effective. There are several other varieties more or less golden and variegated, all of which are good and useful ornamental plants, and deserve to be extensively planted.

TAXUS PASTIGIATA AUREA.—This is a golden variety of the Irish Yew; it is an effective plant and a valuable addition to golden-foliaged trees. It forms a striking contrast, as regards colour, to the sombre type when planted near or alternately with it on a lawn or terrace.

GEORGE BERRY.

Longleaf.

HINTS ABOUT TRANSPLANTING.

MULCHING is excellent for newly-planted trees, but the work is often wastefully or injudiciously done. I saw the other day a pile of horse manure, enough to manure a square rod, heaped around a young Apple tree set this spring. The chances are that this tree will die, and "killed by kindness," might appropriately be written on its label. Even if so much manure does no harm, it is a wasteful mode of applying it. What the tree needs is just enough shade over the roots to keep the soil around them moist, but not to exclude air and light entirely. A little straw, or, better still, green Grass spread over the surface will do all that mulching can do. Manure is not needed. It takes some time for the roots of a newly-set tree to recover from the shock caused by transplanting. Until they begin growing they are so much inert matter, full of sap, and ready to rot at the slightest provocation. Manure in such cases can only do harm. And yet thousands of trees are immersed in a hole filled with manure and rotting soda, and then the wonder is that they do not grow. I would not plant an orchard on a newly-turned Clover sod, as it is sure to be filled with decaying vegetable matter. Another frequent mistake about transplanting is that newly-set trees or other plants are benefited by heavy applications of water either on the surface or at the roots. For the first twenty-four hours after setting water is an injury, and cold (as it is sure to be in early spring) is especially so. The soil should be fairly moist, nothing more. After the roots have started to grow, water, if warm, may be beneficial. So far as possible, the leaves of the plant or the leaves and trunk of a tree should be moist. This will check evaporation and thus stimulate root growth. Great care, however, should be taken not to wet the surface of the ground, especially if the soil be heavy. If a crust forms on the surface to exclude light and air, root growth ceases until the crust is broken. This explains why hoeing often benefits newly-planted trees much more than watering them. A little water applied frequently to the leaves of plants or trees is far better than applying large quantities to the roots. If from neglect in mulching it becomes necessary to water the roots the surface should be removed and warm water turned in; then cover with dry earth and afterwards mulch. Do not trouble the roots, except to frequently hoe the surface of the ground until growth has commenced. The starting of the buds is a pretty sure sign that root growth either has commenced or soon will do so. In transplanting young trees it is best to cut away the top vigorously, provided it be done at the time of planting or soon after. When growth has commenced pruning checks the roots and injures the tree. I have had the best success with young trees in cutting back to from three to six buds, enough to form a head according to the variety. Each bud would push strongly and become a vigorous branch the first season.—W. J. F., in "Cultivator and Country Gentleman."

AVENUE TREES.

MISTAKES are not unfrequently made in the choice of these. For example, one can hardly admire an avenue bounded on both sides by rows of formal-looking Araucarias. It is a good ornamental tree for some situations, but it is not an avenue tree. Besides, the danger of its being injured by frost and its habit of losing its bottom branches by disease is another good reason for not employing it for such purposes. But it is used for avenues in some places; hence the allusion to it here. The Wellingtonia and the Deodar are not open to the same objections. The first, where it grows well, and is not cut up by winds, which completely ruin its appearance, is a grand avenue tree. It grows fast, too, and soon becomes a striking object. 6-ft. trees, planted in good soil, soon grow to a large size. It should, however, be planted well back from the drive—50 ft. or more at least. There should also be room between the trees. If this be not seen to, the avenue will be destitute of breadth and freedom, and will look like a narrow alley when the trees grow up. In a great number of cases this matter is lost sight of in planting avenues. The trees are planted not many feet from the side of the road, and soon their branches are encroaching upon it and have to be lopped back, which completely spoils the effect. One of the grandest approaches we ever saw to a fine mansion was a broad avenue, with the trees thrown back nearly 100 ft. on each side, with Grass between them and the road. The trees were not formally planted, however, but just formed the margin of the wood. When the Deodar is planted along an avenue, the trees should not be more than 20 ft. or 30 ft. from the road. It is a tree which grows slowly, and never gets very lofty, and it looks diminutive if placed too far back. A grand palatial mansion requires a correspondingly broad and spacious approach, furnished with trees of noble height and character; but such an approach would look ridiculous if it led to nothing better than an unpretentious villa. In the latter case the Deodar will be found a very suitable tree to plant, also Cupressus Lawsoniana, and others. In some parts, where the more tender Pines do not thrive well, the common Spruce will be found a good subject, but only in moist localities; and Pinus Nordmanniana is better still—in fact, it almost rivals the Wellingtonia in height, and exceeds it in breadth of base, while it is an excellent grower. What applies to the Pine tribe of course applies also to deciduous trees, whether planted in lines along a drive or in masses.

CHER.

NOTES AND QUESTIONS ON TREES AND SHRUBS.

Hollies in Terrace Vases.—I noticed lately in a garden in Suffolk what appears to me to be a novel and excellent idea. Some large vases on the terrace in front of the house, such as we usually see filled with Geraniums, &c., were planted with variegated Hollies, which are allowed to grow loosely. The effect was very good, the pretty variegation giving them a bright appearance. Where flowers are not required or cared for, might not many evergreens, such as the Phillyrea, Osmanthus, and others of slow-growing or dwarf habit be similarly utilised?—ROBERT OSBORN, Fulham.

Berberis pallida.—This species, which is to be met with only very rarely in our gardens, where it ought to be found much more frequently, is known in some establishments under the name of Berberis Hookeri. It is a native of Mexico, where it is found in different parts of the country, more especially in the neighbourhood of Real del Monte, where it was discovered in 1831 by Mr. John Bull, who brought the seed to Europe. Some years later Hartweg re-discovered it near Cardonal and Zimapan. It somewhat resembles another species which, like itself, has almost disappeared from our gardens, where it was at one time found under the name of Berberis macrophylla. The Berberis pallida (B. Hookeri, Hort.) is hardy in the climate of Paris, although it suffers slightly during very severe winters. It has been described and figured by Van Houtte in his "Flore des Serres," vol. vii., p. 23, and by Lindley in Paxton's "Flower Garden." The latter author describes it as having its fruit grouped in large hanging panicles, the berries being of a dark greenish-purple, the effect of which is sufficiently pretty to the eye, but their very pronounced acidity is out of keeping with their pleasing appearance.—C. W. QUIN.

Scarcity of Laburnum Bloom.—I notice the remark of "J. G." (see Vol. XIII., p. 560) about the scarcity of Laburnum blossom this year, and the enquiry whether this failure is local or has the same thing been noted in other places. Upon reading this it occurred to me that our Laburnums, 10 ft. to 20 ft. high, and marvels of beauty every year with their pendent golden trusses, similar to, and contrasting so well with the white and purple Wistarias which grow near by, had not been noticed this season, and

upon further enquiry I learned that our large trees yielded scarcely a single flower. It certainly is remarkable that the failure should extend to both continents. These failures are unaccountable. This year every Apple tree was loaded with bloom, but the Pears are almost an entire failure—the first time for twenty years, yet the autumn was pleasant and warm and the winter unusually mild. Why should the Pear alone of all our fruit trees fail? My theory is, that they have borne two successive and enormous crops (1876 and 1877) and now want a year's rest.—C. M. HOVEY, *Boston, Mass.*

Double Wistaria sinensis.—This is a very vigorous and hardy plant, and its general appearance reminds one of that of the ordinary species, *Wistaria sinensis*. The bark is of a dark reddish colour and lightly speckled; the leaves are of a long oval shape, and when very young are downy, but soon become smooth and shining, and are borne upon a stalk $\frac{1}{2}$ in. long. The flowers are sweet smelling and full, closely resembling double Violets in their general appearance. They hang in long bunches on a short, violet-red stalk, and bear a strong likeness to those of the common species; they are of a deep lilac or rather of a lilac-violet colour; the petals are numerous and irregular, some being larger than the others, and look as if they had been slit. This kind, which has just flowered for the first time in France in the gardens of MM. Transon Frères, horticulturists at Orleans, is a native of Japan, whence it was introduced into America by Mr. Parkman, a member of the Boston Society of Horticulture, in 1869. Specimens may be procured from MM. Transon.—C. W. QUIN.

Bronze Filbert, and other Coloured-leaved Plants.—This free-growing plant, which is very effective in shrubberies, has large leaves of a deep bronze colour. We lately saw a number of bushes of it in the Slough nurseries, where there were also growing fine dwarf, highly-coloured bushes of the Golden Elder and the white-leaved *Acer Negundo variegatum*. A striking effect could easily be produced by associating these three plants in woodland scenery. In order to have them good in colour it is necessary to keep them well pruned, especially the Golden Elder, which should be cut down nearly to the ground every year; thus treated, its foliage comes large and of a brilliant golden colour, but if allowed to grow to a large size it reverts to the original green-leaved kind.—C. S.

Ancient Cedars at Gunnersbury.—One would scarcely believe, when standing beneath the shade of these ancient-looking trees by the lake at Gunnersbury, that such a lovely spot could be almost within earshot of the bustle and turmoil of the London streets; and one cannot help admiring the way in which the venerable aspect of the trees is preserved by the evident care that has been bestowed in holding them together by means of chains, iron bands, or props. Many of the trees overhanging the lake are carefully shored up from the water-side. I need scarcely remark how much nobler an aspect is imparted to an estate by the preservation of old trees, than no amount of money could procure or transplant, than by the too often commonplace adornments one sees imported into otherwise good gardens. I may also remark that the Ivy here plays an important part in garnishing old trees and forming canopies of verdure overhead, and also carpets on the ground; for I observed that the too often bare spaces under such trees as the Cedar of Lebanon were here covered with a dense growth of Ivy.—J. G.

Propagation of Xanthoceras.—M. Baillon, in the "Journal of the Société d'Horticulture," gives an account of the *Xanthoceras*. When first this very beautiful tree was introduced into Europe it was propagated with extreme slowness and difficulty, owing to our arboriculturists being ignorant of the right means to take to secure its easy fructification. Of late years, however, it has been known to flower very readily, but in order to produce a supply of fruit we must have recourse to artificial fertilisation, taking care to choose the proper flowers for the purpose. This is no easy matter, for some of the flowers are males by abortion, especially those at the ends of the branches. Flowers of this kind are, of course, useless for the purpose, and only those with perfect pistils should be chosen for the operation. Last year a large number of the seeds of the *Xanthoceras* were successfully gathered and sown. It has also been found, on the other hand, that this species is easily propagated by cuttings from the roots. In this respect it may be placed on the same category with certain woody subjects with pinnate leaves, such as the *Cedrela sinensis*, the *Ailantus*, &c., which likewise possess the power of being multiplied by root cuttings. M. Baillon says that one of the oldest known specimens of this tree is to be found in the south of Russia, where, according to a letter received by that gentleman, this tree has existed for the last thirty years. With us the *Xanthoceras* rarely grows to the height of 6 ft. or 7 ft.; but in its natural habitat (Mongolia) it far exceeds these dimensions, and figures as a beautiful tree.—C. W. QUIN.

THE FLOWER GARDEN.

YELLOW-FLOWERED BEDDING PLANTS.

I HAVE been much pleased this season with two circular beds of *Calliopsis coronata* and *Drummondii*. The colour of the latter is bright orange with a dark disc. *Coronata* is a bright canary-yellow with a spotted disc less dense in colour than *Drummondii*. Both are very free flowering and showy; the individual flowers measure nearly 3 in. across, and are mounted singly on wiry stems, which yield to the motion of the air, and thus obviate that tiresome rigidity which, in the case of many closely-cropped or pinched plants, suggests the idea of daubs of paint on canvas. These two forms of *Calliopsis* belong to a genus of hardy annuals introduced from America nearly half a century ago, and good masses of them were common thirty years since; but of late, when flower gardening became so formal, all plants with a free, flowing outline were discarded, no matter how effective they might be. From this cause, many exceedingly showy and useful plants have well-nigh disappeared, as, for instance, the Sages—such as *Salvia patens* and *S. fulgens*—and many other plants equally bright and showy, but which could not easily be made to assume a low formal outline without losing most of their flowers and, consequently, their beauty. The seeds of *Calliopsis* may be sown on the beds where they are intended to bloom the first week in April, covering very lightly with dry soil, and, as soon as large enough, they must be thinned out to 6 in. or 8 in. apart. Timely thinning and frequent earth stirring are most important details of culture in connection with these plants, and it is advisable to pick out the points of the leaders or main shoots once or twice, a practice which keeps the growth bushy and robust, and allows the plants to get well established before flowering and seed bearing commences. As far as possible the seed-pods should be picked or cut off early in August and onwards, although in this respect there will be less labour required than would be necessary in the case of *Pelargoniums* or *Calceolarias*. I have said the seeds may be sown in the open air, but as they are light and scaly I prefer sowing them and all similar seeds in boxes under glass in a cold frame. The soil and the season are often, early in April, very ungenial, and many good seeds may perish from that cause; but under glass shelters there is no fear of failure, and the young plants can be planted out in the beds early in May 6 in. or so apart. The soil should be good and deep, and if, during very dry, hot weather, they are well watered twice a week, there will be less time consumed in picking off seeds, and the flowers will be larger and more numerous in consequence. E. HOBDAY.

TIME OF BLOOMING OF LILIUM CANDIDUM.

I BELIEVE that "Dunedin" is in the main correct in his remarks on Lilies, but he does not write for everybody when he says that *Lilium candidum* or "The White Lily" has done blooming early in July." Here, in one of the later districts of South Yorkshire, this Lily seldom flowers earlier than the middle of July, and that, too, on a south border. We have it still in flower (July 29), and had it not been for the late warm weather it would have been later still. Manifestly, therefore, it would not have been wise for us to have taken it up and re-planted it two months before September, as "Dunedin" recommends. No doubt our experience is the same as that of others in late districts in the north. Our bulbs of *L. candidum* and the scarlet *Martagon* were planted five years ago. The first year they did not flower, the second they did, the third year they flowered well, and last year, the fourth season, they were very fine, and created quite a display in our herbaceous borders. Last November, while making some fresh plantations in another part of the ground, all were taken up, when it was found that the bulbs had accumulated to clumps the size of one's head, or larger; these were divided and re-planted, and, though some of them have flowered this year, they are by no means so fine as usual. Our bulbs, I may remark, were planted very carefully at first, but later than "Dunedin" recommends, and I think, according to his showing, they should have flowered best the second year, but they did not, but continued to increase in strength and floriferousness till the fourth year. Nor do I agree with him in thinking that "very little science tells us that the first season is the only one in which the Lily can have a sufficiency of fresh and sweet food." Surely the Lily can be fed as successfully as any other plant of the herbaceous kind. J. S. W.

Flowers in Churchyards.—A good example of the use of *Convolvulus sepium* for enclosed grounds may be seen in Kensington Churchyard, where it was planted apparently at the time when the burying ground was closed. It now runs all over the place, climbing up the shrubs beautifully. Some of the weeds there, however,

require more oversight, as, for instance, the *Enothera*, which is now dying off and scattering its seeds by the bushel. It is desirable that more judgment should be shown in the selection of plants for burying grounds, so that their neatness should not be wholly destroyed by annuals. Surely a flower list of perennial plants might be made out, and the sorts that flower in succession distributed over the place in such a manner as to keep the general aspect fresh and cheerful with blossom from April to October. This graveyard now offers a curious contrast to the Duchess of Teck's garden a few yards distant. *Chacun à son goût!* [The great Bindweed (*Calystegia dahurica*) is a much finer plant than our common white Bindweed.]

The Climbing Fumitory (*Adlumia oirrhosa*).—That this it would be difficult to find a more elegant object amongst hardy plants. It possesses several good properties; it is a rapid grower, and soon covers the object against which it is placed. Its Maiden-hair Fern-like leaves are borne in great profusion on the slender, twining stems, and the blossoms which are white and about $\frac{1}{2}$ in. long, are also borne very freely; altogether, making it a most desirable plant. There is also a variety of it with purple flowers (*A. cirrhosa purpurea*), which if grown with the type, forms a pleasing contrast. It is properly a biennial; that is, it makes growth one year, flowers the next, and then dies, but it bears seed so profusely—which comes up year after year without being sown—that it may well claim to be perennial. It is a native of Canada and Carolina, and was formerly known under the name of *Corydalis fungosa*. Although it has been introduced about a century, it is not so frequently seen in gardens as it deserves to be.—A.

Spiræas.—*S. Lindleyana*, which is a native of the hills of Northern India, thrives well in an exposed situation here, grows about 5 ft. high, flowers freely, and is a very ornamental plant on the lawn. *S. japonica*, now called *Hoteia japonica*, is the best known of its class, being so extensively used for decorative purposes when forced. *S. palmata* is a truly handsome species. It does not, however, get a good name as a forcer, but in the herbaceous border it is far more showy and perfect than the *Hoteia japonica*, which, in consequence of coming so early into flower, gets injured by winds and frost; the latter is seen to best perfection when forced. *S. Ulmaria* fl. pl. is a double variety of the common Meadow Sweet, and very much superior to it in appearance. The plant is a strong grower and free flowerer, and should be in every collection. It is a good companion to the pink *S. palmata*. *S. Filipendula* fl. pl. and *S. japonica variegata* are also attractive kinds.—J. S., *Sheffield*.

Badly-designed Rockwork.—One of the worst rock gardens which I have yet seen is that in the gardens of the Preston Nursery Company. It consists of large square flat stones, placed like shelves one above the other, with vacant spaces between them filled with soil in which it would be impossible for plants to grow, as neither light, rain, nor sunshine could ever reach them. On the top of these stones are planted Scarlet Pelargoniums, Golden Pyrethrums, and similar subjects, the effect of which any one can easily imagine. With Nature in her most picturesque form so close at hand to teach what should be done, it is astonishing how any one could have constructed such an hideous piece of work. Nowhere, perhaps, in England could be found a more charmingly situated spot than these gardens occupy. Nature has added unsparingly to their attractions. They contain situations suitable for Alpine or rock gardens, bog gardens, and wild gardens, and the latter is the true name for the gardens as they now exist, for comparatively little has been done, except planting a few Sweet Williams and unsuitable Roses about the banks and jungles. The taller-growing native Ferns flourish here amazingly, and so do some of the wild Spiræas. If some of the hundreds of free-growing hardy plants which we now possess were judiciously planted, and fine-leaved trees and shrubs introduced among those which now exist, this might be made one of the most attractive gardens in England, and one which every one who loves scenery and semi-wild gardening would be pleased to see.—C. S.

Exhibiting Carnations.—The exhibition of the Carnation and Picotee Society, which took place the other day at South Kensington, was very successful regarded from the point of view of the professed florist. The several classes were well represented, and the skill of the cultivator, as well as the beauty of form and colour of the flowers, were well displayed. No attempt was made to break from the traditional mode of exhibiting these flowers, a tradition so venerable and so religiously acted up to that it would appear as if the height of excellence as regards practice had been reached, and that long experience had shown that no improvement could be made. At the risk of being considered rash heretics, we venture to dispute the assumed excellence of the present mode of exhibiting these flowers. Is it necessary, for instance, that the flowers, no matter what their colour may be, should be throttled by a stiff collar of dead white cardboard, projecting all round the flower for some

distance? Assuming that some support of this kind is necessary to prevent the effect of the bursting of the calyx, is it necessary that such support should be so conspicuous? The effect is often distasteful, often ludicrous, and nearly always detrimental to the lighter colours of the flowers themselves. The card might be so curtailed in its proportions as not to be objectionable, and it might be of some light warm neutral tint which should enhance, not detract from, the colour of the flower.—“Gardeners' Chronicle.” [It is high time to protest against the way in which these lovely flowers are made hideous at shows. A bed of seedlings left alone has a better effect than all the collared Carnations ever seen. We do not now wish to quarrel with the “florist” for his ideal, and let him lay down all the rules and standards of perfection which he likes. What we have to deplore is the fact that, after ages of effort and not a little vaunting of what has been done, the ideal flower is only to be seen in a deep paper collar, with all its delicate beauty of varied petal destroyed, flattened, or picked out. Each exhibitor is armed with a small series of instruments, reminding one of a dentist's collection, wherewith the said exhibitor extracts small petals, flattens others, and goes through a variety of operations to force the flower to assume for an hour or two before its death a shape which he calls perfect. All this one might tolerate if at the same time these beautiful flowers could be seen as they grow. This is all we ask for. A show of Carnations and Picotees well grown in pots, and allowed to bloom without mutilation or objectionable collars, would be a charming novelty, and we should see in which way the flowers look best. We believe the usual way of showing them is that calculated to exhibit to the least possible advantage the beauty and grace which Carnations and Picotees naturally possess.]

Helichrysums as Biennials.—These well-known showy flowers, so useful for drying as Everlastings, are generally treated as annuals, and, unless exceptionally well managed by sowing early under glass, the season is so far advanced before they commence flowering, that the best period for laying on the brightest colours is lost, and early frosts find the plants just approaching their best, as regards flower-heads. During mild winters I have on several occasions found a good number of these Everlastings to stand the winter, and to be the most continuous flowerers next year even in the driest and hottest of summers. The *Helichrysum* is particularly adapted for a background plant on dry borders. I would recommend a few pans or boxes to be sown with it, where they can be slightly protected during winter, and, if planted out early in April, they would have a chance of producing a good crop of flowers for drying.—G.

Delphiniums from Seed.—The fine race of Delphiniums which now adorn our gardens through the summer months with a variety of rich purples and blues, colours such as no other plants, hardy or tender, can rival, are easily raised in great variety from seed. If the flower-stems are cut down promptly after blooming, they flower again in autumn. Rich soil, or a place in the choice border is not even necessary for them, though they are worthy of both. They thrive freely without attention or staking, either in shrubberies or copses, and also well in open situations. We say so much for them now through seeing a square of them in Messrs. Carter's seed farm the other day—all seedling plants, and yet including many beautiful kinds and a great variety. They were in bloom in a very exposed spot, rather close together, the stems tall, erect, and unbroken, without any stakes being used.

Miles' Spiral Mignonette.—Great improvement has of late years been effected as regards the habit of growth, size, and colour of Mignonette, while, at the same time, the agreeable perfume which has so long rendered ordinary Mignonette so valuable has been retained. Amongst varieties with highly coloured or red flowers, the sort known as the Victoria Mignonette is possibly the best, while the spiral variety is without doubt the best of all the varieties having light-coloured flowers. As a pot plant I have as yet had no experience with it, but in the open air it is most satisfactory, producing spikes of bloom from 15 in. to 18 in. in length, and this without any attention in the way of pinching the side shoots or extra treatment of any kind. This result, too, has been obtained on very light soil, and during an exceedingly unfavourable season, on account of long-continued drought. The seed was sown in pans about the beginning of April, and as the few packets I obtained did not contain a great number of seeds, the plants were potted singly into 3-in. pots, and ultimately planted in the open border.—P. GRIEVE, *Culford*.

White Lilies and Rabbits.—Of white Lilies I have had a magnificent show, but not in the woods; although they promised so well there, the rabbits got a taste of them, and eat every flower, stalk, and leaf which they could find. They are evidently so fond of the white Lily, that it is useless planting them out in woods, unless they are wired round. Another showy plant to which they are partial is the oriental Poppy; they devour it like Clover; Malgadinum they do not touch, nor the Comfrees, nor *Bocconias*.—G. BEECH, *Langley*.

GARDEN DESTROYERS.

PIERIS RAPI.

(THE SMALL WHITE OR TURNIP BUTTERFLY.)

THIS insect is very similar to *P. brassicæ* not only in form and colour, but in its habits and economy. It is, however, considerably smaller. The male measures across the wings when they are fully extended about 2 in.; the female is somewhat larger. The wings are white in both sexes, dusted with black at their

Small White Butterfly.

bases, the upper wings having the tips and the front margins black, more or less sprinkled with white. The lower wings have a blackish spot near the upper margin. On each of the upper wings of the female, about two-thirds of the distance from the base to the side margin, there are also two black spots, one above the other, the lower of which is sometimes hardly visible. The under sides of the upper wings are white, with yellowish tips and with black spots similar to those on the upper side. The lower wings are yellow beneath in both sexes. The body and thorax are black above and yellowish-white underneath.

Chrysalis and Caterpillar of the Small White Butterfly.

The head and antennæ are black; the latter are slender and slightly clubbed. The eggs much resemble those of the White Cabbage Butterfly, but they are laid singly instead of in clusters on the under sides of various cruciferous plants, Mignonette, Nasturtiums, &c. The caterpillars are hatched early in June, and when fully grown are about 1 in. long, seldom longer, and so thickly covered with fine hairs as to be quite velvety; they are dull green in colour, with three yellow stripes, one down the middle of the back and one on each side. The chrysalides are of a light pinkish-brown or pale gray colour sprinkled with fine black dots, and are generally found in some sheltered place, such as on posts or palings, near the plants on

which the caterpillars have fed. This butterfly is even more common than *P. brassicæ*, and is generally distributed throughout the United Kingdom. It may be found from May till October.

The caterpillars are very destructive in gardens, as they feed voraciously on Turnips, Cabbages, and other cruciferous plants, Nasturtiums, and Mignonette; this latter plant it sometimes entirely strips of its leaves. They have been found feeding on the Weeping Willow. The natural enemies of this species are the same as those of *P. brassicæ*. There seems to be no way of destroying this insect, except by catching the butterflies, picking the caterpillars off the plants infested, and killing them and the chrysalides wherever they can be found. Any chrysalis, however, of a brown appearance should be spared, as it is sure to contain the larvæ or grubs of ichneumons or other insects which are parasitic on the caterpillars of white butterflies. Very small yellow cocoons found on leaves and dead caterpillars are often mistaken for the eggs of insects, but they should never be destroyed, as they are the chrysalides of small insects belonging to the Ichneumonidæ, which kill great numbers of caterpillars, and thus render good service to the gardener.

S. G. S.

Phloxes.—These rank next to Larkspurs amongst herbaceous plants, and afford many pleasing shades of colour; between the early and late kinds, the *suffruticosa* and *decaessata* types, a fine display of flowers may be maintained throughout the summer and autumn. Phloxes require the same general treatment as Larkspurs, and succeed anywhere. It is needless to propagate them from seed, except to raise new sorts. After two seasons young shoots push from the base of the flowering stems, and these may be used for cuttings, which should be made about 3 in. long, and inserted in a sandy compost, under a hand-light and shaded. They will soon strike root, and should then be potted off or planted out.—S. J.

Ornamental Gardens at Rochester, U.S.—In a notice of the visits made by the members of the recent Nurserymen's Convention at Rochester, we ("Country Gentleman") alluded to the examination of the grounds of Ellwanger & Barry and others. A few additional statements of what they saw may not be out of place. The home grounds at these celebrated nurseries are widely known as affording an excellent specimen of landscape gardening, several acres of lawn in perfect condition being bordered with beautiful and rare specimens of native and exotic trees, and occasionally ornamented with plantations of shrubs and beds of blooming herbaceous plants. A bed of *Pæonias*, 30 ft. in diameter, containing many of the best varieties, was in full bloom. Several variegated and rainbow beds, made of plants with coloured foliage, were variously interspersed through the grounds. The *Roses* were in perfection. Among the trees were fine specimens of purple Beech, weeping Birches of several sorts, many rare Conifers, and a number of *Magnolias*. We measured a flower on a tree of *Magnolia macrophylla*, and found it to be 20 in. across. Their *Sequoia* trees are about 40 ft. high, and last winter was the first in which they were not at all affected with the cold; in previous winters the shoots were more or less browned. The Japanese Maples, of which there were many specimens, attracted much attention. This firm still keeps up its great nursery to its full extent, occupying now 650 acres with trees. The flower farm of Mr. James Vick, in the eastern suburbs of the city, has many acres devoted exclusively to flowers, including a vast collection of bulbs. The immense beds of *Pansies*, at the time above mentioned, were kept in the richest bloom by the city water, which was constantly supplied through hose-pipes, the fine roset terminæ of which, held high on standards, showered the water in mist over the beds. By actual estimate, we found that the flowers in these beds of *Pansies*—which were of every imaginable shade and variegation—were literally numbered by millions. Nothing does more than fine specimens of ornamental planting towards stimulating a correct taste in the details for carrying it out, and Rochester is largely indebted for its many fine places in the city and suburbs, to Messrs. Ellwanger & Barry and to Mr. Vick in floriculture, as well as to others, by the examples which they have afforded, and by the plants and trees which they have introduced.

Caterpillars Attacking the Oak.—When on a visit lately to a friend in the neighbourhood of Sheffield we took a drive one day to Wharnclyffe Crags, where one of the finest views in Yorkshire is to be had. On passing through an Oak wood some 14 miles in extent, part of the old Sherwood Forest, we were struck with the blighted appearance of the trees, and, upon examination, we found the mischief to be the work of caterpillars. I would scarcely have believed it had I not found them in hundreds upon the trees. Through the kindness of Lord Wharnclyffe this wood and drive are thrown open to the public three days a week.

—A. McINTOSH, *Paxton House*.

THE INDOOR GARDEN.

LUCULIA GRATISSIMA AS A WALL PLANT.

IN this fine evergreen shrub are combined vigorous growth, a remarkably free habit of flowering, delicious fragrance, and a disposition to produce blooms through the autumn—a combination of good properties surpassed by few plants in cultivation. Considering the length of time it has been known in this country—over half a century—it seems strange that it is not more generally met with than it is at present, a circumstance that can only be accounted for by the fact of its requiring to be grown in an intermediate heat, *i.e.*, between that of an ordinary greenhouse and a stove, a temperature which many plant growers have not the means of affording, and which is the more to be regretted as the non-presence of such precludes the possibility of growing many of the very finest plants we have, that will not succeed well without more warmth than that afforded by a greenhouse, and yet cannot bear so high a range of temperature as many of the occupants of the stove, wherein, if kept, as is the case with this plant, growth is so much over-excited, that they appear never to have time to flower, or, if they do, the bloom is of a meagre, puny description. With sufficient room this plant attains a considerable size, reaching, where desired, a height of 10 ft. or 12 ft. when trained, so as to occupy the end or back wall of the house in which it is located. For this latter purpose there are few plants more suitable, and in such positions its cymes of pinkish flowers are seen to the best advantage. It is equally suitable for training round a pillar, or it can be grown in a pot or tub, trained bush fashion, to which its natural habit adapts it; but, although from its free disposition to flower, it will bloom in a small state, yet to have the plant in a condition such as to exhibit its full beauty when grown in the latter way, it should neither be stinted for root-room nor the head kept too much cut in. It is easily propagated by cuttings of the half-ripened wood, which should be put in during the early spring—say the beginning of March—for with this, as with most stove subjects, it is of importance to start sufficiently early to admit of the plants attaining size and strength before autumn. Insert the cuttings singly in small pots, drained, and half-filled with a mixture of sandy loam and peat, the upper portion being sand. Keep them moist, cover with a bell-glass, and let them have a night temperature of from 60° to 65°. They will root in a few weeks; then gradually admit air until the propagating glasses can be dispensed with altogether, when the young plants should be placed where they will receive plenty of light. As soon as growth commences pinch out the points, so as to induce the formation of several shoots near the base.

When the pots are fairly filled with roots shift at once into others 4 in. larger, using a mixture of two-thirds loam to one-third of peat; a liberal sprinkling of sand is indispensable, as, being free-growing, the plants require a plentiful application of water during the summer season. When they have got fairly established, a night temperature of 65° through the spring and summer will be sufficient, with a rise in the day proportionate to the state of the weather, for the plant, being a native of the high, comparatively cool, yet humid country of Nepal, will do better in such a temperature than if warmer. A little shade in the middle of the day during very bright weather will be an advantage. Syringe freely in the afternoons, in order to keep the atmosphere moist. So managed, the young plants will make rapid growth, and may be expected to require more root room by the beginning of July, when give a 3-in. or 4-in. shift, according to the greater or less root progress that has been made. This liberal amount of pot room is for such as it is deemed desirable to get on to a considerable size without loss of time; yet if a portion of the stock be required to produce some flowers in the autumn, they will do so, in which case it will be better not to give them another shift. After potting them again, pinch out the points of the shoots, and continue to treat as already advised until the middle of September, when dispense with the shading, giving more air; but keep on syringing for another month, after which it may be discontinued. A night temperature through the winter of from 46° to 50° will suit the plants, keeping them drier at

the root, but on no account withholding moisture, even at this season, to the extent that some plants would bear; for it must always be borne in mind that the moisture-loving nature of these hill-region plants does not in any way change under cultivation, and if ever kept too dry they get into a languid state, which renders them susceptible to the attacks of red spider and other insect pests, which appear to prefer preying upon plant life when under conditions that reduce its vital force. By the middle of March it will be necessary to determine whether the plants are to be turned out or grown in pots; if under the latter system they may have a 3-in. or 4-in. shift, now using the soil in a more lumpy state, if possible containing more fibrous matter. Pot firmly by ramming the new soil well in, which with most plants has the effect of inducing a more bushy habit of growth, with shorter-jointed wood, more disposed for an even production of flowers than the few gross, over-luxuriant shoots generally resulting from light potting. Pinch out the points of any shoots that are taking an undue lead, training the strongest growths out to sticks inserted just within the rims of the pots, leaving the weaker shoots in a more erect position, by which means they will acquire strength to an extent that will more evenly balance the plants. All now required through the summer is to treat as recommended the previous season, giving them liberal applications of water at the root, and syringing freely.

By the beginning of September the plants will push up strongly, and when in bloom they may be removed to a conservatory, kept at a temperature such as is in accordance with their requirements. When the flowering is over they may be moderately shortened back, and kept on through the winter as before, giving them a liberal shift in the spring, and, to still further promote growth, supply them with manure water during the summer. They will this season make fine decorative objects when in bloom, after which treat as previously, giving more root-room in the spring, where space to grow them to a large size is available. This wanting, it is better to discard them after flowering, keeping smaller plants propagated annually to supply their places, which, where the glass accommodation is restricted, will be found the most advisable course. Where intended for planting out, a moderate extent of border must be prepared, sufficiently drained by the presence of 2 in. or 3 in. of broken bricks, pebbles, or anything of a similar character, as well as egress beyond this for the water, as where a considerable space has to be covered with a corresponding amount of root-room, several gallons of water will need to be applied at a time. The plants should be turned out in the spring, just before growth commences; if delayed until later on, some check to the young shoots will follow the necessary disturbance of the roots, which if coiled to any extent round the ball inside the pots should be loosened, so as to direct them into the new soil, which make moderately firm, otherwise the water will pass through it in a way so as to leave the ball dry, a condition essentially opposed to free growth. When preparing the soil if, in addition to sand, a sprinkling of grit, stone, or broken pot shreds is added to it, it will benefit the plants, as I have always noticed that the material in inside borders is more disposed to get into a sour, unhealthy state than when it is fully exposed to the open air. The plants should be spread out to cover the wall or end of the house, as the case may be, so as to furnish the whole properly from the first, as where attention is not paid to this matter the growth is naturally directed upwards, leaving the lower space deficient, a condition which it is afterwards difficult to remedy. Where a pillar has to be clothed, instead of stopping the plants so as to induce their branching out more than requisite, it will be well to allow one or two of the strongest shoots to take the lead in a way to attain the required height, merely pinching the points at intervals that will cause them to sufficiently furnish the space as they progress. *L. Pinceana* is also a native of Nepal; this has white flowers sometimes slightly tinged with pink. T. BAINES.

Fuchsia acubæfolia.—This *Fuchsia* is now seldom seen and is somewhat difficult to obtain. It is, however, well worth attention on account of its large variegated leaves. Its flowers are little inferior to those of many which are grown for their blossoms only, and a good specimen of it is very attractive. I lately saw plants of it in Messrs. Laing & Co.'s nursery at Forest Hill.—S.

POTTING AND DRAINING SIMPLIFIED.

THESE are the points connected with the culture of plants upon which success may be said to principally depend; the loss that is entailed in garden practice by ignorance on either of them is almost inconceivable. To begin with potting, and dealing chiefly with general principles, we have first to consider the kind of subject we have to deal with—whether it be a strong or a weak grower; whether grown for fruit or flowers, or only for its foliage; whether, also, it is a plant producing strong, thick, fleshy roots, or roots of a small fibrous nature—all of which are conditions more or less affecting the question of potting and composts to be used. Mainly, however, the question in general plant culture is one of loose or firm potting. Formerly, in potting such plants as Heaths and Azaleas, hard potting was carried to extremes; the operator was not content with ramming the soil about the roots with a heavy wooden rammer till it was a mass as hard almost as a brick, and becoming when dry not unlike a brick in texture, but he even introduced stones to help to obstruct the roots still more. Recently, however, more rational practices have prevailed. It is not found in Nature that the plants are usually placed in a rooting medium of such a texture as is here described; and it is found in plant culture that such treatment is neither necessary nor desirable. The effect of too firm potting is that free root action is obstructed; and what is worse, after a while, when the roots do to some extent permeate the soil, it becomes a hard baked ball, almost impervious to water, and without which it shrinks and leaves the sides of the pot, to the great injury of the roots. I have seen Heaths so hard potted that the water would lie for hours on the surface of the pot before it soaked away, and such plants I never saw do any good. The Strawberry is a plant which should be firmly potted, but if the plants are rammed too hard they will never make good ones, as I have proved by experiment.

As a rule, all hard-wooded stove and greenhouse plants require moderately firm potting, but it is difficult to describe clearly in words how firm the soil should be made. It may just be stated that considerably more soil can be pressed into a pot, by dint of finger-and-thumb work, than would be compatible with the necessary porosity; but, as a rule, most good cultivators are satisfied if the compost be just so firm that it will not subside much after potting in the course of the season, and it will be found that not much ramming or squeezing is necessary to secure this end. When firm potting is necessary, the ramming should be chiefly confined to the layer of soil next to the drainage. The worst consequence of loose potting is that the roots soon find their way down amongst the crocks—a thing which should be prevented if possible, for once the best part of the roots get there, they cannot be brought back again without shifting the plant. A good hard seat below the ball of roots is therefore a necessity in most cases, and if that is attended to, it matters little if the soil above is rather loose and open. I have noticed this very frequently. At one time I were taught that pot Vines and Pines could not be potted too loosely to secure a free growth, which may be true, but we found that plants so potted had always the best part of their roots among the drainage by the end of the season, while there would be comparatively few roots near the surface of the ball. By beating about 2 in. of the bottom soil pretty hard, however, and filling in the rest round the roots rather loosely, we find by long experience that rooting in the drainage can be almost wholly prevented, and that the roots push up instead of down, until they quite crowd the surface of the ball, thus presenting excellent facilities for feeding by means of top-dressings.

I have said that something depended upon whether fruit or flowers, or only luxuriant foliage, was the object. It may be observed that what induces a floriferous habit will also induce fruitfulness, and for both the treatment may be the same. It will hardly be disputed, I think, by experienced cultivators that a soil of tolerably fine texture is the best for those subjects which are cultivated for their fruit; but of course something depends upon the species. All stone fruits succeed best in a rather rich soil, but a soil that is permitted to settle of its own accord, not one that is trodden or beaten hard. Apples and Pears succeed in a pretty firm soil, but I believe the finest examples of both are produced from trees that grow in deep and not too hard loam, and in situations, of

course, where the wood is ripened annually. At Lord Ducie's, Tortworth Court, I understand all Apple and Pear tree borders were specially prepared and filled in with good loam from the fields, in which the trees were planted, and that garden has long been celebrated for its fine fruit. Instances of successful orchard-house culture also prove that a border of a moderately adhesive texture is best, and in potting such trees one may safely take a lesson from outdoor borders. As regards fruits produced from plants of a herbaceous character, like the Pine before mentioned, or the Plantain, a freer rooting medium is to be recommended. As regards plants grown for their large and fine leaves, it is only necessary to state that the richer and freer the compost they are allowed the better, if light and temperature be afforded according to their wants.

DRAINING.—On this subject many particular instructions have been given. By some it is considered necessary, when crocking or draining a pot, to arrange the potsherds according to their sizes in the most particular fashion, beginning with pieces of the largest size, and ending with the smallest. In some gardens, indeed, preparing the crocks and draining the pots is nearly a man's work; but it is all utterly useless labour. All that anyone wants is a hammer to break the potsherds, and 1-in., $\frac{3}{4}$ -in., or $\frac{1}{2}$ -in. sieve. With these a boy may prepare as many crocks in a few hours as will nearly last an entire season. First he has to pound up with the hammer the broken pots, next he has to first put them through the 1-in. sieve, then the $\frac{3}{4}$ -in., and lastly the $\frac{1}{2}$ -in. one, to shake the dust out of them, and he has then all he needs for particular subjects, from Orchids to Scarlet Pelargoniums. The chief and only point is to provide a clear waterway at the bottom of the pot. To effect this he has first to put in one, two, or three handfuls of the roughest crocks, according to the size of the pot, in the bottom, then a handful of the next size on the top of these, and in very particular cases some of the smaller siftings on the top of all, and on the top a piece of turf or Moss, and the drainage is as safe as it can be made by the most elaborate precautions. In potting very small plants in small pots, and such as require a fair amount of water, drainage is hardly necessary at all, for the evaporation from the sides of the pot (if it be made of unglazed earthenware) is almost more than enough to rob the roots of their moisture as fast as they can conveniently be supplied again. For all common plants, therefore, such as are put in small pots in which they have not to remain long, one crock at the bottom of the pot is quite enough, and I speak from years of experience in the matter.—“Field.”

THE GLAZING OF HOTHOUSES.

It has been the aim of horticultural builders for some time back to devise a form of structure that would permit of glazing without putty, and at the same time obviate the necessity of frequent painting, which, as hothouses are built at present, add so largely to the expense of keeping them in repair. It is certainly most desirable to get rid of the outside putty at least, for it is a source of much trouble and expense in keeping the roof in repair. It is the putty far more than the wood which necessitates painting so often, and it also hinders repairs, for when glass is broken, which frequently happens in gardens, the putty has all to be chipped out piecemeal, and the new has to be painted three or four coats again after it has hardened. But even in the best-managed places this work is too frequently neglected, and the putty cracks and leaves the wood, the damp gets in, produces rot and drip, and in the end the ruin of the structure. In going through an extensive garden the other day, and one supposed to be well kept up, the damage through frequent repairs to glass roofs and the after neglect of painting was very apparent. In the case of some of the houses, indeed, the idea of repairs had been given up, and the houses (not very old) were destined to come down when anything was done to them. Any plan, therefore, by which hothouse roofs can be made thoroughly drip-proof without putty, and at the same time strong enough to withstand storms of wind, and close enough in the laps to keep the wind from blowing in, thereby reducing the temperature seriously, will assuredly soon become popular. As yet none of the patented systems

of glazing without putty have found much favour among gardeners, as much because of the open laps as anything else. The plan answers well enough for railway stations and sheds, &c., where temperature is no consideration; but in plant structures the windage and loss of heat are too great. This was the fault of "Ayres' Imperishable Hotheuses," as Mr. Ayres once told us himself. In calm weather they answered well enough, and at all times the structures looked well; but in windy weather the wind blew through the laps like a hurricane, and the same objection applies to some of the other systems. While in a winter garden at the seaside some time since, which was glazed on one of the puttyless methods, we observed that every puff of wind heaved the panes up so far that one could push a quill under them, and the superintendent told us that during cold weather he could just keep up the necessary temperature by dint of hard firing and an extra consumption of fuel. That it is, however, practicable enough to render such roofs fairly air-tight, we do not doubt. We had an opportunity at the Leeds Horticultural Show the other day of examining Hellewell's new system, and, though we cannot say how the structure may behave in a gale of wind, it seemed to meet the end in view more nearly than anything we have seen yet. The panes are edged with india-rubber pads at the holdfasts, which keep the panes down very closely. We could not insert the thin blade of our penknife under the laps, which is a pretty good test; but in some other cases, as, for example, at the winter garden before mentioned, we could push the haft of a budding knife under the laps and prize the glass up sufficiently almost to admit one's finger. By Hellewell's plan the panes are laid on with their laps from the wind as much as possible—that is, the side laps, which are the most exposed. What we considered the faults of the system were the large size of the panes and the wooden framework, which seems too light; the structure has the appearance of being all glass—no fault, certainly, from a gardener's point of view, but still a proportionately strong framework is indispensable. The glass sides of the house especially needed to be better stayed. Another advantage of the system is that it does away with nearly all outside painting—there are no outside rafters, all the woodwork is inside under the glass, except the gutters, and, of course, the doors and the wooden sides. The system has yet to be fairly tried, however, and we are not recommending the plan here before all others; but we are mistaken if it does not meet with the approval of plant and fruit cultivators.

J. S.

— There is, I imagine, considerable doubt in many people's minds as to the plan of glazing without putty being able to keep out rain and prevent drip equally well as houses glazed on the old-fashioned principle. Having, however, lately had an opportunity of inspecting a little greenhouse glazed without putty, I can confidently state that such structures may be rendered perfectly water-tight without any brickwork or putty at all. The heating apparatus in this case consisted of a large flat lamp, with two burners, for paraffin oil, one burner being sufficient to keep out a moderate amount of frost, and the two together in full play severe frost. Under such conditions was one of the best collections of zonal, double, and Ivy-leaved Pelargoniums that I have ever seen, and that, too, in a house which can be taken to pieces and easily re-erected.

J. G.

Lapageria alba.—The flowers of this are so much prized in a cut state for floral decorations, that Mr. Wills is building in his Folham nursery a house which is to be entirely devoted to it. The house in question is in a north-west aspect, and the plants are to be planted in an outside border, where, with a little protection in winter, a fine crop of flowers may reasonably be expected.

Fuchsia penduliflora.—This is one of the best of Fuchsias for baskets or for training up pillars. It flowers freely, has handsome light green foliage, and its blossoms, which are bright crimson, have tubes $1\frac{1}{2}$ in. to 2 in. in length. It is a hybrid, the result of a cross between two of the old species. Plants of it are now in good flower in the Victoria Nursery, Holloway.—S.

Small Plants of Anthurium Scherzerianum Best.—I find small plants of this better than large ones for decorative purposes. The spathes certainly are smaller, but the quantity of bloom produced even by a small plant is astonishing. This Anthurium is easily grown if potted in soil consisting of Sphagnum and peat, divested of its dust, intermixed with plenty of sandstone about the size of nuts. It should, when well rooted, be given liquid manure occasionally, and care must be taken to see that the drainage is in good condition.—JOHN CLEWS, *Headfort, Killy, Co. Meath.*

PLATE CXXXIX.

BOUQUET AND FANCY DAHLIAS.

Drawn by Mrs. DUFFIELD.

BOUQUET or Pomponé Dahlias form quite a different section from the Fancy and Show kinds. They are of Continental origin; and while the plants have the tall growth of ordinary Dahlias, the flowers are much smaller, bearing the same relation to the group of Show and Fancy Dahlias as the Pomponé Chrysanthemum does to the large-flowering section. For some time we had only varieties of tall growth, but of late years plants of dwarf and close growth have been obtained, having the same small compact flowers freely produced, and of varied and attractive colours. It is scarcely necessary to give a list of the best varieties, but such catalogues as those of Messrs. E. G. Henderson, Mr. Charles Turner, and others will be found to contain a good selection. The tall-growing varieties are very useful for the centre of a large bed, with the dwarf-growing forms forming a hand round them.

Of the term "Fancy Dahlia," the following definition was given a few years ago: "In the composition of a fancy Dahlia two or more distinct colours are essential. If the variegation be in the form of stripes or flakes, as in the Carnation, this arrangement of colours, whether the light or the dark predominates, is in itself sufficient to constitute the sub-division distinguished as striped fancy Dahlias; but if the variegation consists in the edges or tips of the florets differing from the general or ground colour, then the relative position of the colours determines whether the flower be a fancy one or otherwise. Thus a white, yellow, or any pale variety, edged, tipped, or laced with a dark colour, after the manner of the Picotee, is denominated simply an edged, tipped, or laced Dahlia, but when this disposition of colours is reversed, *i.e.*, when the florets of a dark flower are tipped with a light colour, the variety so marked is termed a tipped fancy Dahlia." At that time the foregoing accurately described what was commonly understood by a fancy Dahlia, but since then the two divisions of show and fancy Dahlias have approached each other so closely that it is sometimes very difficult to classify them with accuracy, and at many country shows edged flowers are admitted to be fancy flowers in contradistinction to those of purely self colours. It frequently happens that fancy Dahlias will revert to a self form, and, when that occurs, the fancy flowers in their true character and the self flowers can be shown as distinct varieties.

There is yet another section of useful Dahlias, viz, the bedding varieties. These are of dwarf growth with unusual free flowering properties, and they are at the same time continuous bloomers. Every batch of seedlings will be certain to produce some of this character.

It is in large gardens that Dahlias come in most serviceable, and when a great number of cut flowers are wanted at the end of the summer and in autumn, Dahlias prove very useful. But to prolong their bloom and floral attractiveness, the plants should be mulched with manure, kept well watered at the roots, and occasionally syringed overhead when the weather is dry; the decaying flowers should also be removed. In this way the cultivator renders substantial assistance to his plants, and they reward his timely attentions by bringing forth flowers in plenty when they are most wanted.

D.

[The flowers from which our plate was prepared were supplied from the collections of Messrs. E. G. Henderson, Pine-apple Place.]

The Violet-scented Fern (*Nephrodium fragrans*).—This North American Fern is one of the few scented kinds which we have, especially amongst the hardy class. It is a small-growing plant with a tuft of much-divided dark green fronds from 6 in. to 9 in. long. It is covered on the upper surface with minute glands which yield a delightful fragrance, much resembling, but superior to, that of Violet blossoms. Like many other good plants, it is rather difficult to manage, but I find it to succeed best in a moist, shady, yet well aired, situation, and it must be guarded against slugs. It likes a compost consisting of peat and leaf-mould, with the addition of a little loam and sand.—W.

MASSACHUSETTS
AGRICULTURAL
COLLEGE.

BOUQUET DAHLIAS

PROPAGATING.

CARNATIONS AND PICOTEEES.—These are best increased by means of layers put in in August; loosen the surface soil with a trowel, and mix with it a portion of fine garden soil and a little sand; trim off the leaves with a sharp pair of scissors, cut as shown in the annexed figure, and peg the shoot down; then cover with soil, and give a good watering to settle all closely down. If the weather be very dry, give a watering now and then late in the afternoon. In two or three weeks

layers thus treated will begin to grow, and in about the second week in September they may be taken up with a trowel and potted either in pairs or singly as required. They should then be placed in a cold frame that can be kept close for a few days, after which air may be gradually given them, and they will soon become established.

MULE PINKS.—These may be increased in autumn by means of the side-shoots, which should be put in as cuttings under hand-lights out of doors, or in spring by getting the plants into warmth and treating them in the same way as Tree Carnations.

TREE CARNATIONS.—The best month for increasing these is the latter end of January. Let cuttings be made of the side shoots that show no sign of flowering, as represented in the annexed illustration. Well drain the pots for their reception; the best and handiest sizes are $4\frac{1}{2}$ in. and 6 in. Let the soil, which should be sifted and thoroughly mixed, consist of equal parts of yellow loam, leaf-mould, and sand; take care to clear it of wireworms, which are little, hard, darkish yellow worms, about 1 in. long; if only one of these be left in a pot it will destroy the whole of the cuttings in a day or two. The soil must be pressed rather firmly into the pots, and sand should be laid on the top; then water and insert the cuttings firmly with a small dibber, give a good watering, and place them on a shelf near the glass in a close house, the temperature of which is about 65° ; they must not be covered at all. In three or four weeks they will be well rooted, and fit for potting off. Any new or scarce sorts may also be increased in March by putting the plants in a house in which the temperature is 65° to induce growth. The cuttings may be prepared in the same manner as those just named, but they must be placed in bottom-heat and covered with a bell-glass, occasionally airing and sprinkling with water early in the morning, and shading from the mid-day sun with sheets of paper.

H. H.

PROPAGATION OF VERBENAS AND OTHER BEDDING PLANTS.

AUGUST is essentially the time for looking over flower garden stock, taking note of such additions or alterations as may with advantage be introduced into the bedding list for another season, and, in case Verbenas are considered worthy of a place in the flower garden, the requisite number of stock plants should be propagated without delay, in order that they may become established before the dull days of winter set in.

Many ills, it is true, attend plants that are tenderly nursed and coddled late in the autumn, and especially Verbenas, which are subject to the attacks of mildew and thrips on the first approach of wintery weather, but the remedy by means of which difficulties such as these can be surmounted is early propagation and a liberal course of treatment up to a given time, after which all growth should be thoroughly hardened and ripened. The routine duties connected with autumn propagation are simple enough. First of all, see that your plants are in a fit state from which to take cuttings, and next determine the most convenient plan of propagation, and have all ready before a single cutting is taken off. The propagating frame, if a temporary one, should stand in a comparatively shaded position, and be filled up to 12 in. or 13 in. deep with s ent leaves freshened up with short Grass—just enough to generate a gentle warmth, which will accelerate root action and promote a free and steady growth; then have the pots or pans washed clean, crocked and filled up with leaf-mould and sand in the proportion of two-thirds of the former to one of the latter, sprinkle the surface of the soil in the pots or pans with water through a fine rose; then have the cuttings taken off, and while they are being prepared for insertion dew them over with water through a syringe to keep them from flagging. As the process of insertion is being proceeded with, see that every cutting is made fast at its base and not about the middle. Water well, so as to fill in the holes, and place the pans level in the frame already prepared for their reception. No hard and fast line can be laid down as to the atmospheric condition of a propagating frame, so much depends on circumstances, such as the state of the material or that of the weather, but it is a safe principle upon which to act to keep the cutting from flagging from the time when it is severed from its parent till it has formed roots and become an independent plant. This is done by shading and by frequent syringings overhead, which may be reduced gradually as the plants become established.

The next matter to be attended to is transplanting the rooted cuttings into pans of rich soil. In doing this one must be mindful not to compromise or impede their future health by exposing them to influences that would cause any check to growth. The pans for this purpose should not be less than 4 in. deep, and be clean washed and carefully drained. There is little necessity for warming soil at this time of the year, but in case the compost heap be located in cold quarters, and the soil be many degrees colder than that of the cutting frame, the usual remedy should be applied to reduce the disparity between them. Of the soil itself little need be said. It can hardly be too rich, and it should be thoroughly prepared beforehand, such preparation depending, of course, on the nature and quality of the material about to be used. Keep the plants from 2 in. to 3 in. apart in the pans, and make the soil firm about their roots, so that while the soil encourages vigorous growth the latter may be moderated by the mechanical pressure brought to bear upon the roots, thus inducing them to become fibrous and compact rather than straggling. Return the plants to the cutting frame in which the heat has now subsided, and keep the frame close for a few days and the plants watered overhead. Admit air as they lay hold of the soil, and eventually throw the sashes off altogether, except during boisterous weather. By this careful mode of treatment a fine healthy growth will be established, and the next thing is to ripen it in such a way that the stock will not be decimated through the winter by insect pests and damp. Prevention is better than cure; therefore follow up the principle suggested at the commencement of these remarks, and ripen the wood gradually but thoroughly till it has a hazel-brown appearance. Winter the plants on a shelf near the glass in a cool, airy structure, where fresh growth will not be excited before cuttings are required the following spring; then introduce the plants in gradual batches to a sharp, moist heat, and strong, healthy cuttings may be obtained by the thousand.

Many other popular flower garden plants that require to be propagated in the autumn for stock are so like the Verbena as regards their requirements that further allusion to them, except in a collective sense, would be unnecessary. Amongst their number are *Koniga variegata*, different varieties of *Tropæolum*, *Heliotropes*, *Iresines*, &c., while *Lobelias* and

Mesembryanthemum cordifolium variegatum are best kept as surplus stock either in pans, pots, or boxes. W. HINDS.

Otterspool.

GARDENING FOR THE WEEK.

Indoor Plant Department.

Cypripedium.—The different varieties of *Cypripedium barbatum* are most useful plants both for general decorative purposes and for the production of cut flowers. The leaves of all this section are more or less handsomely marked, and the flowers are of a most enduring character, lasting in good condition for eight or ten weeks. Those who use them largely for exhibition purposes generally put from one to three crowns together in small pots, and before or about the time of their flowering turn them out of these and put them together in considerable masses in pots of the requisite size; thus treated, they make a more imposing appearance than they otherwise would do. For general decoration they are best grown in 8-in. or 9-in. pots, six or eight crowns being placed in each pot, as if allowed to grow on until they have increased to a large mass, the inner portions of the plants get so crowded that they become weak, neither attaining their full strength, nor increasing as they will when further divided. In most cases before this the flowering will be over and growth will have commenced, and where that has occurred, unless the plants are suffering very much from want of room, it will be better to let them finish growing before interfering with them, but with such as have bloomed late and are only now slightly advanced in growth, good sized specimens may with advantage be divided into three or four, shifting them into pots sufficiently large to admit of the increase which they are likely to make for a couple of years; good fibrous peat and Sphagnum in the proportion of three parts of the former to about two of the latter, with a liberal sprinkling of fine broken crocks added and a little sand will suit them perfectly. They succeed well at the coolest end of the East Indian house, or where they can be kept slightly warmer than the majority of growers keep intermediata house plants. They require a good supply of water at the roots whilst growing, but not too much atmospheric moisture; give them plenty of light, in order to avoid the leaves getting drawn up weakly. Of the Long-tailed *Cypripedium* (*C. caudatum*) there are several forms, all of which well deserve attention. By many they are grown, like the East Indian plants, in strong heat, but I have found them to succeed best in a lower temperature than most of the *Saccolabium*, *Aerides*, &c., require; they will now be making active growth and should be well supplied with moisture at the roots. The handsome *C. villosum*, *C. Stonei*, *C. Lowi*, and *C. levigatum*, all very distinct and equally worthy of cultivation, will succeed well under similar treatment. They will now be in the height of their growth, and should be kept, independently of fluctuations of weather, at an even temperature, lower, of course at night than in the daytime. The old but useful *C. insignis*, with its handsomer form *C. Maalei*, the beautiful *C. venustum*, and *C. Schlimi* will also now be growing freely. Being mostly plants from a considerable altitude, they naturally grow under the influence of copious moisture, and any check through a deficiency of this will injure their growth.

Anæctochili.—These most exquisitely beautiful of all variegated-leaved plants are, by the majority of growers, found very difficult to keep in a healthy thriving condition for any considerable length of time. The experience of most cultivators is that they grow and increase satisfactorily for possibly some years, after which, without being subjected to any difference of treatment, they at once become a prey to that most fatal of all Orchid diseases, spot, which, in their case, usually affects their soft, succulent stems to a much greater extent than the leaves. This leads to the conclusion that there is something wrong in the way in which they are generally managed, and points to the apparently healthy growth which they make for a time being the result of either over-stimulating treatment by too much heat during the summer season whilst active growth is going on with an insufficiency of light and air, or that the plants are kept too continuously in a state of growth by not giving them sufficient rest in winter. The want of success in the case of the majority of growers may be traced to a combination of the above conditions. The golden-veined kinds, comprising the different varieties of *A. setaceus*, *A. xanthophyllus*, with *A. striatus*, and the large-leaved *A. Lowi*, are all natives of hot Eastern countries; consequently, they need considerable warmth; the way in which they are kept confined with comparatively little air under bell-glasses is quite opposed to the conditions essential to continued health. They should have more light and air, even though their progress under such treatment may be slower, and the leaves they form somewhat smaller and less brilliant in colour than when managed otherwise. The same holds good in the case of the silver-veined species, such as *A. argenteus* and its several varieties; these do not, even when growing, need nearly so much warmth as the golden-leaved kinds; they are more tenacious of life, but generally, like the golden ones, after a time they succumb. Nor can this be wondered at, seeing they are kept continually under the excitement of more heat and moisture than they need. From the effective contrast which they produce when associated with the golden-leaved varieties, they are almost invariably kept in the East Indian house with them; but, in addition to giving the silver ones more air than they usually receive, they will do much better in the Cattleya house, and if they can be set near the end or side lights, where they will get more light when the sun is not absolutely on them than when placed, as they generally are, for the convenience of inspection, nearer

the centre of the house, they will be found to continue longer in a healthy condition than they otherwise would. They will succeed in a mixture of chopped dead Sphagnum, but not too far decomposed, to which a liberal amount of sand has been added, and some charcoal broken into pieces about the size of Horse Beans. So far as potting goes, there is nothing better than the usual method of growing them two or three crowns each in small pots from 2 in. to 3 in. in diameter, and these should be plunged several together as closely as they will stand in larger pots or pans also filled with Sphagnum. Keep them moderately moist at the roots whilst growing. Shade neither too heavily nor too slightly when the sun is on them, but subject them to all the light which they can get at other times, and tilt the glasses so as at all times to allow as much air as possible. Very great care should be taken with the roots of these plants, as if, by the slightest injury from whatever cause, the tender extending points are damaged, the same root will never either grow any further or break out afresh in the way in which other Orchids will do. If roots thus injured do not at once decay altogether they will do so gradually, very often affecting the stem of the plant from which they proceed.

Vanilla aromatica and V. planifolia.—These plants, the former of the Vanilla of commerce, although not held in much favour by Orchid growers generally, are, nevertheless, very interesting plants. They are very suitable for running up a wall, say at the gable end of a general plant stove, where such exists, a position in which their numerous clinging roots will fix themselves like Ivy. Here they will also be more likely to receive the treatment which they require than amongst East Indian Orchids, for although, as is evident from the country where they are indigenous, they enjoy a high temperature, still, like most West Indian Orchids, they do better with a drier atmosphere and less shade than are usually given to Orchid houses. Now, whilst they are making their growth, syringe them freely every day so as to moisten the medium to which their roots cling, as, unless special provision is made by placing some material for them to run on, they are dependent for moisture upon the supply which they receive in this way.—T. BAINES.

Conservatories.—Although most kinds of indoor plants will now have completed their growth, they should nevertheless still receive abundance of water, be kept far apart to prevent crowding, and have plenty of ventilation. Such as are in flower on front stages will still be benefited by a little shading. Amongst plants at present in bloom are—*Fission*-flowers, *Hydrangeas*, *Fuchsias*, *Pelargoniums*, *Begonias*, *Campanulas*, *Carnations*, *Heaths*, *Clerodendrons* of the *Kæmperii* section, *Lilies*, *Petunias*, *Mitrisia coccinea*, *Tritonia aurea*, *Heliotropes*, shrubby *Calceolarias*, *Lobelias*, *Leschenaultias*, *Agapanthus umbellatus*, *Hippeastrums*, *Vallota purpurea*, *Lechenia corymbosa*, late-blooming *Clematites*, *Vinca oculata* (red and white), *Lantanas*, *Bouvardia angustifolia* and *Vreelandi*, *Lasiandra macranthus*, *Franciscea eximia*, *Achimenes*, *Gloxinias*, *Lapagerias*, *Roella ciliata*, *Allamandas*, *Asclepias curassavica*, and others. Introduce from frames, pits, and greenhouses successions of flowering and fine-leaved plants, and those turned out to accommodate them, if annuals or biennials, and seed sowing is not an object, should be discarded at once; perennials should be retained, and have their flower-spikes cut off, and the plants placed on north borders, or, if necessary, potted and placed in frames. Green fly, thrips, mealy bug, and scale must be vigilantly searched for and destroyed.

Greenhouses.—Even the freest-blooming hard-wooded plants, such as *Cytisus*, *Asclepias*, *Clinanthus*, and *Euparacis*, are much benefited by some exposure to the open air after their growth is completed. It frequently happens that improper directions are given for the summer treatment of these plants, such as, for example, exposing them to the open air early in the summer, the effect of which is to restrict growth, and, in many cases, to cause the plants to set their flowers at once, and consequently come into bloom before the time they are wanted. This should never occur, for the great charm in a garden is to have some plants coming into flower all through the season, and to keep back as much as possible those grown under glass for the winter. Neither is there a necessity for thus exposing any plant in the open air for the length of time often supposed to be needed. With most hard-wooded subjects usually grown in pots a month out-of-doors is sufficient, and it is much better to defer this until there is just enough time for the completion of the ripening process before it is necessary to take them in through danger of frost. For this there is now ample time if the plants be at once put out. They should for the first few days be placed on the north side of a wall, or at a short distance from a tree that will shade them from the midday sun till they get a little used to the change. After they have been thus gradually inured to the sun, they may be placed where they will be fully under its influence, yet still so far sheltered as not to receive the full force of the wind. The outsides of the pots, especially the side next the sun, should be protected, or the roots which lie thickly against the inner surface will suffer. For this purpose any flexible material, such as a piece of canvas or bast mat tied round will answer. The drying influences to which plants are subjected when in the open air are much greater than in a pit or greenhouse, requiring closer attention as to watering, especially if the pots be very full of roots. They should be looked over twice a day when the weather is hot.

Heaths.—Conspicuous amongst such kinds as are in bloom are *Maronckiana*, *Anstianina*, tricolor and its varieties, *Douglasi*, *ampullacea*, *Williamsi*, *rubens*, *retorta*, *Savileana*, *vestita rosea*, *Aitoniana* and its varieties, and several others. Pick off decayed blooms and encourage the ripening of the wood by fully exposing the plants out-of-doors, or by keeping them in pits or frames that are well ventilated night and day.

No more pinching should be done now, unless it be to remove any useless growths in the centre of large specimens, which growths are generally very weakly and subject to disease. Do not water the plants overhead, but supply them liberally at the root and pour plenty of water about the floor of the house or on the beds.

Azaleas.—The earliest Azaleas should now have completed their growth and formed well-developed flower-buds; therefore, remove them to cooler quarters that are light and well ventilated. Water them plentifully at the roots but not overhead, and maintain a moist atmosphere by spilling plenty of water about the floor and on the stages. Indeed, towards the end of this month all the plants, both early and late, should be transferred to cooler houses, but on no account put them out-of-doors. Pick off weathered leaves and destroy thrips, scale, and any other depredators that may make their appearance. No more pinching of the shoots should be done now; on the contrary, the maturation of the wood should be the main object kept in view. It is a curious fact, however, that young Azaleas may be treated, for the first twelve or eighteen months after being grafted and re-potted, as cool stove plants, with beneficial effects in the way of securing a strong and rapid growth, and, if properly attended to in the matter of pinching, they will form excellent and stubby plants.

Herbaceous Calceolaria seed should be sown without delay, as upon a vigorous development of the plants before autumn depends, to a great extent, their health through the winter and a satisfactory flowering in the spring. An ordinary seed-pan is the most suitable in which to sow them. Put 1 in. of fine corks in the bottom, and on this some dry, flaky manure to keep the soil out of the corks; use finely-sifted soil, with one-fifth leaf-mould, also sifted; add to it one-sixth sand, fill to within 1 in. of the rim, pressing the surface smooth, and watering it to close up the holes before sowing. This should always be done as a preparation for very small seeds, or they are liable subsequently to get washed down too deeply to germinate; after this, allow the pan to stand for an hour or two before putting in the seed, which should be scattered evenly over the surface, and then covered with about an eighth of an inch of very fine soil (not more than will just hide the seed); press the surface smooth with the bottom of an empty flower-pot, place the pan in a pit, greenhouse, or garden frame, in a position where the sun will not shine upon it so as to dry the soil. If a bell-glass, hand-light, or cloche be at hand to place over the pan till the seeds are up, letting it stand on a moist surface of sand or ashes, the soil will be kept in a fit state for the seed.

Flower Garden.

The heavy rains which we have lately had have a tendency to produce a crust on the surface of the soil almost impervious to water. This, therefore, should be broken up as soon as a favourable opportunity occurs. Where the surface has been mulched with Cocoa-nut fibre, or 1 in. of dry rotten manure that has been passed through a ½-in. riddle, the advantage will be seen in the better growth which the plants will have made, the less water required, and the less baked condition of the soil. Lobelia seeds should be picked as fast as they appear, or the plants will not hold out flowering until autumn. Any Pelargoniums that produce seed-pods freely, such as the old pink variety *Christie*, must have them regularly taken off, or the blooming will be much reduced. Such plants as *Humea elegans*, *Canna*, *Cestor-oil* plants, *Wigandias*, and other large-leaved subjects must have abundance of water given them when the weather is dry, or they will soon get unsightly, and if the soil be at all poor liquid manure will help them. Where *Yuccas*, *Agaves*, or *Palms* in pots are plunged in beds out-of-doors care must be taken that they do not suffer from want of water; this is especially necessary when the pots are plunged so deep as to be below the surface in such a way that the dry condition of the soil in them cannot be readily seen. Many kinds of *Yuccas* are now beautifully in flower, and when properly placed are very effective. Among others one called *Y. angustifolia* is exceedingly pretty, being a profuse flowerer, and dwarf and compact in habit. The time has now arrived when it is generally considered advisable to commence the propagation of the various species of plants used for the purpose of bedding out in the flower garden, &c.; but in this part of the country, and no doubt in many other parts, there will this season be found a difficulty in obtaining material wherewith to form cuttings, more particularly as regards the different kinds of Pelargonium, which generally play so conspicuous a part in the ornamentation of the parterre, and it may, in some instances, be necessary to delay for a time the propagation of this family of plants. But there are several other varieties of bedding plants, of each of which it is only necessary to have a few store pots to preserve during winter, in order to produce cuttings for the purpose of increase during spring, such as the *Verbena*, *Petunia*, *Fuchsia*, *Lobelia*, *Coleus*, *Iresine*, *Heliotrope*, *Ageratum*, *Alternanthera*, &c.; therefore, if cuttings of these can be obtained now they should be inserted without delay in pots some 6 in. or 8 in. in diameter, which should be well drained, using a soil composed of about equal parts of river or silver sand and finely-sifted leaf soil, putting in each pot 1 in. or 2 in. of somewhat rough soil upon the Moss which covers the drainage. The pots should then be filled with the prepared soil, and the cuttings inserted, watered, and placed upon cinder ashes in a frame or pit, which should be kept quite close and moist for a few days, and shaded from bright sunshine. When the cuttings are fairly rooted, they should be at once exposed to the open air night and day, when they will become well hardened and robust, and may so remain until there is danger from frost, when they should be placed in a greenhouse or pit during winter, and if introduced into genial warmth in spring, say early during the month of March, they will then produce abundance of cuttings which will root freely, and are much to be preferred to autumn-struck plants for planting in the

flower beds. It may, however, be necessary to observe that such plants as the *Alteranthera*, *Iresine*, and *Coleus*, being somewhat tender, will require to be wintered in a stove temperature. The various sorts of bedding Pelargoniums should all, if possible, be struck early in the autumn, placing four cuttings in a 4-in. pot, and these should be potted off singly in spring. This should be done with all the zonal varieties, and it is more particularly necessary to do so with the variegated zonal or tricolor sorts, which should be strong, well-established plants when turned out, as their development in the flower beds is not so rapid as that of the green-leaved zonals and the various Ivy-leaved sorts, which will generally succeed well if struck as cuttings in 4-in. or 5-in. pots and separated when planted in the flower beds. The various varieties of this section of the Pelargonium family form excellent bedding plants, and do not as yet appear to be appreciated according to their worth or adaptability for this purpose. They, however, form exceedingly effective bedding plants, and are very suitable where the soil is light and dry, and will be found to succeed well during seasons and in situations in which the *Petunia* and *Verbena*, &c., would entirely fail. Among the best bedding varieties in this section of plants are the old crimson Ivy-leaved, the pink-flowering variegated Duke of Edinburgh, Bridal Wreath, the last-named forming one of the most beautiful and effective white beds which can be imagined, together with some other varieties which are hybrids between *P. lateripes* and zonal species, such as *Willis*, *Willis roseum*, *Lady Edith*, and *Dolly Varde*; the last is a variety with beautiful zoned bronzy foliage, and pretty pink-magenta-coloured flowers. Cuttings should also be struck, as soon as they can be obtained, of the more free-growing sorts, such as *petalum elegans* and *L'Elegante*, which are useful for training upon the haandles of rustic baskets or drooping from the sides of vases, &c. Continue to regulate the development of climbing plants of all sorts, such as *Honeysuckles*, *Clematises*, *Tropaeolums*, and similar plants, which are so useful and ornamental when trained in the form of standards and pyramids, &c.

Evergreen hedges that are kept annually trimmed should now be clipped; it will have been necessary to defer this work longer this season than usual, on account of the growth being later than ordinary. Evergreen hedges should never be cut until the summer's growth is completed, which is easily seen by the shoots ceasing to extend further, and the leaves at the extremities attaining their full size and solidity. When cut too early a second growth is made, necessitating a second cutting in the autumn or winter, which tends to increase the weakening influence inseparable from all restriction of growth in the way practised with hedges confined within the usual limits. The management of hedges is often worse than anything connected with a garden. When, as is usual, it is necessary to keep a hedge cut within certain limits as regards height and breadth, the work should be carried out so as to leave it as even as a wall at the top. Nothing is more common in carrying out this kind of work with a hedge in which there are weak places, or where some portions have not attained the full size required, than to see the operator cutting almost as much away from the weak places as he does from the strongest, overlooking the fact that cutting at all makes weak plants of any kind still weaker. There is also a great want of consideration as to the nature of the plants of which a hedge is composed. As a rule, it may be taken that the larger a plant grows if left to itself the less able will it be to bear being kept continually cut in close, yet all plants are not quite alike affected in this way. A Holly hedge will remain for a generation in a healthy state if kept trimmed in to 5 ft. or 6 ft. in height, and something less in diameter, provided it is widest at the bottom and tapers up to the top so as to give the lower portion the advantage of light and air. The continued health of a hedge is more dependent upon the breadth to which it is allowed to grow than the height. A Yew hedge, for instance, will remain in health a long time when kept low if it be allowed sufficient width, whereas if permitted to grow to a height of 10 ft. and kept cut in very thin, the plants get so weak as to barely exist. Hedges consisting of any plant that is deciduous should never be cut in the summer unless they are very strong, as the removal of the shoots before the leaves have fallen off weakens them very much. The boundary hedges, especially in small gardens, are very often spoiled by allowing deciduous trees to grow in them, the roots of which impoverish the soil, and the branches overhang to an extent that renders a healthy condition of the hedge impossible. In most gardens of limited extent a certain amount of privacy is desirable. There is nothing that will afford this and have such a pleasing effect as a close line of Holly allowed to grow upwards, the lower branches being permitted to extend with little cutting. Winter and summer it always looks well, and also affords excellent shelter.

Kitchen Garden.

A little winter Onion seed should be sown; it is better to put some in now, and again in a fortnight's time, than to trust to one sowing; as, in severe winters, the plants from one will frequently succeed when the others fail. Very much depends on the kind of weather prevailing during the autumn, for the young plants of the first sowing will sometimes get a little too large, and in other seasons the second will be too late. Prepare the ground well by deep digging and moderate manuring; sow in rows 1 ft. apart. In very bleak, cold situations the *White Lisbon*, being very hardy, is suitable for sowing; in milder localities, *Giant Rocca* and *Globe Tripoli* are good kinds, both very large. Cut out the flower-stems of *Globe Artichokes* as soon as the heads are gathered; neglect in this matter at this season is often the cause of the plants dying off through the winter. The young growth makes little progress until the old stumps are removed, not having time to get strong enough before autumn. Finish planting late Broccoli and all kinds of winter Greens. Walcheren and

Veitch's Autumn Giant Cauliflowers should also be planted for late autumn use on well-manured land in an open position. Sow a good breadth of Prickly Spinach for standing the winter. Parsley may yet be sown for late spring picking; it will not run to seed quite so soon as that sown earlier. Make a good sowing of Endive, of both the green curled and Batavian varieties for winter. The earliest sown crop will now be full grown, and portions of it should be tied up and blanched in succession. The blanching may easily be effected at this season by covering each plant with an inverted flower-pot, with a bit of Moss twisted into the hole to keep out wet, air, and light. Plants from the successional sowings, now that rain has come, should be planted out on well-prepared land, 1 ft. apart, at intervals of two or three weeks. Chervil is always in request, therefore make a sowing for winter; and when the plants are large enough to prick out fill a box or two with the thinnings to place in a frame for use in bad weather. Provision should also be made to have a supply of Sweet Marjoram in a green state through the winter. This is best done by filling a box or two with the young plants in May and keeping them pinched back, but plants may be lifted now from the border, shortened back, and planted in boxes. It bears forcing well for the production of young green shoots in winter, and as it strikes freely from cuttings in heat if desired, a stock of young plants may be worked up in spring for planting out. Early Horn Carrots may yet be sown to supply small young roots in autumn and winter. The blanching of early Celery usually requires about four or five weeks, and as there is not much chance of watering it effectually after earthing up has commenced, it is better to delay this process till the Celery is nearly fully grown, or till within a month or so of its being required for use; then earth it up the full height at one operation. Ridge Cucumbers will now require a good deal of attention as regards the proper regulation of their growth and pinching out the points of the longest shoots; in all cases mulching should have been resorted to during the late dry weather. The season during which Cucumbers can be successfully grown in the open air in this country is usually a short one, therefore every expedient that has a tendency to make the growth healthy, regular, and continuous should be adopted. Box edgings may still be cut, and advantage should be taken of this change in the weather to have all gravel paths firmly rolled down.

Extracts from my Diary.

Aug. 5.—Sowing Mustard and Cress. Putting in a batch of tricolor Pelargonium cuttings. Clearing off a piece of Turnips and forking the ground; also a piece of Strawberries, and planting the same with Coleworts and Conve Tronchuda Cabbage that have been previously transplanted. Tying Raspberry canes temporarily up to prevent the wind from blowing them about.

Aug. 6.—Sowing Chirk Castle Black Stone Turnips. Putting in Crystal Palace Gem and Ivy-leaved Pelargoniums. Lifting a piece of Gloucester Kidney Potatoes for seed. Planting a small border with Leeks. Staking William I. and Laxton's Unique Peas. Looking over Peaches and Nectarines, and removing ties, nails, &c., where not required. Thinning Turnips and Spinach. Cutting Laurels overhanging walks. Turning manure for Mushrooms.

Aug. 7.—Planting a border with Endive and Lettaces; also Savoy for small green heads, and planting out the last batch of Melons. Putting cuttings of Viola Blue Perfection and Golden Gem under hand-lights. Layering Strawberry runners on square pieces of turf, in order to obtain plants for a new plantation. Thinning, weeding, and hoeing Turnips. Pruning Apple and Pear trees.

Aug. 8.—Sowing Early White Naples, Giant Rocca, and Giant White Tripoli Onions for spring use; also Fraser's Broad-leaved and Green-cried Endive in well-watered ground. Putting in cuttings of Colens and Centaurea. Potting Campanula pyramidalis and also C. calycanthema. Stopping shoots of Tomatoes and exposing the fruit to the full force of the sun. Digging heavily-manured ground for Endive and Lettaces. Lifting Porter's Excelsior and Scilly Red Potatoes. Watering Peach houses and late Vinery borders.

Aug. 9.—Sowing Early London, Large Asiatic, Walcheren and Veitch's Autumn Giant Cauliflowers. Potting Queen Pines in peat, loam, and rich bones, emptying the pit and re-arranging the plants. Earthing up Celery, Cardoons, and Leeks. Hoeing amongst Gooseberries and Currants. Gathering Green Gage Plums for preserving. Watering part of the Pines; also Celery and Cabbage plants.

Aug. 10.—Sowing a few pots of Mignonetta; also a border of Turnip Radish. Clearing off Peas that have ceased bearing. Picking over and weeding carpet beds. Fruit in use for dessert: Pines, Melons, Grapes, Figs, Plums, Cherries, Pears, Apples, Gooseberries, and Currants.—W. G. P., Dorset.

Seedling Poppies.—For some years past the yellow Alpine Poppy has seeded freely with me, and latterly the white and the deep orange less freely. Can any of your readers tell me if the latter be a distinct plant? as I have repeatedly, with great care, saved the seed of the orange, and have always found the majority of the seedlings to be of different shades of yellow, and only exceptionally the real deep orange. I almost doubt if the white comes always white. The old plants in my stiff soil seldom survive, but the self-sown plants are lovely from May till autumn. I have been which work freely among my Poppies.—J. R. Droop, Stamford Hill.

GARDEN BOTANY.

(Continued from p. 84.)

VARIATIONS IN THE STRUCTURE AND INSERTION OF THE ANTHER.
—We have stated that the number of cells in the anther is usually two, rarely one or three or four. One family, the Malvaceæ, is characterised by having invariably one-celled

Fig. 387.—One-celled versatile anther of *Moringa*.

Fig. 388.—Reniform anther of Ground Ivy finally one-celled by the fusion of the two original cells.

Fig. 389.—Stamen of *Iris* with two nearly parallel cells dehiscing by longitudinal slits.

anthers; and there are instances of it in other families. The genus *Moringa* (fig. 387), which of itself constitutes a family, has also normally one-celled anthers. Originally two-celled

Fig. 390.—Flowers of *Ephedra altissima*, showing the four-celled anthers.

Fig. 391.—Androecium of a *Laurineæ* with four-celled stamens opening by as many reflexed valves.

anthers sometimes become one-celled by the fusion of the two cells (fig. 388). Four-celled anthers are common in the *Laurineæ* (fig. 391); and the anthers of *Ephedra* (fig. 390) have

Fig. 392.—Stamen of *Monimia*, dehiscing by two recurved valves.

Fig. 393.—Stamen of *Azulea*, dehiscing by two apical pores.

Fig. 394.—Front and back views of a stamen of *Achemilla*, which dehisces transversely.

been described by different writers as one, two, and four-celled. Duchartre describes them as one—four-celled. When the pollen is mature, the anthers open, or dehiscence, to allow it to escape. The dehiscence is by longitudinal slits (fig. 389), by transverse fissures (figs. 394 and 395), by apical orifices (pores—fig. 393), or by recurved valves (figs. 391 and 392). The anthers of the *Laurineæ* and *Berberis* dehiscence by recurved valves; of the *Ericaceæ* by apical pores; and of the great ma-

jority of plants by longitudinal slits. The side of the anther towards the pistil is called the face, and the side next to the petals the back. When the dehiscence is down the face, it is

Fig. 395.—Front and back views of a stamen of *Mercurialis*, with globular cells. Fig. 396.—Stamens with united (syngenesous) anthers, as in almost all the *Compositae*. Fig. 397.—Corolla of *Sideritis perfoliata* cut open to show the didynamous epipetalous stamens.

termed introrse; when down the back, extrorse; and when at the sides, lateral. Anthers are free from each other and from other organs, or they cohere and form a tube around the style,

NUMBER AND INSERTION OF THE STAMENS.—In the paragraph treating of the insertion of the petals will be found definitions of the terms hypogynous, perigynous, and epigynous, which terms are also applicable to the insertion of stamens; and we have only to add that when the stamens adhere to the corolla, they are termed epipetalous (fig. 397). The stamens of most gamopetalous flowers are epipetalous; whereas, there is seldom adhesion between petals and stamens in polypetalous flowers, or it is very slight. The number of stamens in each flower

Fig. 404.—Flower of *Hypericum*, showing triadelphous stamens. Fig. 405.—Flower of *Sparmannia africana*, with tetradelphous stamens.

varies in different plants from one to very many. When the number does not exceed ten or twelve, it is, to all intents and purposes, constant in the same species; though when above that number, the absolute number is liable to fluctuate. To indicate the number of stamens, the term andros is employed in connection with the following Greek prefixes:—

	No. of Stamens.	Examples.
Mon-androus	1	Lemna, <i>Centranthus</i> .
Di-	2	<i>Veronica</i> , <i>Ligustrum</i> .
Tri-	3	Grasses, <i>Iris</i> .
Tetr-	4	<i>Cornus</i> , <i>Linnaea</i> .
Pent-	5	A vast number of plants.
Hex-	6	<i>Liliacæ</i> , <i>Berberis</i> .
Hept-	7	<i>Trientalis</i> .
Oct-	8	<i>Daphne</i> , <i>Fuchsia</i> .
Enne-	9	<i>Butomus umbellatus</i> .
Dec-	10	<i>Rhododendron</i> .
Poly-	more than 10	<i>Papaver</i> , <i>Rubus</i> .

The prefix poly here signifies that the number is above ten, but when coupled with sepalous or petalous, it simply indicates that there is no cohesion, regardless of number. When the number of stamens exceeds ten, they are indefinite; when ten or fewer, definite. Indefinite stamens are extremely rare in the gamopetalous natural orders. *Styrax* and some of the *Sapotacæ* are nearly the only examples of gamopetalous flowers

Fig. 398.—Polyandrous flower of *Tetragonia expansa*. Fig. 399.—Monadelphous stamens of *Eschynomene*. Fig. 400.—Monadelphous stamens of *Erythroxyton Coca*.

as in nearly all the *Compositæ* (fig. 396); or they adhere to the pistil, as in the *Orchidææ*. When the anthers are united

Fig. 406.—Flower of *Eurycles*. Fig. 407.—Longitudinal section of a flower of *Eurycles*, showing the monadelphous stamens, the tube of which adheres to the perianth.

having very numerous stamens, but the cohesion of the petals is very slight.

Fig. 401.—Flower of *Orange*, with monadelphous stamens. Fig. 402.—Diadelphous stamens of *Kidney Bean*. Fig. 403.—A flower of *Hypericum ægyptiacum*, with triadelphous stamens.

as in the *Compositææ*, they are syngenesious; when the stamens are confluent with pistil, they are gynandrous.

VARIATIONS OF THE FILAMENT.—These are innumerable, and therefore it will be sufficient to point out two or three of the more striking forms. In the *Rhododendron* and some *Fuchsias* they are very long and slender (filiform); in the *Barberry* they are thick and fleshy; and in the *Sweet Bay* they are furnished with two glandular appendages near the base. The union of the filaments in one or more groups or clusters is a character not to be overlooked. When they all cohere together they are

monadelphous; they form a closed tube, as in the Orange (fig. 401) and *Erythroxylo* (fig. 400), or the continuity of the union is broken down the posterior side, as in many Leguminosæ (fig. 399). In a very large number of the family just mentioned the stamens are diadelphous; nine of them cohere

Fig. 408.—Tetradyname stamens of *Sterigma sulphureum*.

Fig. 409.—Tetradyname stamens of *Anthonium Billardieri*.

Fig. 410.—Flower of *Oxalis Deppei*, with ten stamens, five of which are shorter than the others.

by their filaments, whilst the tenth and posterior one is free (fig. 402). Some species of *Hypericum* have triadelphous stamens (figs. 403 and 404), whilst others (for example, *H. Androsæmum*) have them pentadelphous, or in five clusters; and in *Sparmannia africana* (fig. 405) they are tetradelphous. When the number of clusters of stamens exceeds five, they are denominated polyadelphous. In *Euryclæ* (fig. 407) the stamens

Fig. 411.—Androecium of *Hugonia*; 10 stamens alternately long and short.

Fig. 412.—Androecium of *Humiria*; 20 stamens of four different heights.

Fig. 413.—Diagram of the flower of *Humiria*; the stamens in one whorl.

are monadelphous and adhere to the perianth, and the tube is lobed between the anthers.

RELATIVE HEIGHT OF THE STAMENS.—Stamens are of equal height or length, or they vary in this respect. In the bilabiate corolla there are usually two pairs of stamens, one pair longer than the other (fig. 397), and they are termed didynamous.

Fig. 414.—Diagram of the flower of the Winter Aconite (*Eranthis*); petals in two series; stamens numerous in many whorls.

Fig. 415.—Diagram of the flower of *Valerianella Cornucopia*; stamens two.

There are six stamens associated with the cruciform corolla, two of which are shorter than the others (figs. 408 and 409), or what is called tetradyname. Frequently the stamens are double the number of petals or lobes of the corolla—for example, *Oxalis* (fig. 410) and *Hugonia* (fig. 411). *Humiria* (fig. 412) has twenty stamens alternately of four different heights.

POSITION AND NUMBER OF THE STAMENS WITH REFERENCE TO THE OTHER PARTS OF THE FLOWER.—The number of sepals,

petals, stamens, and carpels of a flower may be the same, when the flower is isomerous, but it frequently happens, as we have already shown, that they are unequal in number, or anisomerous. The calyx and corolla generally have the same number of parts, and it is the stamens and carpels that usually differ in number from the floral envelopes. *Humiria* (fig. 413) has five sepals, five petals, and twenty stamens all in one whorl. The Winter Aconite (fig. 414) has very numerous stamens in several whorls. Sometimes the number of stamens in otherwise closely allied plants is different. The Valerianæ offer an

Fig. 416.—Diagram of *Valeriana*; three stamens and five petals.

Fig. 417.—Diagram of the flower of *Monsonia* (*Geraniaceæ*); fifteen stamens in two whorls, the outer whorl containing ten.

illustration of this. A theoretical diagram would show five stamens, but on account of the suppression of some of them, a real diagram gives a smaller number: thus, *Centranthus ruber* only one, *Valerianella* (fig. 415) only two, and *Valeriana* (fig. 416) three. *Monsonia* (fig. 417) has five petals and fifteen stamens in two whorls; ten in the outer and five in the inner. The Flowering Rush (fig. 418) is the only British plant having nine stamens, and these are in a single whorl and associated with a six-leaved perianth. *Anchusa* (fig. 419) and *Hermannia* (fig. 420) have both five petals and five stamens; in the former

Fig. 418.—Diagram of the flower of the flowering Rush (*Butomus*); stamens nine.

Fig. 419.—Diagram of the flower of *Anchusa italica*; stamens five, alternate with the petals.

the stamens alternate with the petals, whilst in the latter they are superposed to the petals. The flower of *Hermannia* is isomerous and *Anchusa* anisomerous, as there are only four carpels in the gynœcium.

W. B. HEMSLEY.

Market Gardeners' Waggons.—It is surprising that the attention of the medical journals has never been called to the manner in which vegetables are conveyed to market. We have frequently to pass through Covent Garden, and a sight of the waggons in which the produce is brought there is enough to produce nausea. They are, without exception, all used on the return journey for the conveyance of manure and all kinds of filth to the garden ground. This idea would not be pleasant even if the vehicles underwent a thorough cleansing after each journey; but this is never done, and it is quite a common thing to see a load of Lettices or spring Onions—esculents not cleansed by boiling before being eaten, like Turnips or Cabbages—put in a waggon of the most filthy description. The danger to health of these doings speaks for itself, and we trust that the "Lancet" or THE GARDEN may take the matter up, and in the meantime we will make a note of a few of the names of the chief offenders.—"Weekly Times." [Attention has already been directed in THE GARDEN to this matter (see Vol. IV., p. 142); but the evil still exists, and will continue to do so, we suppose, until market gardeners see it to be to their interest to stop it.]

THE FRUIT GARDEN.

BEST BEARING APPLES AND PEARS.

IN looking over the report of the fruit crops given in THE GARDEN (see p. 39) one is struck by the frequency with which the names of certain kinds of Apples and Pears occur as carrying good crops of fruit in all kinds of soils or situations, and we have attempted to summarise the list roughly, just to see what sorts are the most eligible for general planting. It will be remembered that last summer and autumn was very unfavourable to the ripening of the wood, and poor crops were predicted in consequence, and in many cases also the weather was severe when the trees were in flower. The names of those kinds, therefore, that have passed through these vicissitudes are worth noting by those who contemplate the culture of the Apple and the Pear. Both Apples and Pears, it may be stated, blossomed freely; but, owing to the immature growth last year, and the frosts in spring, much of the fruit failed to set, or it dropped afterwards. Taking the report as it is arranged, let us begin with the metropolitan and south-eastern division. The names of the Apples which are mentioned in this division are, first, Lord Suffield and the Codlins, which appear to have missed nowhere. The next best are Hawthornden, Blenheim Pippin, King of the Pippins, Wellington, Cox's Orange Pippin, Yorkshire Greening, Ecklinville Seedling, Northern Greening, and Alfriston. Pears are the Hazel, Comte de Lamy, Hacon's Incomparable, Marie Louise, Beurré d'Amanlis, Seckle, Duchesse d'Angoulême, Beurré Hardy, Ne Plus Meuris, Althorp Crassane, Louise Bonne, Beurré Diel, Jargonelle, Glou Morceau, and Josephine de Malines. These sorts are spoken of by several correspondents as bearing the best crops. In the south-midland division the best bearers are again Lord Suffield, all the Codlins, Stirling Castle, Blenheim Pippin, Wellington, Blenheim Orange, Royal Pearmain, Hawthornden, Sturmer Pippin, Bess Pool, Red Quarrenden, Royal Russet, Scarlet Pearmain, Ribston Pippin, and Waltham Abbey Seedling. Pears: Marie Louise, Glou Morceau, Duchesse d'Angoulême, Jargonelle, Ne Plus Meuris, Beurré Rance, Beurré d'Aremberg, Beurré Superfin, Louise Bonne, Seckle, Hazel, Easter Beurré, Williams' Bon Chrétien. Next come the west-midland division, including Great Malvern, Bristol, Stourport, Tamworth, and Ledbury, &c. In nearly all the reports we again find Lord Suffield, Manks and Keswick Codlins, Hawthornden, Ecklinville, Blenheim Orange, and Stirling Castle Apples to the front, followed by Yorkshire Greening, Warner's King, Cox's Pomona, Lord Grosvenor (the latter spoken of as being exceptionally fine), Sturmer Pippin, Winter Pearmain, Tower of Glamis, Tom Putt, Cellini, Red Astrachan, and Ribston. In some districts Cellini is spoken of as an Apple which never misses a crop. Pears consist of Knight's Monarch, Glou Morceau, Duchesse d'Angoulême, Beurré Superfin, Marie Louise, Beurré Diel, B. Rance, Louise Bonne, Gansel's Bergamot, Althorp Crassane, Beurré d'Amanlis, B. Clairgeau, Seckle, and Williams' Bon Chrétien.

The north-midland division includes part of Notts, Derby, and Lincoln. The names of the good bearing Apples and Pears given are, with few additions and exceptions, exactly the same as those already recorded in the other divisions—Hawthornden, Lord Suffield, Cellini, Sturmer Pippin, Irish Peach, King of the Pippins, Margil, Scarlet Nonpareil, Cox's Pomona, and Rosemary Russet being mentioned as "fail-me-nevers" in bad seasons. From Sherborne Castle, in the south-western division, the report says that Pears are a failure, with the exception of Easter Beurré, Passe Colmar, Glou Morceau, Ne Plus Meuris, Beurré de Capiaumont, Jargonelle, and Marie Louise, on walls. At Carclew, in Cornwall (same division), on an unsuitable and shallow soil, the following Apples are said to do best: King of the Pippins, Oslin, Braddick's Nonpareil, York Pippin, Blenheim Orange, Golden Harvey, Boston Russet, Adams' Pearmain, Keswick Codlin, and Hawthornden. Beurré Clairgeau, Marie Louise, Gansel's Bergamot, Beurré Diel, and Duchesse d'Angoulême in the same district are mentioned as the best Pears. The north-western division includes the Manchester district, Crewe, Chester, Grantham, Liverpool, and Wigan. From these districts the lists are again nearly the same as those already given. Lancashire reports speak

particularly of the Irish Peach, Lord Suffield, Keswick Codlin, and Cellini Apples as being the most reliable kinds. Mr. Ingram, of Belvoir, Leicestershire, refers specially to the Northern Greening as a constant bearer, the King of the Pippins as being very prolific, and the Yorkshire Greening and Frogmore Prolific as unailing. The best Pears generally are Marie Louise, Louise Bonne, Beurré Diel, Passe Colmar, Glou Morceau, Winter Nelis, Williams' Bon Chrétien, and Beurré d'Aremberg. Turning to the eastern district, including Bury St. Edmunds, Norwich, Ipswich, and Saffron Walden, we find that severe frosts about the beginning of April did much mischief in some places, proving fatal in a great measure to the Apple and Pear crops. Among Apples which had to some extent escaped, and which are bearing crops, the following are mentioned: Keswick Codlin, Kerry Pippin, Warner's King, New Hawthornden, and Cellioi. Apples on cordons and protected while in flower: Lord Suffield, Nelson's Glory, Tower of Glamis, Red Astrachan, Ribston Pippin, and Cox's Orange Pippin. Pears: Williams' Bon Chrétien, Comte de Lamy, Beurré Bosc, Josephine de Malines, Jersey Gratiote, Beurré Clairgeau, Marie Louise, Glou Morceau, and Louise Bonne. Coming to Yorkshire, embracing an extensive tract of country from the neighbourhood of Nottingham to the borders of Durham, we find the following Apples and Pears only mentioned as good: Keswick and Manks Codlins, Lord Suffield, Lord Nelson, Hawthornden, Ribston Pippin, Cox's Orange Pippin, Warner's King, and Cockpit. Pears in some places are good, especially Marie Louise, Beurré Diel, Winter Nelis, Glou Morceau, and Beurré d'Aremberg.

From Durham, or northern division, we have reports of light crops of both Apples and Pears, which is attributed chiefly to late frosts and unfavourable weather when the trees were in flower. The kinds spoken of as bearing crops are—Apples: Ribston Pippin, Mannington's Pearmain, Scarlet Nonpareil, Boston Russet, Magnum Bonum, Keswick Codlin, Rymer, Lord Suffield, Blenheim Orange, Cockle Pippin, Claygate Pearmain, King of the Pippins, and Hawthornden. Pears: Easter Beurre, Jargonelle, Hazel, Green Yair, Louise Bonne, Althorp Crassane, Beurre de Capiaumont, Vicar of Winkfield, Beurré Superfin, and Comte de Lamy. What cannot fail to strike any one who reads over the list just given is the occurrence of the same names of Apples and Pears, with few variations, in nearly all the districts between Cornwall and the northern borders of England. The situations, as regards soil and climate and other conditions, in which they are found, must differ greatly; but, contrary to our expectations, we find that the varieties of the Apple and Pear which have done best in all the districts are nearly the same. Another thing: they are mostly all good old sorts, and many of the varieties, of the Apples especially, are among the hardiest kinds. Many varieties of the Pear did not bloom at all—doubtless owing to the unfavourable season—last year; and, if a list of these had been furnished, they would doubtless have been found to be the same generally all over the country. What the reports show more clearly, perhaps, than anything else is that the Apple and Pear thrive pretty well in all parts of England, and on soils of the most varied descriptions; and that what we have to fear chiefly is the weather—the occurrence of cold and wet seasons on the one hand, when the growth fails to get properly matured, and spring frosts about the time when the trees are in flower on the other.—"Field."

FRUIT GROWING IN ITALY.

THAT good fruit can be grown in Italy has been fully proved by the beautiful display of Apples and Pears made by Signor Francesco Cirio, of Turin, at a meeting of the French Société Centrale d'Horticulture held at the beginning of last May. With a few exceptions, the fruit exhibited were distinguished by local names; the different varieties were therefore somewhat difficult to distinguish. Some of them, however, have kept their real names, such as the Calville and Canada Reinette Apple, and the St. Germain and Martin Sec Pear. The whole of the fruit exhibited was grown on untrained trees in the open ground, trained fruit trees of any form being very rare in Italy. The specimens were remarkably well preserved, considering the advanced period of

the year at which they were shown. According to the account given by Signor Cirio to the Committee of Arboriculture, it consists in placing the fruit in dark, well-ventilated cellars, or indeed in any very dry place from which the light has been shut out. They may be piled in layers not exceeding 10 in. in depth. The fruit intended to be preserved should be gathered as late as possible, being allowed to remain on the trees till the month of November. It seems that, by gathering them so late in the season, they keep better than if plucked at an earlier period. The process is carried on by Signor Cirio on an extensive scale, and a large amount of business is done by him in this direction both by home and foreign fruit-sellers. In the Italian section of the Universal Exhibition in the Champ de Mars Signor Cirio exhibits several large cases of Apples and Pears preserved according to this method. The quality of the fruit shown by Signor Cirio was acknowledged to be excellent. Amongst them were several specimens of the St. Germain Pear, which had thoroughly preserved the whole of its characteristic merits at even so advanced a period of the season as the beginning of May. Signor Cirio also exhibited preserved Peaches of good quality of the Pavie variety, the flesh of which, however, adheres strongly to the stone, although it is exceedingly sweet and agreeable to both palate and smell. These preserves can be sold in Paris at 1s. 5d. per kilogram, about 7½d. per lb., each kilogram containing twelve Peaches. Amongst other fruits in Signor Cirio's collection, says the secretary of the Committee of Arboriculture, are two varieties of Chestnuts, one of which, when once cooked, may be kept in a perfect condition for two or three years. There is also a variety of Apple which has been kept in water for three months, the flesh of which has become converted into a kind of jam, which, although somewhat recalling the flavour of a sleepy Pear, is still quite eatable. The Committee of Arboriculture awarded Signor Cirio a first class prize with an expression of regret that, in consequence of a rule of the Society, they could not recommend the exhibitor for a reward of a higher order. In the cases shown by Signor Cirio at the International Exhibition there are specimens of other fruits both in the natural and preserved condition. Amongst them are some Tomatoes grown last year, but which are still perfectly fresh, although the only treatment they have received has been to suspend them in a dark, dry room. Signor Cirio's principal customer seems to be Germany, who took 552 railway vansful last year, Austria following with 405, and France with only 7.

C. W. QUIN.

HELPS DURING THE FRUIT HARVEST.

THE old practice of clubbing the trees, to make them give up—or rather down—their fruit, is well nigh a thing of the past. When it is shown that the careful handling of fruit actually pays in dollars, people learn, though slowly, to adopt better methods. Picking by hand has generally taken the place of shaking and beating the trees. In picking, ladders are needed, and for all trees of moderate size some form of the step-ladder is preferable to any other. The accompanying (fig. 1) is a sketch of a home-made ladder, which is found to be useful in the orchard. A ladder similar to this, in having but one upright, has long been in use in Europe, but this is much simpler, and may be made by almost anyone. A pole of the desired length is split at its lower end, and furnished with rungs, reaching between the two parts below, and passing through the unsplit portion above. The pole may be of any green wood that will split readily, but the rungs should be of tough, well-seasoned wood, and 1½ in. through. We would suggest that an iron ring be placed upon the pole, or a bolt be put through, at the point where the split terminates. A ladder of this kind is much more easily placed in the branches of a tree than one of the common form, and, being so wide at the base, will stand more firmly, especially on uneven ground.

An orchard hook will sometimes be found convenient. This, as shown in fig. 2, is a wooden rod with an iron hook at one end. A piece of wood a few inches in length slides upon the rod, and has a strong peg near the end. By placing the hook over a branch it may be drawn near to the picker, who catches the sliding piece under a lower branch, pushing the piece along the rod as may be necessary; the pressure coming upon the peg, the sliding piece is held by the side-wise strain and cannot slip. By the use of this, the picker can often avoid moving his ladder in order to reach the fruit, and it leaves both his hands free.

Fruit pickers have been invented in great numbers, and the amount of ingenuity expended upon them is all out of proportion to

their real usefulness. Some are made to cut, and others to pull off the fruit; some catch the fruit in a little bag at the upper end of the affair, and others let it run down through a long sleeve into the band or basket, and so on in great variety. Still, where fruit is upon a slender branch—and the finest specimens are often provokingly out of reach—some help of this kind comes in play, but in picking for market they make too slow work. We have seen a very effective

Fig. 1.—Orchard ladder.

picker extemporised in a few minutes. An old fruit can had a long V-shaped notch cut in the side; by means of a large-headed nail put through the bottom the can was made fast to the end of a pole; a handful of Grass put into the can made the picker complete. The stem of the fruit being caught in the notch, it readily parted from the tree, and the Grass prevented all bruising. The following is an illustration of an implement called a "jack-knife picker," because a

Fig. 2.—Branch-hook.

Fig. 3.—Fruit-gatherer.

man or boy can readily make one with his pocket-knife. The engraving (fig. 3) will show how it is constructed. A light lath, or other strip, ½ in. by 1½ in., and about 10 ft. long, is fitted with a projecting piece at the end; a lever, also curved at one end, passes through the long strip near the top, and is provided with a spring of hoop-spring wire to keep it open. The lever is worked by a stout cord, such as a fishing-line, which is attached to one end, passes through the pole, down through another hole, and attached to one

end of a lever which is at the lower part of the lath. By depressing this lower lever the cord moves the upper one, and it is made to grasp a Pear or other fruit, pick it, and hold it until it is placed in a basket, which, for convenience, should be placed as far off from the operator as the length of the picker. We would suggest that much friction on the cord would be avoided by running it through a couple of screw-eyes screwed into the lath.

Baskets used in picking should be of medium size, as the larger the basket, the greater the risk of bruising its contents. Some orchardists have them small enough to be turned inside of a barrel, so that when filled they may be emptied into the barrel in such a manner as to allow the fruit to roll out gently rather than to fall from the top of the barrel. It is convenient to have the handles furnished with hooks, by which they can be hung to a branch; these should have a ring at one end large enough to allow it to slip along on the handle, and so closed that it will not drop off the hook and be lost. It is sometimes convenient to hang the basket to a strap, which passes over one shoulder.—“American Agriculturist.”

FRUITLESS!

(A Groan from SUSAN GINGHAM.)

“The extraordinary fecundity of the United States in the matter of fruit is proverbial; but it may not be generally known that 3,000,000 Peach trees bloom every spring on the sunny plains between the Delaware and Chesapeake Bays. The details of the American fruit crop almost savour of romance. The Apple crop of the country is past counting; the surplus fruit, if properly saved, would keep all Europe in table luxuries. The birds on New Hampshire hills are feasted with Raspberries, the mountains of North Carolina and Tennessee are purple with Blackberries which go to waste; and the time has been when an extra good crop of Peaches in Delaware has meant a million baskets of fruit untouched upon the trees.”—“Standard.”

MR. PUNCH,

This startling extract, which I venture to enclose, Tom, my nephew, read out loud, in aggerawation, I suppose. I was picking a few Gooseberries, with a eye to jam, and he said he thought it aperyco—whatever that may chance to be.

Which I call it downright riling. Gracious goodness! here am I paying sech a price for fruit as is enough a saint to try, while in Delaware by millions Peaches waste upon the trees, and on the New Hampshire hills the birds eats as much fruit as they please.

Well, them Yanks is precious lucky. Things in England is gone queer.

Fruits with us ain't wot they was, but mostly poor, and likewise dear.

Wot with blights and sopping summers, big jam makers, and them clubs,

Little fruit we gets, and wot we do is windfalls, specks, and sorubs.

Storberries ain't got no sweetness; as for Apples, bless yer 'art, Not one sample in a dozen 's fit for pudden or for tart; For Cherries they're all skin and stone, and as for Ribeting Apples, lor!

They're like good Cheshire cheese, a pleasink mem'ry, and no more.

True, there's lots of rum new-fangled things as they call foren fruits,

Eatin' like raw Scarlet Runners, or as tough as Rhubarb roots, Prickly Pears and them Bananas, tasting jest like sweetened soap, But you won't find British housewives cottoning to sech, I hope.

England's fruits was England's pride, and 'ome-made jam our bones-hold boast;

O the rare tucks-out I've had of Gooseberry-fool and buttered toast! Then the jars of Raspberry jam—but there, it doesn't bear a thought. If there'e any Raspberries grow'd they're all by Crosse and Black-well bonight.

Them shop jams is hatter 'umbig; but we never has no sun, And the fraiting eason's over most afore it seems begun. Tom declares Pomoner's cat us; wot he means I do not know, But I'm s're our fruits to-day ain't like the fruits of long ago.

Apples! Wy, the shams we gets is jest heartbreaking. I believe If they'd grow'd like that at fast, one never would have tempted Eve;

Which I've always felt conwinned the fruit as caused that fatal slippin'

Mast a' bin that British pride, a regular good old Ribeting Pippin!

Haven't seen one not for years, the fraiterers say they're dying out. Wy the dickens did they let 'em? Wot must they have bin about?

Now we've nowt but measley windfalls, tasteless and but seldom sound,

Sold in open shops by Jews, and, like Pertaters, by the pound.

Then to read about them Yankees, with their splendid Apple crop, Their three million blooming Peach trees, and—but there I'd better stop!

Which I'm a patriot, I 'ope, but a turn in Tennessee

Would, I fear, make half a Yankee of

Yours sadly,

—“Punch.”

SUSAN G.

FRUIT CROPS IN WORCESTERSHIRE.

I AM sorry on the whole to have to make an unfavourable report as to the fruit crops in this neighbourhood. The blossom on nearly all kinds of fruit was profuse, that of the Pear, perhaps, being the greatest exception; but it is rather a remarkable fact that, considering the scarcity of Pear bloom, Pears have set more fruit in proportion to the bloom than any other fruit. The Apple bloom was abundant, and till the cold weather and continuous rains in April and May the crop promised to be one of the greatest on record; but the fruit failed to set in any quantity, and a great portion of that which did set afterwards dropped, so that the Apple crop, for the most part, may be considered a great failure. There are, of course, some few exceptions on heavier soils and in sheltered situations. Plums set a large crop, but during the recent dry weather a great portion of the crop has fallen. There will upon the whole, however, be a larger crop of Plums than of any other fruit. The Pears which carry anything like a crop are chiefly Bon Chretien, Louise Bonne of Jersey, Beurré d'Aremberg, Beurré Diel, Beurré d'Anjou, Easter Beurré, and Beurré d'Esperen; whilst Beurré Superfin, Doyenné du Comice, Comte de Lamy, Marie Louise, and some others have only a very small crop. Amongst Apples, Small's Admirable again bears the palm; but there are small crops of Lord Suffield, Keswick Codlin, Blenheim Orange, Cox's Orange, Ribston Pippin, Melon Apple, and Dumelow's Seedling. Perhaps the best crops out of some fifty varieties are Small's Admirable, Cox's Orange Pippin, Melon Apple, Lord Suffield, and Dumelow's Seedling. Of Plums, Rivers' Early Prolific, Victoria, Pershore, and Mitchelson's bear the largest crops. Protected trees on walls of all kinds are in tolerably full bearing, but the same cannot be said of Peaches and Nectarines, which, despite the greatest care as to covering, are but a very slender crop. The Peaches doing best are Early Rivers, Alexandra, Noblesse, Bellegarde, and Princess of Wales. The Nectarine crop is very meagre indeed, and scarcely any sorts that I could particularise are doing well. Aphis blight has prevailed to a great extent on these and most other kinds of fruits—on Plums equally so with Peaches and Nectarines. Apricots are a moderate crop, but the fruit is dropping fast, and, unless rain soon comes, most of the fruit of all kinds will fall, and what remains will be very small and ill-shaped. Gooseberries are a partial crop, and for the most part very scarce. Currants (Red and Black) are abundant and fine. Lee's Prolific Black Currant still holds its own as a great improvement as to sweetness and flavour. Raspberries here are doing well, but the crop generally is under the average. Strawberries have been plentiful, but the season the shortest I ever recollect—ripening commenced about the 16th of June, and now (July 18) the season is nearly over, the earliest to ripen being Amy Robsart, Hundredfold, Early Prolific, and Early Crimson Pine, and the latest now remaining being Mrs. Laxton, Excelsior, and Bonny Lass. The first of them (Mrs. Laxton) will be a valuable addition to the latest sorts, being very late and of delicious flavour. Filberts are scarce. Cherries have been greedily devoured by the birds, and it seems useless to grow them out-of-doors—even Kentish and Morellos sharing the same fate during the hot, dry weather. The soil here and in this neighbourhood is light, on a gravelly subsoil.

W. RODEN.

Fruit Crops in Caithness.—In your notices of the fruit crops throughout the country I see no mention made of those in Caithness, where I have been lately. Both Apples and Pears are very fair crops, and Gooseberries are something extraordinary, both in Caithness and in the northern parts of Sutherlandshire. At Stangergill, the residence of Mr. James Traill, within ten miles of John o' Groats, Gooseberry bushes were when I saw them (June 20) being propped up to keep them from being broken down by the enormous crop which they were carrying.—J. DOWNIE, *Pink Hill Nursery, Corstorphine.*

Apple Mildew.—At the sitting of the French Academy of Sciences, on July 8, it was announced that the Paradise Apple crops of the present year are severely attacked by some peculiar disease, chiefly characterised externally by a whitish efflorescence upon them.

An opinion was hazarded by M. Dumas that this appearance might be attributable to Oidium, and that the disease would give way to the sulphur treatment so successful in the Oidium of the Vine. MM. Decaisne and Duchartre were deputed to make a special study of the disease, and report upon it as soon as practicable.

SUMMER PRUNING FRUIT TREES.

If we examine closely about this season any healthy Apple or Pear tree, or indeed any other kind of fruit tree that carries its fruit for the most part on spurs, we shall find no difficulty in identifying the short stout spurs within whose plump terminal buds are folded up the embryo crop of next year. In a free-bearing tree they will be found on the main branches as well as on the younger wood, and they usually vary from $\frac{1}{2}$ in. to 1 in. in length. Some kinds of Pears, such as Marie Louise, bear on much longer spurs than others; but they are exceptions to the general rule. Usually the leaves on the young branches of fruit trees are placed alternately; but round the points of the fruit buds some five or six leaves are gathered into a sort of whorl or cluster, as if for the double purpose of supplying nourishment and protection. Now, I think it must be obvious that next year's crop must in a great measure depend upon these embryo fruit-buds reaching a proper state of development and maturation. In maintaining the balance of power that exists in fruit trees, the main factor in the cultivator's hands is the manipulation of the growth in summer. By stopping the young growth, or by thinning crowded shoots, he can let in floods of sunshine and currents of air, to impart strength and substance to the foliage surrounding the fruit-buds, that will not be without influence upon next year's crop. Many blossoms in a tree crowded with wood and foliage never attain the strength necessary to bring forth perfect fruit, because of imperfect development due to want of exposure to sun and air this season. This fact, then, alone should be sufficient argument in favour of the proper thinning and shortening back of the young shoots made in summer by all fruit trees planted in situations where they must necessarily be trained or restricted. All good cultivators acknowledge that the principal part of the pruning, so far as it is likely to react upon the roots, and consequently upon the tree's healthy development, should be done in summer. Of course it does not follow that all increase of size should be severely checked; on the contrary, a moderate and steady increase in size should be encouraged. Summer pruning may be—indeed, often is—carried too far. There must be sufficient young wood left in all trees to promote a healthy circulation. To permit a rapid extension in spring and then to trim it all off at once, as is too commonly done, is wrong in principle, no matter whether the operation be performed in July or delayed till winter. In the former case the sudden removal of the outlets for the sap may, and in many cases will, excite the embryo fruit-buds to break into growth, and thus prevent, for this year at least, all possibility of their maturation. More mischief is done in this way than is commonly supposed, though it will be easily understood that, if during the steady process of building up the fruit-buds any sudden pressure of sap takes place at a critical moment, the buds may be pushed into growth prematurely. It is easy enough to lay down a general rule for the performance of any given operation, but it is not wise in all cases to follow it, as much depends upon soil, situation, and the habit and constitution of the different subjects operated upon. But this much may be said: in no case should the young shoots, termed leaders, be shortened till autumn; nor yet any others which it may be necessary to leave to fill up vacancies, so as to make the tree perfect in shape. Leaving those terminal shoots unstoppered will greatly aid the roots by promoting regular, steady, reciprocal action all through the various parts and organs of the tree. From the first week in June till the beginning of August is the best time for the thinning out or removal of summer growths; and this space of time will give sufficient latitude for the due encouragement of the weakly growers, or for the timely repression of those which are betraying a tendency to a dangerous degree of vigour. In cutting back the young wood a medium course should be pursued, not cutting so close as to cause the production of an inordinate amount of breast wood later on; nor yet leaving the spurs so long as to defeat one of the objects which we have in view, viz., converting them into fruit spurs in some future year. Usually the safe and proper course is to cut back to four or five perfect leaves. By the first week in September the trees should be gone over again, and all growths that have been made since the late July pruning should be removed to facilitate the thorough ripening of the wood generally. I have said nothing about early disbudding, because the proper season for that is past. I think, however, there cannot be a doubt that in many cases much good would be done by an early removal of all weakly growths that are never likely to be required for the proper furnishing of the tree.

E. HODDAY.

Second Crops of Melons.—We frequently hear of good second crops of Melons, and even three distinct crops from the same plants; but, although such things are possible, I should, from my own experience, say that one good crop from a plant is the most profitable course to follow; if a second crop be required, fresh plants should be in readiness, and directly the crop is cut new soil should be ready to replace the worn-out material. Thus two really good crops may be gathered from each portion of pits or houses devoted to Melons during the season. Although good Melons may be grown in frames during the hottest summer months, they are of comparatively little value for the earliest or latest crops, as in our uncertain climate the use of artificial heat is an absolute necessity to insure first-class flavour in a fruit that delights in a tropical heat, and the flavour of which so much depends on the surrounding atmosphere. Span-roofed pits, with a border for soil on each side, may be planted one side at a time; and houses if span-roofed, with a central bed, may be planted at three distinct periods. By replacing each set with fresh plants as soon as the first crop was fit for cutting, I have had far more continuous and finer fruit than ever I could have got from the same plants. By a good crop on a plant, I mean from four to six fruits, according to the size of the variety; but late in the season a lighter crop must be left. Two or three fine fruit on a plant of Eastnor Castle, or any similar good sort, well ripened off as late as the end of October, by means of a good command of artificial heat, and by elevating the fruit well above the foliage to get all the benefit of the declining power of the sun's rays, will be found useful, and worth a little extra attention. Retaining the foliage in perfect health up to the period when the fruit is fit for cutting is an important point. By foliage I mean all the main leaves, which should be retained quite down to the ground on the stems of plants that are trained upon trellises. All the unnecessary weakly growths should be pinched out before they make much progress, so as to concentrate the energy of the plants in the main stems, which will in due time perfect fine fruit of the highest quality. There is no necessity for drying the plants to such an extent, to produce ripeness, as to induce red spider, the ordinary accompaniment of a Melon house so managed. There is nothing gained by leaving the fruits in the house after they commence to show signs of ripening; for, if cut at that stage and placed in a cool fruit room, a much longer supply and better flavour will be secured while the space is being utilised for another crop. Green and black fly frequently attack Melons in the early stages of growth; but they should be kept down by prompt attention to fumigation, and the best antidote to all such pests that prey on plant life is a rapid and healthy development, and that can only be secured by supplying the plants with a maximum of air, light, and heat, and a root-run of fresh turfy loam at a temperature to promote free root growth.—J. GROOM.

An Early Apple.—A pretty little early Apple on the Paradise Stock in Mr. Turner's nursery at Slough, named Gladstone, is worth attention. It ripens earlier than all other Apples, is bright in colour, and of fairly good flavour.—S.

Russian Apples.—Professor Budd, of the Iowa Agricultural College, says he is testing 1000 or more varieties of Russian Apples, and if he secures a dozen late autumn and winter sorts of fair size and quality, combined with hardiness of tree requisite for the northern prairies, their value will be difficult to estimate. The trouble heretofore with this class of Apples has been their early season of ripening, hence the call for later kinds.

Plenty of Water Good for Vines.—On this point I would like to remark that, from experience and observation gathered from practising in the very wettest and the very driest districts, I feel convinced that in districts where the rainfall does not exceed 36 in. per annum, Vines rarely ever get as much water at the root as is good for them, and have far too much supplied to the atmosphere of the Vineries by sprinklings. Where the drainage of Vine borders and the soil are as they ought to be I have never known Vines suffer from too much water in their growing season, and have known them get 6 ft. of rain in the year, besides artificial waterings in inside borders amounting to even more than 6 ft.—D. THOMSON, in "Journal of Horticulture."

Berberries.—This is a Barberry season, and a fine time for the makers of Barberry wine. The evergreen species, particularly B. Darwini, B. Aquifolium, and B. stenophylla, are smothered with berries, and the birds are enjoying an unwonted feast. I am well aware that the fiery berries of B. vulgaris are the proper Barberries for wine; but I know that the purple berries of the evergreen kinds are also capital wine makers, that is, when they are made into good wine. If I could do everything I would try the berries of B. Darwini as a preserve, for I fancy they would be equal to Whortleberries; but I must content myself with a guess until I can fit up an experimental kitchen and employ an army of cooks to "tell or to hear some new thing." To make stock of Berberries will be easy work this year, and those who are not used to it may be recommended to sow the berries in boxes, and keep them where they will be constantly under observation.—S. H., in "Gardeners' Magazine."

ANSWERS TO CORRESPONDENTS.

Silkworms.—I have a large stock of silkworms in cocoons, which I want to sell. Can you inform me where I can dispose of them, or if they are saleable in the cocoon state?—H. D. S. [Send half-a-dozen cocoons as a sample to Mr. S. H. Gaskell, 17, Bayley Street, Stalybridge. If they are the right sort they are saleable in the cocoon state, but there is no time to lose, as the moths emerge in about three weeks after the cocoons have spun if the weather be hot.—W.]

Names of Plants.—*Statice*.—Mr. Baines will write an article on this for THE GARDEN shortly. *Northumberland*.—*Ruellia affinis*, a rather rare Brazilian stove shrub. *J. C.*—*Veratrum nigrum*. *C.*—*Teucrium fruticans*.

Gumming in Plums.—A week ago I had in my orchard house a fige tree covered with healthy fruit, and now there is not a Plum but is affected like the specimens sent. The wounds are all on the sunny side of the fruit. On opening them you will see the injury or disease seems to be in the stone, and the gum with which they are covered appears to exude from the centre.—M. S. [This is an ordinary case of gumming, a disease to which the Plum is very subject. It often occurs in the stems than in the fruit, but the affection is the same. Any sudden check to the flow of the sap will cause the evil.—B.]

Hylobius abietis.—I have sent you some leaves of *Dracænas* and *Platycerium* to show the way in which they are eaten by this insect. It seems to injure not only these plants, but also Vines, the young shoots of which appear to be their favourite food.—J. GILBERT, *Duddon Hall, Lancashire*. [On examining the leaves

Parts of gnawed leaves of *Dracæna* and *Platycerium*.

of the *Dracænas* and *Platycerium* I found that both had been eaten away in various places round the margin, sometimes to the depth of nearly $\frac{1}{4}$ in., thus destroying their appearance, as shown in the annexed illustrations.—W. W. S.]

Culture of Carnations.—I should be much obliged if anyone conversant with Carnation culture would tell me how to grow them to perfection, especially the kind called *Malmaison*.—AMATEUR. [Carnations are all sufficiently hardy to withstand our ordinary English winters, but some are cultivated in pots in order to have them in flower at a time when it would not be possible to have them out-of-doors. *Malmaison* is doubtless the sort with very large flesh or salmon-tinted flowers named *Souvenir de la Malmaison*. It is classed with the *Perpetual* or *Tree Carnations*, although it does not grow so rampantly as some others. *Guelder Rose* (a pure white variety, with fringed petals), *Empress of Germany* (a very large, white flower, occasionally flaked with rose), *King of the Belgians* (a large, rose-coloured variety), *La Belle* (white, one of the best and the freest grower), *Miss Jolliffe* (flesh-coloured or pale pink—one of the best to produce flowers in abundance through the winter), *Prince of Orange* (a very strong grower with large, edged flowers), *Proserpine* (the best scarlet), *Scarlet Defiance* (a very free-blooming variety), and others that might be named require the same routine of culture. Nearly all the *Tree Carnations* are increased by means of cuttings struck in bottom-heat, but *Souvenir de la Malmaison* forms an exception; its stout, fleshy "grass" is most readily propagated by means of layering. When the layers are fairly rooted they should be separated from the parent plant and be potted in good

soil, made porous by the addition of sand or pounded charcoal and a fourth part of leaf-mould. When the plants have become well-established in small pots they should be shifted into the pots (6-in. ones) in which they are to flower. Drain well with broken potsherds, and place some clean fibre, shaken from turfy loam, over the drainage to keep the particles of fine soil and sand in the compost from sifting into it. See that the soil in the pots, and also the compost used in potting, are moist, as it is well not to water for at least twenty-four hours after potting. The plants should be kept near the glass in a warm greenhouse, and they will continue to produce flowers all through the winter months. During winter, if a temperature of from 50° to 55° can be maintained, they will produce much finer blooms than in less heat. Green fly and thrips are apt to attack Carnations, but both may be destroyed by occasional fumigations with Tobacco smoke. When the flowers are opening earwigs find a secure hiding-place at the base of the petals, which they eat through and quite spoil the flowers. They can be best destroyed by looking for them with a lamp while they are feeding at night. It may be added that the following is a good compost in which to pot flowering plants, viz., four parts turfy loam, one part leaf-mould, one part rotten stable manure, and enough sharp sand to keep the whole open and porous.—J. D.

Injury to *Magnolia grandiflora*.—I enclose two leaves of a young *Magnolia* planted last October; both young and old leaves are attacked by some insect, which spoils the foliage and disfigures the plant. Can you suggest any remedy or name the insect?—M. S. [The two leaves in question are severely injured, but from what cause it is difficult to say. One, the larger leaf, has the left side nearly eaten away to the midrib, while the right side is partially eaten away at the apex, and is remarkably cracked or torn in two places, the rents nearly reaching the centre. The other leaf shows no decidedly eaten-away portion, but exhibits the same peculiar rents as noticed in the first leaf, and has besides desiccated portions, the larger of which are already attacked by a minute fungus belonging to the *Sphaeria*s. The injury done is probably not of recent date. The peculiar tearing or rending, I think, cannot be attributed to insect action, but the portion eaten away of the largest leaf may have been caused by insects when the leaf was younger and more succulent. The small insect sent with the leaves is one of the well-known frog-hoppers, and cannot be the cause of the injury in question, having only a sutorial mouth with no power of gnawing away any portion of the leaf.—W. W. S.]

Half-hardy *Salvias*.—In reply to the remarks (see p. 73), I may state that the plant which I intended to describe as *Salvia farinacea* is, I am certain, true to name, although, perhaps, I did not describe it properly. The plant in question is not, as I before remarked, identical in colour with the plant figured in THE GARDEN. *Salvia leucantha* I know equally well as I do *S. farinacea*; it is a totally distinct species.—W.

***Salvia gigantea*.**—Like Mr. Harpur Crewe, I am of opinion, from the description given (see p. 73), that the plant bearing this name is *S. bracteata*. The latter plant when much handled emits a very disagreeable odour.—THOS. WILLIAMS.

***Pyrus japonica*.**—Is it not unusual for this *Pyrus* to fruit? There is now growing in a garden here a small plant with several fruits upon it; I have not seen it fruit before.—RICHARD MAIRIS, *Lytham*.

Sub-dividing Varieties of Lilies.—Now that Lilies are becoming so justly popular, the temptation to divide and sub-divide such varieties as show the most trifling difference as regards marking seems to be so great, that the task of looking through a list of so-called varieties will soon be a tedious affair. If every one who grows *Lilium auratum* alone, to say nothing of other sorts, were to distinguish every deviation from the type with a name, our catalogues of *Geraniums* and *Roses* would be brief compared with our lists of Lilies.—J. GAOM.

Lilies Planted Out.—It may be interesting to know that I have growing here (very near the sea) *Lilium auratum* planted out two years, with from ten to sixteen flowers upon it; also a plant of *L. Humboldtii*, bearing upwards of fifty flowers, and about 10 ft. high; *L. californicum* and the old scarlet *Martagon* very fine. The fine early-flowering variety *L. Szovitzianum* has likewise been very good, as well as many other varieties. I think it is quite a mistake to grow them in pots, except under particular circumstances.—RICHARD MAIRIS, *Lytham*.

Variegated-leaved American Elm.—I saw, some few weeks ago, one of the finest specimens of this which I have ever witnessed. It is situated about the centre of the quaint village of Leek Wootton, in Warwickshire, close to the road leading from Warwick to Coventry. It is over 50 ft. in height, and measured at the base 96 in. in girth, and 6 ft. from base 84 in. It is clothed from top to bottom with foliage showing the finest silvery variegation possible, and seemed to be growing vigorously.—ROBERT GREENFIELD, *Priory Gardens, Warwick*.

THE members of the National Sunday League went last Sunday by special train from Paddington to Taplow, and spent the day at Clivedon, the seat of the Duke of Westminster. The grounds were thrown entirely open.

Erratum.—For *Cunninghamia trimaculata* (see p. 73) read *Cummingia*.

THE LIBRARY.

THE NATIVE FLOWERS AND FERNS OF THE UNITED STATES.*

It is with great pleasure we have received and turned over the pages of the first five parts of this book, devoted to the illustration in colours of the flowers and Ferns of North America. Our pleasure is greater than it would be in the case of our more familiar European flowers. Yet, so far as done, these numbers contain not a few old friends of both botanic and private gardens, for the hardy flowers of America have long been among the most important flowers of our gardens. In turning over these well-printed numbers we find the Spider-wort (*Tradescantia virginica*), *Viola cucullata*, the noble Golden Columbine (a recent gain), *Pachysandra procumbens* (an old botanic-garden friend, bearing the ugly "English" name of "Thick-Stamen," a kind of English name better not printed), and *Hellonias bullata*, long grown with us, but always rare from not being grown in places wet enough. Mr. Meehan says he knows of no successful attempts at cultivating it, and adds that it is "quite possible it is a real swamp-loving plant," which seems odd to us, who, with a very short experience of American botany, remember it as growing in water, though, from the Moss and other plants on the surface, the place in which it grew looked somewhat like solid ground till one tried to walk on it. The Skunk Cabbage, the Moss Pink (*Phlox subulata*), and the poor old Virginian Saxifrage—in fact, half the plants chosen for figuring so far—are well known to those acquainted with our hardy garden flora. Among those less known and interesting are the Carolina Jasmine (*Gelsemium sempervirens*) of the warmer States, Nuttall's Pasque-flower (*Anemone patens* var. *Nuttalliana*), *Orchis spectabilis*, and the Yellow Dog's-tooth Violet (of which there is a good plate).

The plates are exceedingly well done, though sometimes the colour is not exactly true, as in *Tradescantia virginica*; but those who best know the difficulties of colour printing will appreciate the care and good taste shown in this book and the perfect cleanliness of the execution. The drawings are free and artistic, so far as they can be when the botanical details are drawn on the same page with the whole plate—an established custom which is wrong and the cause of spoiling the effect of many a plate. The paper and print are excellent. The descriptions are also good, though the book follows what we think the bad European fashion of saying too much about the origin of the name; what old botanists said and did, and quoting poetry of often very remote connection or none at all with the subject described. What we really want is the actual facts about the plants, so far as they are known, their distribution, the soils and localities which they frequent, and those in which they are most at home, and their uses, if they have any. What we mean is, that much of the matter, apparently thought essential in such books, is really non-essential, and not entitled to the first place. It is, for example, quite common to omit any accurate description of the stature or port of a plant, or the part which it takes in the aspects of vegetation in its native places, while we may be treated to matter more or less fanciful, as regards the origin of the name, and certain unimportant botanical details—all of which are carefully given. Mr. Meehan's book, however, is very full as to essential information, and is in all ways a good book, and a credit to both author and publisher. W. R.

THE BULB GARDEN.†

It has often occurred to us that bulbs were deserving of a special treatise, which, if well done, would be very useful to gardeners and amateurs. This is a well-printed little book, with a few coloured prints in it and some woodcuts borrowed from catalogues, but it is a most incomplete attempt to do justice to the numerous and extensive families of garden plants grouped under this name. Imagine a book on bulbs which mentions only two or three of the Scillas! Various plants are

named which are not included among the bulbs, such as *Lycchnis fulgens*; while many very important bulbs are left out, as, for instance, the Quamash-root (*Cassia*), the Snowflake, the Blood-root (*Sanguinaria canadensis*), the Trilliums, the handsome bulbous *Asclepias*, and *Calochortus*! When we have said this we need not go any further to find that not only has the author not done justice to his subject, but has literally omitted names of many of the most beautiful and important families with which he should have dealt. The book contains cultural details of some of the commoner families of bulbs.

R.

REPORT ON KEW GARDENS.*

THIS, although dated January 1, has only just been published. It is more like what the annual report of a large national establishment should be than the meagre pamphlet of some 8 or 10 pages that did duty for a report about six or seven years ago. Last year an attempt was made to improve matters, and a pamphlet of 33 pages was the result. Very much valuable information on many subjects of the greatest importance to our colonies was collected, and for the first time the report, which was well worth perusal, could be purchased by any one. This year's report contains 20 pages in excess of its predecessor. A large sheet, showing plans illustrative of the general arrangement of the hot-water boilers of the great Palm Stove, accompanies the report, thus giving all a fair chance of judging for themselves the value of the system, a new one lately invented by Mr. Rivers. Another illustration is given, one representing the peculiar growth of the *Bamia Cotton*, the wonderful accounts of the productiveness of which caused such excitement amongst Cotton planters last year. As there are some statements with which we do not agree, we will comment on them. After complaining of the damage done to tender plants—such as Ferns, &c.—by large crowds of visitors, Sir Joseph Hooker expresses an "apprehension that it may eventually prove impossible to admit the public on exceptionally crowded days to visit certain of the collections, at any rate except in restricted numbers, which must be eventually exterminated in the process" (see p. 5). What does this extraordinary sentence mean? It is certainly ambiguous; is it the plants or the visitors which must be eventually exterminated? Seriously, however, why should the visitors on Bank holidays be deprived of the pleasure of seeing Nature in some of her most beautiful forms? Granted that a certain amount of harm is done on the four Bank holidays of the year, it is surely so small that any attempt to establish such a dangerous precedent should be viewed with grave suspicion. The letters of Sir B. Hall, when First Commissioner, to Sir W. J. Hooker hardly bear out the statement of the present Director that it has always been the aim of his father and himself to render the Gardens as attractive to the public as possible. Those who know even little of the Gardens will be surprised at the pertinacity with which we are told that the gardening staff is principally employed in looking after the visitors during the afternoon, and that the forenoon is the only time for doing the general work of the Gardens. Of course there is a small substratum of truth in this, for nothing can be done during Bank holidays; at all other times, however, the labourers may be seen at their ordinary employment just as if no visitors were about, the policemen and constables being quite able to manage the public without any assistance from the rest of the staff. We are also informed, as an additional reason for keeping the Gardens closed as at present, that permission to draw during public hours is practically useless to artists. We, however, confidently state that a request to draw during private hours was frequently refused until the recent agitation for the earlier opening of the Gardens had commenced, when the more generous policy of admitting all who give satisfactory reason for the granting of the privilege was adopted. The list of Aroids cultivated at Kew is a step in the right direction; we should like to see similar lists of the living Palms and other special groups. The names of a number of the plants of more especial interest, which flowered during the past year, are given. Most of those were noted and described in THE GARDEN as they appeared. The rest of the report contains much valuable information for colonists and manufacturers concerning Cinchona, India-rubber, and many other plants and their products.—*

"This is an art
Which does mend Nature: change it rather: but
THE ART ITSELF IS NATURE."—*Shakespeare.*

ROSES AT CHESHUNT.

Those who have not paid a visit to the Cheshunt Nurseries can form no adequate idea of their extent and attractiveness; but, as regards Roses, which, it is well known, are Messrs. Paul's speciality, some idea may be formed of the sight to be seen when it is known that nearly 50 acres are devoted to their culture alone. This year the flowers have been fairly good, and the plants are all that can be desired. Especially fine are those planted on ground which has never before grown Roses—thus showing that the Rose, like many other plants, is grateful for a change of soil. The display of bloom is now a little past its best, but it will amply repay a journey of any distance. In addition to the thousands of standards and half-standards and dwarfs of the most popular kinds, some of the older ones are not neglected, and one can see many of the original plants of some of our best English-raised Roses.

Of new Roses there is a rich collection this year, and it is satisfactory to find that many of the new kinds are noted for their profusion of bloom in the autumn. Indeed, in this class of Rose Mr. Paul has lately been paying much attention, for really good autumnal Roses are comparatively scarce. It is almost to be regretted that some of the Rose societies do not hold a show in September expressly to bring out the best kinds of autumn-blooming Roses, for these are, if possible, of more value than those produced in summer, when our gardens are rich with all kinds of flowers. Among novelties the following appeared most noteworthy:—

Marquis of Salisbury is a Hybrid Perpetual with large, many-petalled flowers of a fine rose colour, the edge being shaded with bright orange or salmon colour, and it will doubtless make a fine exhibition Rose.

Charles Darwin is a remarkably free-blooming kind, growing well on the Manetti, and giving a fine display in autumn. Its blossoms are of good form, and of a splendid crimson colour.

Duke of Teck is the most brilliant scarlet Rose ever yet raised, and it is a great advance upon the reds, of which there is such an abundance. It is a good grower, and if grown in groups pegged down, the effect, when in flower, would indeed be brilliant.

Dr. Hogg is the nearest approach to a real purple we have yet seen. It is very distinct, and will become an effective kind in the exhibition stand.

Mrs. Laxton is a fine new Rose, and Jean Liabaud is in good condition just now, its flowers being a rich black.

Mrs. Bellenden Kerr is an excellent new white autumnal Rose, and Souvenir de la Malmaison, on its own roots, is doing better than ever we remember to have seen it in any other way.

Duchess of Edinburgh, raised in the Cheshunt Nurseries, is one of the best kinds for forcing in pots. Its flowers, which are of a rich crimson, of fine form, and produced in profusion even on small plants.

A seedling kind, as yet unnamed, but the flowers of which somewhat resemble those of Charles Lefebvre, is interesting on account of its extremely vigorous growth. It makes shoots in one season as thick as a good-sized walking-stick, and from 4 ft. to 5 ft. long, and, as far as can be seen, it will make a fine Rose for growing into large untrained bushes.

Maréchal Niel, trained over the roof of a house, has borne thousands of blossoms, and from this were cut the great baskets of Roses seen at the London shows last spring. When the plant has ceased flowering all the wood is spurred in like a Vine, after which abundance of strong shoots are soon emitted, which grow on and yield a crop the next year. The flowers of Maréchal Niel are always borne freely on long sprays of medium-sized wood, and in order to provide these this method of pruning is considered the best. The plants in

question are very large, their main stems being as thick as a broom-handle, and to keep these from getting "bark bound," as is often the case with Roses as well as fruit trees, the bark is scored down with a knife, a process which not only allows of the full expansion of the stems, but also causes them to break freely, even from the oldest of the wood. Another advantage in this practice of pruning is that more light is admitted in the houses. The same kind of Rose, grown in pots for planting out, grow amazingly under the shadow of those on the roof without becoming too lanky or too much drawn. S.

COLOURLESS BLOOMS OF MARECHAL NIEL.

It was with extreme interest that I read the discussion which was carried on in the pages of THE GARDEN some few months since concerning the probable causes of the failure of some blooms of this most deservedly favourite Rose to assume that rich golden tint to which it is so desirable they should attain, and the remedies proposed for the mitigation of the evil. My interest arose from the fact that I was myself then awaiting the result of an experiment which I had made upon a fine old standard of Gloire de Dijon. This old friend, though in apparently vigorous health and a really perpetual bloomer, had in its flowers assumed a hue so pale as to be almost unrecognisable, and which called for prompt remedial measures. Those adopted were of the following nature: In the beginning of November last the surface soil, to the depth of about 2½ in., was removed, commencing about 6 in. from the stem and extending to a distance of 3 ft. all round. The remaining soil over the roots was gently loosened with a fork, and the usual annual dressing of rich, well decayed stable manure applied, over which the surface soil was then replaced and all made safe for the winter. In March, I, as usual, pruned sparingly, and about the first week in April, after having carefully and repeatedly inserted a long five-pronged fork over the roots so as to render the superincumbent soil thoroughly permeable, I applied a top-dressing of the Rose Manure, prepared by Messrs. W. Paul & Son, of Waltham Cross, being somewhat more liberal in the application than is recommended in the directions for use; and this having been washed well in by a copious drenching of water, all was made tidy, and the result patiently awaited. Of this result I am now in a position to speak, as I have now before me blooms cut from my old patient, which in size, symmetry, and depth of colouring, I have never seen surpassed. I can thus confidently recommend this manure, which, so far as my experience has gone, has decidedly both increased the size and intensified the colour of my Roses. Having applied it also to the Hybrid Perpetuals Duke of Edinburgh, Baron Haussman, Hippolite Jamain, Victor Verdier, and Magna Charta, I have been rewarded with some truly splendid flowers the tints of which are of unusual brilliancy. It may, therefore, prove not unworthy a trial by the gentleman who has had reason to complain of some little disappointment at the hands of Monsieur le Maréchal Niel, who has hitherto occupied in his friend's esteem a place so high as to be above all praise.

W. B. H.

Dublin.

The Cape Gooseberry Out-of-doors.—It may be of interest to know that this delicious fruit-bearing plant, when planted in the open air, attains a far higher degree of productiveness and vigour than when grown under glass. My mode of procedure is to plant out, in a compost of rich loam and manure, fair-sized plants against a south wall, taking the precaution to nail a board about 9 in. wide at right angles to the wall over each plant. To this I nail a piece of canvas long enough to reach the ground, and this I let down in frothy or cold windy weather as a protection to the plants, and also put a mulching round the roots in winter. In the spring I give an abundant supply of weak manure water, withholding it later on, and under this liberal treatment they will grow vigorously, and will require to have the shoots stopped, as with Tomatoes. Throughout the summer the plants are in blossom and fruit, which latter, from its peculiar yet agreeable acidity, is adapted either for a dessert fruit, or for making excellent preserves. My plants have been under the above treatment several years, and have withstood the winters with impunity, and I find that they are not so liable to the attacks of insect pests as when grown under glass.—A.

SPIRÆA PALMATA ELEGANS.

PERMIT me to answer the criticisms which have been published in THE GARDEN in July last (see pp. 2 and 62) against this new plant, which I put into commerce at the end of last year. Whilst I am far from wishing to suspect the impartiality and the perfect ability of your correspondents, yet in this matter, as in many others, in order to be able to express an impartial judgment, it is necessary to keep clear of a certain precipitancy. This is especially the case when it concerns a new plant weakened by extreme propagation, and the first blooming of which ought necessarily, as I understand it, to leave much to be attained. I find no fault with criticism, but when expressing an opinion publicly, which is calculated to injure respectable interests, one should be in such a position as to leave no room for injustice. Your correspondents, I think, in this case, have judged from weak specimens, and, therefore, of imperfect bloom. My experience at my own establishment proves this to me. Here the first blooms produced on plants after the autumnal and spring propagations have been very puny; but, at the present time, established plants are four times stronger than those of the *Spiræa palmata*, which is growing under the same conditions as regards soil and culture, and they will flower in large masses in the course of this month. I shall send you specimens of it directly they expand.

I cannot say if this second flowering in bulk is an abnormal fact; but if it were regular in certain conditions of culture, viz., planted in soil deeply broken up and fertile, and well supplied with water, I should be right in saying that the new *Spiræa* is not only much more vigorous, but infinitely more productive of bloom than the *Spiræa palmata*. The *Spiræa* that I have called *S. palmata elegans* was obtained by a person who occupies in Ghent one of the highest positions in the horticultural world, and who allowed me to "send it out." I do not say he is infallible, but it is impossible to put any doubt upon his complete good faith. Now he declares that he has not cultivated any other species of *Spiræas* than the *S. palmata* and the *S. (or Hoteia) japonica*, and that he has gathered and sown with his own hand the seeds which have produced the new plant. Besides, and opposed to what one would be disposed to believe from its appearance, it is not the *Spiræa palmata* which is the mother plant, as I had understood when the first particulars were given to me as to its origin, but it is the *Hoteia japonica* which has performed the office of seed-bearer. The fact is stated in the most positive manner by the producer, who is not a man to be easily misled himself or to deceive others. Now, beyond the scientific question which gives a great importance to the new *Spiræa*, all true amateurs, when they will have before them a vigorous and well cultivated plant, will not hesitate to declare that it is a great acquisition to our gardens. E. PYNART-VAN GEERT.

Ghent.

[M. Pynaert sent us a vigorous specimen of the plant, which, however, did not come in such condition as would enable us to judge of the flowers. The plant is, no doubt, a pale variety of *S. palmata*.]

Viola lilacina.—This has been all the summer, and continues to be, the most charming bedding *Viola* in flower here, its exceedingly dwarf habit and free-blooming qualities, allied to its somewhat novel colour—a many-lilac—render it specially attractive in masses. It would be very effective if mixed with some silver-grey colour, such as *Pelargonium Manglesi*, if that were pegged down. It would also look exceedingly pretty if planted thickly with the variegated *Mesembryanthemum*.—A. D.

The Species of Dahlia.—My collection contains *D. variabilis*, *D. coccinea*, *D. Cervantesi*, *D. imperialis*, and *D. glabrata*. These are all fully described in the review of the genus given in THE GARDEN last year. The following two species I have also, which, though not flowered yet, are very distinct from either of the preceding, and of which I can find no account, viz., *D. arborea* and *D. Maximiliana*.—A. [The last-named species was brought over by M. Roezl, and is mentioned in THE GARDEN, Vol. X., p. 75, and Vol. IX., p. 335. For *D. arborea*, see Vol. V., p. 238.]

Seedling Alpine Poppies.—In reference to the note on these (see p. 114), in which the writer asks if the white and yellow forms are distinct, I may state that experience has taught me that they are not, for, by sowing seeds of plants of either colour, I have

obtained seedlings with flowers of all three colours, thereby proving that they are but forms of one. There seems some confusion about the names *Papaver alpinum* and *P. nudicaule*, which are by botanists regarded as synonyms. The only difference between them is that the true Alpine Poppy is but a few inches in height, and has small leaves on the flower-stem; in *P. nudicaule* the flower-stem is leafless and grows much higher. Both species bear blossoms with the same variation in colour, the white form being the supposed type. The yellow form is named *aurantiacum*, and the deep orange colour *miniatum*.—W.

Veronica repens.—I have seen enough of this pretty hardy plant this season to be able fully to recommend it as a green carpet plant, and even think it preferable to the two most accepted for that purpose, the dwarf *Mentha* and the green *Sedum Lydium*. It is a dense, close-growing creeper, covering the soil as it proceeds with a perfect soft carpet of bright green foliage, and it only needs occasional lateral trimming to keep it in place. It seems to thrive well on soil that is moderately dry, as my patch of it is in a dry spot, and it covers much more rapidly than any other carpet plant. Those in want of a good carpet plant should try this mountain *Veronica*.—A. D.

The Lyme Grass.—In looking through the gardens of the Preston Nursery Company, on the occasion of the late flower show, I was struck by the beauty of a large clump of *Elymus arenarius*, a tall Grass with rather broad, long, graceful leaves of a hoary, blue-green colour. This plant is so bold and graceful in habit, and so uncommon in colour, that I can imagine it to be a most befitting subject for the adornment of the bog garden and the banks of streams and lakes, and it might even enhance the beauty of the herbaceous border; and I have seen less ornamental and less appropriate plants forming clumps and filling circular beds on the lawns of some of the best of our public and private parks.—G. SYME. [We have long tried this fine Grass, which is excellent for rough and semi-wild places, or isolated, or in groups on Grass, but it runs too vigorously at the root for beds or borders.]

The Variegated Moneywort (*Sibthorpia europæa variegata*).—As a suspended basket or pot plant, in a cool, shady greenhouse, or in a plant case in a room, this little British plant stands unequalled for its gracefulness and beauty. To be grown at its best it requires perfect drainage and a cool and moist atmosphere, but it is very impatient of too much moisture at the root or overhead. It may be readily propagated by division, after which process the divided plants should be kept under bell-glasses or otherwise confined for a few days. The type of this plant is also very desirable for the same purpose, though lacking the beautiful variegation of the leaves. Another little native plant which makes a charming basket plant is the Bog Pimpernel (*Anagallis tenella*). Treated in the same manner as the above, it produces long pendulous branches of its small round leaves and rosy blossoms in profusion.—W.

Golden Conifers.—Allow me to supplement Mr. Berry's descriptive catalogue of Golden Conifers, which appeared in your columns last week, by adding another to the meritorious list, namely, *Retinospora pisifera aurea*. Botanically considered, it is probably the same as the one described by Mr. Berry as *R. plumosa aurea*, but by those possessing microscopic vision, and from a horticultural point of view, the two forms are very distinct. The *R. pisifera aurea*, when better known, will be considered the better of the two for certain purposes, for planting in certain positions, inasmuch as it possesses the vigour, the handsome open habit, and the long, recurved, feathery branches of the well-known green form, and its colour is altogether brighter than that of the *plumosa aurea*. I may here be allowed to express my dissent from Mr. Berry's opinion that these golden varieties of *Retinospora* "will succeed best in a cool and rather shady situation." Place them in the shade of other objects, and they lose their character; expose them to all the light possible, and they will repay you for your kindness. Our strongest sunshine will not scorch them, provided that they have sufficient moisture at their roots.—GEORGE SYME.

At this moment in the Paris Exhibition can be seen between the galleries reserved for the vegetables and the cut flowers, and near the conservatory constructed by M. Cochin, a very happy innovation as regards some remarkably fine *Phlox decussata* cultivated in pots. The innovation may be thus described: In the centre of a pot sufficiently large has been planted a *Phlox*, the shoots of which have been laid radiating towards the rim of the pot, where they form a circle and rise vigorously, giving a strong inflorescence. The number of flowering stems, sometimes reaching ten or twelve, thus disposed as a sort of crown, afford a graceful and elegant effect.—A.

NOTES OF THE WEEK.

The Vine Pest in Burgundy.—French horticulturists and wine-growers are greatly alarmed owing to the recent appearance of the dreaded Phylloxera in the Côte d'Or, in the village of Mersault, in the very centre of growth of the best wines of Burgundy—the country of Pommard, Volnay, and Beaune, and not far from the Chambertin and Clos-Vougeot district. The same pest has also attacked the fine collection of 900 different species and varieties of Vines in the Dijon garden, and the Vigilance Committee of the Côte d'Or has ordered its complete destruction, the earth to be afterwards disinfected.

Early Beatrice Peach.—We learn that fruit was gathered at Cherchell, in Algeria, in this variety on June 10 in the present year. So we shall probably soon see other Peaches in early summer than those that are forced under glass.

The Paris Exhibition.—Our correspondent, Mr. J. Simpson, of Wortley Hall Gardens, has been appointed to report on horticulture for the Society of Arts at the Paris Exhibition. Mr. Simpson's love of progress in his art and independence of judgment fit him well for the work, and we look forward to some interesting notes from his visit to the Exhibition and the gardens of Paris and its neighbourhood.

Paris Exhibition.—We may remind those who, contemplating a visit to the Paris Exhibition, attach any importance to the horticultural department, that the competitions take place on the 1st and 15th of each month, and that consequently it is at those periods that take place the introduction of new specimens, or the renewal of those already shown. In making their visit coincide with those dates they will see the objects in all their freshness, an important point, especially as concerns fruits, vegetables, and cut flowers. Occasionally, in consequence of fêtes or other unforeseen circumstances, these two periods may be a day later, but they never occur before the 1st and 15th of each month.—“*Revue Horticole.*”

The Caucasian Scabious.—What a valuable perennial this is—handsome, very large (3 in. across the flower), good in colour, and flowering throughout the summer and early autumn! It blooms for four months continuously.

Pontederia crassipes.—This is now in bloom in the Royal Botanic Gardens, Regent's Park. Its blooms last only a day or so in perfection. It will live in water in a Hyacinth glass, and in that way forms a good window plant.—R. KENNEDY.

Grass in Hyde Park.—It would not be easy to find in any part of the country a fresher, softer, or greener carpet of Grass than that now near the end of the Serpentine in Hyde Park, proving that with sun, good soil, and water, the best carpet of garden turf is attainable in London. Rivaling the verdure of this turf is the foliage of three trees, the American Plane, the Honey Locust (*Robinia*), and the Caucasian *Pteryocarya*. We notice this the more particularly because the foliage of some of our native trees is either quite a dull green, or even in some cases beginning to wither.

Balsams at Forest Hill.—There is now a fine display of Balsams in Messrs. Carters' nursery at Forest Hill. The plants, which are grown expressly for their seed, number nearly 5000, and, being now all in full bloom, they present a sight not often to be seen in the way of Balsams. The flowers are large, well-formed, and varied in colour, and we notice that many of the most prominent kinds are named. As a whole, the strain is excellent, both as regards habit of plants and quality of flowers.

The Rock Abslia (*A. rupestris*).—This beautiful shrub, to which there was but slight reference made in the review of the genus (see Vol. X., p. 58), is now in flower with me. At present it is against an outside wall, and about 3 ft. high. It has oval, shining leaves about 1½ in. in length, and slightly toothed. The blossoms are borne in threes, and form clusters at the tips of the young shoots, and are about 1 in. long and ¾ in. wide, with a curved tube. The colour of the lower three segments of the flower is pure white, and these are hairy, whilst the upper two are hairless and of a delicate mauve tint, which contrasts agreeably with the ruddy colour of the thrice-divided calyx. It is a native of China, and was introduced about thirty years since, but is still uncommon in gardens. Certainly such a desirable shrub is deserving of more attention.—W.

A New Experimental Garden.—A proposition has been set on foot to institute a garden for experimental purposes, to be kept up by subscription. Its promoters propose to establish the garden in a central locality and within easy access of London, for the purpose of hybridising, cross-breeding, and selecting fruits, vegetables, flowers, ornamental and economic plants (chiefly hardy and half-hardy); for the raising and propagating of useful and choice novelties, scarce and little known plants of beauty and utility; and for the trial of

new fruits, vegetables, flowers, &c. For the purpose of successfully carrying out the plan, endeavours are being made to secure two or three acres of good staple garden land with a limited amount of glass. Mr. Thomas Laxton, 53, Tavistock Street, Bedford, who is to be the conductor, hopes, as soon as a suitable site can be procured, to receive contributions of plants, stock, &c.

Haplophyllum patavinum.—This has been in flower for a long time and will continue for weeks to come. It is a shrubby perennial about 1 ft. in height. The flowers are borne in numerous umbels, much like *Aeclepias curassavica*, and are of a bright shining yellow colour. It is a fine showy plant.—MAX LEICHTLIN, *Baden-Baden.*

Hardy Plants in Flower at Colchester.—The following hardy plants are now flowering in our nurseries here, viz., *Iris kumaonensis*, an extremely rare kind from the mountains in the north-west provinces of India; *Iris iberica*, extremely late; *Gladiolus Saundersi*, *G. dracocephalus*, and *G. purpureus*; *Hyacinthus candicans*; *Cammimgia trimaculata*; *Lilium Wilsoni*, *L. Leichtlini*, and an entirely new species; and *Romneya Coulteri*, very fine.—A. WALLACE.

Eugenia apiculata in Ireland.—This is now in bloom in Merlion Square, Dublin, where about five or six years ago I planted it in a sheltered but open border, doubtful as to its success. Without any special protection it has, however, never suffered more than at occasional browning of some of the tips of its shoots in spring. It has not flowered every summer, but it has now abundance of bloom on it, and it is a compact, symmetrical, and very pretty little shrub about 3 ft. high.—JOHN ADAIR, *Dublin.*

Nicotiana acutifolia.—There is just now a very striking specimen of this plant in flower here from Uruguay. From a neat rosette of leaves rises a freely branching flower-stem to a height of 3 ft. The flowers are sparingly dispersed along the main branch, and the branchlets, from fifteen to twenty, opening at one time. They are star-shaped and measure 1½ in. across on a tube 4 in. long; they are beautifully white, opening in the afternoon and fading the next morning, when they are succeeded by others. The effect of these beautiful white shining flowers when seen at dusk is really remarkable. It is an annual of easy cultivation, and altogether a very desirable plant.—MAX LEICHTLIN, *Baden-Baden.*

The Viceregal Gardens.—We learn from the “Gardeners Record” that the Viceregal Gardens at Dublin are now being conducted partially on the market garden principle, which does not seem to give satisfaction to the citizens or the critics.

Cultivated Arums at Kew.—As an appendix to the report of Kew Gardens for 1877, lately published—which contains much useful and interesting information on economic botany of an authentic character—a list of the Arums growing in the Gardens is given. This has been prepared by Mr. E. N. Brown, of the Kew Herbarium, and contains nearly 250 species.

Some wonderful examples of flower gardens and flower-beds have been engraved and published of late. In the presence of such amusing sketches, horticultural literature can scarcely be considered “dry.”

The late Mr. Henry Parnall, the clothier, 187, Bishopsgate Street, has bequeathed £1000 upon trust to the vicar and churchwardens of St. Botolph, Bishopsgate Without, the dividends thereon to be applied to maintaining and keeping up as a garden the churchyard of the parish, and to the planting and renewing the trees, shrubs, and flowers.

Leptospermum lanigerum.—This is now producing its white flowers freely on a wall here, but the plant itself is not so free in growth as some of the other species. It has a somewhat prostrate habit, but it is distinct and desirable on account of its flowering at this time of year.—T. SMITH, *Newry.*

Aristolochia altissima.—This desirable hardy evergreen climber has glossy leaves which are produced in a dense manner, and it bears curious chocolate and yellow flowers in the axil of every leaf; it is of free growth, having made about 4 ft. this season. Two other species, *A. Kämpferi* and *tomentosum*, are also distinct and desirable rapid growing climbers for warm situations; the three are totally distinct from each other.—T. SMITH, *Newry.*

Taberosea Out-of-doors in the Isle of Wight.—I wish to know if any of your numerous readers can say whether *Taberosea* will winter well in the ground out-of-doors. They are now blooming very freely in the open air. I send an example.—J. B. [A very fine massive specimen was received with this.]

Elymus glaucus.—Allow me to speak a word of praise for this really distinct and useful Grass. In colour it is quite unlike any other, being bluish-green, and it extends itself freely in every direction. It succeeds both in wet and dry places; in fact, it seems to grow anywhere; and ultimately it becomes a densely matted mass from 2 ft. to 3 ft. high. I may add, too, that in addition to its value from a decorative point of view, it makes a first-rate corner plant.—T. SMITH, *Newry.*

Cool Orchids from Columbia.—Mr. Horeman, of the Colchester Nurseries, has just arrived from a collecting tour in the high altitudes of Columbia, South America, with thousands of the best varieties of cool Orchids, to wit, *Odontoglossum Pescatorei*, *Phalenopsis*, *coronarium*, &c., and a number of other choice kinds; also a new double *Amaryllis* of great beauty.

NOTES FROM KEW.

Hardy Shrubs.—The St. John's-worts are among the most valuable of late summer-flowering shrubs; we now enumerate the best of those in the Kew collection. *Hypericum hircinum*, a South European kind, which makes an excellent plant for the wild garden or for the borders of plantations, has large leaves, and grows about 6 ft. or 8 ft. high; the rather small flowers are produced most freely. *H. chinensis*, about 3 ft. high, is a pretty shrub, with good-sized, bright yellow blossoms, which are rendered very conspicuous by the long stamens. *H. pralum*, from Nepal, attains a height of 3 ft. or 4 ft., and has oval leaves and pale yellow flowers, much larger than those of the next two species. *H. prolificum* and *H. Kalmianum* are two kinds from North America; both have narrow, Willow-like leaves and small yellow flowers; the former grows about 2 ft. high, while the latter is a shrubby plant at least 5 ft. high. *H. oblongifolium*, a handsome Nepanless bush, is a near ally of *H. patulum*, and is certainly one of the most attractive of the hardy shrubs at present in flower; it grows 5 ft. high or more, and the large flowers, borne in great abundance, make a fine show. *Desmodium Dilleni*, though very frequently killed down to the ground during our winter, springs up freely from the roots and makes a mass of shoots, about 3 ft. long, terminated by panicles of purple Pea-shaped blossoms; for the front of the shrubby this is a useful plant. *Dorycnium ibericum*, from the Mediterranean region, is a pretty member of the Pea family, which forms a compact bush, about 2 ft. high, the long-stalked heads of small, white, Clover-like flowers making up in numbers what they lack individually.

Hardy Herbaceous Plants.—One of the most striking and beautiful of the Mint family is the Siberian *Nepeta macrantha*; it grows about 3 ft. high, has very large dark blue flowers, and is by far the finest species of the genus. *Pentstemon Torreyi*, a North American kind, sometimes grows 7 ft. high, though the Kew plant is only 5 ft.; it somewhat resembles the old *P. barbatus*, but is much taller; the tall panicle of bright scarlet blossoms is very handsome. *Antirrhinum rupestre* is a neat-habited annual about 6 in. high; it has small, hairy leaves and large, pink flowers. *Mimulus ringens*, although introduced to English gardens from North America more than a century ago, is not frequently met with now; it grows 1 ft. or more in height and flowers freely, the colour of the blossoms being light blue. *Campanula Langsdorfi*, a dwarf sort, with long, grassy leaves and long-stalked, purple flowers, is not the least desirable of the Bell-flowers. A charming Composite is the New Holland *Podolepis rugata*; it grows 1½ ft. high, and bears numerous large heads of bright yellow flowers. *Erigeron mucronatus*, a Mexican Composite, forms compact masses covered with Daisy-like flower-heads, pink on opening, but changing to white as they grow older; this beautiful plant is sometimes met with under the name of *Vittadenia triloba*, with which, however, it has nothing to do. The best of the Globe Thistles at present in flower are *Echinops sphaerocephalus*, *E. ruthenicus*, and *E. Ritro*; all have Thistle-like leaves and flowers arranged in dense clusters at the ends of the branches; the first, 5 ft. high, has pale blue blossoms; those of the next, which grows about 4 ft., are deep blue; the last, also with deep blue flowers, is only half the height of the preceding. *Kniphofia Macowani*, a small kind with spikes of bright, orange-red flowers, is an exceedingly pretty plant; it is found in a wild state in Grassy places of the Boschberg Mountains, Cape of Good Hope, at elevations of from 4000 ft. to 5000 ft. *Eupatorium sgeratoides*, a Hemp Agrimony from North America, grows 3 ft. high and is covered with white flowers; it is a very useful perennial. Two of the prettiest of the Sea Hollies are *Eryngium blaudum* and *E. giganteum*; the latter, an oriental species, has steel-gray leaves and Thistle-like heads of whitish flowers borne on stems 3 ft. high; the former more resembles our native kind *E. maritimum*, and grows 2 ft. high. A distinct and handsome Himalayan Aconite is *Aconitum ferox*; its dark purple flowers are very conspicuous. *Centaurea Delaestrei*, a recently introduced sort, has narrow leaves and beautiful feathery heads of mauve-coloured blossoms; it grows to a height of about 2 ft.

Greenhouse Plants.—One of Messrs. Veitch's African novelties, *Hæmanthus Kalbreyeri*, is a fine greenhouse plant, the large globular head of deep crimson flowers, borne on a purple-spotted scape, being very handsome. *Rhododendron Brookeanum gracilis* is a fine shrub with pale sulphur-yellow blossoms; the type is a native of Borneo, and Mr. Low, in speaking of it, says, "I shall never forget the first discovery of this gorgeous plant; it was epiphytal upon a tree which was growing in the waters of a creek. The head of flowers was very large, arranged loosely, of the richest golden yellow, resplendent when in the sun; the habit is graceful, the leaves large." *Mussaënia aurea*, a native of Madeira and Teneriffe, is a very handsome Bell-flower with a candelabra-like panicle of upright golden-yellow blossoms.—†

A THAMES-SIDE GARDEN.

(GREENLANDS, HENLEY-ON-THAMES.)

As we have often pointed out in THE GARDEN, it is not to the large country seats of great families that one must look for good design in gardens, and Greenlands is one of the places that illustrate the truth of the remark. Originally laid out by Mr. Marnock for Mr. Marjoribanks, it has been ever since we knew it a model of good taste and good keeping. Since coming into the possession of Mr. W. H. Smith it has been very much improved, and in various departments the gardens have been much extended. The situation of the house by the river is well shown in our engraving. The various pretty river and other views from the house must be left to the imagination. As will be seen, there are no terrace gardens, no walls for stucco or terra-cotta vases; one passes easily from the house to a pleasant lawn, which slopes gently till it touches the river. From this lawn one passes easily to the wide and well-planted grounds around, studded with numerous fine trees, among which are beautiful groups of Cedars and one huge and very picturesque Walnut. It may be noticed that the common fashion of a garden in front of the house is here avoided altogether; but at some little distance there are various flower gardens which, without being exactly under the windows, are within very easy reach, and as richly stored with flowers and flowering shrubs as anybody could desire. It need scarcely be pointed out that this plan keeps the lawn immediately in front of the house fresh, unbroken, and quiet, instead of what it too often is—patched with brown earth or not always happy masses of flowers. There are two excellent kitchen gardens and many plant and fruit houses, all in the best order and well cultivated. In the houses the Bougainvillea is very successfully grown planted out. In the kitchen garden we noticed a beautiful hedge of various new kinds of Clematis, a mass of flower trained on wire fencing. The houses for the gardener and young men are models of their kind. As before remarked, the gardens were designed by Mr. Marnock, whose ideas have been well carried out by Mr. Good, who has been gardener and bailiff here for twenty-four years. B.

Streptocarpus floribundus.—This plant might almost be termed a hardy Gloxinia, and is a very charming flower. It is little known, but if all lovers of good plants knew of its excellent qualities, there are few who would not cultivate it. I cannot assert that it is hardy out-of-doors, but I have had it blooming freely in a pan in the open air for some time, and I look for it to continue in bloom for several weeks yet. It comes true and quickly from seed. My present plants are from seed sown on the 1st of November last in a gentle warmth, and were kept in a cool house all through the winter. I should think it would thrive well on rockwork, where, if needed, the crowns could be protected during the winter.—A. D.

The Portuguese Sundew (*Drosophyllum lusitanicum*).—This peculiar plant, which is reputedly insectivorous, much resembles the Cape Sundew. It has narrow leaves from 3 in. to 6 in. in length, densely covered with glandular hairs, and, when young, they roll inwards, much in the same manner as Fern fronds. Its mode of treatment in cultivation is in direct opposition to that of the other Sundews, which inhabit bogs and other moist places. It is found on dry, sunny banks in Portugal; therefore requires all the exposure to direct sunlight that we can afford in this climate. My plants, including some raised from seed this season, are plunged in ashes in the open air, with flat pieces of glass over each plant, placed in a slanting position about 6 in. above them, to protect them from rain, and they are growing vigorously. The second year the plants will flower, after which they will throw out offshoots, which, if taken off and treated as cuttings—but keeping them rather dry—will soon take root and make good plants. Seeds may be procured from some seedsmen, and should be sown in the beginning of the year; they are in the soil about three months before germinating, and when large enough should be potted off in small pots. The soil I find best suited to them is a mixture of fibry loam, finely broken charcoal, and sandstone in equal parts. The pots must be thoroughly drained and care taken in watering, for if allowed to become too moist, with a little sunshine the plants will damp off. I winter the plants in a dry unheated frame with a bell-glass over each plant. The ill success in the culture of this plant appears to me to be owing to growing it under glass in company with bog plants.—W.

THE PRINCIPAL TYPES OF HARDY EXOTIC FLOWERING PLANTS FOR THE WILD GARDEN.

(A Chapter from the re-written "Wild Garden.")

ACANTHUS (Bear's-Breech).—Vigorous perennials with noble foliage; mostly from Southern Europe. Long cast out of gardens with other fine plants, they are now beginning to receive more of the attention they deserve. In no position will they look better than carelessly planted here and there on the margin of a shrubbery or thicket, where the leaves of the *Acanthus* contrast well with those of the ordinary shrubs or herbaceous vegetation. Though quite hardy in all soils, they flower most freely in free, loamy soils. Not varying very much in character, all obtainable hardy species would group well together. The most vigorous kind at present in cultivation is one called *A. latifolius*, almost evergreen, and a superb hardy

sation. Various other *Achilleas* would grow quite as well in copses and rough places as the common Yarrow, but we know of none more distinct and brilliant than the preceding. The vigorous white-flowering kinds are superb for shrubberies where their numerous white heads of flowers produce a singularly pleasing effect under the foliage in summer. With few exceptions these plants have never been grown out of botanic gardens, many of them being thought too coarse for the mixed border. They are, nevertheless, remarkably beautiful both in flower and foliage, and many effects never before seen in gardens may be obtained by massing them under trees in shrubberies or copses, as a rule allowing one species to establish itself in each place and assume an easy, natural boundary of its own. The small Alpine species would be interesting plants for stony or bare rocky places.

ACONITUM (Monkshood).—These are tall, handsome perennials

A Thames-side Garden (Greenlands, Henley-on-Thames).

plant when well established. Few plants are more fitted for adorning wild and semi-wild places, as they grow and increase without care and are for foliage or bloom unsurpassed by any of the numerous plants that have been so long neglected through their not being available in any popular system of "flower gardening." They will be equally effective in grassy places or associated with low shrubs.

ACHILLEA (Yarrow).—A numerous family of hardy plants spread through Northern Asia, Italy, Greece, Turkey, Hungary, &c., but more in Southern than in Central or Northern Europe. In the Alps and Pyrenees numerous species are found. The Golden Yarrow (*A. eupatoria* and *A. filipendula*) are stately herbaceous plants, with broad handsome corymbs of brilliantly showy flowers, attaining a height of 3 ft. or 4 ft., and growing freely in any soil. These are well worthy of natural-

with very poisonous roots, which make it dangerous to plant them in or near gardens. Being usually very vigorous in constitution, they spread freely, and hold their own amongst the strongest herbaceous plants and weeds; masses of them seen in flower in copses or near hedgerows afford a very fine effect. There are many species, all nearly of equal value for the wild garden. Coming from the plains and mountains of Siberia and Northern Europe and America, they are among the hardiest of plants. When spreading groups of *Aconites* are in bloom in copses or open spaces in shrubberies, their effect is far finer than when the plants are tied into bundles in trim borders. The old blue-and-white kind is charming in half-shady spots, attaining stately dimensions in good soil. The species grow in any soil, but are often somewhat stunted in growth on clay.

AJUGA (Bugle).—Not a very numerous family so far as represented in gardens, but some of the species are valuable for the wild garden, notably *Ajuga genevensis*, which thrives

* This will contain many Original Illustrations by Mr. ALFRED PARSONS.

freely in ordinary soils in open and half-shady places among dwarf vegetation, and affords beautiful tufts and carpets of blue. It spreads freely and is hardy everywhere. The plants mostly come from the cool uplands and hills of the temperate regions of Europe and Asia.

ALLIUM (Garlic; Onion).—A most extensive genus of plants scattered in abundance throughout the northern temperate and Alpine regions of Europe and Asia, and also in America. Some of the species are very beautiful, so much so, as to claim for them a place in gardens notwithstanding their disagreeable odour. It is in the wild garden only, however, that this family can find a fitting home; there species that do not seem attractive enough for the garden proper would afford novel effects at certain seasons. One of the most desirable effects to produce in the wild garden would be that of the beautiful white Narcissus-like *Allium* of the south of Europe (*A. neapolitanum*). The sheets of this in the Lemon orchards of Provence will be remembered with pleasure by many travellers. It would probably only thrive in warm and sandy soils, but there is an allied species (*A. ciliatum*) which would do well in any soil, affords a similar effect, and produces myriads of star-like white flowers. Numerous singular effects may be produced from species less showy and more curious and vigorous.

ALSTROEMERIA.—All who care for hardy flowers must admire the beauty of *Alstroemeria aurantiaca*, especially when it spreads into bold healthy tufts, and when there is a great variety in the height of the flowering stems. A valuable quality of the plant is, that in any light soil it spreads freely, and it is quite hardy. For dry places between shrubs, for dry or sandy banks (either wooded or bare), copses, or heathy places, this plant is admirable. I have noticed it thriving in the shade of trees. It is interesting as being a South American bulb, thriving freely in the wild garden where the soil is sandy or light.

ALTHEA (Marsh Mallow).—These are plants never seen out of botanic gardens now-a-days, and yet, from their vigour and showy flowers, they may afford unique effects in the wild garden. The common Hollyhock in its single form is an *Althæa*, and it is typical of the vigorous habit and the numerous showy flowers of other rampant species, such as *A. ficifolia*. A group of these plants would be very effective seen from a wood walk, no kind of garden arrangement being large enough for their extraordinary vigour. It is not a numerous genus, but there are at least a dozen species, principally found on the shores and islands of the Mediterranean, and also in Western Asia.

ALYSSUM (Madwort).—In spring every little shoot of the wide tufts and flakes of these plants sends up a little fountain of small golden flowers. For bare, stony, or rocky banks, poor sandy ground, and ruins, they are admirable. *Alyssum Wiersbecki* and *A. saxatile* are strong enough to take care of themselves on the margins of shrubberies, &c., where the vegetation is not very coarse, but they are more valuable for rocky or stony places, or old ruins, and thrive freely on cottage garden walls in some districts; some of the less grown species would be welcome in such places. There are many species, natives of Germany, Russia, France, Italy, Corsica, Sicily, Hungary, and Dalmatia; Asia, principally Siberia, the Altai Mountains, Georgia, Persia, and the entire basin of the Caspian is rich in them.

ANCHUSA (Alkanet).—Tall and handsome herbaceous plants, with numerous flowers of a fine blue, admirable for dotting about in open places, in sunny glades in woods or copses. They mostly come from Southern Europe and Western Asia. *A. italica* and *A. capensis* are among the most useful. The English *Anchusa sempervirens*, rare in some places, is an excellent wild garden plant.

ANEMONE (Windflower).—A numerous race of dwarf herbs that contribute largely to the most beautiful effects of the mountain, wood, and pasture vegetation of all northern and temperate climes. The flowers vary from intense scarlet to the softest blue; most of the exotic kinds would thrive as well in our woodlands and meadows as they do in their own. There is hardly a position they may not adorn—warm, sunny, bare banks, on which the Grecian *A. blanda* might open its large blue

flowers in early spring; the tangled copse, where the Japan Windflower and its varieties might make a bold show in autumn; and the shady wood, where the Apennine Windflower would contrast charmingly with the Wood Anemone so abundantly scattered in our own woods. The Hepaticas should be considered as belonging to the same type, not forgetting the Hungarian one, *A. angulosa*. The Hepaticas thrive best and are seen best in half-woody places, where the spring sun may cheer them by passing through the branches, which afterwards become leafy and shade them from the scorching heats of summer. This fair family comprises about eighty species, the greater part belonging to the Northern Hemisphere of the Old World. Many species are Asiatic, chiefly coming from Siberia and Daouria. Some are peculiar to China and Japan, while others grow in the mountains of Nepal or on the slopes of the Caucasus. Europe is, after Asia, the home supporting the most Anemones; about twenty are found dispersed through France, Switzerland, Germany, Greece, and Spain. Some of the European species are also found in Siberia and in South America, while others from the basin of the Mediterranean attain the shores of Morocco. North America, particularly Carolina, Pennsylvania, and Hudson's Bay, have sixteen species, while South America has only five. The Anemones have two zones of preference on the globe—the banks of the Mediterranean and the colder regions of Europe, Siberia, and North America.

ANTHERICUM (St. Bruno's Lily).—One of the most lovely aspects of vegetation in the Alpine meadows of Europe is that afforded by the delicate white flowers of the St. Bruno's Lily in the Grass in early summer, looking like miniature white Lilies. All who have seen it would no doubt like to enjoy the same in their turfey lawns or Grassy places, and there should be no difficulty in establishing it. The large-flowered or major variety might be tried with advantage in this way, and the smaller-flowered kinds, *A. liliago* and its varieties are equally suitable. They are not so likely to find favour in gardens as the larger kind, and therefore the wild garden is the home for them, and in it many will admire their graceful habit and numerous flowers. All the species best worth growing are natives of the Alpine meadows of Europe.

ANTIRRHINUM (Snapdragon).—The common Snapdragon and its beautifully spotted varieties are easily naturalised on old walls and ruins by sowing the seed in old or Mossy chinks. *Antirrhinum Asarinum*, *rupestris*, and *Molle* do perfectly well treated in the same way. Probably many other species would be found good in like places. About two dozen species are known, but comparatively few of these are in cultivation. They mostly come from the shores of the Mediterranean.

AQUILEGIA (Columbine).—Favourite herbaceous plants, generally of various shades of blue and purple, white, and sometimes bright orange. The varieties of the common kind (*A. vulgaris*), which are very numerous, are those most likely to be naturalised. In elevated and moist districts some of the beautiful Rocky Mountain kinds would be worth a trial in bare places. In places where wild gardens have been formed the effect of Columbines in the Grass has been one of the most beautiful that have been obtained. The flowers group themselves in all sorts of pretty ways, showing just above the long Grass, and possess great variety of colour. The vigorous and handsome *A. chrysantha* of Western America is the most hardy and enduring of the American kinds, and would be well worth a trial in the wild garden. The species are of a truly northern and Alpine family, most abundant in Siberia.

ANDROSACE (Androsace).—An exquisite family of little plants which have never yet been grown with success in gardens generally, owing to the conditions of lowland gardens being so unlike those they enjoy in their native localities. I believe they could be easily naturalised in a well-chosen bit of mountain. No experiment in the way of wild gardening would be more interesting. Crevices in rocks, in which they would have no competitors for the scanty soil, would suit them well, as would also bare spots among the rocks, with their deep gritty, or sandy, but not boggy soil. The species of this genus, to the number of more than forty, embellish the rocks of high mountains and the regions approaching the Pole. Europe has nearly twenty—in the Alps, the Pyrenees, and the moun-

tains of Greece—and an equal number live in Asia, chiefly in Siberia, after which come India, Nepal, China, the Caucasus, Persia, and the Levant. North America has several known species extending to the Arctic part of that continent.

ARABIS (Wall Cress).—Dwarf Alpine plants, spreading in habit, and generally producing myriads of white flowers, exceedingly suitable for the decoration of sandy or rocky ground, where the vegetation is very dwarf. With them may be associated *Cardamine trifolia* and *Thlaspi latifolium*, which resemble the Arabises in habit and flowers. All these are particularly suited for association with the purple Aubrietias, or yellow Alyssums, and in bare and rocky or gravelly places, old walls, sunk fences, &c. These pretty plants, numbering about sixty species, belong to the north temperate zone, chiefly Europe. The Arabis is known in all parts of Europe, from Lapland and the coldest quarters to Spain, Sicily, and the Grecian Islands. It is in the mountain chains and at a great elevation that they best develop themselves; so the Alps, the Pyrenees, the Carpathians, and, above all, Switzerland and Carinthia are the best peopled with these elegant plants.

ARENARIA (Sandwort).—A most important family of plants for the wild garden, though perhaps less so for lowland gardens where more vigorous types flourish. There are, however, certain species that are vigorous and indispensable, such as *A. montana* and *A. graminifolia*. The smaller Alpine species are charming for rocky places, and the little creeping *A. balcarica* has quite a peculiar value, inasmuch as moist rocks or stones suffice for its support. It covers such surfaces with a close carpet of green, dotted with numerous star-like flowers. Some of the smaller species, such as *Arenaria cæspitosa* (*Sagina glabra* var.), better known as *Spergula pilifera*, might be grown in the gravel, and even used to convert bare and sandy places into carpets of Mossy turf. In certain positions in large gardens it would be an improvement to allow the very walks or drives to become covered with very dwarf plants—plants which could be walked upon with little injury. The surface would be dry enough, being drained below, and would be more agreeable to the feet. Removing any coarse weeds that established themselves would be much easier than the continual hoeing and scraping required to keep the walk bare. Of course this only refers to walks in rough or picturesque places—the wild garden and the like—in which formal bare walks are somewhat out of place. Nearly 200 species of Sandworts are spread over the world, Europe having about half of these, for the most part from countries round the Mediterranean and its islands. Other series abound in the Alps, the Pyrenees, and the Caucasian range, and through the hills of central Europe. Many come from northern Asia and America. In fact, all temperate and cold regions of the northern hemisphere are embellished by these light and graceful plants.

ARMERIA (Thrift; Sea Pink).—Charming plants, the stouter kinds producing much showy bloom in early summer. Some of them are easily naturalised in good ground, and the very dwarf-cushioned Alpine species is one of the most delightful subjects people fortunate enough to have rock gardens could concern themselves with. The genus comprises about thirty species, found in Alpine, Arctic, and maritime north temperate regions, and in Chili. Separated from *Statice* chiefly on account of their inflorescence, which gives them a peculiar habit.

ARUM (Cuckoo-pint; Lords and Ladies).—Mostly a tropical and sub-tropical family, some of which grow as far north as southern Europe. These are quite hardy in our gardens. The Italian Arum is well worthy of a place in the wild garden, from its fine foliage in winter. It should be placed in sheltered half-shady places where it would not suffer much from storms. The old Dragon plant (*A. dracontium*) grows freely enough about the foot of rocks or walls in sandy, or dry, peaty places. The nearly allied Arum Lily (*Calla ethiopica*) is quite hardy as a water and water-side plant in the southern counties of England and Ireland.

ASCLEPIAS (Silkweed).—Usually vigorous perennials, with very curious and ornamental flowers, common in fields and on river banks in North America and Canada, where they some-

times become troublesome weeds. Of the species in cultivation, *A. Cornuti* and *A. Douglasi* could be naturalised easily in rich deep soil in wild places. The showy and dwarf *Asclepias tuberosa* requires very warm sand soils to flower as well as in its own dry hills and fields. A good many of the hardy species are not introduced; for such the place is the wild garden. Some of them are water-side plants, such as *A. incarnata*, the Swamp Silkweed of the United States.

ASPHODELUS (Asphodel).—The Asphodels are among the plants that have never been popular in the mixed border, nor are they likely to be so, the habit of the species being somewhat coarse and the flowering period not long, and yet they are of a stately and distinct order of beauty, which well deserves to be represented in open spaces, in shrubberies, or on their outer fringes. The plants are mostly natives of the countries round the Mediterranean, and thrive freely in ordinary soils.

ASTER (Michaelmas Daisy).—A very large family of usually vigorous, often showy, and sometimes beautiful perennials, mostly with bluish or white flowers, chiefly natives of North America. Many of these, of an inferior order of beauty, used to be planted in our mixed borders, which they very much helped to bring into discredit, and they form a very good example of a class of plants for which the true place is the copse, or rough and half-cared-for places in shrubberies and copses, and by wood walks, where they will grow as freely as any native weeds, and in many cases prove highly attractive in late summer and autumn. Such kinds as *A. pyrenæus*, *amellus*, and *turbinellus* are amongst the most ornamental perennials we have. With the Asters may be grouped the *Galatellas*, the *Vernonias*, and also the handsome and rather dwarf *Erigeron speciosus*, which, however, not being so tall, could not fight its way among such coarse vegetation as that in which the Asters may be grown. Associated with the Golden Rods (*Solidago*)—also common plants of the American woods and copses—the best of the Asters or Michaelmas Daisies will form a very interesting aspect of vegetation. It is that one sees in American woods in late summer and autumn when the Golden Rods and Asters are seen in bloom together. It is one of numerous aspects of the vegetation of other countries which the “wild garden” will make possible in gardens. To produce such effects the plants must, of course, be planted in some quantity in one part of a rather open wood, and not repeated all over the place or mixed up with many other things. Nearly 200 species are known, about 150 of which form part of the rich vegetation of North America. These fine plants inhabit that great continent, from Mexico—where a few are found—to the United States and Canada, where they abound, and even up to the regions altogether Arctic of that quarter of the world.

ASTRAGALUS (Milk Vetch).—An enormously numerous family of beautiful hardy plants, represented to but a very slight extent in our gardens, though hundreds of them are hardy, and many of them among the most pleasing of the many Pea flowers which adorn the hills and mountains of the northern world in Asia, Europe, and America. They are mostly suited for rocky or gravelly situations, or bare banks, though some of the taller species, like *A. galegiformis*, are stout enough to take care of themselves among the larger perennials. This plant is valuable for its handsome port and foliage, though its flowering qualities are not such as recommend it for the garden proper. The numerous species from the Mediterranean shores and islands could be successfully introduced on banks and slopes in our chalk districts and in rocky places.

ASTRANTIA (Masterwort).—This is an elegant genus, of which few species are known, five being European—found in Italy, Carinthia, Greece, and the centre of Europe—others from Northern Asia. They are among the few umbellates with attractive and distinct flowers, and yet they are rarely seen in gardens. In the wild garden they are quite at home among the Grass and medium-sized herbaceous plants, and partial shade prolongs their quaint beauty. In fact they are far more at home in the thin wood or copse than in the open exposed mixed border.

AUBRIETIA (Blue Rock Cress).—Charming dwarf Alpine plants, with purplish flowers, quite distinct in aspect and hue from anything else grown in our gardens, and never perishing from any cause, except being overrun by coarser subjects. They are admirable for association with the Alyssums and Arabises in any position where the vegetation is very dwarf, or in rocky bare places. There are several species and varieties, all almost equally suitable, but not differing much in aspect or stature from each other. The Aubrietias come chiefly from the mountains of Greece, Asia Minor, and neighbouring countries. Wherever there is an old wall, or a sunk fence, or a bare bank, evergreen curtains may be formed of these plants, and in spring they will be sheeted with purple flowers no matter how harsh the weather. W. R.

SCHOOL GARDENS AT MARLBOROUGH.

It has often been noticed how the love of gardening and interest in gardens have of late years progressed in this country. I had lately an opportunity of observing this progress in a place where some people would have hardly expected to find it, viz., at a public school. As I was to be at Marlborough on prize day, one of the masters, who has in his own garden many interesting Alpine and herbaceous plants, asked me to assist in the judging at their flower show. One of the prizes was "for the best kept kitchen and flower garden, showing superior cultivation in all departments" (glass excluded), and for this seven of the master's gardeners competed. The general schedule of the show included plants, fruit, cut flowers, and vases of wild flowers. The gardens were most creditable; in addition to the three prizes offered we had to highly commend two others. The first and second prize gardens were within the gardening power employed upon them, and were admirably kept; the third was not only well kept, but had a considerable collection of very interesting plants; some of the others were very good. In one garden I noticed some well-kept "boys' gardens." The show (not a large one) was held in a field adjoining the head master's pretty house and lawn; the situation was favourable, and many of the exhibits were good. Being enumerated home suddenly, I had not time to study as thoroughly as I had hoped all the objects exhibited, but the principal ones, and those on which there could be any question, were judged before I left. I never before saw wild flowers so well arranged; many of the bouquets were beautiful; cut flowers in banoeas, perennials and annuals, were very good, the first prize lot beautiful. It was very pleasant in chapel to see so many of the boys and young men with "button holes." The Marlborough people ought to have good taste with Savernake Forest so near. It was my good fortune in spring to visit, in three successive weeks, three of the most beautiful woods in the country—Windsor, Richmond, and Savernake—and I thought that Savernake was in some respects the most beautiful of the three. I should add that the bouquets were arranged with great taste, and a decorated dinner-table was much admired by the judges.

Heatherbank, Weybridge Heath.

GEORGE F. WILSON.

International Horticultural Exposition.—On the 25th of August an International Horticultural Exposition will be opened at Versailles, on the date of the visit to Versailles of the International Horticultural and Botanical Congress, meeting at the Trocadero at Paris. This exposition promises to be a great success. The French Government has offered a magnificent Sèvres vase for the grand prize, besides medals and prizes worth from 800 to 250 francs and lower, for competition among exhibitors in the 100 classes which are open. Messrs. Veitch, Wills, Linden, Van Geert, and the principal horticulturists and amateurs in France have accepted the office of jurymen at this exposition, or, as it may well be termed, this horticultural fête. Particulars and programmes can be had on application to Mons. Truffant, Horticulturist, and Secretary of the Exposition, Versailles.

Lambeth Palace Park.—Would it not be an estimable boon to the inhabitants of Southwark if, during these hot summer months, the fine park adjoining Lambeth Palace, some 18 acres in extent, which is now so jealously guarded, were opened to them for at least a few hours in the day? The nearest breathing spot for the poor of this district, pent up in low-lying and unhealthy dwellings, is Kennington Park. Is it not an anomaly that in so over-crowded a district there should be an extensive park, but rarely used by its owner, and to which the public has no access? —PRO BONO PUBLICO, in "Echo."

A Good White Lobelia.—The best white Lobelia of the speciosa type is one named White Perfection. It keeps on flowering for a long time, and stands drought with impunity.—S.

TREES AND SHRUBS.

THE LINDEN.

THE genus *Tilia*, trees characterised by their delicate, lopped, heart-shaped leaves, gracefully toothed at their margins, and the curious, broad, membranous bract adherent to the flower-stalk, would not be known to the primitive Aryans, since it is confined to the north of America and Asia, and is irregularly represented in Europe. Thus, while the Roman named it *Tilia*, the Teuton, perhaps already aware of the tough "liber" or "bast," reminding him of the "lin" or "lint" (*Linum*), named it also "linta," "linde," or "lind." The first of these is the old German form, the second the modern, whilst the third is common to early English, Swedish, and Icelandic. But several forms are included under this popular name. Linnæus, or Karl Linné, who derived his name from one of these trees growing near his ancestral home, very plausibly ranked them all as merely forms of one species, *Tilia europæa*; but four forms may be distinguished in England, of which one only can claim to be indigenous. This is *T. parvifolia*, a small tree, a native of Siberia and of all Europe, except Turkey and Greece. The leaves are seldom over $2\frac{1}{2}$ in. in diameter, and the fruit is faintly ribbed when ripe. It occurs in woods from Yorkshire southwards. Then there are the three larger forms, *T. intermedia* (D. C.), distinguished by its smooth twigs and unribbed, spherical fruit; *T. grandifolia* (Ehrhart), with downy twigs and from three to five prominent ribs on the fruit, and its variety *T. corallina*, with a reddish-brown bark to the young branches. The last two are confined to Europe south of Denmark. Evelyn encouraged the plantation of Limes in London and elsewhere, and the fine avenue at Ashstead Park, Surrey, is said to owe its existence to the partiality of William III. for this tree. There are fine specimens in Bushey Park, some at Sion House from 70 ft. to 80 ft. high, and some reaching 90 ft. at Ken Wood. The honey made from the flowers is, I believe, pale in colour and excellent in quality; whilst, besides the valuable already-mentioned bast, which is manufactured into cordage in Germany, the sugary sap can be fermented into an agreeable wine, and the fine, even-grained wood is highly prized for charcoal, for musical instruments, and for carving. The work of Grinling Gibbons in the choir of St. Paul's, at Windsor, in the library of Trinity College, Cambridge, and at Chatsworth is in this wood. The four rows of large trees, mostly Limes, which give the name Unter den Linden to one of the grandest streets in Berlin, are widely known, but the finest avenue I have myself seen is one in Dromana Park, Co. Waterford, where each tree has been able to grow to the fullest perfection; its stem draped with leafy boughs from the ground to its summit, so even in their development, that the whole tree has that noble cylindrical or columnar outline which is the perfection of its beauty. The modern name Lime is merely a corrupt form of Line. G. S. BOULGER.

11, Burlington Road, Westbourne Park.

The American Cork or Western Rock Elm (*Ulmus racemosus*).—This tree is quite widespread from Vermont to Canada and Illinois, but is most abundant in Michigan and Missouri. It is distinguished by the thick, corky ridges which extend along the young branches. The specific gravity of the wood is .832, while that of the American Elm is only .619. The wood is fine-grained and compact, and shows but little of that inclination to splinter which renders the wood of the American Elm unfit for many purposes of construction. The wood is susceptible of high polish, and is well fitted for hard finish and interior decoration. In localities where the tree grows wild it is much used in making agricultural implements, &c., but as yet the wood is not found in the eastern markets. In point of heating power, the Rock Elm is but little inferior to Hickory, and very much better than White Oak. It seems a pity that this valuable tree should be rapidly disappearing from the country. Those who contemplate the planting of forests should see that this species is in their list.—Prof. SARGENT.

Acer Wagneri laciniatum.—Permit me to direct the attention of planters to this very desirable ornamental Maple, which is, I think, the best of all the cut-leaved varieties. It is a strong vigorous grower, with large, glossy, deeply cut leaves, some of which measure fully 12 in. across, and they are divided into seven lobes, each from 6 in. to 7 in. long. This variety is also ornamental in autumn, its foliage dying off a deep yellow colour.—G. B.

GARDEN DESTROYERS.

TIPULA OLERACEA.

(CRANE FLY, DADDY LONGLEGS, OR JENNY SPINNER.)

THE male and female of this insect are very similar in general appearance. The female is, however, rather larger than the male, which is about $\frac{3}{4}$ in. long and $1\frac{1}{2}$ in. across the wings when fully extended. The female is about $\frac{1}{2}$ in. longer than the male, and her wings expand nearly $\frac{1}{2}$ in. more. The body of the male is club-shaped at the end, while that of the female is pointed; in other respects, to the ordinary observer, they are alike. The general colour of the insect is a yellowish-brown; the eyes are black, the thorax more or less striped with dark brown; the body is greyish-brown above; the head is small and furnished with a pair of short, slender antennæ; the fore part of the head is produced into a kind of beak. The shape of the head and the attitude of the insect gives it and several allied species, when flying, somewhat the appearance of cranes; hence the name of Crane-flies. The wings are somewhat smoky, the nervures or veins being yellowish-brown. Near the base of each wing, on either side of the thorax, is a short thread-like organ terminated by a knob. The use of these organs, which are called halteres, poisers, or balancers, is uncertain; they are supposed by some to take the place of the lower wings with which most insects are provided (insects, if winged, have usually four, except those belonging to the Natural Order Diptera, or two-winged insects, which includes all true flies); others think that they are in some way connected with the respiratory organs. The legs are very long and

Daddy Longlegs (Tipula Oleracea).

slender, the hindmost pair being the longest. The eggs are very small, black, shining grains, of which over 300 have been taken from the body of a female. They are laid by means of a short ovipositor in the ground at the roots of Grass and herbage, where the grubs when hatched can at once procure suitable food. The grubs are commonly known by the name of Leather Jackets, on account of their particularly tough and leathery skins. When full grown they are about 1 in. long, of an earthy-grey colour, with black heads. Like the grubs of all two-winged flies, they have no legs. In August or September they assume the chrysalis state. The chrysalis is about the same size as the grub and of the same colour. The head is furnished with a small horn on either side, and there is a transverse row of small spines on the underside of each joint of the body, by the assistance of which the chrysalis is enabled to work its way to the surface when it is time for the perfect insect to appear.

The Daddy Longlegs may be found from the middle of summer until they are killed by autumnal frosts. In some years they are very abundant, and may be seen on lawns and meadows in immense numbers; in other years hardly one is to be found; they are in no way hurtful to vegetation. The grubs, however, do an enormous amount of damage both in the flower and kitchen gardens. At times lawns suffer much from the grubs eating the roots of the Grass, causing it to wither and die; they also feed on the roots of Dahlias, Carnations, Zinnias, Balsams, China Asters, Potatoes, Beans, Beetroot, Carrots, Turnips, and Lettuces, committing much havoc among them from May till they assume the chrysalis state in August. The best means of reducing the number of these insects appears to be by keeping all garden ground as clean as possible, for it is chiefly in undisturbed, weedy ground that they are bred. When a plant withers and droops, and there is any suspicion that these

grubs may be attacking it, a careful search should be made at its roots for them. Wet weather seems to have no injurious effect upon them, as they are fond of damp, moist places. They appear to be able to bear almost any amount of cold, for they have been known to revive after having been frozen until the fluids in their bodies were quite congealed. The chrysalides may often be found when garden ground is being dug, and should always be destroyed. The perfect insects, if in great numbers on a lawn, may be destroyed by passing a roller or mowing machine over them. Rooks, starlings, and other birds destroy great numbers of the grubs. S. G. S.

THE KITCHEN GARDEN.

SOWING AND PLANTING CABBAGES.

I do not think that anything is gained by growing too many varieties of Cabbage. One or two early quick-heating kinds of the Early York or Little Pixie type, to be planted thickly on a well-sheltered border with a south aspect, come in usefully in February and March, and these may be cleared off in time for early Potatoes or French Beans. For the main crop, on open quarters, such sorts as Early Battersea, Wheeler's Imperial, or Enfield Market, are all good if carefully selected. In sowing select an open piece of ground that has been dug for some time in order to get mellow and consolidated sufficiently to retain moisture without much artificial application of water. The best plan is to make two sowings, one now and another about Aug. 30. Sow thinly in order that every plant may have room to properly develop itself. Keep the soil continually moist and free from weeds. Beds about 5 ft. wide, with an alley on each side, are most convenient, and shallow drills about 4 in. or 6 in. apart offer greater facilities for cleaning with a narrow hoe between the drills than broadcast sowing. The main crop on open quarters I have for years planted after spring-sown Onions, as that crop is harvested early in September and leaves the ground in good condition for any succeeding crop. When the land has been well manured for Onions, good Cabbage could be produced without digging by simply drawing deep drills and soaking them with water, if the ground be at all dry. As, however, the land for Cabbages can scarcely be too rich, I have generally dug into it deeply a heavy dressing of rotten manure, for if the stalks be left to produce a second crop of crowns, the produce will well repay a little extra preparation. The advantage of this second crop over young crops following in quick successional order is not acknowledged by many good cultivators, but from my own experience I must say that a good bed of Cabbages following a crop of Onions, and succeeded by an abundant second crop of Sprouts, is a great gain; and when the stumps are cleared off, the ground, being firm, will be in good condition for Celery treuches. I may remark that while $2\frac{1}{2}$ ft. is not too much space for the rows of the largest Cabbages, $1\frac{1}{2}$ ft. is sufficient for small early kinds. Medium-sized kinds at intermediate distances will prove the most useful for the majority of cultivators. I may remark that any plants showing a tendency to start prematurely to seed should be pulled up and thrown away at once, and replaced by fresh plants from the seed-bed. The remnant of the plants left on the seed-bed should be pulled up and pricked out into nursery beds, to stand the winter for filling up gaps and for making a small successional planting in March for succession during the summer, by which time spring-sown crops will be ready for use. J. GROOM.

VEGETABLES IN TRENCHES.

THIS season has illustrated in a remarkable manner the variable character of our climate, and from the beginning of June the constantly saturated state of the soil through heavy rains, accompanied by a low temperature, brought tender vegetation to a standstill, especially on heavy, retentive soils. But a sudden change to brilliant skies and drying winds has already given the vegetable quarters on light soils a dried-up aspect, and with a continuance of the present weather choice vegetables will soon be suffering from want of water. The Potato

crop, which at one time showed here and there unmistakable signs of disease, is now ripe and ready for lifting, with the exception of the latest varieties, and the disease, through the drier weather, is apparently arrested in its course. We are so accustomed to moist summers, that many believe artificial watering or irrigation to be useless, and doubtless if sufficient water be only given to moisten the surface, thereby drawing the rootlets up where they will be most likely to be scorched, such may be the case. But we have abundant evidence that even the raised up flower-beds, now-a-days so fashionable, may be kept as luxuriant as possible, no matter how hot and dry the weather may be, if water be liberally given to them. In the kitchen garden, where a supply of succulent vegetables is in constant request, many of the crops for midsummer and autumn use may be grown in trenches similar to those used for Celery, but not quite so deep. In fact, depth is a mistake to be avoided, as if too much of the top spit be taken out the crops will be in some cases brought in contact with a sour, hard subsoil. Where these conditions exist, the bottom spit should be thrown out and replaced by the top one, mixing with it a good dressing of well decayed manure. There is one advantage belonging to this system of culture, viz., a saving of labour. In the case of laud that has been cleared of any of the Cabbage family, or of any crop that leaves the ground very hard, it would be simply hoed and raked level, and the trenches marked out at the required distance apart. When ready for the seed or plants, they need not be more than 3 in. or 4 in. below the ordinary level, as the soil thrown out will keep the drought from acting on the intervening spaces, and a mulching of partly-decayed manure should be applied over the roots as soon as the crop is in active growth. This will prevent evaporation, and one good soaking of water will keep any crop in a growing condition for several days, no matter how hot or dry the weather may be. All kinds of tall Marrow Peas will continue in bearing for a long period if treated in this manner and kept closely gathered as soon as the Peas are fit for table; the same remark also applies to Scarlet Runners that drop their blossoms instead of setting them when dry at the root; likewise to Freuch and dwarf Beans, and we may also add Cauliflowers of all kinds, that in hot, dry seasons invariably button or form heads prematurely. Of small-growing crops that require little room two or three rows may be planted in wide trenches, such as Turnips, Radishes, Lettuce, and Spinach, for in addition to the advantage of keeping the moisture confined to the roots, the full glare of the sun does less harm than in the case of crops on level ground. A few light evergreen branches laid across the trenches act as a good screen for fresh-planted or newly-sown crops. These are all simple and inexpensive remedies, which, if droughts were of annual occurrence, would be much more generally appreciated than they are at present.

J. GROOM.

Culture of Asparagus at Chester.—Having seen some remarkably fine Asparagus grown near Chester by Mr. Viggers, we asked him for a few words as to the mode of culture which he pursues, and which is as follows:—"First year: Sow the seed on well-manned ground about 12 in. apart in drills, and let the seedlings grow for two years. Third year: Prepare some good sandy ground for the best plants; manure 25 to 30 tons to the acre; form out beds 4 ft. wide, and plant three rows in each bed. Fourth year: Manure and salt in winter, and in the spring soil the beds up a little, say about 3 in. or so. Fifth year: Cut till the end of May. Sixth year: Manure and salt every other year, and cut till the end of June. We have about 6 acres of Asparagus of different ages. I took some thirty-year-old plants up last year, about 2 acres, and sold them for forcing; they were very good—quite equal to some plants nine or ten years old. I have had a portion of Asparagus ground set apart for sewage irrigation; if I find that answer, I intend putting the sewage over the whole of the ground, as I have pipes laid all along it."

Hathaway's Excelsior Tomato.—Having grown several varieties of Tomatoes this season in pots, viz., Criterion, Old Red, Excelsior (Hathaway's), Orangefield, Trophy, Green Gage, and Kay's Prolific, I consider Hathaway's Excelsior far superior to any of them for general purposes, being a good grower and cropper, and having a handsome fruit, very large and as round as an Apple. Out-of-doors, too, it promises to be a desirable kind, as it ripens early, an important point in connection with Tomatoes in the open air.—J. WILLIAMS, *Dunorlan, Tunbridge Wells.*

THE FRUIT GARDEN.

DANGERS IN THE USE OF TINNED FRUITS.

PINE-APPLES, Peaches, Apricots, and other fruits preserved in tins and imported from America constitute at the present time a considerable supply of food in this country. The advantage accruing from delicate fruits being obtainable at all seasons of the year at a moderate price needs no comment. I feel it my duty, however, to direct attention to the fact that the benefit anticipated is of a doubtful character, since the juices of the fruit are, under certain conditions, able to dissolve portions of the tin from the tin-plate in sufficient quantities to cause sickness. The following facts are of sufficient importance, both to the medical profession and to the general public, to warrant their being made known. Having lately had occasion to examine some liquid vomited during sudden sickness, with the view of detecting a poison of an unknown nature, either organic or metallic, I submitted it to a very complete chemical analysis. The absence of any poisonous alkaloid was proved by the process of Stas. Arsenic, antimony, and mercury were proved to be absent as well by Rainach's process as by subsequent operations. A small quantity of a brown metallic sulphide was obtained, soluble in sulphide of ammonium, and reprecipitable from this solution by acids. The actual amount of precipitate was inconsiderable, only sufficient, in fact, to cover a very small filter. It was impossible to attempt any quantitative estimation of this substance, but it was decided to put its identity beyond doubt. This was done by reducing the sulphide to the metallic state by means of the blow-pipe. The minute globules of metal, which could not have weighed more than a few thousandths of a grain, possessed the colour, hardness, malleability, and other properties of metallic tin. The minute quantity found was that only which had escaped absorption by the system, and in all probability much less than the whole amount taken. Having no further information concerning the case, I cannot say decidedly what was the source of this metal, but I was previously aware that it is occasionally present in the juice of fruit preserved in tins—as, for instance, Peaches. My friend, Dr. C. R. A. Wright, Lecturer on Chemistry at St. Mary's Hospital, informed me that he had detected it in the remains of a can of fruit, to the eating of which in a tart an attack of sickness was attributed. One of the students in the chemical laboratory of King's College—Mr. A. E. Menke—has lately been estimating, under my direction, the amount of metal present in two or three samples of tinned provisions. In the syrup from a tin of Pine-apple, of about a pint in capacity, there was found a grain of tin (0.15 grm.); in a large tin of Apples, a little less than 4.100ths of a grain; and in the liquor from a tin of lobster, mere traces of the metal were found. (See "Chemical News," July 6). No information of importance concerning tin poisoning has been recorded, hence it is difficult to say what quantity of the substance may be looked upon as dangerous. It will be advisable in future to throw away the syrup contained in fruit tins, and indeed the whole contents of every such vessel the surface of which is at all corroded. Regarding the cause of the occasional solution of the tin, a careful examination has shown that at the point where the drop of solder seals the aperture made for the escape of steam during the preserving process a galvanic action is set up between the lead of the solder and the tin of the tin plate. A possible remedy exists in sealing the can with a drop of pure tin.—W. N. HARTLEY, F. Inst. Chem., F.R.S.E., in "Lancet."

Market Pears.—In the London market gardens there is a fair crop of Pears on standard trees and on those on walls of some kinds, whilst others are almost a failure. It is satisfactory to find, however, that that excellent Pear, a coloured plate of which was given in THE GARDEN (see Vol. XII., p. 234), named the Pitmaston, is bearing a fair crop where grafted on the Pear stock, i.e., old Pear trees cut back and grafted on the Quince. On walls or espaliers this Pear does well, but as a standard, owing to the great size and weight of its fruit, it is unsuitable.—S.

Madresfield Court Grape.—The true value of this excellent Grape is only now beginning to be understood. It has been for some weeks past the best Black Grape in Covent Garden Market, and its fine appearance obtains for it higher prices than those paid for any other kind. Its great fault with most growers is that its berries crack after stoning, a circumstance which completely destroys its appearance and quality. One of the most successful growers of it, however, and one who has at the present time a large house of ripe fruit of it, in which a cracked berry cannot be found, informed me that the way in which he succeeds so well with it is by withholding water from the roots until some time after the berries have stoned, when a good soaking was given. As long as they felt hard and solid no water was administered.—S.

THE LIBRARY.

PINE PLANTATIONS IN FRANCE.*

NINETY years ago the Landes of Gascony alone formed an area of 300 square miles of barren, ever-shifting sand, the dread of the inhabitants, which in times of storms actually covered cultivated fields, villages, and even entire forests. Since then these and the extensive Landes of the Gironde have been largely and profitably reclaimed by the planting thereon of *Pinus maritima*. Numerous books have been written by Frenchmen and others detailing the means employed in fixing and utilising these shifting sands, and it is by a judicious selection from the best of these that our author has compiled this little volume. *Pinus maritima* is a native of both coasts, and also of a few of the islands of the Mediterranean, growing luxuriantly in the poorest of sandy soils; hence the success that attends its cultivation on the sand dunes of the French coast bordering on the Mediterranean. For the mode of sowing the seed of this Pine and the after means employed to protect the seedlings from the shifting sands; for the cultural details of this Pine as a forest tree, and its comparative value as a Coniferous timber tree, as well as for its commercial products, such as yellow resin, pitch, turpentine, &c., and their uses, those interested ought by all means to consult this volume. There is also a chapter on the diseases and enemies (animal and vegetable) to which this tree is subject in France, and another most interesting chapter is devoted to a consideration of the comparative merits of the various geographical varieties of the *Pinus sylvestris*, which we commend to the consideration of those who are interested in the cultivation of that species. "This volume," we are informed in the preface, "was originally compiled in view of what seemed to be required at the Cape of Good Hope. It has been revised and printed now only as a contribution towards a renewed enterprise, to arrest and utilise sand wastes which stretch from Table Mountain to the Hottentot Holland Mountains." There are similar sand wastes in this country, particularly those on the Lincolnshire coast; and as the very poorest of us have an interest in the reclamation of waste land in Britain, we gladly contribute to that end by commending this volume to all whom it may concern. GEO. SYME.

THE STUDENT'S FLORA OF THE BRITISH ISLES.†

It is seven years since the first edition of this very useful handbook was published, and a second edition has now, somewhat tardily, appeared, the previous one having been out of print for a considerable time. Too much praise cannot be bestowed on the general design of the book; the faults, as a rule, are mainly in points of detail, and do not seriously detract from the value of the work. As a matter of fact, the information given could not possibly have been collated had not the enormous botanical library and immense herbarium (the largest and most complete in the world) of the Royal Gardens been at the complete command of the author. We may enumerate a few of the particularly good points of the work in hand. The essential characters and properties of the Natural Orders and genera are given, their distribution, the number of genera in each Natural Order, and the number of species in each genus. The student can thus with ease form a tolerably correct estimate of the proportions which the indigenous members of any Natural Order or genus bears to its relatives in the rest of the world. The geographical distribution in a wild state of each species is fully given, and when a plant has become naturalised to any extent in a foreign country the fact is mentioned. For careful and correct diagnoses, however, the critical British botanist will find works which, from his standpoint, are much superior to "The Student's Flora of the British Isles," although none can compare with it in the vast mass of information which it contains. Some of the more obvious mistakes of the first edition have been corrected in the present one, but many still remain, and these we hope to see rectified in future editions. After his expression of dissatisfaction with the arrangement of the aquatic Ranunculids, and his regret that he had not in that group secured the co-operation of Mr. Baker (in the preface to the first edition), we fully expected that the author would have made some alteration

in the revised edition. None, however, has been made, if we except the addition of a variety, *R. fissifolius*, under sub-species *heterophyllus*. The arrangement of the Cryptogams has been totally altered; the genera *Selaginella* and *Isotetes* have been taken from *Lycopodiaceæ* and a separate Order created for them, viz., *Selaginellaceæ*, as it is given in the body of the work, or *Selagiaceæ*, as it appears in the synopsis at the commencement. Then, again, the whole of the Cryptogams have been divided into two natural groups—those with spores of one kind only and those with spores of two kinds. The Ferns, Horsetails, and Club Mosses come under the first group, the *Selaginaceæ* and *Marsilaceæ* under the second. The Mosses have been somewhat re-arranged; in the first edition but five species are given, with numerous sub-species and varieties; whereas now the British forms are grouped round seven species. These are the principal modifications of importance. We may add that *Cicendia filiformis* has been dignified with generic rank, and now goes under the name of *Microcala filiformis*. The distribution of some of the more critical species and varieties throughout the British Isles leaves much to be desired; and much thoroughly authenticated information upon this point might have been obtained, had the recent volumes of the "Journal of Botany" and other works been consulted. There are many typographical errors, too, which seem to indicate that sufficient care has not been spent on the work as it passed through the press. What, for instance, could be made of the following were it detached from the letter-press accompanying it?—*This species differs from U. (Utricularia) Minor and its more robust habit and orbicular life.* The initial letter of *minor* should not have been a capital, and should have been *in*, and the final word of the quotation *leaf*, not *life*. In several instances the essential characters of the Natural Orders are not comprehensive enough, e.g., *Scrophulariaceæ*, where the calyx is represented as having five divisions, whereas in *Veronica* the number of sepals is nearly always four.

SKETCHES FOR COTTAGES.*

MR. LASCELLES sends us a copy of this book of designs for constructions in the patent cement slab system to which he has paid so much attention. It would have added to the value of the designs if some idea of the price at any given time or place had been added. The designs, it need hardly be said, are interesting and good—we like those best which are not stingy of light, and have not the very long, bare roofs. It is odd how little light architects will allow us in this dull climate, and curious to notice how light is generally more limited near the top of the house, making it thereby heavy where it ought to be the reverse. These cottage designs cannot fail to interest those concerned in the improvement of the dwellings on their estates. They begin with a very simple type of cottage—the "But and Ben" of the Scotch.

We believe the material employed by Mr. Lascelles in such structures is well adapted for the construction of improved garden walls. The old wall is too expensive and needlessly heavy; and we trust Mr. Lascelles will turn his attention to the subject. A good system carried out by one of such proved skill and enlightened enterprise in the building art could scarcely fail to be very successful. Dr. Johnson said he never ate as much wall fruit as he should like: the remedy is still wanted—more walls for the choicer fruits that will not ripen without their aid, and close covering of every square foot of available wall with the best varieties.

M. E. Andre.—We have received a very interesting report of this gentleman's scientific mission to South America—so fruitful in discoveries of valuable plants; it is in French, and is extracted from the "Archives des Missions Scientifiques et Littéraires." We hope to illustrate some of M. André's most remarkable plant discoveries in THE GARDEN as soon as good specimens are procurable.

The Pentstemon as a Bee Plant.—We have at present a bed of *Pentstemon*, 70 ft. by 18 ft., in full bloom, and the number of bees that is among them from morning to night is something wonderful. Oddly enough, there is a bed of *Antirrhinum* still larger not far off, and not a single bee is to be seen amongst them, although they are also in full flower. I have some very fine seedling *Pentstemons* I obtained some years ago by introducing a strong-growing variety amongst our plants of them; they seem to have crossed freely with it, and it has been the means of nearly doubling the length of the flower-spikes.—J. DOWNIE, *Pinkhill Nursery, Corstorphine.*

THE INDOOR GARDEN.

CEREUS SERPENTINUS.

This is an erect-growing plant until it attains a height of about 3 ft., when it remembers, as it were, its name, and begins to twist. Its spines are what is termed setose, of a silvery white colour, and densely set on the stem, which never gets more than 1 in. in diameter. Its flowers, which are white, with a slight tint of brown, are about 9 in. in length; they open in the evening and close the next day. The Night-flowering *Cereus* is generally considered to be exceptional as to its time of flowering, but it is in reality not so; the only difference is that some last longer than others; but most of them go off when the sun begins to shine strongly. It is

Cereus serpentinus.

quite a greenhouse plant, and one by no means difficult to cultivate.

J. CROUCHER.

Sudbury House, Hammersmith.

Storing Gesneraceous Roots in Winter.—We were agreeably impressed last spring with the completeness of the arrangements made for storing tubers of *Gloxinias* and other Gesneraceous plants in the horticultural establishment of M. Louis Van Houtte, of Ghent. A long room, provided with several tiers of stages, was completely filled with tubers of all sorts and sizes in the most perfect state of preservation, and in numbers so astounding that we forbear to quote how many are in this way stored annually. With us too often the returning spring finds the tubers either rotted, or parched up, or etheralised—gone! This often results from keeping them in too high a temperature—from 70° to 80°, which is much too hot. The secret of M. Van Houtte's success in their preservation is that they are not subjected to extremes of any kind; they are dug up and turned out with their roots and leaves attached and such of the soil as will hang about them, and they are allowed to dry very slowly surrounded by these *impedimenta*. During winter the bulb stores is kept at about 50° Fabr. The result is that the roots turn out plump and fresh when required for planting.—“Florist.” [Such roots have often been lost through being stored in rooms not protected from excessive cold.]

PLATE CXL.

VARIETIES OF EPIPHYLLUM TRUNCATUM.

As decorative plants during winter and spring the different varieties belonging to this section of Cacti have few equals. They bloom well even in a very small state, and they can consequently be used either as plants in 5-in. or 6-in. pots to decorate the side benches in a small stove or intermediate house, or they can be grown to a size sufficiently large to fit them for the central position in large plant structures. In no way, however, are they seen to better advantage than when grown on their own roots in the form of low spreading bushes 12 in. or 15 in. in diameter. The pots should be plunged in a neat wire basket, of suitable size, fringed with *Lycopodium caesium* or others, and suspended from the roof of the house in which they are placed. In this way their drooping flowers are seen to the best advantage. Showy flowering plants with a drooping habit are not over plentiful, and it is well to use such as these *Epiphyllums* in that way, for if hanging baskets were employed to a greater extent than they usually are in plant houses, both warm and cool, the appearance of the houses would be enhanced. *Epiphyllums* of this class are easily propagated either by grafting them on the *Pereskia* stock or by striking cuttings of them for growing on their own roots. Cuttings made from pieces of the shoots consisting of three, four, or half-a-dozen joints taken off before growth has commenced, and inserted singly in small pots drained and filled with a mixture of equal parts of sand and peat or sand and loam, will strike root freely if placed in a brisk heat and slightly but not over moistened. They should be kept moderately near the light, but not enclosed under a propagating glass or similar contrivance, as they are liable to rot if confined. When the pots are filled with roots give a shift into others a size or two larger, but they must never be over-potted. A mixture of five parts turfy loam to one of sand, with a sprinkling of potsherds, will be found to suit them perfectly. Soil of an adhesive character, that will hold too much moisture, they cannot bear. Grow them on in an ordinary stove temperature without shade during the summer, and pinch the points out of any shoots that take too much lead. A temperature of 50° through the winter will be sufficient for them, and they should be kept drier at the root than when in active growth. In spring increase the pot room according to the progress which the roots have made, and grow them on as in the preceding season until the end of July; then turn them out for a month under a south wall, where they will be exposed to the full influence of the sun. In cold parts of the country, where this cannot be done, instead of turning them out of doors, they should occupy a dry shelf in a greenhouse or an equally airy light position in a pit or frame, and they should have less water given to the roots than whilst they are growing. *Epiphyllums* of the *truncatum* class, being originally from Brazil, will consequently bear a high temperature, and their progress, other details in their cultivation being equal, will usually be more or less in keeping with the amount of heat to which they are subjected. They are generally grown as standards, so as to form either a drooping pyramidal head, or as plants of a spreading, umbrella shape. Their cultural requirements when on the *Pereskia* stock are similar to those under which they succeed on their roots; but on this stock they will frequently bear more indifferent treatment than on their own roots. The *Pereskia* stocks on which to grow them are easily struck from cuttings put in in the spring and subsequently treated in a similar way to the generality of the Cactus family, with the exception that they do not like such a continuous dry condition of the roots as some of the most succulent species will bear. The following are good varieties, viz., *E. violaceum* Snowi, *E. v. superbum*, *E. v. grandiflorum*, *E. splendens*, *E. salmoneum*, *E. s. marginatum*, *E. albo-violaceum*, *E. Bridgesi*, *E. bicolor*, and *E. Ruckeri*.

T. BAINES.

[The specimens from which our plate was prepared were grown by Messrs. Veitch & Sons, of Chelsea.]

SOME *Lilacs* now in bloom are far too strongly scented to be kept in rooms.—S.

A GROUP OF EPIPHYLLUMS (VARIETIES)

PROPAGATING.

DOUBLE PRIMULAS.—The best months in which to increase these are May, June, and July. Plants intended for propagation must be got into the house and kept syringed two or three times a day and shaded from hot sunshine; cut away all bad leaves and give a liberal supply of water at the root. In about a fortnight they will supply cuttings, which are best put in singly in 2½-in. pots in finely-sifted soil consisting of yellow loam, leaf-soil, and silver sand; prepare the cuttings as shown in the annexed illustration, after which press them gently into the soil and water with a fine-rosed pot, but not over the leaves; plunge the pots half way up in the propagating box on a brisk bottom-heat, put on the glasses or lights and shade from all sunshine, open the box every morning early for an hour or two and sprinkle overhead with water gently according to the weather. They must not on any account be allowed to flag. In three weeks they will be ready to take out, when they

Cutting of Double Primula.

must be carefully and gradually hardened off. The temperature necessary to bring forward the cuttings should be from 65° to 70°.

H. H.

GARDENING FOR THE WEEK.

Flower Garden.

Auriculas.—When hot dry weather sets in green fly is almost certain to attack the plants, and it spreads at a rapid rate if not destroyed or checked. Fumigating with Tobacco smoke is the only remedy which I have found to destroy it; but it is very dangerous to do this when the plants are in full growth; even if very great care be exercised, the young and tender leaves, that it is most desirable should be preserved, suffer. Mr. Meiklejohn, of Stirling, who grows Auriculas most successfully, destroys green fly by using a powder made of dried Tobacco. He dries the Tobacco until he can rub it into a powder with his hands; a small pinch of this dropped in the centre of a plant infested with fly will destroy that pest. I find that Scotch snuff in a dry state, or Pooley's Tobacco Powder answers the same purpose. Perhaps the better plan is to remove the fly with a small camel's-hair brush; but in a large collection this is a tedious process. I have just finished re-potting; it is much later than usual for this operation, but the crowns are very strong and the plants will soon become established. The offsets put in early in spring (February) have also been re-potted into 3-in. pots. Many of these are now strong plants; they will produce trusses with from three to six pips next year, and many of them are much better than those on the older plants. Robert Trail, Colonel Champneys, Pizarro, Lord Lorne, John Waterston, Mrs. Smith, and, indeed, many other sorts are most satisfactory from small plants. It is a good time now to remove offsets. Very scarce sorts should be placed under a bell-glass; they are certain to root in such a place if they be not overwatered. I put the ordinary stock under hand-lights, where they will nearly all form roots. These most difficult to manage are those formed on the stem above the surface of the ground, but there will be no difficulty if a bell-glass be used.

Carnations and Picotees.—The blooming season for these is now nearly over; still, there are large numbers of side shoots which will yield us a few blooms for cutting a week or ten days longer. As soon as they fade we remove the plants out-of-doors. Perhaps half of our plants are

already in the open air, and before this appears in print all that portion of our stock will be layered. It is necessary to do this at once in order to check the growth of the "grass," which, in the case of many of the plants, will run to flower. The check which the growth receives by cutting it nearly through arrests the flow of sap, and in nearly every case prevents spindling. Before layering, the surface soil in the pots should be removed and be replaced with some light material consisting of about equal parts of loam, leaf-mould, and sand.

Pinks.—The pinks which were put in six weeks ago are now well rooted, and the boxes containing them have been placed out-of-doors. If this be not done the plants get very much drawn. They must now be planted out about 4 in. apart in fine soil, to be re-planted again in October. If there be not a sufficient number of plants, it is not difficult to obtain plenty of good side growths from the strong shoots. Such plants will not be large, but they will produce a few good, full-sized, well-marked flowers. If the space is now vacant where it is intended to put out the plants, it ought to be trenched up and some good rotten manure be mixed with it. It is not often that this can be done, but, when possible, the plants will succeed all the better.

Gladioli.—The spikes of these are now showing themselves and require attention. Stoutish sticks must be put into the ground near the bulbs, but not so close as to injure them, and to these the spikes must be fastened. If it is intended to hybridise any of the flowers with the view of saving seed, those that open earliest should be selected, as many of those that bloom late will not produce seed, owing to cold wet weather setting in before it has had time to ripen. The very best varieties only should be selected, both as seed bearers and also to take the pollen from. There is no flower easier to hybridise than the Gladiolus. Before the flower is quite open the anthers should be removed, and next day take the pollen from the selected variety and dust it on the stigma of the flowers from which the pollen has been removed. I do not trust to one application, but make a third, and even a fourth. The beds are mulched and water is applied when necessary. I only use clear water, but many use guano water or drainings from the manure heap. I fancy manure water aids decay in many of the bulbs, and as the strongest spikes can be produced without its aid it is better not to use it.

Dahlias.—These are now growing with great vigour, and will require considerable attention. Nearly all the varieties produce too many shoots; all should be removed but three or four, and the flower-buds must also be thinned out. This is a matter requiring some experience, inasmuch as some varieties have a tendency to coarseness, and this will be encouraged, not checked, by thinning out the flowers too much. Flowers possessing refinement in a high degree and that are usually undersized cannot, on the other hand, be overthinned. See that traps are set for earwigs, which are very destructive to the blooms; they eat the edges of the yet unopened petals. Bean-stalks, inserted between the shoots and the sticks to which the plants are tied, form a good hiding-place for the insects; they crawl into them at night and can be blown out in the morning into a pail of water.

Hollyhocks.—These require much the same attention as Dahlias, such as fastening the main growth to the sticks and removing the side shoots. If eyes can be obtained from these, they make excellent plants. I simply take the eye and cut it out with about ¼ in. of stem attached; these are inserted about four or five together in a small pot, using fine soil with a little leaf-mould and sand added to it. See that the stems are fastened to their supports as they progress in growth, else they are likely to snap over during a gale. Mulch round the roots of these as well as Dahlias; both are gross feeders and will take liberal drenchings of manure water. In the case of the Dahlia, the variety must be again taken into account, as manure water has a tendency to produce coarseness in some sorts.—J. DOUGLAS.

Autumn Roses.—Independently of the disposition which particular groups of Roses, such as the Bourbons and Noisettes, and some of the so-called Hybrid Perpetuals, have to flower through the autumn months, a good deal depends upon the way they are treated. During the scorching weather that has been experienced in most parts of the kingdom, with, in many places, up to the present time, very little rain for six or seven weeks, the ground has necessarily got very dry, and as the autumn flowering is dependent upon the growth the plants now make, unless they are copiously watered, little bloom may be looked for. Mere sprinklings are useless; one thorough soaking, whereby enough is given to penetrate to a depth of 8 in. or 10 in., is immeasurably preferable to frequent dribbles, which only serve to excite the fibres immediately near the surface into growth, yet do nothing to stimulate the main roots that lie deeper. Where the ground has been mulched, as advised early in the season, with rotten manure, the surface will not have become so hard and impervious as to prevent the water penetrating freely. If this has not been attended to, and where, with a view to keep up a trim appearance, the ground has been raked, it will, in many cases, be smooth and hard, necessitating loosening before watering. This may be done with the hoe, or where it has got into a very hard state through treading in gathering the flowers, 1 in. or 2 in. of the top will be easiest broken up with the fork. Care must be taken not to thrust the fork in so as to injure the roots, or more harm than good will result. Anything in the shape of liquid manure will be better than simple water.

Roses on Walls.—I have repeatedly urged the necessity for paying more attention to Roses on walls than they usually receive. From their position, very little rain reaches their tops, and the roots, much oftener than otherwise, are either confined in narrow, insufficient borders or force

their way into the rogenal materials of which the walk is formed. In the latter case nothing can be done in the shape of supplying food to the roots, except liberal soakings of water containing some fertilising elements, such as guano. As a matter of course, in these places whatever is used must be in a clear, transparent state, for if at all thick or muddy it will give a dirty appearance to the walk; but by using such as suggested the roots in these positions can be moistened and receive the nutrition they require without staining or disfiguring the walks. Frequent and copious applications of clean water with the garden engine or syringe, so as to free the foliage from the accumulation of dust and from red spider, which so frequently attacks wall Roses, will also materially assist the formation of young flowering wood. In the case of the latest blooming kinds, like the old blush and crimson Chinese varieties, which in many localities will often continue to produce flowers up to December, the attention advised is a positive necessity.

Mildew on Roses.—In most places comparatively little mildew has yet been seen, owing to the copious rainfall we had in the spring. This parasite generally attacks Roses, like other cultivated plants, when growth becomes stagnated through insufficient root moisture, and is always proportionately aggravated where the Roses are too much confined by trees and shrubs or buildings. Where, as in most private gardens, the quantity grown is limited, it is worth while to syringe the affected plants with a weak solution of Gishurst, or with water impregnated with sulphur, which will generally be found much more certain in its effects than dusting them with sulphur, which is so apt to get blown off with the wind or washed away by showers before it has effected its object. To those who grow Roses, and who, after the spring operations of pruning, tying, nailing, &c., leave them comparatively little cared for, such attention as here advised may appear to entail unnecessary trouble, but with Roses, as with other plants, the result will always be proportionate to the attention bestowed, and the flowers that may be had by this necessary care will be doubly acceptable when the season's comparative plenty is past.

Selection of Autumn-blooming Roses, as also for Flowering Earlier in the Season.—There is no better way to arrive at satisfactory results than to note particularly the different kinds that succeed best in any given locality, for it must be borne in mind that the soils and situations are comparatively few wherein Roses can, even with the greatest skill and attention, be grown in anything like the condition they are produced by the leading Rose growers; in fact, there is nothing more deceptive than the magnificent blooms shown, many of them of delicate kinds that will only succeed under the most exceptional conditions of soil and climate; consequently, in forming a conclusion as to what it is best to plant, it is much better to see the kinds growing, especially noting such as succeed in the immediate neighbourhood where additional varieties are desired. Under no consideration should I advise ordinary Rose cultivators to plant any that are shy growers or delicate in constitution. This particularly holds good with the Hybrid Perpetual varieties grown for general display. It is also applicable in the case of the late summer and autumn-flowering kinds. Where high walls, tall pillars, the trunk of a dead tree, or anything of a similar nature is to be covered, suitable kinds should be selected, choosing only such as are the most vigorous and will grow to a considerable height in a short space of time. In such positions varieties that naturally produce their flowers in large trusses, such as *Aimée Vibert*, *Lamarque*, and climbing *Devoniensis*, *Gloire de Dijon*, *Mlle. Marie Berton*, *Belle Lyonnaise*, and *Fellenberg*, may be suitable. Those intending to plant, for whatever purpose, when not familiar with Roses generally, will do well to note during the flowering season those sorts that will suit their respective purposes, by which means they will be in a position to satisfy themselves better than by relying upon descriptions given in catalogues.

Propagating.—Budding should be continued without intermission until the whole to be done are finished, and cutting and striking followed up. It is much better to have more than are required than to be deficient, as Roses may with the best advantage be largely introduced into shrubberies, mixed borders, on iron archways, over walks, on divisional screens supported by wood or ironwork, for hedges to hide the less dressed portion of the ground. In few private establishments are the plants for such purposes forthcoming in sufficient quantities, unless where propagation by cuttings is largely carried out.—T. BAINES.

Bedding Plants.—Ordinary bedding plants, such as *Pelargoniums*, *Verbenas*, *Calceolarias*, *Heliotropes*, and similar subjects, may now be regarded as at their best; this is, therefore, a good time for considering what plan of bedding shall be adopted next year, as well as for noting the improvements and rectifications that may be necessary in order to set off the ground or beds to the best advantage. In dry weather, plants in active growth will require abundance of water, as well as occasional applications of weak liquid manure; strong-growing plants will require stakes, but as few as possible should be employed. Where *Petunias*, *Verbenas*, and similar plants are used as edgings, they should be kept pegged neatly down. Now that the plants in the carpet beds will be growing freely, both knife and shears must be used freely, so as to preserve exactitude in the pattern, for confusion, as regards design, in this mode of gardening is anything but imposing. Decaying flowers should be removed, seed-pods picked off, and unhealthy or exhausted plants replaced by fresh and vigorous ones from the reserve garden.

Let every effort be used to render the flower garden as interesting and attractive as possible. Zonal *Pelargoniums*, when fairly established, will continue healthy and will flower well with a somewhat restricted supply

of moisture; the tricolor sorts, which are generally grown for the beauty of their foliage only, should be divested of their blooms before they expand, and should be encouraged by every possible means to grow freely. Continue to thin, stake, and tie up the shoots of *Dahlias* and tall-growing herbaceous plants wherever this is required; also remove decayed leaves and flower-stems as soon as the flowering period is over; and it is very likely that many species of *Larkspur* and other hardy plants will, this season, flower freely for the second time in the course of the autumn. Many annual flowers have been of short duration this year; they should, however, be cleared off as soon as they are out of bloom, unless seed is required, and this should never be saved promiscuously, or the strain will gradually deteriorate, as it generally happens that the worst flowers are the most productive of seed. If new and distinct varieties are desired recourse must be had to artificial fertilisation; but if improvement of strain is merely what is sought for, that can, with more or less certainty, be secured by judicious selection, a practice which should be invariably pursued with annual flowers generally, and more particularly with such plants as the various sorts of *Stocks* and *Wallflowers*, *Mignonette*, *Anemones*, *Columbines*, *Antirrhinums*, *Pinks*, *Larkspurs*, *Helichrysums*, *Phlox Drummondii*, &c., as, by this means, annual flowers, as well as culinary vegetables of various kinds, may be brought to a very high degree of excellence. The marking of the selected blooms may be effected by attaching to them small pieces of coloured worsted or some such material; and the seed produced by the marked blooms should be carefully collected as soon as fairly ripe. Where the production of hybrids or cross-bred plants is attempted, fecundation must be induced artificially, an operation which requires considerable care, and, as indispensable to success, it is necessary that the blooms selected to bear seed should be emasculated at an early period of their existence, that is, the anthers should be carefully removed, and in the case of some species it is necessary to do this even before the blooms have expanded, in order to prevent the possibility of self-fertilisation; in the case of some small-flowering species, however, there is some difficulty in effecting this, although it is easy enough to accomplish it in the case of such plants as the *Petunia*, &c., by merely shutting a small portion of the tube of the corolla and removing the unripened anthers, taking care at the same time to avoid injuring the stigma, which should be afterwards carefully watched; its slightly glutinous condition will indicate its readiness for the application of foreign pollen, which should be carefully applied with a camel-hair pencil or otherwise.

Pansies and Violas.—Cuttings of these should now be put in. They strike freely in the open air under a north wall, but must be well supplied with water. The *Violas* especially deserve a place in every garden; the profusion of flowers they bear and their continuous blooming habit place them in the front rank of hardy decorative plants. *Pansies*, particularly the self-coloured varieties, are very beautiful during spring, but do not flower as long as the *Violas*; yet if a succession of plants be kept on hand, by putting in a few cuttings every six weeks through the season, from the time growth commences in spring until autumn, uninterrupted bloom may be had; but in the hot summer months they should be grown on the north side of a wall, or they will not produce good flowers, as they do not like exposure to the drying influence of the sun.

Herbaceous Plants.—Amongst these we have now in bloom several *foe Spiraeas*, *Tradescantias*, *Campanulas*, *Asters*, *Achilles*, *Potentillas*, *Lathyruses*, *Veronicas*, *Tritomas*, *Statice* (such as *S. latifolia* and *S. Portuensis*), *Pentstemons*, *Phloxes*, *Stenactises*, and others. In order to have fine flowers the shoots should be thinned out a little and small earth basins formed around the roots of each plant for the retention of water. Cut over at about half the length of the stems such plants as have done blooming for the sake of neatness. Many kinds of perennials may yet be propagated from cuttings, as previously recommended, and also by means of seeds, which may be either sown in a border out-of-doors or in boxes in frames. Gather all seeds as soon as ripe, dry them, and dress them, and either sow them immediately or keep them till spring.

Indoor Plant Department.

Stoves.—Stove plants will now be fast maturing their wood, and should have more sun and air, but here the latter must never be admitted, even at this time of the year, in anything like the volume that greenhouse subjects require. In this respect most growers commit serious error, for if stove plants—especially such as come from the hottest countries—are too much exposed to cold currents of air, it destroys all their energies. With stove plants a maximum of light, which may be obtained by keeping them elevated near the glass during the whole of their growing time, imparts strength and substance to the wood as it is formed, and does away with the necessity of subjecting them to treatment that stops all growth during the remainder of the season. A much shorter period of rest will suffice for these than for greenhouse subjects. The great heat we have lately experienced will have caused a rapid increase in the numbers of all insect pests, and unless means are being taken to keep them down, their destruction will be a work of considerable difficulty. The worst to contend with are mealy bug, as they insinuate themselves into every crevice about the plants, and even in the ties and sticks supporting the same. There is no better way to eradicate these at this season than to use a soft sponge and give them a thorough hand-washing, as any mixture made sufficiently strong to destroy these marauders would be sure to injure the leaves in their present tender state, if not to destroy the plants altogether. The same remark applies with less force to brown scale, but as they do not increase at anything like the rate of mealy bug, it is a much easier matter to hold them in check, or even to get rid of them altogether. Thrips are more readily dealt with either by dip-

ping the plants in strong Tobacco-water, or by giving the house two or three good fumigations in quick succession; but where the plants are in pots, and of moderate size so as to admit of being readily handled, the former method is the best, as the Tobacco-water not only destroys the living thrips, but those in embryo as well, especially if made more penetrating by having a small lump of washing soda dissolved in it, or an ounce or so of Fowler's Insecticide added to each gallon of water. This will soak through the varnish-like covering with which the thrips' eggs are coated over, and so carry the strength of the Tobacco in with it, thus making much cleaner and more durable work than the smoke alone would do. In cases, however, where large plants, roof climbers, &c., are infested with these pests, the latter mode of extirpating them must be resorted to as the only practicable means of getting rid of such troublesome enemies. Those who wish to be clear of the above should assail them the moment they show themselves, for if left alone for only a short time during the present hot weather they do a great amount of injury, and entail a vast deal more labour and time in the end. Where roof climbers are grown all superfluous growth should now be cut out, so as to admit plenty of light and air to the plants beneath, to aid them in maturing their growth. No stove, however small, should be without a plant of *Bougainvillea speciosa*, which can either be grown in a pot or planted out, according to the space that can be allotted to it. Whichever it may be, the roots should be entirely under control, and the top so trained as to be near the glass and fully exposed to the sun, without which it is impossible to ripen the wood properly, and unless this be thoroughly matured they seldom produce much flower. To assist in this ripening process, the plants should now be kept moderately dry at the roots, increasing the same by degrees till flagging takes place, as it is only rather severe drying that will cause them to produce a profusion of those lovely mauve-colored leaf-bracts that renders them so exceedingly attractive and of such great value for cutting. By getting them to rest early, they may be had in bloom much sooner than if they are allowed to grow on and ripen off naturally in the autumn; and as the coloured leaflets last for some months, rather improving by age than otherwise, it is very desirable to have them in as soon as possible. In cases where the growth of these has been allowed to become at all thick, the strongest and most sappy-looking pieces should at once be cut away in order to admit light and air to those of medium size, which alone produce flowers in a free, satisfactory way. The robust, free-growing habit of *B. glabra*, when planted out, renders frequent attention necessary to keep them properly thinned and regulated, without which they soon become a confused mass, and are then most difficult to separate or get into anything like order again, the hook-like thorns lacerating the leaves of the shoots left on, rendering them shabby in appearance. The supply of water to this variety should now be somewhat diminished, but not to anything like the extent advised for the other, as *B. glabra* will continue to grow and produce flowers till near Christmas, if in a suitable situation. Any of this variety in pots that have been kept back for late blooming should now be afforded plenty of light and air, and liberally assisted by giving them plenty of manure water, as when confined to so limited a feeding ground, their free-flowering habit renders help in that way absolutely necessary to maintain the plants in health and keep the leaves a good colour. Allamandas that have been loosely trained or slung to the rafters, with a view of transferring them to suitable trellises for removal to the conservatory, or for other uses, should now be carefully tied down by bringing the shoots into position gradually, so as not to give them too sharp a bend, the effect of which would be either to break them off or to stop the flow of sap, and so starve the flower-buds. Any plants of these that were got into bloom early and are now becoming exhausted, should be placed in light, sunny positions in the stoves, where they can have plenty of air to assist in maturing their wood. By getting a portion of the stock early to rest, the same may be started immediately after the turn of the year, so as to get them in bloom at a time when their large, showy flowers are most valuable. Cuttings struck in the spring may still be grown on by giving them a shift into larger pots and keeping them in a growing atmosphere, where they can get plenty of light, to prevent them from drawing.

Cinerarias should at once be placed in their flowering-pots—6 in. or 7 in. in diameter is large enough for ordinary purposes—and, if the plants are well managed, these will grow them to a size that will produce fine heads of bloom. They are very subject to green fly, which must never be allowed to get established upon them, or both appearance and vigour will be sacrificed. As soon as the pots are filled with roots they should be regularly supplied with manure water. Never allow them to become cramped at the root before moving them into their flowering-pots, or they will not attain their wonted strength and size. Grow them in good loam, with one-fifth of rotten manure and leaf-soil in equal parts added, and as much sand as will keep the soil porous. They do not bear Tobacco smoke well, as it often injures the leaves if applied of sufficient strength to destroy aphides, to free them from which dipping in a pailful of Tobacco water is the best remedy.

Primulas.—These continuous winter-blooming plants should also be moved into 6-in. flowering-pots. They are somewhat spare-rooting subjects, and do not require a great body of soil to grow in, being more subject to damp off in large pots. Drain them well, using soil similar to that need for Cinerarias. Put both in pits or frames, facing northwards, and give air freely, taking the lights completely off the Primulas during the day; but do not allow them to get saturated with rain. In very bright weather, a piece of old fruit-tree netting placed over them will be useful to break the sun's rays, but will not obstruct the light as a mat would do. If too thick material be used the leaves get drawn up weakly, in which state it is impossible for them to flower as they ought.

Indoor Fruit Department.

Vines.—Wasps and large flies are frequently very destructive to Grapes where they are hanging ripe on the Vines. They not only destroy whole berries, but make small holes in others, necessitating their being cut out, and spoiling the appearance of the bunch. Hamburgs and other somewhat thin-skinned kinds are generally attacked to a greater extent than thick-skinned varieties. In order to keep these insects out of Vineries, in which there is ripe fruit, nail some closely-meshed netting over the ventilators; but, where the ventilators are so arranged that the netting cannot be used in this way, small bags should be made of it, in which the bunches should be encased. This generally proves a safeguard, though not so effectual as the other. Grapes are often put into paper bags to keep them from such depredators, but that is a bad practice, as the berries often decay when air cannot reach them, and unless the paper is removed daily—an operation which seriously damages the bloom—numbers of berries may be rotten before the evil is detected. Bottles containing sour beer are hung up amongst the bunches as traps, but for one wasp or fly that enters them two keep out. Do not let the surface soil in Vineries, in which the fruit is ripe, become dust dry. A little moisture in the atmosphere does little harm, so long as there is a circulation of fresh air, and the dust does not rise and settle so freely on the bunches when the soil is a little damp as when it is dry. When the Vine borders are finally watered the soil may be raked finer than it has hitherto been, in order that its surface may look tidy for the remainder of the season.

Pines.—Lose no favourable opportunity of admitting a free circulation of fresh air to all Pine plants in active growth, so as to keep them dwarf and stocky. Plants which are drawn up tender never do well throughout the winter. Look over the first potted suckers, and water such as are dry and have their roots appearing on the outside of the ball of soil. Do not be in a hurry to expose them too much to sunshine, especially if they have been kept somewhat closely shaded while making roots. Old plants will, however, bear and be benefited by fuller exposure to the sun now than earlier in the season; care should be taken, however, not to allow the leaves to become brown, or the completion of their growth may be retarded.

Kitchen Garden.

Spring Cauliflowers are an important crop in most places, and require a considerable amount of attention for a long period in order to secure a satisfactory result. The time of sowing has great influence upon the future crop turning out satisfactory or otherwise, for if sown too early—and a very few days will sometimes make an important difference—many of the plants may button or turn prematurely, and thus be useless. To obviate this difficulty wherever it may have been felt, it will be better to divide the seeds into three portions and make three sowings, at intervals of about a week or ten days. In the north, the first sowing should be made about the 10th of this month; in the midlands, about the 15th; and in the south, from the 20th to the 25th; and the last sowing, at least, should be made in a frame. In cold, late situations I have always found it the best and surest plan to delay sowing till about the middle of September, and to sow in boxes in a frame; but, after the seedlings have come up, in order to have sturdy little plants, abundance of air should be given. Fill up all vacant ground in the kitchen garden with winter greens as Peas, Broad Beans, Cauliflowers, and Potatoes are cleared off. It is important that no time should be lost in this kind of work, as delay at this period of the year is more injurious than at others, inasmuch as these crops are not allowed time to grow to a useful size before winter has set in. The plants may now be put in closer together than would be advisable earlier in the season, as they will not get so large. If there happens to be a vacant place at the north side of a wall, some Cottager's Kale may be planted upon it. This will, after the first cutting in the spring, throw up quantities of sprouts without running to seed so early as it would grow in a situation under the influence of more sun. By this means a supply of useful greens will be secured that will last until early Cabbages are ready for use.

Turnips.—The ground that is cleared from Potatoes, Peas, French Beans, and similar crops should at once be sown with Turnips; not a day should be lost in getting the seed in, as upon this depends the crop getting to a useful size before growth is stopped by the cold weather.

Cabbage.—Make another sowing of Cabbage. Where a serviceable crop is required there is nothing better than Enfield Market to come in after any of the smaller more early kinds. Some object to its being too large; this objection may hold good if it be allowed to attain its full size, but the best way is to commence cutting it early enough, and there is no variety I have ever grown that makes such a quantity of useful sprouts after the first cutting. To assist the production of these, from the crop that has already been cut the old leaves should be cleared off the stools; by this means slugs and caterpillars that harbour in them are got rid of. The ground should then have a good soaking of moderately strong manure water.

Radishes.—Of these a sowing should be made every three weeks now in rich ground; these will be much better in quality than such as have been coming on through the middle of summer. Where Mustard and Cress are required they should be sown every ten days; these, with Radishes and Lettuce, must, to have them fit to eat, be regularly well watered, without which it is impossible to have salad of good quality. I have heard some gardeners speak against the necessity of watering in the kitchen garden, asserting that by deeply trenching, sufficiently manuring and mulching, watering was not required; but the chief reason why the

productions of the French salad growers are better than ours during the summer months is that they are continuously supplied with copious applications of manure water, so as never to allow the crop, from the day the seeds vegetate until it is gathered, to want moisture.

Celery, more than most crops, will now need to be well soaked with water. After a good soaking, 1 in. or 2 in. of soil may be put to even the late crops; it will prevent the roots, which lie close to the top and are still further encouraged to the surface by watering, from being so soon dried up, and will diminish evaporation.

Late Peas should have a ridge of soil drawn on each side of the row, and within 2 in. of it, so as to confine the water, which should be applied without stint, or it will be impossible to keep them from becoming a prey to mildew. One good drenching, so as to moisten the soil down as deeply as the roots descend, will be of more service than six partial applications. Scarlet Runners must be similarly treated, or the produce will not only be small, but the bearing capabilities will be so far reduced that the blooms will refuse to set at all. These and all other crops will be much benefited by mulching 3 in. thick with littery manure. If the land be at all poor, nothing is better than to use it fresh from the stable, laying it on before the water is given. By this means the fertilising elements of the manure are immediately washed down to the roots of the crop, upon which they at once act beneficially.

Extracts from my Diary.

August 12.—Sowing Black-seeded Brown Cos, Stanstead Park, and All the Year Round Lettuces. Putting in cuttings of Heliotrope, Fuchsia, and Tricolor Pelargoniums. Planting Endive and Lettuce. Preparing soil for Pine-apples; potting and re-arranging the Black Jamaica Pine-apples. Cutting back Laurels and other shrubs overhanging the walks in the pleasure grounds. Stopping the laterals through all the Vineries. Watering Celery, Lettuce, Endive, Cabbage, and Walcheren Broccoli, the weather being dry.

Aug. 13.—Sowing Sweet Basil in pots; also Mustard and Cress. Potting a few more Cinerarias and Primulas. Putting in Pelargonium cuttings. Putting one houseful of Smooth-leaved Cayenne Pines into fruiting pots, using equal parts of loam and peat, and adding abundance of silver sand. Mowing. Clearing off Strawberry runners. Watering Carrots, Onions, Celery, Lettuces, Endive, Cabbage, and Broccoli plants.

Aug. 14.—Sowing Chirk Castle Black Stone Turnips. Potting Cyclamens and Colens. Putting in a few more Centaurea cuttings. Lifting Ashtop Fluke Potatoes. Thinning Spinach, Lettuce, and Endive. Turning manure previously mixed with salt and soot for general crops. Mowing, weeding, and cleaning in the pleasure grounds. Gathering first outdoor Peaches. Watering flower-beds; also Scarlet Runner and Dwarf Beans, and the early Peach house.

Aug. 15.—Potting and re-arranging a large house of Smooth-leaved Cayenne Pines. Putting tiffany over open Vinery lights to keep off wasps and flies. Looking over Peach trees and removing nails, ties, and leaves where not required. Picking over carpet bedding. Turning manure for a Mushroom bed. Mowing, weeding, and clearing in the pleasure grounds. Watering late Peas, Celery, and Strawberry runners in turf.

Aug. 16.—Sowing last crop of Spinach; also Mustard and Cress. Covering Peach walls with netting. Pulling up all spring-sown Onions and laying them out with the roots upwards to dry. Lifting part of a collection of Potatoes. Clearing off a batch of Broad Beans. Watering Peas, Celery, Lettuce, Endive, Strawberry runners, and Pines.

Aug. 17.—Potting and putting away Pine suckers. Looking over all Vineries, and taking off laterals and shanked berries. Renovating manure linings round all frames. Picking over and weeding carpet bedding. Cleaning gravel walks in kitchen garden. Clearing off a piece of Peas and hoeing the ground ready for other crops. Cleaning up mould yard, sheds, tools, &c. Fruit in use for dessert: Pines, Melons, Grapes, Peaches, Figs, Cherries, Pears, and Apples.—W. G. P., Dorset.

Dioscorea retusa.—This elegant plant has been several times exhibited in charming condition by Messrs. Veitch, who obtained it through Colonel Trevor Clarke from South Africa. The name will suggest to the horticulturist that it is a near relative of *Dioscorea batatas*, the Potato Yam. There are in cultivation—or should be, according to the books—about a dozen species of Dioscoreas, and all of them are elegant plants; indeed, the one named above, which has been tried as a substitute for the Potato, is handsome enough to have a place in the garden without any regard to the suitability of its roots for the table. In respect of relative beauty, perhaps, *Dioscorea retusa* is the most desirable species, and it has the advantage of being nearly hardy, so that if planted out in some of the more favoured localities in the south-west it might remain to become established as a valuable adornment of a trellis or wall. It is, however, in London, best treated as a cool house plant, the comfort of a moderate degree of warmth with shelter being favourable to its full development. In common with others of the genus, this is a free-growing, twining plant. The leaves are distinct in form and strikingly veined; the flowers are produced in pendulous clusters, and are in themselves inconspicuous, but collectively they constitute a very pleasing feature, their delicate form and soft creamy colour aiding the effect resulting from their elegant disposition. They are, moreover, agreeably fragrant. When shown by Messrs. Veitch at the great International Exhibition, at Brussels, it attracted much attention and deserved admiration.—“The Gardeners' Magazine.”

GARDEN BOTANY.

(Continued from p. 116.)

Disk, Nectary, Staminode.

These terms have been so differently employed, confused, and interchanged by writers on botany that it seems better to treat of them under the same head. Hitherto we have only

Fig. 420.—Pistil of *Tribittia*, invested with a cup-shaped disk.

Fig. 421.—Pistil of *Balsanites*; stamens cut away, revealing the disk encircling the ovary.

Fig. 422.—Pistil of *Diosma rubra*, showing the cup-shaped disk immediately surrounding the ovary.

mentioned sepals, petals, stamens, and pistil, but there are often other bodies in a flower coming under one or more of the above denominations. The term disk is applied to the central flowers of such inflorescences as that of the Daisy, and its application is explained under the definition of a capitulum or

Fig. 423.—Section of a flower of the Grape Vine after the petals have fallen away, showing a lobe of the disk on the left.

Fig. 424.—Disk of *Cordia Toona*, with the stamens seated upon it.

Fig. 425.—Flower of *Xanthoxerus*; the sepals and petals removed to show the disk, consisting of five fleshy, horned processes outside the stamens.

flower-head. The solid axis from which the scales of a scaly bulb proceed is also called disk. But here we have to deal with what may be termed the floral disk. In many books the floral disk is defined as any body or bodies that intervene between the stamens and pistil, but this is a very imperfect

Fig. 426.—Double flower of *Anemone*, the stamens being changed into staminodes. Reduced.

Fig. 427.—Section of a flower of *Batterscup*, to show the insertion of the free ones-ovules on the conical receptacle.

definition. In general terms the floral disk may be described as a fleshy excrescence, or outgrowth of the floral axis (receptacle or torus), but its position in relation to the other parts of the flower is very varied. In form, also, it exhibits numerous modifications. It is continuous and cup-shaped and immediately surrounding the ovary (figs. 420 to 422), or lobed, or consisting

of separate parts (sometimes called nectaries), as in *Sedum*, &c. In *Cedrela* (fig. 424) the disk is lobed and the stamens are seated upon it, and in *Xanthoceras* (fig. 425) it consists of five free, horned processes between the petals and stamens. A very common condition may be seen in the *Rose* and *Lady's Mantle*, where it lines the tube of the calyx or cup-shaped

Fig. 423.—Section of a flower of *Helleborus foetidus*, with a conical receptacle and several many-ovuled ovaries.

Fig. 429.—Flower of *Strawberry*.

expansion of the floral axis (see some of the figures illustrating the floral receptacle). The flesh of the *Apple* and *Pear* is for the greater part of the same nature. The term nectary is sometimes given to the disk or the parts of the disk, as well as

Fig. 430.—Section of a *Strawberry* flower, showing the ovaries inserted on the conical receptacle, which afterwards enlarges and becomes fleshy.

to glands or other bodies in the flower which secrete honey, but it is rarely used now. A staminode is a metamorphosed stamen. Thus the *Anemone* (fig. 426) becomes double, in consequence of the stamens being transformed into staminodes

Fig. 431.—Flower of *Myosurus minimus*.

Fig. 432.—Section of a flower of *Myosurus minimus*, showing the insertion of the numerous free ovaries on a long slender receptacle.

or barren petal-like bodies. In *Lopezia* there is one fertile stamen and one staminode; and stamens frequently alternate with staminodes.

Fig. 433.—Flower of *Paronychia serpyllifolia*.

Fig. 434.—Section of the same, showing the one-celled, one-ovuled free ovary in a cup-shaped receptacle.

The Floral Receptacle.

This should not be confounded with the receptacle of an inflorescence, which is defined in the paragraph on the capitulum.

The floral receptacle is the extremity of the flower-stalk (peduncle or pedicel), upon which the parts of the flower are seated. Commonly, the receptacle is very short, all the parts of the flower being inserted very close together on the flattened

Fig. 435.—A flower of *Alchemilla*. Enlarged.

Fig. 436.—Longitudinal section of a flower of *Alchemilla*, showing the free ovary having a basal style, and seated in a hollow receptacle.

end of the pedicel, but there are many departures from this, some of which are very remarkable in their ultimate development. In the *Buttercup* (fig. 427) and in the *Hellebore* (fig. 425) it is conical, the former having several series of one-seeded ovaries, and the latter one series of several-seeded ovaries. The floral receptacle of the *Strawberry* (figs. 429 and 430) is comparatively small when young, and the ovaries are close together, though it subsequently enlarges into a fleshy, spheroidal, or irregular body, the mature seed-vessels

Fig. 437.—Section of a flower of *Calycanthus*, showing the insertion of the ovaries in the concave receptacle, and the bracts and sepals outside of the same.

being thereby separated from each other. In the *Mousetail* (*Myosurus minimus*—figs. 431 and 432) the receptacle is very much elongated, even in the flowering stage. In many cases the receptacle is depressed instead of being elevated; thus in *Paronychia* (figs. 433 and 434) the one-celled one-ovuled ovary is seated in a cup-shaped receptacle, and the same thing occurs in *Alchemilla* (figs. 435 and 436), though here the fleshy disk almost completely closes over the ovary, giving it the appearance of being inferior. In consequence of this mode of

Fig. 439.—Section of a flower of *Rosa pimpinellifolia*, showing the insertion of the free ovaries in the urn-shaped receptacle.

growth of the receptacle, the insertion of the stamens and other parts of the flower is above the pistil. Already we have had occasion to allude to the flower of *Calycanthus* to point out the gradual transition from bracts to sepals, and sepals to petals. On reference to fig. 437 it will be

seen that the ovaries are inserted within a hollow receptacle, the floral envelopes outside of it, and the stamens around the rim. Almost anybody would at first regard the fruit of a Rose as inferior and the separate seed-vessels it contains as seeds; but, on examining a flower, it will be found that there

Fig. 439.—Flower of *Capparis spinosa*; the ovary is borne on a long slender stalk (gynophore) exceeding the stamens.

are numerous free ovaries in an urn-shaped receptacle, as shown in the section (fig. 438). There is yet another type of receptacle. The more or less elongated receptacles illustrated by figs. 427 to 432 present no naked space between the different whorls of the flowers. In *Capparis* (fig. 439) the sepals, petals, and stamens are inserted nearly on the same plane, whereas there is a long interval between them and the ovary, which is borne on a slender, stalk-like elongation of the receptacle termed a gynophore. The ovary and the stamens of the

Passion-flower (fig. 440) are carried up some distance above the petals; and in *Silene* (fig. 441) the petals also are carried up, so that there is a considerable space between their insertion and the base of the calyx.

W. B. HEMSLEY.

Vegetation of Cyprus.—Speaking of the flora of this island, Drs. Unger and Kotschy in their work "Die Insel Cypem," say:—"There is great resemblance in the vegetation throughout the island to the Mediterranean. In February and March there is upon all the river edges a profusion of Lilies; in April and May on the land side is one carpet of flowers. During the heat, however, the land assumes a yellow tint. Pine forests abound, Olives, Myrtles, and Laurel trees. As far as the island has as yet been explored, we know that there are 1000 different sorts of plants. No island can show such a rich forest growth as Cyprus.

THE FLOWER GARDEN.

FROM THE BIRTH TO THE DEATH OF THE LILY.

IN the hope that some of the readers of THE GARDEN may have had an opportunity of dissecting a few bulbs in the manner pointed out by me in my last paper (see p. 91), I shall now proceed a few steps further with my remarks on the growth of the Lily. Those parts of the subject most worth attention at this time are the decay and death of the parent bulb and the early lifting and re-planting of its successor, the new bulb. On these points some writers have no faith, and in order, therefore, to raise the knowledge of the Lily from the confused state in which we find it, let us endeavour to calmly discuss the facts. "W. J. T.," of Brixton, says: "I do not venture to express an opinion on the question of the renewal of the bulb so ably discussed by 'Dunedin,' but I may say that when re-potting I have never discovered traces of a decayed old bulb." Now if "W. J. T." will consider for a moment, I think he will find that there is nothing antagonistic to my doctrine in the fact he relates. In the month of September—when he re-potted—there was no likelihood of the old bulb being reduced to mere traces of decay. In fact, it was the old bulb itself he was then handling and re-potting, the new bulb being within it. If he will refer to my paper (see p. 91) he will see that, when lifting and re-planting several clumps of Lilies, I dissected a bulb of *L. candidum*, and had to pick off twenty-five old scales before I cleared all away from the new bulb. If he will do this now, he will find, as I did, a distinct new bulb within the old bulb, and the old scales still, apparently, in good health. In connection with "W. J. T.'s" remark, "Amateur" says: "The main questions to be decided are, whether or not the bulb after flowering decays; and, secondly, whence springs the flower-stem of the succeeding year. 'W. J. T.' so far corroborates my experience that he has 'never discovered traces of a decayed old bulb.' But in order to settle the question beyond dispute, I will grow in pots different bulbs so close to the surface that the tops of the bulbs may be readily exposed and watched during the season; and in October or November I shall be most happy to turn them out and show 'Dunedin' the results." "Amateur" here promises to do more than he can perform. He may certainly plant the bulbs in the manner he proposes; but neither in October, nor November, nor in any other month will he be able to prove that the old bulb does not decay and die. The present is the time, however, without waiting for October or November, that he can settle the question. Let him dissect any number of bulbs, and he will find that it is an entirely new bulb that "is now shooting up from the precise centre," as he calls it, "of the (old) bulb as previously," pushing aside the old stem as it grows larger and larger. Great Max Leichtlin, of Baden-Baden, seems to place great faith in "Amateur's" proposed experiment, as he says: "I am of opinion that 'Amateur' is right in his views, and that he will certainly be able to prove that the old bulb does not decay every year." M. Leichtlin, in believing that such will be the result of "Amateur's" experiment, is leaning on a broken reed. He can, however, prove the case for himself, without loss of time, by dissection, as I have explained; and if he will, six months hence, take up a similar bulb, he will see a vast difference between the appearance of the scales of the old bulb as they now are and the scales as they will be then, as decay will have more distinctly marked them for its own. I ought not, however, to be so much surprised at M. Leichtlin's opinion when I read that he, like "Amateur," judges more from outward "visible growth" than from any examination of the interior reproductive organisation of the bulb. As to "Amateur's" second proposition, viz., "Whence springs the flower-stem of the succeeding year," a settlement of the first will, as a mere matter of course, settle the second question.

With respect to the second part of my subject, viz., "Early lifting and re-planting," I may mention that, on looking over the columns of certain horticultural periodicals published within the last two or three weeks, I have noticed that amateurs and Lily growers in general are told "that it is detrimental to disturb the bulbs before they are quite matured, which is always denoted by the foliage turning yellow." This is erroneous teaching. The Lily is cultivated by most of us for the sake of

its beauty, and we therefore feel an interest in causing it to bloom as early and as long as possible. Were it not for this, we might safely lift and transplant the bulb before it had half done flowering, for the growth and roots of the new bulb within it would be by this time so far advanced as to enable it to take care of itself. Flowering, we are told, is an exhaustive process, drawing out the whole of the nourishment that has been stored up in the cells of the scales. To this I may now add that seeding is even more exhaustive, injuring very materially the new bulb. If, therefore, the stem be not cut down immediately after flowering, abortive attempts at seeding will be made by the stem, and in doing so it will draw upon the resources of the new bulb, the materials of growth, or elaborated sap, in the scales of the old bulb being all exhausted. The old stem, though kept green, can give back to the new bulb nothing whatever in return for what it takes from it—all these abortive, or even successful, attempts at seeding being just so much robbery of the growth and strength of the new bulb. I say, therefore, to amateurs especially, Cut down the stem the moment the bloom is fairly over. This advice, though not directly, is indirectly corroborated by your American correspondent, Mr. Hovey, of Boston, Mass., in Vol. XIII., p. 337. In speaking of *L. candidum*, he says: "They should always be transplanted, if they are to be removed at all, the very moment the last flower has faded, cutting away the old stem as low as possible." This is in accordance with my experiences. And though at present Mr. Hovey thinks that *L. candidum* "has no analogy whatever, as regards treatment and growth, with many other Lilies," he will find, on close examination, that the reproductive organisation is the same in all true Lilies. The remarks of "J. S. W." (p. 105) and "A. K." (p. 100) shall have my earliest attention.

DUNEDIN.

CULTURE OF CAMPANULAS.*

CAMPANULAS have been long cultivated in British gardens, numbers of them having been introduced from the Continent as early as 1597. Of those I may name *C. Medium*, from Germany; *C. pyramidalis*, from Carniola; and *C. Speculum* (Venus' Looking-glass), from the south of Europe. A number of years have elapsed since I first commenced to improve them by careful cross-breeding; but at the outset I laboured for a year or two without knowing that in this genus the flowers are self-fertilised before they expand. It is, therefore, needful to cut up the flower-buds, in order to remove the stamens, and, as soon as the flowers expand, to fertilise the pistil with the pollen of a different kind. After that, the flowers must be protected from wet or other accidents, and as soon as the seed ripens, it is best to sow it at once in a cold frame or greenhouse, and, as it is very small, the soil in which it is sown must be made very fine on the surface before sowing. Give the pots a good watering, then dust the seed on the surface and cover the pots with a piece of glass. This will keep in the moisture and prevent the young plants from being injured by too much sun. If the soil becomes too dry, dip the pots into a pan of water up to the rim, a process which will prevent the seed from being disturbed in the pots. If the seed be good it will germinate in two or three weeks, although part of it may possibly be dormant until spring. My first batch of seedlings from hybridised flowers showed one peculiarity: they came with variegated foliage; in fact, a portion of them had pure white cotyledons, but these soon perished. As those that were slightly marked grew into good plants they lost their variegation, but next summer all the plants that showed the slightest marks of white produced white flowers of different shades.

As regards cultivation, Campanulas are in no way difficult, and they are remarkably free from most of the pests that frequent other kinds of plants. *C. pyramidalis* (blue and white), *C. Hendersoni*, *C. Medium* (including the varieties of *calycanthema*), and *C. grandiflora* grow from 2 ft. to 4 ft. high when well treated and might be useful for greenhouse decoration, while on the front of stages or in hanging baskets might be placed such sorts as *C. Barrelieri*, *C. fragilis*, *C. garganica*, *C. muralis*, and *C. turbinata*. For the herbaceous border and rockery Campanulas are indispensable, but it is important that they be

supplied with good rich soil and plenty of drainage. A rockery for such plants as these must not be a mere heap of earth with a few stones laid on the surface; it must consist of plenty of stone, corks, or rough gravel mixed with the soil, which ought not to be useless rubbish, but of such a quality as will maintain plants in good health and vigour. Damp about the necks of Campanulas is about the only thing that requires to be guarded against. As to propagation, they are easiest raised from seed, which should be sown in pots well guarded from slugs and snails. In the case of particular varieties the stems and roots must be used for the purposes of propagation, or they may be divided in spring.

The following selection will be found suitable for rockeries, however small, for borders, or for pot culture, viz., *C. Allioni*, *cæspitosa*, *fragilis*, *garganica*, *Haylodgensis*, *hederacea*, *isophylla*, *i. alba*, *pulla*, *pumilla*, *p. alba*, *Raineri*, *rhomboidea* fl.-pl., *rotundifolia*, *r. alba*, *Smithi*, *turbinata* *Dicksoni*, and *Waldsteiniana*. For large rock gardens, in addition to those just named, I would recommend *C. aggregata*, *alliarifolia*, *alpina*, *betonicaefolia*, *bononiensis*, *carpatica*, *c. alba*, *elegans*, *grandis*, *grandiflora*, *Hendersoni*, *H. alba*, *Hosti*, *longiflora*, *nitida*, *Portenschlagiana*, *rubra*, *soldanelleiflora*, *tenella*, *turbinata* *macrocarpa*, *urticaefolia* fl.-pl., *Van Houttei*, and *Wanneri*. These should be placed where they are not likely to get overrun with other straggling-growing plants. Of tall-growing and vigorous sorts suitable for borders or the wild garden I would select *C. celtidifolia*, *grandis*, *glomerata* fl.-pl., *lactiflora*, *latifolia*, *macrantha*, *m. alba*, *persicifolia* (single and double), *pyramidalis*, *p. alba*, and *sarmatica*. Of annual and biennial species useful for borders and the flower garden, the following will be found to be suitable, viz., *C. Lorei*, *macrostyla*, *Medium*, *m. calycanthema*, *pentagonia*, *Speculum*, and *thyrsoidea*.

NOTES AND QUESTIONS ON THE FLOWER GARDEN:

Eulalia japonica.—There appears to be some slight confusion with regard to this plant, which perhaps arose in the first instance through the variegated form having been figured in the gardening papers under the above name only, without the addition of *variegata*. As a rule, we usually get the typical forms of plants and trees before we receive their varieties, and this happened in this case. The typical *Eulalia* is of somewhat freer growth than the variegated form. It has bright green ample leafage, with a distinct silvery midrib, and appears to be a little hardier (as might be expected) than the variegated form; the yellow-barred one is the less robust and hardy of the two. Both are highly ornamental.—T. SMITH, *Newry*.

Oxalis luteola.—This is one of the most lovely of Oxalises. When planted out, its close compact growth clasping the soil and neat circular outline remind one of *Sempervivum tabulaforme*. The leaves are three-lobed, hairy on each surface, and beautifully olistated along the margins. The flowers in the bud state are of a soft creamy-yellow, $\frac{1}{2}$ in. in length, but when open pure white, shading to yellow towards the centre, and as large as a half-crown piece. In pots under glass the foliage gets higher and the plant looses that close compact habit which characterises it out-of-doors; but even indoors the habit is better than that of any *Oxalis* with which I am acquainted. Some potsful of it are now flowering freely, eight or ten flowers being expanded at the same time, thus forming an exceedingly attractive object.—P.

Arum italicum in Cornwall.—Mr. J. Ralfe, of Penzance, has determined the *Arum* in several localities in West Cornwall to be *A. italicum*. It grows in Love Lane, close to Penzance; at Trereife, by the road to the Land's End, abundantly; and in three or four spots between Leland and St. Ives. The ordinary species, *A. maculatum*, however, also occurs; but Mr. Ralfe has not been able to visit all the recorded stations, so as to trace the actual distribution of each species; he has not seen *A. maculatum* nearer Penzance than at Marazion; it also occurs near Helston and Truro. *A. italicum* grows in more shady spots than *A. maculatum*. This is a very interesting determination, and will necessitate a search throughout the west of England. In Jersey and Guernsey *A. italicum* appears to be the only species; at least during my short visit the other species could not be detected.—HENRY TRIMEN, in "Journal of Botany."

Ageratum Imperial Blue.—This is dwarf in habit, branching, and bears large, fine blue flowers on every shoot, thus forming a compact cushion of bloom. For pot culture this *Ageratum* would be well worth attention.—S.

* Paper read by Mr. James Grieve, Pilgrim Park Nursery, at a recent meeting of the Scottish Horticultural Association.

M. PHILIPPE VICTOR VERDIER.

SUBJOINED is a portrait of this eminent French Rose grower, who died at Paris in February last in his seventy-fifth year. M. Victor Verrier, as he was generally called, may be said to have been one of the fathers of modern Rose growing in France, and ought to be held in affectionate remembrance by all lovers of the queen of flowers. M. Verrier was born in 1803 at the little village of Yères, in the department of the Seine-et-Oise, and first began serious work under his uncle, M. Jacques, head gardener to the Duke of Orleans, at the Chateau de Neuilly in 1822, when he was barely nineteen years old. To the joint efforts of M. Verrier and his uncle we owe a number of well-known varieties of the Rose, such as *Rosa sempervirens*, *Adelaide d'Orleans*, *Felicite Perpetue*, still our best Arch Rose, *Princess Louise*, *Princess Marie*, *Melanie de Montjoie*, and *Leopoldine d'Orleans*, all of which are still universal favourites. It was about this time that M. Verrier produced the standard Rose *General Athalin*, from whose seeds the first hybrid climbing seedlings were produced which were the origin of all the other climbing hybrids of which we are at present in possession. His first establishment, devoted entirely to the cultivation of Roses, was founded at Neuilly in 1827, one of its first fruits being the climbing Hybrid *Perpetuelle de Neuilly*, which was soon followed by the *Bourbon Rose Madame Breve*, from a specimen sent home from that island by M. Breve, and later by the climbing Hybrids *Madame Pepin*, *Madame Andry*, *Madame Knorr*, *François Lacharme*, *Olivier Delhomme*, *Vicomte Vigier*, *Turenne*, *La Brillante*, *Madame Furtado*, and a number of others. He was the first to appreciate the beauty of the dark coloured *Bourbon Roses*, such as *Proserpine Souchet*, *Charles Souchet*, and *Georges Cuvier*, of which he was the first possessor and propagator. His first nurseries, as we have said, were formed at Neuilly, where he had purchased some land near the duke's chateau, and he had formed a complete collection of the then grown Roses, but it was only in 1838 that he left Neuilly to entirely devote himself to his own establishment. At this time Rose culture was at the height of its prosperity. New varieties began to take the place of old ones, and Victor Verrier, who possessed a complete collection of the latter, was thus forced to get rid of them. Fashion, that capricious goddess, was for Roses which flowered during the entire season, and, consequently, he was compelled to recommence his new collection with the Roses of the period. His successes now began to bear fruit. The botanical knowledge which he had acquired by study and from his uncle enabled him to classify the Roses in his collection. The first catalogue which he published appeared in 1832; it comprised the different varieties of each kind. These were arranged alphabetically with their old and new varieties, followed by a short description of their relative hardness, the nature of their foliage, and the size and colour of their flowers. The list of Roses produced and sent into the market by M. Verrier is undoubtedly a long one, but it would be much longer had he not scrupulously rejected large numbers. The Roses which he gave to the world still keep their ground, and are as distinct in colour and form as the day they quitted his nursery. In addition to cultivating Roses, M. Verrier was also one of the first to produce seedlings of the hardy *Gandavensis* varieties of the *Gladiolus*, of which he obtained several remarkable varieties. In his professional capacity he was greatly respected. He was one of the leading members and founders of

the *Société Centrale d'Horticulture* in 1827, as well as of the *Cercle Horticole* in 1841, which later on united itself with the first-named body, of which M. Verrier was one for many years of the vice-presidents. He also founded the "*Portefeuille des Horticulteurs*," a periodical which was stopped by the political events of 1848. In 1865 he deservedly received the cross of the *Legion of Honour* at the end of the great exhibition of that year. M. Verrier was a typical specimen of his class. To a large amount of special successful horticultural talent he added untiring industry, extended experience, unswerving probity, and in his private relations great amiability of disposition. The thorough honesty of his character and the soundness of his judgment frequently procured for him the honourable position of arbitrator in trade disputes, and his decisions were always accepted without a murmur by those who appealed to him. Towards the close of his life M. Verrier became partially blind, an affliction that, of course, interfered greatly with his physical activity, but which never prevented him from exercising his active brain until the hour of his death. We are indebted to his son, M. Charles Verrier, for most of the above particulars, and a photograph from which our illustration has been taken. He was, perhaps, one of the best judges of a Rose we ever had.

C. W. QUEN.

Philippe Victor Verrier.

Disfiguring Carnations.—I entirely endorse your remarks as to the practice of dressing up the blooms of Carnations and Picotees for exhibition. It is not the flower as produced by Nature, but one shaped and fashioned as far as possible by the hand of the expert, who, with his tweezers, manipulates it in such a way as that it shall be not grown, but pulled into his ideal. If this practice were permitted with the Rose, for instance, what would be said? and if it be necessary for one flower, why not for another? An honest judge should disqualify all dressed flowers, and that would soon stop the process. The carding is identical with that usually applied to *Asters*, and is absurd. The purpose of it is to give to the flowers, however perfect and beautiful, the meretricious aid of an ornamental decoration; and judges, unfortunately, are swayed by it. It is pleaded in the case of Carnations that the card is with some necessary to make them assume a flat shape, otherwise they would be too much retaxed. Does it not occur to readers that all such

flowers are unnatural? It should be the aim of all to discourage this kind of dressing, as it too often enables a skilled expert to make good flowers out of bad ones.—A. D.

Morfit's Process for Preserving Vegetables.—We have received from Dr. Campbell Morfit a number of interesting specimens of both animal and vegetable food preserved in a variety of forms. These specimens have been tested, as a rule, with excellent results. There are some cocoa and milk biscuits which are delicious, and similar praise may be extended to some sylimatified maizena, which consists of Maize starch, cream or milk, sugar and gelatine, combined in a solid mass in the proper proportions to form a perfect food. Dissolved in hot water, this mixture ought to form a most nutritious and palatable food for infants. Some cocoa biscuits, in which the Cocoa-nut with the proper amount of milk, sugar, and flour, are combined, are also very nice; and some blanc mange stock, which needs only to be dissolved in hot water and corked to be ready for table, is very good indeed. Dr. Campbell Morfit has tried his process on Tomatoes, and, we are not surprised to find, with but a small amount of success. The delicate flavour of the Tomato is as evanescent as the bloom on a Peach, and it was almost a hopeless task to try to preserve it. A compound Tomato soap is, however, not bad, but it owes its flavour to other ingredients besides the Tomato. One of Dr. Morfit's most successful results is the Cocoa-nut

biscuit, which ought to become a prime favourite, preserving, as it does, the original cool milky flavour of the real nut. The Lime-fruit juice biscuits we have already noticed; and some jubebes, in which Lime-fruit juice is combined with liquorice, cocoa, and gelatine, are very agreeable. The biscuits into whose composition pork and beef are said to enter cannot be considered successful. Taking the whole of Dr. Campbell Morfit's specimens, they are, on the whole, satisfactory, but we must not expect too much from his process, which seems to succeed perfectly in the case of vegetables whose flavour is somewhat strongly pronounced.—C. W. QUIN.

ANSWERS TO CORRESPONDENTS.

Fairy Rings.—Can anything be done to stop the growth of Fairy Rings in lawn Grass?—S. C. G. [Fairy Rings are seldom or never seen where Grass is healthy and luxuriant. As a rule, they are confined to positions where the pasture is poor, and where the soil is poor in nitrogen and potash. High manuring always has a deterrent effect on the growth of Fairy Rings, especially when highly nitrogenous manures are used.—W. G. S.]

Eradicating Bindweed.—How can I get rid of Bindweed? Every thing in my garden is more or less spoiled by it. The roots penetrate the shale below the soil.—A. R. W. [There is no way but to trench deeply and pick out every scrap that can be found. Constant pulling it up and leaving part of the roots in the ground only increases the stock, as the smallest particle soon makes a vigorous plant.—W. W.]

Weeds in Ponds.—How can I best get rid of weeds in a large piece of water?—E. C. S. [Mow the weeds twice a year—early summer and autumn. I do not know of any other method.—J. M.]

Grape Mildew.—Is Foster's White Seedling Vine more subject to mildew than other kinds? I have a house which I planted four years ago, and for the last two years mildew has made its appearance, in both cases beginning with the White Seedling, and gradually extending to the other kinds, although in a much milder degree.—Q. [Yes; it is considered to be more liable to mildew than some of the more robust kinds. The best remedy for mildew is dusting the parts affected with flowers of sulphur the moment it makes its appearance.—W.]

Couch Grass in an Old Asparagus Bed.—Is it possible to get rid of Couch Grass in an old Asparagus bed without spoiling the bed? I have tried forking it out, but the roots of the Grass are deeper than those of the Asparagus.—R. E. P. [No. Why not, as the bed is an old one, dig the whole up? a young plantation is in every way desirable. The only other mode of keeping the Couch under is to well dress the beds with salt in the month of March. This is the best of all manures for Asparagus, and the Couch will, though not destroyed, be thereby kept down till quite the end of summer.—W. W. H.]

Liquid Manure and Vines.—Kindly inform me as to the best way of applying liquid manure to Vines in an outside border. Also at what stage of their growth liquid manure would be most advantageously applied.—G. H. G. [Carefully prick over the surface with a small fork and apply the liquid manure through a coarse rose. It will be better to repeat the watering several times, as all the soil will then be thoroughly wetted; from the time the berries have stoned until they begin to colour, manure water is most beneficially applied. After watering, a good mulching of half-rotted stable manure will prevent evaporation and keep the soil moist.—C. W. T.]

Red Spider on Peach Trees.—The Peach trees in one of my houses with an iron roof have been attacked by red spider, and I should feel much obliged if you would advise me what to do. The fruit is not fully grown, not having been forced at all.—P. H. [Use the garden engine freely night and morning; there is nothing so effectual as frequent washings with clear water. See that the borders are kept well watered; drought and an arid atmosphere are usually the predisposing causes of the attacks of red spider.—W. W. H.]

Blighted Violas.—I send you three plants of Violas in three stages of disease. Thinking it might be mildew, I applied sulphur, but apparently with no good effect. No doubt the root is first attacked. I have had them attacked by mildew before, and always found sulphur a specific.—P. J. N. [The decay arises from the heat and drought affecting the plants, aggravated in all probability by their being in stiff and sour ground. In dry, hot localities Violas and Pansies are apt to go off in this way during summer.—R. D.]

Blight on Apple Trees.—C. F. C.—The Apple leaves received are injured by an aphid, and I have no doubt that the aphid might be destroyed by using the well-known ordinary means of killing the green fly. When injury of this kind becomes extensive its cure is troublesome, and takes up much time. It is during the early stages of the growth of the insect that great care should be taken to stop any advance. "A stitch in time saves nine" is here well exemplified.—W. W.]

Names of Plants.—*Col. P.*—*Pavia macrostachya*, a middle-sized, deciduous tree, belonging to the Natural Order Sapindaceae, and distinguished from the *Horse Chestnut* by having a smooth (not prickly) capsule. *C. B.*—1, *Thuja gigantea*; 2, *Thujaopsis borealis*; 3, *Cupressus Lawsoniana*; 4 (next week) *H. J. E.*—The blue flower is a *Gentian* of some kind, but which it is we cannot say from the very poor specimen sent; the *Stonecrop* cannot possibly be named from such a flower as the one sent; leaves as well as flowers should be forwarded if possible. *A. P.*—Flower much withered, but apparently *Epipactis palustris*. *H. C. S.*—*Betonica grandiflora*, a species of *Salvia*, of no particular value; and *Papaver alpinum*. *H. B.*—A dwarf species of *Epilobium*, which we might be able to identify with the aid of complete specimens; we presume it was truly wild in the locality in which you found it? *E. T. H.*—*Williams*, of Holloway, *J. D.*—*Bignonia Cherere*, a very fine flower—so neat, that it may be an improved variety or nearly allied species. *J. P., Switzerland.*—1, *Cyrtopteris fragilis dentata*. 2, *Cryptogramma crispata*. 3, *Polypodium Phegopteris*. 4, *Cystopteris Regia*.

Peach Stump the World.—As I have not noticed an answer to Mr. Henderson's question (see p. 48) respecting this fine Peach, I think it cannot be so generally grown as it deserves to be. In the autumn of 1874 we received from Messrs. Veitch & Sons a healthy young tree of this variety. It was sent as a substitute for another,

and was recommended as an American kind which would be enre to give satisfaction. We have it in an unheated house, where it closely follows Stirling Castle in ripening. It has a good constitution, grows freely, and its fruit, as Mr. Henderson says, is large and handsome. We have now a full crop of what promises to be very fine fruit. It is one of the best of its season, and is excellent both for table and exhibition.—THOS. COOMBS.

Culture of *Todea superba*.—I have a very fine plant of this, but for the last three months the tips of the fronds are turning brown. What is the cause and remedy? I keep it carefully shaded from the sun, and water it daily.—R. A. [Want of air is generally the cause of the tips of the fronds of *Todea superba* turning brown. When the plant is kept too confined the water which it is necessary to give it overcharges the air with moisture, which condenses and falls back on the plant, causing the injury. Nothing is worse for plants of any kind than moisture so obtained. Alternations between a moist and a dry state of the air around the plant will also cause the *Todea* fronds to turn brown. "R. A." had better cover the stem of his *Todea* all over with living *Sphagnum* Moss. Water copiously with rain water. Place it where it will get plenty of light and as little heat as possible; a temperature of 45° is enough for the winter.—J. O'B.]

Diseased Cucumbers.—I have sent two or three small Cucumbers which go off yellow at the points and come to nothing. They are grown on the roof of a Cucumber house, to which air can be given at the top, but not at the sides. I may add that I have lost quite one-half of the crop from the failure in question. I have sufficient fire-heat at command, and I can give plenty of bottom-heat. I also send leaves of the younger and older foliage. Abundance of water is given them three times per week.—J. W. [The leaves, which are very thin, have apparently been attacked by red spider. Maintain a moist atmosphere in the house, give more air, shade during bright sunshine, and stop the points of the shoots at one joint beyond the fruit as soon as the latter is set.—S.]

Plants for Wardian Cases.—What are the best dozen plants or so for a case 3 ft. long and 20 in. wide?—E. F. [The name Wardian case is not applicable to the present plant cases. They are more properly miniature portable conservatories. In our Albert plant case we put Ferns, *Aspidistras*, small Palms, and, to give a little colour in season, *Caladiums* and ornamental-foliaged *Begonias*. Small, well-coloured plants of *Draconas* look well. We clothe the surface with *Lycopodium denticulatum*, green or variegated. As to the number of plants, this is quite a matter of opinion. We put as many in as the case will hold. Some people will put as few as they can, but then the difference is simply a richly or meagrely furnished case.—B. S.]

Fruitless Pines.—I have a number of Pines in 10-in. and 12-in. pots which, unfortunately, have failed to show fruit this year. They are large healthy plants, and no doubt the pots must be well filled with roots. In order to successfully fruit them next year, should I keep them in the pots they are in without disturbing them in any way? or should I take the tops off and treat them as snokers, of course discarding the old roots?—ENQUIRER. [Do not by any means disturb the Pine plants, but remove part of the surface soil and strip off a few bottom leaves; top-dress them with fresh soil and plunge the pots up to the rims into bottom-heat from 80° to 85°; surface temperature of 90° to 95° through the day. If very dry a good watering once a week. I have always found the above method successful in starting old Pine plants.—D. M.]

Questions.

Veitch's Autumn Giant Cauliflower.—Is it usual for Veitch's Autumn Giant Cauliflower to produce purple heads? At present mine are so coming at the rate of three to one, and for the purpose intended they are useless.—T. C.

Scott's Favourite Lettuce.—I should like to know whether Scott's Favourite Cabbage Lettuce is black or white-seeded. Last year the seed sent was bla k, and I had splendid Lettuces through the hot weather, but this season the seed supplied for it was white and the produce worthless, inasmuch as the plants "bolted" before they folded.—T. C.

Light-coloured Evergreen Shrubs.—I want two or three good foliaged and flowering evergreen shrubs of a light tint of foliage. In looking through the evergreens I find them to be nearly all of a dark shade, except, perhaps, some of the *Rhododendrons* and a tall *Hypericum*; *Kalmia latifolia*, if I mistake not, is moderately light in shade; *Andromeda* and *Skimmia* are of medium green or olive shade, but few are really of a light shade. If any of your readers can name a few I shall be obliged.—JOHN SRAYNS.

Winter Flowers.—I have a small greenhouse heated by a flue which I can keep up to from 55° to 65° at night during winter, and I wish to devote it principally to growing flowers for cutting to supply the church vases through the winter. The flowers must be white and different shades of scarlet and crimson, those which last longest in water after being cut being preferred. Would any of your readers kindly tell me the best sorts (not expensive) to grow?—G. S. M.

SOCIETIES AND EXHIBITIONS.

ROYAL HORTICULTURAL SOCIETY.

AUGUST 6.

THE principal feature at this meeting was Begonias, of which there were numerous large groups. A large collection of Gladioli from Messrs. Kelway, Langport, a collection of insectivorous and other plants from Messrs. Veitch & Sons, and stands of brilliant Verbenas from Mr. Cannell, Swanley, added greatly to the attractions of the meeting.

First-class Certificates were awarded to—

Gladiolus Telamon (Kelway & Son).—A finely-formed flower, with bright pink, purple-striped petals and creamy-yellow throat.

G. Gorgonius (Kelway & Son).—A kind with remarkably well-formed spikes and unusually large and perfect blossoms of a pinkish-red colour, striped and spotted with dark crimson and purple. Well worth adding to any good collection.

G. Herois (Kelway & Son).—A kind with perfect spikes and flowers of a pinkish-scarlet colour with creamy-white throat.

Begonia Mrs. Dr. Todd (Leing).—A kind having a good habit and brilliant crimson wax-like flowers produced in great profusion.

B. Chiswick Blush (Society's Gardens).—A dwarf-habited kind with slender flower-stalks and large trusses of medium-sized, blush flowers. A capital sort for baskets.

Botanical Commendations were awarded to—

Torenia Bailioni (Veitch & Sons).—A dwarf yellow-flowered form of a well-known plant, and one likely to prove as useful in gardens as *T. Fournieri*, when the best conditions of its culture are known. The reason why such a plant should be put aside with a botanical certificate is not easily understood.

Dendrobium d'Albertisi (B. S. Williams).—A small-flowered kind, a full description of which was given in THE GARDEN (see p. 55).

Gold Medals were awarded as follows:—To Messrs. Veitch & Sons for groups of Pitcher-plants and Begonias; to Messrs. Kelway & Son for Gladioli; and to Messrs. Laing & Co. for group of Begonias.

Silver Medals were awarded to Messrs. Hooper for Begonias and Gloxinias; and to Mr. B. S. Williams for group of fine-leaved plants.

The collection of insectivorous plants from Messrs. Veitch & Sons attracted much notice on account of their curious construction and interesting character. They ranged from the miniature *Dionaea* and *Cephalotus* to the noble *Nepenthes Hookeri* and *Rafflesiana* and the trumpet-leaved *Sarracenia Drummondii*.

Mr. B. S. Williams exhibited a miscellaneous collection of fine foliage and flowering plants, among which were particularly noticeable *Caladium La Perle de Bresil* and *C. hybridum*, the latter a curious-leaved kind, the result of a cross between a *Caladium* and an *Alocasia*. The fine new Fern *Mirolepis hirta cristata* was also shown; likewise several fine-leaved *Crotons*, *Dracenas*, and *Colasces*, the latter being very bright and distinct.

Verbenas from Mr. Cannell were distinct in character, large, and of fine colours. Among the most striking kinds were *Lady of Lorne*, with remarkably large flowers, resembling those of a white Phlox; *Lord Leigh*, brilliant scarlet, clear white eye; *Swanley Gem*, white, edged with lavender; *Purple Emperor*, rich dark purple, distinct white eye; *Nemesis*, dark crimson; and *La Lovie*, mauve. Mr. Cannell also sent a box of blooms of *Pelargonium Echinatum Spotted Gem*, which were bright in colour and very effective. Striped *Venus Pelargonium* was likewise contained in the same collection.

Gladioli.—These, from Messrs. Kelway, Langport, consisted of forty-eight varieties, a large number of which were seedlings, and fine both in colour, size, and form of bloom. Among the most attractive kinds already in commerce were *Sir Thomas Symmonds*, a rose and crimson-striped flower with well-formed petals; *Acantha*, a showy kind, white, and striped with bright purplish-rose; *Faust*, brilliant orange-scarlet with purple veins; and *Eclat*, bright scarlet and white throat. Among the best seedlings were *Herois*, *Gorgonius*, and *Telamon*, to which reference has already been made. Other kinds worthy of notice were *Damocles*, fine purplish-crimson with white claret-striped throat; and *Gabinus*, very large white flowers delicately tinted with pink, the lower petal being blotched with bright purple. Mr. Bates is a kind with silky, white flowers, and bright purple throat and lip, very showy and distinct.

Gloxinias from Messrs. Hooper & Co., Covent Garden, which had been raised from seed sown one year ago, were remarkable for their

size and profusion of bloom, considering the age of the plants. The flowers were large and varied, some of the kinds being well worth naming.

Begonias.—These were chiefly shown by Messrs. Laing & Co., Messrs. Froebel, and from the Society's garden. The first-named exhibitors' plants were chiefly seedlings, the result of careful crossing with the best kinds. The flowers throughout were of fine form and colour. A good white-flowered kind of the *Pearcei* type was Mrs. H. J. Elwes, and there were several kinds with flowers almost golden-yellow. We also noticed in this group a plant of *Begonia diversifolia*, a kind not much grown, but one of the most beautiful. It grows from 2 ft. to 3 ft. high, and bears rich rosy flowers all the way up the stems. The plants exhibited, which were in 6-in. pots, were the produce of seed sown on Jan. 24 of this year, and served to show how quickly good decorative plants may be obtained. The best kinds in Messrs. Froebel's group were *Moonlight*, *White Queen*, *Solfatara* (sulphur), *Gloire de Nancy* (double scarlet), *Feu de Joie* (round flower), *brilliant rose*, *Eldorado* (yellow), and *Corneille* (clear rose). In Messrs. Veitch's group of Begonias were the brilliant crimson Mrs. Charles Scorer, B. Veitchi, Queen of the Whites, and several good seedlings; also the dwarf, scarlet-flowered B. Davis and a kind of similar habit of growth, named Mrs. Arthur Potts, having deep blood-red blossoms.

Miscellaneous Subjects.—Mr. Dean sent a dwarf kind of *Pyrethrum Golden Feather*, which is likely to prove useful in "carpet bedding," requiring evidently much less trouble to keep at the desired height than the one in general cultivation. Mr. Osborn, gardener to F. Buchan, Esq., Southampton, showed a flowering plant of *Odontoglossum Lindenii*, being the first that has flowered in this country. Its blossoms are of a lemon colour, and, as a variety, it is doubtless an acquisition. A group of small plants of *Hydrangea paniculata grandiflora*, from Messrs. Veitch & Sons, was very showy.

Fruit and Vegetables.—Mr. Thomson, of The Vineyards, Clovenfords, sent a bunch of Duke of Buccleuch Grapes of large size and noble appearance, both in bunch and berry. Several Melons of no particular value were also shown by other exhibitors. A collection of Potatoes was shown by Mr. Ford, gardener to E. Hubbard, Esq., Leonard's Lee, among which the most noticeable kinds were *International Kidney*, *Fenn's Bountiful*, *Yorkshire Hero*, *Snowflake*, and *Rector of Woodstock*.

During the afternoon Mr. Jennings, the assistant-secretary, gave a lecture on "Tuberos-rooted Begonias," in which he alluded to their form, seeding qualities, conditions for their successful culture, and their value for baskets and general decorative purposes.

Public Park at Wigan.—Mr. N. Eckersley, High Sheriff of Lancashire, has just opened the first public park in the borough of Wigan. Many thousands of persons witnessed the ceremony. The greater portion of the land was given to the town by Mr. Eckersley, who purchased it from the rector and patron for £2000, and the grounds have been laid out by the Corporation from designs by Mr. Maclean, of Derby. The park is nearly 30 acres in extent, and is centrally situated.

Scottish Horticultural Association.—At the monthly meeting of this Association, held on Tuesday last, Mr. Alexander Honeyman read an instructive paper on "The Nutrition of Plants." Mr. William Black next read a paper on "The Cultivation of the East Lothian, Warriston, and Ten-Week Stocks." He described the modes of cultivation followed in the Dean Cemetery, where these Stocks grow so luxuriantly. Messrs. Dicksons & Co. received a certificate for the new Phlox Surprise, and Mr. Robert Robertson received certificates for new Carnations *Rosy Queen* and Mrs. Robertson.

Fremontia californica.—On the outside walls of glass houses in the Coombe Wood Nursery about the end of June this was covered with bright yellow flowers and good foliage, not unlike small Fig leaves. In habit it has more the character of a dwarf bush than of a wall plant, and would make a conspicuous object in positions where it could receive a little protection during severe winters. As a wall plant it would be very effective in contrast with *Clematises* and similar summer-flowering plants used for wall gardening.—J. Groom.

Scottish Arboricultural Society.—The first excursion of the members of the Scottish Arboricultural Society took place a few days ago. The party proceeded by train to Scone Station, and during the day visited the plantations of Scone and Lyndoch, on the estate of the Earl of Mansfield, Mr. W. M'Corquodale, forester and wood surveyor, acting as conductor. The members were accompanied by their photographic artists, who carried home with them souvenirs of the excursion.

Excursion to Brighton.—On Friday, Aug. 2, the employees of Messrs. Sutton & Sons, the Queen's seedsmen, with their wives and friends, and accompanied by the members of the firm and their families, numbering in all between 300 and 400, had their annual excursion to Brighton.

"This is an art
Which does mend Nature: change it rather: but
THE ART ITSELF IS NATURE."—*Shakespeare.*

ENGLISH AND FOREIGN BOUQUET-MAKING.

ALLUSION is made (p. 101) to the comparative merits of French and English bouquets. Although willing to admit that in the matter of arrangement our London artistes may claim a superiority over their Continental colleagues, yet I cannot help thinking that in some respects we in this country might profitably take a leaf from their book. The system in this country of placing as many choice or other flowers as possible in a bouquet is a bar to many who cannot afford the outlay which the purchase of any great quantity of them entails. It is just in this respect that Continental people—especially in Germany—excel, they having the knack of making attractive bouquets without using so many flowers. In the middle of winter it is impossible for the many to indulge in a bunch of flowers; our nurserymen and florists profess not to be able to make anything of a cheap description at that time of the year. But in Germany this is just the time when a large trade is done in cheap bouquets, which they are there enabled to make by a judicious employment of flowers and foliage. Of course in a shilling bouquet at Christmas one would not expect to see Camellias or Roses, but there are plenty of flowers which, sparingly used, will suffice. As an instance, I will briefly describe one method which I have not seen employed in England. Some green Moss is procured, tolerably long, so that it may be made up into little bunches, which are attached, by means of strong thread, to some sprigs of anything of a pliable nature, such as Spanish Broom, and two or three short sprays of the small Periwinkle are attached in the same manner. The flowers, consisting of anything that can be procured, are mounted in the usual way, only that there will be but little need to wire them, just tying on being sufficient. A neat deal stick is taken and the centre flowers affixed to the end of it; next to this is placed a row of the Periwinkle, and around this a row of the little Moss bundles; then again come flowers, and then again Moss and Periwinkle, or the latter may be worked in amongst the rings of flowers. The whole is edged with some *Tbuja* sprigs, or something of a like character. In this way the flowers are spread over a greater surface, and it is possible to make a fair-sized nosegay at a cheap rate. In these cheap bouquets such plants as *Gypsophila*, *Ammobium*, and *Helichrysum*, dried in their natural colours, are mixed with the natural flowers; and as most nurserymen make a practice of growing and drying a quantity of these plants, they can be plentifully used. Were it understood that a good shilling bunch of flowers could be had in January as well as in June, buyers would greatly increase; and, as it is the cheap article that pays the best, makers would soon find their production profitable.

J. CORNHILL.

DINNER-TABLE DECORATIONS.

MY impression concerning these is that even making a good custom assume unreasonable proportions may soon not only render it objectionable, but a positive nuisance. This does not, however, apply to a few flowers being placed on the table. I see, indeed, no reason why flowers should be considered "out of place" on a dinner-table; but the question is, How can we improve such decorations? for it is impossible to fix rules for such work. It is true some good general principles may be laid down, such as not obstructing free intercourse across the table, and leaving ample margin for plates, glasses, &c.; but if any set of rules were implicitly followed table decorations would soon be reduced to a very stereotyped affair indeed; if the operator does not possess originality enough to extemporise a design by means of which he can work harmoniously with surrounding objects, I should have but little hopes of a

successful result from following any set of fixed rules. As dinner-table decorations are usually seen only by artificial light, it follows that the candelabra or whatever mode of lighting is adopted will, in a great measure, determine the form and extent of the floral decorations. Presentation plate, prize cups, and similar silver services often well-nigh fill the centre of the table, and leave only a small margin for flowers and foliage. An ornamental dessert service, too, skillfully filled and garnished, has a very pretty effect, and since the flat form of decoration has become so popular, a design on the white cloth, or on a centre of coloured silk or satin, is very speedily arranged in Fern fronds or ornamental foliage, and a few brightly coloured or graceful forms of flowers are added merely to give life to the arrangement. A few trailing sprays of foliage and pendant blossoms may also drape lightly from the candelabra, and there should be a specimen glass to each guest, containing a choice button-hole bouquet. Surely such decorations as these cannot, with justice, be termed incongruous. The principal evil to be guarded against is overcrowding. If ample space be allotted to each guest for all the necessary adjuncts of a dinner-table, I see no reason why the central portion, not required for any useful purpose, should not be gay with flowers. I would, however, encourage, as much as possible, originality of design. If A delights in fountains, waterfalls, and water bouquets, why should not B enjoy his Ferns or Mosses, or C only display his choicest fruits? Whether in the castle or the cottage there is room for endless variety in the way of table decoration, and the best effects will, as a rule, be obtained not by copying others, but by originating designs to suit special occasions as they arise. J. GROOM.

EXHIBITION CARNATIONS AND PICOTEEES.

As a grower and exhibitor of these flowers I cannot permit the criticisms in *THE GARDEN* (see pp. 106 and 142) to pass without remark. It is evident that none of the writers in question grow Carnations themselves, and it is equally plain to those conversant with these flowers that the said writers have but little knowledge of the way in which they are prepared for exhibition. It is a misleading remark to say, for instance, that the flowers "are throttled by a stiff collar of dead white cardboard," placed there, as is further stated, "to prevent the effect of the bursting of the calyx." It is wrong to say that the flowers are "throttled," as the card has a hole in the centre sufficiently large to prevent its coming in contact with the calyx, a fact which disposes at once of the statement that the card is put there either to prevent the bursting of it, as some suppose, or to mitigate the effect of its bursting, as stated by others. I think I can show, too, that *THE GARDEN* is responsible for some crude remarks on dressing. "What we have to deplore," says a writer in that journal, "is the fact that, after ages of effort, and not a little vaunting of what has been done, the ideal flower is only to be seen in a deep paper collar, with all its delicate beauty of varied petal destroyed, flattened, or picked out." This statement is altogether at variance with the intentions of the florist. His aim is to improve the appearance of the flower, to assist Nature, he would say, which he does by bringing out the "varied beauty of the petal," not destroying it. Some flowers have been brought to such a high degree of perfection that they do not require any artificial aid, either in the way of card or tweezers. Others are much improved by having some of the petals slightly moved aside in order to show the varied beauty of those that are hid underneath. In a large collection many flowers occur in which the outer petals are quite hid, owing to the inner ones overlapping them; in other flowers the petals are heaped together, as it were in segments, and therefore, by simply moving these to the right or to the left, their beauty is set forth. Again, in my opinion, such flowers are all set off to better advantage with cards than without them; in many cases, indeed, their aid is almost indispensable. Let a stand of blooms be set up without cards and one with them, and leave the flower-loving public to judge the two stands; I am certain that by far the larger proportion would select the carded flowers. That there might be some alteration in the way of exhibiting them I will admit. The monotony connected

with the long lines of boxes certainly affords room for complaint, and the same may be urged against long lines of Dahlia boxes, or even of Roses. Groups of small fine-foliaged plants, including Ferns, might be introduced in some way between the different sections of flowers, and the stages might be fringed with a row of Creeping Jenny, *Isolepis*, or *Selaginella*. To any external adornment of this kind no florist would object. What they want at a Carnation exhibition is to study the flowers in all their points of excellence, to admire the regularity and brightness of marking in the Carnation and the pure ivory-white petal, edged with red, purple, rose, or scarlet, in the Picotee. Few of them care much about the way in which they are arranged. Still, I would do florists injustice did I say that they would not appreciate a better arrangement. Let us now advert to the remarks of "A. D." (see p. 142). What can the general reader think of a writer who describes a plain circular card as "the meretricious aid of an ornamental decoration?" I trust, also, that "A. D." will see that, by implication, he accuses certain judges of dishonesty. It would have been better to say in the place of "an honest judge," &c., judges should disqualify, &c. The weakness of "A. D.'s" remarks culminates, however, when he says dressing "too often enables a skilled expert to make good flowers out of bad ones." Critics like "A. D." often rush into print without having studied the subject about which they write. Let us take an illustration. Let us suppose that a person having no knowledge of the art of painting visits a picture gallery for the first time. He walks carelessly through the rooms, and the less he knows of pictures the more freely and loudly will he express his opinions of what he considers the best, and it is also very unlikely that he will select as the best those paintings marked with the stamp of genius; rather will he choose those where high colour and showiness obtain. It is so, too, with the study of sculpture, and it is the same with florist flowers. The showy border Polyanthus is preferred at first to the delicate refinement of the gold-laced flowers, and the gaudy colours of the self-edged Alpine Auricula to the matchless purity of Taylor's Glory or Smiling Beauty.

J. DOUGLAS.

SPECIES OF SABBATIA.

Of this lovely genus of the Gentian family we have at present three species in cultivation, all natives of North America; and, though over half a century has elapsed since they were first known, they are but rarely met with in gardens. The kinds are—The Field *Sabbatia* (*S. campestris*), an erect-growing plant about 1 ft. high with many-branched, angular stems, which form a broad head. The leaves are stem-clasping and oval-shaped, pointed, and with from three to five veins. The blossoms are borne at the tips of numerous short stalks, and are about 1 in. across, with five oblong divisions. The colour is a light rose with a greenish star in the centre. It inhabits the open prairies of the Arkansas and Red Rivers. The Chloralike *Sabbatia* (*S. chloroides*), the finest of the genus, is rather a weak-growing kind, about 1 ft. high, with lance-shaped, erect leaves. The flowers are not borne in such profusion as in the preceding, but are much larger, being from 1½ in. to 2 in. across, with from seven to thirteen divisions, and of a bright rose colour. It is found in boggy places from New York to Carolina. It was introduced in 1817. The angular-stemmed *Sabbatia* (*S. angularis*) is of erect habit, with oval, stem-clasping leaves. The blossoms are of a purplish-red colour, about 1 in. across, and are borne on short stalks in profusion, which form a broad, fan-shaped head. It inhabits the hilly shady woods from Canada to Carolina, and was introduced in 1826. The variety *S. angularis alba* has pure white blossoms, and is also at present in cultivation. They are not difficult to manage, provided the peculiar habitat of each species be imitated as nearly as possible. For instance, *S. chloroides*, being found in bogs, requires a very moist position; *S. campestris*, an open and drier place; *S. angularis*, a more sheltered situation and more shade than the others, and it must also have partial shade in imitation of that afforded by the surrounding vegetation amongst which it is found growing in a wild state. The soil I use consists of equal parts of good fibry loam and

finely sifted leaf-mould, with enough sand to make it open. The only means of propagation I find is by seeds, which should be sown now, as no advantage is achieved by sowing in spring, the seedlings being apt to become drawn during hot weather; whereas, if sown now, the seeds soon germinate and attain a fair size before winter. The seedlings should be potted off before they become in the least drawn, or they will make but weakly plants, and should be wintered in a cold, airy frame. In spring, repeatedly stopping the shoots will induce them to form bushy plants before flowering. All the above kinds are but of biennial duration, but as they can be raised so plentifully from seeds, it would always be a source of perennial enjoyment to have a succession of flowering plants. There are several other hardy species which, I believe, are not in cultivation at present, including one or two perennials. They all have either rose or white coloured blossoms, with the same style of habit as those enumerated. The best are *S. paniculata*, *calycosa*, *stellaris*, and *gracilis*. W.

Bamboos for the Conservatory.—When well grown in pots the smaller Bamboos make admirable subjects for the conservatory or greenhouse, or for standing in recesses in rooms they may be used with advantage. Sprays of their glossy green foliage are also among the best material which can be used in large vases of cut flowers, or for edgings of bouquets. We lately noticed a collection of Bamboos in pots in Mr. George Paul's nursery at Cheahnut. The kinds most favoured are *Bambusa glauca*, *B. mitis*, the true *B. nigr*a, and *B. arundinacea*.—S.

Flowering of *Odontoglossum Lindenii*.—Referring to your notice of the *Odontoglossum Lindenii* which I exhibited at the Horticultural Society the other day, and which has never before flowered in England, permit me to say, for the information of your readers who may have a similar plant in their collections, that I purchased it at Messrs. Stevens' about six years ago, and that it was kept in a temperature the same as that in which Cattleyas and Vandas are kept for four years. Finding, however, that it did not bloom, I had it two years ago placed with *Ocicidiums* and *Odontoglossums*, and subjected it to a very low temperature, my house not exceeding 55° all last winter, and since the early part of May no fire-heat whatever has been applied. I think this proves it to be a specially cool *Ocicid*, and I make no doubt that if so treated it would push up a flower-spike every year.—H. J. BUCHAN, *Wilton House, Southampton*.

Myrtles at Lochryan.—These grow to a larger size as standard shrubs at Lochryan, Wigtownshire, the seat of Sir William Wallace, Bart., than I have ever seen in this country. Some of the bushes are over 10 ft. high and as much through, the foliage most vigorous and healthy, and the whole plants thickly covered with flower-buds just bursting into bloom. The Myrtle is common all through the sea-coast gardens of Great Britain as a wall shrub, but it is only where it is planted as freely as *Rhododendrons* that its full beauty can be seen. There are also several fine specimens, about 25 ft. high, of *Acacia dealbata*, which it is unusual to see so far north.—SALMONICEPS.

Plants for Churchyards.—I notice in the papers mention of another churchyard to be planted, and it is likely to be followed by many more. It has therefore struck me as worth considering whether shrubs which are sure to grow large are suitable for the purpose. I imagine that even the Lilac will produce roots sufficiently strong to disturb the graves; and I see in Kensington Churchyard many shrubs which, if left there, will, after a lapse of twenty years, smother the whole place. I would suggest that, except there happen to be spaces quite away from graves, the decoration by plants should be confined to such as the Broom, the Box, and a few others of slow growth, and that there are plenty of other tall-growing plants (including the Pampas Grass) which may be trusted not to grow in the way of roots to any troublesome extent. Between the graves the *Campanula patula* would be an excellent subject, as it is so hardy in London; in shady places I would put *Fumaria*.—J. S.

Second Growth in *Lilium longiflorum*.—I have a bulb of this Lily which sent up two stems in the spring in the ordinary way, neither of which, however, bore any bloom. Thinking that I should have to wait till next year, I put the pot aside for a time, till some time afterwards, perhaps in June, I observed four new stems rising from the bulb. These stems are now about 8 in. high, and I am told that they are all likely to bloom, and, indeed, I think I can feel the buds at the top of the stems. May I ask if it is not unusual for this or any other Lily to make a double growth, as it were, in one season?—W. J. T., *Brixton*.

NOTES OF THE WEEK.

The White Irish Heath (*Menziesia polifolia alba*).—I saw this growing most vigorously at Woodlawn, Castlewellan, forming tufts, fully 4 ft. in diameter, which were sheets of white flowers. It is planted in the hard gravel soil of the garden.—T. SMITH.

Desfontainea spinosa.—I saw some beautiful bushes of this handsome shrub, fully 4 ft. high and proportionately wide, literally loaded with flowers, in the gardens of Earl Annersley, Castlewellan, Co. Down. They were formerly grown in pots, but have been planted out in the open ground for some years, to their advantage in every way. They had evidently flowered equally well last year, as a large number of seed-pods were upon them; but all I examined were seedless, probably owing to last season being cold and sunless, and consequently fertilisation imperfect.—T. SMITH.

Harrison's Musk.—This will hereafter have to be classed with yellow bedding plants. I saw the other day a beautiful bed of it in the gardens of Narrowater Castle, Co. Down. The beds are all raised slightly above the level, and the ground is very stony and dry and exposed to the sea breezes. It had not been watered since planted in May last, and has grown well from the first, it being the first plant to cover the ground, forming a sheet of yellow, with the leaves beautifully green and healthy. This very much surprised me, as I thought it would not do without abundance of water. It was likewise used as a basket plant in the conservatory, and for this purpose also it was quite charming.—T. SMITH.

Delphinium cardinale.—Specimens of this Delphinium are now finely in flower in the Royal Botanic Garden, Edinburgh, and at this season of the year few plants are more imposing. They vary from 3 ft. to 5 ft. in height; one specimen 4 ft. high and 40 in. in circumference contains sixty branchlets, each bearing on an average from six to eight flowers of a bright orange-red colour, forming a strong contrast with plants of *Delphinium grandiflorum album* that stand in close proximity to it. *D. cardinale* is quite distinct from *D. nudicaule*, and will make a grand plant for the wild garden.

Plants in Bloom at Tottenham.—Amongst hardy plants now in bloom at Tottenham are the rare and beautiful *Pentstemon Cobæa*; varieties of the handsome *Sparaxis pulcherrima*; many plants of the new Lily alluded to above; a handsome and singular *Stobæa*, which is quite hardy and very distinct; a fine Japanese herbaceous *Veronica*; the hardy dwarf form of the common *Agapanthus*; *Campsnula Vidalli*; *Spiræa palmata elegans*, not a hybrid at all, but a pretty plant if allowed to stand on its own merits; it is probably what used to be called *S. lobata*, or a form of it. Along with these was also the showy *Chrysanthemum lacustre*, of which we have lost sight for some time, and which is a perennial well worthy of culture; in fact, it is a vigorous and fine ox-eye Daisy. Added to the above were likewise *Ramanas Roses*, in three colours; the large noble Day Lily, the double Tiger, and other beautiful Lilies.

Double-flowered Bramble.—One of the finest and most suitable of flowering shrubs for the wild garden or woodland border is a double form of one of our commonest native Brambles—*Rubus discolor* fl.-pl. A large specimen in the Kew collection has been one mass of rosy-pink blossoms for some time past, numbers of the individual flowers being as large and as perfectly double as those of many Pompon *Chrysanthemums*. This kind will flourish in almost every soil and situation, and, in the mixed shrubby border, will furnish for several weeks a colour which is, at any rate, somewhat uncommon among shrubs. Another Bramble, *Rubus laciniatus*, has beautiful, somewhat Parsley-like leaves, and fruits very freely. Like the last, it will grow anywhere, but it is well worth a place in the kitchen garden, and it will well repay liberal treatment.—†

Loasa volcanica.—In the herbaceous collection at Kew there is now in flower this new and beautiful plant, recently figured in "L'illustration Horticole." It is a robust-growing annual, about 3 ft. in height, with dark green, three-lobed, toothed leaves. The blossoms are borne in profusion and are about 1½ in. across, with five divisions, which form a regular pentagon. The colour is very peculiar; on the outside are the bright green calyx lobes, half as long and alternate with the boat-shaped petals, which are pure white, inside of which lie the yellow stamens. In the centre are five small, two-horned petals, united in a button-like form, which on the surface are of a bright scarlet, marked by transverse white lines, and golden-yellow at the edges and sides. Altogether, it forms a very striking object. The dettractive points are that it is beset with numerous stinging hairs, which produce the same effect as a Nettle, and also its being but of annual duration. It is, we believe, one of the many discoveries of Mr. Wallis in New Granada.—A.

Seedling Petunias.—We have received from Mr. Marcham, Springfield Nursery, Isleworth, a boxful of seedling *Petunias*. They consist of selfs of the richest crimson, rosy-purple, and white; white grounds, flaked with crimson and purple; crimsons, flaked with white; and rosy-purple, with a white centre running with heart-shaped terminations into the coloured margin—together, very striking flowers.

The Paris Exhibition.—Among the artisan reporters selected by the Society of Arts to examine and report on the various industries at the Paris Exhibition we learn that Mr. George Stanton, gardener to Mr. Noble, Park Place, Henley-on-Thames, has been appointed to report on horticulture. Mr. Stanton was selected by the above-mentioned Society for the same purpose also at the Paris Exhibition in 1867.

Aerides Lobbi var. Ainsworthi.—A plant of this fine form of *A. Lobbi*, exhibited by Mr. Mitchell, gardener to Dr. Ainsworth, Manchester, at the Royal Horticultural Society's recent show at Preston, deserves more than a passing notice on account of its finely-developed and beautifully-coloured flowers. It was a medium-sized specimen, consisting of two growths, each furnished with about sixteen leaves. One growth bore two flower-spikes, the longest of which measured 28 in., and had three side branches; the others were very little shorter, and the flowers were equally well coloured.—T. B.

A Few Stately Plants.—The present season has produced a degree of development rarely seen in hardy plants; they grew away in the spring without any checks from late frosts, such as we often have. *Aconitum Stokesianum* has grown 8 ft. high; *Bocconia japonica*, 7 ft. to 8 ft., exceedingly fine; *Eryngium paniculatum*, 6 ft. high, most ornamental; *Hemerocallis quanso* fl.-pl., in large masses, fully 4 ft. high, and with hundreds of flowers; *Silphium gummiferum* and *S. laciniatum*, 5 ft. to 6 ft. high, the former with deep yellow and the latter with paler-coloured flowers; one of the best features of these plants is that they are continuous-blooming, like the *Dahlia*.—T. SMITH.

A New Cattleya.—One of the most gorgeously-flowered hybrid *Cattleyas* that has yet been raised may now be seen in flower in Messrs. Veitch's nursery, Chelsea. Mr. Dorniny believes that it is the result of a cross between *C. Dowiana* and *C. exoniensis*. It is a strong grower, and its flowers are of large size; the lip, which is of a rich velvety maroon shaded with purple, measures from 2½ in. to 3 in. across, and forms a striking contrast to the broad, delicate violet, transparent petals and sepals. Although *Cattleyas* are not so popular as *Odontoglossums* and other cool *Orchids*, owing to their requiring more heat and care to grow them, yet such kinds as the one just alluded to fully repay, by the remarkable splendour of their blossoms, any care or trouble which may be bestowed upon them.

Gardening in the Green Park.—We notice a great improvement in the Green Park by Piccadilly, owing to the suppression of a number of the ugly and monotonous beds which were placed by that thoroughfare. The trees have also been thinned, and the remaining ones look much more healthy and promising.—V.

A Highly-coloured Masdevallia.—A medium-sized plant of *Masdevallia Harryana*, designated, I believe, the *Drumlanrig* variety, shown by Messrs. Veitch at the late horticultural exhibition held at Preston, exemplified more fully than usual the great variety in colour that exists amongst these plants. The peculiar shades in *Masdevallia* blooms are almost as difficult to describe as they are to paint, but we have hitherto seen nothing to equal the depth and intensity of colour in the plant alluded to, which may be described as a vivid magenta-crimson, unequalled by the flowers of any plant we have ever met with.—T. B.

Lilium Batemanniae.—We have received permission from a well-known lover of Lilies, Mrs. Bateman, to name a fine autumn-flowering Lily from Japan *Lilium Batemanniae*. We first had it over three years ago and flowered it, but, owing to the weakness of the specimens, were then unable with certainty to bring it forward as something really new. This year, however, having obtained larger plants, we can now with confidence introduce it as hitherto unnoticed in England. It grows from 3½ ft. to 4 ft. high, and has a slender stem, light green, inclined to bronze at the insertions of the lower leaves. The latter are long and slender and arch downwards. The flowers are semi-cup-shaped, with spreading segments, somewhat recurved, medium sized, of a deep apricot tint, and unspotted. They are produced in umbels of from four to eight or twelve, not unlike in tint those of *Thunbergianum venustum*; but the plant, as to bulb, habit of growth, foliage, and time of flowering, resembles very closely *L. Leichtlini*, to which it is closely allied.—A. WALLACE, Colchester. [We have received fine specimens of the same Lily from Mr. Ware's collection under the name of a variety of *L. Thunbergianum*. Mr. A. Perry considers it a tall form of what is known as the Armenian variety of *Thunbergianum*.]

NOTES FROM KEW.

Hardy Shrubs.—Foremost in beauty among the hardy shrubs now in flower are several species of the North American genus *Clethra*. All have deciduous, somewhat Alder-like leaves, and terminal racemes of white, *Audromeda*-like flowers; *C. acuminata*, *C. paniculata*, and *C. Michauxii* are well worthy of a place in any pest border.

Hardy Herbaceous Plants.—*Zephyranthes Lindleyana*, from Mexico, with its grassy leaves and erect, funnel-shaped blossoms, pure white inside and tinged with red on the outer surface, is one of the most handsome of the hardy *Amaryllid*ae. *Gladiolus dracocephalus*, a kind first discovered at the foot of the Drachenberg Mountains, in Natal Colony, by Mr. Cooper, when collecting for Mr. W. W. Saunders, is, according to Sir Joseph Hooker, remarkable for the contrast it affords in the lurid hue of its flowers, which are wholly unlike those of any of its congeners known to him. The upper parts of the flower have a yellowish ground colour, closely and finely striped with dull red-purple; the lower portions are bright green spotted with purple. *Clematis Davidiana*, though somewhat similar to *C. tubulosa*, is, however, totally distinct from that species from a horticultural standpoint, and, according to the same standard, a much more desirable plant in every way. It was a few years ago brought to the Paris Jardin des Plantes from China. In dry, sunny spots few annuals make such a gorgeous show as the *Portulacae*, *P. Thelluseoni*, with its large, rosy-rose, white-centred blossoms, being one of the best. *Hypericum empetrifolium* is a beautiful plant, and a near ally of the lovely little *H. Coris*, noted some weeks ago. It grows less than 1 ft. high, has pretty, Heath-like foliage, and loose panicles of bright yellow flowers. *Malvastrum Munroanum*, from Columbia, although introduced to English gardens more than half a century ago, seems to have been long almost lost sight of. It is, however, a very handsome perennial, bearing an abundance of bright salmon-coloured flowers. *M. lateritium*, from Buenos Ayres, has large, salmon-coloured, saucer-shaped flowers on stalks, 3 in. or 4 in. in length; each flower has a ring of yellow round the base of the brush-like mass of yellow anthers, and another ring of deep red round that. It is easily propagated, as the creeping stems root freely at every joint. *Linaria dalmatica*, with its shrubby habit, glaucous leaves, and large yellow flowers, is one of the most distinct and desirable members of the Snapdragon family. A Mediterranean Boragewort (*Echium cretitanum*) is a very showy plant; it grows about 2 ft. high, and bears a profusion of large deep red flowers. *Sericocarpus solidaginis* grows about 2 ft. high, and has very narrow leaves almost hidden by the white flowers; it is a graceful and pretty Composite. *Chrysopsis pilosa*, 2 ft. in height, has large flower-heads 1½ in. across, of a beautiful clear bright yellow colour; this North American perennial should be much more frequently met with. A Himalayan Composite (*Saeneurea albescens*) is yet very rare in collections; it is a very floriferous perennial, about 5 ft. high, with lance-shaped leaves white underneath, and innumerable, rather small flowers, light purple in colour. The handsomest of all the Groundsels is *Senecio pulcher*, figured in THE GARDEN (see Vol. IX., p. 572); it is a fine plant from 1 ft. to 4 ft. high, with large purple flower-heads; it was discovered many years ago by Tweedie, at the foot of Sugarloaf Mountain, in South Brazil, but was only recently introduced to this country by Mr. J. Tyerman, of Penlee, Tregoney; in a cool, moist spot this plant seems to escape the attacks of the fungus, which often proves so fatal to it in drier, more open places. *Opuntia Rafinesquiana*, with its large yellow flowers, is one of the best of the hardy Cacti; it grows well and flowers freely, if planted in a position where there is rapid and thorough drainage, and if care be taken to prevent injury from the too abundant wet in winter; any rough-and-ready means to attain this end will do, e.g., a piece of board or glass fixed 1 ft. or so above the plant, so as to shoot off most of the water which falls. *Stokesia cyanea*, a perennial from the United States, grows 2 ft. high and has large, showy flower-heads of a blue colour.

Greenhouse Plant.—A very striking and handsome plant is *Hibiscus Manihot*, a native of the East Indies; the flowers are 4 in. or 5 in. across, and are primrose-yellow, with a central blotch of deep crimson-purple.—†.

Common Jasmins in London.—The pretty white flowers on this old plant are so scanty that one is curious to know whether any attempt has been made by pruning or other means to make it flower more freely. There need to be a very fine specimen of it near Apsley House, and I continually see masses of the dark foliage, unrelieved by flowers.—J. S.

Salvia gigantea has been determined at Kew to be merely a strong form of *S. Sclarea*. *Salvia patens alba* is a very charming form, either planted alone or mixed with the blue one; both are hardy here.—T. SMITH, *Newry*.

THE KITCHEN GARDEN.

SPADE CULTURE BEST.

THE amount of produce raised upon land which has been subjected to spade culture is so much greater than that under the plough, that one cannot but wish that it were possible to bring more of the soil under spade culture. I know of many broad fields which the holders often maintain do not pay them to cultivate, and, judging from the crops which are seen thereon, I can well believe the assertion. The reason alleged is that the soil is so poor that nothing can be done with it, and, yet, strange to say, portions of that same ground turned into labourers' gardens are made in a short time to yield abundant crops of excellent vegetables. The corner of a light sandy field, on which I never saw a good crop of any kind when under the plough, was some four or five years since allotted to two cottagers. The first season both Peas and Beans in these two gardens were meagre, the Potatoes seemed to dwindle away instead of becoming properly developed, and everything appeared to wither up on the advent of dry weather, even the fruit bushes seemed to burn up. The occupiers, however, were apparently not daunted, for next season found them digging away again. That year there was a visible improvement; the spade began to make itself felt, the field that season was nowhere in the race, and succeeding seasons have but served to increase the gap, until now these gardens produce plentiful crops of all kinds. Let us cite another example. In this instance a piece of ground was considered so poor that no one was willing to work it, and for many years it had been suffered to lie waste. The owner, however, at length conceived the idea of cutting it up into small portions, and letting it free of charge to the working men of the neighbourhood. For the first two or three years it did not pay for the labour, and many of the first holders retired from the struggle. Others took their places, and those who persevered had their reward, and that land, once the poorest and least valuable in the neighbourhood, now produces excellent crops. Stronger arguments than these cannot be needed to convince us of the desirability of increasing the area of ground under spade cultivation, for every rod of soil brought under the dominion of the spade is a clear gain to the community.

Byfleet.

J. CORNHILL.

American Rose Potato.—Although a very variable sort as regards quality, this is one of the most prolific Potatoes grown, and in dry light soils it is one of the earliest. In this locality it is superseding old sorts rapidly; this year I saw excellent crops of it, quite ripe enough for storing away, lifted in the middle of July; and crops of winter greens, Turnips, &c., being sown immediately, a good early start is effected—a great point where winter crops have to be grown principally after Potatoes.—J. GROOM.

Foot's Green-fringed Lettuce.—We have not tested this as a Lettuce; but, judging from the appearance of a plantation of it in Messrs. Carter's seed farm at St. Osyth, it is a very ornamental plant. The leaves are finely fringed, and, forming a large rosette, the effect is better than that afforded by many of what are called "fine-foliated plants." We believe this Lettuce is of Californian origin. Canon Hole once, on being conducted along an immense series of ribbon borders, &c., requested to be allowed to cool his eyes on the Parsley. He may henceforward find relief in at least one other plant not usually included among ornamental ones. We should not be surprised to see it used as an edging to beds of flowers.

Good Lettuces.—As I think it the duty of every correspondent to give his experience for the benefit of others, I wish to say a word in favour of Jefferies' Little Queen Lettuce. This is a smallish, dark green, black-seeded Cos, coming in early, with thick, fleshy ribs, very sweet and tender, yet crisp and of first-rate flavour; I think it the best and most delicate variety I have yet tasted. The St. Alban's All Heart is another good Cos Lettuce of a much larger growth. The Hanson is a fine pale green Cabbage variety of very large growth, but not so good in quality, perhaps, as Neapolitan, which I consider the best of Cabbage Lettuces. One of the best for all purposes is Hicks' Hardy White Cos, a good summer sort, and invaluable for winter culture; I have entirely given up Hammermith in its favour. But no garden should be without the Little Queen.—W. RODEN, M.D.

Potato Disease in Ireland.—The disease has made its appearance among the Potato crops here, and in some places very badly. Ashleafs are, however, as yet sound. Climax and Early Rose were the first to suffer. I have cut off all the affected haulm Scotch Dons are very badly diseased.—JOHN CLAWS, *Heaford, Kells, Co. Meath*.

Tomatoes.—It is said that Tomatoes given to cows improve both the quantity and quality of the milk, imparting to the butter a golden colour. Does anybody know if in this last respect there is any difference whether the red or golden varieties be given to them? No wonder the Americans marvel when they see Tomatoes marked at 2s. a pound in Covent Garden.

THE FLOWER GARDEN.

HARDY WATER PLANTS.

IN addition to the list of hardy Water Lilies enumerated at p. 54, there are many other aquatics which, when associated with them, much enhance the beauty of ornamental water. Those which are mentioned below are the finest selected from the large number now in cultivation, on the principle that one good plant is preferable to many inferior ones. This list is confined to those water-loving plants which require to be grown so that, whether in deep or in shallow water, the surface of the water quite covers their crowns. Although amongst these there are some very beautiful plants, yet they are surpassed both in beauty and number by those which inhabit bogs and other damp places. These deserve to be dealt with in a separate paper. All the following are in cultivation in this country, and the majority may be obtained from any hardy-plant nursery. They may be grown in pots, boxes, &c, using the same kind of compost as recommended for Water Lilies, or they may be planted in the bottom of the lake, &c. For small spaces I consider the former plan preferable, as many of the kinds rapidly develop underground stems which, if allowed to

The Cape Pondweed (*Aponogeton distachyon*).

remain, would soon render the plants an entangled mass. Another advantage of pot culture is, that the plants may be raised or lowered as required by each kind. In large lakes, &c., where the bed is sloping from the edge, the planting-out system may be carried out with advantage, as suitable depths may be given to each kind. Care should be taken in planting to allow ample space for the strong-growing kinds, or they will soon overrun and destroy the weaker. First on the list is the beautiful *Aponogeton distachyon*, which has deservedly become a popular favourite on account of its pure white blossoms and delightful perfume. It is a native of the Cape, but is sufficiently hardy to withstand our ordinary winters, provided it be planted at a depth of 2 ft. below the surface. This plant has been so often described, and cultural notes have been so frequently given in THE GARDEN, that I think further comment on it is needless, except to say that a more desirable water plant either for the indoor or outdoor garden would be difficult to find. There are several varieties given in trade lists, but none can lay claim to be very distinct from the type. *Aponogeton spathaceum* is of quite recent introduction to our gardens, and may now be seen in flower at Kew. It also is a native of the Cape, and in its present stage of development is smaller in every part than the preceding. Its leaves are about 1 ft. in length, very narrow, and standing erect out of the water. The flower-spikes are freely produced, and are about

6 in. long, branching at the ends in the same fork-like manner as in *A. distachyon*. The blossoms are densely arranged on the forked spike, and are of a delicate blush tint, but scentless. The plants are growing in water about 1 ft. in depth. It is a very desirable acquisition, and will doubtless soon become as popular as its well-known congener. The North American species of *Pontederia* are quite hardy and very beautiful. There

Bog Arum (*Calla palustris*).

are four kinds which differ but slightly from each other, except in the form of leaf; they grow to about 3 ft. in height, with the flower-spikes rising above the foliage, on which the bright blue flowers are closely arranged. The kinds are *P. cordata*, with heart-shaped leaves; *P. angustifolia*, narrow-leaved; *P. lanceolata*, lance-shaped; and *P. cœrulea*, with blossoms of a rather darker hue. They all require to be so immersed in the water that the crowns are below the surface. *Caladium virginicum* is another North American plant, and has very ornamental, arrow-shaped, dark green leaves, but the flowers are inconspicuous. *C. canadensis* is a species with slender leaves and longer lobes than the preceding. Closely allied to this is the well-known favourite *Calla æthiopica*, which, if planted at about 2 ft. below the surface, withstands with impunity our ordinary winters. Few plants are more effective than this when seen in company with other aquatics. The white-spotted-leaved *Richardia* (*R. albo-marginata*) has also withstood the past mild winter unprotected, and is now in full vigour. The Bog Arum (*Calla palustris*) is also a very desirable kind; its flower leaves contrast well with its bright green foliage. The three last-named should be placed with the crowns considerably beneath the surface. The rare *Orontium aquaticum* belongs to the same family, and is a very beautiful plant. The leaves, which stand erect out of the water, are about 1 ft. in length,

A hardy Marantad (*Thalia dealbata*).

of a beautiful glaucous green colour. The flower-spikes are of a bright canary-yellow colour, and are about 4 in. in length. It is found in ponds from Massachusetts to Virginia, near the coast, and to the southward of North America, and it deserves more extensive cultivation with us. It is perfectly hardy, and requires to be grown in rather shallow water. Than *Thalia dealbata*, a more stately plant amenable to cultivation in the open air is not to be found. In the neighbourhood of London

it is apparently quite hardy if planted at a good depth. At Kew there is at the present time a good specimen of it in the hardy aquatic collection. It has broad leaves of a glaucous green borne on long stalks. The purple blossoms are borne in panicles, which, covered with a mealy-like substance, give it

Nymphaea-like Villarsia (*Villarsia nymphaeoides*).

a peculiar appearance. It is a native of South Carolina, and, though uncommon in gardens, may be procured from most nurseries. *Justicia pedunculosa* is a North American plant, and has long been a garden favourite. It forms handsome specimens about 4 ft. high and as much across. The leaves are narrow and bright green, and from their axils the clusters of its purple and white blossoms are produced. It also enjoys the name of *Dianthera americana*, but under either it is a very desirable plant. *Jussiaea grandiflora*, also a North American

The Buckbean (*Menyanthes trifoliata*).

plant, is a member of the Willow-herb family; it has long, trailing branches tinted with a dull red colour. The leaves are small and spoon shaped below, those above being lance-shaped. The blossoms are borne on short stalks of a bright yellow colour and about $1\frac{1}{2}$ in. across. If planted at the margins of

water, it soon spreads, and covers a large space with its floating branches.

We have in our native flora some very fine aquatics well deserving of culture, the following being among the finest. The Nymphaea-like Villarsia (*V. nymphaeoides*) is a somewhat rare native plant, and quite surpasses in beauty many of the

Flowering Rush (*Butomus umbellatus*).

exotic kinds. Its leaves are like those of the Water Lily in miniature, borne on long creeping stems which float on the surface. The blossoms are borne in profusion on short stalks rising out of the water, of a bright yellow colour, and about $1\frac{1}{2}$ in. across. It spreads rapidly, and should therefore be afforded a considerable space, and should be planted at the

Sweet Flag (*Acorus Calamus*).

bottom at a depth of about 2 ft. Belonging to the same family, and scarcely less beautiful, is the Buckbean (*Menyanthes trifoliata*), a common native plant, but one which should always be included in the aquatic collection, both on account of its peculiar trifoliate leaves and its clusters of fringed rosy

Arrowhead (*Sagittaria sagittifolia*).

blossoms. The Flowering Rush (*Butomus umbellatus*) is a highly ornamental plant, with erect, narrow leaves from 2 ft. to 3 ft. high, above which rise the flower-stalks, bearing large umbels of rosy-coloured blossoms. The variegated forms of the Sweet Flag (*Acorus Calamus*) are very desirable. The beautiful striated sword-like leaves of *A. Calamus* variegatus

rise about 3 ft. out of the water, and are tinted at the base with a deep pink colour. A much smaller plant is the Chinese variety (*A. gramineus*), with narrow Grass-like leaves, the variegated form of which is very pleasing. Some of the Arrowheads are attractive water plants. The common British kind (*Sagittaria sagittifolia*), with its double variety, is well worth growing; the flowers of the latter variety last a long

Pontederia cordata.

while in good condition—much longer than those of the type. The North American kinds, *S. obtusa* and *S. heterophylla*, are not more beautiful than our native kind, but are well worth growing. Of our three native Water Plantains the best is the dwarf *Plantago ranunculoides*, which is a charming plant in spring, when it forms a mass of blossoms of a light pink colour. The great Spear-wort (*Ranunculus Lingua*) is a very ornamental plant, with large, glaucous leaves and handsome blossoms of a bright yellow colour, about 2 in. across. All the preceding native plants, with the exception of the *Villarsia*, may be planted either at the margins or in shallow water in

Water Soldier (*Stratiotes aloides*).

boxes or pots. The following are either floating or submerged kinds. Frogbit (*Hydrocharis morsus-ranæ*) is an interesting plant which is found in still waters, at the bottom of which it hibernates. It makes its appearance in the spring, and later on bears its pretty yellow blossoms from amidst its tuft of round leaves. The Water Soldier (*Stratiotes aloides*) is a very peculiar plant, reminding one of a submerged Pine-apple

plant. The flowers spring from the centre of a rosette of sword-shaped leaves and are of a white colour enclosed in green sheaths. It is not a stationary plant, but moves about at the bottom of the water. The Water Violet (*Hottonia palustris*) is a highly interesting and beautiful plant. It has much-divided, submerged leaves and large, pale purple flowers arranged in whorls on a spike rising sometimes 2 ft. out of the water. It is well adapted for shallow water. One of the Water Crowfoots (*Ranunculus floribundus*) is well worth a place. It has finely-cut, submerged leaves, and very numerous

Common Water Crowfoot.

yellow and white blossoms rising about 1 in. above the surface, which in spring form, for a considerable time, very attractive objects. Many other submerged aquatics are very interesting, such as *Lobelia Dortmanni*, the Bladder-worts (*Utricularias*), the Pond Weeds (*Potamogetons*), &c.

For planting at the margins of lakes, &c., many members of the Galingale, Sedge, and Mace-reed families are very ornamental and graceful. The most desirable are *Cyperus longus*, which grows to a height of 5 ft., and makes fine specimens when kept from spreading, which it does rapidly; *Typha latifolia*, *angustifolia*, and *stenophylla*, upright-growing plants with Grass-like foliage, rising to a height of 6 ft.; the Bur-reeds (*Sparganium simplex* and *S. ramosum*) having much the

Yellow Water Iris (*I. Pseud-acorus*).

same habit as the preceding, with round heads of inconspicuous flowers; the triangular Club-rush (*Scirpus triquetus*), and many of the large-growing kinds of *Carex*, all very ornamental, as is also the Prickly Twig-rush (*Cladium Mariscus*). The yellow Water Iris (*I. Pseud-acorus*) forms a very attractive object in the beginning of summer with its blossoms of yellow colour of many shades. Various kinds of the Horse-tails are very graceful, the best being *Equisetum variegatum*, *fluviatile*, and *Telmateia*. W.

Lobelia Lady Macdonald.—This is one of the most showy of the bedding Lobelias. Its flowers are larger than those of any other kind, and they last for a long time, even during hot weather. The flowers are of snowy whiteness, except the petals, which are deep blue. We saw a large bed of it in the Chesnut nurseries the other day which was very attractive.—S.

FLOWER GARDENING IN HYDE PARK.

THIS differs but little this season from that of former years. The plants and flowers and their arrangements equal anything seen elsewhere, but we have no new ideas set forth, no fresh experiments tried, and but very little improvement generally. True, there have been new and, in some cases, superior kinds of Pelargoniums, Alternantheras, and similar subjects substituted for older sorts, but the style of planting in lines, in squares, or other formal-shaped beds, and of arranging these in pairs, is the same. Considering the great resources, as regards the varieties of plants, which we now possess for use in flower gardening, one cannot help thinking that in public gardens, at least, every bed should be as dissimilar from its neighbour as possible, in order to produce variety. Why, too, should the majority of the flower-beds in this our principal London park be of rectangular shape? The long lines of scarlet, blue, or yellow used along the margins of the shrubberies for so many years in succession might also now be changed with advantage. Another improvement would be the abolition of Pelargoniums and similar plants that have been planted immediately under the shade of trees, where they drag out a miserable existence during the summer. Such places might easily be covered with Ivy, or planted with hardy Ferns, or both; or there are endless varieties of Sedums and other hardy carpet plants which would succeed in such positions and have a much more pleasing effect than a few lanky scarlet Pelargoniums. To plant every available space with herbaceous plants might be objectionable, but, nevertheless, some of our showy hardy flowers which are found to succeed in London might, at least, find a place in our park borders, from which at present they are absent. In justice, however, to those who have the arrangements of the flower gardening here, it must be admitted that the style of gardening, as it at present exists, is carried out in the highest state of perfection. The beds are kept in excellent trim, and the condition of the Grass is unequalled anywhere near London. Two large clumps of *Erythrina Crista-galli* are full of flower, and some of the *Yuccas* planted in large groups have also blossomed profusely. The Palms dotted about in the Grass beneath the shade of trees are bright and healthy, and appear to be rather better disposed than usual. We noticed many thrifty Bananas of small size, and, where planted in groups, they are much more effective than larger plants, as their leaves do not get torn through rough winds to the extent of those of larger plants in isolated positions. Tobacco and Castor-oil plants have not yet attained a large size, and groups composed of Abutilons, Maize, Aralias, and similar plants are far too much crowded to be effective. The "dell" at the head of the Serpentine is better this year than we have ever before seen it; the plants which it contains are more happily disposed than in former years. Tall Cordylines have been introduced among the Ivy and low shrubs near the edges of the stream, as have also been Tree Ferns and Bananas; and Palms, &c., have been placed so as to leave a good breadth of green turf between them. The carpet bedding is, if anything, more formal in design than ever, but the plants have not been sheared down quite so much as formerly, which is an alteration in the right direction. The bronze-leaved *Oxalis* (*O. atra-purpurea*) is used with good effect, narrow bands of it being associated with green *Mentha*, grey *Cerastiums*, Golden Feather, *Alternantheras*, &c. Among Pelargoniums in beds the most striking are *P. Jealousy*, a kind with orange-coloured blossoms and crimped foliage. Robert Fish, a kind with yellowish Ivy-shaped leaves, is very dwarf, and bears bright orange-scarlet flowers on short foot-stalks. It is very floriferous, and one of the best of the dwarf bedding Pelargoniums. Wm. Wright is a good dwarf scarlet, and *Amaranth* is the best pink. Effective beds are composed of silver-leaved Pelargoniums planted alternately with *Viola Blue Bell*, and also of the same *Viola* and *Iresine Lindenii* edged with *Pyrethrum Golden Feather* and blue *Lobelia*. *Viola Golden Gem* is also mixed with *Iresine*, but the colours do not harmonise well.

C. S.

Arundo conspicua.—Seeing notices of the Elymus, or Lyme Grass, in THE GARDEN, reminded me that I have a few thoughts to put on paper concerning that very elegant Reed, the *Arundo conspicua*. This plant is truly named conspicuous, as when in flower its

tall plumes, from 9 ft. to 12 ft. high, may be seen from a great distance. The hot weather of the present summer seems to have brought this noble Grass earlier into flower than usual. My plants of it throw up their culms in June, and in the first week in July they were in perfection—and herein lies one of the causes that give the plant a value over its rival the Pampas Grass, for, while the latter plant in late October or November seems considering whether it shall bloom or not, the *Arundo* has been in flower for months. The peculiar grace of the *Arundo* consists in its tall slender culms, which carry the fine, drooping panicles clear of the foliage; being so tall and slender they are always in motion, and when viewed from a distance the plumes seem detached from the plant altogether. For planting in masses, in open spaces, on the margins of woods, drives, &c., especially when seen at some distance off, this fine plant would be very effective, and it would be equally eligible for planting round the margins of streams, &c., to which it would give character, and when planted in sufficient quantity it would form a fine cover for wild fowl, as its dense, fountain-like leaves interlace and grow into their neighbours, so as to form a jungle; and, like our native *Aira cæspitosa*, such is its extreme rigidity, that I believe it would be cattle-proof.—T. W.

Preparing for Spring Gardening.—Where spring gardening is carried on, provision must soon be made for it by putting in cuttings of *Pansies*, *Alyssums*, &c., and dividing the roots of *Daisies*, *Anbrietias*, and such plants as are increased readily by such means. Seeds must also soon be put in of plants that are naturally of an annual character; they will flower early enough the succeeding season to entitle them to a place amongst spring flowering plants. Wallflowers, Forget-me-nots, and such plants must be sown at once to get an early display of bloom. *Myosotis dissitiflora* is now largely grown from cuttings and divisions of the roots. There still remain large numbers of useful additions to the spring flower-beds that are easily raised from seed, such as *Silene pendula* and its pink, white, and rose varieties, *Virginia Stock* (pink and white), *Saponaria* (pink and white), *Nemophila insignis* (blue, white, and spotted), *Limnanthes Douglasii* (yellow), *Honesty* (*Lunaria biennis*—purple), *Collisias* (purple and white), *Candytuft* (crimson, lilac, and white), *Arabia alpina* (white), *Asperula azurea setosa* (blue), *Alyssum maritimum* (sweet-scented, white), and *Clarkia pulchella* and *alba* (dark rose and white). These constitute only a few of the many plants available for the purpose, but in conjunction with *Pansies*, *Violas*, *Primroses*, *Polyanthuses*, and a good sprinkling of bulbs, they may be skilfully contrasted in colour with the other occupants of each bed, and, collectively, form both an interesting and striking combination.—J. GROOM.

Flowers for Churchyards.—Allow me to solicit assistance on a subject which will, I trust, elicit sympathy. I am one of the few men who look upon a churchyard as not only "God's acre," but, if I may so express it, "a garden of sweet memories and holy thoughts." Everything that I can do to make this sacred place beautiful I do, but, up to the present, I do not think I have succeeded as I ought to have done. In the first place I have been a little selfish; being a great lover of the Rose and an ardent exhibitor, I have therefore devoted the various beds, more or less, to the exclusive cultivation of the Rose, and the consequence is that for nine months a year I have no flowers. This, however, is now at an end. I am gradually increasing my varieties of flowers and excluding Roses. My desire is to have the very earliest and latest flowers. I wish to commence with the earliest Aconites and bulbs and to finish with the latest *Chrysanthemums*, and here I crave assistance. I must inform you that I have no monnds. A cross of iron marks the head of the grave, and a bed from 3 ft. to 4 ft. runs at the bottom. In the churchyard there are eighteen beds of various lengths, and the whole is enclosed by a wide bed bordered by a very fine Box hedge, and protected from the west by one of Yew. The wide border I devote to herbaceous plants, of which I have commenced forming a collection. I think I may keep four of these beds for Roses. Concerning the rest I want advice as to what to plant. I must, however, say that I find it almost impossible to grow soft-wooded florists' flowers, as rabbits are numerous and eat all my Stocks and Asters. I intend, however, to wire one bed for Carnations and Picotees. I shall be exceedingly grateful if any of your readers will advise me on this point, and give me a list of plants which will provide me with blooms for at least ten months of the year.—A DORSET VICAR.

A Fine Grass.—A correspondent informs us of a plant of *Arundo donax* at Orchardleigh Park, near Frome, bearing forty-one spikes over 12 ft. high. This noble Grass is as well worthy of a place as the Pampas Grass.

It was curious, last week, to see an old member of the once famous "Young England" party denouncing the appearance of ragged children in St. James's Park. The Young Englanders liked to patronise and play cricket with their own tenantry; but the sight of real poverty availing itself of the few opportunities for enjoyment which London affords offends them.—"Examiner."

"THE LAST OF THE GIANTS."

THE late Charles Kingsley, in his "At Last," thus describes a part of his visit to the West Indies, and their rich woods and plantations and his experiences of the giant tree growths of those regions: "One clearing we reached—were I five-and-twenty, I should like to make just such another next to it—of a higher class still. A cultivated Scotchman, now no longer young, but hale and mighty, had taken up 300 acres, and already cleared 150 acres; and there he intended to pass the rest of a busy life, not under his own Vine and Fig tree,

but under his own Castor-oil and Cacao tree. We were welcomed by as noble a Scot's face as I ever saw, and as keen a Scot's eye; and taken in and fed, horses and men, even too sumptuously, in a Palm and timber house. Then we wandered out to see the site of his intended mansion, with the rich wooded hills of the Latagual to the north, and all around the unbroken forest, where, he told us, the howling monkeys shouted defiance morning and evening at him who did 'Invade their ancient solitary reign.' Then we went down to see the coolie barracks, where the folk seemed as happy and well cared for as they were certain to be under such a master; then down a rocky pool in the river, jammed with bare white logs (as in some North American forest), which had been stopped in flood by one enormous trunk across the stream; then back past the site of the ajoupa, which had been our host's first shelter, and which had disappeared by a cause strange enough to English ears. An enormous Silk-cotton near by was felled, in spite of the negroes' fears. Its boughs, when it fell, did not reach the ajoupa by 20 ft. or more; but the wind of its fall did, and blew the hut clean away. This may sound like a story out of Mun-

chausen; but there was no doubt of the fact; and to us who saw the size of the tree which did the deed it seemed probable enough. We rode away again, and into the 'Morichal,' the hills where Moriche Palms are found, to see certain springs and a certain tree; and well worth seeing they were. Out of the base of a limestone hill, amid delicate Ferns, under the shade of enormous trees, a clear pool bubbled up and ran away, a stream from its very birth, as is the wont of limestone springs. It was a spot fit for a Greek nymph—at least for an Indian damsel. Then we went in search of the tree. We had passed as we rode up some Huras (Sandbox trees), which

would have been considered giants in England; and I had been laughed at more than once for asking, 'Is that the tree? or that?' I soon knew why. We scrambled up a steep bank of broken limestone, through *Feras* and *Balisiers*, for perhaps 100 ft.; and then were suddenly aware of a bole which justified the saying of one of our party—that, when surveying for a road he had come suddenly on it, he 'felt as if he had run against a church tower.' It was a *Hura*, seemingly healthy, undecayed, and growing vigorously. Its girth, we measured it carefully—was 44 ft., 6 ft. from the ground, and as I laid my

face against it and looked up, I seemed to be looking up a ship's side. It was perfectly cylindrical, branchless, and smooth, save, of course, the tiny prickles which beset the bark, for a height at which we could not guess, but which we luckily had an opportunity of measuring. A wild Pine grew in the lowest fork, and had kindly let down an air-root into the soil. We tightened the root, set it perpendicular, cut it off exactly where it touched the ground, and then pulled carefully till we brought the plant, and half-a-dozen more strange vegetables, down on our heads. The length of the air-root was just 75 ft. Some 20 ft. or more above that first fork was a second fork; and then the tree began. Where its head was we could not see. We could only by laying our faces against the bole, and looking up, discern a wilderness of boughs carrying a green cloud of leaves, most of them too high for us to discern their shape without the glasses. We walked up the slope, and round about, in hopes of seeing the head of the tree clear enough to guess at its total height; but in vain. It was only when we had ridden some half mile up the hill that we could discern its masses rising, a bright green mound, above the darker foliage of the

The Last of the Giants.

forest. It looked of any height, from 150 ft. to 200 ft.; less it could hardly be. 'It made,' says a note by one of our party, 'other huge trees look like shrubs.' I am not surprised that my friend M. St. Luce D'Abadie, who measured the tree since my departure, found it to be 192 ft. in height. I was assured that there were still larger trees in the island. A certain Locust tree and a *Ceiba* were mentioned. The *Moras*, too, of the southern hills, were said to be far taller. And I can well believe it; for if huge trees were as shrubs beside that *Sandbox*, it would be a shrub by the side of those *Locusts* figured by *Spix* and *Martius*, which fifteen Indians with out-

stretched arms could just embrace. At the bottom they were 84 ft. round, and 60 ft. where the boles became cylindrical. By counting the rings of such parts as could be reached, they arrived at the conclusion that they were of the age of Homer, and 332 years old in the days of Pythagoras. One estimate, indeed, reduced their antiquity to 2052 years old; while another (counting, I presume, two rings of fresh wood for every year) carried it up to 4104.

NOTES AND QUESTIONS ON TREES AND SHRUBS.

Rhus Cotinus in Masses.—This beautiful feathery Sumach is a grand object when grown in large irregular masses or clumps on the Grass. I lately saw an immense bed in full beauty, and although I have frequently stopped to admire this beautiful plant as a single specimen on Grass, I must confess that one only realises the full effect of which it is capable when planted in quantity and left to develop its full beauty undisturbed by pruning or training.—J. Groom.

The Rose Acacia as a Standard.—Many plants that have long been familiar, and perhaps on that account less prized, renew their charms when presented under some better form. Such a plant is the Rose Acacia (*Robinia hispida*) which under its low form is very attractive, but straggling even to unsightliness. The flowers must be always beautiful and the foliage graceful and delicate, but, grown low, the bloom is often obscured and the leaves trailing in the dirt. Let it, however, be once raised up by grafting on a high stem of Yellow Locust (*Robinia pseud-acacia*), and it becomes graceful and weeping. Both flowers and leaves suggest tropical vegetation. Indeed, the rosy colour and curious form of the flowers and the elegant appearance of the leaves attract the eye more readily than choicer and rarer plants. Even in this form, however, the Rose Acacia is not perfectly satisfactory, for the stems of the Robinias are very apt to be disfigured sadly by the borer, for which pest no efficient remedy seems to exist. Meanwhile, many years may pass before the borer fairly gains sway, so that abundant time for enjoyment will remain to repay the trouble of setting out the tree. Once unsightly, the axe will readily remove it.

Two Hydrangeas.—In dwelling on the great attractions of the *Hydrangea paniculata grandiflora*, probably almost an autumn-flowering shrub, we are apt to forget that there are other *Hydrangeas* possessing very charming qualities. For the present season of mid-summer *Hydrangea nivea* and *H. cernicea* are very valuable. If their flowers are less showy than *H. paniculata grandiflora*, they are earlier, large, of fine tint, and of curious formation. The shades of white or flesh colour that distinguish either variety are indicated by the names *nivea* and *cernicea*. They present, however, special attractions in their foliage over that of *paniculata grandiflora*, on account of the white colour of the under-sides of their leaves, as shown when tossed up by the breeze. A varied group of *Hydrangeas* forms an effective feature on the lawn.

A Late-flowering Weigela.—*Weigela Lavallée* is again proving itself a most noteworthy plant. After all other *Weigelas* have long done blooming, it puts forth a second and most vigorous set of its chocolate flowers, a fact that quite distinguishes it from others of the species. The foliage is equal in vigour and health to any *Weigela*, while its flowers are unsurpassed for peculiar beauty. It remains, however, rare and, like most choicest shrubs, grows in popularity slowly.—S. PARSONS, in "Rural New Yorker."

Menzies' Arbutus.—A few of the species and varieties of *Arbutus* are, as ornamental evergreen shrubs, deservedly popular, but I have sometimes wondered that the noblest of all, *A. Menziesii* or *A. procera*, as it is sometimes called, is not more extensively planted. It is not less hardy than the common *Arbutus*, and its distinctiveness lies in its speedily attaining to a spacious tree, with large, handsome, oval, leathery leaves of a blue-green colour. When young it is of a compact, ovate-conical habit, and as such it is a suitable subject either for a promiscuous shrubbery or for an open lawn. When it attains maturity, as seen in the rather poor sandy lands near the coast in Upper California, where it is popularly known as the "Madrona," it forms a large tree from 30 ft. to 50 ft. in height, with wide-spreading head, and a bole from 2 ft. to 4 ft. in diameter. A striking and peculiar feature of it is the smooth, reddish bark of the trunk and older branches, which contrasts pleasantly with the glaucous leaves. Before me is a piece of petrified wood, exhumed from the sand and gravel formation on which the plant grows, which is either this or a closely-allied species.—GEO. SYME. [We noticed it also on the Californian mountains, at about 5000 ft., among the great Pines, a fine, stately, spreading tree.—En.]

THE FRUIT GARDEN.

REPORT ON FILBERTS GROWN AT CHISWICK.

FILBERTS have generally been divided into two classes, viz., (1) Filberts—Long-bearded—i.e., having the husks longer than the Nuts; (2) Nuts—Short-bearded—i.e., having the husks shorter than the Nuts. These distinctions, however, cannot be maintained. Popularly they are pretty correctly classed as follows:—

1. FILBERTS.—Varieties of oblong shape, like that of the finger-nail, and generally remaining in the husks: Bond, Barr's Espagnole, Barcelone de Loddiges, Cosford, A Grappes, A Grappes précoce, Frizzled, Lambert's Hartington Prolific, Lichtenstein's Zellernuss, Siegel's Zellernuss, Red Filbert, and White Filbert.

2. COBS.—Varieties of short broad shape, like that of the thumb-nail, large, and with thick shells generally falling freely from the husk: Atlas, Burchardt's, Merveille de Bolwiller, and Weismann's Zellernuss.

3. NUTS.—All the smaller varieties without husks: Arelina de Provence, *Corylus arborescens*, *Corylus laciniatus*, à Fruits striées, Small Cluster, and St. Grisier.

ATLAS (Synonymus—Downton; *Corylus algeriensis*).—Husk hairy, about equal in length to the Nut, of a dark brown colour. Nut large, broad, angular, with a broad irregular base, parting freely from the husk when ripe; shell dark brown, very thick, and hard; kernel large, full, and of excellent quality. Plant of strong growth; fruit freely; ripe midseason. A splendid Nut of the Cob class.

AVELINE DE PROVENCE.—Husk hairy, a little longer than the Nut, light coloured, sharply but not deeply toothed. Nut short, pointed, with a rather broad base, of a light grey colour, and parting freely from the husk when ripe; shell very thick and hard; kernel full. Plant of moderate growth; a great cropper, but late in ripening. This appears to be the same as the light-coloured variety of the Barcelona Nuts of commerce.

AVELINE ROUGE.—See Red Filbert.

BARCELONE BLANC.—See White Filbert.

BARCELONE DE LODDIGES.—Husk very large, full, covered with short hairs, twice the length of the Nut (which in some cases it completely covers), sharply serrated, light coloured. Nut of medium size, being almost hidden in the large husk, angular, bluntly pointed at the ends, dark coloured; shell very thick and hard; kernel full. Grows in clusters of five or six. Plant of very robust growth, with large dark green leaves; a moderate cropper; fruit ripens early. Very distinct, but too small.

BARR'S ESPAGNOLE.—Husk downy, short, about two-thirds the length of the Nut (which it presses closely), deeply and irregularly toothed, of a dull grey colour. Nut much exposed, short, having a broad base, and tapering very nearly to the apex; shell downy, but very hard, of a dull grey colour. Grows in clusters of from four to six. Plant of medium growth; moderate cropper; ripens late.

BARR OR BARN.—Not fruited.

BIZARRÉ.—Not fruited.

BOND.—Husk downy, about one-third longer than the Nut, very deeply toothed, the segments very long and narrow. Nut exposed, medium size, ovate, light coloured, very soft and downy; shell soft, may be pierced with the thumb-nail; kernel small. Grows in clusters of from four to six. Plant of slender growth; midseason; prolific; does not keep well.

CAPE NUT.—See Frizzled Filbert.

BURCHARDT'S.—Husk downy, a little longer than the nut, deeply toothed, dark coloured. Nut medium sized, very broad, the breadth exceeding the height, angular, or nearly square, with a broad flat base, light coloured; shell thick; kernel very large, full, of excellent flavour. Plant of moderate growth; late growing; fruit ripens early.

CORYLUS LACINIATUS.—Husk very small, lacinated to the very base, and much reflexed. Nut quite exposed, small, short, somewhat flattened, but of even regular form, of a pale grey colour; shell very thick and hard. Grows in clusters from three to five. Plant of slender growth; leaves deeply out or lacinated; fruits freely. This appears to be merely a cut-leaved variety of the ordinary Hazel (*Corylus avellana*). Ornamental.

CORYLUS ALGERIENSIS.—See Atlas.

CORYLUS ARBORESCENS.—Husk small, downy, about the same length as the Nut, lacinated to nearly the base; the segments long, linear, and reflexed. Nut small, does not part freely from the husk, flattened and broadly pointed, light coloured; shell very thick and hard; kernel full. Grows in clusters of five or six. Plant of moderate growth. A worthless variety.

COSFORD (Synonyms—Miss Young's; Thin-shelled).—Husk downy, about equal in length to the Nut, very close fitting; toothed, light coloured. Nut large, oblong, rounded, remaining in the husk; of a warm light colour; shell very thin, may be easily broken between the thumb and fingers; kernel large, full, of excellent quality. Grows in clusters from three to five. Plant of moderate growth; leaves pale green; fruits freely; ripe mid-season. One of the finest Filberts in cultivation.

DOWNTON.—See Atlas.

DOWNTON LARGE SQUARE.—See Atlas.

FRANCHE ROUGE.—See Red Filbert.

FRIZZLED (Synonym—Cape Nut).—Husk large, downy, somewhat exceeding the length of the Nut, pale or dull coloured; deeply lacinated or toothed, and reflexed to one-half its length, giving it a frilled or frizzled appearance, and thus exposing the Nut. Nut oblong, from 1 in. to 1½ in., somewhat flattened and broadly pointed; shell pale, thick; kernel large, full, of fine flavour. Grows in clusters of four or five. Plant of moderate growth; free fruiting; late in ripening. A very pretty and distinct variety.

A FRUITS STRIÉES.—Husk downy, longer than Nut; deeply toothed or lacinated, and opening away or reflexing, thus exposing the Nut when ripening. Nut small, long, and narrow, with a flat point; base irregular, pointed, light coloured; shell thin, hard. Grows in clusters of three to six. Plant moderately robust; grows late; free fruiting; ripens early. A very pretty Nut, but too small.

A GRAPPES.—Husk hairy, about the same length as the Nut, in two parts, which spread out from the Nut as it approaches ripeness; sharply serrated. Nut quite exposed, small, long, flattened, spoon shaped, light coloured; shell thick and hard; kernel full. Grows in clusters from five to eight; strong grower; ripens late.

A GRAPPES PRÉCOCE.—Husk large, very downy, about the same length as the Nut; very deeply toothed and partly reflexed. Nut small, long, narrow, and gradually flattened towards the apex like a wedge; shell downy, pale grey, thin. Grows in clusters of six to eight. Plant of slender growth; prolific; early.

GROSSE PRÉCOCE DE FRAUENDORF.—See Red Filbert.

GROSSE RONDE DE PIÉDMONT.—See White Filbert.

A GROS FRUITS NOIR.—Husk very dark coloured, hairy, nearly as long as the Nut, in two divisions, fitting very close to the Nut, thereby giving it a bare appearance. Nut of medium size, long; the base narrow, widening to the apex, dark or dull coloured; shell very thick; kernel small; a moderate grower; prolific; does not ripen well.

HARTINGTON PROLIFIC.—Husk hairy, one-third longer than Nut; the extending portion deeply lacinated and reflexed. Nut small, long, narrow, and pointed at both ends, irregular, light coloured; shell thin; kernel full; fine flavour. Grows in clusters of six or seven. Plant of moderate growth; very prolific and very early. The earliest Nut to ripen, but too small.

JEEVES' SEEDLING.—See Siegel's Zellernuss.

KENTISH COB.—See Lambert's Filbert.

KNIGHT'S SMALL.—See White Filbert.

LAMBERT'S FILBERT (Synonyms—Kentish Cob; Filbert Cob; Spanische Nut).—Husk downy, large, about one-third longer than the Nut, close fitting, and over the apex, of which it is occasionally contracted so as to enclose the Nut; very slightly toothed; dull coloured. Nut large, remaining in the husk; oblong, pointed; somewhat furrowed and irregular, of a dull grey colour; shell thick; kernel full. Grows in clusters of five or six. Plant of medium growth; a very great and certain cropper; fruit ripens mid-season. One of the very best Filberts in cultivation; very largely grown in Kent under the name of Kentish Cob.

LICHTENSTEIN'S ZELLERNUSS.—Husk downy, large, a little longer than the Nut; bluntly toothed, the segments slightly reflexed. Nut medium size, long, pointed at both ends, of irregular angular shape, and nearly closed in by the husk, of a dull grey colour; shell very hard. Grows in small clusters. Plant of strong, late growth; ripens late.

MISS YOUNG'S.—See Cosford.

MEVEILLE DE BOLWILLER.—Husk downy; about one-third longer than the Nut in two divisions; deeply and irregularly toothed, and pressing closely to the Nut. Nut large, rounded at base; very broad, the breadth nearly equal to the height, tapering to a broad point; very regular and uniform; light coloured; shell thick; kernel large; fine flavour. Plant of strong growth; grows late; prolific; fruit ripens mid-season. A very handsome and excellent variety.

PURPLE-LEAVED.—This is merely a purple-leaved variety of the Red Filbert. A very ornamental plant.

RED FILBERT (Synonyms—Aveline rouge, Franche rouge, Rouge d'Algers, Grosse précoce de Frauendorf).—Husk downy, of a reddish

brown colour, nearly twice the length of the Nut, round the apex of which it is contracted, thereby enclosing the Nut. Nut remaining in the husk small, long, and pointed at both ends; shell thin but hard; kernel very full, having a red skin; finely flavoured. Plant of slender growth; very free fruiting; ripe mid-season. A very excellent variety.

ROUGE D'ALGIERS.—See Red Filbert.

SMALL CLUSTER.—Husk small, hairy, deeply divided into two parts of about the same length as the Nut; toothed, and pressing closely to the Nut. Nut small, short, with a broad-pointed base; light coloured; shell thin but hard; kernel full. Grows in clusters of from eight to ten; slender growing; prolific, but too small. Worthless.

SIEGEL'S ZELLERNUSS (Synonyms—Sickler's Zellernuss; Jeeves' Seedling).—Husk downy, short, extending to three-quarters of the length of the Nut; very deeply toothed and reflexed, the Nut thereby being almost entirely exposed. Nut large, oblong, with a broad rounded base, becoming flattened towards the apex, light coloured; shell thin; kernel large, full. Grows in small clusters; moderate grower; ripe mid-season.

SPANISH NUT.—See Lambert's.

ST. GRISIER.—Husk downy, or having only short hairs; a little longer than the Nut, which it presses closely; sharply toothed. Nut of medium size, short, roundish, with a broad base; of a dark brown or reddish colour; shell thick, but easily broken; kernel large, full, of excellent flavour. Grows in clusters of three to six. Plant of slender growth; very prolific; ripens early. This appears to be the same as the reddish coloured Barcelona Nut of commerce; perhaps the finest flavoured of all Nuts.

WEISMANN'S ZELLERNUSS.—This is very similar to Merveille de Bolwiller, but larger.

WHITE FILBERT (Synonyms—Knight's Small; Barcelone Blanc; Grosse ronde de Piedmont).—Husk hairy, light coloured; nearly twice the length of the Nut, round the apex of which it is contracted, thereby enclosing it. It frequently bursts a little on one side, whereby the Nut is exposed. Nut long, small, remaining in the husk, pointed at both ends; shell thin, very firm; kernel large, full, of fine quality. Grows in clusters of from five to eight. Plant of slender growth; a very heavy and certain cropper; fruit ripens mid-season. A very excellent and useful variety.

LIST OF SELECT NUTS FOR GENERAL CULTIVATION.—Atlas, Cosford, Lambert's, Merveille de Bolwiller, Siegel's, Zellernuss, and White Filbert.—"Journal of the Royal Horticultural Society."

A GEORGIA FRUIT FARM.

DR. HAPE has a farm eight miles from Atlanta, consisting of 275 acres, of which fully one-half is cleared, and 100 acres are in fruit of every description. He has between 4000 and 5000 Peach trees and 1000 Pear trees, as many Apple trees, and 1600 Grape Vines. The larger part of his Peach orchards are of the early sorts, as these are the most profitable. Dr. Hape has whole orchards of a single kind of Peach. For instance, he has 500 trees in a body of the Early Tillotson. His trees are loaded with fruit, and are a marvel of prolific beauty. He had the Amsden and Alexander Peaches first, then the Beatrice, then the Louise, then Hale's Early. This latter variety has rotted badly this year. He has a young orchard of 300 Crawford's Early trees about ready to bear, and also an orchard of the Amelias. The Chinese Clings, the earliest and finest of our Clingstone Peaches, are about ready to come into bearing. Dr. Hape is the originator of a seedling Peach, called Hape's Early, that bids fair to equal if not to surpass any early Peach now known in flavour, size, hardiness, capacity for shipping, and beauty. He has thoroughly tested it. It has also been critically examined by the Pomological Society, and, after severe inspection, unhesitatingly endorsed as a new and valuable early variety. It is a distinct Peach of marked features. Dr. Hape has been shipping his fruit to New York and Baltimore, averaging 10s. 5d. per bushel, which leaves him a fair profit. He ships in quarter of a bushel and sixth of a bushel crates, which he makes upon his place, at his own saw-mill, costing him about 4d. a crate. He has the fruit gathered by hand by negro women, and laid carefully in the crates. The crates are then culled by a careful hand, and over-ripe and imperfect Peaches are removed. None but solid, perfect fruit is allowed to be shipped. Fruit just ripe and mellow is sold in the home market here. The imperfect fruit is given to the hogs. The ripe fruit, too soft for shipment or home sale, is made into Peach "leather," as it is called. The Peach is pressed through a sieve, getting rid of the skin and stones. The moisture is then dried out of the Peach, and the pulp is made into sheets of pure sweet Peach "leather," infinitely better than dried Peaches, with all the flavour of the fruit thoroughly preserved.

Adding water and boiling gives you Peach for preserves, pastry, sauce, or rolle. In the management of his *employés* Dr. Hape is very successful. He carries on all his enterprises on shares, giving his labourers an interest in the crop. In this way he makes everything pay. His Grape Vines are very thrifty, and well cared for. They are staked and tied up strongly, and pruned judiciously. He has 150 Scoppington Vines, but does not speak favourably of his experience with them. His Vineyards show care and skilful attention. He has all the common varieties, but I believe prefers the Concord and Delaware. His Pear and Apple orchards show the same care. The blight has been making havoc in the Pear trees in this section, but for some reason or other Dr. Hape's trees show an almost entire exemption from it. In his large orchard I noticed only two cases of blight. The most attractive sight on his farm is the nursery of young fruit trees. He has fully 60,000 young trees in this nursery, which covers an extent of nearly 20 acres, and finer, more vigorous, healthy young trees I have never seen. In addition he has fully 70,000 young stocks ready for grafting next season. He pays especial attention to his stocks, and the result is that he has always very superior trees. He raises all the finest Strawberries—the Monarch of the West, Eclipse, Parulee's Crescent Seedling, &c. He made £60 this spring selling the berries from a small bed, and said that he could as easily have sold £200 worth. He says that any man who will raise early and fine fruit can find sale for it. The most signal achievement that Dr. Hape has performed, however, and of which he is evidently the most proud, is the reclaiming of about 25 acres of useless marsh land by underground draining, making it the most valuable bottom land, of a productive capacity that can hardly be estimated. He has done this at a cost of not much more than £50. His drains are all covered. He has tried several styles of drains—the log drain, the rock drain, and the plank drain, the latter a triangular drain. As he has his own mill, he finds the latter the cheapest. This worthless bog has been brought into the highest state of fertility, and I saw crops of Cabbage and Tomatoes on it that could not be beaten.—“Country Gentleman.”

Apples in June.—In the grounds of the Paris Exhibition is a fine collection of fruit trees, trained in a variety of forms. The following are the names of a portion of the collection of Apples, remarkable for the time of year, shown at the Trocadero by Messrs. Francesco Cirio & Co., of Turin, in the latter part of June last: Magnana, Rosso Comune de Borge, Loea, ReINETTE Rouge, Kovetti, Rosso Rosso, Bocchard, Rosso Piatta, Marseille, Bedra a Ferojhe stria, Calville Rouge pauchée, ReINETTE Eigrorgne, Palanchino, ReINETTE Francator, Bigea Fanger, Carli de Mondor, ReINETTE Michel, and ReINETTE Savoye. These Apples had been kept for a very long time.—R. S.

A Plate of Early Peaches.—The following notes of some of our early Peaches were made from specimens taken from the orchards of H. M. Engle, of Lancaster Co., Penn., and although some of the fruit was not in proper condition for eating, the test was fair in regard to the time of maturity, &c. The best variety, perhaps, was the Musser, a Lancaster County seedling, measuring 6½ in. in circumference, very handsome, and of excellent flavour; in every respect, excepting, perhaps, the fault of clinging too tightly to the stone, a first-class variety; but its early period of maturity amply compensates for that. The next in point of excellence, and very little inferior to the above, was the Wilder, a seedling of Mr. Engle's own production from Hale's Early, I believe. In outline and colour closely resembling the Musser; the Wilder is 6½ in. in circumference, of very fine flavour, and abounding with a pleasant juice. This specimen was from the original tree. Another fine specimen was from a young tree, and measured 8 in. in circumference. The Alexander was unripe, and in consequence lacked flavour; it was 6½ in. in circumference, but inferior to the foregoing in appearance, and evidently later in ripening. Among the noted Rivers' varieties, Early Louise appears to be the most valuable, measuring 6½ in. in circumference, but with a dry and rather insipid flesh. The specimens of Early Beatrice did not do this fine variety justice, as they only measured 4½ in. in circumference, and were poor in quality. The Early Rivers, a poor specimen, badly decayed, was only medium in size and quality, yet rather showy in appearance. The foregoing were tested July 6, and, considering the latitude where grown, was a great point gained over the early Peaches of a few years ago. The only fault these early fruits have, and it seems common to them all, is the cling-stone nature of the flesh. If this can be remedied, their value will certainly be greatly enhanced; our Northern buyers, at least, are prejudiced against this character, and many purchasers will not use them. As redeeming points, however, they are all very juicy, and possess a fine flavour, singularly alike.—JOSIAH HOOPES, in “New York Tribune.” [All of these early Peaches seem to merit trial here.]

PLATE CXLI.

JAPANESE CHRYSANTHEMUMS.

Drawn by Mrs. DUFFIELD.

FROM an artistic point of view these are among the most valuable flowers introduced for many years. On their introduction, some few years ago, a very decided adverse opinion was expressed as to their merits. Those who had grown the neatly-shaped and symmetrical incurved, Anemone, and other varieties were disconcerted by their (at that time) ragged appearance and somewhat dingy colours. Since then, however, the flower has received very careful attention from many first-class raisers and growers, with the result that the improvement has been so great that, as regards colour, they have distanced the incurved varieties, though, of course, they do not present the uniform appearance of the older section. In a yellow variety, named Peter the Great, the points of the petals incurve, a style to be deprecated, as the blending of the incurved and the Japanese sections does not appear, to my mind, to be at all desirable. They should be so distinct that no error could possibly arise as to their position amongst Chrysanthemums, and their fine distinct form should not be destroyed. The prejudice against them is now (with the exception of a very few of the old school of Chrysanthemum growers) wearing away, as it certainly must do, considering the fine colours and handsome forms that most of the varieties possess. For grouping among tall plants for the decoration of the conservatory they are unrivalled, and a few so placed add a charm to that structure at a time when it is very often somewhat deficient in flowering plants, as a suitable selection will ensure bloom from October till January is far advanced. The following embrace a few of the most desirable varieties; they are all well tried, and can, without exception, be depended upon as a fair representation of the Japanese section:—

WHITE.—Elaine, Fair Maid of Guernsey, Emperor of China (not pure white; very late).

YELLOW, &c.—Meteor, Gloire d'Or, Gold Thread, Golden Dragou, Fulton, Sir H. Brock, grandiflorum.

ROSE, &c.—Baronne de Prailly, James Salter, roseum punctatum, Gloire de Toulouse, Mdlle. Delaux, Comtesse de Beauregarde, Belle Castallane, Aimée Maurel.

Bronze, &c.—Bronze Dragon, Bismarck.

Red, &c.—Dr. Masters, Garnet, Hero of Magdala, Dictator (highly perfumed), Triomphe du Nord, The Cossack.

F. T. D.

[The specimens from which our plate was prepared came from Mr. F. T. Davis, of Plumstead, and are the yellow grandiflorum, the Comtesse de Beauregarde, and Dr. Masters.]

Shelter and Shade in Nursery Grounds.—I recently observed a good system of affording shelter from cutting winds by means of Privet hedges about 20 ft. apart, with Cherry trees planted at intervals. These gave considerable shelter, and afforded a congenial position for planting the numerous subjects that are introduced to the glass structures during winter and spring, such as Spiræas, Roses, bulbs, &c., which, although quite hardy if left continuously out-of-doors, need some kind of shelter when removed from the glass roof, and for which, during the early spring months, shelter from winds is of greater importance than even protection from actual frost.—J. G.

Emigrant Sparrows.—Great alarm is expressed in America at the increase of the English sparrow, which was first welcomed as a deliverer, and is now in many places a great pest. Dr. Cones has a long and spirited paper on the subject in the “American Naturalist.” He adds that the article is to be regarded as a mere outline of so important a subject. He has collected a voluminous mass of testimony during the past two or three years, which he intends to digest, in order to place the whole matter in its true light on permanent record, in treating of the species in the “Birds of the Colorado Valley.” For the plague has spread even to that remote portion of much-be-sparrowed America.

Mr. CHARLES DARWIN has been elected corresponding member of the Paris Academy of Sciences in the section of zoology by twenty-six votes against fourteen. This success is all the more notable that Mr. Darwin obtained only five votes in a scrutiny which took place quite recently. Professor ASA GRAY has been elected corresponding member in the section of botany in succession to the late Dr. Braun, of Berlin.

JAPANESE CHRYSANTHEMUMS

PROPAGATING.

CUPRESSUS LAWSONIANA.—This elegant Conifer may be propagated by means of cuttings put in in August. Prepare well drained 6-in. pots and fill with finely-sifted soil consisting of equal parts loam, leaf-mould, and peat, placing a good layer of the siftings over the crocks to ensure good drainage; press down the soil rather firmly and place $\frac{1}{4}$ in. of sand on the top of it, then give a good watering, and when settled down prepare the cuttings as shown in fig. 1. In inserting them tighten

Fig. 1. Cutting and Grafts of Cupressus Lawsoniana.

well in with a peg or dibber and water with a fine-rosed pot; plunge the pots, half way up, in a tan bed without any covering and without surface-heat. Under such conditions, they will root in about three months, when they may be removed to the shelves of a greenhouse to be ready for potting off or planting out in the following spring. This Cypress may also be increased by grafting in March. Fig. 2 represents the stock, and fig. 3 the scion. Use either matting or strong thread for binding them together, place them in the grafting box, and keep close. Two months generally elapse before they are fit to be removed.

H. H.

THE PROPAGATING SEASON.

CULTIVATORS are pretty generally agreed that the propagation of bedding stock and many kinds of border plants should not be delayed much beyond the beginning or middle of August. They would indeed propagate some plants earlier, Pelargoniums particularly, if it were not for damaging the beds early in the season. The reason of propagating most kinds of stock before the heat of summer declines is that cuttings do not root so freely in autumn under the influence of artificial heat. Pelargonium cuttings of all kinds, even to the tenderest tricolors, will root freely in the open air about this time, and it is a mere waste of time and means to try to strike them under glass; but a month later they will require protection, though the greater portion will fail. The best way to strike Pelargoniums is in shallow boxes about 4 in. deep; no drainage more than one crock over each hole in the bottoms of the boxes is necessary. A finely-sifted compost, consisting of leaf-mould, loam, and sand in equal parts, should be used, and nothing like fibry material should be placed in the bottoms of the boxes under the compost—a common practice—because the roots get into it, and when the plants come to be potted off, it is impossible to disentangle them without injury. Good, large Pelargonium cuttings should be selected, smoothly cut over at a joint, and inserted in the boxes in rows about 2 in. apart; and after having been watered, they should be placed in the ground in some warm, sunny situation, and be left there till they are rooted. Over-watering must be avoided, but at the same time the soil should not be allowed to get dust dry.

This treatment is all that is necessary to ensure a good strike of Pelargoniums of any kind.

Lobelias are now very generally propagated by cuttings, owing to the superiority of the named sorts over seedlings, which always run too much to grass. It is often difficult to get good cuttings at this season, but usually a sufficient quantity of soft shoots are to be found springing from about the base of the plants; these should be secured. Have the flower-buds picked off them, and cut at about the third joint with a sharp knife, and before they have time to flag prick off into 6-in. pots filled with light, rich compost consisting of two parts sand and one part loam and leaf-mould. The pots should be plunged in an unheated frame, which should, however, be kept closely shaded and moist till the cuttings are rooted. Afterwards the plants may be gradually hardened off and stored for the winter in any cool, dry house where they can have plenty of light and air. Such plants are, of course, not intended to afford cuttings in spring, and need not be potted off. By February and March they will yield thousands of good tender cuttings which will root readily and make fine plants. Heliotropes, Gloxinias, Verbenas, Ageratums, and such like should be treated in the same manner, but a little later in the season. Most of these will require the assistance of a little artificial heat. It is safe to say that they will not root readily under a temperature of 65°, with a proportionate rise in the daytime. The great secret of striking all kinds of soft cuttings is a proper temperature, shade from strong sunshine, and a genial, moist atmosphere. Air should, of course, be admitted to the frame, but not in sufficient quantity to cause the plants to droop. In an unheated frame an opening sufficiently wide to admit a label will be enough. Viola, Cerastium, and other hardy subjects may be easily propagated by division or cuttings about this season, or a little later in open borders; Pentstemons and Calceolarias under hand-lights or in a cold frame, but the latter must not be propagated till October.

Coming to herbaceous plants, Carnations and Hollyhocks should be propagated without delay. Layering is the best way with Carnations. A heap of sand and leaf-mould should be laid round the collars of the old plants, and into this the young grass must be pegged, first clearing off a few leaves from the shoot and making a slit with a knife upwards from one joint to another, when it should be pegged, keeping the split heel down in the soil. Hollyhocks usually yield plenty of young growths from the base of the plants, and these should make cuttings to be struck in a cool frame or under handlights. Now is a good time to sow that effective spring-flowering Stock, the East Lothian. If sown now, in pots or in a bed slightly protected during the winter, they may be put out in spring in the borders, where they will flower early, and if some are kept in their pots they will make good conservatory ornaments. Of course good plants that have been sown earlier than these may be planted out at once to stand the winter, but this is not advisable where rabbits abound, as they are very fond of them and will be sure to devour them during the winter.

Those who desire to grow Roses on their own roots should at once put in Rose cuttings, which should be from 6 in. to 9 in. long and taken off with a heel. The cuttings should be inserted 3 in. or 4 in. deep into a sharp and rather light sandy soil on a shady border, where they can remain till the following February or March, when they may be transplanted.

Turning to plants in glass houses, several things require attention. Named Cinerarias should be propagated by slips from old stools, which, if they have been properly cared for, will be pushing freely from the base of the old stems. To have a good succession, batches should be potted in 4-in. pots, and be shifted on as required during August, September, and October. The best place for the young plants is a cool frame, but when they come to be shifted into larger pots they will require to be housed. Calceolarias for blooming next summer should be sown about the middle of the present month. The seed should be sown very thinly in fine, light, rich soil and loosely covered over. It will come up sooner if a pane of glass be placed over the seed-pan, which should be kept continually moist. Early-struck Poinsettias will now be growing apace, and later batches should be put in during the next month. The cuttings should be struck singly in 4-in. pots,

from which the latest need not be shifted, as the plants will flower in that size, and be useful for edging the front of shelves of the conservatory and for decorative purposes in the house.

Mignonette for winter flowering should be sown without delay. It should be sown in the pots in which the plants are to flower. 7-in. pots are a good size; these should be drained and filled with a compost consisting of loam and a little leaf-mould, well-rotted cow manure, and a sprinkling of sand and lime rubbish. The pots may be plunged out-of-doors in a warm situation until the plants come up and are well grown and coming into flower. About six weeks hence or later they should have a place in the cool greenhouse, where they can have plenty of light and air.

In the fruit department there is not so much propagating to do. Strawberries and Cucumbers are the two items of importance. It is still time to pot Strawberries; indeed, no time will yet have been lost if the runners have been laid in good time and are still growing freely in the open quarter; but they should be transferred to pots as soon as possible, and any pots of moderate size should be used, even for strong-growing kinds, so late as this, else the plants will not be well matured. Good loam should be employed, and the plants should be rather firmly potted. Those who have not layered runners for the purpose, and which are always preferable, may raise tolerably good plants by taking up stools not too old and dividing and potting them in 5-in. and 6-in. pots. For early winter crops of Cucumbers this is just the time to sow. The seedlings should be raised in a smart stove heat, and be potted off as soon as they have made their first rough leaves, and when established planted out in the bed, which will be about the beginning of September. If from that date they are pushed on gently with plenty of air and not too much moisture, they should begin to bear in October or November, and continue to do so till well on in spring, or even till summer if the plants have not been overcropped.

J. S.

PROPAGATING PINKS.

PLANTS of these may be raised in two ways, viz., from seed and pipings. If new varieties are wanted seeds must be saved from hybridised flowers, that is, the pollen must be removed from the flowers to be operated upon before it is in an active state, but the stigmatic portion must be kept uninjured; this, then, will be the seed bearer. The pollen must be taken from a suitable variety when its flowers are fully expanded, and be applied with a camel's-hair pencil. The seed should be sown in April in pots, and when the plants are large enough to handle they should be pricked out on a level surface of fine soil, consisting of equal parts of sifted turfy loam, well-rotted leaf-mould, and sharp sand. Prick the plants out 2 in. apart, as they do best when not too far apart at first. When they have quite filled the space allotted to them they should be moved to 4 in. apart, to be a third time planted out in their permanent quarters in October of the same year, where they will flower with the named sorts the following season. The named kinds are propagated by taking cuttings or pipings at the time the plants are in flower. Thin wiry Grass strikes root more readily than that of a stinger and mere succulent character; but if the centres of the strong growths are pinched out, lateral growths will be formed, and when large enough these may be slipped off from the main stem and inserted at once without any other preparation. I have tried different systems of management with the Pink pipings both in England and Scotland; but I never was more successful than when I took the pipings when young and small, selecting a shady position out-of-doors—for want of a better, the north side of a hedge or row of Gooseberry bushes—and put them in at once. I always choose a wet day for the purpose, if possible, and herein lies, to some extent, the secret of success. In this way I got ninety plants at least out of every hundred cuttings. I have tried different and mere scientific systems, but with less favourable results. In the hotter and more arid atmosphere of the south-eastern counties, where the pipings will not strike root readily out-of-doors, the plan I have successfully pursued has been to obtain boxes of any

convenient size about 3 in. deep, and, having drained them well, to fill them with a compost consisting of sifted loam and leaf-mould, and adding to it one-third part of sand. Use the siftings for the bottom of the box, and the finer portion, mixed with sand, for the top, pressing all firmly, and making the surface quite level. The pipings may be put in firmly about 1 in. apart in rows 2 in. apart; larger pipings may be a little wider. I put the boxes in a frame over a little bottom-heat, and if the frame be placed under a north wall all the better. Shade from bright sunshine and remove the lights entirely on quiet dewy nights. If the Grass be in good condition, but few losses occur in this way. When most of them have formed roots, the lights are removed by day, and the boxes ultimately placed in the full sunshine. When they can stand this I plant them out, in August, 4 in. apart, finally planting them in highly-manured soil at a distance from plant to plant of 9 in. If it be possible to obtain a layer of about 2 in. or 3 in. of fine maiden loam to place on the surface before planting, a much more luxuriant and healthy growth will be the result.

The following is a list of the best Pinks at present in cultivation: Annie (McLean), Bertram (Turner), Devise (McLean), Dr. McLean (Turner), Emily (Battersby), Excellent (Turner), Excelsior (Marris), Freedom (Hooper), John Ball (McLean), Godfrey (Turner), Harry Hooper (Hooper), Lady Craven (Hooper), Lord Kirkaldy (Turner), Mildred (Turner), Mrs. Hewarth (Hooper), Mrs. Mitchell (Hooper), Nonpareil (Bragg), New Criterion (McLean), President (Turner), Prince Frederick William (Hooper), Princess of Wales (Hooper) Reliance (Hooper), Rev. G. Jeans (Kirtland), Sarah (Turner), Victory (Hooper). There is not much being done now in the way of raising new varieties; Shirley Hibberd, a very large, full flower, with broad, richly laced petals, is, however, a good kind; Dr. Masters is also a large full flower, rather weak in growth, but very distinct; and Boiard is perhaps the finest Pink yet raised; the petals are very broad, the flowers full and of good shape, the lacing purplish-red and well defined.

J. DOUGLAS.

PROPAGATION AND GENERAL TREATMENT OF TRICOLOR PELARGONIUMS.

THE tricolor section of the Pelargonium family is justly esteemed for the contrast which it affords to the plain-leaved kinds. They are popular both as pot plants and for beds, and would be much more extensively employed in the latter capacity were it not for the fact that they are not so robust in habit and free in growth as the zonal kinds. They are both more difficult to obtain a stock of and to keep in health during the winter. Mrs. Pollock is, perhaps, even now the most useful of the tricolor bedders, but it does not keep well with the ordinary treatment which Pelargoniums get in winter time, and consequently comes out in spring in a debilitated condition, often requiring half the summer to re-establish itself in health. This is more especially the case with respect to plants which have been taken up and potted in the autumn. The rains and damp nights render them sappy, and, not becoming established before winter sets in, they soon lose their leaves, and, unless very carefully handled, they damp off entirely. The best way to ensure a stock of healthy plants is to put in a batch of cuttings early in the summer, grow them on in a house or frame, getting them well established in 3-in. pots by the autumn. On very hot days they may be afforded a little shade for two or three hours, but from the middle of August they should get the full benefit of the sun and air. They will thus make strong, sturdy plants, possessing a store of vitality which will carry them well on through the winter. The best place to keep them is on a shelf near the glass in a light, dry house, and during the dull months they should only get enough water to keep them from flagging. Until March they should be kept as cool as possible, merely firing on cold, damp days, to promote circulation and expel the damp air. This is a necessary attention, as they suffer acutely from a continuance of cold combined with a stagnant atmosphere. If thus treated they will come out in good, fair condition, and, although they will perhaps have become somewhat devoid of leaf, they will start with the season, and will be ready to make

good growth when planted out. If in March they can be placed in a house where they get the benefit of a rise in the temperature for about six weeks, they will make larger and handsomer plants than they would otherwise do. In this case a shift into 4-in. pots will benefit them, giving them a generous compost of leaf-soil and manure. They must, however, in no wise be stinted of air at this period, but may be shut up early and syringed on fine days, which will have the effect of increasing the root action, and will produce a corresponding effect upon the foliage. About the latter end of April remove them into a cold frame and gradually harden them off. One plant treated in this way will produce a greater effect than half-a-dozen autumn-struck cuttings. I do not approve of planting out the tricolors too early. They are not so vigorous in the roots as most other kinds of bedding plants, and, consequently, do better if not put out until the ground gets warmed a little. Sometimes heavy rains during May sodden and chill the soil to such an extent, that the plants are much better in the pots. The soil, too, should be well prepared for their reception; an admixture of leaf-mould, or the knockings out of pots, added to the ordinary garden earth, will suit them well. A hard, sour soil is fatal to them. When once a stock of tricolors is obtained it is easy enough to keep it up, but as they do not grow so strongly as other kinds, the process of working up a stock in the ordinary way from a few plants is rather tedious. When planted in the open ground they must needs take the weather as it comes; and a cold, wet, or very parching summer will so stunt their growth, that but few cuttings are procurable. One of the best methods of increasing any particular kind is to plant the stock out in frames in a good, free, rich compost, preserving a good distance from each plant. They should be put out early in April, and will then have a good long season for growth. As soon as there is a cutting to be got, take it off and insert it in the soil in the frame, if there be room, with the mother plants; or if not, in a frame prepared in the same manner. It will speedily root, and, starting strongly into growth, will soon furnish more cuttings, which are to be similarly treated. There are several advantages accruing from this plan. In the first place, there is no waiting to get a batch to take off, no preparation of cutting pots needed, and there are scarcely any losses from damping. The plants grow more strongly as one is better enabled to regulate the atmosphere, and propagation is rendered easier and more certain. In very hot weather a little shade may be given, and they should be supplied with plenty of moisture at the root. The sashes are to be kept on in cold weather, leaving air constantly, but on warm nights they should be withdrawn entirely. It is really surprising what a stock may be worked up in this way; and those who may have but a few plants of any kind which they would wish to increase to any extent, would do better to thus treat them than to plant them out in the ordinary manner. By the beginning of September it is advisable to pot them, as they then get rooted by the winter. The young plants will come up with good balls, and should be placed in pots sufficiently large to admit the roots. In a few days they will have made root, when they must be exposed to the sun and air, but not to the rains; in fact, it is as well to place them at once in an airy house, as if left out the damp nights cause them to keep on growing, whereas the object should be to harden the wood and foliage as much as possible. A damp atmosphere induces flaccidity of the leaf, and renders them unable to withstand the vicissitudes of the winter months. Those taken up from the beds should be crammed into as small pots as possible; and if they can be plunged in a gentle bottom-heat for a week or so, it will much benefit them. These old plants are very apt to waste away in winter from want of root action. When thus treated, however, they form a fresh lot of fibre, which enables them better to stand the dark months. These same old plants, if well attended to in the early part of the year, will furnish cuttings in early spring. It is, indeed, better to cut them back, even if only for the purpose of making the remaining plants themselves more uniform and dwarf. The cuttings, if cut back to the old wood, will, if placed in a genial temperature, make good plants the same season; and the old plants, if kept near the glass and with the advantage of artificial heat, will break and form fine bushy material; they should, however, on no account be cut back

unless they can receive the care described, as, if not thus treated, they are liable to die gradually away. In a cold house they fail to break again, owing to the torpidity of the root, which a low temperature induces. The cuttings should be inserted in 3-in. pots and placed upon a shelf in the full light; no shading or coddling of any kind is necessary. They will then root freely, and there will be no danger of damping.

Byfleet.

J. CORNHILL.

GARDEN BOTANY.

(Continued from p. 140.)

Gynœcium or Pistil.

DEFINITION.—The gynœcium occupies the centre of the flower, and within it the seed or seeds are generated. It consists of a single body, as in *Platystigma* (fig. 442), and in the Sweet Pea, Lupin, Kidney Bean, &c.; or of several, often numerous, bodies, as in the Globe Flower (fig. 443), in the Buttercup, Clematis, Larkspur, &c. When there is only one

Fig. 442.—Flower of *Platystigma*; pistil consisting of one body.

Fig. 443.—Flower of Globe-flower (*Trollius*); pistil consisting of several bodies.

body it may be composed of one carpellary leaf (carpel), as in the Pea family, or it may be built up of two (*Wallflower*), three (*Violet*), four (*Willow-herb*), five (*Pelargonium*), or many, as in *Mallow*. How to determine whether the body consists of a single carpel or several cohering together we shall presently learn. When there is only one body, and that made up of a single carpel, the gynœcium is apocarpous, as it also invariably

Fig. 444.—Section of Apple flower, showing the inferior ovary.

Fig. 445.—Calyx and ovary of *Pimpernel*, showing the superior ovary.

is when it consists of two or more free bodies. When two or more carpels cohere to form the gynœcium or pistil, then it is syncarpous. Taking one of the bodies of an apocarpous pistil (of *Clematis*, for example, or the solitary one found in a Pea flower), we find in the young state, at least, that it consists of a basal enlarged portion, the ovary, containing the ovule or ovules (young seeds), attenuated upwards into a more or less slender style, which terminates in or bears somewhere on its surface a thicker cellular portion viscous at some stage of its existence. This is the stigma. The position of the gynœcium is assumed to be always central or terminating the floral axis, though we sometimes find that other parts of the flower appear to be seated on the top of the ovary. When this is the case, as in the *Cucumber*, *Gooseberry*, and *Apple* (fig. 444), the ovary is inferior. It results either from the adhesion of the calyx to the ovary, or from a cup-shaped expansion of the floral axis, so that it is lowest in the centre. Sometimes the ovary or ovaries are only apparently inferior, being enclosed in a tubular calyx or floral axis, but free from its sides, as in *Roses*, *Corn Cockle*, &c. When the ovary is above and free from the calyx

it is superior, as in the Tomato, Cherry, Grape, and Pimpernel (fig. 445).

APOCARPOUS PISTILS.—We have already shown that when the gynoecium or pistil consists of a single body it may be either apocarpous or syncarpous, but when it consists of several or numerous separate bodies it is invariably the former; that is to say, when the gynoecium of a flower comprises several distinct free bodies, as in the Buttercup, Columbine, &c., each body always consists of a single carpel; consequently, the whole is apocarpous. There are many varieties of the apocarpous pistil; and when it consists of a single body it can usually be distinguished by its stigma being simple (not divided or lobed), as

carpous pistils, but it is unnecessary to particularise them in this paragraph, because the figures illustrating the insertion of the ovules, &c., show many of them, and no further explanation is required.

STYLES.—The presence or absence (see fig. 447) of a style or

Fig. 446.—Apocarpous pistil of Kidney Bean.

Fig. 447.—Apocarpous pistil of Nettle, with a single ovule in the ovary.

Fig. 448.—Apocarpous pistil of Barberry, the upper part removed, showing several ovules in the ovary.

in the Kidney Bean (fig. 446) and all the large family to which it belongs, or, failing this, by the insertion of the ovule or ovules, or by the oblique shape of the ovary itself. The ovary contains several ovules in the Pea and Bean attached along one side, but in the apocarpous pistil of the Barberry (fig. 448) they are inserted in the base of the ovary, the style is very short and thick, and the stigma expanded into a circular disk or what is termed capitate. In the Stinging Nettle (fig. 447) there is a solitary basal ovule, and the tufted stigma is sessile. Apocarpous pistils consisting of more than one carpel have

styles in syncarpous pistils, their degree of separation or union, their shape, and the part of the ovary from which they proceed are some of the chief points for our consideration under this

Fig. 454.—Pistil of *Chaillitia pedunculata*; styles free towards the top only.

Fig. 455.—Pistil of *Erythroxylon coca*; styles free to the base.

Fig. 456.—Pistil of *Balanites aegyptiaca*, with a terminal style.

head. In by far the larger number of syncarpous pistils the styles cohere in a single column throughout their whole length (for example, Fuchsia, Lily, Azalea, &c.), and these confluent styles are often described collectively as the style in the sin-

Fig. 449.—Flower of Strawberry in section, showing some of the carpels of the apocarpous pistil, the ovary of each carpel containing a single ovule.

only one ovule in each ovary, as in the Buttercup and Strawberry (fig. 449), or several, as in the Larkspur and *Spiraea* (fig. 450).* Apocarpous pistils are always superior.

SYNCAPOUS PISTILS.—These always have only one ovary, which is built up of two or more carpels, and the edges of the carpels simply meet in the circumference of the ovary, thus forming only one cavity or cell (fig. 451); or they are turned inwards, meeting in the centre, thus forming as many cells as there are carpels constituting the pistil (fig. 452). There are numerous other modifications of both apocarpous and syn-

Fig. 467.—A single carpel of Strawberry, with a lateral style.

Fig. 458.—Pistil of *Scirpus Sprucei*, with basal style.

Fig. 459.—Stems and pistil of *Malesherbia*, the three distinct styles arising below the summit of the ovary.

gular, although the lobes of the stigma, and sometimes also the cells of the ovary, plainly enough indicate that there is a fusion of several styles. When the union is complete there is little objection to this in descriptive botany, because it saves several words in a description, and it is not misleading. The style,

* In some botanical works, both English and foreign, each separate carpel of an apocarpous gynoecium is termed a pistil, as well as the combined carpels of a syncarpous one, but in most modern English works pistil is employed in the same sense as gynoecium. The term pistil has also been restricted to the style.

then, using the word in the sense just explained, of a Fuchsia, Lily, &c., is usually very long and slender, whereas in Trichilia (fig. 453) the ovary tapers gradually into a short style. The styles of Mallow are numerous and free from each other in the upper part only, as likewise are the five styles of Chaillatia (fig. 454), whilst in Erythroxyton (fig. 455) they are free down to the ovary. A more familiar example of the latter condition is offered by Thrift (*Armeria vulgaris*), in which, however, the number is five. With regard to the position of the style or styles on the ovary it is usually terminal (fig. 456), but in the Strawberry (fig. 457) it proceeds from the side, and in Soridinum (fig. 458) from the base of the ovary. *Malesherbia* (fig. 459) has three distinct styles, which, instead of being clustered

describe the stigmatic surface of the style, as it is difficult to separate the two. In Iris, for instance, the styles are petaloid and arched over the stamens with only a narrow line of stigmatic surface on the under side, but it is usual to describe the stigmas as petaloid. The stigma of the Goodenivæ (*Goodenia*, *Leschenaultia*, &c.) is very singular, the apex of the style being cup-shaped or two-lipped, and the stigmatic surface covered with a membrane. In the Poppy (fig. 467) the stigmas are sessile in lines radiating from the centre of the apex of the ovary, the number of lines corresponding to the number of carpellary leaves forming the ovary. *Argemone* (fig. 468), a member of the same family as the Poppy, has three sessile stigmas. One considerable family, the *Guttiferæ* (for example, *Clusia* and *Garcinia*) is characterised by having almost sessile stigmas with free, radiating arms, or all the branches united in a single peltate stigma. Sometimes the stigmatic surface is exceedingly small, the style tapering upwards to a point with a stigmatic tip. This is the case in numerous *Leguminosæ*. Very commonly the apex of the style has a knob-like expansion, as in the Primrose family, when the stigma is capitate (fig. 469). Water Lilies have a remarkably large stigmatic

Fig. 460.—Calyx and pistil of a Boraginæ, to show the position of the style. Fig. 461.—Style of *Thymus patavinus* arising from between the lobes of the ovary (gynobasic). Fig. 462.—Calyx and pistil of *Limnanthes Douglasii*, to show gynobasic style.

together at the summit of the ovary, as in most plants, arise from distant points below its summit. Two families, the Labiata (for example, *Salvia* and *Stachys*) and Boraginæ (for example, *Myosotis* and *Omphalodes*), are characterised by having a deeply four-lobed ovary with the style arising from the centre between the lobes (see figs. 460 and 461). The style is then gynobasic, that is, springing from the centre and base of the carpels forming the ovary. The same thing occurs in *Limnanthes Douglasii* and in the genus *Gaudichaudia*. Generally speaking, the style withers and falls off soon after fertilisation has taken place, but in many of the *Ranunculaceæ* (*Buftercup* family) the styles persist, harden, and grow out considerably after the fall of the floral envelopes. The feathery styles of *Anemone* and many species of *Clematis* are good examples of this, as well as the spreading, hardened styles of

Fig. 467.—Pistil of Poppy, showing the sessile radiating stigmas. Fig. 468.—Pistil of *Argemone*, showing the three sessile stigmas. Fig. 469.—Pistil of Primrose, with capitate stigma.

surface. There seems to be no direct relation between the extent of the stigmatic surface and the number of seeds normally produced.

W. B. HEMSLEY.

Fig. 463.—Pistil of *Gaudichaudia*, showing the gynobasic style. Fig. 464.—Flower of *Goodenia*. Fig. 465.—Section of the stigma of *Goodenia*. Fig. 466.—Enlarged stigma of *Goodenia*.

Nigella. In the genus *Martynia* the styles grow out into formidable sharp woody hooks or beaks. There is little striking variety in the shape of the style. Perhaps the most remarkable is that of the *Sarracenias*, which is umbrella-shaped. A similar kind of style characterises the genus *Aspidistra*.

THE STIGMA.—As already explained, the stigma is the papillose or glandular part of the style, which is humid or viscid at some stage, that is to say, when it is ready to receive the pollen, for it is through the stigma that the pollen penetrates to the ovules in the ovary. This process is more fully described under another head. Strictly speaking, only that part, or parts, of the style capable of receiving the pollen is stigmatic, and in some modifications of the style it is not unusual to

Early Opening of Kew Gardens.—Sir Trevor Lawrence, M.P., has addressed a note to Mr. Colman, honorary secretary of the committee for obtaining an earlier opening of Kew Gardens, to the following effect: "I have been reluctantly compelled to surrender all hope of obtaining this session a satisfactory opportunity of bringing on my motion for the earlier opening of Kew Gardens. Some of the friends who promised me their support have already left town, and many others will leave at the end of this week. A small vote like that for the royal parks, &c., will be taken at any moment, without affording me a fair opportunity of raising the question contained in my motion. No doubt you saw the explanation I gave in the House of Commons on July 15 of the circumstances under which I lost my opportunity of bringing on my motion on June 7. I greatly regret that I was induced to withdraw it on that day; but I fully relied on the distinct promise made me by the Secretary of the Treasury that he would give me an equally good opportunity on June 13, after the Whitsuntide recess. The Director's Report for 1877, lately issued, refers to the earlier opening question. I could hardly have believed that it could be seriously argued that mowing, sweeping, and rolling, which is really all the work to be done in the 'pleasure grounds,' would be interfered with if they were opened at 10 a.m. The 'constant improvement and development,' the 'laying out' and 'planting new collections,' the 'verification, examination, and rearrangement of old ones,' form a string of phrases intended to create an impression that a great scientific work is being constantly carried on in the 'pleasure grounds.' Such an impression would be entirely erroneous. Let any one of ordinary common sense visit the Gardens and judge for himself. From my communications with the First Commissioner I do not understand him to attach weight to any of the arguments urged against opening the 'pleasure grounds' at 10 a.m., except that of increased cost. As to this, I am informed by the

police that but a very small increase of expenditure would be necessary. I am glad to tell you that I received a full and detailed report from the police as to the conduct of the many thousands of visitors on Whitson Monday, and that it was in all respects eminently satisfactory; it as fully corroborated the opinion I formed on the spot of the behaviour of the people as it disposed of grave charges of misconduct which were, I regret to say, brought against them, but not openly. It only remains for me to say that I consider myself pledged to raise the early opening question next session on the first favourable opportunity."

GARDENING FOR THE WEEK.

Indoor Plant Department.

Conservatory.—The deficiency of blooming plants in conservatories at present may be compensated by a liberal admixture of such plants as *Dracæas* and *Coleus*. Of the former take such kinds as *Cooperi*, *ferrea*, and *terminalis*; the bright markings of their leaves will supply the place of flowers, and the plants will not receive injury for the next two months by being placed in a house without fire-heat; neither will they suffer so much as flowering plants would by standing somewhat closely, the greater amount of air and lower temperature of the house, compared with the stove where they have grown, having the effect of stopping them from making much growth whilst in the conservatory. The different varieties of *Coleus* should be placed so as to get as much light as possible, otherwise they become drawn and have an unsightly appearance. The old *Plumbago capensis* is another useful plant for this time of the year, not grown nearly so much as it deserves to be. The present is a good time to propagate it. The small half-ripe side shoots will strike freely inserted in small pots under bell-glasses in a little heat. These, when struck, should be encouraged to make growth before the autumn gets too far advanced. They should be wintered in a temperature of 45° or 50°. In the spring they should be headed down and potted in 6-in. or 8-in. pots, using good fibrous loam. If desired, some may be grown on in larger pots, but for general decoration they are more useful in a comparatively small state. The plants will last for years by cutting them back in the spring just before they commence growth and when they have broken, replacing a portion of the old soil with new material, returning them to the same or a size larger pot. *Fuchsias* should have their seed-pods picked off regularly, or they soon cease to flower freely; they ought to be supplied twice a week with weak manure water. Double *Pectunias* are very useful at this season, either as decorative plants or for furnishing out flowers. These should receive regular attention in the way of stopping and tying, to induce them to break back, or, from their quick, somewhat straggling habit of growth, they become unsightly. *Lilium auratum* is a most useful subject for conservatory decoration at this season, but should not be introduced in too great numbers at a time, as its perfume, being so powerful, is oppressive. Attend well to the different varieties of *Lilium lancifolium*, by keeping them neatly tied out, and supplying them regularly two or three times a week with manure water, otherwise the soil becomes exhausted, and they lose their bottom leaves, which destroys half the beauty of the plants. They must on no account be allowed, at this season especially, to suffer from want of water, even for ever so short a time, or the same mishap will follow.

Eucharis amazonica.—Valuable as this is at any season, it is never more welcome than during the autumn and winter months, a time of year when such choice blooms are doubly appreciated. Fortunately, they may be had at that season almost as readily as at any other, provided there be the necessary convenience for growing them and a good stock of plants to work with. Where this is the case, a portion of the plants should be always resting and others coming on in different stages, so as to keep up a constant succession of flowers for cutting or other purposes. Those intended for blooming during October, November, and December, should now be at rest in a cool house or pit, where they have only had just sufficient water afforded them to keep the leaves alive and fresh. If a portion of these be transferred into brisk hothouse heat and kept well supplied with tepid water, they will soon commence to throw up their flower-spikes, and when these are cut the plants should be grown on for a time before they are again put to rest. Owing to the rapid way in which the bulbs increase in number, frequent division and re-potting are necessary in order to renew the soil and make a separation of the large flowering roots from those of smaller size, which can either be discarded or kept for stock. The soil that suits them best is rough lumps of peat, leaf-soil, and a sprinkling of rotten manure, to which should be added sufficient sand to keep the whole porous and open, so that the water may pass freely through. To aid this the pots must be thoroughly well drained by placing at least 2 in. of crocks in them, over which some half-rotten leaves should be scattered, to prevent the finer soil from running amongst them and filling the interstices. Water somewhat sparingly for the first week or two till they get fresh hold of the soil, and then gradually increase the supply as the pots fill with roots, after which, if the heat be sufficient, they can scarcely have too much, either at the roots or overhead, where a good syringing is always acceptable. *Pancratiums*, such as *P. fragrans* and *P. rotatum*, are almost equally valuable, and may be had in bloom at different periods of the year by growing on and resting a portion of the stock in succession. These delight in a soil composed principally of fibrous loam, enriched with some mild manure, such as sheep droppings that have been laid aside for a time.

Achimenes.—These should have every attention as they go out of bloom to assist them in forming and ripening their tubers; the best place in which to treat them at this season for that purpose is a pit or frame where they can be kept moderately close and shaded, in addition to which they should be freely syringed overhead that the leaves may be maintained in a fresh, healthy condition. *Achimenes* are too frequently stowed away directly they cease flowering or become the least shabby, and water entirely withheld from them, a course of treatment the reverse of what they require, as it is just at that time assistance is needed in rendering the drying-off process gradual and natural. By affording the first batch a little extra attention they will form an abundance of fine, large tubers, superior in every way to any that can be obtained from those now coming on, which may therefore be discarded as soon as they have discontinued blooming.

Gesneras, such as *cinnabarina*, *exoniensis*, and *zebrina*, are among the most useful autumn and winter-blooming plants, independently of which the great beauty of their rich velvety-looking leaves makes them quite worth growing for decorative purposes. They require a rich, vegetable soil, such as leaf-mould and peat, which may be used in the proportion of two-thirds of the former to one of the latter, or the peat may be substituted by adding a less quantity of rough fibry loam. This must be kept free and open by using some sharp, clear sand, in order that the great quantity of water they require while making their growth may pass readily through. In re-potting any of these, see that the old ball is not disturbed any more than is necessary for the purpose of removing the crocks, as most of the fibre they make will be found clinging around the insides of the pots.

Imported Orchids.—The immense quantity of Orchids now imported points to one of two things, either that great numbers are, subsequent to their introduction, killed, or that their cultivation is largely on the increase. Possibly to both these causes may be attributed the continuous demand; but, although many of the more popular and useful species can now be obtained for much less than the prices they once realised, still there is no doubt very great quantities are destroyed by injudicious treatment during the first efforts the plants make in growth after the severe ordeal they pass through from the time they are gathered in their native habitats until they reach the hands of the grower in this country. There is one thing to be said in favour of imported plants, that although weakened by packing and transit, still they are free from disease such as is often met with in plants that have been for a considerable time in the country. Hence it is often more advisable for those commencing to form a collection to confine themselves in a great measure to imported plants rather than depend upon such as have been long under cultivation, however superior the latter may appear to be. A few words as to the treatment of imported plants may not be out of place to those who have had but a limited experience of them. First, as to the cooler section, such as come from the Brazils and the warm as well as cooler regions of continental America, and which, in a great measure, consist of species forming pseudo-bulbs. It may be observed that generally the larger the masses are when brought over the more likely they are to get fully established in a comparatively short space of time, for, although Orchids that form these pseudo-bulbs will bear partition or division to an extent that few other plants will, there is no doubt that the larger the masses are up to a reasonable size when in this country first placed under conditions calculated to excite them into growth, the sooner they get established. On the other hand, though almost every pseudo-bulb (when the plants are so far divided as to separate the masses into two or three or even a single stout pseudo-bulb) will make growth, supposing that each possesses a healthy dormant eye, still, the first growth made from these small detached pieces will, under the best treatment, be comparatively weak and small proportionate to the extent to which this sub-division has been carried; therefore, I would by no means advise beginners intending to cultivate the plants for purposes usual with private growers to divide newly imported Orchids into small pieces. It is necessary to allude to this, inasmuch as I have frequently met with young hands in their cultivation who look upon a small bit of an Orchid when healthy and prepared to start into growth much in the same way they would a cutting of any easily propagated plant possessing the free growth and recuperative powers that enable them in a short time to attain size and vigour equal to the specimen which the cutting was taken from, and which Orchids, from their naturally slow growth, are wholly incapable of, as is evident from the fact that when such subjects as *Cattleyas*, *Odontoglossums*, *Oncidiums*, *Burlingtonias*, *Anguloas*, *Barkerias*, *Brassias*, *Coleogyas*, *Chysis*, *Epidendrums*, *Stachopeas*, *Lælias*, *Lycastes*, and all plants of similar habit are divided into small pieces, it takes several years to induce the sub-divided pieces to form a single bulb fully up to their natural size. With all such plants I have found it better, after being newly imported, to grow them on for about a couple of years in considerable masses, and then, if deemed more advisable to increase their number at a sacrifice of individual size, to divide them; in a couple of years after this the pieces so separated will be much larger and stronger than they would if divided when first imported. Neither is this to be wondered at, as the weakening influences they have been subject to during their transmission from the collector to the grower are very much increased when subjected to dividing into small pieces before they had time to recover. When first unpacked, the whole leaves and bulbs should be carefully sponged, so as to free them from all dirt or insects, and any decayed portions should be cut away.

Heat to which Newly-imported Orchids should be Subjected.—The treatment as to temperature the plants should first receive at the hands of the grower ought to a certain extent be more

regulated by the condition they are in when they arrive than by the country they have come from, as if in a weak state if subjected at first to a temperature that will excite them other than very slowly, the chances are that they either perish at once or make a spasmodic attempt at growth, and die before they mature it or form efficient new roots to support it. Even with plants in the best condition when imported, the first growth induced should be gradual and slow. If the plants arrive late in the spring, summer, or autumn, the temperature of a cool house without any fire-heat will be sufficient for the species already named.

Light for Orchids.—If, as is often the case with plants like Cattleyas, Lælias, and Odontoglossums, an attempt at growth has been made during the transit, this will necessarily be weak and quite blanché, necessitating their being very gradually exposed to light, otherwise the partial growth thus begun will be almost certain to go off, which is so much lost at the expense of the stored-up strength in the plants; consequently, it is requisite that the house, pit, or portion of either they occupy should, until growth is fairly commenced, be somewhat more shaded than would be advisable for established plants; in addition to which a little extra shade, such as that afforded by white paper laid immediately over them on the shelves they occupy, will be of benefit.

Air and Moisture.—With most species some slight moisture-holding material, such as a little Sphagnum, shell gravel, or the like, laid upon the shelves or stage they are on, kept a little damp, but not wet, will assist the development of growth more safely than the direct application of much water. The atmosphere should be kept closer than that of an ordinary greenhouse, but not so confined as would be advisable during the growing season with well-established plants.

Potting Orchids.—When a little progress in growth has been made, and a disposition to form roots is apparent, the plants should be potted, using very great care not to injure the young roots. Two or three sticks ought to be inserted in the pots, to which tie the plants in a way to make them quite secure so that they cannot move, otherwise the young rootlets, before they get well hold of the potting material, are sure to get damaged. Where fossil Oak is to be had I prefer at once, before any roots are formed, tying the plants to small pieces of this with a little bit of Sphagnum attached, but not enough to hold much water; to the roots, as soon as they are made, will cling. The advantage in the use of this fossil wood is that it affords something at once for the roots to adhere to that, from its non-perishable nature, is suited to them, and when once they have fastened to it the whole can be transferred to the pots and secured better than by tying to sticks. Where Orchids, when first imported, are thus tied to material of this description, which is the best, or any of the more common kinds of wood used, many growers suspend them head downwards for a time in the house or pit in which they are started. This prevents too much moisture accumulating about them, and is, so far, a safeguard, for, over-much moisture in any shape, above all things, must be avoided until they have attained some strength. As growth proceeds they will gradually bear subjecting to ordinary treatment found best suited to their respective kinds, but on no account should they be hurried, or after their first growth is completed submitted to that severe drying ordeal which fully-established plants by some growers are subjected to.—T. BAINES.

Indoor Fruit Department.

Pines.—As soon as these are cut in any of the pits get the latter thoroughly washed, cleaned, and repaired, the woodwork painted, and the walls lime-washed. The heating apparatus should likewise be seen to and all got into good working order. Remove such suckers as are good and strong as soon as they are ready for separation, with a heel of the old wood attached to them if practicable; pot them at once, and start them in a kindly temperature. Crowns, as a rule, should be avoided, unless for the perpetuation of new or scarce sorts, and then only those from first-class fruits ought to be chosen. No matter at what season suckers are ready, they should be potted. Shift all plants that require it, shade them, and keep them a little close for a time, and dew them overhead with tepid water through a fine rose or syringe at shutting-up time. Those intended for early summer fruiting should now have their pots well filled with roots, and should be kept moderately dry, but at no season of the year absolutely so. Such plants as are about to throw up their fruits enjoy a good growing temperature and a kindly bottom-heat, and for this purpose fresh linings and plunging may be necessary.

Vines.—Remove the lights if practicable from the earliest Vineries in which all the wood is thoroughly well ripened and the fruit cut, and paint and repair the house. Where Grapes are now ripe and hanging, precaution should be taken against the ravages of wasps and other depredators, either by placing the clusters in little muslin bags, or, if convenient, covering over all openings for ventilation with sheets of tiffany, hexagon netting, or frigi dome. A somewhat dry atmosphere is necessary where Grapes are ripe and colouring, but still guard against too much avidity. In late Vineries where the berries are swelling, give air night and day, and maintain an equal temperature by means of a little fire-heat, which dispels stagnant damp in dull weather and renders the atmosphere sweet and healthy; give also abundance of water, and sometimes manure water to the borders, and liberally damp all paths, walls, and floors during the day, otherwise shrivelling soon sets in, and red spider makes its appearance. The earliest pot Vines will now have their canes well browned off and thoroughly matured, and as soon as this is the case they may be turned out-of-doors and set in well sheltered places where their rods can be kept erect. Turn the pots on their sides when it rains heavily. Other pot Vines may be kept in a growing condition until they are ripe, when they should be treated like the earliest ones.

Peaches and Nectarines.—In order to give late fruits every chance of ripening properly, fully expose them to the influence of the sun. Trim out all shoots not required for next year's work, so as to thoroughly ripen those retained. Where the fruit has been gathered, and the wood is well matured, ventilate the houses as much as possible night and day, and syringe with a solution of sulphur for the eradication of red spider, and use some dissolved soft-soap or Gishuret's Compound in the water when syringing for the destruction of scale. Keep the borders moderately moist, for drought under any circumstances is exceedingly deleterious to the trees.

Figs.—The second general crop of these will now be ripening, and consequently the atmosphere should be kept a little drier than usual, and the house more freely ventilated so as to improve the quality of the Figs. Trees swelling their fruits must be liberally fed and syringed, and scale and other vermin eradicated.

Melons.—Prevent over-luxuriance by means of kindly treatment and a little ventilation at night as well as during the day, in preference to stinting the supply of moisture and pinching severely. However, their growth must be regulated and held in check, and attention must be paid to the fertilisation of the blooms. To those whose fruits are swelling, give heavy applications of water, and occasionally some liquid manure.

Cucumbers.—The plants for winter fruiting should now be sown, and cuttings struck from present fruiters to succeed them. Worn-out plants may now be cut in rather severely, and the borders mulched and well watered, and the linings renewed; the plants soon make a fresh start and bear well for some time yet. Attend to the usual routine of thinning the leaves, shoots, and fruits whilst in a young state.

Hardy Fruit.

It is now time that all summer pruning and stopping of shoots should be finished, as there is now no danger of the trees making growth, to be in any way detrimental to the formation and full development of fruit-buds for next season. Any such work still to be done should be completed as soon as possible, after which the shoots should be neatly laid, or tied in, and the ripening fruit be exposed to the influence of sun and air, by having the foliage drawn on one side, or, if need be, removed altogether, but this should only be done when the leaves cover the fruit, and so hinder its colouring properly. Should the summer continue hot and dry, watering will be a serious item of garden labour, as it is from this date to the end of September that fruit trees require most water. If that should be scarce, mulch deeply with litter or Grass. Gather Apricots, Peaches, and Nectarines a day or two before they are intended to be used, and before the sun touches them in the morning; they will then keep for several days in a cool room, and be all the better for it; of course they should be laid on some soft substance, such as dry Moss or wadding. Early kinds of Pears, such as Citron des Carmes, Belle de Bruxelles, and Jargonelle, are now sufficiently ripe to gather; it is not well to allow them to fully ripen on the trees, as then the flavour is not nearly so good, and the fruit soon decays. Let all runners required for forcing and new plantations of Strawberries be taken off as early as possible, in order that the beds may be cleared of runners and bad foliage, after which slightly point over between the rows, and give a fresh mulching of rotten manure. Water freely all newly-planted beds, to get growth completed by the end of September. A nursery bed of runners should be kept on hand to make good any failure that may occur.

Kitchen Garden.

August, like March, is a month of sowing and transplanting. If the weather be dry, then the seeds require moisture; and in order to best ensure it, let the ground be deeply dug, levelled, and rolled, and sown with as much expedition as possible, so as to prevent it from parting with its moisture; a mat or some litter placed over it until the seeds begin to germinate will also be found useful in periods of drought. The hoe should be in constant use, and all weeds and vegetable refuse should be collected into a heap, where, by mixing it with lime and by means of frequent turnings, insect life, and also that of the seeds of weeds, may be destroyed and decomposition accelerated. Hoeing and surface-stirring should be rigorously persevered in, and slugs and insects should be kept in check by means of dressings of soot and lime. Never permit vegetables to run to seed, unless required for that purpose, and then they should have a place set apart for them. Manure well and trench every spare piece of ground, which if uncropped should be ridged. In dry weather abundantly water all kinds of crops that will be removed before winter, but to such as remain during that season water should be very judiciously applied, as too much induces soft growth liable to be destroyed by frost.

Endive and Lettuce.—Ground should now be prepared for the principal crop of Endive and autumn Lettuce; for these it ought to be well manured and in a moderately dry position. Do not overcrowd the plants, especially Endive. It is no uncommon practice to plant these so close that there is not room to step between the rows to tie them up; planted thus thickly, the hoe cannot be used amongst them to loosen the soil and keep down weeds. The rows of Endive should be 15 in. or 18 in. apart, according to the condition of the soil, giving the most room where the growth is likely to be strongest. Lettuce, especially where the small Cabbage varieties (such as Tom Thumb) are planted, need not have so much room. More Endive should now be sown. For general use the Green Curled is most esteemed, but where the Broad-leaved Batavian is liked a pinch of each should be put in. Do not sow the seeds too thickly; they are little liable to the attacks of birds or insects, and usually almost every seed vegetates. Previous sowings that are already up, if too thick, should be thinned out sufficiently to allow them room, or they get drawn

up so weakly as to be long in getting hold when planted out. Some Lettuce—Tom Thumb, Black-seeded Bath Cos, and likewise the hardy Hammersmith—should also be now sown; the last-named sort is not equal in quality to the Cos varieties, but in many places it will stand the winter where other kinds would fail.

Ridge Cucumbers and Vegetable Marrows must be plentifully supplied with water, or they cannot possibly keep on bearing. It should be given in quantity sufficient to reach as far as the roots extend.

Onions.—These are this season more than usually late, but in many cases very small and much affected with the maggot. As soon as they show signs of completing growth they should at once be pulled up, or they will commence to make fresh roots, which injures their keeping properties. They are all the better for being dried quickly. Where a moderate quantity only is grown that can be dealt with in this way, the old method of spreading them thinly on a slate or tile roof has the advantage that if much wet weather should follow immediately upon their being drawn they are not so liable to rot afresh as if laid on the bed to dry; or the simple plan may be followed of tying them in bunches of eight or ten immediately they are pulled and hanging them up on the outside walls of a building that has an overhanging eave sufficient to throw off the rains; the north side is the best for keeping them late in the spring, as there they have not the disposition to grow so early. Shallots, if not already taken up, should be at once removed to a dry place and kept there.

Box Edging that was not cut in the spring should be gone over now, for if the cutting be deferred until later in the autumn it often suffers through frost, whereas if the work be done now the danger of this is avoided.

Extracts from my Diary.

August 19.—Sowing Early White Naples, White Tripoli, and Giant Rocca Onions for spring and summer use. Putting in Santolina cuttings under hand-lights in sharp sandy soil in a shady situation. Earthing up Celery and Cardoons whilst the plants are perfectly dry. Putting a little fresh soil on the roots of newly-planted Cucumbers and Melons. Salting gravel walks in order to kill weeds. Watering all newly-planted trees and shrubs that are likely to suffer from drought; also Celery, Carrots, Turnips, and Radishes.

Aug. 20.—Planting Antirrhinums and Sweet Williams; also Lettuce and Endive in good rich soil. Potting Cinerarias; also small Dracenas for table decoration. Pruning and nailing Rose trees on walls. Heavily manuring and trenching a large piece of ground previously occupied by Raspberries in which to plant Strawberries. Removing all overgrown heads from Globe Artichokes to prevent them weakening the plants. Watering newly-made Asparagus beds with liquid manure; also Pines, Celery, Scarlet Runners, Beans, Lettuce, and Endive.

Aug. 21.—Sowing Walcheren, Early London, Large Asiatic, and Autumn Giant Cauliflowers on well-prepared borders for spring and summer use. Taking up sorts of Potatoes in the following order: Snowflake, Porter's Excelsior, Ashtop Flake, Scilly Red, King of the Potatoes, Hundredfold Flake, Yorkshire Hero, Breadfruit, Lady Paget, Perfection Kidney, Model, Rector of Woodstock, Fenn's Bountiful, Fenn's Early Market, Magnum Bonum, Blanchard, Favourite, and Red-skin Flourball. Watering Viole borders.

Aug. 22.—Sowing Red and White Turnip Radishes on moist soil. Putting in a batch of Pelargonium cuttings for border use. Sorting over Potatoes, and placing those intended for seed in shallow boxes. Making new gravel walks. Cleaning and weeding shrubbery and Ivy banks in the pleasure ground. Watering Pines with soot water; also the Peach house border.

Aug. 23.—Cleaning out Melon pit, turning and well watering the soil, and planting it with Osborn's Forcing French Beans. Pruning pyramid Apple and Pear trees. Nailing and tying Peach trees. Earthing up Celery and Leeks. Gathering Plums, Jargonelle Pears, and a few Tomatoes.

Aug. 24.—Potting Cyclamens. Planting Lettuce and Endive. Looking over Vines, and taking off laterals and any decayed berries. Stopping shoots of Melons and Cucumbers. Hoing surface soil between all growing crops. Cleaning and weeding gravel walks.—W. G. P., Dorset.

Balm of Gilead.—Dr. De Hass gives the following particulars as to this far-famed specific for all diseases: The name of Gilead was sometimes applied to all trans-Jordanic Palestine; properly, however, it only included the country east of the Jordan from the head of the Dead Sea to the foot of the Lake Genesareth, of which Mizpeh Gilead was the crowning point. It was here, along the Jordan and about Jericho, the balsam or balm once so highly prized was procured from an aromatic tree, supposed still to be found in this region, and known as Spina Christi, or tree from which the Saviour's Crown of Thorns was woven. This most precious gum was obtained by making an incision in the bark of the tree; it also oozed from the leaves, and sometimes hung in drops like honey from the branches. The tree, which originally was found in Palestine, was transported by Cleopatra, to whom the groves near Jericho were presented by Marc Antony. The shrub was afterwards taken to Arabia and grown in the neighbourhood of Mecca, whence the balsam is now exported to Europe and America, not as Balm from Gilead, but Balsam of Mecca. The gardens round Heliopolis and the "Fountain of the Snn," in Egypt, no longer produce this rare plant, and it has long since ceased to be an article of export from Gilead.

THE PEDIGREE OF THE WATERING-POT.

THE application of water to growing plants, in one form or another, would seem to be coeval with horticulture itself. The importance of plentiful supplies of water for this purpose is constantly brought before our notice in the oldest books we possess, in which there are numerous passages showing that water springs, dew, and rain were looked upon as the most valuable of earthly gifts; hence the frequent allusion to them in a metaphorical sense as types of the most precious of terrestrial and celestial blessings. The author of the book of Deuteronomy, whose style is singularly poetical, even for a Hebrew, gives us a charming picture of what he describes as a "good land of brooks, and of waters, and of fountains in the plains and the hills, of which deep rivers break out. A land of Wheat and Barley and Vineyard, wherein Fig trees and Pomegranates and Oliveyards grow: a land of oil and honey." It would be needless to multiply quotations, either from sacred or profane ancient authors, from all of whom we learn, over and over again, that the only way of supplying water to plants parched by the heat of the sun was from natural springs or artificial wells, the water being distributed over the soil by means of buckets or pitchers, of whose precise form we are ignorant. The ordinary vessels, great or small, which were used in the household were, no doubt, employed at first; but watering-pots, in the modern sense of the word, are a comparatively modern innovation. Old Adam Littleton, one of our earliest Anglo-Latin lexicographers, tells us that the Romans had a special word, "harpagium," which signifies watering-pot, as distinguished from "hydria," which meant an ordinary pitcher for holding water, and not for letting it out; but Alexander Aphrodisianus, a Greek writer who lived about the

Fig. 1.—Watering-pot of Fifteenth Century.

Fig. 2.—Watering-pot of Sixteenth Century.

end of the second century, was the first to use the Greek word from which it is derived. This seems to prove that the watering-pot proper, in our sense of the word, must have been unknown to the Greeks and Romans. In any case the first specimen of a real watering-pot with which we are acquainted apparently belongs to the thirteenth or fourteenth century. In case 117 of the British Archaeological collection in the British Museum there are three specimens of the earliest form of watering-pot, made of ordinary red earthenware, one of which is here figured (fig. 1). In shape they may be described as that of an elongated hemisphere, with a very narrow mouth, and a flat bottom pierced with a number of small holes, some of them being with handles and others without. The specimen shown in the figure is ornamented with horizontal white stripes, and is partly glazed. It will be seen from the description and figure that these vessels must, when used, have been plunged into water, lifted out with the thumb stopping the mouth, and carried to the required spot, where, on removing the thumb, the water was distributed over the plants through the holes in the bottom. At one time a contrivance in tin, constructed on similar principles, was used for watering shops and offices, and possibly may be so still in remote places. No doubt the "fleurs partie white and red," which the "faire Emelie," in Chaucer's "Knight's Tale," gathered "to make a votel gerlond for hire heede," were watered, perhaps by herself, with some such appliance. Towards the beginning of the fourteenth century, however, a genius arose who may well be called the Newton, the Bacon—in fact, the James Watt—of watering. Old Fuller, in his "Worthies," tells us that the world knows nothing of its greatest men, so the name of this daring innovator has not descended to posterity. It evidently

struck this great inventor that if the perforated portion of the watering-pot were transferred from the bottom to the side there would be no need to use the thumb as a temporary stopper; he therefore produced, no doubt after much brain cudgelling, a watering-pot of the shape shown in fig. 2, which is unquestionably the lineal ancestor of our present appliance for local irrigation. The watering-pot in the cut was found, along with a number of others, in Moorfields, where there seems to have been a manufactory of them, and is a comparatively modern specimen, for Home, in his "Year Book," tells us that he remembers, when a boy, having seen a feeble widow in an almshouse tottering with one of these earthen vessels and dribbling the water over the plants in her little garden. Strangely enough, they were closed at the top, evidently for some unknown reason, for it would have been less trouble to have left them open; they filled, therefore, through the same holes that let out the water. The connection between this rude earthenware contrivance and the ordinary modern watering-pot can be seen at a glance.

The watering-pot shown in fig. 1 is about 9 in. in height and 8 in. broad at its greatest diameter, with a flat bottom, and is pierced with twenty-nine holes. That figured in the second cut was found at St. Katherine's Docks, at a depth of 30 ft., and belongs to the fifteenth century. It is 10 in. high and 8 $\frac{3}{4}$ in. in diameter. The paste of which it is made is red with a yellow surface, and a faint and partial green glaze. Specimens like those engraved are extremely scarce, there being only about twenty of them in all England. As the direct progenitors of a familiar garden utensil this brief account may be interesting to both our professional and amateur readers.

C. W. QUIN.

ANSWERS TO CORRESPONDENTS.

Grubs and Pansies.—How can I kill grubs which are eating the roots of choice Pansies without, in so doing, causing injury to the plants? Is nicotine soap a remedy? [Remove the soil carefully from the plants with the fingers, and pick the grubs out by hand; then place some fresh soil round the plants in the place of that removed. Any mixture strong enough to kill the grubs would also injure the plants.—J. D.]

Preserving Rose Leaves.—What is the best way of preserving Rose leaves for keeping in a room for the sake of their perfume?—*Srascausa, Belfast.* [Pick as many Rose leaves as you can at one time; spread them upon a sheet of white paper in the shade, placed either on a gravel path or garden seat; turn them often, for the more rapidly they dry the better will be their perfume hereafter. The addition of some Sweet Woodruff greatly improves the scent.—P.]

Removing Carnations.—When can beds of Carnations which have been infested with Couch Grass be cleared of plants and trenched without injury to the plants lifted?—*W. B. H.* [The plants can be removed as soon as they have done flowering; if, however, it is intended to save seeds, wait till the seed pods ripe. If you intend to replant on the same ground, add rotten stable manure at the time of trenching, and, if possible, a layer of 3 in. of good loam on the surface before planting, meantime, laying the plants in a moist soil in a shady place.—J. D.]

Eradicating Bindweed.—In reply to "A. R. W." in last week's GARDEN (see p. 143), allow me to state that the least troublesome way of eradicating Bindweed is to crop the ground with subjects that will allow of the stems and leaves of the Bindweed that show above ground being removed every second Monday during the growing season. By perseverance in that system for a few years, the roots will cease to give much trouble.—*B.*

Scott's Favourite Lettuce (see p. 143).—The seed of this variety is black; therefore you have been supplied with the wrong sort. The true variety will stand the hottest and driest summers, and seldom "bolts" till too late in the season to ripen its seed.—*S.*

Allow us to state that Scott's Favourite Lettuce is black-seeded, and is identical with a well-known Continental variety.—*JAMES ASTRA & CO., High Holborn.*

Strawberries for Clayey Soils.—Could you inform me what kind of Strawberry is most likely to succeed in a clay soil in the north of England?—*H.* [The varieties of Strawberries most likely to succeed in the north of England under any conditions are Vicomtesse Hélicart de Thury (or Duc de Malakoff, as it is called in Lancashire), Underhill's Sir Harry, Auguste Nicaise, President, and Sir Charles Napier. Given one variety only, there is nothing to equal the Vicomtesse, next to which I would place Underhill's Sir Harry and Auguste Nicaise.—*W. H.*]

Light-coloured Evergreen Shrubs.—The best with which I am acquainted is the Japanese *Griselinia littoralis*, with very ornamental bright apple-green leaves, and of rapid growth and compact habit. *Berberis Beali* has very handsome light-coloured foliage, inclining to yellow. *Pittosporum Tobira* (bright green) and *P. Eugenioides* (very pale ashy-green) are quite hardy near the sea.—*SALMONICAPS.*

Of hardy yellowish-green foliaged plants there seems to be very few besides those mentioned at p. 143, and the green colour of all is very much modified by the soils in which they are cultivated. In a general way, the following are of the shade desired, viz., *Griselinia littoralis*, *Skimmia oblata*, *Viburnum Sieboldi*, *Choisya ternata*, and *Ceraea Laurocerasus rotundifolia* (or round-leaved Laurel). *Libocedrus chilensis* is also of this colour, but its foliage is not bold.—*GEO. STRA.*

Grapes Diseased through Non-fertilization.—Can you give me any information why my Lady Downes Grapes go off in the way in which you see them? They are grown in a house with Black Hamburgs and get the same treatment, yet I have lost half of the crop by the berries becoming discoloured as if scalded, and Muscats of Alexandria grown in another house go off in the same way, while Black Hamburgs do very well.—*F. J. B.* [The diseased berries have been imperfectly fertilised. If you cut them open you will find that they contain only two stoves, whilst good berries properly fertilised have four. Lady Downes and Muscats are more liable to such mishaps than other kinds.—*S.*]

Paris Daisy.—*Cheltenham.*—Its botanical name is *Chrysanthemum frutescens*; it is a vigorous, half-hardy plant, extensively grown about Paris in the summer time. It is readily propagated by means of cuttings, which may be wintered like those of ordinary or half-hardy plants.—*M.*

Names of Plants.—*Pool Court.*—*Catalpa bignonioides* (United States) and *Pyrethrum Balaamita* (Levant). *Manchester.*—1. *Potentilla ambigua* (Himalaya); 2. *P. alpestris* var. (Britain). The large white Everlasting so common in the chaplets sold in the shops is a species of *Helichrysum*. *C. Zichie.*—*Mirabilis Jalapa.*—*Killenaule.*—Apparently *Carex muricata variegata*, but a better specimen should have been sent. *G. M.*—1. The Magnolia Holly (*Ilex latifolia*). 2. *Pittosporum* species; impossible to say which without much fuller material.

Carnation Souvenir de la Malmaison.—A year or so since I bought a plant of this Carnation which was then in flower. After flowering, I took off six cuttings and struck them in small pots in a Cucumber frame. As soon as the pots were full of roots they were shifted into 4 $\frac{1}{2}$ -in. ones, and about October they were placed in the greenhouse. They are now plants from 18 in. to 24 in. high, strong and healthy, but they show no sign of flowering. What is the proper course to adopt? had they better be cut down, or allowed to remain as they are? If allowed to remain, will they flower during the winter or next spring?—*H. M.* [Do not cut them down; that would only retard their blooming. They will flower in winter or early in spring provided a little heat be given them. If kept in an ordinary greenhouse they will bloom in April or May. You had better shift the plants into 6-in. or 7-in. pots.—*J. D.*]

Scale in Greenhouses.—The plants in my greenhouse are infested with scale. Is there any means of getting rid of it by fumigation or syringing, the foliage being too dense for cleaning each leaf?—*F. T. B.* [It is not stated whether it is brown or white scale that infests the plants. The former may be readily destroyed by perseverance in washing with Stevenson's Abyssinian Mixture, the most effectual insecticide with which I have ever met and the most harmless to the plants. Dip or syringe them, so as to wet every part, in a solution consisting of 5 oz. or 6 oz. to the gallon dissolved in boiling water, repeating the dressing three or four times in the course of two months. No better time than September and October can be selected for the purpose, when the growth is almost matured. White scale is difficult to kill, and it will take a stronger dressing to destroy it than the leaves of most plants will bear. Anything that can be cut back close in the winter, so as to divest the plants of leaves, and allow the wood to be washed with the mixture at 8 oz. to the gallon, can in this way be cleansed. It must not be used at more than 5 oz. to the gallon in the autumn for Camellias when the buds are set, or they may fall off.—*T. BAINES.*]

Flowering Stephanotis in Pots.—How can I flower this in pots? I have very fine plants, but they do not flower although they are luxuriant in growth. Also, are there two kinds of Stephanotis?—*G.* [Had the exact conditions been stated under which the plants of Stephanotis were grown as to heat, light, moisture, and how trained, all of which have a good deal to do with the flowering of this plant, it would have been much easier to prescribe a remedy for its not blooming. It succeeds best grown in a moderate stove temperature, say 70° to 80° in the daytime, and from 60° to 65° by night during the growing season, with from 50° to 55° night and 5° or 10° warmer in the day in winter. If required to be grown permanently on the roof of the house it should be trained to wires near the glass on the sunny side of the house; if to be trained on a trellis when in flower, strings may be used in place of wires, keeping it on these, except during the time of blooming. Shade no more than is necessary to prevent scorching, and none at all if this does not occur. Water moderately during the growing season and syringe overhead. Keep the plant much drier in winter, and do not prune, except immediately after flowering. Do not ever over-pot the plant; keep clear from insects, and I have no doubt it will flower. I have not found any difference as regards varieties, although some growers maintain there is.—*T. BAINES.*]

Weeds on Lawns.—How can I get rid of Plantains from a lawn? I have tried extracting them with a Plantain-fork, but that, I found, left most of the roots behind. I then tried loosening the turf with a Potato-fork and then using the Plantain-fork. In this way I got out most of the roots; but still fragments remained, and wherever one was taken up, half-a-dozen appeared in a few weeks. I should also be glad to know, in connection with this subject, whether any one has observed the effect of using a mowing machine without the Grass box. I have a strong suspicion that it encourages

the spread of Plantains. The seed of that pest comes to maturity very rapidly, and I cannot help fancying that scattering the heads on the turf causes it to seed itself. At any rate, the Plantains on my lawn appear to have increased very much since I adopted this plan of mowing, and, the effect of my attempts to proot them being as stated above, the lawn will soon be nothing but Plantains, unless some kind friend can tell me how to get rid of them.—A. M. A. [A drop of sulphuric acid applied with a pointed stick to the crown of each will most effectually rid you of Plantains by killing every particle of root. We have no experience of the latter part of your query, but think it most improbable, *i.e.*, if the lawn were mown weekly, as every lawn should be in early spring and summer.—W. W. H.]

Winter Flowers for Cutting.—"G. S. M." (see p. 143) will find the following plants suitable for his purpose, and they are neither difficult to grow nor expensive: *Calla* (*Richardia*) *æthiopica*, double white and red *Primulas*, *Eupatorium odoratissimum*, *Abutilon Boodle de Neige*. The temperature named would be too hot for *Camellias*, or they are excellent winter-flowering plants, but it would suit many of the *Begonias*, such as *insignis* and *marginata*. *Chrysanthemums*, of course, should be grown in quantity, and these, as well as most of the other plants named, would do better in the open air in summer, which would keep the growth compact, and secure its proper maturation. Trees *Carnations*, *Daphnæ rubra* and *alba*, would be useful. *Epiphyllums*, again, would flower beautifully in winter, and when the plants have attained to some size, cutting them moderately would benefit them, and keep them properly in bounds. *Bouvardias*, *Cinerarias*, several of the winter-flowering *Salvias*, such as *splendens* and *gemmeriflora*, *Eucharis amsonica*, might be so managed as to flower in such a house in winter by placing the pots on or near the fire to start up the spikes. On the shelves near the glass a grand show might be made of zonal *Pelargoniums* alone, and a bit or two of scarlet *Geraniums* in a vase of flowers in winter, seems to impart a warmth of colouring quite unequalled by any other flower. Of course to bloom them successfully they must have special preparation. Strong cuttings of the right kinds should be put into single pots in spring. After the majority of the bedding plants are out of the way will do. They must be shifted on as they require it, and have all flower-buds pinched off. As soon as they show themselves, and after the middle of May, they should be placed on a coal-ash bed in the open air. In this way dwarf, sturdy plants will be produced that will not disappoint. The long, slender spray of *Thyracanthus rutilans*, falling over the sides of a vase, has a charming effect, and it is an easy plant to grow, and never fails to flower well. If a plant or two of *Tropæolum Lobbianum* could be trained up the rafters they would supply many bright and useful flowers during the dull season, as well as drooping sprays to hang over the edges of vases, and the flowers last a long time in winter. An almost endless variety of names might be added to this list, but I will now only mention two or three hardy shrubs, *viz.*, *Deutzia gracilis*, *Andromeda floribunda*, *Prunus triloba*, and *Spiræa prunifolia* fl. pl. Of course *Spiræa japonica* is quite indispensable. Strong crowns potted in autumn would be in flower in such a house as that named by Christmas. Your correspondent writes from a district where the *Laurustinus* does not flower well in winter in the open air. He certainly ought to have a few plants of it in pots to be introduced to the greenhouse just before the cold weather sets in. The flowers are exceedingly beautiful, and scarcely anything will give so little trouble for the return which it gives in pure white flowers. Something, too, ought to be done with bulbs. Roman *Hycinths* might be had in bloom early in autumn, to be followed by other bulbs and Lily of the Valley. In the open air, where a little shelter could be given if required, it would be desirable to have a good bed of Christmas Roses; indeed, these alone, and a good batch of *Callas*, would, for a long time in the depth of winter, yield a supply of flowers that would be most effective in large vases when set off with the necessary foliage.—E. HOBDAY.

The following plants will suit "G. S. M.'s" purpose, *viz.*, the different varieties of *Cyclamen persicum*, *Eupatorium riparium*, *Bouvardia jasminoides*, *Vreelardi*, and *longiflora*; Trees *Carnations*, particularly of whites—*La Belle*, the *Bride*, *Lady Blanche*, and *Queen of the Whites*; of scarlets—*Dragon*, *Covent Garden Scarlet*, *Boule de Feu*, and *Vulcan*; white *Geraniums* of the *Madame Vancher* type and scarlets of the *Vesuvius* type. The following Ivy-leaved kinds are also exceedingly useful, *viz.*, *Gem*, *Nemesis*, *Bridal Wreath*, *Progress*, and *Miss Blanche*. *Tropæolum Cooperi*, planted now and trained up the rafters, will produce abundance of bloom all winter. Shelves near the glass should be occupied with *Primula sinensis fimbriata*, *rubra* and *alba*, and the double-flowered types. If desirable, a few *Camellias*, early-flowering *Azaleas*, and *Chrysanthemums* might be added; also *Narcissus Queen of the Netherlands* and *Primula nivalis*. The latter is hardy and flowers early in spring, but when grown in pots and put in a greenhouse it

flowers much earlier and produces exquisite heads of bloom.—J. OLLERBEAD.

Alphabetical Hand-book for England and Wales.*—This is the handiest, readiest, and, in many respects, the best book of reference for tourists and business people visiting any part of England and Wales we have yet seen. The information is not only well selected and condensed, without bearing signs of mutilation or suppression, but in its place this hand-book seems better conceived than other books of a similar kind. One instance will show its merits in this respect. A visitor to Bedford would find in most hand-books information upon Bedford alone; here, however, he finds added to that the description of Elstow, Clapham, Bromham, Sharnbrook, and other places of interest within easy reach of Bedford, but of which, if the book had been arranged in the ordinary way of alphabetical hand-books, the visitor would have had no trace. The information as to excursions worth making from all the centres of interest is well conveyed, and the editor tells us that they are principally the results of his own personal experience. In a work of this kind it is of course impossible to be perfect in a first edition, but apparently the faults are few. More care in a few small details might, however, have been shown. For instance, we are told that Danstable has a station "on the Great Northern Railway, 36½ miles from King's Cross, *via* Hatfield and Luton," and another "on the London and North-Western Railway, 47½ miles from London." Of course the latter should read, 47½ miles from Easton, *via* Loughton. The book is excellently printed, and a good map is appended.—T. G. A.

The first volume of the continuation of De Candolle's "Prodromus" has just been issued. It comprises monographs of three Orders. The official title of the work is "*Monographiæ Phanerogamarum, Prodromi nunc continuatio, nunc revisio*," a title that sufficiently indicates the nature and objects of the volume.

DR. BALFOUR has a very elaborate paper on the genus *Pandanus* in the last number of the "Journal of the Linnean Society" (July 31).

Grapes in Covent Garden.—However highly the Black Hamburgh may be esteemed in private gardens, it is not a favourite in Covent Garden Market when placed in competition with such kinds as Gros Colman or Madresfield Court. The former kind, owing to its large berries and fine appearance, realises more money at this season of the year. Though generally considered a late Grape, market gardeners manage to have it ready for market before the middle of August, *i.e.*, during what is termed the London season, for after that time the demand greatly decreases and prices diminish. One of the most extensive growers of Grapes near London, who has some fifteen or twenty large Vineries, has at the present time scarcely a bunch of Grapes left, it having been found that late Grapes do not pay nearly so well, all things considered, as those that are sent to market from June to August.

Glasgow Botanic Gardens.—We are informed that the *Fouquieria gigantea*, a plant closely allied to the genus *Agave* (*Aloe americana*) is at present sending up a bloom-scape in the Kibble Conservatory, Royal Botanic Gardens, Glasgow. The plant in question is believed to have been in the garden collection since its formation in 1817, and, judging from the height of its aërescent stem, is likely even at that time to have been of considerable age. Indeed, the popular fable of the plant, which blooms once in 100 years, is likely to be fully realised in this instance. The growth of the spike is extremely rapid, and attains a height of 20 ft. to 30 ft. in its native country (South America), producing numerous alternate branches, from which hang the white depending flowers on short stalks.—"Glasgow News."

Porous v. Non-porous Vases.—I saw at Woodlawn, Castlewellan, Co. Down, two fine plants of *Veronica Andersoni variegata* growing in iron vases, in which they have been more than two years. They were growing and flowering in the most vigorous and profuse manner, and seemed quite at home.—T. SMITH.

The Swamp Lily (*Lilium spurbum*).—This stately American plant is now in fine flower about London. It enjoys a moist, deep, peaty or sandy soil. A few years ago this species was rarely to be seen in cultivation.—V.

OBITUARY.

ROBERT SIM died at Sidcup Hill, Kent, on the 3rd inst., in his eighty-seventh year. He was an ardent lover of Ferns and their varieties, both British and foreign, and cultivated a large collection of them in his nursery at Footscray.

"This is an art
Which does mend Nature: change it rather: but
THE ART ITSELF IS NATURE."—*Shakespeare.*

AUTUMN TREATMENT OF APRICOTS AND PEACHES.

Now that autumn is approaching, a few notes by way of reminders as to what ought to be done in order to obtain a good supply of fruit next season may not be unacceptable. The best men amongst us are far too apt to neglect fruit trees when once the crop has been gathered. As regards Apricots, our trees have borne a very fine crop of fruit, which is now over with the exception of *Pêche Tardif*, a good late variety. The trees are on south and west walls, and do equally well on both aspects, having never failed to produce a crop for these past eight years, and this we attribute in no small measure to the autumn treatment the trees have had, which is, that they are never allowed to want water. If the rainfall is insufficient, we set to work and water artificially. Insects of any kind are not allowed a lodgment on them. Red spider as soon as perceived is removed by means of a shower bath, vigorously administered. Soft brown scale has once or twice bothered us, but this we settled effectually last winter, by painting the whole of the trees with a solution of soft soap and Tobacco water, made adhesive with cow manure. Mildew has never troubled us, doubtless because the trees have had abundance of water, and every branch and leaf have been afforded breathing space. Some of the trees are now manifesting a tendency to make fresh growth, which growth we shall endeavour to repress by occasionally pinching out the points of the new shoots, for at this late season all the functions of the tree should be concentrated on the thorough maturation of the wood and plumping up of the fruit buds. As soon as the foliage turns yellow and begins to fall, any trees that have to be moved or replanted will be done at once, for if done thus early the trees will next season fruit as well as if they had not been moved. Our soil is a light loam, which requires to be made very firm and to be liberally manured, which is always done as soon as the leaves are off by removing any loose, liert soil, and replacing it with maiden loam, some $\frac{1}{2}$ -in. bones, and afterwards mulching with stable manure. Of course, in heavy soils, drains are of the first importance, and, to ensure their efficiency, they should be examined annually. Peaches have a great deal in common with Apricots—with this exception, that they more readily fall a prey to parasites and insects, and greater vigilance is, therefore, required to keep such pests at bay. At the beginning of the present season our trees, through press of work, were allowed to get badly infested with green and black fly, but a couple of good dressings of soap-suds, to which was added a quantity of Tobacco water, cleansed them thoroughly and apparently promoted more vigorous growth than usual. Unfortunately, they are now affected with red spider, which, as soon as the fruit is off, will be dislodged in the same manner as that named for Apricots. I acknowledge being beaten by this insect when once it gets a firm footing on Peaches, having tried all means likely and unlikely to effect a riddance, and nothing I have ever tried has proved so effectual as liberal waterings of root and branch. All the new shoots for next season's fruiting are now laid in close to the wall, and some of them are now making soft, watery side-laterals; these we shall now keep pinched with the same object as that given for Apricots. We gathered ripe fruit of Rivers' Large Early Mignonne on the 8th of the present month, first-class both as regards size and quality. *Violette Hâtive* and *Royal George* will not be ripe till the end of the month, thus showing what a valuable kind this is; of course, *Early Louise* and *Early Beatrice* are much earlier, but, compared with *Large Early Mignonne*, they sink into insignificance, being too small and often of indifferent quality. When once the fruit is off, Peaches soon begin to shed their foliage; then is the time to commence lifting such as require that

operation. Moved with care, we have seen as fine fruit the following season from trees planted out at the end of September as from those thoroughly established. Notes of all trees to be planted, replaced, or renovated, should now be made, and soil prepared; also plans of drains and drainage materials should be got in readiness, in order that there may be no unnecessary delay when the time arrives; and, finally, if no other holiday comes in the way, take a trip to one of the nurseries and select the trees required. W. W. H.

Osborn's Prolific Fig.—Small plants of this new Fig are now bearing ripe fruit in Messrs. Osborn's nursery, Fulham. It is a remarkably free-fruited kind, even small plants bearing several good-sized fruits. In appearance the fruit resembles that of the *White Marseilles*, but the plant is more productive. Additions to our gardens in the way of new Figs are most welcome, as the Fig, though the most luscious of all fruits, is, to some extent, neglected.—S.

Summer-pruning Currants.—This, although a good practice if done judiciously, is liable to do more harm than good if carried to excess. I recently observed some bushes pruned in as closely as they ordinarily are at Christmas. The effect of thus cutting off nearly all the new growth is anything but beneficial to the well-being of the bush. I would strongly recommend the stopping the shoots early on trees trained to walls, as, if left too long, the lower leaves drop off, and without good foliage the fruit never keeps well. But on open bushes merely stopping the strongest leading shoots is all that is necessary, and this only when the growth is luxuriant.—J. G.

Reported Appearance of the Phylloxera in the Vineyards of Greece.—The *Phylloxera vastatrix*, which has done so much damage to the Vines of France, Italy, and other wine-growing countries, does not appear as yet to have been introduced amongst the Vines of Greece and the adjacent islands. A short time ago it was rumoured that this formidable pest had made its appearance in several Vineyards in the neighbourhood of Corinth, Misseolonghi, and Patras. I may remind your readers that it is from these districts that the chief supply of Currants for their Christmas puddings and mince pies are obtained. The Hellenic Government, with praiseworthy promptitude, immediately despatched a commission of experts to investigate the matter on the spot. The outcome of their labours has been that they have certified that although a few of the Vines amongst the hundreds of thousands growing in these localities have withered away, the evil has not been caused by the *Phylloxera*.—X. LANDERER, *Athens*.

Gathering Peaches.—The Peach, more than any other fruit, requires careful handling when plucking it from the tree, as the least bruise leaves a dark speck on its tender skin, that rapidly spreads. Like any other operation that requires delicacy of touch, some experience is necessary before one can gather Peaches rapidly without damaging them. Grasp the fruit gently but firmly, so that the slight force used is pretty equally distributed, and brought to bear at the back of the fruit, pressing it outward from the stalk. If the fruit be ripe enough for gathering, a very slight pressure will detach it from the stalk; and if the eye and hand act together, there will be no difficulty in hitting upon those fruits only which are fit to gather, and which if left much longer would fall and be bruised. Even where precautions have been taken by covering the border deeply with soft litter, or by suspending nets to catch the falling fruits, it is better to look over the trees daily, and gather all that part readily from the stalk, as those fruits that fall from the trees through being dead ripe will not keep so well as those that have undergone the finishing process gradually in a cool airy room. The flavour of Peaches under glass is often deteriorated by having too much water given in the later stages of their ripening, or by deficient ventilation. Peaches ripening now in unheated houses can scarcely have too much fresh air, either by night or by day, unless during severe storms of rain or wind.—E. HOBDAY.

Early Peaches.—We send by mail a couple of specimens of the *Alexander Peach*, rather over-ripe. The Amsdens were all disposed of earlier. These two Peaches are so much alike in size, colour, season and quality, that we cannot separate them. *Beatrice* is ten days or two weeks behind; we send one to show you, as all stood together and had equal chance. These are from indoors, but after the fruit was set, the glass was off, so that they do not ripen much sooner than in a good place outside.—ELLWANGER & BARRY, *Rochester, N. Y.* [These specimens of the *Alexander Peach* came in good condition—beautiful in appearance and excellent in quality. They measured over 2 in. in diameter, and, growing in a house, were obviously several days earlier than they could be in open ground, as the specimens on our trees in a warm exposure are still green and not quite so large as the above-mentioned. The *Beatrice* was hard and green, with a full red cheek in process of development, and about one-third or one-fourth the bulk of the *Alexander*.—"Country Gentleman."]

EXHIBITION CARNATIONS AND PICOTEEES.

IN saying a few words in reply to Mr. Douglas on this subject, I shall try not to miss any point in his argument, as I find it is rather common in discussions of this kind to glide by the strong and central points of your adversary, and to dally with him on minor ones, or to beg the question by asserting that he cannot know anything about it. It is by no means "evident that the writers do not grow Carnations themselves," as he asserts; but this surely has nothing to do with the question! As to their knowledge of the way they are prepared for exhibition, it is scarcely necessary to say that those who doubt the wisdom of the artificial way of preparing them for show have no desire to master the details of an art the result of which they deplore. Whatever the cause of the cardboard being placed around the flower, the effect is, from any but a technical point of view, deplorable. As to the varied beauty of the flower being destroyed, that, after all, is a case of the florist's taste against that of the artist or the lover of Nature. I admire florists' Carnations and Picotees, but I admire them more still when the centre is irregular and when "some of the petals are not slightly moved aside, in order to show the varied beauty of those that are hid underneath." For me, and I fancy for numbers of others, the beauty suggested by a flower or other object is as delightful as that which is shown. This, indeed, is a mere truism of art, and ought to be known and recognised by all those who have Rosebuds opening about them. I am barbarous enough to like "the flowers with the petals heaped together, as it were, in segments." As to the cards, it is interesting to know that some people like them, and perhaps they may have some value in setting off the formal flower on the flat, but to most people they are wholly ridiculous when seen around flowers on growing plants. It will probably do good to find so skilful an exhibitor as Mr. Douglas objecting to those long and ugly lines of Boxes which do so much to steal the beauty of many of our finest flowers. Groups and edgings of green plants, as he suggests, would be for the better, but much will also depend on the way in which the individual flowers are arranged. Let us follow Mr. Douglas for an instant in his reference to a picture-gallery. That of all places would be the least likely to justify what is done by the florist. The artist is, in fact, the opposite pole, so to speak. He delights in irregularity, in change, in play of light and shade, in the infinite variety of surface and of form found in most natural objects. The true artist, instead of flattening out, or making an object formal, cannot even be got to draw or to look at anything which has these characteristics. The argument with which Mr. Douglas finishes, that the more one knows of any subject the more one enjoys it, is no doubt true of many things, some of them far from being artistic. Nobody can for a moment doubt that those old gentlemen who played dominoes at the same table every night for twenty years or so must know a good deal about the subject and find much delight in it, but surely we are allowed to have our own opinion of this "pastime" without making a profound study of the game! If this be not granted to us, then the prisoner may dispute the right of the judge to deal with him on account of his lordship's want of knowledge of his speciality in crime. In the case of these flowers, they are exhibited, it is fair to suppose, for the admiration and instruction of the public, and, therefore, even those of the public who do not grow Carnations have a perfect right to express the impressions made upon them by the exhibition. For my own part, I am, unlike many of the public, somewhat acquainted with Pinks and Carnations both in their native homes and in gardens, and I can only repeat that the present mode of showing them prevents the public from seeing much of the beauty that they naturally possess. I take up the thing wholly in the interest of the flowers and of those who grow them, and mainly to say that if we want Pinks and Carnations to take anything like their due place in the gardens of those who now neglect them, we should show them in some other and more natural and artistic ways than those in which they have been shown in London recently. Those who know them best could suggest what is best to be done, and, we suppose, would not object to well-grown plants of certain varieties or races being shown in pots, the stakes to be as inconspicuous as possible, and of course with

flowers and buds in all stages and without "collars." On the other hand, certain races could be shown cut in vases of such simple and artistic design as has not been uncommon of late in certain houses in London. In this last case, at least, we should have something that everybody would be charmed with and that an artist would draw. That any artist respecting himself (an artist, he it understood, and not a mere drawer of diagrams, and of the coloured falsehoods which frequently appear as illustrations of florists' flowers—as, for example, Rose Beauty of Glazenwood) would draw an arrangement is, it may be considered, a proof of its merit, and I think it would be not only possible but easy to so arrange these Carnations and Picotees at flower shows that an artist would be charmed to draw a vase of flowers to make a little picture of it; and this might be done without prejudice to the florist's way, as he might have his table apart and all that he considers necessary. His danger is that he prevents the public seeing all the charms that are in these flowers, owing to showing them, even at national and international shows, only in one formal way, which is all very well if he only desires his favourites to be grown or seen by those who take his point of view; but we should like to see those delightful northern flowers, more precious for our English gardens than any tropical plants, grown ten times as much as they are at present, and we should like to see a show of them attended by the general public as well as by specialists. But even from the purely technical point of view we may ask again, Why, after so much effort and so much talk as to what has been done, are you not able to produce flowers that answer your ideal without the aid of a variety of instruments? Mr. Douglas says that some varieties come up to the ideal without the aid of the instruments or the knowledge to use them. Is it fair, then, to put what we may call manipulated flowers in competition with those that come up to the ideal without artificial assistance? For the rest we shall, though we desire to see the plants shown in a variety of ways, and, above all, in ways not offensive to the artist or general lover of flowers, be pleased to print anything florists may have to say on the matter, always excepting those general charges of ignorance, which have long disappeared from much of our best writings, and only remain to disfigure horticultural journals. If any correspondent of ours does show that he is not acquainted with the subject, then the florist has him at a great disadvantage, and can show by facts and reasoning his own superior knowledge without condescending to assert that any one is unfitted to express an opinion as to a plant, which, before "bedding out," had quite done its work, was grown in every bit of ground to which the name of garden was given. W. R.

— Notwithstanding what Mr. Douglas has said (p. 145) in favour of "dressing" Carnations and Picotees, I still maintain that the practice is a vicious one. They should be shown as they are grown, as Roses are, and not as manipulated by an expert. The pulling out of petals and arranging the remainder, not as Nature placed them, but as the operator thinks Nature ought to have placed them, is an outrageous violation of good taste. Of cards or paper backs I will, at present, say nothing, but if they were abolished, would the flowers suffer? Mr. Douglas's metaphor of the picture gallery is so forcible, that I almost hesitate to blunt its point. It means that I am the "ignorant critic," and he the painter whose works bear the "stamp of genius."—A. D.

The Golden Japanese Box.—This at present is the brightest golden plant in the grounds here. Quantities of it, from 8 in. to 1 ft. in height, grouped together, look like a mass of burnished gold. Unfortunately, this colour is only developed in such young plants, or in old ones that are regularly clipped or pruned; the latter, when allowed to grow at will, are but sparingly variegated. It is of moderate growth, which adds to its value as an edging plant, if, indeed, this colour can be considered suitable in edging plants. It might not be in good taste against a reddish-brown gravel walk, but this plant makes an excellent edging to ashed or asphalted walks. Besides, I have often thought that this Box, retaining, as it does, a large proportion of its brightness and beauty throughout the winter, when there is such a paucity of colour, might be effectively used as a permanent bedding plant.—GEORGE SYME, *Elvaston Nurseries, Borrowash.*

NOTES OF THE WEEK.

Horticulture at the French Exhibition.—We have never witnessed anything in the way of horticulture more remarkable than the display of their products made at this Exhibition by the horticulturists of France. It is impossible to give an idea in writing of the confusion that reigned around these holdings in winter and spring, and yet at present there is the most perfect order and keeping, and whole gardens of evergreen and other shrubs, fruit trees, flower gardens, collections of forest and ornamental trees, and numerous fresh lawns, dotted with subjects of the greatest interest to all who care for gardens or trees. All this is the more remarkable when we consider the state in which many of the best nursery gardens about Paris were a few years ago. There is one fine shrubbery of evergreens and Conifera, in the grounds of the Trocadero, that comes from a nursery south of Paris. We visited that nursery about the 20th day of March, 1871, and there was not one tree or shrub in its whole extent that was not cut down to the ground by the soldiers who had occupied the place. The rooms in the houses were heaped with rubbish, and neither the owner nor any of his men had returned at the time, but now he sends specimens to the Exhibition, such as the Waterers might send to one in England! It is wholly impossible to give any idea of the wealth of horticultural material at the Exhibition. The enormous and confusing mass of buildings is everywhere surrounded and separated by plantations more or less interesting, and even the Fig and Asparagus plantations of Argenteuil are represented by small plantations, and many of the trained trees bear fruit, though only transplanted here in March and April. It is to be regretted that, owing to some mistake or omission in entering, or probably owing to absence of home organisation, which might have helped us to act together, and in good time, English horticulture is but little represented at the Exhibition. This is certainly an oversight, as it is seldom such an opportunity occurs of bringing our productions before the eyes of Europe and the world, for no other city attracts so many enlightened visitors from all parts of Europe, and, indeed, from all parts of the world, as Paris on an occasion like this.

American Aloe in Flower.—I have in my garden an Aloe (so-called)—that is, an *Agave americana*—that is now in full bud; a beautiful plant, 20 ft. 4 in. high, with thirty-six blooming branches, and, I suppose, nearly or quite 3000 buds upon them, and apparently just about to burst into full bloom, but for the last ten days it has made but little progress, and there are some fears as to whether the buds will really fully expand. I have known the plant forty-six years, and my impression is that forty-six years ago it was forty to fifty years old. It has been taken much care of, and has always been vigorous and healthy. The full height above the leaves of last year was made in little more than two months.—BURWOOD GODLEE, *Leighside, Lewes.*

Heckfield Place Gardens.—It may interest some to know that these gardens are to be thrown open to the public from September 2 to 7. They have a high reputation for the excellence of their carpet bedding; also for the good examples of Grapes and other fruits, as well as vegetables, which they contain, and, not least, for their many lovely natural beauties. The nearest railway stations are Winchfield, Reading, and Wokingham, from either of which the drive to Heckfield is over a delightful stretch of country. Tickets of admission may be had on application to Mr. Wildsmith, The Gardens, Heckfield Place, Winchfield.

Single Dahlias.—*Dahlia glabra* is blooming freely in the Botanical Gardens, Birmingham, and for those desirous of obtaining plants from which they can cut freely, I think it worth while mentioning. The flowers are lilac and the plant is dwarf in habit. I would also mention as a companion *D. coccinea*, a rather taller species with bright scarlet flowers, which are also produced in profusion.—J. TREVOR.

The Flowering Rush.—This very beautiful water plant is now to be seen in full beauty, growing naturally, in or on the banks of streams and small rivers where the current is not too rapid and the bottom of a somewhat holding nature. It should form a feature in all pieces of natural or artificial water, into which it is easily introduced. It flourishes best rather away from the margin and in the full sun, in which situation its distinct character is best displayed.—J. CORNHILL.

Segrez.—The members of the Botanical and Horticultural Congress, recently assembled in Paris, were entertained last Sunday by M. Lavallée, at his country seat at Segrez, where he has collected and planted what is probably the fullest collection of trees and shrubs that has ever been got together in one collection, there being between 4000 and 5000 species of trees and shrubs planted in the open

sir. With a great number of visitors from all parts of Europe and America in the grounds, many of them old friends, and all of them delighted and enthusiastic spectators, it was not possible to give that attention to the trees which so extensive a collection demanded, but we hope to have at another time an opportunity of examining in some detail and saying something in THE GARDEN concerning this unique collection. It only remains for us to say now that M. Lavallée's many visitors were charmed with Segrez, and carried away agreeable souvenirs of the courtesy of its owner, of his hospitality, and of a day most profitably and pleasantly spent.

Illuminations and Trees.—Among the various attractions provided for his guests by M. Lavallée was that of illuminating his grounds with various coloured lights. The effect of these on the numerous lawns round the house, as they showed the different forms of the trees in different colours, was very charming.

Alisma sinensis.—This is a fine tall water plant with large white, but not numerous, flowers. It grows about 4 ft. high, and is a graceful object for the water side. It is now in bloom in M. Lavallée's collection at Segrez.

Bignonia erecta.—This is a very handsome kind, near the well-known *Bignonia grandiflora*, so handsome an ornament on walls in some districts, and very often grown in France. The present kind forms a handsome and graceful bush, with fine leaves and every shoot tipped with fine flowers.

Polygonum Sachalinense.—This enormous species is now in flower in M. Lavallée's collection, and is not devoid of beauty, the blooms somewhat resembling those of the better known *P. cuspidatum*, produced, however, in a more open manner. The effect indeed of this enormous Knotweed, with its large flowers, great arching shoots, and fine leaves, is very singular and fine.

Clethra paniculata.—This is a very interesting, white-flowered, sweet-scented bush, about 3 ft. high, now flowering freely in M. Lavallée's collection at Segrez, where it grows freely in peat soil.

New Begonia.—One would almost imagine, from the great variety of Begonias shown at South Kensington the other day, that any hope of gaining anything distinct was almost impossible. In looking over a stock of seedlings the other day in Messrs. Veitch's nursery, however, we noticed one with very large rose-magenta flowers with deeply serrated petals. From a florist's point of view they may not be considered any improvement on existing kinds, but they nevertheless are quite as effective as those with round formal petals.

Lilium auratum var. Emperor.—In a bed of imported Lilies of the auratum type we have found a very singular variety, which we have named Emperor, and which we also flowered in 1855. It is remarkable for the deep purplish-crimson tint of a broad streak which runs from the tips of the petals to their base, forcibly contrasting with the vivid deep yellow, narrow, central band, which in continued more than half-way up the petals. There are in this variety few or no spots. It resembles *rubro-vittatum*, but differs from it in the absence of spots, the intensely deep purple tint, and in the presence of the yellow streak, which is absent, or almost entirely so, in *rubro-vittatum*. The petals are somewhat narrower than those of the ordinary *L. auratum*.—A. WALLACE.

Nerine cornusca major.—Good examples of this attractive *Amaryllid* may now be found in several of the London nurseries. Its flower-trusses are large, and also the individual blossoms, which are cinnabar-scarlet. The greatest drawback belonging to it is that it flowers while the plants are leafless, but the objection is easily overcome by introducing the pots containing them among Ferns or similar handsome-leaved plants. Its culture is by no means difficult; all that is required is merely giving the bulb a shift as soon as they have flowered, keeping them in a pit or greenhouse, and supplying them well with water whilst the leaves are growing. When they begin to die down water should be gradually withheld until every leaf has died off, when they may be placed under a greenhouse stage or in a room until the following summer. As soon as the flower-epikes show themselves liquid manure will greatly assist their development and add to the size and colour of the flowers.

Arbutus Menziesi and procera.—Mr. George Syme speaks (p. 154) of *Arbutus Menziesi* and *A. procera* as if they were one and the same species, an opinion in which I venture to think he is mistaken, as the handsome *Arbutus* sent me about two years ago by Messrs. Osborn, of the Fulham Nurseries, is quite distinct and different from what I have long grown as and believe to be the true *Arbutus procera*. The leaf of the first named is distinctly fibrillated and longer and more pointed than that of the latter, the edge of which is quite smooth.—W. E. GUMBLETON, *Belgrove, Queenstown.*

Cool Orchids from Columbia.—A portion of Mr. Horsman's Orchids, to which we lately alluded (p. 115), was sold the other day at Stevens', and realised good prices—452 lots fetched £355. We learn that the last portion of his plants will be offered next Thursday.

NOTES FROM KEW.

Hardy Shrubs.—One of the most charming of flowering shrubs, and the most handsome one at present in flower, is *Eccalonia floribunda*; it has neat, glossy, dark green leaves, very finely toothed, and huge panicles of large, pure white blossoms; add to this that it is an extremely free-flowering kind, and enough has been said to prove its value as a hardy decorative plant. *Dioscorea japonica* makes an elegant covering for arbours, &c., in sunny spots; it has dark green, heart-shaped leaves, somewhat resembling those of the Black Bryony of our English hedgerows, and short spikes of small, greenish-white flowers, which are gracefully arranged on long, leafy branchlets. Although possessing no colour or scent to recommend it, this will be admired by all to whom grace of habit and beauty of form are as important as colour. *Ceanothus latifolius* has large leaves and bears good-sized panicles of blue flowers. C. Leon Simon has flat-topped panicles of blossoms rather paler in colour.

Hardy Herbaceous Plants.—Some of the American Eryngiums are so widely different from the Sea Holly of our British coast, and also from all the Old World kinds, that no one unacquainted with them and seeing them out of flower would ever suspect them to have anything in common. Few hardy plants give such a sub-tropical aspect to the garden, and none with which we are acquainted resemble them; they furnish us with a style of beauty all their own, and, on this account, are especially valuable. Those mentioned below are distinct and striking kinds, and all like a tolerably moist position. *Eryngium pandanifolium*, from Monte Video, attains a considerable size, and has long, glaucous leaves, much resembling those of the Screw Pine family; *E. Serra*, a Brazilian kind, has short, broad, strongly-spined leaves, and is a dwarfier species than the preceding; *E. præratum*, from Central America, has strap-shaped leaves; *E. bromeliæfolium*, a Mexican sort, has dark green, very spiny-edged foliage; *E. aquaticum*, a North American kind, has glaucous, strap-shaped leaves; *E. eburneum*, *E. Laseauxi*, and *E. paniculatum* are all from Monte Video. The first is a noble species, attaining a height of 10 ft. to 12 ft., and having bright, glossy green leaves with spiny edges; the second has long, narrow, glaucous leaves, edged with short teeth; *E. paniculatum* is a very neat plant with rosettes of curved leaves, much resembling those of many Bromeliads. A handsome *Scabiosa* is *Scabiosa graminifolia*, a prostrate-growing sort, with whitish, grassy leaves and showy blue blossoms. *Sedum Ewersi*, a native of Siberia, is a very beautiful Stonecrop; it is a most free-flowering kind with red blossoms. *Seaeli gummiferum*, a stout-growing Umbellifer about 3 ft. high, has fleshy leaves, similar in outline to those of the common Samphire, and large umbels of white flowers. *S. glaucum* is a smaller kind, like the last named in habit. *Allium carinatum* and *A. flavum* resemble each other in habit; both grow about 1 ft. to 1½ ft. high, and bear large heads of small, long-stalked, drooping flowers—purple in *A. carinatum*, yellow in *A. flavum*. *Stevia serrata*, 2 ft. high, has small leaves and innumerable small heads of purple flowers. *S. paniculata*, 3 ft. high, has white flower-heads which present, at first sight, a considerable resemblance in size and arrangement to the common Woodruff. *Aster sericeus*, with small silky leaves and purple flowers, is a very distinct sort growing about 1½ ft. high. *Wahlenbergia grandiflora*, a splendid Bell-flower, bears long-stalked blossoms at the extremity of the branchlets; the flowers are similar in size and colour to those of *Platycodon grandiflorum*, but the plant is prostrate, not erect as *Platycodon*. *Symphandra pendula*, a Caucasian perennial, has large, white, bell-shaped blossoms; from its very floriferous properties and elegant habit this would make a first-rate plant for hanging baskets. The pretty little, white-flowered, New Zealand *Lobelia litoralis*, which we recently noted, has now a good crop of purplish, berry-like fruits, handsome enough to cause the plant to be grown. *Phalocallis plumbea*, a South American Irid growing to a height of 3 ft., has long, narrow, sword-shaped leaves and large blossoms of a leaden hue; deep orange and white help, however, to make a peculiar and attractive combination. Although the blossoms of this plant, like those of *Tigridia* and several others of its relations, last but a few hours in beauty, the great number produced for a long period in succession makes up for the fugitive character of the individual flowers. *Dianthus dentosus*, a plant rarely met with, is a dwarf kind with purplish flowers and one which has a longer flowering season than most of its relations, blooming under favourable conditions for the greater part of the year. An Irid from North China, *Iris dichotoma*, is a noble species of distinct habit; it grows about 4 ft. high and bears a much-branched panicle and numerous mauve-coloured blossoms, the three sepals being deeper in colour than the rest of the flower, and spotted and blotched with pure white. *Chelone Lyoni*, a United States plant, somewhat like the better known *C. obliqua*, has large pink flowers crowded at the tips of the branches; it grows about 1½ ft. high.

Greenhouse Plants.—The New Zealand *Metrosideros buxifolia* with its neat, small, dark green, Box-like leaves and white flowers makes a charming shrub either for cultivation in pots or for planting out in the cool conservatory. *Indigofera decora* is a very pretty shrub worthy of general cultivation; it has light green pinnate leaves and racemes of pink and white flowers.—†

TREES AND SHRUBS.

LIME AVENUE AT TORQUAY.

In a late impression of THE GARDEN much praise is bestowed on a Lime avenue at Oromana, in the county of Waterford, but no mention whatever is made of its dimensions. There is a Lime avenue here in Torquay, which I myself have just been measuring. It is one of three (the other two are much smaller) which radiate in three directions from near the entrance of old Forse Abbey. It is 1380 ft. in length, 15 ft. in breadth, and the space between the trees is just 14 ft. The girth of each tree is, as nearly as possible, 7½ ft. at about 3 ft. from the ground. I did not count the trees, but a late "History of Torquay" tells me that there are 143 of them, and that their age is supposed to be 70 or 80 years. The avenue in question runs north and south, with a slight curve towards the east at the southern end, and the ground is slightly undulating, having a gentle rise in the centre. It is truly a gem of its kind, claiming one's highest admiration even in this beautiful spot—Torquay.

ASHLEY LA TOUCHE, R.N.

Inglewood, Torquay.

ANNUAL TIMBER SALE ON THE LONGLEAT ESTATE.

This took place at Horningsham on August 1. The average prices realised are as under. In consequence of the dull state of trade generally, the price of timber at this sale is about 15 per cent. lower than that of last year's sale. The prices will, however, bear favourable comparison with other sales throughout the country:—

No.	Description.	Average contents in each.	Average price per ft.	No.	Description.	Average contents in each.	Average price per ft.
146	Oak	13 ft.	s. d.				s. d.
57	"	16	1 8	3	Abele Poplar.	205 ft.	1 4½
284	"	11	1 7	1	Walnut.	100	2 0
66	"	21	1 11½		Elm—		
9	"	11	1 8½	3	English.	18	0 11

The timber is cut and lying in the wood where it was felled.

Longleat.

GEORGE BERRY.

Acacia dealbata.—I observed in your number for August 17 that this graceful *Acacia* grows well so far north as Wigtonshire. Does it flower there or elsewhere in Britain? I have a specimen of it (nearly killed in 1860-I, but since recovered, and now about 25 ft. high) which was well furnished with flower-buds last year, but only a few flowers opened, and those were on the sunny side, January 25. I succeeded the same season in raising a few plants from suckers which were thrown up from the roots.—J. J. R., *Penrose, Helston*.

Cedrus Deodara.—A plant of this Cedar, planted here in 1841, has produced a large quantity of male catkins annually for the past eight years, but I have watched in vain for the female. The oaks have appeared from August 2 to 25, and remain until December; they vary from 1 in. to 2½ in. in length. I fear our summers are never hot enough to produce the cones, though instances have occurred of cones ripening in Devonshire and elsewhere. What is the experience of other counties?—J. J. R., *Penrose, Cornwall*.

Bambusa Ragamowski.—This very ornamental dwarf Bamboo is valuable from its distinctness in size and form of leaf from the others, the leaves being large as compared with other hardy forms.—V.

ST. PETER'S-WORTS.

(SYMPHORICARPUS GLAUCA AND S. VULGARIS VARIEGATA.)

The Snowberry, which is the commonest and best known of this family, is often a nuisance in shrubberies, owing to its tendency to extend itself by means of underground roots and suckers to the injury of better shrubs. That is not so, however, with the kinds here named and to which I call attention now, mainly because I have found their long elegant sprays of neat foliage so useful for mixing with cut flowers in filling vases, &c. The foliage of glauca, as its name implies, consists of a mixed tint of green and greyish-blue, which towards autumn merges into bronze, and is very effective. The variegated kind is also exceedingly pretty for cutting to form a base for flowers in vases. The selection of foliage for mixing with cut flowers is quite as important a matter as that of the flowers themselves, and opens up quite as wide a field for the exercise of taste and judgment. Ferns, of course, are always effective, but in arranging flowers in vases, I have felt the want of something light and elegant with slender, wiry stems capable of supporting the individual blossoms in their assigned positions without confusion or crowding; these shrubs I have found very useful for a change at this season. It is not the quantity nor yet the rarity of the flowers, but their arrangement and setting up that give the greatest satisfaction. A few common blossoms, tastefully arranged amid elegant foliage, so that the individual beauties of each are brought out, has a more pleasing effect than rare choice flowers if arranged in a meaningless way. Two artists may have just the same colours with which to work, and yet one may produce a delightful picture, whilst the work of the other may be a mere daub; and so it is in the arrange-

ment of flowers in a bouquet or vase. The St. Peter's-worts form dense bushes from 4 ft. to 6 ft. high, and produce in August numerous small clusters of pale-coloured flowers at the axils of the leaves. These are followed in autumn by clusters of small bright-coloured fruit or berries, and these, from their arrangement along the slender branches, produce rather a singular and not uninteresting appearance.

E. HOBDAY.

Lilac Charles the Tenth.—This is an excellent variety for forcing, and where Lilac in or out of season is appreciated it ought to be largely grown. At present large quantities are imported, but as Lilac flower so freely in our ordinary English climate, there is no reason why home-grown plants should not be equally good if specially grown for the purpose. I recently saw a quantity of this variety, and every terminal growth was already showing the bloom-buds prominently. Few plants submit to forcing more readily than the Lilac, and when we consider the length of season it may be enjoyed, the facility with which the flowers are blanched, and their delicious sweetness, a largely-increased demand for the flowers may be looked for during the early spring months.—J. GROOM.

EVERGREENS WITH LIGHT-COLOURED LEAVES.

If Mr. Stevens had said (p. 113) where he resided, he would have greatly simplified the matter about which he enquires, as many plants hardy in one place are not so in another. In looking through a large collection of evergreens, there is really much more uniformity of colour amongst their leaves than one would expect, and as Mr. Stevens requires handsome flowers as well as good foliage, he asks a rather difficult question, and I am afraid that he will have but a meagre list from which to select. However, as there are many beautiful shrubs whose individual leaves may not be called handsome, but which would still make good contrasts associated with ordinary evergreens, I will just name a few. *Berberia japonica* (Besli) has very handsome foliage, which normally is of a glaucous green colour, but the upper leaves very often in the winter and spring become bronzed freely with yellow, and in this state contrast beautifully with anything in their neighbourhood. *Cassioia fulvida* is a distinct free-growing Heath-like plant, whose stems and under leaves are yellow, and which produces heads of white Aster-like flowers in the summer. *Ceanothus azureus* and *C. Gloire de Versailles* have both pale green leaves and blue flowers, which appear during summer and autumn.

Choisya ternata has very distinct foliage of a light Pea green, and produces a beautiful white, sweet-scented flowers in spring. *Daphne japonica* *Mazeli* is a free-growing, leafy shrub, pale green, and having the upper portion of each leaf bordered with creamy white; it produces freely in spring rosy flowers of the most delicious sweetness. *Escallonia stenopetala alba* has light green leaves and terminal bunches of white flowers. *Leptospermum lanigerum* has pale green, slightly tomentose leaves and bears white Myrtle-like flowers in July. *Ligustrum Simoni* has the palest green, and, I think, the largest leaves of the tribe, and also white flowers. *Laurastinus lucidus variegatus*, a handsome shrub, has glossy leaves, which are freely blotched with yellow. *Olearia Hasti* is a sturdy-growing bush, furnished with

Weeping Birch and Cascade.

small leaves and white flowers. *Ozothamnus rosmarinifolius* is, in my opinion, the most beautiful white-flowered shrub which we have. *Pittosporum eugenioides*, *Mayi*, and *tenuifolium* are the most distinct and handsome light-coloured shrubs, with glossy foliage, with which I am acquainted, but we can say little about the flowers. *P. Tobira*, however, has foliage of quite another character and sweet-scented white flowers. *Phlomis Russellianus* has grey, downy leaves and stems, and terminal heads of bright yellow flowers. *Skimmia japonica* and *oblata*. Of these the flowers are not showy; the former, however, bears freely its bright scarlet berries, but requires a cool northern aspect. Several of the above would not be hardy far away from the seaside, except on a wall. All the above are decided shades of green when compared with such shrubs as *Rhododendrons*, &c.

T. SMITH.

Robinia Pseud-Acacia aurea.—This variety, judging by the rate at which it grows, is equal in vigour to the species; and, as compared with other pictorial deciduous trees, it must be considered peculiar. Its leaves are long, narrow, oppositely-lobed, and pendulous; and it does not present, as several other trees do, one mass of golden foliage; on the contrary, only a few of the leaves towards the extremities of the growing shoots are of a pleasing yellow colour,

which in turn, and I may say haetily, change to rich green. Its great attractiveness lies in its presenting at all seasons of its growth a sufficient number of golden leaves, which appear like so many sinuous lines of light against the background of its own rich green (older) foliage. It is a magnificent object, and increases in beauty as the season advances, there being towards the close of the growing season a greater contrast between the yellow of the young and the green of the older leaves. It is of good colour now, after all the rain and sunless weather which we have had, but it was much finer last summer.—G. SYME.

NOTES AND QUESTIONS ON TREES AND SHRUBS.

Retinospora on Rockwork.—The silver-leaved *Retinospora squarrosa* makes a fine plant on rockwork, as does also *R. Lycopodioides*, which is one of the most difficult of the Conifers to grow. In raised positions and planted in good soil it succeeds perfectly.

A Fine-leaved Cypress.—The *Cupressus Lawsoniana alba pendula*, a variety which was sent out some years ago by Messrs. Paul, of Cheshunt, is one of the most beautiful of Conifers. It grows well, and its fine, gracefully drooping leaves are richly tipped with a silvery sulphur colour. It is remarkably showy, and worthy of a place even in the most select collections of Conifers.

Ceanothus velutinus.—This makes an excellent wall plant. If planted in good soil it grows rapidly, and its large glossy green leaves have always a pleasing appearance. It grows well in London, and would form a good plant for graveyard gardens either grown as a bush or for covering bare walls. We lately saw some fine healthy specimens of it in Messrs. Osborn's nursery at Fulham.

Ligustrum japonicum lucidum.—Grafted standard high on the common Privet, this is equal in effect at this season to a well-grown Lilac. We lately saw plants of this description in Mr. Paul's nursery at Cheshunt, the heads of which were literally studded with large trusses of white blossoms, which last in good condition for a considerable time. This Privet is well worthy of being planted largely in fronts of shrubberies or in other conspicuous positions.

Hydrangea paniculata grandiflora.—Several complaints have been made respecting the non-flowering of this shrub this season, a circumstance attributable probably to the plants complained of having got into a poor condition. For its best development it requires to be cut back freely in the spring just as one would prune a Rose bush, to be well fed, top-dressed or otherwise with rotten manure; in fact, to get the strongest possible shoots, and to develop them to the fullest extent, in order to obtain large trusses of bloom.—T. SMITH.

Treatment of the Umbrella Pine.—The Umbrella Pine (*Sciadopitys verticillata*) grows luxuriantly at Cheshunt planted in pure peat. Abundance of water is given to it during dry weather, and when it becomes necessary, some of the natural soil is taken away from near the root and replaced by peat.

Two Good Avenue Trees.—A very good effect is produced by specimens of the Golden-leaved Poplar and the Purple-leaved Birch, planted alternately. The Poplar grows rapidly and is a most useful tree. The Birch assumes a pyramidal habit; its branches are light and graceful, and its leaves of a dark purple-bronze.

The Purple-leaved Peach.—When grown in the form of a standard this is very effective, either in shrubberies or in isolated positions. Associated with the white-leaved *Acer Negundo variegatum*, it would form a striking contrast. It grows freely in Messrs. Osborn's nursery at Fulham, where its appearance, as regards colour, reminds one of that of the well-known *Iresine Lindenii*.

The Tamarisk.—In flower gardens this maritime shrub is usually seen in the form of a dwarf bush, which is annually headed down; and, thus treated, during summer and autumn its light green feathery spray has a pretty effect. It also looks well as a wall plant if closely espurred in winter. In positions where even Elms and similar hardy trees assume a burned look the moment they get above the shelter of a wall or other fence, this plant flourishes, and seems to enjoy the bracing atmosphere. Therefore, wherever evergreens become seared or blighted, it is good policy to make the best use of plants that flourish in the locality under ordinary conditions.—J. G.

Eugenia apiculata.—There is at Ravensdale Park, near Newry, a very large specimen of this, at least twenty years old I should say, growing on a wall, and every season it is loaded with large terminal bunches of white flowers, which are succeeded by an abundance of jet black fruit, of which the birds are very fond. This shrub seems to be quite hardy in all sorts of positions; it grows very freely, and when planted side by side with narrow and broad-leaved Myrtles, it does not get injured even when they are severely out up.—T. SMITH.

HILLFIELD, REIGATE.

In looking over the garden at Hillfield, Reigate, the other day, I was much charmed with the effect of *Taxus adpressa*. It is a beautiful object, rolling over tier upon tier down the bank which bounds the terrace. It will bear cutting freely, but its beauty comes out most when naturally spreading down a slope. Fourteen years ago the plants were about 3 ft. across; now they are 12 ft. to 14 ft. I was also much struck with the rapid growth of a tree of *Wellingtonia gigantea*. I planted it in 1858 from a pot; it was then 3 ft. high; it is now (August 1878) between 40 ft. to 50 ft., clothed to the ground with a base 4 ft. in circumference. The soil these plants are in is a soft burr-stone just below the chalk hills. There are also two fine plants of *Abies excelsa elegans*, about 25 ft. This is an exceedingly graceful variety. One feels grieved to see a place so rich in plants of all kinds left in the hands of unappreciative owners. The weakest plants are allowed to go to the wall and the strongest spoil for want of space. It is, however, a treat to go into a garden like this where a man of taste has lived, and find so many subjects new and rare at every turn, even though their friends have gone. It is so interesting in comparison with ordinary places, where Laurels, Rhododendrons, Roses, Pelargoniums, Fuchsias, and the like swamp everything else; not that these plants are not extremely beautiful in themselves, but because so much of one thing offends the sense of beauty and harmony. I see no reason why all gardens of moderate space should not give a home to, if not collections, at least selections of hardy herbaceous and Alpine plants, hardy trees and shrubs, Conifers, Ivies, and other hardy climbers, Ferns, Grasses, bulbous plants, and the like. At Hillfield there are plants of *Fuchsia Riccartonii* 8 ft. high; there the various forms of *Cotoneaster rotundifolia* abound, and the *Acanthus* is quite at home in company with hardy *Oxalis* and the *Megasea* section of *Saxifraga*. On the banks the several varieties of *Helianthemum* grow in grad masses, and in the bottoms *Gynerium* and *Arundo* conspicuous do exceedingly well. In the damp parts *Arundinaria falcata* waves gracefully in the breeze, and *Equisetum fluviatile* grows wild here; this latter is worth an effort to establish in any place on the margins of water. One thing I noticed in this place that is a common but a sad error, that is, that fine specimens are spoiling and in danger through the encroachment of unimportant trees or shrubs that were originally planted for nursing or protecting the others only. The want of boldness in cutting away such in time, often ruins the best places for all time.

Sudbury House, Hammsmith.

J. CROUCHER.

Forcing by Smoke.—Senhor Ernesto do Canto, of the Pine-apple and Orange-producing island of St. Michael, contributes an interesting article to the "Illustration Horticole" of Ghent, in which he shows that wood smoke has an important and beneficial influence on the growth of plants. In the island of St. Michael some 30,000 Pine-apple plants supply the English markets with their delicious fruit every year; and as the prices which are fetched in winter are higher than at any other time of the year, the St. Michael's growers have adopted a system of forcing which enables them to keep pace with the demand. Some of the growers tried the application of artificial heat below the roots in a very scientific manner, while others adopted the rough-and-ready method of growing them in houses heated by open *braseiros*, in which wood or charcoal was burnt. It was soon discovered that whenever a hot-house was constantly filled with smoke from the burning wood the plants flowered at least a fortnight earlier than when a more scientific mode of heating was used. Even freshly-struck suckers began to flower prematurely under this method of treatment. The fact seems to admit of no doubt, for the whole of the growers, even those whose hot-houses were heated with the most modern appliances, have adopted the plan of keeping their forcing houses constantly filled with the smoke of burning straw or wood chips. It would be interesting to know whether the active agent is the smoke itself or the carbonic acid produced along with it by the burning wood or straw. M. Georges Ville, the eminent French agricultural chemist, tells us in his "Engrais Chroniques" that *Cladadium* grown in an atmosphere strongly charged with carbonic acid and ammonia increase and multiply at an astonishing rate, and Senhor do Canto's observations appear to confirm his statement. In any case the experiment is easily tried.—C. W. QUIN.

Blackheath.—The improvement which the Metropolitan Board of Works has effected on the Heath by the simple process of leaving Nature alone is now fully apparent, for the old gravel-pits have grown into green and pleasant dells; the rusty clumps of trees and *Fir* bushes have become picturesque features of the scenery; and the stagnant ponds, through which the horses used to splash, have been converted into lakes, dotted with small islets, blooming with *Hollyhocks* and *Nasturtiums*.—"Standard."

ROSES.

THINNING ROSES IN AUTUMN.

On examining our Roses recently, it occurred to me that it would be a great advantage if, instead of deferring the thinning out of the shoots until the spring, we performed that operation in autumn. Other plants are benefited by skilful thinning, and why not Roses? The late dry weather has affected the prospect of a good Rose harvest next season; the plants have suddenly ceased to bloom, although they looked all that could be desired before the hot weather set in. Our soil is light, and therefore we felt the effects of the dry weather much more on that account; and, to make matters worse, for appearance sake we removed a thick mulching from off the surface of the beds just before the hot weather set in. The effect of this was such, however, as to induce us to remulch and syringe overhead every evening, in addition to watering at the roots. The result of this second mulching was most satisfactory, and, a change of weather occurring as well, our Roses made, and are still making, excellent growths; some are, however, sickly, and others will die outright, but these are fatalities that must be looked for more or less after periods of severe drought. But cannot we assist them by removing all weakly superabundant shoots in good time in the autumn, and thus direct the energies of the plants into a limited number of stems according to their size and vigour? The autumn thinning of Roses, instead of being general, is, as a rule, only recognised by Rose growers who make a speciality of their culture. Hitherto it has been my practice to thin out all weakly shoots early in spring, and to leave the shortening back till the ordinary pruning time. This practice, though good in its way, falls short of what it ought to do, because we allow the plants to waste their vigour in sustaining an unlimited number of weakly and, for the most part, flowerless shoots. The experiment will be found to work beneficially, especially if, in addition, the roots are well supplied with weak liquid manure. It is really too much to expect good Roses under a system which does not recognise the limitation of the shoots and the feeding of them during the process of formation. But what about a supply of Rosebuds in autumn? Well, provision must be made for obtaining them either by having two sets of plants or, if the collection be a small one, by working it on a sort of compromise principle in accordance with circumstances. No one who has two or three good old plants of Souvenir de la Malmaison or Mrs. Bosanquet planted in a warm sheltered situation need be short of a Rosebud from the month of May till Christmas. W. HINDS.

NEW FRENCH ROSES.

The following is a list of new Roses which I saw on my visit to France last June:—

- BOILEDIEU (raised by Margottin).—Hybrid Perpetual; very much like Paul Neron, but not quite so large; very full, fine form. I think this will be a fine Rose for exhibition.
- ALFRED K. WILLIAMS (Schwartz).—Hybrid Perpetual; carmine, large, full, and fine form.
- EDOUARD DUFOUR (Levique).—Hybrid Perpetual; deep crimson red with brownish shading; large and good form.
- MARIE LOUISE PERNET (Pernet).—Hybrid Perpetual; very high-coloured, large, and fine in form; a very fine Rose.
- GLOIRE DE BOURG-LA-REINE (Margottin).—Hybrid Perpetual; dark velvety crimson, a beautiful colour, not very full.
- SOUVENIR DE M. POITEAU (Margottin).—Hybrid Perpetual; bright cherry-rose, large, and fine in form; good exhibition Rose.
- DA. KEELL (E. Verdier).—Hybrid Perpetual; bright red slightly shaded with purple, medium size, form good.
- EDOUARD PINAERT (Schwartz).—Hybrid Perpetual; bright red, velvety, and of a globular form.
- GRAND DUKE NICHOLAS (Levique).—Hybrid Perpetual; bright vermilion, fine in form, and good size; a promising Rose.
- MADAME JEANNE BOWYER (Gonod).—Hybrid Perpetual; pink, large, and fine in form.
- MADAME LOUIS DOMININE (Gonod).—Hybrid Perpetual; flesh colour, darker in the centre, large, and fine in form.
- SOUVENIR D'ADOLPH THIESS (Moreau).—Hybrid Perpetual; bright red, shaded with vermilion; good in form.

- DAMES PATRONNESSES D'ORLEANS (Vigueron).—Hybrid Perpetual; crimson-red, medium size, not very full.
- PRINCESSE BLANCHE D'ORLEANS (E. Verdier).—Hybrid Perpetual; red, slightly shaded with purple; medium size, good in form.
- MONS. GABRIEL TOURNIER (Levet).—Hybrid Perpetual; deep carmine, flowers globular, and very sweet-scented; a fine Rose.
- DUCHESSE D'OSSUNA (H. Jamin).—Hybrid Perpetual; rosy-vermilion, very bright in the centre, not very full; after the way of Etienne Levet.
- CHARLES BALTER (E. Verdier).—Hybrid Perpetual; carmine, full and fine in form, and very fragrant.
- CANNES LA COQUETTE. —Hybrid Perpetual; salmon colour, shaded with red, large and good in form, quite a novelty; a promising Rose.
- PRINCESSE CHARLOTTE DE LA TREMOILLE (Levique).—Hybrid Perpetual; satiny rose, good size; something after the manner of La France.
- MADAME JEANNIE JOUBERT (Margottin).—Hybrid Perpetual; carmine-red, medium size, good in form.
- MADAME GABRIEL LUIZET (Liabaud).—Hybrid Perpetual; satiny rose, medium size, full, and of good form.
- MADAME CHEVROT (Pernet).—Hybrid Perpetual; rose-pink inclining to salmon; very good in shape.
- MADAME DE LABOULAYE (Liabaud).—Hybrid Perpetual; lightish rose, brighter in the centre, large and full.
- BATHÉLEMI JOUBERT (Robert Moreau).—Hybrid Perpetual; brightish red, large, and of good form.
- CONSTANTINE TRETIAKOFF (H. Jamin).—Hybrid Perpetual; oberry-red, darker in the centre, medium size, and of good form.
- MADAME ANNA DE BESOBRASOFF (Nabonnand).—Hybrid Perpetual; white, centre pink, medium size, imbricated form.
- MADAME ANNA DE BESOBRASOFF (Gonod).—Hybrid Perpetual; dark red, shaded with purple; large and full.
- MADAME MARIA VERDIER (E. Verdier).—Hybrid Perpetual; satiny rose, large petals; in the way of Marquis Castellane.
- SOUVENIR D'AUGUSTE RIVIERE (E. Verdier).—Hybrid Perpetual; velvety crimson-red shaded with maroon; very fine in colour; flowers well formed.
- PRINCESSE LISE TROUBETSKOI (Levique).—Hybrid Perpetual; light rose, petals edged with white, well formed; a promising Rose.
- PRESIDENT SCHLACHTER (E. Verdier).—Hybrid Perpetual; velvety crimson, shaded with purple, large, and of very good form.
- MADAME ALDANI (E. Verdier).—Hybrid Perpetual; brightish red; a fine-looking flower.
- CLEMENT NABONNAND (Nabonnand).—Tea; cream-yellow, shaded with lilac.
- LA COMTESSE DE CASERTA (Nabonnand).—Tea; copper red; flowers large, not very full.
- LOUIS RICHARD (Dacher).—Tea; coppery-rose, reddish in the centre; a promising Tea Rose.
- MILLE. NOELIE MEULE (Nabonnand).—Tea; buff-yellow shaded with carmine; a fine Rose, somewhat in the way of Gloire de Dijon.
- MADAME NABONNAND (Nabonnand).—Tea; white shaded with rose, good habit; a promising Tea Rose.
- LA SAMMONNÉ (Margottin).—Hybrid climber; salmon-rose, medium size, good in form.
- MADAME BERNAIX (Guillot).—Hybrid Tea; high-coloured rose petals edged with white, good in shape; awarded a silver medal.
- MADAME LAMBEARD (Lacharme).—Tea; bright red, large and full.
- MADAME DURRSCHMIDT (Guillot).—Hybrid Tea; white tinted with salmon-rose, large and full; awarded a silver medal.
- MADAME PITTET (Lacharme).—Hybrid Noisette; white, of a globular form; gained the first prize at Lyons. R. S.

Button-hole Roses.—Of all button-hole Roses none are more charming than the medium-sized buds of Catherine Mermet. The colour is a pale rosy-pink, and the form of the flower perfection. It is one of those hues that suit any coloured coat. A number of Tea Roses under glass are just now throwing up their latest growth; this produces small buds that are the most suitable of all for button-holes.—A. D.

Climbing Roses.—In the gardens at Bassett, Southampton, some robust climbing Roses planted some years since close to the stems of Scotch Fir trees have grown so strongly, that they have extended up into the higher branches, and have spread themselves over the trees, and when in bloom they are said to have an attractive appearance, a fact which can well be imagined, as the light-coloured flowers could not fail to look effective amidst a setting of deep green Fir leaves. This combination is worth the attention of those who have wild gardens, as in such places the Rose should be allowed to grow naturally and wildly, and as luxuriantly as does the common

Bramble in hedgerows. The many strong-growing Noisettes, such as Gloire de Dijon, Jaune Desprez, Lamarque, and others are specially suited for such a purpose.—A. D.

THE HORTICULTURAL COMPRACHICOS OF JAPAN AT THE PARIS EXHIBITION.

In that fascinating nightmare, *L'Homme qui Rit*, Victor Hugo tells us that in the seventeenth century there existed in Europe a band of nomads, known by the name of comprachicos, or children buyers, whose special handicraft was the transformation of their unhappy purchases into dwarfs and monsters for the particular delectation and amusement of popes and princes. In the nineteenth century, in our own corner of the world, at any rate, the comprachicos are luckily as obsolete as the rack and the thumbscrew; but the practice of interfering with Dame Nature in her benevolent occupation of strewing our path with things of beauty which are joys for ever still thrives in Japan. The daimios of Yokohama and Nagasaki are not content with the countless beautiful gems of the plant world with which their favoured islands are studded, but they must also have dwarfs and monsters of the vegetable kingdom. They must have Pine trees with the best part of their roots leaping up into the air several feet higher than their topmost twigs, or Kakis with their branches so contorted as to resemble tangled masses of cordage instead of the graceful trees which we know them to be. In the "Revue Horticole" for July 16, Mons. E. A. Carrière gives a long and interesting account of the dwarf and monster plants shown in the Japanese section of the Paris Exhibition. These vegetable abortions have hitherto only been known to us

Fig. 1.—Two young plants of *Pinus densiflora*, deformed.

Fig. 2.—Specimen of *Pinus densiflora*, with the larger portion of the roots growing in the air.

through the medium of the metal and fictile wares of that wonderful country. M. Carrière admits at starting that he can only guess at the methods used by the Japanese comprachicos for producing these vegetable monstrosities, which not only include dwarf plants, but also shrubs and bushes of tender years, which wear a feeble and venerable appearance long before the natural time. Figs. 1, 2, and 3 are good examples of this peculiar development of the art of horticulture. M. Carrière supposes that when the Japanese wish to dwarf any particular subject they naturally choose those varieties which most lend themselves to being checked in their growth by various means. By training their shoots and branches with the utmost patience, they are able to produce the most monstrous forms, while by limiting the amount of nourishment which the plants receive within the narrowest possible limits they become dwarfs. Hence, by adopting the latter method, of checking their growth, they succeed in producing plants which, although they may be over a century old, are still small enough to live and thrive in a medium-sized flower-pot. We must also remember that the climate of Japan is peculiarly favourable to this description of horticulture, and it is doubtful whether this kind of culture could be carried out in hot, dry, sunshiny countries. Of all hardy subjects the Conifers seem to have produced the most successful specimens of dwarfs and monsters, either because they are more fitted for this mode of treatment, or because they are more in favour in Japanese gardens. Amongst the Conifers again Pines seem to produce the happiest results. As seen in figs. 2 and 3, the stem, which is reduced to its very simplest expression, grows at a distance from the surface of the soil, and is supported by a number of simple or branched roots supported by sticks, which float about

in the air as if they belonged to it. The results shown in figs. 1, 2, and 3 are difficult to explain, especially that which, as will be seen, sends up a root from *b*, which, bending round in the form of a syphon at a distance of 2 ft. or 3 ft. above the plants, descends once more as far as *a*, where it splits into a number of branches, if such a word may be applied to a root, and descends into the soil contained in the pot, whence it conveys nourishment to the plant by the circuitous path shown in the cut. In the majority of cases it is difficult to fix the exact spot at which the root ends and the stem begins, as they seem to run into each other. If we carefully examine fig. 3 we shall apparently find that the end of the root-stalk is at *a*, and that from thence to the point *b*, where the cotyledons formerly existed, the part may be considered the collar, so that below this point we may still find a portion of the root-stalk, which, becoming thinner, is easily confounded with the roots properly so called. As shown in figs. 4, 5, and 6, the branches and

Fig. 3.—*Pinus densiflora*, submitted to the same treatment as the specimen shown in fig. 2 (1-5th the natural size).

shoots constituting the head of the tree may be contorted by training into the most extraordinary dwarf and monstrous forms; in fact, everything is done to prevent them from growing in a vertical or horizontal direction. This system of culture seems to be very widespread throughout Japan, and must be practised by a large number of persons, for such specimens as the one shown in fig. 1 are exhibited by hundreds. Worried literally half out of their lives by ill treatment and starvation, it is not to be wondered at if the size of some of these unhappy victims are wholly out of proportion to their age. For instance, the puny-looking plant shown in fig. 1 is ten years old, while that represented in fig. 2 has seen at least eighteen summers; and the *Pinus* in fig. 3 nearly trebles that age. The monstrosity shown in fig. 4 is thirty-four years old, and the *Nageia* (fig. 5) is only five years younger. These ages, it must be observed, are only approximative. Although the Pines seem to be particu-

larly amenable to this mode of treatment, there are other members of the family of the Coniferæ which are also capable of gratifying the perverted tastes of the Japanese aristocracy, such, for instance, as the *Chamaecyparis*, the *Podocarpus*, and even the *Nageia* (as shown in fig. 5). It is clear that other

their extremities in the soil. It is not only in ornamental plants that the Japanese *Comprachicos* work their wicked will, for they apply the same system of dwarfing to fruit trees—first of all in a natural way, by tying the branches together in such a manner that they grow inwards instead of outwards; and, secondly, in an unnatural manner, by excessive pruning, or by checking their growth one way or another. Judging from the specimens shown in the *Trocadero* and at the *Jardin Fleuriste*, the fruit trees best adapted for this method of treatment seem to be *Kakis*, *Peaches*, *Plums*, and *Cherries*. The *Kaki* seems to be designed by Nature for the especial purpose of being dwarfed and otherwise deformed. Some of the specimens exhibited are very dwarf, being only from 16 in. to 30 in. in height, but they are covered with flowers, and, judging from the condition of the shoots, they must have fruited abundantly. In growing fruit trees, the Japanese follow the method adopted by our western fruit growers, and leave only from six to twelve fruits on each tree, according to its natural vigour. Another peculiarity of these dwarfed and deformed trees is that their roots, as a whole, are very small, the subterranean portions being comprised in a few small tufts of rootlets. It is impos-

Fig. 4.—Stunted and deformed specimen of *Rhynchospermum japonicum*.

species of Coniferæ may be submitted to the same process with similar results. This peculiarity of the Coniferæ, no doubt, is caused by the fact of their having excessively long roots, as any one who has grown Pines in pots can readily testify. Without positively asserting anything, M. Carrière gives it as his opinion that the whole secret lies in the choice of subjects with extremely long roots; and in support of it he instances the fact of a seedling Cedar, which was sown in heat in a tube containing Moss, out of contact with the air, and which, in a very short time, produced roots 18 in. or 20 in. in length. It must also be remembered that as the Japanese do all they can to check the growth of the aerial half of the plant, the subterranean portion must necessarily become unnaturally developed. The singular results shown in figs. 1 and 3 lead one to inquire as to whether

Fig. 6.—Full-grown *Kaki*, with the branches deformed by pruning and training, bearing here and there fructiferous peduncles.

Fig. 5.—*Nageia ovata* in a Japanese flower-pot, with the branches growing downwards (1-8th the natural size).

the effects are obtained before or after the plants are placed in pots. Be this as it may, it is perfectly evident that some means are taken to draw the roots out of the soil gradually, without in any way damaging the rootlets, so as to expose all their ramifications to the air, leaving only a small portion of

sible to say whether this is the result of checking the growth of the aerial part of the plant or of perpetual transplanting, so as to keep the subject, so to speak, in a constant state of ill-health. In the absence of any trustworthy information on the subject, we can only surmise that both these methods are practised.
C. W. QUIN.

A Good Way of Keeping Cut Flowers.—A simple and easy way in which to arrange cut flowers for side-boards, &c., is to get a flat wicker punnet, line it with Moss, and fill up the middle with sand. In this the stalks of the flowers can be inserted, not only on the top, but also through the apertures in the sides of the punnet; the whole can then be set in a dish of water, which may be changed as often as desirable. This is a much better way than having to wet the sand or remove the flowers to change the water, and they keep much longer fresh.—S.

THE FLOWER GARDEN.

FLOWER GARDENING IN BATTERSEA PARK.

ALTHOUGH the weather has been unfavourable for flower gardening this season, this park looks as well as we ever remember to have seen it. Sub-tropical and carpet gardening are extensively represented, and even the shrubby borders in places have been improved. In some cases, Pelargoniums, Heliotropes, and other plants have, owing to the excessive rainfall which we have had, grown into each other, so as to produce a mixed and rather weedy appearance; but, speaking generally, Battersea still holds the foremost place amongst the London parks as far as gardening is concerned. The sub-tropical arrangements under the shade of trees are very satisfactory, the plants being plunged round them in such a way as to leave little valleys of turf between them. Amongst other plants employed for this purpose are glaucous-leaved *Zamias*, *Pandanus Veitchii*, Cycads, and Bird's-nest Ferns. Stag's-horn Ferns grown on blocks of wood plunged in the turf are very effective, the blocks themselves being hidden by plants of *Ampelopsis Veitchii* or some other creeper. Dicksonias have not done so well as we have sometimes seen them here, and *Musas* have been sadly cut to pieces by the wind. Groups of *Cannas* just coming into flower are vigorous and healthy, especially those which have been kept in the ground undisturbed for a year or two. *Asplenium bulbiferum* is used with good effect in arrangements under trees, and, considering how easily and rapidly this Fern can be increased, it might be more frequently employed for such purposes than it is. Large, flat beds of *Wigandias*, planted 4 ft. or more apart, are very effective, the plants being from 3 ft. to 4 ft. high, and furnished with massive, healthy leaves. An undergrowth of *Plumbago capensis*, *Lantanas*, and variegated *Veronicas*, edged with silver-leaved *Pelargoniums*, and a final edging of the green-leaved *Geranium tomentosum*, makes this one of the best arrangements in the park.

Another handsome bed is a round one filled with tall plants of *Dracæna lineata*, and an undergrowth consisting of *Iresine Lindeni* grouped amongst white-leaved *Everlastings*, the whole encircled with a band of the silver-leaved *Chamæpuce dicantha* set in round cushions of *Sedum glaucum* edged with *Aloe altunata*, the final edging being of *Golden Feather*, through which runs a narrow band of *Alternanthera amœna*. A raised bank with a background of *Cannas*, a foreground composed of *Aralia Sieboldi*, *A. s. variegata*, and *A. papyrifera*, and an edging of green-leaved *Funkias* was very effective. Another bank similarly arranged opposite leaves a valley of turf between, in which are planted small groups of *Palms* and succulents. Giant *Hemps*, from 10 ft. to 12 ft. high, have been used in several places with good effect. On a raised bank of a small shrubbery was a bed of tuberous-rooted *Begonias*, the best which we have yet seen out-of-doors. They consisted of mixed kinds of various colours, and amongst them were planted *Fuchsia fulgens*, the lace-leaved *Cupania filicifolia*, and *Abutilons*, the whole being encircled with a band of bicolor *Pelargoniums* and edged with *Nierembergia gracilis*, which is allowed to spread gracefully over the edges of the turf. Another effective bed consists of tall plants of *Acacia lophantha* and *Areças*, with an undergrowth of *Eurya latifolia*, finely-coloured *Abutilon Darwinii tessellatum*, and the golden and crimson-leaved *Fuchsia Sunray*. *Polymnia grandis* is one of the finest of sub-tropical plants; it has here already reached from 4 ft. to 5 ft. in height, and is furnished with very large, half-drooping, deeply-cut leaves.

Well-formed standard plants of *Yucca aloifolia variegata*, planted in round beds of mixed *Coleuses*, are very effective, as are also some oval beds planted with *Grevillea robusta*, springing from amidst a thicket of the variegated Vine, and edged with the golden-leaved Japanese *Honeysuckle*, a broad band of *Alternanthera*, and a final edging of *Sedum glaucum variegatum*. Examples of the white-flowered *Brugmansia*, planted in a large group in raised positions, are flowering freely, and contrast strikingly with their surroundings. Amongst beds on a bank was one with a raised Ivy edging, next to which was a band of silver-leaved *Pelargoniums*, and behind that a row of well-developed plants of a golden-leaved *Fuchsia*, and a good

breadth of mixed flowering *Fuchsias* interspersed with robust plants of *Begonia riciniifolia*, backed up by finely-developed specimens of *Aralia papyrifera*, the effect of the whole being much enhanced by a background of bright-leaved *Hollies*. *Epilobium hirsutum variegatum*, an excellent plant, is used here for the adornment of the edges of shrubberies. It grows from 2 ft. to 3 ft. high, and its leaves, which are almost white, contrast well with the blue blossoms which it bears in profusion.

Plants of *Ficus repens*, springing from a thicket of well-flowered *Balsams*, have a fine appearance where edged with rose and scarlet zonal *Pelargoniums* and the variegated *Gazania splendens*. Plants of *Clematis Jackmanni*, associated with the Canary Creeper and allowed to run wild over stakes and tree stumps, form an attractive feature.

Hibiscuses are not yet so full of bloom as we may expect to find them before the season is over, but grouped on a bank, backed up with *Hollies*, &c., and edged with gold-leaved *Fuchsias*, rose-coloured *Pelargoniums*, and *Centaurea maritima*, they are very showy. *Fuchsia Carters' Meteor* is used in several instances as an edging plant; its leaves are of bright crimson and gold, and when the plant is kept well pegged down they are very showy. A large, round bed planted with *Yucca aloifolia variegata*, *Aloe frutescens*, *Echeveria metallica*, and *Sempervivums* arranged in round groups on a carpet of *Herniaria glabra*, encircled with small plants of *Echeveria secunda glauca*, the whole being sunk in a groundwork of green *Mentha*, with a centre plant of a glaucous-leaved *Dasy-lirion*, has a good appearance.

Amongst the most attractive examples of carpet gardening was a long bed with small, oval-shaped groups of *Alterantheras* along the centre, and surrounded by a band of *Pyrethrum Golden Feather*; next to this was a line of *Kleinia repens*, then a band of *Sedum glaucum* and another line of *Kleinias*, the remainder of the space up to the Grass being filled up with *Golden Feather*—a good and effective arrangement. In the shrubbery borders we notice mixed *Petunias*, *Dahlias*, *Tritomas*, *Godetias*, *Sweet Peas*, and similar plants, which are much more suitable for such purposes than long lines of *Pelargoniums* and other bedding plants. Some of the dwarf-growing *Sages* are also allowed to grow over the Grass margins with good effect. Into the Alpine garden has been introduced several graceful *Palms*, but, altogether, it is a poor specimen of what a good Alpine garden should be. We remarked that many of the bare spaces under large trees had been planted with *Yuccas* and edged with *Echeverias*, an improvement in the right direction.

S.

BEDDING PELARGONIUMS.

AMONGST all the plants that have at various times been used for the decoration of the flower garden none have retained their popularity like the *Pelargonium*. It has not only held its own as a flowering plant, but has nearly monopolised the space devoted to other bedding plants by driving the *Calceolaria* and *Verbena* off the field. A list of some of the most noteworthy at present to be seen in Hyde Park and other large floral displays may be serviceable to those readers who have not the opportunity of personally inspecting the beds. I may remark that each bed or pair of beds is planted with one variety only, and all are edged alike—viz., a double row of *Echeveria glauca* next the Grass, and a row of blue *Lobelia* next the *Pelargoniums*. There is one simple point of culture that often mars the good effect of even the best beds of *Pelargoniums*, and that is, allowing the old flowers to remain on the plants too long, whereby a shabby, seedy aspect is imparted to the beds; and the formation of seed-pods being a very exhausting process, the successional display of fresh blooms is much retarded. I have appended a selection of varieties, mostly of recent introduction and of great improvement in form of flower, habit, substance of petals, and brilliancy of colour, that bear ample testimony to the care of the hybridiser and of the success that has waited on the efforts of Dr. Denny, Pearson, and others. I may also add that for pot culture under glass these varieties are excellent; and in midwinter a house filled with the many shades of crimson, scarlet, pink, salmon, and white is a cheering sight. It is worthy of remark that hybrid-

ing Pelargoniums has not only improved the flower, but a sturdier habit of growth, with stiff, erect footstalk, has been acquired, rendering the plants altogether better adapted for decorative purposes and withstanding the vicissitudes of wind and rain to which they are subjected.

DEEP CRIMSON.—General Outram, Mrs. J. George, Caxton, Dora Charlton (white eye), David Thomson (white eye), Pirate, Wellington, John Fellows (crimson-lake), Brutus, Bonfire (scarlet).

PINK.—Lady Sheffield (lilac-pink), Lucy Bosworth, Mrs. Turner, Amaranth, Annie Horton, Master Christine.

SALMON.—Ellen, Maurice Bernardin (light edge), Miss Strachan, Pantaloon (flaked white).

SCARLET.—John Gibbons, Mrs. Hetley, Ernest, Princess of Wales, Captain Holden, Lucius, Harry Hicover, Vesuvius, Mrs. Huish, Waltham Seedling, Star of Fire, Lord Derby.

WHITE-VARIEGATED.—Albion Cliffs, Mrs. Kingsbury, Princess Alexandra, Queen of Queens, Flower of Spring.

J. GROOM.

THE NEW ZEALAND FLAX IN SCOTLAND.

I HAVE now grown this magnificent decorative plant out-of-doors at Castle Kennedy for upwards of twenty years, and the more I see of it the better I like it. As a distinct, striking, ornamental, free-growing hardy plant, it has no equal here. Many of the specimens first planted from large masses from 3 ft. to 4 ft. in diameter, with crowds of upright, long, sword-shaped light green leaves, throwing up every season flower-stems 10 ft. or 12 ft. in height, loaded in autumn with their Bean-like pods, and in most seasons ripening abundance of fertile seeds. This Flax has of late years been extensively and successfully used here. It thrives well in a great variety of soils, preferring a moderate loam to a tenacious clay. In mossy soils it is quite at home, as also in light loams, if not too dry. It thrives much better in a moderately sheltered than in an exposed position, but when planted in an exposed situation, if the leaves are tied together during the winter and early spring months, and slightly protected with a few branches, it thrives surprisingly. In planting in cold localities, a site neither very high nor very low should be selected. I prefer the latter end of April for planting in permanent positions. Strong, well-established plants should be selected, and some slight protection given for a few weeks, till the plants get well established. If the weather be dry, an occasional watering will be beneficial. When planted, as is too often done, during the autumn or winter, they are almost sure to succumb to the first severe weather, especially if the plants are small, and the plant is unjustly pronounced to be "not hardy." I do not mean to assert that in every locality this highly ornamental fine-foliaged plant will prove quite hardy. In inland and highly elevated situations our winters may be too severe for it, but in the warmer and less elevated situations, particularly near the sea-coast, it should be extensively experimented with, and where it succeeds it will well repay the trouble of those who interest themselves in its cultivation. Seeing that the normal species did so well here, I procured eight or ten years ago a few plants of the variegated sorts, and planted them out-of-doors in a warm sheltered situation. The result is that they grow nearly as freely, and are quite as hardy, as the common variety, the variegation being all that could be desired. This year we have introduced some of them as centres of beds in the flower garden with good effect, and I propose shortly breaking up some of the old plants for propagation, and thus largely increasing our stock of variegated plants; others we propose to grow for flowering, when interesting variegated seedlings may justly be expected to follow.

A. FOWLER, in "Florist."

NOTES AND QUESTIONS ON THE FLOWER GARDEN:

Tropæolum speciosum.—This charming creeper is now flowering profusely in Messrs. Ker's nurseries at Grassendale, planted against the wall of their seed shop. It is creeping up a plant of the common Honeysuckle planted against the same wall, and the combination is most effective.—W. HINDS.

Growth of Lily Bulbs.—Since writing the words quoted by "Dunedin" (see p. 140) I have read his subsequent papers upon the above-mentioned subject, and have also had myself a little further experience of Lily bulbs, and I now beg to thank "Dunedin" for his kind explanation as to the appearance of my bulb of *Lilium auratum*

in September, with which explanation I now entirely agree. In support of his theory that the old bulb, though still in existence in September, is nevertheless moribund and about to give place to the new bulb within it, I would mention that last autumn I potted a bulb of *Lilium auratum* obtained from Stevens' apparently in good condition, but, finding that late in the spring it had made no growth, I removed the earth and examined it. The outer scales were much decayed, in fact, rotten; and fearing that the process might extend to the inner scales I removed all that were at all affected, and by this means reduced the bulb to about one-half its former size. I then re-planted it in fresh earth, and in due course it sent up a stem, which has now two blooms upon it. If this bulb had been perennial, i.e., dependent upon itself for existence, and not upon a successive and distinct growth, as maintained by "Dunedin," I cannot think that it would have survived the treatment above mentioned, or, at all events, that it would have had strength enough to flower this season.—W. J. T., Brixton.

Yuccas in Clumps.—Few plants look better in isolated clumps on Grass than the different varieties of *Yucca*. Being very distinct as regards habit of growth, they contrast strikingly with almost any kind of vegetation by which they are surrounded. The stiff erect habit of *Y. gloriosa*, or the elegant curved leaves of *Y. recurva*, constitute, in young vigorous plants, the best examples of what a free-grown symmetrical plant ought to be without training, and after the plants flower and lose their symmetrical proportions, they branch into many crowned heads, thus producing a quaint and picturesque aspect; they also send up a colony of root suckers around the parent plant, and soon make a clump presentable at all seasons of the year.—J. G.

American Dog's-Tooth Violet (*Erythronium americanum*).—I notice (Vol. XIII., p. 484) that some of your correspondents speak of this pretty plant as being very shy in blooming. It grows wild in great abundance in some parts of our grounds, and in the spring it comes up in large patches, which are covered with its yellow blossoms. I notice, however, that it flowers more freely in open places and in a light peaty soil than in shady spots and heavy soil; sometimes nothing will be seen of it when the ground is cultivated for a year or two, but as soon as it is left alone it springs up in its former abundance.—C. M. HOVER, Boston, Mass.

Herbaceous Plants on the Chalk in 1878.—The copious showers and gleaming sunshine which characterised the later spring and early summer months of the present year have caused certain plants to be unusually flourishing and floriferous on the arid chalky soil upon which I have the misfortune to live. The double purple and French white varieties of *Hesperis matronalis* have been a perfect sight, but have been hard run by the double-flowered form of *Spiræa Ulmaria*. A plant of *Ophrys hircina*, just now going out of bloom, is more than 2 ft. high. *Monarda purpurea* towers in purple glory to about 4 ft. *Lilium superbum* has been very fine, and so has *Chrysobactron Hookeri*, which I have hitherto utterly failed to bloom in the open border. *Oxalis Deppei*, *Asiandra* and *vespertilionis*, *sauritanica* and *floribunda*, have been beautiful from breakfast to noon, and *Erodium absinthifolia* and *macradeneum* have been unusually fine. *Orchis latifolia incarnata* and *maculata superba* were grand. *Aneomone narcissiflora* was the admiration of everybody, and *A. rivularis* has far exceeded its usual stature. *Brugmansia sanguinea* and *lutea*, which have both stood the winter, are 3 ft. high, and the latter has a bud nearly ready to open. The hot sun of the last few weeks has been very fatal. All my plants of *Meconopsis nepalensis* have perished, and various others are in a sadly drooping condition. The recent thunder-showers have come just in time to save widespread withering and death.—H. H. CREWE, in "Gardeners' Chronicle."

The Californian *Dicentra* at Home.—I well recollect, says Mr. Drew, in the "California Horticulturist," the first time I found the variety known as *D. formosa*. At that time I did not know we were so highly favoured as to have any member of the family within our borders. It was in a little Grassy vale. When I saw it, so much did it resemble *D. spectabilis*, that I thought it was a stray plant of that well-known Chinese variety, the Bleeding Heart of our gardens. On a slight examination, however, I soon saw my error, but so highly pleased was I with it, that I dug it up and removed it to my garden. In California we have three species that I am acquainted with. *Dicentra formosa* in the Sierra Nevada, at an altitude of 6000 ft. to 8000 ft., is found in Grassy vales near streams of water. It grows from 1 ft. to 2 ft. high. *Dicentra uniflora* is found in the northern part of the State, high up on mountain sides. It is a dwarf-growing species, never exceeding 6 in. in height. *Dicentra chrysantha* is the most robust and vigorous of our native varieties, often growing 4 ft. or 5 ft. high. The leaves are often 16 in. long; the flowers average ¼ in. to 1 in. in length. The foliage is of the most brilliant yellow colour, and when the sun shines, the leaves sparkle and glisten as though varnished. While it lacks much of the graceful habit of the other varieties, this one surpasses them all in brilliancy. In their natural haunts they grow in a moderate light soil, in the vicinity of running streams. The finest flowers I have always found on plants growing in the shade of trees.

A Tall Foxglove.—In a wood near Milford Haven the other day I saw a Foxglove which measured 11 ft. 8 in. in height, and in full bloom. Is such a case uncommon?—B.

PLATE CXLII.

THE CHRISTMAS ROSES.

(WITH A COLOURED FIGURE OF THE GIANT VARIETY.)

Drawn by Mrs. DUFFIELD.

FEW hardy plants possess such pleasant associations as the Christmas Roses. At a season when all kinds of flowers are welcome they produce their handsome blossoms in continuous succession from October to April, and they last a long time in good condition both on the plant and also in a cut state. The common kind (*Helleborus niger*) has long been a garden favourite, having been in cultivation for nearly three centuries; and it has always been mentioned in glowing terms by early writers on horticulture. Much attention has of late been paid to the introduction of new kinds and to the improvement of the most ornamental of those which we already possess by means of judicious hybridisation and careful selection. This has been chiefly carried out in Continental gardens, from whence many beautiful kinds have recently emanated. There is still, however, ample room for further improvement as regards the types, by skilful cultivation, and also by intercrossing the kinds hitherto not operated upon in that way. Much confusion exists in gardens in respect to the nomenclature of Christmas Roses; indeed, it would be difficult to find two collections in which the names are identical, except in the case of such well marked kinds as the common Hellebore (*H. niger*) and the foetid kind (*H. foetidus*). With the exception of a Syrian species (*H. vesicarius*), which is remarkable on account of its large, bladder-like seed vessels, all the known kinds are now in cultivation in this country, but some of these are as yet very rare. The geographical area over which the species are spread is confined to the north temperate regions of the Old World, extending from the extreme western part of Europe to Asia Minor, but the majority are concentrated in the central and south-eastern parts of Europe. Two species—the green Hellebore (*H. viridis*) and the foetid (*H. foetidus*)—reach as far north as Britain, but they are rather rare native plants. The descriptions of the kinds here enumerated have been made from a careful study of the living plants, and the nomenclature will be found to be in accordance with the views of the most recent botanical authorities.

Group 1.—Leaves not Annually Dying—Flowers Varying from Pure or Greenish-white to a Deep Rose Colour.

Black Hellebore (*H. niger*).—This well-known kind scarcely needs description, as it may be at once recognised by its pale green, leathery, and quite smooth, leaves which are divided into seven to nine segments 3 in. to 6 in. long and 1 in. to 2 in. broad, coarsely toothed at the margin of the upper half. The leaf-stalks are about one-third longer than the divisions. The blossoms, which are usually borne singly on stems 6 in. long, are about 3 in. across, with rounded divisions varying in colour from a waxy-white to a delicate blush tint, with a fringe of scale-like petals at the inner base of a yellowish-green colour. It is a native of the southern and central parts of Europe. The variety minor is smaller in every part than the type, and is also known under the name of *H. angustifolius*.

Giant Hellebore (*H. altifolius*).—This handsome kind, the subject of our plate, though considered by some to be a variety of *H. niger*, is nevertheless a very distinct kind, and well merits specific rank. It is much larger in all its parts than *H. niger*. It has leaf-stalks over 1 ft. in length, with the blade large in proportion. The blossoms, which are from 3 in. to 5 in. across, are borne on branching stems bearing from two to seven flowers, and have a stronger tendency to assume a rosy hue than the ordinary kind. Another characteristic is in the leaf and flower-stems being beautifully mottled with purple and green, whilst in *H. niger* they are of a pale green colour. It also flowers much earlier—in some seasons in the beginning of October. I can find no reliable information as to its original source, but it has been known a long time under the names of *H. niger* var. major, maximus, giganteus, and grandiflorus.

Oriental Hellebore (*H. orientalis*).—This is the true Black Hellebore of the ancients, but is of comparatively recent introduction to our gardens, and is yet very rare; therefore is but imperfectly known. It belongs to a set with thick, leathery, dark green leaves, with five to seven divisions, with the two outer divided, each toothed almost to the base. The blossoms vary in colour from green to deep purple, and are produced on forked stems, which rise above the

foliage. The Oriental Hellebore is distinguished from the other kinds by the downy under surface of the leaf and the greenish-white blossoms, the rounded divisions of which overlap each other and are tinted at the margin with purple. It is found in parts of Turkey and Asia Minor.

Ancient Hellebore (*H. antiquorum*) is a kind differing from the above by both surfaces of the leaf being quite smooth and by the greenish-white colour of the flower without the suffusion of purple. It inhabits the Bithynian Mount Olympus.

Olympic Hellebore (*H. olympicus*).—This kind differs from the preceding in the much thinner texture of the leaves and more finely-toothed margins. The flowers are borne in the same manner, but are smaller and the divisions are not so spreading. The colour varies from pure to greenish-white, and on this account it has obtained several names, such as abchasians albus, kamtschatkensis albus, &c. It is a very handsome species, and flowers from February to April. As the specific name implies, it is a native of Mount Olympus.

Spotted Hellebore (*H. guttatus*).—This beautiful kind differs from the last only in the inside of the blossoms being marked with a purple or violet colour. There are several forms of it; in some the markings assume the form of small dots, in others in thin streaks. This is one of the parents of the beautiful hybrids that have lately emanated from Continental gardens, and still more may be done in improving the type by skilful cultivation. The best forms of this kind are, as yet, rare in gardens. It is a native of the Caucasus.

Pallid-flowered Hellebore (*H. pallidus*).—This differs from the two preceding by the blossoms being of firmer texture and less open, and not of such a pure whiteness as in *olympicus*. It is a native of the Caucasus.

Flowers Purple.

Colchican Hellebore (*H. colchicus*).—This is the finest of all the species, and attains a larger size than any other. It may be readily recognised by its thick, dark green leaves, with five to seven broad and coarsely toothed divisions, the veins of which are raised on the under sides and are of a dark purple colour when in a young state. The blossoms are borne on forked stems rising considerably above the foliage, of a very dark purple colour, which contrasts well with the yellow stamens and the striated scale-like petals. Under good cultivation, the leaves attain the length of 1½ ft. and 2 ft., forming fine specimens and producing flowers from the end of January to end of March. It is a native of the north-eastern part of Asia Minor. A fine hybrid has been obtained from it by crossing with *H. guttatus*, the result being a form with large spreading flowers of a lighter hue than in *H. colchicus*, and profusely marked with dark carmine streaks. Another hybrid between this and *H. altifolius* resulted in a form with larger flowers of a lighter purple.

Dark Purple Hellebore (*H. atrorubens*).—This name should have been applied to the last species, as the flowers of this scarcely merit the appellation of dark red. The leaves are much thinner in texture than *H. colchicus*, with finer toothings and smaller flowers, with the divisions not overlapping. The colour is dull purple on the outside and greenish-purple within. It is a native of Hungary, and is a common object of culture in gardens, but is often confused with the following kind.

Abchasian Hellebore (*H. abchasicus*).—This is a more slender and taller plant than the last, but the texture, size, and toothings of the leaves are much the same. The flower-stems are longer, with the space between the fork and the flower much wider. The blossoms are nodding and smaller, and the divisions overlap each other. It is a much superior kind to *atrorubens*, the colour of the blossoms, with a bunch of yellow stamens and the yellowish-green striated, scale-like petals, rendering them very attractive. It is said that this is also one of the parents of the fine hybrids, by crossing with *H. guttatus*. It is as yet rather uncommon in gardens, but many other kinds are designated as such. It is a native of the Caucasus, and has been known about ten years.

Flowers Green.

Caucasian Hellebore (*H. caucasicus*).—The leaves of this species are smooth and glossy and with broad divisions, which, combined with the pale green colour of the flowers, render it a very distinct kind. A native of the Caucasus.

Sweet Hellebore (*H. odoratus*).—This differs from the last in the downy under surface of the leaves and slight odour of the bright green flowers. It is found in various parts of Austria.

Group 2.—Leaves Dying Annually—Flowers Green.

Green Hellebore (*H. viridis*).—This plant, and the others comprising this group, differ in the much thinner texture and narrower

GIANT CHRISTMAS ROSE

divisions of the leaves, and in being deciduous. In *H. viridis* the number of divisions varies from seven to eleven, and they are sharply irregularly toothed. The flower-stems are about 1 ft. high, with narrowly divided stem leaves, and with from two to seven blossoms about 2 in. across, of a bright green colour. It is found in various parts of Europe, including Britain, where it is a rather rare native plant.

Flax-flowered Hellebore (*H. laxus*) differs from *H. viridis* by the greater length between the fork of the flower-stem and the flowers, which is of a paler green, and also by the finer toothed of the leaves. It is found in many parts of Austria.

Thicket Hellebore (*H. dametorum*).—A more slender kind than the two preceding, with smaller flowers and narrower and longer stem leaves. Also a native of Austria.

Circular-leaved Hellebore (*H. cyclophyllus*).—This is very rare in cultivation. It may be distinguished from the others of the group by the downy under surface of the leaves, deeply-forked flower-stem and bright green flowers. The leaflets also assume a circular form; hence its name. It is found at high elevations on some of the mountains of Greece.

Boccon's Hellebore (*H. Bocconi*).—A very distinct kind readily recognisable by the divisions of the leaves being cleft into three or four lobes. The blossoms are of a pale green colour, borne on forked stems, and from six to eight in number. It inhabits various parts of South-eastern Europe. It is known also under the names of *H. angustifolius* and *multifidus*.

Flowers Dull Purple.

Purplish Hellebore (*H. purpurascens*) much resembles the last form, from which it differs by the fewer and dull purple colour of the flowers. It is a native of Hungary.

Intermediate Hellebore (*H. intermedius*).—In habit and foliage this kind is nearly allied to *H. viridis*, but may be known by the smaller and dull purple flowers. It is found in various parts of Turkey.

Rank-smelling Hellebore (*H. graveolens*).—This also resembles *H. viridis*, with more blunt leaf divisions, and with flowers of a brown-purple colour on outside. A native of Hungary and other parts of Austria.

Coppery Hellebore (*H. cupreus*) differs from the last by the coarse toothed of the leaves, very prominent veins, broader divisions, and coppery hue of the blossoms. Also an Austrian species.

Group 3.—With Shrubby, Erect, Perennial Stems and Evergreen Leaves.

Holly-leaved Hellebore (*H. lividus*).—The specific name of this very distinct kind is so evident a misnomer that either of the names *H. argutifolius*, *ilicifolius*, *triphylus*, or *trifolius*, under which it is sometimes known, is far preferable. The *H. lividus*, described by Aiton in the last century, had livid flowers, but this has no tendency to assume that colour, and probably is another plant retained under the name. It is of erect habit, growing 2 ft. to 3 ft. high. It is the only Hellebore with a thrice divided leaf, and in the type is very sharply toothed, whilst in the variety *integrilobus* the margins are quite smooth. The rather small pale green flowers are borne in clusters of about twenty from the axils of the upper leaves. It forms very handsome specimens when well grown. A very distinct race of hybrids could, I think, be obtained by crossing this with the red or white-flowering kinds, but, as yet, I have not heard of its being done. It is found on several of the Mediterranean islands.

Fœtid Hellebore (*H. fœtidus*).—A very distinct native plant with handsome foliage. It grows to a height of 3 ft., with erect stems, on which are crowded its leathery, dull green leaves, with from seven to eleven narrow, toothed divisions. The flowers are borne in drooping clusters, and are small and globose, greenish, tipped with purple. It is widely spread over the western part of Europe.

For further information upon the hybrid Christmas Roses, a detailed description will be found in Vol. VII., p. 463, of THE GARDEN, and various other notes that have appeared at different times.

Culture.

All the kinds will thrive in ordinary garden soil, but for the choicer kinds a prepared soil is preferable, which should consist of equal parts of good fibry loam and well-decomposed manure, half part fibry peat, and half part coarse sand. Thorough drainage should always be given, as stagnant moisture is very injurious to them. A moist and sheltered

situation, and where they will obtain partial shade, is best suited to them, such as afforded at the margins of high shrubberies, &c., but care should be taken to keep the roots of the shrubs from exhausting the border in which the Hellebores are planted. In the flowering season a thin mulching of Moss or like material should be placed on the surface of the soil round the plants, as this prevents the blossoms from being bespattered by heavy rains, &c.

Propagation.

This may be done by division or by seeds, which, in favourable seasons, are produced plentifully; as soon as thoroughly ripened they should be sown in pans under glass, as they soon lose their vitality. As soon as the seedlings are large enough they should be pricked off thickly into a shady border, in a light, rich soil; the second year they should be transplanted to their permanent place, and in the third season the majority will produce blossoms. The process of division may be done either in the spring or autumn, the latter being the most preferable. In cutting into pieces the underground stems care should be taken that a leaf and roots are attached to each piece, or but ill success will be the result. The pieces should be potted in sandy soil, and kept in a close but cool frame until they are well rooted, after which they should be planted out.

The common Christmas Rose is perfectly amenable to forcing, for which purpose strong crowns with well-developed buds should be selected and potted in the autumn and gradually inured to a warm temperature.

Many of the kinds here enumerated are not what may be termed garden plants, especially the green-flowered section, but the foliage of some of them is not inelegant, and they are valuable for naturalising in the wild garden. G.

[The specimen from which our plate was prepared was supplied from Mr. Parker's nursery at Tooting.]

St. James's Park.—Somebody, with quaint notions of park management sends the following note to the "Times": "The most marked feature is the wholesale destruction of the Grass. Paths, needless and unsightly, are trampled hard all over it. The officials encourage this by putting up iron hurdles along the sides of the paths instead of checking the paths by putting the hurdles across; they wage war, too, on their own account on the Grass, cutting away wide margins by the formed paths, and substituting wastes of yellow gravel; they destroy the beauty and the life of trees by heaping up soil about them, or by leaving them to stand in pools; they let the ground remain strewn with filthy paper, dangerous to riders as it blows about; they spend great sums in artificialising, and fail to preserve the natural beauties, the varying surface, the trees, and the soft green Grass."

International Horticultural Exhibition of 1880.—This will attract the attention of all who are interested in horticulture, and London in that year will be the centre of horticultural energy. As the meeting will probably be held in May, the interval between the present time and the opening amounts to but little more than twenty months—time enough, but none too much to ensure the awakening of all interests whose co-operation is requisite to final success. As regards the general plan, there is as yet no division of opinion, and we not only hope there will not be, but we see not a shadow of a reason why there should be. Horticultural interests are at the present time healthily knit together; the Council of the Royal Horticultural Society is in accord with its constituents; provincial societies are thriving; trade will probably revive now that the Eastern Question is settled; and the horticultural papers appear to be on better terms with each other than they have ever been before. There is, therefore, at present nothing to hinder a general and cordial concurrence of activities in favour of the intended exhibition of 1880. If all those who can pull, however little or however much, will sink small and special considerations, in order to make a pull altogether, we shall come through 1880 with glory, and the world will be enabled to declare that it enjoyed its visit to London to see the great horticultural exhibition. A few things must, however, be done at once. The money box must be sent round. There must be an actual fund provided and a guarantee fund promised. There will need to be developed a considerable amount of organisation, the nest egg for which, fortunately, is in existence. And there are leaders wanted, who at the right moment will no doubt be found. There will be an apparently endless array of details to consider, but the end will come, and a right spirit of work will be wanted, as well as a certain degree of activity. The Council of the Royal Horticultural Society will probably set the ball rolling and then leave the government of the whole affair to a special committee. In the formation of that committee lies for the present the vital germs of the whole affair. It must be characterised by breadth. If any particular party or interest has undue prominence in it, a blight will spread over the whole affair and mar its completeness, to the discredit of the self-seeking. We do not fear any such catastrophe, but, on the other hand, hope for the best every way.—"Gardeners' Magazine."

GARDENING FOR THE WEEK.

Indoor Plant Department.

Shifting Spring-potted Roses.—Roses, either struck from cuttings last year and transferred in the spring from small pots into others somewhat larger, or that were taken up from the open ground and moved into pots with a view to their being forced the ensuing winter and spring, will, in some cases, have made more growth than might have been anticipated, completely filling the soil with roots. Roses, more than most plants, should not be over potted, but, where in the condition above described, although somewhat late in the season, I should recommend their receiving a moderate shift, for though they may not be expected to make much more top-growth after this time, still, if the means have been taken as recommended through the season to keep the foliage free from insects and mildew, it will yet remain for a long time fresh and healthy on the plants, in which case such as are newly shifted will keep on rooting freely until late in the autumn, and will thus accumulate strength, which will enable them to bear forcing and to flower much stronger than they would by potting immediately before forcing was commenced, for it should ever be borne in mind that with Roses more than most plants, the flower they are able to produce in any given season is much more consequent on the strength stored up in the plant than anything resulting from the most liberal treatment immediately preceding their blooming.

Potting Roses Struck in the Open Ground.—Roses intended for pot culture struck from cuttings inserted last autumn in the open ground with merely the protection of hand-lights or frames through the winter, these being removed when growth fairly commenced, may, although full of green foliage and yet making growth, still be potted if this has not been done, and if the operation be carefully performed, they will make roots and get established before winter in a way that will enable their making more progress next summer than if the potting were deferred until late in the autumn or till spring. This is particularly the case with the Tea varieties, which, except in the most favoured localities, if left out will require protection of some sort through the winter. The pots used should not be larger than necessary, and the plants ought to be taken up very carefully so as to break the roots as little as possible. There will not be much difficulty experienced in this if the soil in which the cuttings were put had a moderate amount of sand mixed with it, such as usual. Pot firmly, water moderately at the time of potting, and stand them in a pit or deep frame on a moist bottom, keep close with only a little air admitted for a couple of weeks, giving a slight shade when the sun is powerful, damping them overhead with the syringe once a day when the weather is warm, gradually giving more air until they will bear full exposure. By this method I have had much better and stronger plants at the twelve months' end from the time the cuttings were put in than when confined the whole of the time to pots, unless where they have been pushed on under glass during the spring and summer.

Pot Roses Intended for Blooming at Christmas.—Keep a vigilant eye upon the plants that are intended to flower under glass towards the end of the year from buds formed in the open air previous to their being moved inside. Every means should be taken to promote growth by keeping the whole of the foliage healthy and clear from mildew, aphides, and red spider, by an adequate supply of water whilst the weather keeps hot, and the removal of any flower-buds now being formed, which, if retained, would open before the time required. The plants should by no means at any season be allowed to stand too closely together, but, from this time forward, through the autumn, the effects of crowding would be worse than earlier. These Roses, as a matter of course, are not intended to be forced, but simply to open their flowers in an ordinary greenhouse temperature, and for this purpose will principally consist of the Tea varieties.

Roses for the Earliest Forcing.—Such Roses as are intended for forcing, to give a succession after the last-named plants have done flowering, should also consist to a considerable extent of Tea kinds or Hybrid Perpetuals; these must now be well attended to by still keeping the foliage quite clean and giving enough water in dry weather to prevent any approach to flagging. No further liquid stimulants are necessary for them, as the principal object now should not be to excite further growth, but to get that which is already made fully matured. They should have a perfectly open situation, not stood, as these plants are often seen, under the shade of walls or trees, suffering from neglect in a way that precludes the possibility of their answering to the trying process to which they, in common with all hardy plants, are subjected in forcing.

Rose Cuttings.—The batch of these advised to be put in a few weeks back in pots, and confined in a close, cold frame until they have callused, will by this time have arrived at a condition that will permit of their being subjected to gentle bottom-heat, which they should at once receive, paying them every attention, so as to induce the formation of roots and get them fairly established whilst there is solar warmth and length of day to admit of this, for unless they make sufficient progress at the roots, with some shoot growth, they are in a worse position to stand through the winter than cuttings that are put in late and not expected to root until warmth is applied to them late in the winter.

Budded Roses.—Those that were budded the first should now be looked over and the ties slackened, otherwise, through the thickening of the shoots, the bark will be all but cut through so far that the shoots are liable to be broken off by the wind, in which case the labour bestowed will be lost, as well as the season's growth. Where the buds inserted

have started into growth the shoots beyond the junction may be considerably shortened so as to direct the current of growth to the development of the bud-shoot, yet too much of the stock shoots should not be cut away, or the operation will have a corresponding influence in checking the roots, a circumstance that by no means should occur.

Removal of Suckers.—One of the worst evils connected with standard and half-standard Roses, especially when budded on the Brier stock, is their disposition to produce root-suckers. In the spring, when the Roses are receiving the most attention, these are usually removed, but now, when the principal blooming time is over, vigilance in their removal is frequently relaxed, and they are little interfered with, yet it is quite as necessary to take them off now as it is earlier in the season, otherwise they will seriously interfere with the strength and substance which the present season's growth should attain.

Indoor Climbing Roses.—Strong-growing varieties, such as *Maréchal Niel*, *Lamarque*, and others of similar habit, that, after blooming had a considerable portion of their old wood cut away, with a view to the production of strong shoots intended to flower next year, should have the growth of these encouraged by all available means, for upon the development and strength of these in a great measure will depend their next year's flowering abilities. Such shoots as above referred to will yet make a good deal of progress, to assist which, if the soil in which the roots are placed be at all poor or limited in amount, it should be frequently applied with liquid stimulants and the foliage kept quite free from their two great enemies, insects and mildew, without which it is useless to expect the formation of growth of a character able to bear a full complement of fine flowers. It is at this season of the year, when there are so many other subjects requiring attention, that indoor climbing Roses are liable to get neglected in this particular matter, and to it may be attributed the fact that when grown on the rafters or roofs of ordinary plant houses they are so frequently worse managed than any of the other occupants.

Soot Water for Pot Roses.—It may be well to again allude to the necessity for the frequent use of this. Worms have a particular liking for the soil in pots where rich manures are used; on this account there are no plants grown that suffer more from their attacks than Roses. The fact of their bearing strong stimulants admits of the soot water being applied somewhat stronger than would be safe to use for many plants. Before giving it it is well to let the plants get as dry as can be safely done without the foliage being injured; then give a thorough soaking, the effect of which is that generally in a few minutes the worms, especially the large red ones, make their appearance above the surface, when they can be removed.—T. BAINEs.

Stoves.—Such free-flowering plants as *Bougainvillea glabra*, *Allamanda*, and plants of that class having only a limited feeding ground through being grown in pots or planted in confined spaces, should now be liberally supplied with manure water in order to enable them to continue blooming late in the autumn, a time when they will be of much more value than they are now. With such vigorous-growing plants as the above there need be no fear of exhaustion from keeping them in a flowering state too long, as with plenty of stimulating matter applied to the roots they may be had in bloom at least six months out of the twelve, and will start away again in the spring as freely as ever. A top-dressing of thoroughly decomposed manure, such as has been in use for mulching Vine borders, may with advantage be laid over the soil so as to encourage surface roots and obviate the necessity of having to water the plants so frequently.

Gardenias.—Young growing plants of these should now have a final shift so as to get them thoroughly established and the pots well filled with roots before autumn sets in. Nothing suits these so well as good, rough, fibry peat, with just sufficient sand in it to keep it open and porous in order that water, of which they like large quantities when growing, may pass freely through it. A pit or frame where they can be plunged in a bed of gently fermenting leaves or tan is the best place in which to grow them, as there they can be heavily syringed and shut up close early in the afternoon, a course of treatment that expedites growth and helps to keep them free from mealy bug, a pest to which they are unfortunately rather subject. Where any are infested with this troublesome pest the only remedy just now is hand cleaning, as it will not be safe, owing to the soft state of both leaves and the tips of the shoots, to use any of the insecticides sufficiently strong to destroy them. Keep the plants well up to the light, in order that the growth they make may be firm and mature, without which they do not flower at all freely.

Greenhouses.—When dry, parching winds prevail accompanied by brilliant sunshine. It is a matter of some difficulty to keep up anything like the necessary amount of atmospheric moisture to maintain the various kinds of plants in a healthy, growing state. While such weather continues every effort must be made to counteract its effects as far as possible by well wetting the under part of the stages among the pots, and indeed every part of the house where water can be used without being objectionable. Much watchfulness will likewise be requisite to see that hard-wooded plants do not become dry at the roots, to prevent which they should now be looked over both morning and evening. Azaleas, especially, will require much attention in this respect, as they now take up great quantities of water, and any deficiency as regards moisture is sure to show itself in the small size and paucity of the flowers when the season arrives for them to be produced. Where any are found to have thrips on their leaves, means should at once be taken to destroy them, or they will soon initiate themselves into the points of the shoots, and cause irreparable injury to the buds now forming. Although only a few of

these pests may be observable now, they increase at such a rapid rate if left to themselves, as to soon spread over a whole household of plants. The stock of autumn and winter-flowering plants will require unremitting attention. *Rhodanthe Manglesii* is one of the most charming and useful plants it is possible to have for early spring blooming, seed for which for them to bloom at that time should be got in at once. Their lovely pink, satin-like flowers are always greatly admired, but they never show to so much advantage or get so fully appreciated as when cultivated in pots. The seed should be sown in a pan of light rich soil, which should then be kept close under glass till they germinate. As soon as large enough to handle, prick out into 3-in. pots, placing five or six plants in each equidistant apart, after which stand them in a frame, and keep them close and shaded for a few days to give them a start. Damp is their great enemy during the winter months, and to guard against this they must be carefully supplied with water so as not to wet them overhead or keep them too moist at the root. A shelf near the glass, where they can have a free circulation of air, is the best place to winter them, and at the turn of the year they should be gradually shifted on into larger pots, as they require more root-room. After that time they must have a moist, growing temperature, such as an intermediate house affords, and be grown on from then without check till they attain the desired size. The tendency of *Rhodanthes* to produce bloom is so great that, unless they are liberally treated and pushed on by giving them every encouragement, both as regards rich soil and a moist, warm atmosphere before the sun bears much power, it is almost impossible to get them of sufficient size to be really effective. In shifting them on they should therefore have a small portion of thoroughly rotten manure mixed with the leaf-mould and loam in which they are potted, the latter of which should be in about equal proportions. By affording them a rich, stimulating soil of this kind, and giving them plenty of manure water, 6 in. pots will be quite large enough to grow them in, a size that looks more suited to the habit of the plant than others of greater dimensions. Among five-foliaged plants available for greenhouse or conservatory decoration *Marantas* should have a foremost place assigned them, as few plants are more highly prized or produce a better effect than these. They dislike sunshine or dry air, and, therefore, in arranging they should have the most favourable position that can be selected for them. Soft-wooded flowering plants, such as *Balsams*, *Begonias*, *Petunias*, *Achimeas*, *Pelargoniums*, &c., must not be allowed to suffer from lack of water, or they soon shed their bloom and present a shabby appearance. The single zonal *Pelargoniums* will be found to seed rather freely, and, in order to prolong their flowering to the utmost, the whole of it should be picked off as soon as the petals fall, as seed-bearing is a great tax on the plants.

Solanums.—Plants of *S. Capsicastrum* and *S. Pseudo-Capsicum* should now receive sufficient water at the roots, or the berries will not swell freely. Look over them closely from time to time in order to see that the leaves do not get affected with red spider, or this pest will quickly turn them quite yellow, after which they have an uninviting appearance. Where they are grown through the summer in pots they need much attention in this way to keep up the deep green colour of their foliage, which will be greatly benefited by the use of manure water once or twice a week.

Salvias and Veronicas for flowering later in the season, and now set out-of-doors, will by this time have filled their pots with roots, and will require diligent attention in the way of watering. Give them weak liquid stimulants twice a week; this is the more necessary if the pots which they occupy be small compared with the size of the plants. All such plants are better for being plunged through the summer, for in this way they do not need so much care in watering, nor are they so liable to suffer if unobersably the soil get a little dry. In all cases, however, where plants are plunged it is essential that the material in which they are thus placed should be such as will not harbour worms, or they will get in amongst the roots, especially when manure water is used, for which they appear to have a particular liking, and even to strong-habited subjects like the above they soon do serious injury.

Cyclamens that have been somewhat at rest during the summer, and which have now commenced growing, should be repotted, removing all the old soil and replacing it with new material. Some prefer a peaty soil, others loam and leaf-mould, with some manure added in all cases, using sand enough to keep it sufficiently open; put moderately firm, and do not give them too much room (an 8-in. pot will be found of sufficient size for a very large root). After potting, put them in a frame or pit, and keep them a little close, sprinkling them overhead in the afternoons of warm days. These plants, although generally looked upon as succeeding with ordinary greenhouse temperature, are better for being kept a few degrees warmer than is usual for many greenhouse subjects. Keep a constant eye upon them, in order to see that they do not become affected with green fly, to which they are very liable; it gets unobserved on the under sides of the leaves, and frequently before it is noticed so injures them as to do serious mischief to the plants, especially whilst the leaves are young. Fumigating or dipping will rid them of this insect.

Chrysanthemums.—No plants are more useful or more easily grown than *Chrysanthemums*, and that are often seen below mediocrity than otherwise, and this generally through an insufficiency of water in some stage of their growth. After the roots have got fairly hold of the soil in their blooming pots, they should receive strong manure water every other time they are watered. They will bear it as strong as any plant in cultivation. The Mushroom-shaped style of training is the most in favour with those who grow them for exhibition, but it is unnatural and

useless for general decorative purposes. Plants of the larger varieties, confined to from two to five shoots each, neatly tied to a stick, the head of the plant brought out to about twice or thrice the diameter of the pots they occupy, will be found the most useful, and this will give them ample room for the development of their foliage, which, if they are well grown, will be of the darkest green. As the shoots of the large kinds branch out in growth, they should be thinned to the number of flowers the plants are intended to carry, leaving one flower to each shoot. The plants will carry from six to eighteen, according to their strength. To those who have not tried this thinning process, it may appear a great sacrifice in quantity; but either for cutting or for decoration on the plant, one good flower is worth three inferior ones, and flowers so treated will last fresh on the plant fully a third longer than others that have been insufficiently thinned. The *Pompones* also require thinning, but not so much as the large varieties, neither in the reduction of the number of shoots nor to the number of flowers each shoot will carry; these may be left from three to half-a-dozen to each terminal shoot.

Striking Cuttings.—Many find considerable difficulty in striking tricolor *Pelargoniums*. The want of success with these, as compared with other kinds, is attributable to the cuttings not being put in at the most suitable time and managed in the way best calculated to insure their rooting. There is no way in which they do better than when put in about the middle of the present month. Inserting half-a-dozen cuttings, each in 6-in. pots, placed in the open air right in the full sun, drain the pots in the usual manner, and fill them up with ordinary loam sifted, to which add one-half sand; take the cuttings off and prepare them for putting in by removing the bottom leaves, leaving three or four at the top, according to the size of the cutting, remembering that the larger the cutting, provided it be not too rank in growth and soft, the better plant it will generally make in a limited time. Before putting them in allow them to lie on the potting bench for a day, as is usual with the ordinary varieties, so as to allow the base to dry up a little. When they are inserted press the soil tightly to them and give a sprinkling of water. The principal advantage in striking these variegated kinds of *Pelargoniums* out-of-doors at this season is that they will bear a good deal more water without danger of rotting than can be given to them as a time of the year which necessitates their being struck in pits or frames either with or without artificial heat; the great point gained is that they do not lose so many leaves, that they root quickly, and that they make strong plants before autumn, much better calculated to stand the winter than would otherwise be the case. The earlier in the summer suitable cuttings can be got the better they will succeed managed in this way. A dozen plants rooted thus early and kept on growing slowly through the winter will, at bedding-out time, fill as much space as double the number of late-struck small plants. The fine old *Lobelias* of the cardinalis section are not now nearly so much grown as they deserve to be. If these and some other similar-habited subjects were used in sufficient number amongst bedding plants of more procumbent habit, much of the objectionable formality of the latter would be avoided. They are easily grown, easily wintered, and more effective in appearance. There are now a number of fine hybrids varying much in the shade of their flowers, and also in their size and substance. It is well for those who purchase new expensive varieties of *Dablias* to strike a few cuttings of each at this time, as it sometimes happens that the old roots perish in the winter, in which case cuttings struck now will supply their place, and will often produce cuttings in spring more freely than the larger roots. They should be taken off at a joint similarly to the spring cuttings, inserting them singly in 3-in. pots with a little drainage in the bottom, and filling with fine sandy soil, with a little sand on the surface. Keep them under bell-glasses or in the garden frame, shaded from the sun, and sufficiently moist to prevent their flagging. In this way they will root through the pots and not require more room, as they will get sustenance from the roots that thus get into the soil through the little pots, the latter getting quite filled with the tubers. When the tops are ready for removal in the autumn, the pots with the roots in them will merely need putting in a dry place out of the reach of frost.

Indoor Fruit Department.

Melons.—As soon as there is any appearance of cold weather, some fermenting material should be put round the beds. If there be a scarcity of hot stable manure, any kind of vegetable haulm, mixed with Grass mowings, may be used. Keep the shoots well thinned out, overcrowding being one of the greatest mistakes that can be committed in Melon culture, and at no season are its consequences so injurious as in the autumn, when the sun's power is declining. Raise the fruit well up on inverted flower-pots as it begins to ripen, in order that it may be fully exposed to the sun. As it approaches maturity discontinue syringing, and be careful not to give the soil too much water. It is necessary at this time of the year to use less than earlier in the summer, or it will interfere with the flavour, and be liable to cause the fruit to crack.

Cucumbers in frames should, as recommended earlier, be stopped at every joint where they show fruit, a practice which tends to prevent their getting so much crowded with superabundant shoots, as they otherwise would be; but even under this treatment they will get too full of growth unless the knife is freely used from time to time in removing all that is not required. Where Cucumbers are wanted as late in the season as they can be had, and where there are no means of growing them, except in ordinary garden frames, they should be assisted with manure water regularly after they have been some time in bearing, and, above all, cautiously syringed, getting to every part of the leaf-surface, so as to keep them free from insects, without which all other attention will be unavailing. Where there

are bones or pits in which to grow Melons and Cucumbers, the above directions are equally applicable.

Tomatoes.—Towards the middle of the month these will be at their best, as regards quantity of fruit, but it will be towards the end of the month before the ripe fruit can be seen to advantage. As soon as any of the fruits begin to colour, prune in the leaves and laterals pretty closely, so as to freely expose the fruits to bright sunshine. Some growers prefer allowing them to colour and to fully ripen on the plants; others, on the other hand, gather them immediately they begin to colour and place them on a layer of straw near the glass under ashes in frames. Under such conditions they ripen pretty well, and by removing them early from the plants, the remaining fruits have a better chance to swell and ripen.

Hardy Fruit.

Newly-planted Strawberries must be attended to with water, if the weather be dry, or they will suffer to an extent that will greatly interfere with their bearing capabilities the ensuing season. The same applies to Strawberries in pots. Those who cultivate Strawberries in pots may rest assured that a good deal of their success depends on the plants being plentifully supplied with water so long as they are making any growth. Place them in the full sun on slates or boards in a square as close as the pots will stand. By this means they will protect each other from the full force of the sun, which, coming in contact with their sides while at all powerful, is injurious to the roots of any plant grown in pots.

Kitchen Garden.

Celery.—The particular time at which Celery is wanted for use, in the autumn, should regulate the period at which it should be earthed up, for it is not advisable to do this fully thus early in the season, unless it is required for use as soon as blanched, for, when the earthing-up process is completed, it does not afterwards keep so well. There are many who do not value this vegetable whilst summer Lettuces can be had, consequently, where this is the case, it is better not to draw more earth to the rows than is necessary to keep the leaves in an upright position and prevent them from being broken down by the wind. Crops intended for use as soon as they are large enough for the purposes for which they are required should be gone over at once; a few of the small outside leaves and all suckers should be removed, and the whole of the remaining leaves should then be brought together in the hand and tied loosely with a ligature of bast high up the stalks; in fact, just beneath the leaves. If the tie is not slack it does not allow the centre leaves, that are now pushing up, room to grow, in which case they become deformed and spoilt. Hand-pick all weeds that are growing in the trench, give a good soaking with manure water, and then apply 6 in. of fine soil to it; draw the stalks tightly together with one hand, whilst with the other the earth is placed close up to the plants. If this is not done the soil gets into the hearts, causing decay. In the course of a fortnight add another 6 in., carrying on the work as above described, and, after the lapse of a similar period, finish off with 6 in. more, leaving the sides of the ridge sloping and smoothed with the back of the spade so as to throw off wet. It is not good practice, except in the case of the general winter crop, to finish the earthing up of more Celery than will serve for a month or so, for if much is earthed up early in the autumn in a dry season it suffers from want of water, for, as will be easily understood, when the soiling up is complete little can reach the roots. Always allow the leaves of Celery to get quite dry before earthing up, or it is liable to rot. In carrying out the work care should be taken that the roots are not interfered with. This will not occur if, at the time of planting, sufficient room was left between the rows. The use of paper tied loosely round the plants before they are earthed up, with a view to keeping the earth out of the hearts, is advocated by some, but, even when quite thin and good in quality, it always gives a disagreeable taste to the stalks.

Vegetable Marrows.—This crop is now at its best, and some of the most vigorous shoots will require attention as regards pegging down, or placing bits of bricks or stones on them to keep them down and cause them to root. In dry weather water them abundantly, so as to keep them in vigorous health and to prevent the attacks of mildew. Do not allow the fruit to become too old before it is gathered.

Extracts from my Diary.

August 26.—Sowing Black-seeded Brown Cos, Stanstead Park, and All the Year Round Lettuces; Fraser's Broad leaved and Green-curl'd Endive. Manuring and digging borders for Endive and Lettuce. Earthing up Celery and Cardoons when the soil is dry and in suitable condition. Gathering ripe Peaches, Nectarines, Pears, Figs, and Plums, and putting them away in a dry, cool place to keep as long as possible. Watering Pines, newly-planted Strawberries, Endive, and Lettuce.

Aug. 27.—Sowing Intermediate Stocks and Red and White Turnip Radishes. Potting Mr. Pollock and other tricolor Pelargoniums. Staking Laxton's Unique Peas. Thinning Spinach. Clearing out a pit ready for Cucumbers. Looking over Cucumbers and Melons, stopping their shoots, and removing dead leaves, &c. Watering Vine borders, Peach trees, Scarlet Runner Beans, and Carrots.

Aug. 28.—Sowing Sweet Basil for winter use and Mustard and Cress in succession. Putting in Cuttings of Viola Blue Perfection and Golden Gem under handlights against a north wall. Planting a small breadth of Leeks for spring use. Thinning out Vegetable Marrows and closely stopping their shoots. Filling in all Cauliflower drills, giving them a good

earthing. Forking over the ground between Cabbage plants. Gathering Green Gage Plums and Morello Cherries for preserving. Watering late-sown Peas, Dwarf Beans, Celery, Endive, and Lettuce.

Aug. 29.—Sowing Turnips. Putting in cuttings of Heliotropes, Cupheas, and Ageratums. Transplanting Wallflowers, Antirrhinums, and Cauliflowers. Giving all Peach and Nectarine trees a good syringing where the fruit is gathered. Gathering Tomatoes and Devonshire Quarrenden Apples. Spawning a new Mushroom bed and preparing more manure for another. Digging up ground previously occupied by Peas for planting with Coleworts. Giving Peach trees from which the fruit has been gathered a good soaking with water at the roots.

Aug. 30.—Potting off Fuchsias, Verbenas, and Cucumber plants. Putting in cuttings of Salvia splendens and Lobelia pumila. Cutting back and nailing Roses on walls. Clearing off Peas and heavily manuring the ground, afterwards digging it up roughly to remain through the winter. Gathering Victoria Plums and Noblesse Peaches for preserving. Thinning Turnips, Spinach, and Lettuce. Watering Pines, late-planted Strawberries, Cauliflowers, and Carrots.

Aug. 31.—Potting seedling Cyclameus. Planting Endive and Lettuces under the walls. Weeding Strawberries and cutting off the runners which were laid in pots. Emptying and refilling Grape bottles with spring water with a little charcoal added. Cutting and stacking away turf. Gathering Lord Suffield Apples and Jargonelle Pears. Watering Cauliflowers, late-planted Celery, Lettuce, and Endive. Fruit in use for dessert: Pines, Grapes, Peaches, Nectarine, Pears, Figs, and Plums.—W. G. P., Dorset.

GARDEN BOTANY.

(Continued from p. 161.)

NUMBER OF CELLS IN THE OVARY.—The number of cells in an apocarpous ovary is never more than one originally, though, as in the large genus *Astragalus* (Leguminosæ), the ripe seed-pod is more or less completely two-celled by the ingrowth of the dorsal or lower suture. The sutures are the longitudinal lines on the pod corresponding to the midrib and confluent margins of the carpellary leaf. On the other hand, syncarpous ovaries vary from one to many-celled. As already

Fig. 469a. — Ovary, which is four-celled at the base and one-celled at the top.

Fig. 469b. — Ovary, which is five-celled at the base and only one-celled in the upper part.

observed, the number of carpels is sometimes inferred from the number of branches or lobes of the styles. It is open to doubt, however, whether this is an infallible test, because there seems to be no valid reason why the style of a single carpel should not be branched. But, accepting this test, the whole of the ten thousand, or thereabouts, species of the Compositæ have a one-celled ovary composed of two carpels. In the Thrift family the ovary is one-celled with five distinct styles. The Cruciferae have a two-celled ovary, resulting from the development of a partition (septum) from the cellular tissue of the opposite placentas (see next paragraph); but this is, nevertheless, a syncarpous pistil. Many dicotyledonous families are characterised by having a two-celled ovary; thus, Umbelliferae (Parsley), Boraginæ (Myosotis), Solanacæ (Nicotiana), Scrophulariacæ (Antirrhinum), and Labiatæ (Salvia). The last-named family and the Boraginæ have almost perfectly four-celled seed-vessels, from the growing inwards of the dorsal suture finally forming four one-seeded nuts, which fall away separately. Nearly all monocotyledonous plants (Lilies, Irises, &c.) have a three-celled ovary; Orchids, however, have only a one-celled ovary. Among dicotyledons a three-celled ovary is common in the Euphorbiacæ and Malpighiacæ. A four-celled ovary is characteristic of Heaths and the Onagariacæ (Fuchsia and Epilobium); and Pelargonium, Linum, Apple, and numerous other genera have five cells in the ovary, but no family of any extent is characterised by having this number, though five obtains for sepals, petals, and

stamens. In *Linum* the seed-vessel becomes ten-celled by the infolding of the back of the carpels. When the number of cells exceeds six the ovary is commonly described as many-celled, as the actual number is often inconstant in the same species. Thus, in the Mallow there are ten or twelve, or more. It may be mentioned here that there is no hard and fast line between apocarpous and syncarpous pistils. The ovary of Mallow, for instance, is syncarpous, but when the seed-vessel is ripe the carpels separate from each other and the axis and fall away separately. Something of the same sort

Fig. 469c.—Ovary, which is one-celled in the upper part and four-celled at the base, the walls sloping downwards from the circumference to the centre.

occurs in *Pelargonium* and *Geranium*. With a few exceptions, the cells of an ovary are on the same level, not one above the other. The ovary of the Pomegranate is one of the most noteworthy exceptions; here there are two whorls of cells one above the other. An occasional, though rare, occurrence is

Fig. 470.—Diagram of the flower of *Mesembryanthemum violaceum*, the cells of the ovary superposed to the sepals.

Fig. 471.—Diagram of the flower of *Geranium Robertianum*; cells of the ovary alternate with the sepals.

the separation of the ovary into cells in the upper or lower part, but not throughout (see fig. 469, *a*, *b*, and *c*).

POSITION OF THE CELLS OF THE OVARY IN RELATION TO THE PARTS OF THE FLORAL ENVELOPES.—When the number of the cells of the ovary is the same as the parts of the calyx, they

Fig. 472.—Diagram of a Lily flower; the cells of the ovary superposed to the outer divisions of the perianth.

Fig. 473.—Diagram of the flower of *Cneorum tricoccum*; the cells of the ovary superposed to the petals.

are sometimes superposed to them, as in *Mesembryanthemum* (fig. 470), but much oftener alternate with the sepals (fig. 471). On the other hand, in nearly all monocotyledons they are superposed to the outer divisions of the perianth (fig. 472). In the dicotyledonous *Cneorum* (fig. 473) they are superposed to the petals, answering to the inner divisions of the perianth of Lilies. When the number of cells of the ovary is much larger than the number of sepals, as in *Kitabelia* (fig. 474) and *Malope* (fig. 475), they are in clusters superposed to the petals. In the two-celled ovaries of *Solanaceæ*, &c. (figs. 476 and 477), one of the cells is anterior and the other posterior, whilst in the three-celled ovary of *Malpighia urens* (fig. 478) the cells

are superposed to three of the sepals. On the contrary, the three cells of the ovary of the Horse Chestnut are superposed

Fig. 474.—Flower of *Kitabelia vitiifolia*, showing the relative position of the carpels and other parts.

Fig. 475.—Flower of *Malope trifida*, showing the position of the carpels in relation to the other parts of the flower.

to three of the petals, and consequently alternate with the sepals. Hitherto little use has been made in classification of

Fig. 476.—Diagram of the floral structure of *Lobelia urens*; ovary two-celled, the cells anterior and posterior.

Fig. 477.—Diagram of the floral structure of *Solanum dulcamara*; ovary two-celled, the cells anterior and posterior.

the position of the parts of a flower with regard to each other and the mother axis, but the importance of the characters

afforded by the plan of the flower is beginning to be recognised.

Fig. 49.—Pistil of Violet.

Fig. 481.—Pistil of Violet cut transversely through the ovary, showing the three parietal placentas.

THE PLACENTA.—The part of the ovary to which the ovules are attached and through which they are nourished is termed

the placenta, whether there is any special thickening or conformation or not. There are two principal types of placentation—parietal and axile.

PARIETAL PLACENTATION is confined to the ovaries of some apocarpous pistils, and some of the syncarpous pistils with only one cell, or, in other words, parietal placentation, only occurs in one-celled ovaries, but not all one-celled ovaries have this kind of placentation. Sometimes, however, the parietal placentas ultimately meet in the centre of the ovary,

Fig. 492.—Ovary of *Nemophila phacelioides*, torn open to show the two half-circular parietal placentas, which nearly meet at the sides.

Fig. 483.—Ovary of *Eutoca viscida*, cut transversely and torn open on one side to show the two parietal placentas, which almost extend to the centre.

which is thus more than one-celled. In this kind of placentation the ovules are attached to the outside walls of the ovary, or to the partial partitions proceeding therefrom. The ovary of a Violet (fig. 481) has three longitudinal parietal placentas, and when the seed-vessel is ripe it splits open in three valves with a row of seeds down the centre of each valve. The inferior ovary of the Cucumber and Melon has three parietal placentas, though it is only in quite a young state that this can be observed; subsequently the intervening space is filled with pulp, and in the mature fruit the placentas appear to proceed from a central axis. In the superior ovary of *Nemophila* (fig. 482), and also of *Eutoca* (fig. 483), there are two parietal placentas. Here the placenta itself is a distinct outgrowth, as in the Cucumber, in both cases nearly meeting in the centre of the ovary. The inferior ovary of the Gooseberry has two parietal placentas, and the seeds are suspended on long stalks in the pulp of the ripe fruit. In the Poppy (fig. 484) the placentas are numerous, and consist of thin plates extending

Fig. 484.—Ovary of Poppy, cut across, to show the numerous placental plates, which nearly meet in the centre.

Fig. 485.—Ovary of Stock, showing the ovules attached to the outer walls, and the ovary divided by a spurious septum.

almost to the centre of the ovary, and bearing ovules on both sides. The placentation of the Cruciferae (fig. 485) is also parietal; but, as already explained, the ovary becomes two-celled by an outgrowth of the opposite placentas. This partition is called a spurious septum or dissepiment. It is usually thin and transparent, persistent with the framework, if we may so call it, of the fruit after the valves and seeds have fallen away. It is very conspicuous in the oval or oblong seed-vessels of *Honesty* (*Lunaria biennis*). All the foregoing modifications of parietal placentation belong to syncarpous

ovaries, but there is much the same range of variation in the ovaries of apocarpous pistils. In *Astrocarpus*, a member of the Mignonette family, the apocarpous pistil consists of several carpels, each bearing a single ovule on its outer or dorsal wall (fig. 487). *Mignonette* itself, we may mention, has a syn-

Fig. 486.—One of the carpels of a pistil of *Astrocarpus sesamoides*.

Fig. 487.—One of the carpels of *Astrocarpus*, torn open to show the solitary seed inserted on the dorsal wall.

carpous pistil with three parietal placentas. The pistil of Christmas Rose (*Helleborus*—fig. 488) is made up of several carpels, each bearing a double row of ovules down the inner or ventral side. This is sometimes distinguished as marginal or sutural placentation; it is common in the Leguminosae

Fig. 488.—Section of a carpel of *Helleborus*, showing the attachment of the ovules down the inner or ventral side.

Fig. 489.—A carpel of *Butomus*, cut transversely to show the placentation of the ovules all over the surface.

Fig. 490.—Transverse section of the ovary of a Tulip, showing the axile placentation of the ovules.

Finally, the ovules are spread all over the interior of the ovaries in the Flowering Rush (*Butomus umbellatus*—fig. 489); that is to say, the placenta is of the same extent as the cell wall. This condition, as well as that described for the Poppy, is exceedingly rare; in fact, quite exceptional.

Fig. 491.—Pistil of Chinese Primrose.

Fig. 492.—Pistil of Chinese Primrose, cut transversely through the ovary to show the central placenta.

AXILE PLACENTATION.—As the term implies, the placentation is termed axile when the ovules are attached to the centre of the floral axis or the inner angles of the cells of the ovary, as in the Tulip (fig. 490). This kind of placentation is found both in inferior and superior ovaries. When the ovary is one-

celled, and the ovules are borne upon a central expansion, the placentation is free and central. It is one of the characters of the Primulaceæ (figs. 491 to 494) to have a free central placenta. In some of the Caryophyllææ (Dianthus, &c.) the column bearing the ovules reaches nearly or quite to the top of the ovary, the latter often being several-celled at the base, at

Fig. 493.—Pistil of *Anagallis arvensis*, with the persistent calyx at the base and an obscurely five-lobed stigma.

Fig. 494.—Pistil of *Anagallis arvensis*, the ovary separated from the axis, showing the free central placenta.

least when young, and only one-celled at the apex. A common form of axile placenta in the two-celled group is the cylindrical, *Scrophularia* (fig. 495). *Begonia incarnata* (fig. 496) has a three-celled ovary, with a placental plate projecting from the axis far into each cell; in fact, nearly reaching the outside, and

Fig. 495.—Cross section of an ovary of *Scrophularia*, showing the circular fleshy placentas projecting from the axis into each cell.

Fig. 496.—Cross section of an ovary of *Begonia incarnata*, showing the axile placental plates covered with ovules.

thickly studded all over with ovules. In *Leucopogon Cunninghami* (fig. 497) the ovary is several-celled, and the ovules are attached to placental bodies pendulous from the upper part of the inner angle of the cell. It has been stated that parietal placentation occurs only in one-celled ovaries, but

Fig. 497.—Pistil of *Leucopogon Cunninghami*, with one cell of the ovary torn open, the pendulous placenta covered with ovules.

Fig. 498.—Section of the many-celled ovary of *Mesembryanthemum*, showing the attachment of the ovules to fleshy placentas apparently proceeding from the exterior wall of the ovary.

something very like it may be seen in the many-celled ovary of *Mesembryanthemum edule* (fig. 498). The ovules spring from fleshy placentas projecting into the cells from the external wall, and apparently having their origin in it, though in a very early stage of the flower this would appear not to be the case.

W. B. HEMSLEY.

THE INDOOR GARDEN.

FREE-FLOWERING CACTI.

I HAVE read with much interest the remarks of a correspondent, and also those of Mr. Croucher (Vol. XIII., p. 353), on this subject, for it reminds me of earlier days when I used to read with so much gratification the reports of the grand shows of these plants made by Mr. Green and others, and the interesting articles about them by the late Mr. Beaton in "Loudon's Magazine," and also of the fact that in 1837, in connection with an amateur friend, I imported 150 species and varieties from M. Soulage Boin, of Fromont, who had a rare collection, the list of which was published in the "Magazine of Horticulture" at that time, and is now before me. It was one of the largest collections of Cacti in the United States, and one of them, of which we still have the original plant, a night-blooming kind, called *cœrulescens*, from its almost sky-blue, cylindrical stems covered with jet-black spines and pure white flowers, is now in bloom. It is growing in a 10-in. pot, and has never been repotted for ten or fifteen years. It has a straight stem 5 ft. high, with a dozen or more branches at the top. This fine collection included also some of the old English sorts, such as *Epiphyllum Ackermannii*, *splendidum*, &c. Upon the introduction of *Cereus crenatus* we thought there was a grand opportunity to produce something new. All the varieties we had were scarlet, or lighter or darker shades of the same colour. The experiments were commenced by fertilising the scarlet kinds with the white *C. crenatus*, and *vice versa*. The result was, as I anticipated, very beautiful varieties, ranging in colour from the most delicate salmon-pink to deep crimson-scarlet and the most brilliant violet; some of the flowers measuring 10 in. in diameter. These experiments were repeated, and I still have a quantity of seedlings that have not yet flowered. The result so far has been the selection of about twenty varieties, all distinct, which have been named and described. Among the unbloomed seedlings are some from *C. Macdonaldia*, fertilised with the brilliant scarlet seedlings. The growth and habit are entirely new. The best of the several varieties are the following: Exquisite, clear orange-salmon with a pale violet tint; Mauve Beauty, mauve, deeply tinged with violet; Orange Gem, clear deep orange, tinted with violet at the base of the petals; Pink Queen, beautiful mauve-pink and very large; refulgens, dark scarlet with deep violet shading; and superbum, salmon tinted with violet-magenta, and very large. *Cereus C. M. Hovey* is one of the best varieties ever produced, the entire flower being of a clear blue-violet tint, with an extra row of petals, and 8 in. in diameter. The night-blooming kinds with us are *C. Macdonaldia*, *C. triangularis*, *C. grandiflorus*, *C. nyctacaulis* (creamy-white), *C. cœrulescens*, and *Epiphyllum Phyllanthus*. The last is one of the best, because its flowers so much resemble pond Lilies, and remain in beauty two or three days, though partially closed. A specimen 6 ft. high, with fifty or sixty of its pendulous, Lily-white flowers, is a beautiful object. I have not seen the rose-coloured kind (*C. Schrankii*) which Mr. Croucher names, and should like to have it, as it has been my object to produce a delicate rose-coloured flower as fine in form and large in size as *C. crenatus*. I have salmon, salmon-rose, and mauve-pink, but have never had a pure rose, except the old *Epiphyllum speciosum*. Mr. Croucher has not seen anything among the hybrids equal to the old *C. speciosissimus*. Its beauty is unquestionable, but I have sent Mr. Croucher a plant of my finest variety, *C. M. Hovey*, and shall be glad to have his opinion of it after he has seen it in flower. It is of dwarf habit, something in style of growth like *C. speciosissimus*, but it has three rows of petals, and the colour is of the deepest glowing violet throughout, set off by a tinge of scarlet on the outer row of petals. The Echinocactuses are pretty plants and flower freely, especially *Otonis*, *Eyriesi*, and *multiflex*, but they are not quite showy enough for general purposes. Cacti having been always favourite plants of mine, I have been surprised that they are not more extensively cultivated. They will bear more neglect than any other flower, and yet produce a grand display of showy flowers.

C. M. HOVEY.

Boston, Mass.

LARGE-FLOWERING OR SHOW PELARGONIUMS.

THE old practice of placing plants of Pelargoniums out-of-doors when they have done flowering is a good one, because it tends to ripen the wood, and the importance of well-ripened wood for cuttings cannot be over-estimated, especially when the cultivator is put to shifts in the way of striking them. To somewhat lessen labour, the plants that have done flowering should have some shade during the day, so that attention to watering be reduced a little. It is not wise to ripen off the wood too rapidly by keeping the plants very dry and fully exposed to the sun, as this tends to wither and attenuate the wood, and indifferent cuttings result. The stouter and fuller the wood, and the more vigorous the cuttings, the better will be the plants obtained from them. For ordinary purposes of house-decoration, it is not advisable to keep plants after they are three years old. It is desirable to do so when plants are wanted for show purposes, as old bottoms are necessary to get plants of large size. Two-year-old plants, i.e., plants cut back in the previous autumn after flowering for the first time, make very excellent plants for house-decoration if properly managed; but, as a rule, those who are not well up in Pelargonium growing will be more likely to succeed best with yearling plants. There is neither difficulty nor mystery in striking cuttings of show Pelargoniums. They can be put into a prepared bed in the open ground, in shallow boxes or store pots, and placed out-of-doors; they root readily enough and freely. If the cuttings are put into store pots—and this is, perhaps, the easiest method of going to work—they should be well drained and filled with a light sandy soil; let there be sand and leaf-mould in good proportions, and the cuttings pressed hard into the soil. They will not need water for two or three days, but may be syringed occasionally. The pots can be placed anywhere, but not too fully exposed to the sun, and in a few weeks the cuttings will be rooting freely. When sufficiently rooted to be potted off, let them be put singly in small 3-in. pots; and, when well established, the strongest can go into large 4-in. pots to winter. I have wintered a great many plants in a cold greenhouse in which there is no fire-heat simply by keeping them in the warmest part of the house and dry at the roots. In the dull months young Pelargoniums will last a long time without water, but directly a mild sunny day comes, a little water should be given. In the spring, when growth commences, shift into pots a size larger, and grow them on as vigorously as possible. We have yet to deal with the cut-back plants it may be desirable to save. After being deprived of their branches they will soon begin to break into growth. Then is the time to repot. Make up a soil of good light yellow loam, some decomposed manure that has been reduced to powder by decay, leaf-mould, and sand. This suits Pelargoniums well, as it simply needs to be rich and light. The soil and pots ready, the plants should be turned out, a great deal of the soil crumbled away, and the thick long roots cut off, leaving only the fine fibrous roots, and then repot in the smallest pot in which the plants can be put, at least a size smaller than the pots in which they were previously growing. When potted, they should be kept close for a few days till the roots begin to move. A final shift should be given in September or October, according to the progress made; and the plants be kept growing a little all the winter. My greenhouse has been very gay with cut-back specimens; and now that these have done flowering, the floral service is taken up with fine young plants, in 4 in. and 6-in. pots, obtained from cuttings struck in October last. These were kept pinched back up to the middle of June, and then allowed to grow freely. Such varieties as Empress, Rob Roy, Duchess of Cambridge, (very bright), Triomphe de St. Maude, Heroine, and a few others are now very gay, carrying full trusses of bloom. I have been using a little of the buffalo-horn manure in the soil, to the manifest advantage of the plants. It is a good and safe manure, one that can be recommended to amateurs for potting purposes. My recommendation is given only after repeated trials. I have seen the good results arising from this manure, and in consequence can confidently recommend it. D.

Veronicas as Cut Flowers.—Some of the herbaceous Veronicas, often too evanescent in bloom out-of-doors, live after cutting for a considerable time; the flowers of the spike, unopened when cut, expanding freely in a room.

Calanthes in Small Pans.—Calanthes succeed remarkably well in 5-in. pans about 3 in. deep, suspended from the roof, so as to bring the plants as near the glass as possible. Thus situated, they make vigorous growth and fine bulbs, which ripen well, and never fail to produce large spikes of blossom. In this way we find them treated in Messrs. Veitch's nursery at Chelsea.—S.

Erica cerinthoides coronata.—This is one of the best of the hard-wooded Heaths. As a rule, it is rather a shy bloomer, but this fault is in some measure counterbalanced by the size and beauty of its blossoms. They are produced in large whorls, and are bright orange-scarlet in colour.—S.

PROPAGATING.

HOLLYHOCKS.—The best modes of increasing these are by means of tops, as shown in fig. 1, and single eyes, as in fig. 2. As soon as the plants have done flowering cut them down to about 6 in. from the ground, when they will soon produce numerous shoots. When these have made, say, three pairs of leaves, they should be taken off, the bottom pair of leaves should be cut off, and the cuttings inserted singly in 2½-in. pots. The soil should consist of maiden loam, decomposed cow manure, and a little silver sand and charcoal dust mixed together and sifted fine. Put a little of the rough siftings at the bottom of the pots, press the cuttings in rather firmly, and give a good watering, taking care not to wet the leaves; then plunge them in a gentle bottom-heat, and keep them close for three or four days without water, when they may be examined, and if too dry they should be taken out and watered. If treated in this way the young roots will show themselves through the bottom of the pots in three weeks or so, when they may be removed to another part of the pit, where they should have a good watering and be gradually hardened off. In increasing Hollyhocks from eyes, the middle part of the stems must be selected; cut it into pieces 1½ in. long, and split the wood down the centre. Dusting with dry powdered charcoal before inserting in the soil is a good preventive of rotting. Hollyhocks thus treated

Fig. 1.

Cuttings of Hollyhocks.

Fig. 2.

must not be covered, but should merely be plunged in a gentle bottom-heat, and watered very sparingly till the eyes have grown a little, when they may be sprinkled overhead, with the view of inducing more rapid growth. They should not be repotted until the pots are tolerably full of roots. H. H.

Propagating Double Primulas.—"H. H." propagates double Primulas in the very way I do myself. I have this year struck 400, but my cuttings take at least six weeks to be ready to come out of the propagating cases, while "H. H.'s" are ready in half that time. Surely one of us is in error.—R. GILBERT, *Burghley*.

Petunias from Seed.—Where large quantities of summer-flowering plants are required for beds or borders, the many beautiful varieties of Petunia that are so easily raised from seed are most useful, being of easy culture, of quick, luxuriant growth and most persistent bloomers. They also require comparatively but little space under glass. Seeds sown in pans or boxes, and placed in an ordinary Cucumber frame in March, will, if the young plants be pricked off and gradually hardened, be good material by the end of May. The purple and striped varieties are very effective, and rosy-pinks, such as Countess of Ellesmere, are well adapted for back rows in shrubby borders or centres of large beds. Like most of this class of plants, they have been so carefully selected for seeding, that the produce is more like that of named varieties than seedlings.—J. G.

Lilacs from Seed.—At a recent meeting of the French Société Centrale d'Horticulture, M. Carrière exhibited a fruit-bearing panicle of the Lilas Varin, the capsules of which contained a number of ripe seeds. He showed this specimen by way of proving that this Lilac was perfectly capable of producing excellent seed contrary to what has been generally thought and asserted up to the present time. M. Baillon, in laying this sample before the Society in the name of M. Carrière, said that the property possessed by this shrub of being propagated by means of seed had already been pointed out in the "Revue Horticole" for 1877 (p.403). M. Baillon also laid before the Society, on behalf of M. Carrière, a number of wood engravings

showing the capsule, the seed, and the mode of germination of the Lilas Varin. By sowing the seeds which he had collected, he obtained the variety of Lilas with lacinated leaves, which was generally supposed to be the lacinated Persian Lilac. M. P. Duchartre asked M. Baillon whether, in the light of these facts, the Lilas Varin ought to be looked upon as a distinct species, as a hybrid, or as a true variety, but M. Baillon declared himself unable to answer these questions.—C. W. QUIN.

ANSWERS TO CORRESPONDENTS.

Eradicating Bindweed.—In last week's GARDEN "B." gives (p. 165) a very good mode of destroying this obnoxious weed, but he adds that perseverance is required for several years to render the system successful. Allow me to state that by manuring and digging the ground thoroughly well, and afterwards planting it with Flat Dutch Cabbage (I have tried no other), it will at the end of one year be as free from Bindweed as if it had never existed.—THOS. SPELMAN

Slugs in Ferneries.—Can you kindly inform me how to get rid of slugs? I have tried Lettuce leaves, but they only attract a few.—NEW CROSS. [Place little hillocks of bran about the Fernery and examine them every morning, destroying the slugs and renewing the bran.]

The Blue Gum Tree.—Can you give any information as to this Gum tree growing out-of-doors in England, sustaining our winter? [We saw the other day two examples of it 12 ft. high, in perfect health, in the Nottingham Arboretum. It will withstand mild winters in this country, but not severe ones. Many trees of it at Chiswick, consisting of some of considerable size, were killed to the ground in the winter of 1850-1.—M.]

Veitch's Autumn Giant Cauliflower (p. 143).—We have never seen this sort produce purple heads, but in the present case we should say that it has been sown at the wrong time. This Cauliflower should not come in until October. If sown out of season, the plants are apt to become blind, or to produce greenish-coloured heads.

Transplanting Pampas Grass.—At what time may I with safety move a large clump of this Grass?—A. [A good clump of Pampas Grass if it can be moved with a good ball, may be lifted at any time in open weather from October to May; if it is to be sub-divided into small pieces, April is the month, after long experience, which I have found best suited for sub-dividing and planting this highly ornamental Grass.—A. FOWLES, Castle Kennedy.]

Names of Plants.—*L. M.*—The shrub is *Pittosporum Tobira*, the herbaceous plant *Francoa ramosa*. *Dorset Vicar.*—Climatices often produce flowers that have more petals than the normal number. Some are semi-double and some wholly double. *E. J. W.*—*Phlox Drummondii alba* conlatis; handsome, but not uncommon. *Anna P.*—Apparently a leaf of some kind of Cow Parsnip (*Heraclium*). It will probably flower next year.

Melon Seeds Germinating Inside the Fruit.—I was dining with a friend the other day, and at dessert he cut a small golden-coloured, green-fleshed Melon, which contained inside a quantity of seeds which had germinated and produced their two seed leaves on a stalk about $\frac{1}{4}$ in. in length, and, strange to say, quite green. My friend had cut the Melon himself out of the frame just before dinner. The stalk was dry, but the fruit not at all decayed or apparently over-ripe, and when cut it was as firm as usual, but had very little flavour. Can you explain this, to me, very curious occurrence?—G. T., *Mells*. [In this instance there may have been some crack or crevice in the fruit through which the air had access. The want of flavour tends to indicate this, and that there was something abnormally wrong in the ripening process from the want of heat, or too much moisture at the roots of the plant.—W. T.]

Tacsonia Van Volxemi Shedding its Flowers.—I purchased a plant of this *Tacsonia* about two years ago, and planted it in a border in a warm greenhouse, and trained it on the back wall, intermixed with a *Passion Flower*. It has grown vigorously and shown abundance of flowers, but most of them have fallen off in a young state; others have remained until almost ready to expand, and then they have fallen off; the plant, in short, has only brought three flowers to perfection, whilst the *Passion Flower* has flowered profusely. Will some of your readers kindly tell me the reason of this failure?—T. O. [In the absence of further particulars, we can only suggest that a deficiency of water may have been the cause of the *Tacsonia* blooms dropping. Try the effect of a good soaking of water.—D. T.]

Heating Pits.—Will someone be so kind as to assist me as regards the arrangement of hot-water pipes for heating a line of brick pits about 6 ft. wide. I am thinking of having two 4-in. pipes (flow and return) back and front for bottom-heat, and 2 ft. under the glass. Should I have troughs on the 4-in. pipes to hold water? and a 2-in. pipe run round for atmospheric heat? For any information on the subject I shall feel obliged.—NEW SUB. [For a line of brick pits 6 ft. wide, if wanted to grow such tender products as early Melons or winter Cucumbers, two flow and two returns, or two flow and one return 4-in. pipe will not be too much for bottom-heat. For these purposes, too, 3 ft. will not be too much from the glass. For plant growing 3 ft. or more from the glass may also be required. For pur-

poses of propagation 2 ft., as proposed, or even 18 in., may suffice. Better also use 4-in. pipes for atmospheric heat. This will save expense in the end, for coal has to be bought every year—metal, but once; and the more iron, within certain limits, the less coal.—D. T. F.]

Questions.

Barr's Heated Frames.—Will any of your readers who have tried these frames for raising seeds and striking cuttings, kindly inform me if they have found them answer? We suffer so much here from slugs, that an ordinary hotbed is never satisfactory. The idea of these frames appears to me very good, but, as they are rather costly, I should like to have the advice of some one who has tried them before trying one.—DOSSER VICAR.

Fruit Trees Barked by Sheep.—As some of my fruit trees have been much barked by sheep, I shall feel obliged by your stating the best way to treat them so as to induce the bark again to grow.—A. B.

THE NEW BRIDGE NEAR REGENT'S PARK.

It would be hard to find anything more vulgar and mean in design than certain excrescences of this bridge. It is "ornamented," to use the expression of a reporter, by four wholly needless groups of "statues," three in each group, placed on pedestals of such awkward design, that they spoil any beauty of line which the bridge might otherwise possess. Under each of these groups there is a large placard inscription, affording just such an effect as may be seen on some wall unprotected from the bill-poster on the approach of a theatrical benefit. The lamp-posts have such a redundancy of "ornamental" castings, that the designers of public-house gas-fittings need no longer represent the lowest stage of unmeaning design in this direction. It may be noted here that these gross errors in taste concern, for the most part, things wholly apart from the bridge itself. With our noble Thames bridges—some of them the admiration of good judges from all countries—without statues, why was it thought necessary to put as many as four groups of three each on this bridge? If this concerned only the vagaries of some rich imbecile, it could not concern us beyond feeling pity for such a puerile waste of means; but when it concerns public work one is justified in asking, Who allows such waste of public money? A lamp-post, again, is one of those objects which intelligent designers now-a-days consider should be designed in a manner at once simple and elegant. Here the "ornamental castings" seem as abundant as if shot out of barrows. We wonder any person of the slightest sensibility allows his name to be placarded on these hideous tablets—so utterly unlike in their size and wording that would be fitting in such a case. We read on one that this "bridge and roadway was opened," &c. Immediately below this gem all the names of the regiments of which the Commander-in-Chief is colonel are given at full length, and all his other titles too—details very well to be given in many cases, no doubt, in books or journals, for example, but surely not on a bridge, which, of all other structures, seems to call for simplicity and dignity in its treatment. The whole thing is an exhibition of bad taste, vulgarity, and snobbishness such as we have not seen for many a day.

PETUNIAS AT ISLEWORTH.

Last week we spoke favourably (p. 147) of some blooms of single *Petunias* sent to us by Mr. Marcham, of the Sprigfield Nursery, Isleworth. We have since seen the plants on which they were grown, and can, therefore, speak with more confidence as to the excellence of the "strain." The plants, which number some hundreds, are grown chiefly for seeding purposes. They were raised from seed saved from the best hybridised flowers sown in February, and the plants were grown on in a span-roofed house heated by a flue, under which conditions they succeed better than when grown in a house heated by hot water, inasmuch as a dry atmosphere is best suited for them. When grown in a moist heat, as they often are, the plants become lanky and straggling before commencing to bloom. Mr. Marcham, however, under the conditions named, got his plants in 5-in. pots to bloom early in May when not more than 6 in. in height from the rim of the pot, and by keeping them well supplied with water at the roots, they keep on flowering in the same pots until late in autumn. All inferior plants are sent early in the summer to market; the rest are grown on until August, when fertilisation is commenced,

the operation being performed twice or thrice a week whilst the pollen is perfectly dry. Unless properly fertilised, it is almost impossible to get these hybrid *Petunias* to yield a single seed-pod. The plants are at the present time well furnished with seed-pods, and the flowers, therefore, are not quite so fresh and well coloured as they were some weeks back, but even now they represent the most attractive sight in the way of striped single *Petunias* which we have seen.

SOCIETIES AND EXHIBITIONS.

ROYAL HORTICULTURAL SOCIETY.

AUGUST 20.

EXHIBITS at this meeting were comparatively few, the most attractive being several new specimen *Crotons* from Mr. Williams, of Holloway, cut flowers and a large collection of *Abutilons* from Chiswick, *Dahlias* from Mr. Turner, of Slough, and *Verbenas* from Mr. Cannell, of Swanley.

First-class Certificates were awarded as follows:—

Cattleya Veitchiana (Veitch & Sons).—One of the finest hybrid *Cattleyas* ever raised. It is the result of a supposed cross between *C. Dowiana* and *Lælia purpurata*, or *Cattleya exoniensis*. Its flowers are very large and deliciously scented. See THE GARDEN, p. 147.

Cattleya Mitchelli (Mitchell).—A distinct garden hybrid, the result of a cross between *C. Eldorado* and *C. Leopoldi*. The plant is of medium growth, and its flowers are very distinct in colour and form. The petals and sepals are of brownish transparent violet, whilst the lip is white, tipped with rich purple. It is well worth a place in good collections of *Orchids*.

Dahi Prince Bismarck (Turner).—A finely-formed flower, very large^o in size, with cup-shaped petals of a deep magenta. A fine kind for exhibition purposes.

Dahlia Helen Macgregor (Turner).—A large round flower of fine form, and of a creamy-pink colour, the petals being tipped with bright rosy-purple.

Croton Williamsi (B. S. Williams).—A fine robust kind with large, shining, bronzy-green leaves, richly marked with bright rosy-crimson. Large plants retain the colour in their leaves down to the base of the plant. One of the most showy of *Crotons* raised for some time.

Plum Rivers' Sultan (F. A. Dancer).—A round, purple Plum, very early and well worth culture.

Seedling Dahlias.—Of these Mr. Turner, Slough, showed, in addition to *Helen Macgregor* and *Prince Bismarck*, elsewhere described, *Robin Adair*, a brownish-cinnamon-coloured kind; *Miss Molly*, a good lavender flower of fine form, the petals being remarkable for the absence of the cup shape found in most *Dahlias*; *Queen of Italy*, pinkish-orange; *John Ashley*, brilliant scarlet; and *Amy Robart*, bright violet; all good kinds. A *Pomponé Dahlia*, named *Lady Blanche*, was remarkable for its floriferous character and well-formed, creamy-white blossoms. Mr. G. Harris, Orpington, sent *Dahlia Loyalist* and *D. Barrister*, neither of which were considered better than existing kinds.

Miscellaneous Subjects.—Mr. B. S. Williams exhibited a group of *Crotons* and *Coleuses*. *Croton Harryannum* was conspicuous for its strong growth and large golden-yellow leaves; *C. Williamsi*, a good new kind, is alluded to elsewhere. The *Coleuses* named *Kentish Fire* and *Lord Falmouth* differ from other kinds in cultivation.

A cultural commendation was deservedly awarded to Mr. Johnson, gardener to T. T. Clarke, Esq., Uxbridge, for two potsful of *Vallota purpurea*, said to have been raised from seed. The best pot, a 12-in. one, contained no fewer than twenty strong flower-spikes, most of which were surmounted by from four to eight large, brilliantly-coloured blossoms.

Messrs. Laing & Co., Forest Hill, sent a plant of *Begonia Mrs. J. Elwes*, belonging to the *Piercei* type, with whitish flowers. Being very floriferous, it seems well adapted for decorative purposes.

Mr. Cannell, Swanley, again sent a large collection of *Verbenas*, which were, if possible, even more brilliant than those which he previously exhibited.

A fine collection of double *Zinnias* came from the Society's gardens at Chiswick. A large collection of *Abutilons*, cut flowers of *Dianthus Heddwigi* and *Phlox Drummondii* were also shown from the Society's Gardens, all of which were very fine and well worth notice.

Mr. Green, gardener to S. G. Macleay, Esq., Pendell Court, Bletchingly, sent cut spikes of *Gladiolus dracocephalus*, and a hybrid

Nymphaea named *Eugenie*, of a pinkish-rose colour, the result of a cross between *N. Devoniana* and *N. Lotus*; also cut flowers and leaves of *Carica cauliflora*; likewise blooms of *Begoniae* cut from plants grown in the open ground, to show how much brighter in colour they become when exposed to the open air than when indoors.

Mr. G. F. Wilson, Weybridge, showed *Lilium Leishmanni* and a flower of the true old *L. speciosum rubrum*, remarkable for its fine colour.

Mr. R. S. Yates, Sale, Cheshire, sent a fasciated spike of *Lilium auratum* furnished with 150 medium-sized flowers.

Sir Trevor Lawrence contributed a plant of *Odontoglossum Reichenheimi* bearing a flower-spike 3 ft. long, with blossoms having chocolate and yellow-spotted petals and brownish-purple lip, broadly tipped with delicate mauve; also *Dendrobium McCarthiae superbum*, from Ceylon, bearing large, gracefully-drooping, mauve-petalled flowers with rich purple throat and purple-tipped lip.

Fruit.—Messrs. William Paul & Sons showed a collection of early Apples, among which were *Duchesse of Oldenburg*, *Manks Codlin*, *Councillor*, *Kerry Pippin*, *Emperor Alexander*, and *Lord Suffield*. A collection of Apples also came from Chiswick. Mr. F. A. Dancer contributed *Victoria* and *Rivers' Sultan Plum*; and Mr. Hinds, Otterspool, furnished a bunch of *Golden Champion Grapes*, large in size, but otherwise of no particular merit, most of the berries being spotted and unripe. Collections of *Melons*, none of which were above mediocrity, were also shown by several growers.

Lilium Batemannæ.—This can hardly, in my opinion, be regarded as one of the *Thunbergianum* group. It is true that the flower is, in colour, like that of *L. Thunbergianum venustum*, but there the resemblance ends. The bulb has broad, stout scales, the first tier reaching only half-way up the bulb. In that respect, therefore, it is more like the bulb of *L. Maximowiczii* or *Leichtlini* than that of *Thunbergianum*, whose scales are thinner and longer, and reach much higher up the bulb. Next, the height of the slender stem, 4 ft. to 5 ft., crowded with long, narrow, lanceolate, arching leaves, in no way reminds one of *L. Thunbergianum*, whose stems, measuring from 1 ft. to 2 ft. only, are stout, and possess broad, dark green, stout, erect, or semi-erect foliage. Therefore, the habit of the plant clearly resembles that of *L. Maximowiczii* or *Leichtlini*, but the flower is very similar to that of *Thunbergianum armeniacum (venustum)*. It is quite a distinct and new form.—A. WALLACE.

The Lily proposed by Dr. Wallace to be named after Mrs. Bateman is certainly a useful one, especially in Lily nosegays. I do not, however, agree with him in its resemblance to the very graceful *L. Leichtlini*. A number of bulbs were sold a year or two ago at Stevens', so I dare say there are a good many plants of it in the hands of Lily growers. Dr. Wallace speaks of it as "hitherto unnoticed in England." I have more than once thought of taking up a pot to the Floral Committee of the Royal Horticultural Society, but, believing that it would be considered only second-class, and have a certificate accordingly, I have not done so. I recently exhibited it among cut Lilies at Marlborough. Mr. Perry, of the Hale Farm Nurseries, Tottenham, lately sent me a Lily flower to name. In my Lily book last year a note is made that it was like the tall *umbellatum citrinum*. I suspect that we shall receive many hybrid Lilies from Japan, and that this will prove one, and that the one which I took up on Tuesday last to the Floral Committee will prove to be another. Having a flower of *L. Leishmanni* out, and having never before seen this Lily, I took it up to have the name verified. It has the spots of *L. tigrinum* and bits of wool on the stem, but no stem bulbs, and it has not the habit of *L. tigrinum*.—GEORGE F. WILSON, *Heatherbank, Weybridge Heath*.

The Proposed New Experimental Garden.—I notice (see p. 125) a suggestion in reference to the formation of an experimental garden, to be placed under the management of Mr. Thomas Laxton. No man is more capable of conducting such a garden, a statement in confirmation of which we have only to look back upon the work which he has done. Taking first his Peas, who does not know and appreciate William I. and Omega? and, doubtless, one or two others to come out shortly, namely, *Marvel* and *Sturdy*, will be equally esteemed. I have these two just now in bearing, and for crop, colour, and flavour they are unsurpassed. I could write a volume in favour of the good things raised by Mr. Laxton, but will here only mention two more, namely, *Crown Jewel Pelargonium* and *Mrs. Laxton Rose*. These are both valuable acquisitions, and, unlike many so-called novelties that die in a year or two, will live long amongst us. I shall be most happy to become a subscriber to the garden in question, and will do all I can to make the project a success. In starting such a garden, a committee should be formed, and rules and regulations printed; then I feel sure that subscribers will be found, and I hope to see Mr. Laxton once more in his element, and giving us novelties at present unheard of.—R. GILBERT, *Burghley*.

BOULTON & PAUL,

Horticultural Builders and Hot-Water Apparatus Manufacturers, NORWICH.

Plans and Estimates of every description of Horticultural Buildings in Wood or Iron, heating by Hot Water on the best principles and guaranteed. Catalogues 24 penny Stamps. Illustrated Lists post free.

THE GARDEN, VOLUME XII.
containing the Numbers from July to end of December, 1877; 27 coloured plates, and upwards of 500 wood engravings. Of all Booksellers, or direct from THE GARDEN Office, 37, Southampton Street, Covent Garden, London, W.C.

"ALPINE PLANTS IN THEIR NATIVE HABITATS AND IN OUR ENGLISH GARDENS." By RICHARD POTTER, Alpine and Herbaceous Department at J. Backhouse & Sons' Nurseries, York. Price 4d., or 3s. 4d. per dozen; post free, 4d., and 3s. 6d.—Of the Author; or W. Sissons, Printer, 16, Low Ousegate, York.

SITUATIONS.

THE Preston Nursery and Pleasure Gardens Company require the immediate services of an experienced Traveller to represent them in the nursery and seed department. Must be steady and hardworking.—Apply, with testimonials, to Mr. W. H. Cowall, Secretary, 143, Church Street, Preston.

WANTED, by a Medical Man in the country, a **GROOM and GARDENER** (single, to live in the house); one horse kept; liberal wages to a steady man with good character.—Apply to "G. W. S." Post Office, Kegworth, Derby.

GARDENER (SINGLE-HANDED) wanted at end of September for kitchen and flower garden and small conservatory at Edgbaston; married, without family, or one boy only; good cottage.—Letter, stating wages expected, &c., to Hugo J. Yoxce, 12, Bennett's Hill, Birmingham.

WANTED, a respectable YOUTH for the Gardens, willing to make himself useful; one that has been in the gardens preferred; age not more than seventeen; must be well recommended.—Apply to A. Bean, Brickendonbury, Hertford.

WANT PLACES.

Head Gardeners.

JOHN LAING & CO. can at present recommend with every confidence several energetic and practical Men, of tested ability and first-rate character. Ladies and Gentlemen in want of **GARDENERS and BAILIFFS, or GARDENERS** for first-rate Establishments or Single-hand Situations, can be suited, and have full particulars by applying at Stanstead Park Nurseries, Forest Hill, London, S.E. No fees charged.

E. G. HENDERSON & SON have many excellent **GARDENERS** of approved testimonials for ability, now waiting in their Nurseries for Re-engagement. E. G. H. & Son will be pleased to answer any enquiries from Noblemen and Gentlemen requiring such.

PINE-APPLE NURSERY;
Maida Vale, London, W.

GARDENER, with a thorough practical knowledge of Alpine and Herbaceous Plants, Hardy Bulbs, &c., and the general routine of gardening, is open to an engagement with any nobleman or gentleman requiring the services of a thoroughly energetic man.—Address, "E. H." care of Mrs. Haude, 58, Margaret Street, Clerkenwell, E.C.

WANTED, a Situation as HEAD GARDENER where two or more are kept; age twenty-eight; Scotch and total abstainer; has had experience in fruit, flower, and vegetable growing and forcing in large places in both England and Scotland, with three years' excellent recommendation from last situation.—Address, R. Parraason, 19, Devonant Road, Holloway Road, London, N.

GARDENER (THOROUGH).—Gentlemen or others contemplating Improvements of Gardens, Parks, Land and Estate, and Alterations, will find the advertiser able to carry out such works, either on job or situation.—"J. N.," 1, Trevor Place, Knightsbridge.

GARDENER, by a respectable married man; no family; age, thirty; seventeen years' experience in all branches; wife good dairy manager; good character; cause of leaving, death of employer.—Address, stating wages and particulars, to **GARDNER**, 46, Cambridge Road, Hastings, Sussex.

AS UNDER GARDENER in a Botby, or Single-handed; ten years' experience in the several branches of the profession; age twenty-four; good references.—Address, stating terms, Thos. Wazn, Coldham Hall, Wisbech.

FOREMAN or first JOURNEYMAN in a good establishment; age, twenty-five; eight years' experience; good references.—"E. P.," 3, Burlington Place, Fulham, London, S.W.

AS HEAD WORKING GARDENER; land and stock if required; middle-aged; wife dairy and poultry if required; many years' experience; good character; near London preferred; please state wages.—"A. B.," The Lodge, Kingston, Arundel, Sussex.

GARDENER (HEAD WORKING), where two or three are kept; good single-handed place not objected to; age, twenty-nine; married, no encumbrance; good experience; good character from last employer.—"A. B.," 27, Railway Place, Feltham Hill Road, Middlesex.

WANT PLACES.

TO GARDENERS.—THE FRIENDS of an intelligent LAD, who is fifteen years of age and very desirous to learn gardening, are anxious to bear of a Situation for him under a good gardener. A moderate premium offered.—H. PARR, Harrow Weald Park, Stanmore, Middlesex.

WANTED, by a Young Man, aged twenty, a situation in a nobleman's or gentleman's garden; five months last place; four years previous; total ab-tainer; first-class references.—H. LINNEX, Jacksmith's Lane, Bullericy, Essex.

WANTED, a Situation as Improver in the houses in a nobleman's or gentleman's establishment; age, nineteen; has been two and a half years in present situation. Good recommendations.—Apply, F. BROOKS, Albary Park, Guildford, Surrey.

WANTED, a Situation (one of trust), to Invalids or Housekeeper.—Address, 34, Jubilee Place, King's Road, Chelsea.

Tice & Lynch, 34, Pine Street, New York. International Money Orders can be obtained at Post Offices in the United States, payable at the Charging Cross Post Office, London, England.

"This is an art
Which does mend Nature: change it rather: but
THE ART ITSELF IS NATURE."—Shakespeare.

BEGONIAS AND PELARGONIUMS AT M. LEMOINE'S.

ALL lovers of flowers, if on the Continent, should visit M. Lemoine's gardens at Nancy. They are but a short distance by rail from Paris or Brussels. Being at Paris and desirous of seeing his Begonias and Pelargoniums, for the excellence of which he has a wide-spread reputation, I visited Nancy and met with a most cordial reception. The gardens are but a short distance from the station at Nancy, and are easily found by a stranger. I found M. Lemoine among his Pelargoniums, admiring them with the eye of an enthusiast, which, indeed, he is, over Begonias and Zonal Pelargoniums. His double Zonal Pelargoniums are, indeed, wonderful; they are of all shades of colour and habit of growth. He has accomplished almost perfection in this most useful of plants. He has two houses, 75 ft. by 20 ft., which are now one sheet of bloom, all the shades of colour being present which we find in the single varieties, and there is a generous sprinkling of good double white varieties. Lucie Lemoine is a particularly fine dwarf, free flowering, pure double white, and, associated with it, were the following new ones not yet sent out, viz., *Triomphe de Nancy*, bright orange red, with the reverse of the petals salmon-rose, truss very large; *Nymph*, a kind with unusually large trusses of a delicately tinted white colour; *Le Violet*, a sort with small trusses of a beautiful violet shade, habit dwarf, and very floriferous; *La Lorraine*, with trusses of unusual size, of a salmon-buff colour; *Psyche*, semi-double, beautiful deep rose, almost tending to carmine; *Le Centenaire*, crimson-purple, suffused with red, trusses very large; also some new shades in orange and salmon single Pelargoniums as yet unnamed. Those which I have named are only a few out of two houses, consisting wholly of fine kinds. M. Lemoine's seedling Pentstemons are also very fine, and likewise his Delphiniums. The following were some of the finest double sorts: *Trophée*, Nancy, *Illustration*, *Stuart Mill*, *Suffrage*, *Livingstone*, *La Lorraine*, and *Rayon de Soleil*. He has many fine seedlings as yet unnamed, to be sent out next year, as full and double as *Ranunculus* flowers. But his Begonias! They must be seen to be believed. He has about 15,000 seedlings, all planted in the open ground in beds 4 ft. wide by 50 ft. in length, and partially shaded by means of lattice work from the sun. Several of these beds consist of small seedlings; others are flowering now for the first time, and of these very many promise to be exceedingly fine. The most wonderful sight is four beds of the larger plants, selected varieties not yet in the trade. They are indeed magnificent, and alone are worth a visit to Nancy. Both single and double varieties of a great number of colours may be found amongst them, from the deepest scarlet to a pure white; and some are so very large and double, that they reminded me more of small Holly-hock flowers than anything else with which I can compare them. While some are easy of propagation and multiply rapidly, others are just as slow, and it is many years before M. Lemoine has plants sufficient to enable him to offer them to the trade. A very fine single variety with very large flowers he has had several years, and as yet has only had five plants of it; it will, however, be worth waiting for. Of the varieties in flower, the finest which I saw were *Lemoinei*, *President Burelle*, *W. E. Gumbleton*, *Gloire de Nancy*, *Louis Thibaut*, *Marie Lemoine*, *Sceptre*, *Emile Lemoine*, and *Miracle*, all particularly noticeable amongst a hundred others; also the following new varieties not yet sent out: No. 2, *Madame la Comtesse Horace de Choiseul*, a very fine double kind of a most beautiful and delicately-tinted white; flowers very full and imbricated. No. 3, as yet unnamed; flowers very double, full, and of a dark rose colour, resembling, as M. Lemoine says, *Bengal Roses*; habit erect and tall. No. 46, *rosæflora plena*, erect in

growth and very fine; one of the most double and similar in habit to the single. No. 48, *Prof. Edouard Morren*; flowers very large and full, of the most intense fiery scarlet. No. 55, unnamed; flowers very full and imbricated like a *Camellia*, and of a beautiful dark red. These are only a few out of many fine sorts, and the grand or great grand parents of all these were, B. Pearcei, B. Veitchi, and B. rosæflora. Truly, M. Lemoine has had wonderful success with his Begonias, and also with zonal Pelargoniums! He has many glasshouses, and about 10 acres of land well cultivated; he has, moreover, some remarkably fine seedling *Lantanas*, also *Fuchsias*, amongst which are some fine new hybrids of the *F. Dominiana* type, some new *Phloxes*, and, in fact, many new plants well worth seeing. C. H. HOVEY.

JAPANESE GARDENING AT LAMPOR T HALL.

By Sir CHARLES ISHAM.

THE Japanese pigmy trees figured in the last number of *THE GARDEN* (p. 174), and also the one in the number for August, 1874 (p. 99), are valuable as demonstrating what it is possible to accomplish in that way. There is here a rockery in which *Abies pygmaea* and other dwarf trees are cultivated with the greatest care. One, with a double stem, twenty-five years old, is but 9 in. high, although the top has never been shortened; others, fifty years old, are 2 ft. 6 in., with dense or branching heads, and what with their visible roots, which also receive careful attention, and the pigmy and miniature *Ivies* growing up them, I think it not presumptuous to denominate it a Japanese rockery. I am anxious to know whether there is any other of the kind in England, or even in Europe, for, although not a great traveller, I would go a long distance to see it. The one in question was commenced in 1847, and there has seldom been a day out of nine months of the year that it has not had some hours devoted to it. I fancy I could give even the Japanese a hint or two. There is another class of plants which may be quickly converted into miniature trees, viz., the *Retinosporas*; indeed, there are few shrubs which, by the aid of shears and fine-pointed scissors, could not be more or less adapted to the purpose. There will doubtless be an outcry against "mutilating" such naturally beautiful objects, but I have never been able to see why these should not be trained as well as bedding plants, the chief difference being that the labour of training a flower bed confers a benefit of but short duration, whereas an hour's work at a Japanese tree may be visible for a lifetime, and even may go down to posterity. Having decided opinions on the matter, I affirm that there is not a tree or shrub, large or small, which may not be more or less improved by treatment, and that the miserable bushes which so frequently disfigure our parks and gardens might, many of them in a few hours or minutes, be converted into picturesque objects. Nature provides the raw material, which is capable of being developed. A straight, crooked, drooping, or prominent-rooted tree, such as the *Beggar's Oak* at *Bagot's Park*, might each have its character manifested to a greater extent and become still more striking and beautiful. Distortion, such as the Japanese adopt, should not be encouraged, but the natural growth of a tree bears assisting, as do the natural faculties in a child. Foresters may disagree with me, but they usually only consider a tree as so many feet of timber, and, therefore, they should be the last persons to consult on such matters. It is clear that however much we may love Nature, art may also have its merits. Flax is beautiful when growing, so it may be when converted into a table-cloth. The subject of training dwarf miniature trees, to do it justice, would require a volume with photographs; but their beauty must be apparent to all who have seen them; and this, I believe, may be increased beyond a dream when they become venerable with age, and more miniature ones with *Alpine* plants cover the ground amongst their roots. Diminutive figures under the trees, such as *Loudon* idealised in a woodcut in one of his books, but which he had never seen carried out, add greatly to the charm, and when done properly, are the admiration of most beholders. I should be happy to show my garden to any one interested in horticulture; like all other earthly things, it is capable of

vast improvement; but that is only accomplished by time and constant attention. Lamport Station is three-quarters of an hour from Blisworth, on the London and North-Western Railway.

ARBUTUS ANDRACHNE.

Of all the varieties of the genus *Arbutus* this is, in my opinion, the hardiest and best. The true variety is not often met with; I, however, recently saw several large bushes of it in the pleasure grounds at Eastnor Castle; there was also growing near them a bush of *A. procera*. The latter has large, handsome foliage, but it is scarcely so hardy as *Andrachne*; neither is its bark so bright and red. This latter is a striking and distinct feature of *A. Andrachne*. *Arbutus hybrida* is also harder than *A. procera*, and is but little inferior to *A. Andrachne*. There is a magnificent specimen of it growing in Bath Park; it is about 25 ft. high and 30 ft. in diameter of spread of branches. The appearance of this (I may say) tree in autumn, with its waxy, Lily of the Valley-like flowers, when in blossom, or during winter, when laden with its golden and red fruit, is a sight to be taken note of and one which will hardly ever be erased from the memory. *Arbutus Andrachne* is, I believe, rather scarce in the trade, and probably *A. hybrida* may often be substituted for it, the latter being more plentiful. The two kinds are, however, very distinct when seen growing together; the leaves of *A. hybrida* are roughly serrated, while the foliage of *Andrachne* is broader and rounder, and slightly, if at all, serrated. My advice to planters who wish for a superior evergreen shrub, and who have not already secured it, is to buy *Arbutus Andrachne*. GEORGE BERRY.

Longleaf.

NOTES AND QUESTIONS ON TREES AND SHRUBS.

Deafontainea spinosa.—I have a bush of this 6 ft. high, and proportionately round, that flowers for ten months every year in the open air. Last autumn some insect bored holes at the base of every flower, and so extracted the honey. Can any one tell me what insect it was? The flowers continued to be attacked long after wasps had disappeared.—H. F.

Althæa in London.—Just below Holland Park, on the Kensington Road, is a fine specimen of a dark lilac-flowered *Althæa* in full flower. About six such shrubs in the Park Lane Gardens would have a fine effect.—J. S.

Acacia melanoxylon.—This flowers freely. I have a stump of one 51 in. in circumference 18 in. from the ground. When the old tree failed, or was blown down, young shoots came up, one of which is now 30 ft. high.—H. F., *Rosehill, Falmouth*.

The White Shrubby Hibiscus.—There is a pure and delicate white variety of this valuable shrub now in flower which deserves the attention of all interested in good autumn blooming shrubs. To us it seemed more beautiful than any of the coloured forms, and good white shrubs that flower in autumn are not common. This white variety may be seen in a small state among the shrubs at the Paris Exhibition.—V.

Menziesia polyfolia alba.—This, though a most interesting plant, is comparatively little grown in private gardens. Either as a pot plant or grown in beds or borders, it grows freely and yields a succession of white waxy blossoms, equal in appearance to those of the Lily of the Valley. A large bed of it in the Tooting Nursery is now quite a mass of blossom, and it has been in that state for these four months past.—S.

Hydrangea paniculata grandiflora.—I have some plants of this hardy shrub in fine bloom. The flower-heads, which vary from 8 in. to 10 in. long, and from 6 in. to 8 in. broad at the base, are borne on the end of the current season's shoots. A rich soil to grow in, and a thick mulching with manure in spring, is the kind of treatment which this *Hydrangea* requires to produce vigour in growth and a profusion of huge panicles of flowers.—G. B.

The Blue Gum Tree.—At Penmere, one mile from Falmouth, there are several of these trees over twelve years old. One of them is about 50 ft. high, and its trunk, 2 ft. above ground, measures 39 in. in circumference. I have a tree five years old about 25 ft. high.—H. F.

Acacia dealbata.—This flowers freely every spring with me both in a young and old state.—H. F., *Rosehill, Falmouth*.

NOTES OF THE WEEK.

Coreopsis nudata.—This rare aquatic, a Composite from North America, deserves special mention, not only for its rarity and very peculiar structure, but also on account of its beauty. It grows about 2 ft. high and bears numerous deep purple flowers 1 in. or more in diameter. The leaves are upright, round, just like those of a Rush, and totally unlike the foliage of any cultivated member of this well-known and favourite genus. In a wild state it grows in company with some of the Sarracenias in the North American marshes, and, under cultivation, does well with its pot plunged nearly up to the rim in water.—G.

Watsonia.—These are now beautiful in Mr. Ware's collection. A white one (*W. alba*) is particularly beautiful and graceful. *W. rosea*, with its large purple-pink flowers, is a good companion to it.

Small Pomegranate Bushes in Flower.—In the Paris markets now there are little bushes of one of the small varieties of Pomegranate not more than 8 in. through the head. They are little standards supported on slender stems about 15 in., high and sparkling with bright flowers and buds. This is one of the plants one would like to see in our markets, but perhaps it is better markets should not be all alike; in any case it is very interesting to see these and the pigmy Oleanders when one goes abroad.

Phalænopsis grandiflora.—A new importation of plants of this beautiful Orchid, now flowering freely in Messrs. Veitch's nursery, shows a marked improvement in their flowers on any we have before seen. The blossoms are of perfect form and of the purest white, the lip being slightly tinted with golden yellow. Even small plants at present bear flowers which measure over 4 in. across.

Sedum trifidum.—This old, yet uncommon, Himalayan Stonecrop is one of the prettiest rock plants now in flower. Its slender, procumbent stems bear at the tops rosettes of deeply-toothed, lance-shaped leaves, in the centre of which is a tuft of bright rosy blossoms. Why it is so uncommon I cannot imagine, as it is one of the easiest of plants to grow and propagate.—A.

Sagittaria variabilis.—This interesting aquatic plant is now flowering for the first time in a tank in the Wellington Nurseries. It grows about 18 in. high, and its leaves, which are very narrow, vary very much in form. Its flowers are pure white, with green stamens, and, as a water plant, it will doubtless be appreciated.

A Fine Liliun auratum.—We have received from a correspondent at Leytonstone a very fine example of this Lily, said to be a cross between *auratum* and *lanifolium rubrum*. In the flower sent, however, we can discover no trace of the latter variety. It measures from 11 in. to 12 in. across, and the petals are 2½ in. broad, gracefully recurved, and beautifully spotted. It is one of the best forms of *Liliun auratum* we have seen.

Rubus nubigenus var. macrocarpa.—A coloured figure of this remarkable *Rubus* is given in the last number of "Illustration Horticole." It has red flowers and large, bright crimson fruit, which seems to be produced in profusion. It is stated to have been sent to M. Linden from the Andes of Bogota in 1876.

Two Rare Orchids.—The white drooping-flowered *Pajus Dodsoni* is now blooming freely in the Holloway Nurseries. It is quite distinct from any other *Pajus* and is well worth culture. A good plant of the new *Odontoglossum pardinum* is also showing flower in the same establishment.

Viola Loveliness.—This *Viola* sent out this year by Mr. Williams, of Holloway, will be found to be a valuable addition to the already numerous varieties of that class of plants. Its flowers are very large, of fine form, and of a rich plum colour. It grows well and flowers freely all through the summer. We have lately seen several good beds of it in gardens about London.

Anemones, Phloxes, and Begonias.—Established plants of the beautiful *Anemone Honorine Jobert*, tall-growing *Phloxes*, and *Begonias* make an effective combination on a piece of rockwork in Messrs. Veitch's nursery at Chelsea. Planted in deep sandy soil, the plants are healthy and vigorous, and, associated with hardy shrubs, &c., they show what can be done in the way of effective gardening, even within reach of the London smoke. The plants used are all hardy, but they are all the better for a little protection in the way of a few inches deep of ashes round their roots in winter; while such effects as we find here can be produced in the smallest London gardens, we are surprised that people incur the trouble of filling their flower beds with *Geraniums* and other tender bedding plants, which are far more expensive to keep, and certainly much less attractive.

Although the Begonias consist of nearly all the best known kinds, none are so attractive at present as Emperor, which can be seen in the form of specimens 2 ft. to 2½ ft. high and as much through, loaded with blossoms. These have been wintered out-of-doors for several years.—S.

Anchusa incarnata.—This pretty hardy plant, grown in a pot in Messrs. Rollisson's nursery at Tooting, has been yielding abundance of pretty flesh-coloured blossoms ever since last May. It grows about 2 ft. high, and is, in every way, well worth adding to good collections of hardy plants. It seeds pretty freely, and will, therefore, soon become plentiful.

Bouvardia angustifolia.—This is one of the oldest of the Bonvardias, but still well worth attention. Either in pots or in beds out-of-doors, under good culture, vigorous plants of it 4 in. or 5 in. high, profusely laden with bright scarlet flowers, may be secured at nearly every season of the year.

Lobelia Emperor William.—This is one of the best of Lobelias of the speciosa type. It is compact in habit, and its flowers, which are very large, are of good form and of a deep blue colour. It is grown largely in Messrs. Rollisson's nursery at Tooting.

Nymphaea odorata minor.—For growing in small tanks or in glass vessels in rooms this plant is admirably adapted. Its leaves, which are small, are round and of a reddish-bronze colour on both sides. Its flowers, which are not half the size of those of the common Water Lily, are produced freely; they are exquisitely formed and of snowy whiteness, the stamens being sulphur-coloured. In a cool conservatory or greenhouse, where a tank exists, this Lily will flourish, and it will even withstand severe frost. It is now flowering freely in the Wellington Nursery.

Pancretium fragrans.—Finely flowered plants of this beautiful Amaryllid were lately to be seen in Mr. Williams' nursery at Holloway. Some of them were furnished with flower-spikes bearing a whorl of twelve unusually large pure white deliciously scented flowers. Comparatively few people grow this Pancretium, which is surprising, considering its easy culture and its effective character when in bloom. For the centres of bouquets the flowers are unsurpassed, and they last in good condition a long time in water. A small-flowered variety is now very beautiful in Covent Garden Market, where it is much prized for its purity of colour and sweet perfume.

Symphytum asperum variegatum.—This is a new variegated form of the Prickly Comfrey now in Messrs. Henderson's Nursery at St. John's Wood. It differs from *S. officinale* variegatum in being of stronger growth, hardier, and in its leaves being edged with a broad margin of bright yellow; it also stands hot weather without becoming scorched. For shrubbery borders, or in isolated groups on lawns, this Comfrey will be an effective plant, its brightness vying with that of the Golden-leaved Elder.

Pulmonaria dahurica.—This rare little gem is now in flower with me. It is the smallest as well as the best of the Lungworts. Its leaves are oval-shaped, about 4 in. long, ½ in. wide, dark green, without spots, and beset on the surface with short, stiff hairs. The blossoms are borne on slender stalks about 6 in. high and are about ½ in. long, of a bright, clear blue colour, and they last a long time in good condition. It is one of the most difficult plants to manage in cultivation, hence its rarity. It does best in frames, for, though hardy, it does not succeed well if planted out-of-doors.—A.

Fitcher-planta at Holloway.—The large collection of Nephentes in Mr. Williams' nursery is now very attractive. The plants, which are suspended from the roof of span-roofed houses, are furnished with a profusion of large, finely-coloured pitchers, which look all the more graceful for being allowed to droop down and intermix with the foliage of *Cocos Weddelliana* and fine-leaved *Crotons*.

The White Water Lily at Kensington.—The large round tanks in the Royal Horticultural Gardens at Kensington, filled with *Nymphaea alba*, are now very attractive. The plants grow here with remarkable vigour, and the blooms are much larger than we often find them in the open country. When the rose-coloured variety comes to be sufficiently plentiful to allow of plants of it being introduced among the white kind the effect will indeed be excellent.—S.

Amaryllis O'Brieni delicata.—This is now in flower in the Pine-apple Nurseries. It is one of the best Amaryllises ever raised. Its flowers, which are perfect in outline, are pure white, delicately traced, and dotted with clear rose. The foliage is dark green with a broad white band down each leaf. It is the result of a cross between a fine form of *Hippeastrum pardinum roseum* and *Amaryllis reticulata* major, and, when better known, it will doubtless hold a foremost place amongst Amaryllises.

Double Zinnias.—In mixed borders, or in beds among sub-tropical plants, these are always attractive when well grown. They require a deep loamy soil, and if other conditions are suitable they

will bloom freely from July until the frost cuts them down in autumn. There is at the present time a fine collection in the Royal Horticultural Society's Gardens, at Chiswick; the flowers are as large as those of an Aster, perfect in form, and varying in colour, there being golden-yellow, magenta, rose, pink, purple, and cream colour. For cutting for vases they are invaluable, for, in addition to supplying so many colours, they last for a long time in water. The plants in question were raised from seed saved in Bengal, where the Zinnia is grown during the moist months of the year, namely, from May to September, thus teaching us that, in order to grow Zinnias well, a warm situation and abundance of water are necessary.—C. S.

Agapanthus umbellatus Out-of-doors.—Though this may not withstand the winter out-of-doors in many parts of England, yet good effects may be produced during the summer by planting out established specimens of it in spring. Either isolated on lawns or planted in borders or in mixed beds, good plants of it will produce abundance of flowers. During winter the plants should be lifted and stored in any dry shed free from frost. In this way they get a season of rest, and flower all the better when planted out the next year. Several large beds of this plant treated in this way are now in flower in the Tottenham Nurseries.

Mutisia decurrens.—Grown at the end of a glasshouse or on an open wall, this Mutisia, if planted in good soil, will make an attractive object during the summer. It is at present little grown in our gardens, although there is no reason why it should not be used in conjunction with the smaller-growing *Nasturtium* or *Convolvulus*, and similar plants for covering fences, walls, or bare stones on rockwork. Its bright Cinnamon-orange flowers are very showy, and will last in bloom for a considerable time. It is now flowering at the end of one of the glasshouses in the Pine-apple Nursery.—S. C.

Begonia Mrs. Arthur Potta.—This is a dwarf Begonia of the Davisii type, and is, indeed, probably a seedling from that kind. When in flower established plants are not more than 6 in. high, and their brilliant, blood-red blossoms are produced in great profusion. Either of these kinds make admirable plants for growing in pots or pans, or if planted out as an edging, or in groups in the conservatory, they would constitute a striking feature from June to November. They are now in fine condition in Messrs. Veitch's nursery, Chelsea.

Overcrowding Plants in Beds.—Among the mistakes made in "bedding out" a common one is putting plants close together that can only be seen to advantage when seen by themselves or at some distance apart. We have lately seen some beds of Begonias that were not effective because the kinds were such as could only be seen to advantage when the sides of the plants as well as the tips could be seen. Lately also, at the Paris Exhibition, we saw some fine collections of Gladioli so crowded together, that only the tips of the shoots could be seen. Numbers of plants will bear to be overcrowded without their beauty being wholly lost; and plants are easily divisible into two classes as regards their fitness for being placed close together. Those who have to deal with them would do well to more frequently consider their habits of growth in relation to the positions in which they are placed.

Exhibition Carnations.—At the Woodbridge flower show, usually held early in July, Carnations, Picotees, and Pinks are generally largely exhibited, and so distressingly formal in their paper collars, that one naturally turned to the Roses that had a few buds and leaves attached to them as a positive relief from such formalism and wasted skill. Amongst miscellaneous contributions at the same show I have, however, invariably stopped to admire a large flat basket of pot Carnations (principally of the tree section), a complete mass of the finest blooms, varying from fiery scarlet to the purest white, and as they were sent by Mr. Keen, the raiser of Miss Jolliffe, that lovely, free-flowering, flesh-coloured kind, I need scarcely say was largely shown. They were fine plants tied to single stakes, and allowed to mingle somewhat loosely together. No paper, except a slip for the name, was observable, and the pots were plunged and covered with Moss, like an ordinary nursery hamper of plants prepared for travelling. I merely offer this as a suggestion as to the possibility of those lovely flowers (Carnations, Picotees, and Pinks) being exhibited in a way which shows their beauty equally well as the single bloom system.—J. GROOM.

Messrs. Rollisson's Failure.—A meeting of the creditors of Messrs. William Rollisson & Sons, of Tooting, was held last Tuesday at No. 8, Old Jewry, E.C., when a trustee was appointed. The meeting was largely attended, and at the close the chairman remarked that much sympathy had been evinced by the creditors present for Messrs. Rollisson, whose business is still being carried on, and it is confidently hoped that an arrangement may be arrived at whereby the uninterrupted continuance of the firm, which has now existed for nearly 100 years, will be ensured.

NOTES FROM KEW.

Hardy Trees and Shrubs.—Two kinds of *Rhus*, *R. glabra*, from North America, and *R. semialata*, from China, are among the most striking of the hardy ornamental shrubs for the present month. The first has elegant, pinnate leaves, composed of twenty or more leaflets, the general leaf-stalk, as well as the midribs of the leaflets, being a fine red colour; and the beauty of the plant is still further enhanced by short, dense panicles of small, bright red fruits. *R. semialata* is a much larger sort, with noble leaves made up of from five to nine leaflets; the small, whitish flowers are borne in large panicles. *Koeleria paniculata* is a handsome small tree from China; the foliage is very elegant, the leaflets being variously lobed, and the little flowers—yellow, with a small, orange-red centre—are so numerous as to make a tolerably good show in spite of their small size. Amongst shrubs remarkable for their handsome foliage, one of the best is *Aristotelia Macqui variegata*, a native of Chili; the variegation is most pleasing and constant. Provided a fairly-sheltered spot be chosen, the plant will do well—in the southern counties at any rate. *Calycanthus occidentalis*, a Californian shrub, also requires to be planted against a wall or amongst shrubs, as it is too tender to do well in the open in most localities; under favourable conditions, however, its large, handsome, deep brownish-red flowers—sometimes more than 3 in. across—are freely produced. *Potentilla fruticosa floribunda* is a charming dwarf shrub of good habit, and an extremely free flowerer, the yellow blossoms making a fine show.

Hardy Aquatic Plants.—A beautiful little Water Lily, *Nymphaea pygmaea*, deserves special mention; it has rather a wide geographical distribution, being found in Siberia, China, and on the Himalayas. The early part of the present century first saw it introduced to English gardens, and it was long ago figured in the "Botanical Magazine." For many years, however, it seems to have been totally lost to cultivation. Its little blossoms are pure white, not larger than a half-crown piece, and its leaves small in proportion; altogether, this is one of the most charming of all the smaller ornamental water plants. Another, very interesting water plant, though somewhat less beautiful than the last named, is *Hydropeltis peltata*; the shape of its leaves has earned it the name of Water-Buckler. The floating, oval leaves are very pretty, and the flowers are of a purple colour. Its distribution, like that of the Water Lily mentioned above, is very interesting and peculiar. It has been found in the United States, Canada, the Himalayas, and Australia. *Trapa natans*, the Water Caltrop, growing with the two plants just noted, is doing better than we have before seen it in the open air; some of its leaves have assumed fine reddish and purplish tints which are especially attractive. *Selliera radicans* is a dwarf Australian plant of neat habit, bearing numerous whitish-pink blossoms singly on stalks 2 in. in length. The North American *Cyperus vegetus*, a fine plant 3 ft. high, is equally as pretty as many of the kinds that are thought worthy of cultivation in the greenhouse or stove; it is of a pleasing, Grass-green colour, and furnishes a colour and habit not possessed by any of our native plants.

Hardy Herbaceous Plants.—*Cosmos bipinnatus*, a Mexican annual, is perhaps the loveliest and most graceful of all the Composites at present in flower; the large blossoms exhibit various shades of purple, and the foliage is light and feathery; under good treatment, the plants attain a height of from 3 ft. to 5 ft. The variegated form of *Symphytum officinale* is very striking on account of its large arching leaves broadly margined with cream colour. *Rudbeckia speciosa*, a United States perennial, is probably the most desirable member of a showy genus; it grows about 2 ft. high, and bears abundantly its handsome blossoms, the large ray being bright yellow and the disk a black-purple. A Michaelmas Daisy of very recent introduction, *Aster tortifolius*, will become a general favourite when more known; it has curiously cut leaves and showy blossoms of a pleasing mauve colour; its height is 1 ft. or rather more. *Browallia demissa*, a South American annual about 2 ft. high, has beautiful blue flowers. *Calceolaria glutinosa*, another very showy annual, grows about 18 in. high, and has bright yellow blossoms. *Convolvulus Dorycnium*, a South European plant with a very long flowering season, has charming pink flowers and narrow leaves; it is of shrubby habit, and grows about 1 ft. or 1½ ft. high. *C. scammonia*, the plant yielding the cathartic gum resin called scammony, is a fine decorative plant having long-stalked, arrow-head-like leaves, and long-stalked, white flowers borne in twos or threes. *Lobelia ramosa*, from the Swan River, in Australia, is an exceedingly showy annual, about 1 ft. high, the large flowers being a deep bright blue and having a white centre. *Cuphea silenoides* grows about 1 ft. high, and is covered with rose-coloured blossoms. Its variety of *Zauperi* is nearly double the height; the upper part of its large flowers is a black-purple, the lower being a dark crimson. Another variety, *splendens*, is about as tall as the type, but the

flowers are of a dull, red-brown colour, the upper petals being edged with purple. *Psoralea physodes*, 8 ft. or 9 ft. in height, a North American perennial, is now in flower.—†.

THE LIBRARY.

A SCHOOL FLORA FOR THE USE OF ELEMENTARY BOTANICAL CLASSES.*

THIS handy little volume possesses many advantages over several works which have, of late, been published for the use of those who have mastered the elements of botanical science. In it the author has adopted the analytical method which Lamarck was the first to develop—a method which is, in our opinion, by far the best for enabling beginners to arrive at a correct conclusion concerning any (to them) unknown plant. Roughly stated, the arrangement consists in continually coupling together two opposite characters, and in deciding at each step which of these characters are exhibited by the plant under examination. Of course great care must be taken to ensure accuracy at each step, but, with a tolerable amount of diligence, any one who understands thoroughly the meanings of the more commonly-used botanical terms can run a plant down, as it were, and name it correctly without much trouble. This, of course, could hardly be done at all by beginners without such aid as that explained above. A good many woodcuts—some rather roughly executed, but all very characteristic—illustrate plants of interest, and also points of structure, far better than mere descriptions. The book contains also a small glossary, which explains shortly most of the terms used. Such terms, however, as diococcus, tricoccus, &c., are, at the best, but clumsy expressions, and should not be used in any work like the one under review. Surely the Anglicised *aril*, too, is better than the more cumbersome *arillus*. We are told in the preface that, in the first instance, this work was compiled "for the use of the botanical classes of the Giggleswick school, and all the plants which grow within a few miles of that centre have, therefore, been included, whether rare or common; whilst in order that the book may be useful to schools in other parts of the country, all common plants have been included, whether growing there or not." Many widely distributed and common British plants are, however, omitted, and several which we cannot but think must occur within the limits, of which the author says he gives all the plants. The classification into common and uncommon plants by means of different type is, to say the least, somewhat misleading, many of our commonest plants being classed amongst the not generally common ones, and *vice versa*. Many typographical errors occur, and some few mistakes in description, which a future edition—and the work is such as to warrant another—will, no doubt, set right. G.

BENTHAM'S HANDBOOK OF THE BRITISH FLORA. †

A NEW edition of this valuable handbook has just been published. The principal alteration in it seems to be the giving the first place to the Latin names of the genera and species. It was not without some misgiving on the part of the author, that, in the first edition, in deference to the strongly expressed opinion and advice of the late Professor Henslow, an attempt was made to establish an English scientific nomenclature in imitation of the French and German ones introduced in several standard Continental floras. The names were partly framed and almost entirely settled by Professor Henslow himself, and it was hoped that as his successful experience in the popular teaching of botany was fully recognised, they would have met with general acceptance. In this, however, the author has been disappointed, and, at the request of several friends, he has now restored to the Latin names their usual prominence, retaining the English ones only in a second rank. Four species are added in the present edition, *Banunculus ophioglossifolius*, *Teucrium Botrys*, *Juncus pygmaeus*, and *Scirpus parvulus*, all long known as French plants, but only recently ascertained to be growing within the limits of the British Islands.

Glanville's Wootton (Hatchards, Piccadilly) is a neatly got-up volume, consisting of 392 pages, devoted to the zoology and botany of that part of Dorsetshire. The botanical part, which most concerns us, is arranged in the form of a catalogue. Both Latin and English names are given, and they are placed under the different Natural Orders to which the plants belong. Photographic views of the Church and Manor House at Glanville's Wootton are given, and also an introduction describing the parochial history and archaeology of the place. The work will be found useful for reference.

THE INDOOR GARDEN.

ORNAMENTAL TREE STUMPS.

IN a recent number of the "Revue Horticole" M. Carrière describes, under the above title, a method of utilising more or less decayed tree stumps by transforming them into picturesque objects for the decoration of the greenhouse or Fernery. Portions of the dead stump of almost any tree may be used for the purpose, those which have a large number of bold ramifications being the most suitable. In any case additional branches may be always added according to the place which the stump is to occupy, the new pieces being firmly secured to the parent stem by strong nails or, better still, by Oak pegs. Of course, in fixing the added branches, care must be taken to give the whole an irregular and rustic appearance, otherwise the artistic effect will be entirely marred. As the subjects to be placed on these ornamental tree stumps will require a constant supply of moisture, the stump must be surrounded with common Moss, Sphagnum, or some other substance which will maintain the whole arrangement in a continual state of humidity. If the plants used require a greater amount of nourishment than they can get out of damp Moss, a certain proportion of garden soil or well rotted manure should be added. The framework being put together, the next thing to do is to ornament it. Although the method of doing this must be left to the individual taste of the operator, nevertheless there are certain general rules to be observed in order to obtain as pleasing and picturesque an effect as possible. While avoiding monotonous regularity on the one hand, we must always proceed on some sort of system, so that a natural appearance may be given to the whole. The ornamental tree stump here shown is drawn from a beautiful specimen in a hothouse belonging to M. Worth at Turenne, and is the handiwork of M. Barré. As the form and dimensions of these ornamental tree stumps may be varied to a considerable extent, we can also exercise our choice in the description of plants to be used for ornamenting them; but here no fixed rule can be laid down, for everything depends upon the position which the ornamental tree stump is to occupy. Graceful variety should be the leading principle of the display, and the plants should be so arranged as to appear growing naturally. The following list will help beginners in selecting a proper collection, viz., *Æchmea fulgens*, *Alocasia spectabilis*, *A. Lowi*, *Anthurium magnificum*, *A. Scherzerianum*, *Aralia Veitchi*, *Adiantum gracillimum*, *Bilbergia Leopoldi*, *Cureuligo recurvata*, *Dracæna Baptisti*, *D. imperialis*, *D. umbraculifera*, *Eranthemum igneum*, *Fittonia Verschaffelti*, *Hechtia Jourvillei*, *Nidularium spectabile*, *N. latifolium*, *Pandanus pumila*, *Philodendron lucidum*, *Peperomia argentea*, *P. eburnea*, *Tillandsia sanguinolenta*, *T. Zahni*, *Vriesia splendens*, &c. It is to be understood that the plants in the above list are not the only ones which may be used for the purpose, for almost any kind can be used, according to the opportunities of the grower and

the place which the group is intended to occupy, but it must be borne in mind that certain classes of plants, such as the Ferns, the Aroids, and the Bromeliads, lend themselves more particularly to this kind of decoration. Although these ornamental tree stumps are most frequently employed in the ornamentation of conservatories, they are quite as applicable for open-air decoration, especially in places where the surface of the ground is somewhat irregular, as, for instance, in the neighbourhood of rocky eminences, grottoes, near fountains, springs, and waterfalls, in the wild garden, in artificial bogs, everywhere, in fact, where the surroundings of the spot are calculated to harmonise with this mode of decoration. If the position chosen be a dry one, succulent plants, such as the *Sedum* and *Sempervivum*, may be used with advantage. Climbing plants, such as *Ivy* of different kinds, *Delaireas*, *Periwinkles*, and even wild *Briers* and *Vines* may be used. Plants with variegated foliage, such as the variegated *Periwinkle* and *Grasses* (*Phalaris arundinacea picta*) may likewise be chosen. It cannot, however, be repeated too often that there is no absolute rule in the matter. Most kinds of plants, both tender and hardy, may be used in this way.

C. W. QUIN.

Ornamental Tree Stump (1-5th its natural size).

NEAPOLITAN VIOLETS.

WHERE Violets of this class are grown for winter flowering the time for transferring them from their summer to their winter quarters is close at hand. Presuming that the plants have been duly cared for during summer by copious waterings having been given them, and all runners having been cut off, they will now be sturdy plants with large, central crowns, good healthy foliage, and abundance of flower-buds. The position for the frames should be well sheltered from the north and east by a high wall or evergreen hedge. If quite open to the south, elevate the backs of the frames on temporary brick piers, so as to secure a steep incline, in order to catch every ray of sunlight and avoid drip. The surface will thus be dry, which is a great safeguard against damping off, which is very destructive when severe weather makes it necessary to close the frames for any length of time. The interior may be filled with dry leaves and stable manure trodden very firmly to insure a gentle, lasting warmth, allowing 1 ft. from the glass for plants and soil. Commence by putting a layer about 2 in. thick of good new loam over the manure, and on this set the plants, which should be lifted with the balls of soil entire by means of a steel fork. Thus treated, when replaced in the frame only some good, fine soil to fill the intervening spaces is needed, and no check whatever is experienced; a good soaking of tepid rain-water is then given them, when all is complete, and a mulching of *Coccoloba* fibre spread over the surface keeps the delicate flowers from being soiled while watering. The middle and end of September is the best season for transplanting, as the sun's rays are then sufficiently powerful to induce an active growth before the dull, dark days of winter set in. The flowers usually open in abundance during October, after which little water will be needed until the days begin to lengthen in spring. Damp is especially to be guarded

against by continually admitting air when the atmosphere is above the freezing point, and by taking the lights off entirely on mild or bright sunny days. All decaying leaves should be carefully removed, and the surface soil should be stirred occasionally in order to preserve a sweet and healthy atmosphere. Only the fully-expanded blossoms should be gathered, and, if produced under the above conditions, they should be of a deep lavender-blue. Although a hardy plant, frost must be carefully excluded by closing the lights on the first indication of frost, and covering the glass with reed or other mats and dry litter. The sides of the frames should also be well protected with dry leaves, but on no account should the covering be left on an hour longer than is necessary in the morning. As soon as a thaw sets in remove the covering, and admit just sufficient air to provide a free circulation and sweeten the atmosphere. The glass should be kept scrupulously clean by washing it both inside and out, removing the sashes during the operation, and drying them before replacing them. As the days lengthen more moisture and air may be indulged in, and a good soaking of well-diluted manure and rain-water may be advantageously applied to assist the early spring flowers. Under the above treatment I have had abundance of flowers from October until the following April, when the plants will again be needed for division, in order to provide runners for the following year's supply of plants. J. GROOM.

FEEDING AND DISBUDDING CHRYSANTHEMUMS.

CHRYSANTHEMUMS that are grown as standards either for decorative purposes in large houses, or for furnishing flowers for exhibition, are greatly improved by frequent supplies of liquid manure from this time and onwards; indeed, the present is perhaps the most important period of the whole season of Chrysanthemum culture. In the first place, as to feeding, I would observe that the old-fashioned idea of feeding only after the buds are set has long been set aside by good growers, who have found out that if a plant be not grown with sufficient strength to swell and develop a large bud, it is a hopeless case to endeavour to expand it by giving the plant superabundant supplies of stimulating liquids in the last stages of its growth. I mention this as an important fact, but let there be no misunderstanding. The feeding of these plants even now is but very imperfectly understood, and the consequence is, that many collections are either sadly undergrown, or, what is perhaps a still more common occurrence, they are permanently injured by being over-watered with strong liquids given at long intervals, a system that cannot be at all commended as discreet practice. To be clear, therefore, an intermediate line must be drawn, and the composition in which the plants are growing must be taken into account, as must the time of potting and the size of the pot, as well as drainage. All this may seem collateral evidence, but in reality it is the very foundation upon which every cultivator must base his treatment if a satisfactory result be expected. It is safe practice to let every second or third watering be weak liquid manure specially prepared for the purpose, up to the time the flower-buds are formed, after which, the strength of the liquid may be considerably increased according to the capacity of the plant for taking it. As a rule, tanks that are the ordinary receptacles or reservoirs for all sorts of manurial liquids are not safe; nothing excels cow manure with a mixture of soot, which latter imparts to the leaves a deep green colour and a healthy tone to the plant. As a change, a mixture of pigeon manure may be used with advantage. Let the motto be "often, but weak," and mulch the surface of the pots with fresh horse or cow manure to encourage and stimulate surface roots. The disbudding of Chrysanthemums is, without doubt, an important item in their cultivation. The feeding (although it takes precedence from a certain point of view) is actually of secondary importance, but both are at the same time inseparably connected where high cultivation is desired. First, you feed in order to secure a strong, vigorous plant, which will produce a large, well-developed bud; next, you select the proper bud according to the variety, and then the bud has to be supplied with the requisite nourishment to cause it to swell and develop itself into a perfect flower. The exact rule to be observed in disbudding can only be

attained by careful observation and long experience. Chrysanthemums that are grown for the quality of their flowers alone are furnished with from one to three stems, according to circumstances. If the plant has not been pinched at any time during its growth, it will branch into three stems in July, and it may probably show a bud on the point of the main stem about the same time; this bud should be removed carefully, or if allowed to remain, the stem will branch into three shoots just the same. Generally speaking, most of the finest varieties of the incurved section will do best on the next bud that is formed on the point of each of these shoots, that is, of course, assuming that there has been no check to growth, and that the buds are neither too early, nor too late. I know of many instances this season where early propagated plants are giving some trouble in this respect. The remedy is of course to remove the bud, and allow the flower to be produced on the terminal shoot, because if this bud were taken, and the growth of the plant stopped, the probability is that the flower would be loose and unshapely, instead of being conical-shaped with broad deep petals of a self-incurving habit. In order to be clear I would further remark that the last days of August are early enough to risk stopping vigorous plants, especially varieties that have a tendency to be coarse, but are at the same time indispensable as show varieties, such as Alfred Salter, Lady St. Clair, Empress of India, and others of like habit. These are best grown on the terminal bud system, if the bud before alluded to (the crown terminal) should show itself before the very last days of the present month or early in September. When the latter bud is formed late it is by all means the one to secure, and if well treated will produce a very large flower. Where a bud shows itself, say the third week in August, and it is seemingly perfect in all its parts, it is a good plan to retain the bud, but in stepping the plant only pinch off two of the breaks and allow the third to grow alongside the bud for a time. As the bud develops itself satisfactorily and requires that the natural vigour of the plant should flow into it, this shoot will of course be pinched away. Another very good plan is to work the process of disbudding on a sort of compromise principle by adopting the plan just alluded to with one shoot and taking the terminal bud of another, thus securing two chances on the same plant. It is also necessary in disbudding to keep in view as much as possible the individual characteristics of each variety, as, for instance, White Globe and Jardin des Plantes, both grand old varieties and well adapted for exhibition, are better taken somewhat early, so that there may be uniformity in the time of flowering if a stand of show flowers be required. Mistakes are made in disbudding (owing to an imperfect idea of the number of times a plant should break before the bud is taken) which need not occur if it be borne in mind that it is not the number of breaks on a plant that has anything to do with the quality of the flower, but catching the bud at the proper time. The disbudding of general collections is not as yet recognised beyond a very limited extent, and yet the quality of the flowers on bush-grown plants may be vastly improved by growing plants for grouping purposes on a limited number of stems and taking one flower each from a stem. I allude to private collections; those who grow flowers for market of course adopt the system of culture which pays them best.

The Japanese section is becoming more popular every year. The disbudding of the early varieties, which may be performed earlier than the incurved sorts—at all events standard kinds such as Elaine, Fair Maid of Guernsey, and Jane Salter—produces noble heads of bloom when the latter is reduced to from three to six flowers on a plant, and, grown on the crown terminal bud plan, Elaine (snowy-white) and Jane Salter (lilac) will bear gentle forcing, and may be had in bloom a fortnight before the general collection. W. HINDS.

Otterspool.

The White Roman Hyacinth.—For house decoration in small pots, or as flowers in a cut state for bouquets or otherwise, there is not a more useful plant than the white Roman Hyacinth. If potted now it comes into flower, with scarcely any forcing, during the dullest and darkest months of the year, and by keeping a reserve stock of it in cold frames and introducing a few pots of it into gentle heat at intervals of a week or so, a continuous supply may be main-

tained until the large-flowered varieties of Hyacinths come in plentifully. For indoor decoration three bulbs in 4-in. pots are very serviceable, but, if required for cutting, they may be brought forward just as well in pans or shallow boxes, and, if in light compost, they may be removed with roots intact for table decoration, epergnes, &c.—J. GROOM.

Plumbago capensis as a Standard.—This well-known plant is grown as a standard about 4 ft. high in some of the Paris gardens. The flowers are freely produced, and the standards form good heads. Once seen, however, planted out in a cool house and draping a wall or pillar with its unrivalled sky-blue flowers, few will care to see it in any other way.—V

Culture of Bulbous Plants in Pots.—The finely-flowered plants of *Vallota purpurea*, shown at South Kensington on the 20th inst., confirm my experience that bulbs which have persistent roots do not like shifting. The plants in question were evidently old-established plants, left, offsets and all, undisturbed in a mass, and only shifted when they had got too large for their pots. If disturbed as little as possible, not only do they grow better, and are less apt to decay, but they flower more profusely and with greater certainty. This has been my experience for the last twenty years with large collections of *Vallota*, *Amaryllis*, *Nerine*, *Veltheimia*, *Drimis*, *Crinum*, *Pancratium*, *Griffinia*, *Brunsvigia*, *Hæmanthus*, *Ornithogalum*, and similar genera. When they are shifted it should be in spring when they are growing; if moved when in a partially dormant state, they are apt to lose part of their roots; water should be given with care at all times. The soil which I have found to suit them best is a light turfy loam, with a moderate admixture of sand. I always avoid manure, it being much safer to give a little manure water when the plants require it. When they are growing they should have plenty of air and light. I have also found that *Antholyzas* and *Watsonias* flower best when allowed to get pot-bound. I do not intend these remarks to apply to such plants as *Lachenalias*, *Tritontias*, or *Ixias*.—J. CROUCHER, *Sudbury House, Hammersmith.*

Storing Gloxinia Bulbs.—At this season, when many of the early-flowered Gloxinias are approaching a dormant condition, every precaution should be taken to ripen the bulbs off well by preserving the foliage in health as long as possible, giving them a light, airy position, and gradually reducing the supply of moisture, so that the leaves may fall off naturally, and not, as is too often the case, become withered up while green through lack of moisture, or by being excluded from the light while in a partially resting condition. I have preserved hundreds through several winters with the loss of scarcely 1 per cent. by packing them on a shelf in a dry shed where a steady temperature of from 50° to 55° could be maintained. By packing the largest specimens at the bottom of the tier, and filling in between each layer of pots with Moss, excessive dryness at the root was avoided, and when those for starting earliest were drawn out for potting, an empty pot of the same size as that withdrawn was inserted in the vacancy. By this means the young growths started strongly, and if the position became too hot as spring advanced for the latest batch they were removed to cooler quarters; for, although Gloxinias do not appear to be benefited by an extra long season of rest, they may be kept a long time in a partially dormant state by withholding the moisture and heat necessary for their full development. As seedlings are now, however, raised so easily with flowers of extra good quality that continue in bloom during the autumn months if sown early in the year, it is scarcely worth retarding old roots for a very late supply. In fact, except in the case of extra good named varieties, it is best to raise fresh plants to replace any that are getting overgrown, as plants of the second or third season's growth are preferable to older, although larger, bulbs.—J. GROOM.

Eucharis amsonica.—Among stove bulbous plants most worthy of culture, this is of the first importance. Its flowers are hardly surpassed by those of our finest white-flowered Orchids, even those of the white *Phalænopsis*, while the *Eucharis* is infinitely easier to grow. There are few gardens without it, but the general complaint is that it does not flower, which is not to be wondered at, considering the starvation system of culture to which the plant is sometimes subjected. A native of the tropical valley of the Amazon, this plant requires heat and moisture and a good strong soil. If it be potted in the spring, and subjected to a high stove temperature, good foliage will be developed, and from July or August onwards flowers will be produced in abundance. But the bulbs in the same pot do not all flower at the same time; consequently, the plant should be kept in the same temperature until all have flowered, which they will do later in the season. We have known one pot containing perhaps a dozen bulbs continuing to throw up flower-spikes for perhaps two or three months. This habit of the plant has probably led some cultivators to believe that they have succeeded in flowering the *Eucharis* three or four times during the year. They move their plants, when done

flowering, in the meantime back from the conservatory to the stove or propagating pit again, and a new crop of flowers is the result, but they are not from the same roots. The *Eucharis*, like other plants of the same nature, requires a season of growth before it can produce flowers, and it is not to be expected that fresh crops of flower can be produced from the same root every two months. The plant does not require potting every year, but when it is potted the strongest and largest bulbs should be selected and potted in good strong sandy loam and rotted manure; during growth the plants should have plenty of water, and should be shaded from strong sunshine.—J. S.

ACCLIMATISATION OF PALMS.

PLANTS differ greatly from animals in the closeness of their adaptation to meteorological and other conditions; hence, on the one hand, while in England we can have parrots, monkeys, lions, tigers, and other tropical and sub-tropical animals living at ease during winter, and even the polar bear looking quite at home during our hot summer months, we lose, on the other hand, the enjoyment of many beautiful wild flowers and magnificent forest trees which enliven the scenery and greatly enhance the pleasure of the traveller abroad. Who that has travelled much does not remember the pleasure, nay, the rapture which he felt as he neared his first foreign port—say Madeira, for instance—in beholding the luxuriant “feathery Palm trees rise,” as Heber sang when he linked them together with other of our earthly conceptions of “the better land.” They are undoubtedly the first objects which forcibly strike the wanderer, and enable him to realise that his dear old home is far behind, and that he is, indeed, in a distant land. There is nothing so thoroughly foreign to the eye, and few objects in Nature more attractive. The long-tailed Celestial, the almond-eyed “Jap,” and the black-skinned negro have been long familiar in our streets, but the Palm stands out in broad relief as the first novelty which attracts attention abroad. Having lately spent some months in Shanghai, I have been led to these remarks by observing, during the present severe winter, how well the few Palm trees planted there have withstood the rigour of the climate, and was first forcibly struck with the subject when, one bitter cold morning, a friend called my attention to the almost anomalous condition of Nature, that the Palm trees were covered with snow; and very pretty objects they were. That the specimens planted along the Bund of Shanghai are as graceful as the lofty Cocoa-nut trees of Ceylon or the Sago Palm of Borneo I do not maintain; but they are well worthy of the attention of those interested in the acclimatisation of plants, for few things would add more to the beauty of our parks, or better set off a landscape than endogenous trees, of which our climate has, or is supposed to have, deprived us. Shanghai is situated on the Woosung river, about twelve miles above its junction with the mighty Yang-tze-Kiang; the country around is perfectly flat, and the soil alluvial. Although so far south as 31° N. lat., 20° below the south of England, the winter is rigorous, and altogether the climate bears a most remarkable contrast to places in the Western Hemisphere situated in nearly the same parallel of latitude, e.g., Malta and Bermuda.

The following table shows the average mean monthly temperature of several years past:—

January	40° Fah.	July	83° Fah.
February	42° ”	August	83° ”
March	50° ”	September	76° ”
April	55° ”	October	67° ”
May	69° ”	November	55° ”
June	76° ”	December	47° ”

During the recent winter there has been at least ten days continuous skating, and the thermometer during the month of January was frequently below 20° Fah., or 12° below the freezing-point. During the last six months there has been an extreme range of 82°, i.e., from 99° to 17°.—R. NELSON, R.N., in “*Science Gossip*.”

Plants from Russia at the Paris Exhibition.—In front of the Russian building at the Paris Exhibition, a collection of Russian herbaceous and Alpine plants is planted out and thriving freely. The collection was sent by Dr. Regel, from St. Petersburg, and includes a good many species, rare, and even some new to our gardens.

Eryngium Bromeliæfolium.—This is one of the best of a highly ornamental class of hardy plants, having effective foliage and fine spikes of flowers. It also looks well in pots in a young state, the foliage being rigid and spiny, and, in the case of full-grown plants, about 2 ft. long. In a matured condition this plant has a good appearance on Grass and as a background plant in herbaceous borders.—J. GROOM.

THE FRUIT GARDEN.

STRAWBERRY GROWING MADE EASY.

UNLIKE other kinds of fruit, the Strawberry soon wears itself out and requires renewal; one might, indeed, almost term it a biennial, for, in an ordinary way, Strawberry plants cannot be relied upon to bear well after the second year. It occasionally happens that a plantation will last much longer; but this only occurs in favourable soils, or where particular attention is paid to its culture. In the ordinary way of cultivation fresh plantations have to be made every year, or there comes a time when, through exhaustion or a dry season, the plants die off in the ensuing year, and there is little or no fruit. In places where forcing is carried on, hotbeds serve to keep up the stock of plants. They are planted early enough to bear a good crop the next year, and those who can manage in this way need not fear a dearth; but the amateur generally has no such resource, and he cannot be made to see the necessity of planting annually. I am also inclined to believe that the instructions usually given upon Strawberry culture often have a deterrent effect upon many. The deep trenching and heavy manuring, the planting out at wide distances apart, and the after care required are, though undoubtedly the proper way to insure first-class fruit, often rather more than one is either able or willing to undertake. In soils of an unfavourable character (and there are many such) a considerable amount of skill and experience is required to produce a crop. In order to obviate these drawbacks I propose here to describe a method of growing Strawberries which I have followed with good results, and which, although by no means new, is so sure and simple, that I have often wondered that it has not been more generally adopted. Choose a piece of ground and mark out a bed 4 ft. in width, the length to be optional; let this be dug over, turning in a little short manure. Select a day when the soil is rather dry, rake it level, and tread it firmly; the lighter the soil the harder it should be made. On this bed plant the runners in rows 9 in. apart and 6 in. asunder in the rows, planting firmly. The best and most expeditious method of planting is as follows: Mark the line upon the bed, running the spade along it, withdraw the line itself and set out the distances upon the mark thus made; then with a trowel cut out a piece of soil, lay the roots of the runner against the even part, fill in, and tread firmly. Thus set, no worms or frosts will move them in winter, and they will much better resist the summer's drought. In March they should be hoed between, and they should be kept clean during the growing season. If a mulch of short manure can be given them they will be benefited thereby, and they should produce a fair crop of well-swelled fruit. Beds thus made, if top-dressed annually, will last several years. Being thick together, the leaves shade the ground, consequently they do not parch up in hot weather; the fruit, too, does not fall on or lay upon the soil, and the bloom is not so liable to get cut by spring frosts as it otherwise would be. In fact, I have known beds of this description to bear well when the general crop was almost annihilated. The first and second season the runners should be kept cut off, and when the fruit is gathered, give a top-dressing of soot and a good watering. This will be nearly all the attention which they will require, as, being close together, it is not necessary to promote rank growth. The second year they will have become too thick, when every other plant should be taken out; these, if laid in for a time, will serve to make other beds, being somewhat superior to young runners. I have known beds thus managed to last and bear well for five or six years. The great point is to give them a fresh start when the fruit is gathered, and to keep them just thin enough to allow the crowns to mature. If the planting cannot be done in autumn, it may be deferred until spring, but it should be finished by March; in that case it is better to take up or procure the runners in autumn, and lay them in some leaf-mould; they will then be furnished with plenty of fibres. This kind of culture possesses several advantages, not the least of which is the facility with which the plants can be protected in spring, and again when the fruit is ripening; the fruit, too, is easily gathered without having to trample upon the foliage. One of the best kinds for

this purpose is President, as it is robust and throws up its trusses well above the leaves; the berries, too, being firm, resist the wet better than most kinds. The time is now at hand when the ground should be prepared, and I would strongly recommend those who may have hitherto failed to grow good Strawberries to give the system just described a trial.

Byfleet, Surrey.

J. CORNHILL.

NOTES AND QUESTIONS ON THE FRUIT GARDEN.

Grape Vines at Fulham.—One of the most noteworthy features in the Fulham Nurseries just now is a long Yew hedge covered with pot Vines, put out to ripen their canes. Their growth is remarkable, both as regards length and strength, and they are probably the best examples of pot Vines ever grown in the Fulham Nurseries.—C. S.

Pears in Cellars.—At a recent meeting of the French Société Centrale d'Horticulture, M. Fresgot, an amateur fruit grower, showed a number of Winter Bon Chrétien and Prévost Pears, and some of an unknown variety; also Canada Reinette and Reinette de Caux Apples. To judge by their outward appearance, these specimens were well preserved, but unfortunately the Pears had almost entirely lost their flavour. The Apples had not suffered so much in this respect, especially in the case of the Canada Reinette, which, nevertheless, had gone a little pasty. The Secretary of the Committee of Arboriculture remarked that the Prévost Pear, as a rule, kept very well, but that it was not a good table Pear, and was only to be recommended for pastry. As there had been a discussion on several former occasions on the method adopted by M. Fresgot for preserving his fruit, which consisted in keeping it in a well-ventilated cellar, M. Ferdinand Jamin said that it was a mistake to suppose that underground cellars were the best for preserving fruit. When kept underground Pears lost their flavour, although Apples kept well enough. As for Pears, they required a well-ventilated room on a level with the ground.—C. W. QUIN.

Cherries in Rhenish Bavaria.—The village of Weissenheim has long been noted for its Cherry crops. This year the harvest has been most abundant, not less than 1,500,000 lb. of Cherries, valued at £9000, having been bought up, and despatched to England, Hamburg, Bremen, Berlin, Manich, and elsewhere. Doubts have occasionally been thrown upon the accuracy of statements relating to the Weissenheim fruit crops, but the following fact will tend to show that their abundance has not been exaggerated. In 1875 the inhabitants of a neighbouring village, being unable to come to terms with the directors of a contemplated railway as to the compensation to which they were entitled, agreed to refer their case to arbitration. From well-authenticated facts placed before them, the arbitrators valued single Cherry trees at £16, £24, and £36 apiece. One tree, indeed, was appraised at the large sum of £86. The secret is that in the villages at the foot of the hills which fringe the valley of the Rhine in this district late frosts are absolutely unknown. When the Cherry crop is ripe the schools are all closed for a fortnight, and young and old, big and little, set to work to get in the harvest. After the Cherries come Apricots, after Apricots Plums, then follow Pears, then Apples, and, lastly, wine of excellent quality fitly closes Pomona's long list of choice gifts of the season.

Fruit Trees Twice Transplanted.—Mr. Green, Clifton, New York, writes in "The Rural Home" in favour of fruit trees twice transplanted. With Apples, Pears, Cherries, Plums, &c., almost one year may be gained by planting the trees closely together, say 3 ft. apart, in trenches made with a plough, the spring previous to planting permanently. The reason that trees make such little growth the first season is not so much owing to their removal as to the loss of the larger part of their feeding roots. By planting the season before wanted, as above, a fine growth of new feeding roots will be formed, but not spreading far enough to prevent their removal entire without mutilation. Thus when permanently planted every one is almost certain to live, and will make a vigorous growth the first season. Nurserymen treat evergreens to several transplantings in order to secure fibrous roots, but I have never known the method to be extended to fruit trees. We have tested it on our grounds, and with very encouraging results; the fruit trees twice transplanted making almost as vigorous growth the first year permanently planted as those planted two years before in the ordinary way. Were the advantages of this method generally appreciated, there would be a demand on our nurserymen for fruit trees twice transplanted. But any planter can, by securing the trees a year in advance, avail himself of the advantages to be gained at a trifling expenditure. A few hundred trees 3 ft. apart in a row could be cultivated very economically as compared with their cultivation when planted over a whole field.

GARDEN DESTROYERS.

MELOLONTHA VULGARIS.

(THE COCKCHAFFER, MAY-BUG, FERN SHAW BEETLE, OR BRACKEN CLOCK.)

WHEN present in large numbers, cockchafers do an almost incredible amount of mischief to various trees by eating great quantities of their leaves, and even at times stripping them all off. They have been known to attack Beeches, Elms, Sycamores, Willows, Oaks, Cherry, Apple, Pear, and Nut trees, and Vines. Lime trees are said by Kollar to be free from their attacks, but Messrs. Kirby and Spence, in their "Introduction to Entomology," give the Lime among the trees on which they feed. The grubs will eat the roots of nearly all trees and plants, particularly those of Cherry, Plum, Pear, and Apricot trees, Rhododendrons, Azaleas, Roses, Strawberries, Lettuce, and Sorrel. The plants attacked by them soon droop and die. It is useless to search for the grubs at the roots of plants which are much withered, as the grubs have probably already left it and commenced their attacks on another. The best way is to look at the roots of a plant immediately it shows any signs of drooping. Some who have suffered much from their Strawberry plants being killed have found flowers of sulphur strewed on the ground and then dug in a very effectual method of keeping them away. One-tenth of gas liquor to nine-tenths of water, or strong salt and water, is very useful for watering Grass in the autumn when attacked by these grubs. Others have planted Lettuces and Sorrel (both of which plants the grubs are particularly fond of) to attract them from other plants. This insect fortunately has many natural enemies—rooks, jackdaws, blackbirds, thrushes, starlings, and many other birds; moles, field mice, pigs, and some beetles destroy large numbers of them.

The Cockchafer, in different stages of development.

The cockchafer belongs to the Natural Order Coleoptera, or sheath-winged, from two Greek words—*kolcos*, a sheath, and *pteron*, a wing. The upper pair of wings form a sheath or covering for the lower ones. This well-known insect is about 1½ in. long. The mouth, antennæ, wings-cases, legs, and upper part of the body are of a bright chestnut-brown. The eyes and the spines on the legs are black. The head and thorax are of a bronzy-green, so thickly covered with yellowish-white hairs that their colour is almost hidden. The wing-cases are covered with very fine white hairs or scales, which are very easily rubbed off. The under side of the body is of a dark olive-green, with an almost triangular white spot on either side of each segment. The body is not entirely covered by the wing-cases, but is produced beyond them into a long, deflexed cone, about 8 lines long. The forelegs are admirably formed for digging, being partially flattened and furnished with two strong spines. The antennæ have ten joints; the seven terminal ones in the male and the last six in the female form a large club, which can be opened like a fan at the will of the insect. The club of the male is considerably longer than that of the female.

The females lay their eggs in April and May at the bottom of a hole some 4 in. or 5 in. deep, which they make in the ground. The eggs are about the size of a Hemp seed, and of a yellowish colour. They seem to vary much in number, but probably less than fifty will seldom be found. The grubs are known by the name of white worms in England and of Connaught worms in Ireland. They are hatched in June or July; they have fourteen joints including the head; their bodies are much wrinkled and of a dirty white colour, with a bluish tinge in the terminal segments. They have three pairs of legs, one on each of the first three joints. The head and legs are of a yellowish-red. The insect in this state has no eyes. During the first summer and autumn the newly-hatched grubs keep together, and the damage they then do is inconsiderable: Before the frosts and rains of winter set in they burrow deeper in the ground and, having changed their skins, remain in a torpid state during the winter. They come nearer the surface in the spring, and then feed singly on the roots of nearly all herbaceous plants. When one year old they are about ½ in. long. At the approach of winter they again descend deeper into the earth, change their skins, and remain torpid; and on the approach of spring commence their depredations with renewed vigour, attacking the roots of fruit and forest trees as well as those of herbaceous plants. During the summer they attain the length of 1 in. At the end of autumn they again bury themselves out of harm's way from frost and rain, as in previous winters, changing their skins and remaining torpid until the return of spring, when they are nearly full-grown and about 1½ in. long and nearly ½ in. in diameter. In July they descend to a depth of 5 ft. or 6 ft., and, having made oval cells in the earth by the movements of their bodies, lined with a glutinous secretion from their mouths, they assume the chrysalis state, whilst in this condition the antennæ, legs, and wing-cases of the insect are easily seen through the thin, pale reddish skin of the chrysalis. They remain in this state until the next January or February, when they emerge as whitish, soft beetles, but in a few days become hard and of their mature colour. They still, however, remain underground until the middle of April or May, when they dig their way to the surface with the aid of their strong forelegs. The perfect insects do not live more than ten or twelve days; their flight is usually slow and awkward, and they seem unable to prevent themselves flying against anything in their way. They seldom fly about till evening, resting on the branches and under the leaves of trees during the daytime. S. G. S.

Lady-birds and Green Fly.—In the cultivation of Dahlias and Roses I have derived so much assistance from lady-birds, that I am desirous of saying a word or two in their favour. I am afraid that large numbers of the larvæ are destroyed owing to people not knowing what a vast amount of good they, as well as the fully developed beetle, are capable of effecting. At the present moment my Roses and Dahlias are being cleared of green fly by the larvæ of the lady-bird, which swarm upon the plants, and I have no fear as to the ultimate results. Some years ago, during the early part of the season, my Roses were so badly infested with green fly that the blooms had to be carefully cleansed with a brush and water before anything could be done with them; but in the course of the summer lady-birds and their larvæ so effectually cleared the plants that in the autumn there was not an aphid to be found.—GEORGE RAWLINGS, in "Gardener's Magazine."

Home Travel.—The variety and richness of English landscapes, the noble coast scenery of Yorkshire, Dorsetshire, Devonshire, and Cornwall, the lovely hills and lanes of Surrey, the Sussex downs, the mountains and lakes of Cumberland and Wales, of Scotland and Ireland, the literary and historical associations which make hallowed ground of so many spots in these islands—here are attractions which should suffice, and more than suffice, to satisfy the curiosity and to delight the eye of the traveller. And he has the satisfaction of feeling that they belong, as it were, to himself. As an Englishman, his own country claims his first regard, but its objects of beauty and interest lie so close to him that he is liable to forget their value. Many cultivated Americans put us to shame in this respect. England, the mother-land of the race, has for them an indescribable attraction. They are eager to visit a country hallowed by so many memories; to see the home of Shakespeare and the scenes immortalised by Scott; to visit our great seats of learning; to explore the ancient buildings and institutions which testify to the durability of English customs; to do homage to what is venerable in a past which belongs to them as well as to us. Even when, like Hawthorne, they exhibit some prejudice, their remarks betray affection for England as well as pride in her greatness; and it may be said with truth that some of the most enthusiastic descriptions of English scenery and of our stately homes and venerable cathedrals have been written by Americans. There is surely a moral in this fact for the tourist.—"Social Notes."

ROSES.

What Constitutes a Good Rose.

BOTANISTS enumerate some eighty or more species of the Rose, while florists give us an almost innumerable number of varieties, of which but few are adapted for the general cultivator in any given soil and latitude. To enumerate the species and varieties does not come within our province, but it may be well to state a few of the leading characteristics of what most of us consider a fine Rose, whether species or variety. Excepting the Moss Rose, all varieties should possess foliage of a bright shining green, which colour, to be perfect, needs to be permanent, although not likely to be found in many varieties, my preference being for a sort of evergreen foliage. However size, form, &c., may vary in different varieties, uniformity in the same variety is desirable. A fine Rose is one which is rich and beautiful in all its stages of bud and blossom, up to, and previous to wide and full expansion. Single and double flowers, while enclosed within their calyxes, are alike beautiful up to a point where they expand to hide the calyx; but the double possess that characteristic which makes them magnificent when full blown, while the single are best shown previous to full expansion. Whatever difference there may be otherwise, the petals of all Roses should be thick, broad, and smooth at the edges. The bud and blossom should possess fragrance, and the higher that fragrance the more valuable the variety. The flower should be double to the centre, high on the crown, round in outline, with regularly disposed petals. The peculiar characteristics of any and all varieties should be strongly and fully developed in each flower.

Soil.

The proper soil for the Rose is a strong, rich, friable loam, well drained naturally or artificially, neither too moist nor too dry, but with such a degree of moisture that the plants will never suffer from want or excess. But we are commonly restricted to "Hobson's choice," and provided with soil, such as we are obliged to use, already made. Such being the case, we must supply any deficiency to the best of our ability. By aid of the present lights of science, and a little labour, we are enabled to largely modify and ameliorate almost any soil, often changing its entire character, and remedying defects in climate, &c. A fine Rose cannot be grown in uncongenial soil, therefore it is idle to expect it. If the soil be poor or ill adapted, the blossoms will be but imperfect, perhaps radically different from those grown in soil well adapted to bring out its strong points. Thorough drainage is essential, and where this is had there is little danger of having the soil too rich; and even when it may be thought sufficiently rich, the addition of a little well decomposed manure or compost will be advantageous. There is no fertiliser better adapted for the Rose than decayed turf from an old pasture—the older the pasture the better—mixed with old cow manure; and especially is this invaluable in pot culture, where the cow manure should be in excess of that needed in out-door culture. I have grown and blossomed Roses in clear cow manure, which has lain out and was gathered from pastures, and pulverised when dry, but I think a portion of soil, to give cohesiveness, is better. Recollect that the best of soil and careful attention is the price of successful Rose culture, and that the soil is just what we have the will to make it, when it is otherwise than an appropriate one for the Rose.

Manures for the Rose.

Roses are high livers and like food in plenty; a meagre diet will not answer the demands of a fine Rose. Of all animal manures that from the cow seems to be the best adapted to the wants of the Rose, but the manure, from whatever animal it may be, should be well rotted or decomposed, and be well incorporated in the soil. Thin turf, from an old pasture, well decayed and mixed with the manure, several times turned, is one of the best of Rose fertilisers; another good one is composed of one part Peruvian guano, three of decayed turf, and six of cow manure, all well mixed and made fine. The turf should be from some rich old pasture, just thick enough to embrace the main part of the grass roots. Pig manure, soot, and wood ashes are each and all good when composted or applied as top-dressing and well worked into the soil. All manures should be administered in allopathic, instead of homoeopathic doses. Scapends are excellent fertilisers and renovators, applied to root and branch. Solutions of guano and other manures in water are excellent, and are generally best applied at night or just before rain. If applied to the roots at any other time the top soil should be removed, making a sort of basin around the stem, the liquid poured in and the soil returned; in this way no crust forms on the surface.

Planting the Rose.

Tender and half-hardy Roses, when planted in the open ground, should be planted only in spring; the hardy sorts may be planted

either in spring or autumn, although I prefer spring planting. It should always be early spring or while they are dormant when the plants are set. Tea-scented and other tender sorts should not be planted out-doors until the danger of spring frosts is past. To plant a Rose properly the roots require the first attention; every bruised, ragged, or torn root should be cut off smoothly above the wound; tap or downward-growing roots should be shortened to discourage downward growing; cut back the top at least one-half, if not already done, in order to keep the balance. Have the holes dug sufficiently large to receive the roots when fully spread; loosen up the ground in the bottom, and mix in several inches of rich surface soil for the Rose to stand in and over. Place the plant in the centre of the hole, so that its collar will stand even with the level surface of the ground, unless it be a budded or grafted one, when it should be set deeper; then fill in the rich soil so that every root and branchlet of root shall be closely embedded therein; the soil should come in close contact with every portion of the root, for on this depends the success of planting. Moderate firming of the soil, only sufficient to hold the plant firmly, is all that is necessary, when the soil is in contact with the whole root. Unless the plant be of the dwarf sort, a stake should be firmly set and the plant tied to it. The mode of planting, whether singly in groups, or in beds, must be governed by the circumstances of the individual planter, but does not in any way affect the manner of setting in the ground. If planted in groups the taller-growing are best set in the centre, or in the background, grading downwards to the outside; if in rows they should be at proper distances, so that each shall form a specific object in itself, as well as a portion of the row. Planted singly on the lawn they form beautiful objects, and ought to be each distinct from the other, blooming at different periods; but where set in clumps or beds they make a greater show to blossom at the same time. The situation for planting Roses, especially the tall-growing sorts, should be one somewhat sheltered from strong winds, and the trellises or supports should be set out before planting, and be firmly fixed in the ground.

Pruning.

The pruning of out-door Roses is best performed in March or April, and must be in accordance with the habits and requirements of the particular variety. While some do best with only moderate pruning, others require to have one-half or two-thirds of the last season's growth removed; but with all pruning a well-shaped top should be kept in view; this can be attained by a combination of cutting and tying to position. The terminal bud at the cut should be left in the position which will most readily promote the growth of the desired form; for instance, if a more spreading form be desired, cut so as to leave the bud on the under or outer side; if a compact or upright head be sought, the reverse course should be pursued. Strong, healthy wood is always desirable, therefore in pruning out the weaker, reserving the strongest to make the new growth from. Always prune with a definite and fixed form or object in view. Vary the pruning with the requirements of the different varieties, and also for the positions they are to occupy, whether as standards, over pillars, flat trellises, walls, &c. If you desire quantity, regardless of quality in bloom, cut and diebud sparingly; but if quality is the first object, cut out all weak wood, and then cut away all wood of last year's growth down to one, or at most two eyes, and then you may go still further and cut out one-half of what is left. If with judicious pruning your Roses do not produce magnificent blossoms, you may conclude that there is something wrong or wanting in the soil, provided the season be an average one. Perhaps it needs some fertiliser added; rich loam or decayed turf mixed with its bulk of rotted manure, is better than clear manure and should be well worked into the soil around the roots; work it in in a circle equal to the circumference of the full spreading top. Budded Roses sometimes send out suckers or shoots from the stock; in planting such, it is well to set them with the junction of the stock and bud below the surface, so that the budded portion may form roots of its own, and thus become independent of the stock. Watch for any indication of suckering, and rub out all buds before growth is made.

Pot Culture.

If out-door culture of Roses is comparatively simple and easy, the culture in the house, conservatory, &c., is generally attended with many difficulties. For pot culture we select the tender or monthly classes, though with care some other sorts may be grown with moderate success. I shall confine myself to dwarf and tender varieties; and these must be selected with reference to the care, &c., which can be accorded them by the cultivator. And first, as to pots—these should be clean, free from mould, and large enough to correspond with the size of plant and roots to be grown in them. Potting soil should be composed of old pasture turf, loam, and rotted cow manure, in about equal proportions, or woods earth and sharp sand may be substituted for turf or loam—say one part of sand to

three or four of leaf-mould, and the same of manure. Provide good drainage by placing potsherds or charcoal in the bottom, which should have a hole in it, and be raised a little from the saucer so as to allow the air to circulate; cover the drainage material with soil; then place the plant in the centre of the pot with the roots well spread; fill in among the roots with fine soil, using every care to bring the soil in contact with each root and every part thereof, firming it moderately, after which give it a gentle watering. If this potting be done before it is desirable to place the plants on the stand, the pots should be plunged out-doors in a somewhat sheltered position in sawdust, tan bark, or some like substance, to prevent drying out, there to remain till desired to place in the house or conservatory. When the plants are potted they should be pruned, as a general rule shortening in about one-half. As a general thing the temperature of our living rooms is subject to too great variations and the atmosphere is also generally too dry for successful cultivation of the Rose; to remedy these defects great care should be used in parlour culture to keep an equable temperature, with suitable ventilation, and then to frequently shower the plants. In the conservatory and greenhouse the temperature can be more equably maintained and we can in some measure remedy a dry atmosphere by evaporation of water, but we may fail by giving too much moisture, causing mould, &c.; good judgment and much experience are required to keep the temperature and atmosphere in just the right state, for doing which no arbitrary rule can be given. The soil of the pots must not be allowed to become dry or be sodden from too much wet; water well and thoroughly when water is given; dig up and stir the soil in the pots occasionally, as far as may be without disturbing the roots. Cut back the plants freely after blossoming, or, which is better, cut back blossom and stem as soon as they have matured. The stronger and more stocky the plant, the better it is able to support itself and produce fine, healthy blossoms. Use the greatest care not to allow the plants to become drawn, but give fertilisers in a liquid form freely. Study in culture to render it suitable to the plant and the object in view.

Propagation and Protection.

There are various methods of propagating and multiplying Roses; such as by seed, budding and grafting, and offsets or suckers. For budding and grafting, stocks of some hardy inferior kind are generally used. The mode of budding and grafting does not vary materially from the same process with other woody plants and trees, and need not here be described. Protection is advantageous even to those which are quite hardy, while it is essential to those less so. The Tea, Bengal, and Noisette classes may be left out during the winter by covering with sand or earth, but usually the top dies and new growth only comes from the roots. Evergreen boughs secured around the more hardy sorts are generally the only and best protection they need or can have; where the sorts need more protection, the plants may be laid flat on the ground and covered with sand or earth 1 in. or 2 in. deep.

Insect Enemies.

Whoever grows Roses, out-doors or in, and is not troubled with insects injuring foliage or blossom is a highly favoured and fortunate individual; for it seems of late that each plant and product from the soil has its peculiar insect enemies, which prove a drawback on our pleasure and a hindrance of our interests, to escape from which there is no patent or royal highway, but they must be firmly met and manfully fought. Still, where proper attention is given to soil, watering, planting, &c., and a few simple precautions and directions are heeded, little trouble or annoyance from insects need be anticipated. In house culture the aphid and red spider are the most formidable; for the first, fumigation with Tobacco, when it can be done, is the best thing, but if the aphid is any ways abundant the plants will need fumigating at least twice, a day or two intervening between the fumigations, to make sure of the destruction of all, young and old. Where the use of Tobacco is objectionable, 4 oz. of Quassia chips, boiled in four quarts of water ten minutes, with 4 oz. of soft soap dissolved in the liquid, and applied with a soft brush to every part, leaf and branch, of the plants will answer as a substitute; after fifteen or twenty minutes syringe the plants with pure water. Out-doors in May, or as soon as the leaves begin to grow, the Rose caterpillar begins to glue the leaves together, to form a shelter for itself. Go over the plants frequently and pinch these folded leaves, thus destroying the insect; this is the most simple and efficacious remedy, if it be a little revolting to the very fastidious. For the sawfly larvæ, and other later appearing insects, syringing with a solution of 4 oz. of whale oil soap in four gallons of soft water will usually destroy them; where this proves inefficacious, powdered white hellebore, sprinkled over the foliage while wet, will prove

effectual; but let no one think that a single application of any one remedy is all that may be needed during one season, but be prepared to repeat whenever necessary. Rose-bugs or Rose-chafers are pests which often destroy the blossoms, their nature depriving us of the opportunity to attack them, except in the perfect state; and then we must destroy them by pinching their heads, stamping on them, and scalding; a little daily attention for five or six weeks will effectually dispose of them. Toads are fond of them and will dispose of large numbers when an opportunity is given them. Mildew sometimes attacks the Rose, and is usually caused by extremes of heat and cold, excessive and continued dampness, with continuous cloudy weather, too little bright sun and fresh pure air; sprinkling with sulphur and soot are remedies, but caution must be used not to give the sulphur too freely, or it will destroy the foliage. To sum up, I would only add that the whole culture is comprised in the reasonable, careful, judicious, and sensible application of the natural laws of cause and effect.—“Transactions of the Massachusetts Horticultural Society.”

Roses and Mignonette.—These form an agreeable combination both when growing and flowering together, and also in a cut state, the only drawback being that the Mignonette, owing to its being a strong-rooting plant, not only robs the Roses of their due share of nourishment, but its top growth injures dwarf Roses by smothering their lower branches. My experience is, therefore, decidedly against employing Mignonette as a carpet plant for Rose beds. If Mignonette be particularly desired, it might be grown in the form of an edging outside the bed and quite clear of the Roses. There are, however, many plants that might be grown amongst Roses and that exhaust the soil less than Mignonette—as, for instance, bulbs of many kinds that do well when left undisturbed for years. I have had Rose beds beautifully edged with Crocuses and Snowdrops, while their centres contained Hyacinths and Tulips. These flower before the Roses have become effective, and, by planting Gladioli of various sorts thinly amongst them, we have had some beautiful spikes of bloom during the late summer months after the Roses had got over their principal blooming season. Where a good selection of the most continuous blooming Roses is grown to supply blooms in a cut state and for general decorative purposes, the second crop of blooms will be produced rapidly in succession by the first cut-back shoots; and some sorts, such as Gloire de Dijon and Céline Forestier, being even more perpetual, as regards their flowering properties, than those designated Perpetuals in catalogues, should always find a place in such collections. When Roses are grown in beds for decoration the dwarfs are most effective when pruned on the long-rod system, *i.e.*, by cutting out nearly all the old spur wood at the winter pruning and retaining and pegging down the strongest shoots of the preceding summer's growth.—J. GROOM.

Utricularias in Glass Globes.—The exhaustive article on water plants, particularly those of our native waters, given in THE GARDEN (p. 149) interested me very much, but perhaps one of the most beautiful, certainly the most singular, the Utricularias received only a passing notice. I have had the good fortune (a boon not often granted to botanists) of seeing it in full bloom in its native ditches, and large masses of this plant in flower is a sight not to be forgotten. Those who have seen the Vallisneria spiralis grown in glass globes may be interested to know that the Utricularias (whose leaves are studded with small, pellucid bladders) when grown in the same way as the Vallisneria, are equally beautiful, and, being natives, far more interesting. There are three recognised forms of this plant found in our waters, and probably two or three more awaiting to be discovered. To grow these plants in a glass globe, having obtained your plants, procure a sod of spongy turf about 3 in. or 4 in. thick of the same circumference as the bottom part of the globe. Make a small hollow in the centre of the sod, and fix the plant in it, making it firm with a little damp earth, introduce the sod with the plant into the globe, and fill it with water; the sod will soon be converted into mud, in which the plant delights. Utricularia minor is such a delicate small plant, that it may be grown in a Celery or finger glass.—T. WILLIAMS, Ormskirk.

Agapanthus umbellatus in Wigtonshire.—This has survived four winters in the open air here without protection, except a mat thrown over it in very severe weather. It is now in full flower, and the colour is much richer than when grown under glass. The flower-stems are somewhat shorter and stouter, and, altogether, the plant is rarely seen to such advantage under glass as it is in an open border.—SALMONICEPS.

THE FLOWER GARDEN.

LILY CULTURE.

WE have had a good deal of theory in THE GARDEN lately; therefore, thinking you might like some good successful practice, I send you the following letter from Mr. Newall, an old friend of mine residing at Rochdale, and a good Lily grower:—

"There is so much discussion in THE GARDEN upon Lilioms, and on the modes in which they should be grown, that I have thought I would, after telling you my experience, ask your opinion respecting it. Remember our cold climate and the exposed situation of my bed (open alike to sun and wind) whilst you read the following letter: It is now sixteen years since the roots were first put into the soil, where you have seen them, and they have never been lifted since. The flowers may be a little smaller, very little, and the plants considerably dwarfed, but I consider that they are acclimatised, flowering earlier every year and requiring less care. Would this have been the case had I moved them? I think the *L. speciosum* (*laccifolium*) album, the one I am speaking of, more delicate than its brethren [sisters, too pretty for brethren] of the same class; it also out-of-doors flowers a little later than *rosam*, and much later than *saratam* or *canadense*. I protected my Lilies the first few years with straw, bark, tan, and shoddy, and in the spring with glass shades; now I only lay cinders and tan over the roots during the latter part of the winter and see no protection in spring, but I water and manure freely. This hot summer, with its drought, has done my plants no good, and, as the subsoil was clay, it was difficult to keep them from scorching; nevertheless, they are full of seed. *Auratum*, which has been out only one winter, is just bursting into flower, eight blooms being on a stem, and the *L. speciosum* will be in flower by the middle or end of next month. The flowers stand a frost that kills Dahlias. To give you an idea of their condition this summer, I may state that the number of stems in a round bed 1½ ft. in diameter was eighty-two, and five the average number of buds on a stem, some stems having seven, on some five, and on some of the young ones three. The stems are so tough and thick, that they require no sticks. In a more sheltered part of the garden, where they have been out about five years, they are taller, but no finer in flower. Would you, in my case, move them? I take as much soil off as I can every year and heap fresh soil on to them. I send you a piece of stem which encroached on the walk too far, and I put in a bud off it; but some of the buds are larger on the other stems. I have out nearly 9 in. from the top. If you think it better I will remove them this autumn. Do you remember the long wall in the kitchen garden? I sowed its border broadcast with annuals, and put in Dahlias; it looks gay now and has given me no trouble, as there was no room for weeds."

My friend's letter was merely intended to ask advice, but it tells such a tale of what intelligent, loving care will do with Lilioms in a very awkward climate (near Rochdale), that I cannot keep it to myself. *Lilium speciosum* album, undisturbed for sixteen years, flourishing on an exposed situation would be a great feat even in the south. You will see by the enclosed stem that Mr. Newall's Lilies are in robust health. My advice was short—"Leave well alone."

Heatherbank, Weybridge Heath.

GEORGE F. WILSON.

Orchis latifolia.—Dr. Moore (see p. 25) seems inclined to doubt Mr. C. W. Dod's estimate of the size of inflorescence attained by this beautiful flower in cultivation. Although I have not measured any equal to Mr. Dod's, "with flower-heads fully 1 ft. long," I have no doubt that, under favourable conditions, it would attain to that size. At all events, Dr. Moore's observation of a "rachis from 2 in. to 4 in. long" is, with all respect to so high an authority, very much under the mark. I recently measured the spikes of a plant in my garden, and found that out of eleven spikes the inflorescence of four spikes measured each between 7 in. and 8 in. As a garden plant I think it is superior to *O. foliosa*, as the markings on the petals give the spike a richness which is lacking in the exotic species. Miss F. Hope, of Wardie, showed me a variety of *O. latifolia*, called the Kilmarnock Orchis, which bore very large spikes; it would be interesting if she would favour us with the measurement of the spikes. A very good accession to *O. latifolia* is obtained by planting beside it that singular Composite *Liatris spicata*, the flower-spikes of which closely resemble at a little distance those of an Orchis.—SALMONICEPS.

Spiræa Filipendula.—This is a charming plant for mixed or herbaceous borders, as, in addition to its elegant, creamy-white corymbs of flowers, it has a neat, Fern-like appearance, even when not in bloom. This is important, for, no matter how gay the flowers of a plant may be, if, when they go off, they leave unsightly vacancies, it is liable to bring herbaceous plants into disrepute.—JAMES GROOM.

PLATE CXLIII.

DAPHNE BLAGAYANA.

THIS *Daphne* is not only new to horticulturists, but also relatively new to botanists. It was first discovered in 1837 by Count Blagay, on his estate at Lorenzberg, not far from Laibach, in Carniola; and it was named in honour of its discoverer. A coloured figure of it was shortly afterwards published in Reichenbach's "Flora Germanica," but it is only quite recently that it has found its way into the gardens of Western Europe. It has also been found near Gratz, in Styria. As a garden plant it is still on trial. The figure opposite, taken from a plant which flowered in the Royal Botanic Gardens, Kew, represents it of natural size and stature. Like most of its congeners, it loves shade, and it grows naturally in rocky places. Its flowers are produced in May in its native country, but they will probably appear earlier with us.

The lovely *Anemone* associated with it in our plate is a native of the Taurus Mountains. In general character it closely approaches the more familiar *A. apennina*, from which it differs in its dwarfer habit and in the principal divisions of the leaf being sessile instead of stalked, &c. W. B. HEMSLEY.

STOCKS AND THEIR CULTURE*.

THE varieties of Stocks which we cultivate are the Warriston, Intermediate, East Lothian (purple, crimson, and white), and Young's Newington Scarlet. With the exception of the last-named, we sow the last week in May in a moderately rich soil on an open, airy border. The plants are taken from the seed-bed about the middle of August and put where they are intended to flower or run out in nursery lines from 4 in. to 5 in. apart. If the latter mode be adopted select a clear, open space where the drainage is good, and after digging deeply stir into the surface a small quantity of half-decayed vegetable matter. On this the young fibres will lay hold, and when transplanted to their flowering lines or beds, which should be done the last week in February, or as soon after that as the weather will permit, they will lift with good balls. These plants will begin to flower in June; many, however, do not flower the first year, and if convenient to leave such standing they will, if double, furnish the finest flowers, and if single they will produce the best seed. I can discover little difference between the Warriston and East Lothian crimson in plants that flower the first season, but old plants of the latter variety clearly distinguish themselves, the fine, clear eye and bright crimson colour coming out distinctly. Soil and situation have, however, much to do with shades of colour. Young's Newington Scarlet is well suited for pot culture, and, as it sets for flower much sooner than the others, it should not be sown earlier than July 15, and should be transplanted from the seed bed in September, putting two into a 4-in. pot. Use turfy loam and leaf-mould, adding a small quantity of peat and sand. If planted out, treat as directed for the other varieties, placing all in a position where shelter can be given during severe weather. An old pit or frame or a few rough boards, on which a sash could be laid, will suit, but be careful that light and air can be given freely on every favourable opportunity, as nothing is more destructive to young stocks than damp. Those in pots should be shifted from 4-in. to 6-in. ones early in March, plunged outside, and removed to the house when they show flower. When the plants come into blossom select those from which it is desirable that seed should be saved, and pull up useless ones. The ripening process may be hastened by nipping the points off the shoots after the lower seed-pods are formed. When ripe pull up the plants entirely, and hang them up in a cool, dry shed, a position in which they should be left until wanted for sowing.

Tall Foxgloves.—When I read "B.'s" note (p. 177) respecting the tall Foxglove near Milford Haven, I measured the tallest stem of an unusually luxuriant group in a bed of Rhododendrons here. It only measured 9½ ft., thus falling short of "B.'s" by 2 ft.—SALMONICEPS.

* Paper read by Mr. William Black, Dean Cemetery, Edinburgh, at a recent meeting of the Scottish Gardeners' Association.

A NEW DAPHNE (D. BLAGAYANA)
THE BLUE WINTER ANEMONE (A. BLANDA)

PROPAGATING.

COBÆA SCANDENS VARIEGATA.—This is rather a difficult plant to increase, and therefore requires to be skilfully managed. The best method of treating it is to take single 2½-in. pots and to fill them with peat and loam, finely sifted, and one-half silver sand; a little sand should also be put on the top; no crocks need be used at the bottom, only about ½ in. of siftings. The cuttings should be made of half-ripened wood, the soft tops

Fig. 1.

Fig. 2.

Cuttings of *Cobæa scandens variegata*.

and hard wood being useless. They may either be single eyes, as shown in fig. 1, or double, as illustrated in fig. 2. When the cuttings are inserted, give them a good watering and plunge the pots half way up in the cutting box on bottom-heat. The glasses or lights must be quite close, but a little air may be given for an hour after the first three days. They must be shaded with papers during sunshine, as they very soon flag, and when that happens it is a hard matter to get them up again without too much moisture, which rots the yellow parts of the leaves. Cuttings of this *Cobæa* may be put in all the year round, but if inserted in April they will emit roots in about three weeks. When they begin to grow, take them out, and if roots be showing themselves through the bottoms of the pots unplug them, but still leave them on bottom-heat for a few days. If attended to properly in this way

Fig. 3.—Layer of *Cobæa scandens variegata*.

success is certain. Layering is another plan by which this *Cobæa* may be increased and by which larger plants may be obtained quicker than by means of cuttings. A strong plant planted out will make good growth the first year, and during the second it will grow rapidly; take 3-in. pots, fill them three parts full of soil; prepare the layers, and peg them down, as represented by fig. 3, with two pegs, covering them over with fine sandy soil, and watering them with a fine-rosed watering-pot. They are generally ready to cut off in about a month or five weeks after layering, according to the season.

H. H.

PROPAGATING IN WINTER.

From the beginning of November up to the middle of February is a dull time for all employed or interested in plant culture under glass. During that period operations consist mainly in

just keeping in health and preserving from injury those kinds of plants which require the protection of a glass roof. More may, however, be done at this time of the year than is generally attempted—much, indeed, that must otherwise be deferred until later in the season, when press of work renders its accomplishment difficult. It is possible to do much, both in propagating and preparing for it, which will considerably lessen that kind of work in early spring. Where a miscellaneous collection of plants has to be kept up, and especially if any quantity of decorative plants be necessary, a propagating house is indispensable; for although propagation may be carried on in stoves and temperate houses, there is seldom that success to be obtained which will be the case in a house devoted wholly to propagating. A span-roofed house is undoubtedly the best form of structure for propagating purposes, as it admits more light than a lean-to one, although the latter has the advantage of being warmer, which, to many to whom the expense of fuel is an object, is no slight recommendation. In any case the roof should be as near the surface of the ground as possible; the deeper the pathway can be sunk the less fuel will be required; and this, apart from economic motives, is a desideratum, as the more fire-heat employed the greater is the difficulty to maintain the atmospheric humidity which is indispensable in these structures; it is easier, too, to cover up when thus constructed. As to size, that will have to be regulated by the requirements of the place, but a house 20 ft. long and 10 ft. wide will suffice for a tolerably large establishment. Supposing a lean-to form of house to be adopted, which, in the majority of cases, would probably be found more convenient to erect, the interior space might be thus disposed: A brick pit should be built along the front 4 ft. in width; of this the half should be covered with slates and supplied with bottom-heat by means of a flow and return hot-water pipe, fitted with a valve in order to allow of the admission of heat when desired; the remaining portion of the pit should be used as a tan bed. The back part should be fitted with a stage on which to place the plants required for propagation and for other purposes. Thus arranged, there will be found ample convenience for striking, potting, and hardening off. Upon that part which is supplied with bottom-heat the greater portion of the winter propagation will have to be carried on. This may be done either under small frames, cloches, or hand-lights. November and December are good months in which to propagate many fine-foliaged plants, such as *Aralias*, *Ficuses*, and *Dracænas*, as they get well rooted and ready to shift by the time the growing season has arrived. The cuttings may be inserted in suitable soil, in single pots, plunged up to the rims in Cocoa-nut fibre. Plants of *Dracænas* that have been standing some time in pots will have formed strong tap-roots, which may be cut away and divided into small pieces. Where there is any length of bare stem, that, too, may be divided into pieces containing about two eyes; the top, being inserted, will also strike root readily. As these cuttings root they should be removed from the glasses, and in the course of a fortnight they will be ready to shift into larger pots. If they are then plunged in the tan bed for a time they will quickly get established, and may be removed to other quarters. Plants started thus early into growth naturally make much larger and handsomer subjects than when propagation is deferred until spring. If good specimens of *Fuchsias* and double *Petunias* be desired, young plants must be obtained and started into growth early in the season. In the beginning of December some plants should be placed in warmth, which will furnish cuttings by February. Each cutting should be inserted in a small pot in a very light and free compost. As they root remove them, and shift them before they get pot-bound. When established they will have to be placed where they can be grown quickly. Handsome specimens may be thus obtained, one of which for conservatory decoration is worth a dozen small, indifferently-grown plants. There are many plants which may be propagated about this time of year, and which may be cleared out before the busy season arrives. Choice kinds of *Pansies*, which have been potted in the autumn and kept in cold frames, will strike readily at this time, and will, if looked well after, either make thrifty plants for bed or border work, or they may be employed for further propagation. *Carnations* should be

struck as early as possible in the year; they require a long season in which to make good growth and to set their bloom. Maiden hair Ferns may be divided into small pieces, and by beginning thus early they will grow into good plants by the end of the season: Cyclamens raised in the autumn may also be potted off, or seed may be sown; and soft-wooded Heaths may be put in, and plunged in the tan bed, and covered with bell-glasses. There is, in fact, a great amount of work of this description which may be accomplished if a suitable place can be provided for the purpose. J. CORNHILL:

GARDENING FOR THE WEEK.

Flower Garden.

Culture of Pansies in Beds.—Amongst hardy border flowers few are more generally grown or appreciated than the Pansy. It is one of those flowers that require but little attention, but, as it will grow almost anywhere, even the small amount of care required to bring it to the highest point of perfection is not always bestowed upon it. A bed of seedling Pansies is easily obtained, and if the seeds be saved from good flowers, the mass of bloom, so beautifully diversified, has a charming effect. The first or second week in September is a good time either to sow seeds or put in cuttings of the named sorts. Those who have the convenience of glass-lights or hand-glasses, would do well to sow the seeds or plant the cuttings in shallow boxes or pans, and place them under glass; not that the seeds will not vegetate or the cuttings strike roots in the open ground, but they will do better under glass. In sowing the seeds I fill the pans nearly full of a compost consisting of loam, leaf-mould, and sand in about equal parts, the loam predominating a little; I make the surface quite level, then I sprinkle the seeds thinly over it, and just cover them with fine soil. The same compost answers well for cuttings, and these should be taken from the centre of the plants. The smallest growths strike roots most readily; the strong-flowering stems take a long time to form roots, and are seldom satisfactory. When the seedling Pansies are large enough to handle, I prick them out in fine sandy soil on a level surface, and I do the same with the young plants raised from cuttings; they are also planted out about 3 in. apart until they are well rooted, when they may be planted out in the beds or borders prepared for them. The Pansy likes a cool soil and climate, and though our garden soil is very light and sandy, on a gravelly subsoil, and the air is hot and dry, we grow Pansies very successfully. This last season I had a bed of them 60 ft. long and 3 ft. wide, which has lasted in flower since March, and which will continue, if it be left alone, in good condition until frost comes. The preparation of the ground for this bed was done in September. It was trenched 2 ft. deep and well manured with cow manure, the best for this purpose. The surface of the bed was also lightly forked over two or three times when it was dry, and I was also able to place some fine virgin loam on the surface before planting. All the attention required after this was merely keeping the ground free from weeds and occasionally stirring the surface. Many may be inclined to think that this is a great deal of trouble to take with such a flower as the Pansy or Heartsease, but those who are really fond of flowers will take a pleasure in doing all they can in order to attain success. Pansies produce flowers in succession, and so freely that they will ultimately come quite out of character. As soon, however, as it is perceived that the flowers are deteriorating by the belting becoming imperfect nearly all the blooms should be pinched off, and the shoots should be pegged down close to the surface of the ground, having previously placed some rotten manure on the surface, and, if the weather be dry, give a good soaking of water. The next flowers produced after this will be of good quality. This same operation must be performed as often as it is necessary, and the result will be good blooms all through the season. When it is intended to exhibit Pansies the shoots should be thinned out to about five or six, and all the flowers should be removed two weeks before the show.

Culture of Pansies in Pots.—The Pansy succeeds so well out-of-doors that it almost seems superfluous to grow it in pots; the only object in doing so is to have the flowers earlier, and also to protect them from the rough weather experienced early in the year. The cuttings for plants in pots should be taken earlier than in the case of outdoor plants, say the first week in August, and they should be propagated in the same way. When rooted they must be potted in small pots, and they should be placed near the glass in a cold frame; when the little plants have quite filled their pots with roots, repot them into 4-in. ones, and by the middle of October they may have their final shift into 6-in. or 7-in. pots, according to the strength of the plants. In all stages of their growth the plants should be quite near the glass in the cold frames; the lights should be removed when the weather is fine, or when rain is falling gently, but they must be protected from heavy thunder showers. Green fly attacks the plants when grown under glass, and would seriously injure them if it were not at once destroyed. I prefer fumigating with Tobacco smoke, and the lights must be kept quite close when the operation is being performed. It is best not to fill the frame too full of smoke; on the contrary, rather fumigate on three successive evenings at intervals of three days. If the frame be placed in a sunny position, the plants will commence to flower early in February if the weather be mild; of course, they will make no progress during frosty weather; they will continue to produce flowers until the

end of April, when those out-of-doors will succeed them. The potting material should be good turfy loam, four parts; leaf-mould, one part; rotten cow manure, one part; with some sharp sand added if necessary. Weak liquid manure should be applied when the first flowers open, if the pots be well filled with roots.—J. DOUGLAS.

Mixed Flower Beds.—Go over the beds and regulate the plants so as to give them an orderly look. It is well now to go over the flower garden, note-book in hand, making an entry of the plants that do best and those that fail, as also to determine what changes are to be made next year, not only as regards alteration in the arrangement of colour, but also in form; the latter of which we hold to be of even greater importance than the former, for, by a judicious use of a few taller-growing, elegant-habited plants, to relieve the generally too evenness of surface of the greater portion of summer bedding plants, a great deal of what is objectionable that exists in this style of gardening can be avoided. For instance, if such plants as *Humea elegans*, *Acacia lophantha*, *Grevillea robusta*, and many others of slender open habit, are sparingly used in the beds they relieve the even surface without hiding to any appreciable extent the colours of the principal occupants. The effect that such plants used in this way would have, can, at this season, when the beds are full and at their best, be better judged than at the time of planting. Carpet beds might cease to bear too close a resemblance to carpets if the arrangement was a little more varied in surface, and would be none the worse for the modification. Whatever alteration is to be made in the ensuing season in these matters can only be adequately provided for by being determined upon at the present time, so as to admit of the necessary propagation of the plants required. Wallflowers, Foxgloves, Sweet Williams, Dianthus, and other plants of similar nature, that were sown earlier in the summer, will now be ready for transplanting from the seed-bed. Choose for them an open situation, the soil of which should be light, so that when in the spring they are removed to their flowering quarters, this can be done without so much injury to the roots as when grown in adhesive ground. For everything of this kind the soil must not be too rich, as over-luxuriance should be avoided in all that can be injured by a severe winter. Put in the plants at a distance of 8 in. or 10 in. apart; if they are too much crowded they get drawn, and are correspondingly weak.

Moving Shrubs.—It is not uncommon to see shrubs which at first, when small, were planted close to give immediate effect, with a view to some being thinned out as they got larger, left until they spoil each other. If, in the first instance, the work were done with judgment, those which were intended to remain permanently will have been put in such position as will afford them enough room by simply moving the others of less value, which were only put in to fill up for a time; but it frequently happens that this course has not been followed, and that the planting has been done indiscriminately, in which case when they are grown so as to be too close, a portion has to be taken out, and many required to remain want moving more or less from the position in which they were first planted. Where removal of this kind becomes necessary, it should be carried out before the shrubs have grown into such a crowded state as to injure the whole, as frequently permitted; for, independent of the injury inflicted upon all, the longer moving is deferred, the worse condition they individually get into for removal. There is no time in the year when evergreens can be more successfully transplanted than from the end of August to the beginning of October; but the earlier in September the better; there is no necessity to wait for showery weather, not even if the soil be apparently so dry as to contain little moisture. In fact, the heat that is in it when in this state is one of the first requisites as regards success, on account of its assisting to promote the immediate formation of roots; whereas, if removed late in autumn, when the temperature of both the air and earth is reduced by waning sun-heat and chilling rains, all this advantage is lost. In planting, however, whilst the soil is in the dry condition above described, it is imperative that every plant should be thoroughly soaked with water when it is replanted. This should not be done by half measures; on the contrary, the whole of the soil that is put in round the roots down to the bottom of the hole should be effectually moistened. Where this is done the formation of new roots, as I have said, commences immediately, and this single thorough watering will generally be found sufficient. If any doubts be entertained as to roots being formed immediately after planting at this season, an inspection, say a month afterwards, will soon dispel them; for those who will take the trouble to look at the point of every root that has been severed will observe a quantity of young feeding fibres which will enable the plant to resist the most severe winter that may ensue, and ready to supply the demands made by spring growth. Each shrub, as soon as it is taken up, should be immediately replanted, not allowing the roots to have time to dry. In this there must be no delay; indeed, this early removal is only to be recommended where shrubs can immediately be placed in the new positions assigned to them from one part of the garden or pleasure ground to another. Presuming that the surplus plants thus taken up will be again planted where more space can be found for them, ground for them should be prepared beforehand by sufficiently deep digging or trenching, so as to expedite the work.

Indoor Plant Department.

East Indian Orchid House.—Those plants here that flowered early in the spring should by this time have made considerable growth, especially the earliest-bloomed *Aerides*, *Phalenopsis*, *Angreum*, *Vandas*, and *Saccolabium*, but must be still further encouraged to keep on for some time longer, as the species that do not form bulbs do not require near so long a rest as the others. Comparatively few of these will be flowering after this, excepting such as *Aerides quinquevulnerum*, *A. su-*

vissimum, and *Saccolabium Blumei*, the bloom-spikes of which by now, in many cases, will be near opening. Orchid flowers of this description now being scarce, it is well to preserve them as long as possible; for this reason whilst in bloom they should be placed at the coolest end of the house, or if, as in most places, where there is a considerable collection of these plants, there is a small compartment wherein to keep them whilst in bloom, they may be accommodated here, but they should not be so treated as to completely stop growth, as it is too soon for them yet to go to rest, and to put them whilst in flower where growth would be quite stagnated, and to excite them again afterwards into a second growth, would cause a derangement in the plants not advisable to bring about, as these transitions from growth to rest, and afterwards the inducement of second growth, frequently engender disease. Another fine late-blooming Orchid usually subject to East Indian houses treatment is *Oncidium Lanceanum*. There are several varieties of this which rank amongst the most beautiful of all *Oncidiums*. The flowers are long, enduring, but liable to spot if in a moist atmosphere, particularly the charming light-coloured form. These also, like the foregoing plants, should be kept in a drier atmosphere whilst flowering. So far as the general requirements of the plants in this department go, especially such as flowered latest, which will be now in full growth, regulate the moisture in the atmosphere in accordance with the state of the weather. Nothing can be worse than an uniform system in keeping the atmosphere equally humid in dull, showery weather, as when it is bright and sunny, as, if the air is kept in an overmoist state, it has a much greater tendency to the production of undue elongation in the growth than even more warmth would have in bright weather, when the action of the sun quickly dries up the moisture and additional light corrects any disposition to a weakly, drawn-up condition of the foliage. The growth made early in the season is by this time more solidified, and the leaf formation now going on is not so soft and tender as that made in the spring; consequently, the plants are not nearly so liable to be injured by exposing them to a little sun early in the day and later on in the afternoons when it is not so powerful. The general tendency of the treatment I have found most conducive to continued healthy vigour is at all times to submit the plants to plenty of light and to gradually shade for a shorter period during the day, when it is required at all, as the autumn advances.

Dendrobiums.—Such plants of *Dendrobium* of the *Wardianum*, *Devonianum*, *crassinode*, and *Pierardi* section that bloomed earliest in the spring will be, by degrees, finishing up their growth; as soon as the terminal leaf at the extremity of the bulb is visible, they may be placed nearest where the air is admitted to the house and have a little less moisture given to them. This will keep the bulbs on assuming a state of maturity, and correct any inclination that there may be to push into second growth from the base, a condition that should by all means be avoided; but any treatment thus advised must not be carried to extremes, or it would have the effect of stopping the full development of the bulbs, upon which not only their ability to produce the full complement of flowers that may be looked for the ensuing season depends, but also the power of the plants to increase in size to the extent of which they are capable.

Mexican House.—The different species of *Pleione* will now be forming their bulbs. Give them every attention, so as to induce their plumping up to a large size, for with these most beautiful winter and spring-flowering plants, it is of the greatest consequence to grow them in a way to induce size and solidity, as upon this depends their ability to increase more than with most subjects.

Calanthes of the *vestita* section should receive plenty of water with abundance of light, so as to invigorate and solidify the bulbs now considerably advanced.

Cattleyas.—Of the late-flowering, two-leaved species, such as *C. violacea*, some plants will yet be in bloom or fast approaching that condition; they are amongst the longest livers in flower of the family, and as they bloom from the mature growth of the present season, they will receive no check or any injury from being kept whilst in flower in a much drier atmosphere than that in which they have been grown. The same holds good with the summer-blooming *C. labiata pallida*, another plant that is very useful from its disposition to flower in the autumn when Orchids are more sparsely represented by blooming subjects than at any other time.

Imported Orchids.—Recently I gave some hints upon the management of imported Orchids requiring medium and cool treatment. I may now add a few words as to East Indian plants. They, in common with the cooler species, often suffer severely in transit, frequently to a much greater extent than such as are introduced from the Western Hemisphere, not alone from the longer time required in their reaching this country, but also from the fact that many of the species, such as *Aeridea*, *Vandas*, *Saccolabiums*, and most of all, *Pfalenopsis*, from their growth being of a different character destitute of pseudo-bulbs, the latter of which enable the plants so formed to resist the adverse conditions to a much greater extent than plants in which these are absent. Through the early autumn months is the best time to receive them, as then they are not subject to the low temperature unavoidable on their approaching our shores in winter or spring, and which is so fatal to them. These likewise, as soon as they arrive, should have a thorough cleaning and be placed in an intermediate temperature for a time, imitating the conditions recommended for the cooler plants in so far as not subjecting them to treatment that will suddenly excite growth, yet they must not have near so much air admitted to the house or pit they occupy as advised for the less heat-requiring kinds; let the atmosphere be slightly humid, but not too moist, suspending the plants head down-

wards until their leaves have absorbed moisture so as to plump them up and their roots show signs of growth, after which they may at once be potted and gradually, but slowly, admitted to more warmth and moisture, to enable their making growth and becoming established. East Indian plants that form bulbs, such as the extensive family of *Dendrobiums*, are much easier managed, and, if they arrive in fair condition, will usually very soon commence growing; with them, as with the cooler, pseudo-bulb-forming species, it is not advisable to cut them in small bits previous to their commencing growth, but, on the other hand, to grow them on in good-sized pieces, in which way it only requires a very few years to induce their making full-sized bulbs, equal to, or larger than they have produced in their native country. One of the greatest essentials in Orchid culture generally, and more especially with newly-imported plants, is to be satisfied with a moderate extent of annual growth made under conditions that will impart to the plants during its formation a full amount of solidity, without which it is useless to expect their continuing long in health.—T. BAINES.

Greenhouses.—As most greenhouse plants will now be out-of-doors maturing their growth, any houses needing repairs or painting should receive that attention, so as to be in readiness to receive the plants should wet or unfavourable weather set in. If this occur before the houses are fit for their reception, raise the pots from the floor of ashes or other bed on which they may be standing, and place them on a couple of bricks, so as to secure perfect drainage, and thus prevent a too great saturation of the soil. They will be in a safer position laid or tilted on their sides during a continuance of heavy rain than they otherwise would be. By excluding the wet from the balls in this way, the plants will be rather benefited than otherwise from the thorough cleaning which the tops will receive. On the other hand, when the weather is dry great care must be exercised to see that they do not suffer from want of water, as plants dry much faster when placed out-of-doors with a constant current of dry air circulating amongst the pots than they do when placed on the stage of a greenhouse. To ensure soaking them through, the first watering which they receive should only be preliminary, and as soon as that is soaked in repeat it once or twice, if thought necessary, as it cannot do the least harm, if no more be administered till the plant is in a fit state to receive it again. It is giving water in small quantities before it is really required that does the mischief, as then the soil becomes water-logged and sour, a condition fatal to all healthy root action. So long as plants remain out-of-doors, they should be freely syringed on the afternoons of fine days, a proceeding which tends to keep down red spider. Heaths, however, should prove an exception to the general syringing, as it is only a few of the free-growing, winter-blooming varieties which derive benefit from it, and even in their case it ought now to be discontinued. Many of these are subject to mildew, and any that show the least symptoms of it should at once be dusted with dry flowers of sulphur, which will quickly rid them of its presence.

Winter-flowering Carnations.—Where flowers are wanted at Christmas and early in spring these will require special attention. Stopping should be discontinued, but they should be cleaned, neatly staked, placed in a cool pit or house where plenty of air can be given them so as to encourage strong growth. Before placing them in the pit or house, however, it is advisable to top dress them with some fresh loam, and to give them a good watering with soot water, or a weak solution of lime water, to drive the worms out of the pots. They will also require dusting occasionally with sulphur, as they are very subject to mildew and red spider, from both of which they often sustain injury. In sulphuring, Carnations require to be carefully gone over so as to distribute it regularly in their stems, and, after it has been on three days, wash it off with the syringe and clear the foliage of all dirt or sulphur. After the plants have commenced to grow moisten with weak guano water or Stander's manure about once a fortnight. Keep them neatly tied up, but not so closely as to prevent the air from circulating among the shoots, for, when bunched up to the stakes with one tie mildew and green fly often do considerable damage before they are noticed; the pores of the leaves and shoots get gummed up and the plants lose their vigorous appearance. In the case of large plants at least three or four stakes should be used. If the plants are well looked after they should commence flowering in November and continue till March, and old plants will furnish plenty of autumn bloom.

Indoor Fruit Department.

Vines.—Now is the best time to cover outside borders attached to *Vinerias* in which Grapes are intended to hang during the greater part of the winter; when delayed until further on in the season the soil often gets thoroughly wet, and the benefit which should result from covering is never realised. Where the border is thatched or covered with litter clear it away, and lightly fork over the soil before putting on the covering. Thin deal shutters, in breadths of 6 ft. by 12 ft., make the best protectors. One end should be placed close against the front of the house, on two bricks, one above the other, and a shutter 12 ft. from this is generally sufficient protection. The lower or bottom end should rest on one brick, thus sufficient incline is given to throw off the water and space is left between the boards and the soil to allow a free circulation of air. Glass sashes do quite as well as wooden shutters, but during autumn and winter these are generally needed for other purposes. Tarpaulin may be used where neither of these protectors can be had, but it is inferior to both of them. The outside borders of houses in which the Vines are to be started into growth about November should also be covered.

Pines.—Queens, intended to be started in the end of December or beginning of January to supply early fruit, must now be kept somewhat drier at the roots than they have hitherto been, and manure water need

not be longer used. The bottom-heat should be allowed to fall to about 70°, and plenty of fresh air should be allowed to circulate about the plants on fine days. Where plants have not been specially prepared for fruiting early the most mature-looking should be used for this purpose. Suckers of all kinds may still be taken off and potted. They will require a bottom-heat of 90° until they are rooted, and plenty of light, in order to insure their keeping well throughout the winter.

Hardy Fruit.

Gathering fruit as it ripens is now an important point, and requires great attention. Fruits must not be gathered when wet, nor during hot, sunny weather, and they must be handled very gently. In the case of early Pears, it is not well to leave them on the trees until they are quite ripe; as a rule, they should be gathered a day or two before they are in that condition, otherwise they are apt to become dry and rotten at the core. The choicest wall fruits should be protected from wasps, birds, and flies, with hexagon netting or other material of that kind. Remove all unnecessary lateral growths, and expose the fruits as freely as possible, particularly the dessert sorts.

Root-pruning Apple, Pear, and Plum Trees.—By continually pinching out the points of the shoots of Apple trees they may be kept as dwarf as Gooseberry bushes, and small trees laden with Apples are very interesting, and are suitable for some situations; but thus to induce a diminutive habit of growth entails continual watchfulness, and is simply beginning at the wrong end—reducing the strength of the trees by removal of the leaves instead of curtailing the root power, whence the superfluous vigour springs. Where very small Apple trees are required they should be procured grafted on the French Paradise stock, which in a small state is favourable to the production of fruit. Trees worked on stocks of this kind can be kept to the size of an ordinary Currant bush and yet bear fine fruit. They are very suitable for gardens of small extent. They also come into bearing in a very short time after planting—generally the second year, if well managed; but where there is a large demand for Apples, full-grown standard trees are required. These should only receive as much pruning as will keep the branches from becoming crowded, and admit light and air to the fruit. I am now speaking of the orchard culture of Apples and Pears; but in large kitchen gardens, where it is usual to grow these fruits on the margins of the walks, full-sized trees are not admissible, as they overhang other crops, and, by their shade and exclusion of air, seriously injure vegetable of all kinds. This is still more apparent in amateurs' gardens, even when these are of considerable size; but it is in such situations that root-pruned trees are the most suitable. Dwarf Apples (i.e., trees which have little length of clear stem, but which are grafted at a short distance above the ground) are the best. In most cases, where the land is suitable for the growth of Apples, the trees of many kinds will grow away freely for a few years after planting without producing much fruit. From the first do not allow more branches to remain than will furnish the tree, as to let these grow to be afterwards cut away is simply a waste of strength and a loss of time. The nature of the soil, as well as the varieties grown, has much to do with an early disposition to fruit. If, when the trees have attained a height of 6 ft. or 7 ft., and a proportionate breadth, they do not, by forming a sufficient quantity of fruit-spurs, show an inclination to bear; this is generally owing to over-luxuriance, which can be checked by root-pruning. The best time for this operation is in September, after the summer growth of wood has been completed. Open a trench 1 ft. wide on two opposite sides of each tree, at, for the size under consideration, a distance of 3 ft. from the stem, this time pruning only half-way round the trees; the trench must be opened as deep as the roots extend, cutting them all clean off to within the 3 ft. space between the trench and the stem. When there are any that are more than ordinarily strong, and that bear the appearance of having tap-roots, the soil should be worked away underneath, so as to get at these and cut them off, as in the case of those that grow in a horizontal direction. This treatment generally has the effect of causing the trees to set a considerable number of fruit-buds, to be still further increased the season following. If, in the ensuing season, they continue to make too much growth, the remaining opposite sides of the trees (the roots of which have not yet been cut back) should be operated upon. Unless where the soil is of a wet, tenacious nature, trees so treated will generally not require their roots being further interfered with for three or four years, when, if again too strong to be productive, they may be similarly root-pruned at about 12 in. further from the trunk. At the winter pruning, each season, the leading branches should be shortened back to some 6 in. of the point to which they were cut the year previous, until the trees attain a height of about 9 ft. or 10 ft. This is as large as they ought to be allowed to grow in such gardens as those under consideration. When they show a disposition to make too much wood at the expense of the fruit, the roots must again be shortened; by this means they can be kept for an indefinite time in a fruitful state. Root-pruning, either with large or small trees, should rather be accomplished early in the autumn than later on in winter; it must never be attempted in spring, when growth is about to commence, or its effects will be most injurious. Bush-shaped or pyramidal Pear trees in such gardens must be similarly treated in every way. Many varieties of these fruits will not bear satisfactory until they have attained a large size, unless growth is checked by root-pruning. Plums do not usually grow so vigorously; but, to keep them within bounds as regards size, it is often necessary to resort to the reduction of root power. One great advantage with trees managed as above is, that the manure used to the vegetable crops grown near them has not the effect it otherwise would have of producing rampant, unfruitful growth. On light dry soils manure is beneficial in its effect upon the fruit of root-pruned trees.

Kitchen Garden.

Tie and earth up Caroons in dry weather. Sow American Red Stone, White Stone, and Strap-leaved Turnips on Potato ground, and hoe and thin previous sowings, always using the most advanced roots first. Sow Radishes according to the demand in a warm position; the early autumn sowings generally yield first-rate produce. Sow some Spinach for spring use, and also some early Horn Carrots on a warm border for the same purpose. Earth up Leeks as they grow. Clear away exhausted crops of French Beans. Potatoes, when lifted, should be stored in a dry place, and not laid more than 1 ft. or so in thickness. Under such conditions, they can be turned over three or four times at intervals of ten days or so, each time picking out any that show signs of decay. Those that remain sound after that will be likely to keep. Potatoes should always (but more especially when disease is prevalent) be stored in a cool and thoroughly dry shed, where air can get to them, except in frosty weather. As a matter of course, they must be kept in the dark, or they will become more or less green, which impairs their value as food.

Extracts from my Diary.

September 2.—Sowing Mignonette in pots and a large breadth of Spinach for winter use. Putting in cuttings of Heliotropes to furnish blooms in winter. Potting Pelargoniums and late-struck Fuchsias. Clearing off Onions and placing them in Vineries cleared of fruit to dry ready for roping. Renovating the linings round Cucumber and Melon frames. Gathering Williams' Bon Chrétien Pears, and putting stakes to all fruit trees that require them.

Sept. 3.—Sowing Mustard and Cress; also Red and White Turnip Radishes. Putting in cuttings of bedding Pelargoniums, Ageratums, and Lobelias. Taking up and storing away whilst perfectly dry Paterson's Victoria Potatoes. Earthing up Celery and Caroons; also putting a little soil round Leeks. Forking over the surface of the ground between late-planted Cauliflowers, in order to admit the rain. Giving Peach and Nectarine trees on open walls a good washing with the garden engine, to keep them free from red spider and other insects. Gathering Lord Suffield Apples and ripe Tomatoes.

Sept. 4.—Thinning Turnips and Spinach. Planting out Coleworts from July sowings to come into use in winter. Making Mushroom beds and spawning others at a declining temperature of 85°. Forking the surface of the ground between newly-planted Cabbage and Broccoli plants. Stirring the soil between late Peas, Spinach, and Turnips. Clearing off Peas and Broad Beans, and preparing the land for other crops. Potting a batch of Carnations and Picotees; also Czar and Neapolitan Violets for early blooming. Tying Chrysanthemums and watering them with guano water. Gathering Summer Thorel, Golden and Kerry Pippin Apples and Pond's Seedling Plums. Watering Lettuce, Endive, and other salad crops, in order to keep them growing and render them crisp.

Sept. 5.—Cleaning and roping Onions when the weather is wet. Picking over Potatoes and sorting out seed and bad ones. Washing shelves and pots. Cutting shreds, labels, and pegs. Cleaning out the fruit rooms ready for storing away fruit.

Sept. 6.—Sowing a hatch of Osborn's Early Forcing French Beans in pots for a supply at Christmas. Putting in Ageratum and Heliotrope cuttings for winter blooming. Rolling gravel walks after rain. Removing runners and weeds from Strawberries in pots which are intended for forcing and placing them further apart so that they may be fully exposed to air and sun and their crowns become more hardened. Thinning Turnips and July-sown Carrots; also late-sown Mignonette. Digging borders ready for planting with Cauliflowers and Lettuces. Shifting a portion of Cinerarias and Primulae to warmer quarters. Earthing up Celery. Gathering Coe's Golden Drop and Kirke's Plums; also Williams' Bon Chrétien Pears. Watering Pines and inside borders of late Vineries.

Sept. 7.—Planting Lettuces and Endive in borders so that they can be conveniently covered with spare frames during winter. Pruning Laurels and other shrubs which require it. Stripping leaves from Cabbage stumps in order to get sprouts for the winter. Making a new Mushroom bed and turning more manure for others. Gathering Louise Bonne of Jersey and Jersey Gratioli Pears. Fruit in use for dessert: Pines, Melons, Grapes, Peaches, Nectarines, Pears, Apples, and Plums.—W. G. P., Dorset.

Failure of Asparagus.—It may be interesting to know that there has been this year, in this part of the country, a very general failure in the Asparagus crop, which, I suppose, may have been caused by the cold, wet season which we had last year preventing the maturing of the buds for this year.—A. C., Melrose, N.B.

Potato Vicar of Laleham.—This is a valuable addition to our stock of main crop Potatoes. It was raised by the Rev. Mr. Peake, Vicar of Laleham, and is the result of a cross between Red Emperor and Paterson's Victoria. The haulm somewhat resembles that of Flourball; the tubers are rich violet-purple in colour, and have flesh of the whitest quality. In shape they exactly resemble the Victoria, and, indeed, might well be described as a purple Victoria. It is ripe several weeks earlier than the white kind, and is a larger cropper.—A. D.

GARDEN BOTANY.

(Continued from p. 185).

MORPHOLOGICAL NATURE OF THE PISTIL AND OVULES.—We have explained in a previous paragraph what is the generally accepted view of the nature of the organs borne by the stem, that they are all modifications of one type of growth; and it

Fig. 499.—Pistil of Celosia, with a single style and a three-lobed stigma.

Fig. 500.—Pistil of Celosia; the shell of the ovary torn away, showing the single cavity and the ovules attached to the base in the centre.

has been shown that there is frequently a gradual transition or progressive metamorphosis from ordinary foliage leaves into bracts, sepals, petals, and stamens. Sometimes there is a more or less complete reversion or retrogressive metamorphosis of the organs, as in the green Rose, in which the parts of the flower are replaced by green leaves, and in the double-

Fig. 501.—Pistil of Rheum, with a three-lobed recurved stigma, denoting the three carpels of which it consists.

Fig. 502.—Pistil of Rheum, the ovary lifted, showing the position of the solitary ovule.

flowered Cherry, in which the centre of the flower is often occupied by an ordinary green leaf or leaves. The ovules are outgrowths from the margin or some other part of the surface of the carpellary leaf, somewhat analogous to the buds which appear on the margins of the leaves of Bryophyllum (fig. 1) when subjected to favourable conditions. It is true, however,

Fig. 503.—Section of the pistil of Rheum, to show the one-celled ovary and solitary erect ovule.

Fig. 504.—Pistil of Nettle, with a feathery stigma.

that some botanists regard the part to which the ovules are attached as always belonging to the axis, and the other part of the pistil as foliar; but this view is not in accordance with some well-established facts. It is quite possible that ovules are sometimes produced on the floral axis, though in the majority of cases they are doubtless borne on the appendages of the axis—the carpellary leaves. A single carpel of a polycarpellary pistil, as that of Columbine, or the monocarpellary pistil of the Pea, is in reality very much like a leaf folded

together and cohering by its edges. On splitting open the ripe pod (legume) the Peas are found attached to the ventral

Fig. 505.—Pistil of Nettle, the upper part raised, revealing the position of the solitary ovule.

Fig. 506.—Section of pistil of Nettle, showing the one-celled ovary containing a single erect ovule.

suture alternately on each side. We may now examine a few of the principal modifications of the pistil.

PISTILS WITH A SUPERIOR OVARY.—When the pistil consists

Fig. 507.—Pistil of Coriaria myrtifolia, having a five-celled ovary and five free styles.

Fig. 508.—Pistil of Coriaria, showing position of the ovules in the ovary.

of a single carpel, this is usually a little excentric and its style oblique, and when, as in the Columbine, there are several free carpels, their styles are oblique and radiate from the centre; but when there are several carpels forming a syncarpous

Fig. 509.—Section of the pistil of Coriaria, showing the solitary pendulous ovule in one of the cells.

Fig. 510.—Pistil of Tropaeolum; three-celled.

pistil, whether the ovary be one or more celled, the combined or free styles are central, at least at the base. The pistil of Celosia (figs. 499 and 500) has a superior one-celled ovary, composed of three carpellary leaves, as indicated by the slightly three-lobed stigma, and the ovules are attached to a

free central placenta, which scarcely rises above the base of the ovary. In Rhubarb (figs. 501 to 503) the pistil is also tri-

Fig. 511.—Pistil of *Tropaeolum*, parted through the ovary, showing the position and number of the ovules.

Fig. 512.—Pistil of *Tremandra verticillata*, with a two-celled ovary and two distinct styles.

carpellary, but it contains only one ovule. The superior one-celled ovary of the Stinging Nettle (figs. 504 to 506) also contains only one ovule, and differs mainly from that of Rhubarb

Fig. 513.—Pistil of *Tremandra*, with the styles and backs of the carpels removed, showing the position of the ovules.

Fig. 514.—Pistil of *Tremandra verticillata* in section, showing the two-celled ovary with one ovule in each cell.

and *Celosia* in being built up from one carpel instead of three. It has an exceedingly short slightly excentric style surmounted by a feathery stigma. The pistil of *Coriaria myrti-*

but in the young stage (as shown in figs. 507 to 509) it may be described as a superior, syncarpous, five-celled pistil, with free styles and one pendulous ovule in each cell. In the *Nasturtium* (figs. 510 to 512) we have a very similar kind of pistil, composed, however, of three carpels instead of five, which cohere

Fig. 517.—Pistil of *Berberis vulgaris*.

Fig. 518.—Pistil of *Berberis*, with the upper part separated to show the insertion of the ovules in the ovary.

more than those of *Coriaria*, though easily separated when ripe. *Tremandra verticillata* (figs. 513 and 514) is an example of a pistil with a two-celled ovary, having one ovule in each cell, and the styles free from each other down to the top of the ovary. In *Polygala cordifolia* (figs. 515 and 516) the ovary is almost the exact counterpart of that of *Tremandra*, but the

Fig. 519.—Pistil, having an ovary which is one-celled with parietal placentation in the upper, and several-celled with axile placentation in the lower part.

Fig. 520.—The same, with a portion separated to show the insertion of the ovules.

styles cohere throughout their whole length. We will now review a number of pistils having a superior ovary containing more than one ovule in each cell, commencing with that of *Berberis vulgaris*. In this the ovary is only one-celled, with several ovules rising from the base of the cell (fig. 518). Note,

Fig. 521.—Pistil of *Hypericum hircinum*.

Fig. 522.—Pistil of *Hypericum*, with portions separated to show the position of the ovules in the ovary.

too, the short stont style and peltate stigma. The ovary of the pistil (figs. 519 and 520) is one-celled in the upper part and five-celled at the base. Something similar occurs in *Hypericum hircinum* (figs. 521 and 522), but there are only

folia (fig. 507) is deeply lobed and almost apocarpous; in fact, the carpels separate from each other and the axis when ripe;

three carpels. In the Violet (fig. 523) the ovary is completely three-celled, with three parietal placentas. In Cleome (figs. 524 and 525) the numerous ovules are arranged on two oppo-

Fig. 524.—Pistil of *Cleome viridiflora*.

Fig. 525.—Pistil of *Cleome*, with ovary opened to show the two parietal placentas.

site parietal placentas, and the pistil is composed of two carpels. A still more simple pistil is characteristic of the Leguminosæ (Pea, Bean, &c.). Here it consists of one carpel,

Fig. 526.—Pistil of *Phaseolus vulgaris*.

and the ovules are arranged in a double row down one side of the ovary, as in fig. 527.

W. B. HEMSLEY.

The Plant-lore of Shakespeare.—Of this book the "Pall Mall Gazette" spoke the other day as follows: "Every one who knows anything of horticultural literature has read of Mr. Ellacombe's famous garden at Bitton, in Gloucestershire. They may now meet him in a less special department of the same ground. Mr. Ellacombe has reprinted from THE GARDEN a series of papers on 'The Plant-lore and Garden Craft of Shakespeare,' and it would be hard to name a better commonplace book for summer lawns. Every passage in which Shakespeare names a plant is cited, illustrations are given from contemporary writers, the plant is identified if need be with its modern representative, and occasionally a few short notes are added on its cultivation. Thus the lover of poetry, the lover of gardening, and the lover of quaint, out-of-the-way knowledge will each find something to please him: how much more when, as we may hope is not seldom the case, all three affections are found growing side by side in the same mind."

THE KITCHEN GARDEN.

NOTES ABOUT LETTUCES.

SOME of the best Lettuces I have ever had have been grown on the ridges between the rows of early Celery, thus proving that depth of soil will, in a great measure, compensate for the disadvantages of an elevated position on a porous soil during a dry season. Of course, a little mulch laid round the plants has kept the surface cool and checked evaporation. I am growing this year two new Lettuces (new at least to me), called Silver Star Cabbage and Little Queen Cos; the former somewhat resembles All the Year Round, but is larger and firmer. The latter is a very close-growing dwarf green Cos, stands dry weather well, and is altogether a most desirable acquisition. They were sent out originally, I believe, by Messrs. Jeffries & Son, of Oxford. All Cos and most Cabbage Lettuces are better for being tied up a few days before they are required for use. Tying up seems to impart a greater amount of crispness to Lettuces, even when it may not be necessary to do so for the purpose of blanching. Two indispensable varieties for sowing now are the Black-Seeded Brown or Bath Cos and Wheeler's Tom Thumb Cabbage. There are several forms of the Bath Cos; but one called Wood's Bath Cos is the best I have had—the growth is more compact, and there is less irregularity among the plants, showing that the stock has been carefully selected. In sowing now, the most open situation should be selected, and the land should be well prepared. The best plan is to sow in drills, 12 in. apart, and, if the weather continues dry, thoroughly soak the drills with water just previous to sowing the seeds, without wetting the intermediate spaces; and cover the seeds lightly with some of the dry soil from the edges of the drills, if it has been well broken up and pulverised, otherwise it will be better to obtain a few barrowfuls from the heap of soil that should be reserved for such purposes when the periodical arrangement of the compost yard takes place. The next sowing, which will, in the majority of situations, be made about the end of the present month, should be on some elevated or slightly raised border sloping to the south, backed up with a hedge or some temporary screen if possible. Lettuce plants in damp situations suffer much both from the natural decay engendered by the presence of too much moisture, and the greater liability to injury from frost; and there is always great difficulty in such situations in keeping snails and slugs at bay. There is nothing better to get rid of the latter pest than a sprinkling of sifted coal-ashes run through a ½-in. sieve, just sufficient to cover the surface, and it is equally effective against worms coming out at night and drawing the plants back with them into their holes. Nothing of a soft, slimy nature that crawls over the earth's surface will willingly face their sharp jagged edges, and they may be used freely among young growing crops in autumn and spring with beneficial effects in other ways; besides guarding the plants from insects' attacks, they attract the rays of the sun, keep the soil from baking, or its pores becoming sealed up after heavy rains, and tends to check any bad effects from too much water lodging round the stems or collars of the plants, and I would strongly advise anyone who has had much trouble with slugs to sprinkle coal-ashes amongst all their young crops. They will be found both a good and cheap remedy, and one that is always available.

E. HODDAY.

Prickly-seeded or Winter Spinach.—No time should now be lost in getting in a good sowing of this where a supply is in demand during winter and early spring. To have the leaves large and succulent the soil should be deeply dug and enriched with manure. The seeds should be sown thinly in drills about 18 in. apart, and, if the soil be at all dry, the drills should be well watered before sowing. If the seed be steeped in water for a few hours previously it will germinate more quickly. Frequent surface-stirring and early attention to thinning the plants is necessary in order to allow the plants to fully develop themselves and yield large foliage. It is always best to allow them to get well established before any leaves are gathered from them. Spinach is liable to go off with a kind of canker at the root in retentive or wet soils. In this case the best way is to sow on ridges or on sloping borders. It is always well to make two moderate sowings to allow for variations of seasons.—J. GROOM.

Planting Cabbages with a Crowbar.—I ventured last year to inform your readers that I always planted my spring Cabbages after Onions without any digging, merely using a crowbar for making the holes. This Mr. Groom designated simply tickling the surface. In a recent impression of THE GARDEN, however, he absolutely advocates my mode of planting, a circumstance with which I am well pleased. Mr. Groom sees the inutility of digging, and I hope he will in future give my modes of cultivation a fair trial before he condemns them.—B. GILBERT, *Burghley*.

GRAPE AND VEGETABLE CELLARS IN THE NORTH OF CHINA.

IN a recent number of the Reports of the French Société d'Acclimatation Mr. J. G. Dunn gives an interesting account of the construction and use of the cellars employed in the north of China for the preservation of fruit and vegetables through the winter. These cellars are called *ti-kiao* by the Chinese, and are generally rectangular in form. Ninety-five times out of a hundred they have the following dimensions, measured inside: 12 ft. to 14 ft. long, 9 ft. to 10 ft. wide, and $7\frac{1}{2}$ ft. to 8 ft. deep. Small cellars of this size are the most common, and are to be preferred on account of their being more easy to keep in order; besides which, the construction of the roof allows of the use of small pieces of light wood, costing but little, a single chimney only being necessary. When the cellar is larger, the roof must be supported by heavier timbers, there is greater danger of the falling in of earth forming the sides, and more than one chimney will be necessary for carrying away the smoke given off by the heating apparatus. The following are the conditions which must be complied with in order to insure success: 1. The cellar must be dug out in a perfectly dry spot far removed from marshes and watercourses, and a position having a natural height of 3 ft. or 4 ft. above the ordinary level should be chosen in preference to any other. 2. When the place intended for the cellar is dug out, the sides must be neatly trimmed in such a way that it is slightly larger at the bottom than at the top; the floor is then properly levelled, and it must be well beaten down with a pavior's rammer, so as to make it as hard as possible. 3. The earth taken out of the cellar must next be well sifted through a fine

Fig. 1.—Ground plan of the cellars used by the Chinese for the preservation of fruit and vegetables.

sieve, so as to get rid of all the stones, after which it is mixed with Millet straw, to which has been added a certain quantity of lime, the whole being worked up into a kind of mortar by pouring water on it. The mortar thus obtained approaches very closely in composition to that generally used in the construction of walls and houses in this part of China, the only difference being that in the first case there is a larger admixture of Millet straw. The four sides of the cellar are covered with this mortar, the beaten floor being left uncovered. The walls are built so as to rise to the height of from 2 ft. to $2\frac{1}{2}$ ft. above the level of the soil, and are allowed to dry thoroughly. When quite dry, the tops of the walls are levelled with care, and light planks are thrown across from one to the other, the whole being covered over with mats made of Millet straw, or else with the loose straw itself, or, in default of this, with light boards. The cellar is now ready to receive its proper roof, which is made of a similar sort of mortar to that used for the walls. This roof ought to be from 2 ft. to 2 ft. 6 in. in thickness, and very carefully laid so that it may have a double inclination, as shown in fig. 3, for the rain to run off. In one of the corners of the roof a hole is made, sufficient to allow the introduction of a basket, of from 2 ft. 4 in. to 2 ft. 6 in. in diameter. The only other opening to be made in the roof is one for the passage of the smoke pipe. To enter the cellar neither a ladder nor staircase is required; the labourer lets himself down by means of a rope, with which the entrance is furnished. In one corner of the cellar, a *hang-tse*, or bed of beaten earth, is formed similar to those used by the inhabitants of the north of China for domestic purposes. It is made with a similar kind of mortar to that used in the construction of the walls and roof. The dimensions are generally 7 ft. long

by 4 ft. wide. Underneath this bed is formed an ordinary furnace, as shown in figs. 2 and 3, which is always lighted during the night until the cellar walls and roof are perfectly dry. When the stock of fruit and vegetables is laid in, the furnace is lit twice a day, at dawn and at sunset. At each firing the furnace consumes about 20 lb. of Millet straw, or about 40 lb. per diem. The chimney carries off the smoke of the straw, and facilitates the circulation of the air. It generally rises about 2 ft. above the level of the roof. There are no internal supports to the roof, the walls, when once dry, being quite strong enough to resist all lateral strains. If there are no inundations, these cellars, when properly made, will last for twenty or even thirty years, necessitating only slight repairs from time to time. A single inundation is, however, sufficient to destroy them, or, at any

Fig. 2.—Longitudinal section.

rate, to render them perfectly useless. No bricks are used in the construction of these cellars. A cellar constructed according to the method described above may be used as a forcing house during the summer for the cultivation of Leeks and other vegetables, which the Chinese epicures like to be as white as possible. These vegetables are grown in baskets made of Millet straw, which contain a suitable mixture of rich mould and manure. Leeks and other vegetables, grown in these cellars, always fetch a higher price in the market than those grown in the open ground in ordinary market gardens. It is not at all improbable that Mushrooms could be grown in these cellars. The baskets are taken away in November or early in December, and the chimney and furnace are repaired, the latter having always been kept alight during the summer, with just sufficient fire to push forward the growth of Leeks and

Fig. 3.—Transverse section.

other vegetables. As soon as the frost sets in the floor of the cellar is covered over with a layer of lime. The vegetables or fruit to be preserved are arranged in double rows, separated from each other by a space of 1 ft. 3 in., to facilitate the circulation of the air. Cabbages are piled up to a height of 4 ft., those underneath being kept from contact with the soil by a layer of dry Millet straw. On the top of these rows of vegetables are placed the fruits contained in baskets. In this way not only ordinary vegetables, but Grapes, Pears, Apples, Plums, &c., are successfully preserved throughout the winter and spring. The fruits are put into the baskets without any previous preparation, except, indeed, the separation of any specimens that seem to be over-ripe, specked, or inclined to decay, all of which must be strictly set aside. If this previous examination is made with a proper amount of care, the number of fruits

which are spoiled in the six months of winter and spring is very small indeed. The baskets containing the fruit are piled one on the other right up to the top of the roof. They must be taken down and examined every day, so as to know if any of the fruit or vegetables shows signs of decay, in which case they must be removed at once for examination. This operation should be conducted in dry weather, or if of necessity in wet, the suspicious fruit or vegetables must be set aside for further examination on the first dry day. A cellar, let us say, of medium size will hold somewhere near 60 tons of Cabbages, and from 50 to 60 baskets of fruit, each basket weighing 50 cabbies, or about 66 lb. Fruits preserved in this fashion keep perfectly good without any perceptible change in their appearance or flavour for from six to eight months. According to the Chinese, Cabbages improve greatly by this treatment, and their flavour far surpasses that of vegetables fresh from the market garden. The loss of weight in the Cabbages during six months is almost inappreciable. To build a cellar of the dimensions given above costs from 8 to 10 dol., say, from £1 10s. to £2. The inner roof and walls, for they are little else, are quite sufficient to protect the interior from all wet and damp. As this account was written in November, at the time, in fact, when the operation of storing is only just beginning, the author was unable to give us the exact degree of temperature which is necessary for the preservation of fruits; but, according to information which he has collected from various trustworthy sources, he thinks that the average temperature of the cellar throughout the winter is from 75° to 80° Fahr. If the cellars were to be kept at a higher temperature than this, the Grapes would be turned into raisins, and the Potatoes and other vegetables would be dried up. Before being stored in the cellars, the vegetables are exposed to a free current of air for one or two months. In the same way the fruits are packed in the baskets some time in advance. Plums and Pears are generally gathered about the month of August or September; Grapes at Tien-tsin at any rate in September and October. A man sleeps near the cellar throughout the winter to prevent the fruit and vegetables from being stolen. The neighbourhood of these is greatly frequented by gamblers, the temperature in their immediate vicinity being extremely agreeable on cold winter days. To build one these cellars, stock it with fruit and vegetables, and keep it in proper order requires but a minimum of care and capital; hence their frequency in the neighbourhood of all large towns and cities in the north of China, where they have been common for centuries past. The opening through which access is gained to the cellar is generally covered over with a piece of matting, usually stretched over a wooden frame, to keep out the cold.

C. W. QUIN.

FLOWER SHOW AT VERSAILLES.

The recent flower show at Versailles was of some interest to English horticulturists, from the fact that Mr. Wills sent so many valuable and rare plants there, and that Messrs. Veitch also sent over one of their select and varied groups of plants. Mr. Wills showed some of the finest specimens known of some of the rarest and most beautiful Palms and Dracænas, and with his varied collection won fifteen of the more important prizes and the major prize of the show, a valuable Sevres vase, offered as the grand prize of honour for the grower who contributed most to the riches and beauty of the exhibition. Messrs. Veitch sent over their superb new hybrid Cattleya, and Mr. Linden had also a fine collection of new plants. Our exhibitors were in good company, for M. Truffaut and other growers present had many collections of exotic fine-leaved plants, very well grown. Among the groups at the show most interesting to the stranger were the free-flowering Oleanders in various sizes; little Pomegranate standards, sparkling with flowers; and a race of double Petunias with fringed and incised petals. To us, however, the most charming exhibit in the show was a large, slightly raised bed of Gloxinias, bright and delicate, and varied in colour. The mass was beautifully softened and varied with tufts of Maiden-hair Fern in small low pots, so placed that only the spray of the Fern was seen here and there among the Gloxinias. These possessed every charm of

colour from the most bright and intense self or margined flowers to the most refined and delicate spottings on pale ground, and to pure large white flowers, many of the blooms being unusually large. This flower has not, as yet, seen its best days in our collections. It requires much less heat than it used to be treated to, and successive batches may prolong the bloom throughout the spring and summer.

ANSWERS TO CORRESPONDENTS.

Bleaching Skeleton Leaves.—How can I bleach Fern leaves that have been skeletonised? [Bleach them in a solution of chloride of lime, made by adding two table-spoonfuls to one gallon of water.]

Cones of Cedrus Deodara.—In reply to "J. J. R.'s" enquiry (p. 170), I am able to state that a well-grown specimen of this tree at Sandes Place, near Dorking, under thirty years of age, produced cones last year for the first time, and they appeared to ripen very satisfactorily.—DROCS ДРЕКОВАЯ, M.D., Sandhills, Betchworth, Surrey.

Earthing up Tree Trunks.—Will earthing up tree trunks 7 ft. kill them or not? In making a garden terrace two fine trees, which we should not like to lose, have been buried to that depth.—H. C. L. [If you wish to keep your trees alive you must build a wall around them at from 9 in. to 12 in. from the trunk, commencing at the base and building a little higher than the present surface of the ground. I know of several large trees that have been treated in this way, having more than 7 ft. of soil over their surface roots, and yet they are still doing well.—G. S.]

Poplar Tree Stumps.—What can be done to destroy vitality in the roots of Poplar trees cut down near the ground, but not grubbed? The roots spread to great distances, and are constantly putting forth shoots and forcing up the gravel walks.—R. R. [You had better blast the stumps with either gunpowder or dynamite, and after wards grub up all the stronger roots that can be found within 18 in. of the surface of the ground. If the roots must remain in the ground, their decay may be hastened by boring holes at or near the point where the suckers protrude through the surface of the ground and filling them with gas tar, but in every case where practicable the stumps should be removed.—G. S.]

Double Primulas.—All I have to say by way of answer to Mr. R. Gilbert (p. 186) is, that if the same treatment he given as is recorded (p. 135), double Primulas never take more than three weeks at the most before they strike root, and upon looking them over some will be found to be ready even within the three weeks.—H. H.

Earthing up Celery.—What is the best method of doing this, where the soil is stiff clay, so as to prevent worms spoiling the hearts?—A. L. S. [Under such circumstances you should blanch with Cocoa-nut fibre, sand, or triable soil put close round the plants. Such materials can be backed up with the clay broken to pieces as much as possible. Celery should always be earthen up when both soil and plants are in a dry state. Common half-drain tiles placed round the plants and filled up with sand is a method sometimes adopted under such circumstances, but it is rather expensive.]

Names of Plants.—Miss T.—The botanical name of the flower which is called by the French Belle de Nuit, and which only opens about six o'clock in the evening, is *Mirabilis Jalapa*, or *Marvel of Peru*. *F. T.*—1. *Acanthus spinosus*. 2. *Helianthus multiflorus* fl.-pl. 3. Apparently a bit of *Alternanthera*. 4. *Phlox subulata*. *M.L.S.*—Smashed to pieces, but apparently a portion of a Giant Puff-ball (*Lycoperdon giganteum*), figured in *THE GARDEN* (Vol. XII., p. 326). *E. M. Cole*.—*Tillandsia xyphium*; an epiphyte, not a parasite, belonging to Bromeliaceæ; it grows generally in the West Indies and Brazil. *Chipping Ladbury*.—Certainly *Hydrangea paniculata*; but from the scrap sent, we are unable to say whether it is the variety called *grandiflora* or not. *E. Leicester*.—Rose-growth such as that which you have sent are not uncommon. They are the result of some disturbance either at roots or top, and show the close relationship that exists between leaf-buds and flower-buds in certain stages of development.

Pruning Cordon Apples and Pears.—I have several cordon Apple and Pear trees, but am not clear as to the method of pruning them. I pinched back the shoots to three or four leaves in June last, but these have again extended themselves. *W.W.H.* is the proper method of dealing with them? and of what does the winter pruning consist?—AMATEUR. [You did quite right to pinch the new growths in June; do them again at once, of course leaving, at least, two or three leaves in advance of where you previously pinched them. Usually free-growing cordons require pinching about three times in the course of the summer. The winter pruning consists in cutting out any ugly or misplaced old spurs, and any long shoots that were not summer-pinched.—W. W. H.]

Melon Seeds Germinating Inside the Fruit.—In reply to "G. T." (p. 187), I may mention that I had a similar experience three years ago at Orotara, in the island of Teneriffe. Don Carlos Smith, a well-known English resident on the island, showed me a large Melon grown in his garden, which contained over a dozen germinating seeds. Neither he nor his gardener had ever observed such a phenomenon before. The cotyledonary leaves were scarcely tinged by chlorophyll. The Melon was quite edible, and, so far as I remember, of good flavour. No explanation was forthcoming as to the cause, and I think there was no breach of surface noticed. I recorded a note of the circumstance in the "Transactions of the Botanical Society of Edinburgh" in 1876, and sent some of the specimens to the University Museum preserved in glycerine. I have

now by me some of the seed of the same stock of Melons, and shall be happy to send some to "G. T." if he will furnish me with his address. I may add that Mr. Smith failed to raise any plants from seeds taken from the Melon particularly referred to. I believe the occurrence is not very uncommon in members of the Cucurbitaceæ.—DYCE DUCKWORTH, M.D., Sandhills, Betchworth, Surrey.

Tuberoses.—I would be glad of some information as to the successful culture of Tuberoses. With me they become "drawn," and the blossoms are very poor. I have had them in a cool greenhouse; would they do better after they are started if kept in the open air?—A. C. [Tuberoses require a rich, light soil, and the roots start best if plunged in a slight hotbed, where they should remain till growth has fairly commenced, and the pots are full of roots; then gradually withdraw them from bottom-heat, give plenty of air, and keep the plants as near the glass as possible. They would, no doubt, succeed well if in a sheltered spot in the open air, in which case the pots should be plunged in ashes or other light material, and their flower-stems supported with stakes as their growth progresses to prevent injury from the wind, &c. They require liberal supplies of manure water, but good results need not be expected unless the highest-priced roots are purchased.—W. W. H.]

Lawns on Light Soils.—I am shortly going to lay down a lawn on a very light soil, sub-soil sand. What will be my best mode of procedure?—G. S. [With such a light soil deep trenching is of the first importance, and should be done to a depth of 3 ft., picking out all weeds such as Couch, Nettles, Brambles, Bindweed, &c., during the operation, as they would all help to smother the Grass seeds. The soil described must necessarily be poor, and though it is not desirable to have good land for a lawn, manure would be a great help in giving a good start to the Grass seeds; stable or farmyard manure would be best, but if that is not to be had conveniently, common salt would prove a good manure for such soil. Apply it thickly over the surface as soon as trenched, which should be done early in the winter and left till February; then roll and rake the surface several times before sowing the seeds, which ought not to be sown until the middle of March. Again rake and roll, keep off birds, and you ought then to have a good sward by August.—W. W.]

Arbutus Menziesii and A. procera.—Allow me to thank Mr. Gumbleton for drawing my attention (p. 169) to the characters of these two forms of Arbutus. I now agree with him in thinking that they are distinct, but after a critical examination of both forms, I find that the leaves of A. procera are not always entire, there being crenated as well as smooth-edged foliage on the same plant.—GEO. SYME.

Questions.

Prince Albert Pine-apple.—Can any of your readers give me the origin of this? The fruit and growth of the plant are so much like those of the Black Prince, that I think they must be of the same parentage.—H. W.

Epilobium obovatum.—This is one of the most difficult plants I have to propagate from cuttings. Can any one give me a hint in order to ensure success?—W.

Wintering Half-hardy Bedding Plants.—I have no greenhouse, but I am desirous of taking a quantity of cuttings, and a few hints as to the best way of keeping them through the winter will be useful to me.—V.

Phloxes Abroad and at Home.—Can Mr. Cornhill or any of the correspondents of THE GARDEN, who have observed what is going on abroad, tell us how it is that the tall autumn Phloxes are so much more healthy, vigorous, and brilliant abroad than at home. About London, even with specialists, I have never seen these fine flowers with anything like the splendour of colour, health, and vigour they show as seen about Paris, both in private gardens and at the Exhibition.—A. V.

Early Peaches.—I should be greatly obliged to any of your correspondents who have a practical knowledge of this matter if they would give me their opinions of Early Beatrice, Dr. Hogg, Early York, &c., under glass. I have already planted these and other varieties, but I am now led to believe that, except for earliness, they are very inferior to the older kinds, and that, on the whole, they are not worth growing. What is the quality of Alexandra Noblesse?—A. SUBSARAZA.

Making an Asparagus Bed.—How can I make an Asparagus bed under the following conditions: Soil from 20 in. to 24 in. deep, and then comes "rab," a gravelly sort of grit which will bind for walks? What age should the plants be to put in with safety to bear next year?—H.

Failure in Parsley.—At the commencement of the season I sowed a quantity of Parsley seed on a bed that has had Parsley on it regularly for the last ten years. The bed is alongside a channel for water to run down from the kitchen. For the last year or two we have gathered very little Parsley from this bed. When the leaves are about the size for gathering they become quite yellow, and consequently are unfit for use. The roots also come easily out of the ground when the Parsley is being gathered. Will some one inform me why a good crop cannot be had from this bed? Have worms anything to do with it?—A. Z.

Some Good Herbaceous Plants.—Will you kindly give me a list of some of the very best herbaceous plants? I have none but Phloxes and one Aquilegia, and wish to form a collection.—DORSET VICAR. [The following is a selection of good herbaceous perennials, excluding to a great extent bulbs:—

Acanthus latifolius	Dodecatheon integrifolium	Linaria dalmatica	Primula denticulata
apinosissimus	Jedreyanum	vulgaris	sikkimensis
Achillea Millefolium	Masala	alpinum	Prænula grandiflora
asplenifolia	Doronicum caucasicum	arcoreum	Pyrranthum carneum
Eupatorium Patricum fl.-pl.	Dracocephalum argusæ	narbonneæ	serotinum
Aconitum japonicum	austriacum	perenna	Ranunculus aconitifolius
variagatum	grandiflorum	lobelia cardinalia	acria, fl.-pl.
Adonia vernalis	Ruyachianum	Lupinus polyphyllus	amplexicaulis
Alstroemeria auræa	Echinops rubenicus	Lychnis diurna fl.-pl.	monsphacalis
Anchusa italica	Epilobium angustifolium	chalconica	montana
Anemone alpinæ	rosemarinifolium	and varæ.	Rhæxis virginea
angustata	Epimedium pinnatum	Hæmanga vespertina	Rudbeckia californica
coronaria fulgens	Eranthis hymalis	Viscaria Lythrum	Drummondii fulgida
Hepatica japonica	Erigeron speciosum	Salicaria roseum	hirta
palmata	Erodium Maucæavi	Malva campanulata	laciniata
Pulegiata sylvæstria	Eryngium alpinum	moscata	speciosa
Aquilegia alpinæ	amathytinum	Mecopopia cambrica	Salvia argentea
coerulea chrysantha truncata	Erythronium Dena-cænia	Medicago falcata	patens
Arum italicum	Ferula lingitana	Melittis Melliaophyllum	Saponaria cymoides
Asclepias tuberosa	Fuchsia grandiflora	Mertensia virginica	Saxifraga cordifolia
Gaillardia aristata	Sieboldi	Monarda didyma	crassifolia
Aster grandiflora	Gentiana Andrewsii	Kalmiana alpina	Scabiosa caucæica
Amellus elegans	Novæ Angliæ	Myosotis dioiciflora	Scutellaria alpina
levia	Novi Belgii	palustris ælyptica	lupulina
Novæ Angliæ	pyræneus	Nepeta Mussini	Sedum kamtschaticum
Revecai	Revecai	Enthara fruticosa	Sieboldi spectabile
terbinellus varicolor	Lambertianum	Jamesi macrocarpa	spurium
Atragalus monspesulanus	platyptalum sanguineum	marginata riparia	Silene alpestris
Baptisia australis	stratum armenum	speciosa	Elizabethæ Schafta
Betonica grandiflora	Geum chilense	Omphalodea verna	Sisyrinchium grandiflorum
Calla palustris	montanum	Onobrychia montana	Spizelia mariandica
Calirhoe involucrata	Gypsophila paniculata	Ononia arvensis	Spiræa Aruncus
Calystoglia dihurica	Steveni	rotundifolia	palmaria venusta
pubescens	Hedysarum obscurum	Orobus cyaneus	Stachys latifolia
Campanula alpina	atropurpureum autumnale	facciosus lathyroides	speciosa tatarica
carpatia gradia	Helianthus multiflorus fl.-pl.	variegatus vernus	Symphandra pendula
obovata	Helichrysum arenarium	Præonia in great variety	Symphytum bohemium
periclyfolia turndifolia	Helleborus niger and its varietica	Papaver bracteatum	caucasicum
Carduus eriophorus	Chelone glabra	lateritium nudicaule	Thymopsis fabacea
Chelone glabra	umbilica	orientale pilosum	Thlaspi latifolium
Commelina celestis	Convolvulus Soldanella	Phlomis herba-venta	Tridacantha virginica and vars.
Ceropegia lanceolata	Coronilla iberica	Russelliana Smia tuberosa	Tritoma Uvaria
Coronilla iberica	montana varia	Corydalis nobilis	Trollia asiaticus europæus
Corydalis nobilis	Orambe cordifolia	Cynara scolymus	napellifolia
Cymbaria latifolia	Delphinium in fine variety	Dentaria laciniata	Tropæolum pentaphyllum
Dentaria laciniata	Dicentra cæxia	dictamnina	polyphyllum speciosum
Dictamnina Fraxinella	Fraxinella	Fraxinella	Verbascum Chaixii
Fraxinella	Fraxinella	Fraxinella	Veronica candida
Fraxinella	Fraxinella	Fraxinella	corymbosa gentianicoides
Fraxinella	Fraxinella	Fraxinella	incarnata incisa
Fraxinella	Fraxinella	Fraxinella	Hendersoni
Fraxinella	Fraxinella	Fraxinella	Vicia argentea
Fraxinella	Fraxinella	Fraxinella	Cracca Vinca
Fraxinella	Fraxinella	Fraxinella	barbacea Viola calcarata
Fraxinella	Fraxinella	Fraxinella	coriuta lutea
Fraxinella	Fraxinella	Fraxinella	pedata

"This is an art
Which does mend Nature: change it rather: but
THE ART ITSELF IS NATURE."—*Shakespeare.*

TUBEROUS-ROOTED BEGONIAS AS SPECIMEN PLANTS FOR THE CONSERVATORY.

ONLY a few years ago we were in great danger of having the floral beauties of our gardens swamped beneath the masses of variegated Begonias. *Begonia Rex* created something like a panic in most gardens. I was myself bitten severely with the variegated *Begonia* mania, and never rested until I ribboned out about 2000 plants of *Begonia Rex*. The result was so discouraging, that I have bedded out none since. The French, however, continue to mass out Begonias in quantities, especially the flowering sections, such as *nitida*, *parviflora*, *Ingrami*, &c. The bulbous Begonias, mostly of the *boliviensis* and *Veitchi* sections or families, may also have a brilliant future in the flower garden. Meanwhile, their proper place seems to be the conservatory, greenhouse, and window garden. For such positions it is well-nigh impossible to match the bulbous-rooted Begonias for brilliance, grandeur, and grace—three qualities seldom combined in the same plant. The plants are also characterised by great distinctness and freshness of style and character. The difference between the male and female blossoms; the position of the flowers on the extremities and outer sides of the branches; the semi-pendulous habit of most of the latter; and the forms, numbers, size, colours of their many flowers furnish a combination of ornamental qualities of the highest value.

Begonias are also easily raised from seeds; and though very few of them come quite true, nevertheless over 75 per cent. of the seedlings from good strains are well worth growing. Seedlings have also the additional merit of speedily proving themselves. Cultivators must keep some plants one, two, or even three years before they are able fairly to test their merits. Not so with bulbous-rooted Begonias. Sow in a temperature of 65° in February, and the seedlings will, under generous treatment, be in flower in May, and will form fine bushy plants in 6-in. pots before the end of the summer. But little loss of time and space is therefore incurred in the proving of tuberous-rooted Begonias; and, of course, as soon as they are proved, any inferior plant can be discarded. It will not, however, be possible to test them fairly in such a high temperature. A cold pit in summer, or a cool, airy conservatory stage, is the best possible place to test tuberous Begonias. In such temperate places the colours of the flowers and the habits of the plants will be displayed in their true characters. Tuberous-rooted Begonias can also be propagated by cuttings, though not by any means so rapidly as the non-tuberous or variegated leaved section. Each leaf, and each inch of the veins of a leaf of the latter, may be converted into a plant. It is, however, widely different with these tuberous-rooted sorts. Sections of the stems and branches of most of them root readily enough; but in regard to these plants, that is by no means all that is needful. Two more steps must be taken before the so-called rooted cutting is of much or any use to the cultivator. It must form a bulb, and that bulb must have the power of throwing up a stem next year. This trinity of processes needs time, and demands a considerable amount of skill. It is obvious at a glance that tuberation is a slower, more difficult, and altogether a different process from the making of roots. The latter may be plentiful, the former altogether absent. Neither does tuberation, as a matter of course, succeed roots; it may or it may not do so. The formation of tubers is much more a matter of condition than an affair of time. Much more vital force is needed to develop tubers than to push forth roots; hence the importance of choosing vigorous growing points, and inserting them close to the light to encourage the transformation of the crude juices of the stems and leaves into the more dense fluids and substance of the tubers. But tubers are also possible that lack the ability to break or grow in the following season. This is

the most provoking stage of all in the culture of tuberous Begonias—any number of roots there may be, and abundance of healthy tubers, but no starts. This brings us to the last and most important point of all in the propagation of tuberous Begonias by means of cuttings. To make sure that the cutting bulbs will break into fresh shoots the next season, each cutting must have a wood bud under or beside the axil of its lower leaf or stalk; this bud forms, as it were, the growing crown of the bulb, and without it there is no living crown; consequently, no start into growth. This inability to form growing tubers without growing buds somewhat limits the extent and rapidity of the propagation of these fine Begonias from cuttings. As, under good culture, each shoot is nearly all bloom, it follows that there is but little suitable material for propagation. Cuttings with flower-buds at their bases will root and grow freely, but the tubers simply decline to start. The tubers should be kept in the pots in which they are bloomed throughout the winter. They cannot well be too dry, and the temperature should not be lower than 50° or 55°. Cold and damp are two of the greatest evils that cripple and destroy tuberous-rooted Begonias. It is also good practice to start these plants in the old soil. Shaken out in a dormant state and potted in damp soil, or watered before starting, not a few of them either continue dormant, or run into rotteness. If started before potting, these risks are avoided. The plants also, when 1 in. or 2 in. high, lay hold of the new soil almost immediately, and seldom look behind them.

A good soil for these Begonias consists of equal parts turfy loam, leaf-mould, peat, and rotten manure, with a liberal admixture of sharp sand and a dash of bone dust. The collars of the plants should also be kept well up in potting, as fine specimens are somewhat apt to give way, the stems being large and fleshy. It is needful also to be careful in watering to keep the stems as dry as possible, for thick, dense plants, 4 ft. or 5 ft. through and about as much high, are apt to lose a branch here and there from damp, to their great disfigurement, if not the absolute ruin of the specimens. For this and other reasons very large specimens are hardly to be desired. Unless for exhibition purposes, fine bushy plants in 8-in. or 10-in. pots are, upon the whole, the most effective and most beautiful and useful. These Begonias are amongst the finest of all floral material for decorative purposes, either in pots or as cut flowers. For vases, baskets, glasses, &c., they are admirably adapted, and some of the smaller-flowering varieties are equally well adapted for bouquet work. The varieties of these Begonias are very numerous, and the cry is, still they come! There is, in fact, great danger that their enormous numbers will produce a reaction against them. I confess to a strong affection for some of the oldest of the type—*boliviensis* and some of its improved forms. This is still one of the most graceful and showy of them all, the length and thinness of its brilliant-coloured flowers giving it quite a unique character. *Stella* is very brilliant, and *Vesuvius* is a grand, free-flowering rosy-red variety, very difficult to beat; *intermedia*, a beautiful soft pink, is a profuse bloomer and excellent in habit; *Acme*, bright rosy-red, is very distinct; *Baronne Hruby*, brilliant crimson, suffused with violet, is also distinct and beautiful; *purpurea magnifica* is crimson-scarlet, and *C. Baltet* crimson, shaded with purple towards the centre; *F. Lecomete* is beautiful bright rose; *Lucien Purcelle*, large, purplish-red, and *W. E. Gumbleton*, rich scarlet, and very large; *Adolphe Dubois* is creamy-white, tinged with yellow, and *Laurent Descours* bright rose, large and good. I have not yet grown any of the doubles, and therefore have not recommended them. D. T. FISH.

FLOWER GARDENING IN VICTORIA PARK.

THIS East-end park is, if anything, more attractive this year than usual. As regards sub-tropical gardening, owing to situation, it is not so well favoured as that at Battersea, but, nevertheless, the plants appear to grow with almost equal vigour. One advantage which this park possesses over that of the other parks is its long lengths of shrubbery borders, all of which are so well adapted for the culture of good herbaceous plants, which are, nevertheless, but poorly represented compared with what they might be. If ordinary and pattern bed,

ding and sub-tropical gardening can be carried out in the perfection in which they may be seen here (styles of gardening, by-the-by, which can only be imitated by those who possess hothouses and their necessary appendages), why cannot herbaceous and Alpine gardening be also carried out in perfection, so as to give those who have only shrubby borders to decorate, a rock garden to plant, or who have not the conveniences for wintering tender plants, an opportunity of judging at all seasons of the year what plants would be most suitable for their own gardens? True, hardy plants are represented here better than in any other London park, but, after visiting a few of the hardy plant nurseries about London, one can see glaring deficiencies as regards variety. It may be urged that public parks are only intended for purposes of recreation, and for affording a pleasant and attractive garden for the people; but, while such large sums of money are expended yearly to produce a striking feature in the way of bedding plants, usefulness might be combined with it without any extra expense, and be of much more benefit to the public at large. Victoria Park, though one of the newest, is, without doubt, one of the best managed of our parks, as far, at least, as gardening is concerned; and, if a little more attention were paid to the adornment of the borders and other places with suitable plants, it would become one of the most useful, as well as attractive, public resorts in the neighbourhood of London. One other remark might be made, and that is, that none of the plants used either in carpet, sub-tropical, or pattern gardening have names attached to them. Why this should be it is difficult to imagine, for it is a practice well carried out in all our public gardens, and through inattention to it here much useful information is lost. Amongst the sub-tropical plants may be seen *Wigandias* planted in groups alternately with *Eucalypti* and edged with golden-leaved *Fuchsias* pegged down, an arrangement which has a fine effect, as have also large mixed beds composed of *Aralia Sieboldi variegata*, *S. papyrifera*, *Ficus elastica*, *Acacias*, and *Abutilons*. *Castor-oil* plants are robust and finely coloured, and, being allowed plenty of room, are very striking where planted in groups with an undergrowth of *Stellaria aurea*. *Cannas* appear to have done well, and form good bands to raised shrubberies. *Tobacco* plants are not so tall as usual, but are very healthy and vigorous, and they rank among the most effective as well as easiest-grown of sub-tropical plants. The old *Erythrina Crista-galli* in round groups flowers abundantly, and forms a striking feature where edged with *Abutilons* and the silvery-leaved *Dactylis glomerata*. The variegated *Abutilon vexillarium* is used here as an edging with good effect to beds of *Acacia lophantha*, which grows amongst a thicket of silver Grass. The *Acacias* are not so tall as they were last year, but they are more branching in habit and equally effective. The carpet beds are everywhere good in their way; they are planted chiefly with green *Mentha*, in which are set out a few simple designs in the form of coloured-leaved plants, altogether devoid of that streaky aspect too often observable in carpet gardening. The flower garden properly so called is one glaring crowded mass of colour. The plants, which consist of *Pelargoniums*, *Heliotropes*, *Ageratums*, and the orthodox bedding material, have grown well and are kept in excellent order, but we cannot help thinking that if every alternate bed were removed a much better effect would be produced. Round beds in front of the shrubby borders, planted with mixed *Verbenas* and edged with *Stellaria aurea*, are very pretty; also beds filled with silver-leaved *Pelargoniums* intermixed with blue *Violas*. The borders are planted with *Helianthus multiflorus* fl.-pl., *Dahlias*, *Antirrhinums*, *Asters*, &c., among which are growing annuals, *Lilies*, &c.; but there is, as we have already said, an absence of really good hardy plants. The rockwork is this year, as usual, a source of attraction; it contains a large variety of *Sedums*, &c., among which are planted *Euonymuses*, *Aralias*, *Agapanthus*, &c., with a few brightly-coloured *Coleuses* and *Alternantheras*.
C. S.

Daphne Blagayana.—This pretty dwarf *Daphne*, of which a coloured figure was given last week (p. 200), is stated to grow well on the chalk; it will, therefore, be a valuable plant for calcareous soils.

NOTES OF THE WEEK.

Tyerman's Groundsel (*Senecio pulcher*).—This is a noteworthy addition to our hardy plants. The ranks of the *Compositae* family are full enough of good things already, but this is too distinct not to be valuable. It quite comes up to the estimate formed of it last year, and, in addition to the beauty of its thick, fleshy leaves, which have a family likeness on a large scale to the common Groundsel of our kitchen garden borders, its strikingly brilliant flowers possess a decided odour of vanilla.—SALMONICEPS.

Lilium auratum in the Isle of Wight.—In the grounds of my neighbour (General Tate) there are some good specimens of *Lilium auratum* in blossom. Some of them are more than 9 ft. high, and I do not think that I have seen better *Lilies* of the sort outside of the garden of Mr. McIntosh at Weybridge. I think them worthy of just a brief notice, because the gardener tells me that they were planted five years ago, and from that time to this nothing at all has been done to them. This is rather against some advice that has been somewhat hastily given in your columns, and in favour of the policy of "letting well alone," which has been advocated by one of your correspondents.—H. EW BANK, *St. John's, Ryde*.

Eulalia japonica zebrina.—This promises to be one of the most ornamental of Grasses for isolated positions on lawns or for planting in the shrubby border. In warm, deep, rich sandy soil it grows rapidly, and its leaves become effectively variegated. One of the best specimens we have yet seen is now growing vigorously in Messrs. Laing & Co.'s nursery at Forest Hill, where it has stood the past winter without any protection whatever, and without sustaining the least injury.

Torenia Fournieri in the Open Air.—It may not be generally known that this beautiful Mexican annual will thrive during ordinary seasons in this country planted out in the open air; in fact, it forms an exceedingly beautiful bedding plant. Some plants of it were put out-of-doors here in the early part of last June, but the weather soon afterwards set in very dry and they made little progress for some time; on a change taking place, however, they grew vigorously, and they are now (the first week in September) in full bloom, and very beautiful they are. They are dwarfer and more robust in habit than others growing in the plant stove. This *Torenia* may be propagated by means of cuttings, but they are apt to damp off in winter, and plants raised from seed are to be preferred.—P. GRIEVE, *Culford, Bury St. Edmunds*.

Thladiantha dubia.—This very ornamental perennial Gourd does remarkably well when planted amongst shrubs, and its long shoots allowed to climb at will among their branches. It is not leafy enough to do any harm to most shrubs, and its wreaths of large, bell-shaped, bright yellow blossoms, and neat, heart-shaped pale green, hairy leaves, show off extremely well against a background of dark green, such as that afforded by the Yew, and many other Evergreens. It forms large tuberous roots, and seems to be quite able to hold its own even in rather unlikely spots. We have also seen the beautiful Rose-coloured blossoms of the true Jalap (*Exogonium Purga*) produced in wild luxuriance and profusion among low shrubs, these forming quite sufficient protection for the tubers during winter. No care in either case is required, and no trouble, except merely that of first planting the tubers in the positions which they are intended to occupy.—G.

Heading Back Sweet Peas.—Visiting Heckfield a few days since, I noticed a row of Sweet Peas just coming into flower. Remarkable upon the late period of the year at which they were blooming, Mr. Wildemith mentioned that they had been previously finely in flower, but that when getting rather past their best they had been cut down, even with the tops of the sticks, and renewed growth was the result. From the bottom to the top a new growth had sprung up, and there will be an abundance of bloom until the end of October. I saw just such another row of Peas elsewhere a few days previously that had run to seed and that were almost flowerless, yet not a pod of the seed was wanted. Had the heading-back process been adopted there, the result might have been much more satisfactory.—A. D.

Mr. Laing's Begonias.—These are at the present time, if possible, more attractive than they have been all the season; the plants have gained strength, their flowers are larger and richer in colour, and are produced in greater profusion than they hitherto have been. Ever since early in May a houseful of them has been a source of attraction, and to all appearance they will keep on flowering far into the winter. A large breadth of ground in an open sunny position, planted with small seedling plants of these *Begonias* in May, is now one mass of blossom, and, whilst *Pelargoniums* and other bedding plants are almost flowerless on account of the heavy rains to which they have lately been subjected, the beauty of these *Begonias* appears rather to improve than to be impaired by the wet.

Those planted out at present consist of the drooping-flowered kinds, of which there is now an abundance, varying in height from 4 in. to 2 ft.; they may, therefore, be used in beds or borders of any size. For edgings some of the dwarfer kinds will no doubt be largely used, and it is not improbable that these *Begonias* will become important market plants. The erect-flowered type have not yet been fairly tried out-of-doors; at present, therefore, it is uncertain whether they will withstand the weather so well as those with drooping blossoms.

Variegated Ontario Poplar (*Populus canadensis*).—There is a very handsome variegated form of this Poplar in the Lawson nurseries, Edinburgh, the foliage of which may now be seen in fine condition there.

Bedding Plants in 1878.—We do not remember to have seen bedding plants looking so wretched in the first week of September as they do at present in the London parks. This is, no doubt, owing to the heavy rains.

Acer Schwedleeri.—This is just now very beautiful. It is making its second growth, and the colour of the leaves on the young shoots seems to look richer even than it did in spring.—G. B.

Clematis Pitcheri.—In consequence of a paragraph in a contemporary respecting this plant, we may say that the true species bears really a very bright and pretty red flower. We saw the first plant that flowered in Europe, and were much struck with its brightness and novelty.

Galingale (*Cyperus longus*).—What a beautiful native plant this is! I, however, write to claim a place for it in the garden in wet ground or in water, owing to its elegant and stately habit. It is also in perfection just now when fine plants in flower are diminishing in numbers. There is no ornamental Grass or water-side plant more worthy of a place.—R.

Plumbago capensis.—This fine old plant is now a picture in the conservatory in the Botanic Gardens, Regent's Park, clothing a high pillar, and spreading from it far beneath the narrow of the roof on each side, the numerous weeping shoots as thickly set with fine flowers as Alpine meadow Grass in June. It is the best and easiest to grow of all climbers for pillars in cool houses planted in the floor or bed of the house in ordinary soil.

Oxalis Plumieri.—This *Oxalis*, though little grown, might be cultivated with advantage wherever a warm house exists. Plants of it growing in 5 in. pots in one of the houses at Pine-apple Place have borne a profusion of pretty golden-yellow blossoms all through the summer.

Dwarf Antirrhinums at Tottenham.—A large breadth of seedling Antirrhinums in Mr. Ware's nursery is now a fine sight. The plants themselves are not more than 4 in. or 5 in. high, and their flower-spikes, which are very numerous, are thickly clothed with blossoms ranging in colour from white to deep magenta and crimson. For edgings of shrubby borders, or for pot culture, plants of this dwarf strain are admirably adapted; and they are also well suited for small gardens in towns.

Richardia albo-maculata.—Grown in groups in deep, rich soil, this plant produces a fine effect. It should be planted early in spring, and, if in a light, sunny position, its leaves will become large and finely spotted, and from good roots flowers will be produced freely. After the leaves have died down in autumn the roots should be lifted and stored in sand or dry soil in a shed or cellar. If wanted for pots a few roots may be started when required; they force well and make excellent window plants. Market growers are paying attention to its culture, and it will soon be as plentiful as the green-leaved form.

Tigridia grandiflora at Tooting.—The most brilliant display of colour we have seen for some time may now be found in Mr. Barr's nursery at Tooting, in the shape of six or seven large beds containing upwards of 2000 bulbs of this showy plant. These bulbs were planted about two months ago in rich, well-drained, sandy soil, slightly shaded from sunshine by tall, round-headed *Acacias*. They have been in bloom for several weeks past, and are remarkably strong and healthy, the flower-spikes being from 2 ft. to 3 ft. high, and each bearing from four to seven buds and blossoms. As is well known, a flower of *Tigridia*, when fully expanded, does not last more than twenty-four hours, but fresh buds open daily on the same stalk, and thus a succession of bloom is maintained. Planted in groups, this charming plant would afford a display of flowers for at least six or eight weeks; and, if associated with white Lilies, *Gladioli*, and similar bulbous plants now in bloom, a striking effect would be the result. Although the flowers of this *Tigridia* are useless in a cut state, if gathered when fully expanded, they may, if desired, be cut whilst in bud, and if the stalks be then immersed in

water every flower will open perfectly. Some of the blossoms on the plants at Tooting measure more than 6 in. across, from the point of one petal to that of the other. Some of the petals are 3 in. broad, and of the most brilliant colour imaginable. After flowering has ceased and the plants have died down, it is advisable to lift the bulbs and store them away in dry soil or sand in a shed, as, if left in the ground, they are liable to perish during cold, wet winters, and especially in this the case where the soil is not sandy and light, and thoroughly drained.

Clematis Henryi.—This is the best of the white-flowered Clematises of the lanuginosa type. It is a very free grower and an abundant bloomer, the flowers being of fine form and of satiny whiteness. It grows and flowers luxuriantly, rambling over dead tree stumps in Mr. Parker's nursery, Tooting.

Cattleya Eldorado var.—A plant of a variety of *Cattleya Eldorado* has been in bloom in the Pine-apple Nursery for over six weeks. The flower is of a clear but peculiarly woolly-looking white, with a white lip and an orange throat. It is a lovely variety and very sweet-scented.—S.

Saccolabium Blumei majus.—A fine variety of this beautiful Orchid is now in flower in Messrs. Veitch's nursery at Chelsea. Its flower-spikes are very large, as are also the individual flowers which, singularly enough, first expand at the extremities of the drooping spikes and gradually open upwards.

Begonia Queen of the Whites.—This blooms as freely as any *Begonia* in cultivation. Its flowers are of snowy whiteness, and withstand heavy rains with little or no injury. Being of the Veitchi type, it is a dwarf grower, and will be valuable for planting in small beds or for edging, and its flowers when in a cut state would be useful in floral decorations.

Tropæolum Hunteri.—A remarkably dwarf bedding *Tropæolum* now growing in Messrs. Veitch's nursery bears this name. It is not more than 3 in. or 4 in. high, plant and flowers included, and it forms itself into a compact mound of small green leaves and brilliant scarlet blossoms. It is well adapted for edgings to small beds, or it might almost be used in carpet gardening.

Gardens Open to the Public.—During last week the gardens at Englefield, near Reading, the residence of Mr. R. Benyon, and those at Dogmersfield, the seat of Sir Henry Mildmay, besides those at Heckfield, were thrown open to the public, and were visited by large numbers of persons, all of whom were greatly pleased with the treats thus afforded them. The very slight inconvenience which attaches to the privilege might well encourage many others to go and do likewise.—A. D.

Hardy Flowers at Tottenham.—The best hardy flowers now in bloom in Mr. Ware's nursery are: *Armeria mauritanica*, which is distinct in leaf from any other Thrift, and flowers well during autumn; *Orobanchoides* is very pretty, and groups of established plants of *Lobelia syphilitica*, which have attained a height of 3 ft. or more, are masses of blue. A rose-coloured variety is also in flower. *Senecio pulcher* is very fine just now, the flowers being large and bright in colour. *Campanula autumnalis* is a sheet of blossom, and *C. Van Houttei* bears numerous large drooping blue blossoms. Large specimens of *Helianthus rigidus* are remarkably showy; as are also groups of the new herbaceous *Veronica Hendersonii*. *Sparaxis pulcherrima* is in flower, also *S. atropurpurea*; the latter appears to flower the strongest and best, and it reproduces itself freely from seed, abundance of young plants springing up all round the old stools. *Trollius Fortunei*, one of the best of the Globe flowers, bears very bright golden blossoms. *Tritoma Macowani* is in good flower, also *Spigelia marilandica*; large breadths of seedling *Delphiniums*, *Pentstemons*, and *Antirrhinums* are likewise very attractive.

The district of Brie Comte Robert, the great Rose-growing district near Paris, sent a wreath of several thousand Roses to the ceremony in honour of the memory of M. Thiers in Notre Dame lately.

OUR good friend and correspondent, Mr. Charles Moors, of the Botanic Gardens, Sydney, and brother of Dr. Moore, Glasnevin, has, we learn, just been made vice-president of the Royal Society of New South Wales in the place of the late Rev. W. B. Clarke, the distinguished geologist.

THE PELARGONIUM SOCIETY held its fourth annual meeting the other day at Chiswick, when the usual formal business was transacted. Sundry modifications were made in the prize schedule for 1879, with the view of inducing wider competition amongst the members; and it was determined to award certificates of merit for deserving novelties produced at the shows. The balance sheet presents a satisfactory view of the Society's financial position, showing a balance in hand of £64, after expending £78 in prizes and about £8 in necessary expenses.

NOTES FROM KEW.

Hardy Shrubs.—Conspicuous among shrubs at the present time is the broad-leaved, deciduous Spindle tree (*Eucynms latifolius*); it has fine bold foliage and large, magnificent red fruits; it is a native of Eastern Europe, and is probably the finest of the deciduous kinds. *Escallonia montevidensis* is a handsome shrub with neat, glossy, dark green leaves, and panicles of white flowers. *Hydrangea paniculata* and its variety *grandiflora* are among the finest of autumn-flowering shrubs. Both—although excellent conservatory plants—do remarkably well in the open border, and the blossoms assume a reddish tinge, which is very pleasing. *Cœnorum tricoccum*, from the Mediterranean region, is a pretty plant with tall, bright yellow blossoms and dark green, Box-like leaves. For sunny spots on the rockery and the open border this charming little shrub is well adapted.

Hardy Ornamental Grasses.—The South European *Erianthus strictus* is a noble sort with fine bold leaves—the midribs of which are whitish—and tall flower-stems 6 ft. or more in height; the upright panicles, reddish-brown in colour, contrast well with the glossy leaves. *Sorghum halepense*, another tall-growing and elegant Grass from the south of Europe, attains a height fully equal to that of the last-named, and for spots were bold and striking, yet at the same time graceful, effects are desired, both this and the last-named are most suitable. *Eulalia japonica* is a kind with Reed-like habit and rather dark green leaves. *E. japonica variegata* is very handsomely variegated with white, and *E. japonica zebrina* is a most peculiar variety with somewhat light green leaves, the variegation running across them in a strange way, and not along them as in *E. japonica variegata*. All are natives of Japan, and are valuable decorative plants. *Panicum bulbosum*, from Mexico, is a light and airy Grass, attaining a height of about 5 ft., and *P. virgatum* is a somewhat similar kind about 3 ft. high; these two have narrow, upright leaves, and are very elegant plants. *Gymnothrix japonica*, about 2 ft. high, is a highly ornamental sort with bottle, brush-like spikes about 4 in. or more in length, and narrow, upright foliage, green on the upper surface and glaucous beneath. *Andropogon furcatus*, from North America, grows about 5 ft. high; the forked inflorescence is more curious than beautiful, but the arching leaves on the tall flower-stems are very graceful.

Hardy Herbaceous Plants.—*Kniphofia sarmentosa*, a rare Cape plant, has channelled, glaucous leaves and a stout scape 2 ft. high, bearing numerous, Alos-like blossoms, salmon-coloured tipped with green; these stand out horizontally instead of drooping, as in nearly all the other species. It is also much unlike them in its manner of growth; the long, creeping stems it throws out just below the surface of the ground affording a ready means of propagation. *Peganum Harmala*—a South European member of the Rue family—grows about 3 ft. high, has out leaves and large, whitish flowers. It is more curious than ornamental. *Lythrum flexuosum*, about 1 ft. high, has slender branches clothed with lovely rose-coloured, white-centred blossoms. *Mabalus asper*, a North American perennial, has Grass-like leaves and a long spike of small, purplish flower-heads. *Naja gracilis*, a Mexican Composite, and *N. falcata*, a South American sort, are elegant plants with needle-like leaves more or less clothed with silky hairs, and fine, showy, golden-yellow blossoms; the former attains the height of about 1 ft., the other grows rather taller. *Polygonum Brunonis*, a native of the Himalayas, about 12 in. or 18 in. high, is a very floriferous perennial; the colour of its spikes of flowers varies from light to dark red. A very striking perennial is *Vernonia noveboracensis*, from the United States; it is 7 ft. or 8 ft. high, and the large heads of bright purple flowers are exceedingly handsome. *Lepachya pinnata*, also from the United States, has Rudbeckia-like blossoms, the light yellow ray-florets being much deflexed; it grows about 4 ft. high. *Tagetes lucida*, a charming perennial, 2 ft. high, has bright green, finely-toothed leaves and innumerable small heads of bright yellow blossoms. *Helianthus mollis* and *H. divaricatus*, are two fine kinds of Sunflower; both hail from the United States. The first has softly-hairy, roundish leaves and large yellow, somewhat cup-shaped flower-heads; the second is double the height of *H. mollis*, has longer, narrower leaves and softer yellow flowers. *Scabiosa grammia*, a neat, dwarf-growing South European Scabious, has pretty blue flowers and finely-cut leaves.

Greenhouse Plants.—*Albuca juncifolia*, from the Cape of Good Hope, is a pretty bulbous plant; from the tuft of Rush-like leaves springs a flower-stem bearing an upright panicle of pendulous, greenish-yellow blossoms. *Daphne panyræa*, a Himalayan species, has pretty pure white flowers and is very interesting, as being a kind affording paper fibre. In North-western India *Daphne* paper is in common use for all important documents, and is extremely strong and durable.

Stove Plants.—*Bilbergia pyramidalis* and *B. splendens* are handsome Bromeliads of easy culture; both have bright scarlet bracts and blue-tipped blossoms of nearly the same colour. As a rafter plant, *Adanocalymna nitidum* makes a fine object; it belongs to the Bignonia family, has leaves made up of three-stalked leaflets and large, handsome, yellow Allamanda-like flowers.—†

ORCHIS MACULATA SUPERBA.

ALLOW me to say, in answer to "Salmoniceps" (p. 200), that in 1877 the average length of spike of *Orchis maculata superba* (the Kilmarnock variety), in a bed of seveny-two, was 7 in. Some were 15 in. in height, with over 9 in. (not 10 in.) of inflorescens. This year I was from home, and did not see them at their best; but, as the whole stock was lifted in 1877, we knew that the apikes would not be so fine as they had hitherto been. The bed this hot season would have been the better for a mulching, or what we find best, stones placed between the plants, any mulching used here simply being an encouragement for birds to rummage amongst it. I saw *Orchis latifolia* at Kew in grand condition last July, and as I very much wish to have this species, I would gladly exchange with any of your correspondents three *O. maculata superba* for one *O. latifolia* (flowering bulbs). Comparisons are odious, particularly where plants are concerned, but I can never understand why *O. foliosa* is considered so very superior to *O. maculata superba*. Here the bed and rows of the latter are far above *O. foliosa*, which does not stand up in the stout, firm way in which *O. maculata superba* does. A bed of this last is faultless; no staking is required, and the stones protect the leaves and flowers from being bespattered with rain and the bulbs from the sun. From the first peeping through the ground the extra dark markings of the leaves of the Kilmarnock *Orchis* make the bed an attractive one for weeks before the flowers make their appearance. One word more. Why is this *Orchis* called *maculata superba*? for so it is known in the nurseries here, and some affirm that it is a distinct species. My own impression has always been that it was a selected plant picked up wild. Oddly enough, I asked no questions when, sixteen years ago, I carried off then and there our original clump (some six or seven bulbs) from the little fourth-rate nursery market garden at Kilmarnock. We grow no other *O. maculata*, and from that original clump hundreds have been raised. My practice is always to cut off the inflorescence merely (not a leaf or inch of stalk) when it is past its best. Is this wise? That it is not the practice of other growers I see, and I am always asked why I do it. To strengthen the bulb is my answer; and, unless we want to save seed of any bulb, is it not a good practice? Lilies are an exception; in their case I gather from the recent discussions that it would be "love's labours lost." F. J. HOPE.

Wardie Lodge.

The Limes at Tor Abbey.—The allusion to the Limes at Torquay (p. 170) induces me to state that the Lime has one great defect, viz., that of shedding its foliage very early in the autumn. Some trees in this locality (Colchester) were nearly bare on August 3, partly, perhaps, owing to the drought; but at the present date numbers are leafless, and those which retain their foliage are deplorably rusty. This I consider a very grave objection to the Lime, as nothing gives such a drear and wintry look to the view as leafless trees; and about Tor Abbey they are so numerous, as to give an appearance of winter at least six or eight weeks in advance of its legitimate season. In warm weather, again, I think the Lime suffers more than any other tree from "honey-dew," and such an exudation must surely prove detrimental to the health of the tree. In addition, too, to this defect, the foliage is, from its pleasant taste, I suppose, the favourite food of the cockchafer; so much so, that young Limes planted in the Abbey field here were completely stripped of their foliage last year by these pests.—LONDON STONE.

Fruit at the Paris Exhibition.—Senator Krantz, General Commissioner for the International Exhibition in Paris has issued the following circular:—"Many exhibitors and horticultural societies have expressed a desire that the exhibition of fruits announced to take place on October 1 should be held on September 16 instead; the demands for admission already received for productions of this nature are so numerous that, without doubt, the exhibition of fruits will be a most important one, and will require much space. Consequently, it has been decided that there will be two shows—the first to commence on September 16, and the second one on October 1; each show to last for fifteen days. Fruits from the south and centre of France, as well as those from other southern countries of Europe, can be exhibited during the first fifteen days, while fruits from the North can be brought to the International Exhibition on October 1. By this means satisfaction will be given to all interested in the matter."

THE FLOWER GARDEN.

AN ORNAMENTAL GRASS.

A FEW years ago, as we ("American Agriculturist") were at the establishment of a florist who is noted for the great variety of his collections, and for trying whatever is offered abroad, the proprietor directed attention to a clump of Grass by the road-side, and asked what it was. Upon our informing him that it was *Panicum virgatum*, he uttered an exclamation of surprise, and then informed us that, seeing this Grass highly praised in England, he had that morning ordered a quantity of it; fortunately the letter had not been posted, and he was saved the mortification of finding that he had imported a plant which grew in abundance at his own gate. Many cannot see the beauty of native plants until it is pointed out to them by Europeans, but we will do the florist in question the justice to say

Panicum virgatum.

that the Grass had already attracted his attention, and it was on account of its ornamental character that he was desirous of knowing its name. The genus *Panicum* includes the common Crab Grass, so troublesome as a weed, the coarse Barn-yard Grass, the Old-witch Grass, which in autumn rolls itself into great heaps in the fence corners, and several others, which are far from attractive in appearance. The *Panicum virgatum* is not only the handsomest, but it is the tallest of our northern species. It is found in Southern New England and New York, near the coast, and farther south it is common, especially in poor and sandy localities. It is a perennial, and forms large clumps 3 ft. to 5 ft. high, presenting a mass of lively green foliage, surmounted by numerous flower-panicles. The flowers appear in August, the panicles at first being narrow, but as the seeds ripen, their branches spread, and give the whole plant a highly ornamental appearance, which continues until after hard frosts. In describing Grasses, terms are used with which those who understand the

structure of ordinary flowers are not familiar, so, instead of giving a technical description, we furnish an engraving, which shows the general aspect of the Grass, and will enable it to be recognised. Large clumps may be removed from their native localities to the garden, and flourish fairly, but better plants may be had by subdividing a clump, and planting out small bits of the mass; these will soon increase and form more vigorous plants than where large bunches are transplanted. This Grass may be used with good effect in sub-tropical groups, and in contrast with the *Arundo*s, and other tall-growing Grasses.

HERBACEOUS PLANTS IN 1878.

THOSE who have the good fortune to possess a collection of these will this year have reason to be well satisfied, for, while the tender summer garden plants were slow in furnishing the beds, herbaceous plants flourished amazingly during the cold and continuous wet, and have been in great beauty. This has been especially the case with Phloxes, the various kinds of Spiræas, Delphiniums, &c., and now the showy Anemone japonica and its white variety are just coming into bloom, and will continue to afford masses of their lovely, salver-shaped flowers till destroyed by frost. These Anemones are so valuable as to be deserving a place in any border, however select, but, having once planted them, they should be undisturbed, as any digging about them or other interference with their roots greatly detracts from their strength and vigour. Plants of this character, that stand a long time in the same position, should have the soil well prepared for them previous to planting, which may be done by breaking it up to the depth of 2 ft. or so, and working in at the bottom a heavy dressing of thoroughly decomposed manure. Managed in this way, their roots have room and freedom to ramify, and, as they can find plenty to feed on below, they strike down and are then independent of the weather. Any one who may not happen to have them in this happy position will find that the best thing to do with them now is to mulch them with Cocoa-nut fibre or some other material that will not be objectionable in appearance, and, having done this, then give them an occasional soaking with liquid manure, the effect of which will be to greatly increase the size, quantity, and quality of the flowers. In dry, hungry soils it is as much as they can do to struggle on just at this season; and without help of some kind, when their energies are being so much taxed, red spider generally gets a hold of them and greatly impoverishes the foliage. All the different kinds of herbaceous Phloxes are much benefited by being similarly assisted, as, indeed, are most other plants of a like character, and nothing gives a better return than a little attention bestowed in this way.

One of the finest herbaceous plants with us, and one that has called forth the largest share of admiration is *Bocconia cordata*, a truly handsome and noble-looking plant, having elegantly cut foliage as large as that of the Fig, with the under side of a rich, shining, velvety hue, which, when seen upturned slightly by the wind, has a very striking effect. Being of a very strong growth, it is only fit for the extreme back of a border, or for planting as isolated specimens on lawns, or to grow in large clumps in semi-wild places near water, or in moist situations, for all of which purposes it is just the plant, being of a bold port and character, and therefore well adapted for such uses. Besides having fine foliage, it also bears large panicles of peculiar-looking, brownish-white flowers, that add greatly to its appearance. In spring it sends up vigorous offshoots some distance from the main crown, and if these be taken up carefully, the plant may be increased in that way. It is necessary, however, to go deep down, in order to get some fibrous roots, without which they are apt to fall on being removed. Another strikingly beautiful, although very old-fashioned, plant is the Bergamot (*Monarda didyma*), with its brilliant whorls of dazzling scarlet, Salvia-like flowers, that brighten up any border in which it is grown. This is a very striking perennial, of which there are also other varieties worth growing, such as the purple and the white kind, the latter contrasting well with the first-named. Where cut flowers are in great request, nothing can be more useful than *Catananche bicolor*. Strong plants of it send up hundreds of heads, and the blooms, being of a dry, papery-like character, are exceedingly durable in water, while their light appearance renders

them very suitable for mixing with others. It is a plant, moreover, that will grow in almost any soil or situation, but does best in a deep sandy loam in an open, sunny locality. It may be increased by division just after starting into growth in spring.

In soils and situations where *Alstroemerias* are found to succeed, a more useful or showy class of plants cannot be had, their large, Lily-like heads of bloom being exceedingly useful for cutting, as well as particularly showy and attractive. In order to get them to do well, however, the soil in which they are to be planted should be deeply trenched or stirred, and if at all stiff, or of a wet, retentive nature, it should have plenty of leaf-soil and sand worked into it, the tuberous roots of *Alstroemerias*, when lying dormant in winter, being readily injured by stagnant moisture, which soon brings on decay. To prevent this, the best way is to thoroughly prepare the bed for them at starting by thorough drainage, as it is an operation that pays well for the labour bestowed on it, *Alstroemerias* being plants that when once fairly established will last a lifetime without much care or attention. A narrow, south border along the front of a greenhouse or other similar position is the best situation for them, as there they get the protection of the wall, and from the slight warmth maintained inside are not subjected so much to the action of frost as they would be elsewhere. Being naturally deep-rooting plants, the drainage should be placed at least 2 ft. beneath the surface, and have some rough material, such as half-decomposed manure or fresh-cut turf, laid on the top to insure the interstices being kept free and open. This done, the filling in and planting may be carried out either now or at any time between this and May; but the best season is after winter is over, as then there is no risk from frost or wet, and the plants soon start away and become established. A good way in which to manage *Alstroemerias* is to sow the seed where they are to remain, as of all herbaceous subjects they are the most difficult to transplant, an operation that can only be successfully performed by trenching the tubers out just as growth commences, and if they are then carefully handled, so as not to bruise or break them, most of the more fleshy portions will be found to grow. In the case of seed sowing, drills of about 1 in. deep should be drawn, in rows 1 ft. or so apart, in which, when the plants come up, they should be allowed the same distance asunder. They will soon furnish the bed or border, and make a grand display. To protect them from frost during severe weather, a slight mulching of some kind is necessary, and nothing answers the purpose better than half-decomposed leaf-soil, which is a capital non-conductor, and as neat-looking as anything that can be used.

Another plant I would specially recommend for the herbaceous border is *Triteleia laxa*, a most beautiful plant, resembling, when in bloom, an *Agapanthus* in miniature, but with flowers of a deeper, richer shade, being of a fine Tyrian purple. The present is a good time to get bulbs of this plant, which should be planted in deep loamy soil, and have some sand scattered on and around them to preserve them from excess of wet while lying dormant during winter. S. D.

PENTSTEMONS AND THEIR CULTURE.

AMONGST hardy herbaceous plants suitable for culture in beds or borders few surpass these useful autumn-flowering plants. Zonal *Pelargoniums* suffer from heavy rains, while *Pentstemons* remain unimpaired. I saw a long bed of them in the Stanstead Park Nurseries a few weeks ago blooming beautifully, and looking as if they would continue in good condition until the dark days of November set in. Their great value lies in the persistent character of the flowers, which defy not only rain, but wind longer than most flowers. The flower-spikes also look well in a cut state, and are very useful indoors. At many of the autumn provincial exhibitions prizes are offered for cut spikes of *Pentstemons*, and useful subjects they prove for making up a stand of hardy herbaceous plants. Grown in pots they also make a very effective display. The varieties at present in cultivation do not seem to be hybrids between different species, but merely varieties of one species, though what that species is I am unable to say. It is in the

colour of the flowers that the greatest variation occurs. Some of the varieties, such as *Lady Countess Lindsay*, have white flowers; others are purple with variously-coloured throats, as in the case of *Midhat Pacha*, *Mr. Fenwick*, and *Mrs. C. Patrick*; there are scarlets, too, of various intensity, as, for example, *Horace Vernet*, *Desilles*, &c., the remaining colours being red, crimson, and rose. Their throats are usually of a pale character, marked with darker lines. Many good and distinct varieties named are annually sent from France. British raisers of *Pentstemons* are Messrs. Downie & Laird, of Edinburgh, and Messrs. Laing & Co., of Forest Hill.

The propagation of the *Pentstemon* is by no means difficult, and the same may be said with respect to its culture. The best plan is to sow the seeds, as soon as they can be obtained, in fine soil in a cold frame; the produce of a single 6-in. pot or pan will be sufficient for an ordinary garden. When the seedlings are large enough to handle, they should be pricked out into shallow boxes or pans, and afterwards planted in the beds, where they are to flower. The produce of seed sown in August or September will flower strongly the following season. The named varieties are propagated by means of cuttings taken from the plants in September, or in the north about the end of August, when they will strike root as easily as *Verbenas* or *Calceolarias*. The small succulent growths from near the base of the plants make the best cuttings. Select those that have no flower-buds on them, and cut the shoot clean across just under a pair of leaves with a sharp knife; the leaves should then be cut off close to the stem, and the cutting is ready for insertion. I use small pots, in each of which I place one variety. The pots should be set in close frames or under hand-lights, where the cuttings will soon form roots if the pots be kept well supplied with water. The glass must be shaded until the cuttings get established. When rooted they may be planted out into the beds or borders at once. What they suffer most from, in the neighbourhood of London especially, is wet in winter, combined with fog, which is so prevalent from November onwards. The best plan is to pot a plant or two of each of the choice sorts, and keep them in a cold frame. They will not suffer under such conditions, as the leaves and roots can be kept dry at a time when wet is injurious to them.

Whether the plants are grown in pots or planted out, they require a rich soil. I always trench the ground and manure it highly, using good rotten cow or stable manure, or both mixed together if such can be obtained. A layer of manure is placed about 2 ft. below the surface, and another layer about 1 ft., and besides this some rich soil is applied to the surface of the ground, in which the *Pentstemons* are planted. They should stand 15 in. apart. If they are grown in pots, let them be 9 in. in diameter, and one well-grown plant will fill that size full of roots by the end of the season. The method to be pursued is this: the plants that were wintered in small pots should be shifted early in March or about the end of February into 5-in. pots; when these are well filled with roots, shift into 7-in. pots, and then into the flowering pots. The potting material should consist of good fibrous loam four parts, rotten manure one part, and leaf-mould one part. All through the period of growth they will do best out-of-doors, and when the pots are filled with roots, and the flower-spikes are visible, liquid manure should be applied. The spikes, when sufficiently grown, must be supported by means of neat sticks, as they are easily broken off at their junction with the main stem. J. DOUGLAS.

LILY CULTURE.

As I am fairly puzzled, may I be permitted to draw Mr. Wilson's attention once more to his friend's letter (p. 200). Mrs. Newall, "an old friend," writes to him about his Lilies and asks advice. Mr. Wilson says: "My advice was short—'Leave well alone.'" Mrs. Newall had written very plainly (as the reader will see), showing that her Lilies were not so well as might have been expected. He was evidently anxious about them, as it was "sixteen years since the roots were first put into the soil, and they had never been lifted since." Mrs. Newall had done everything that one could do for them, save transplanting. She says: "I protected my Lilies the first few years with straw, bark, tan, and shoddy, and in the spring with glass shades; now I lay oinders and tan over the roots during the latter part of the winter,

and use no protection in spring, but I water and manure freely." Notwithstanding all this unprecedented labour and care she says: "The flowers may be a little smaller, and the plants considerably dwarfed, but I consider that they are acclimatised." The fact is, they are dwindling away for want of proper cultivation, being clubbed together, and living on one another, instead of being lifted, separated, and transplanted into fresh and better soil. As to their being acclimatised, Lilies are not perennials, and are, therefore, as much acclimatised in three years as they possibly could be in sixteen. Mrs. Newall further says: "This hot summer, with its drought, has done my plants no good, and, as the subsoil was clay, it was difficult to keep them from scorching." This is another proof of want of proper cultivation. She says: "I take as much soil off as I can every year, and heap fresh soil on them." Had she lifted and transplanted them now and then, giving them a fresh supply of rich, deep, alluvial loam, with a portion of peat or leaf-mould—spending half the time and labour underground that she has been doing above ground—she would not now have to complain of small flowers, dwarfier plants, or scorching. Mrs. Newall evidently feels that she is in a dilemma, for, in her short letter, she appeals three times for advice. She first says: "Would this have been the case had I moved them?" then: "Would you, in my case, move them?" and, lastly: "If you think it better I will remove them this autumn." To all these appeals, and without having seen the plants, Mr. Wilson returns the "short" and ambiguous answer: "Leave well alone." But they are not well, as the reader will see by Mrs. Newall's own showing. Had I been asked I would have said: By all means transplant them as soon as the bloom is over, or next year you will have even less to show. Or, better still, lift one half and replant them as I have directed, and next year you will be able to judge, by comparison, whether "leaving well alone" is good advice or not. As Lilies in general, and especially *L. auratum* and *speciosum*, mentioned by Mrs. Newall, are under artificial cultivation in this country, it will never do to put them in the ground, even in the south of England, and leave them alone to take care of themselves. In their native habitats Nature provides for them all they can possibly require; but here they must be attended to "with intelligent and loving care." Mrs. Newall, doubtless, by a very unusual mode of mulching, managed to keep her Lilies, or most of them, alive; but as the flowers are getting perceptibly smaller, and the plants considerably dwarfed, another and a better method of cultivation is absolutely required. I quite agree with Mr. Wilson that on this subject there are too many theories floating about. On the other hand, I have known that, when practical facts are placed too close to the eyes, they are apt to be overlooked and treated as mere theories, especially if they interfere with preconceived notions.

DUNEDIN.

— Thanking you for the prominent place you gave to the letter on the cultivation of *L. speciosum*, will you allow me to say that my correspondent, the clever Lily grower, is Mrs. Henry Newall, of Here Hill, Littleborough, near Rochdale. I have lately discovered what to me is a new virtue in Lilies. When my family are at the seaside, I am in the habit of bringing down tins of flowers, but, owing to the sea air, or gas in the room, or from some other cause, their life is a very short one. Roses and Japanese Anemones flag very much after the second day, but *L. speciosum rubrum*, brought down a week ago, is still beautiful. The best way to carry these Lilies so as not to lose the beauty of the stamens and pollen is, to cut the buds a little time before they open; they then take little room and open in their full beauty after their arrival.—GEORGE F. WILSON, *Heatherbank, Weybridge Heath.*

VIOLAS.

A FEW years ago there were not many Violas known, and the few that were then grown were never used for the purposes for which we now so extensively employ them—viz., for summer bedding. *V. cornuta*, blue and white, was amongst the first that were soon improved upon. *Cornuta Perfection* was a great advance, and is still a really good variety, possessing, as it does, good habit, sound constitution, pleasing shade of colour, and free-blooming properties. We have for several years taken a deep interest in the culture of Violas, and also in hybridising them, and no plant has given us so much real satisfaction for our labour. In the spring of 1872 we had some difficulty in getting up sufficient numbers of bedding plants with the means placed at our disposal, considering the amount required, and very insufficient material and accommodation with which to do it. The Viola family seemed to open up a possible way. A start was made, and we succeeded after a year or two in getting up stock sufficient to produce a creditable display. We likewise commenced to try to improve the varieties then existing, and also, if possible, to procure new colours. In this we were partially successful, and we are still continuing to try and get some with better habits and constitution. Before mentioning our system of propagation, &c., we may be permitted to say, that we are speaking exclusively of varieties that we

consider suitable for summer bedding—viz., those that will keep up a continuous show of bloom throughout those months that we generally term our gay season from April to September. The varieties named below are such as we have thoroughly tested here, or have seen doing well elsewhere. The latter end of September and throughout October we find the best time for getting good cuttings, which in favourable localities may be put in along the bottoms of walls, or in any well-sheltered situation. Here we put them in cold frames, which in severe weather are covered over with old sashes—the remains of old Vineries. The frames are prepared by putting a few inches of well-rotted manure into them, such as that from spent hotbeds, then 2 in. of sand and leaf-mould in equal quantities. In this we have always found them to do well, and when required in spring to lift with good balls. We generally seize all favourable opportunities in March or the early part of April to get them all planted out. The beds and borders to be occupied by them get, if possible, a liberal dressing of well-decayed, old hotbed manure, pointing it in about 3 in. deep, light soils getting more than stronger loams. We have mostly worked with young plants, preferring them because they make a more even bloom, and last all the season, and the blooms are much finer in quality and colour. Where the object is to have an early display, old plants divided in autumn, or cuttings struck in July and planted in October, will be found the best. The following are a few good kinds, viz.: LIGHT BLUE—Perfection, Lottie. DARK BLUE—Tory, Sir W. Scott. STRAW OR PALE YELLOW—Grievi, Clara. YELLOW OR GOLDEN—Soverign, Dickson's Golden Gem, Golden Perpetual. DARK PURPLE—Lady Diana, Eglintoniana, Lady Sophia. LIGHT REDDISH PURPLE—Ruby King. WHITE—Lady Gertrude, Purity, Mrs. Pease. WHITISH MAUVE—Modesty.—JOHN GRAY, *Eglinton Castle*, in "Gardener."

NOTES AND QUESTIONS ON THE FLOWER GARDEN:

Mentha Pulegium gibraltaria.—Some of the best effects in bedding have been the result of using this lovely green plant as a carpet. Whether underneath stately forms of vegetation, or as a companion to bright-leaved Alternantheras, it is most satisfactory.—J. GROOM.

Lobelia fulgens in Pots.—This, as a pot plant, may be well flowered in London. I purchased some plants in May in 2½-in. pots. Instead of transplanting into larger pots, as I had done before when I failed to flower them, I placed the 2½-in. pots in 5-in. ones, and packed the space between with Cocoa-nut fibre. The experiment succeeded well, and every plant so treated has flowered. Many plants do well when treated in the same manner. Little root room, if only the roots can be kept moist and protected from extreme heat and cold, seems to be favourable to the formation of flowers.—L. S. B.

Arundo mauritanica.—This is a fine Grass—one might describe it as a stately one were it not for its great relation *A. Donax*. *A. mauritanica* is a native of the southern shores of the Mediterranean, hardy in the neighbourhood of Paris, and reaching a height of about 4 ft.—V.

Ionopsidium acule.—If the seeds of this pretty dwarf annual be sown in April or May, and the plants be pricked out-of-doors into beds, borders, or on rockwork, they will form a close carpet of pale lavender flowers, not unlike those of the much esteemed *Houstonia cærolea*, all through the summer.—S.

Epilobium hirsutum variegatum.—This makes an excellent edging plant for shrubberies, or if kept pinched in it would make a good plant for ribbon or pattern gardening. In open, sunny situations its leaves assume a bright cream colour, but in half-shady places the plants grow more loosely and the colour is not nearly so good. It is used extensively in some of the London parks this year and with good effect.—S.

Erythræa Muhlenbergi.—A finer annual than this would be difficult to find. It is neat in habit and grows about 8 in. high, producing many slender branches. It is very floriferous, the blossoms measuring 3½ in. across, with five spreading divisions of a deep pink colour and a greenish-white star in the centre. To grow it well, seeds should be sown now and grown under liberal treatment till the spring; they will then flower much earlier and finer than spring-sown plants.—W.

Verbena venosa Sown in Autumn.—Since the ordinary varieties of *Verbena* have almost disappeared from flower gardens the peculiar colour afforded by this sort (a bluish-violet) has been more than ever valuable, not only for furnishing whole beds with that particular shade, but more especially from the good effect produced by it in mixed beds, as, for instance, associated with variegated-leaved *Pelargoniums*, such as *P. Manglesi*, &c. Its wiry, upright habit of growth, not exceeding 18 in. in height, renders it a suitable

plant for many combinations. It will survive the winter out-of-doors in dry, warm soils, and if lifted and placed in gentle heat abundance of cuttings may be procured in spring that will strike freely. If, however, a large quantity of good, hardy, bushy plants be required, the best plan is to procure seed of it and sow it in shallow boxes in autumn, and, by keeping the seedlings in a cool house or pit during winter, dwarf, bushy plants in abundance may be secured by ordinary planting time in May.—J. GROOM.

Physostegia imbricata.—Bunches of this handsome perennial formed a conspicuous feature on a stand of hardy flowers staged at a recent floral exhibition at Reading. The flowers resemble at first sight those of a Heath; they are of a pale, rosy-purple colour, the tips being of a paler hue, almost white; they are borne on spikes, which attain a great size on well-established plants. A strong plant, if grown in a rich, sandy loam, would grow to a height of 5 ft. or 6 ft., and it should, therefore, be planted at the back of the mixed border.—D.

Saxifraga leucanthemifolia.—Walking one morning last May near the village of Pierfite, in the Bas Pyrenees, I came to the base of some precipitous rocks considerably overhanging my path, forming quite a cave, the shady side of which was covered with a Saxifrage in full flower growing in the narrow crevices of the rocks. Upon examining the plant I discovered it to be the rare *S. leucanthemifolia* of Lapeyrouse, and I believe, from enquiries since made, that it is the only locality in the Pyrenees in which this plant is found. It is totally different from any other Saxifrage, coming nearest to *S. rotundifolia* than any other I know of. The name is a familiar one in catalogues, but I believe the true plant is not in cultivation. It is a handsome species, the branching panicle assuming a pyramidal outline. The flowers are white, with orange stamens, and are produced in great abundance. Some of the plants were 1 ft. in height, growing apparently on the bare surface of the rocks. I collected a few and brought them home, and they are now flowering a second time.—P.

Bouquet or Pomponé Dahlias.—During these last few years this section of the Dahlia family has become very popular; the blooms being small and compact, resembling a Ranunculus more than those of a Dahlia, makes them much more serviceable in outdoor decoration than those of ordinary border Dahlias. I have also found them most effective as a background in mixed borders or for large beds in shrubby grounds. The roots, left in the open ground all winter, are quite safe if a good coating of coal-ashes be put over them when the tops are cut down. If lifted for purposes of propagation they may be safely stored in any cool shed secure from frost, and, if covered with any partially dry material, such as old tan, Cocoa-nut fibre, or leaf-mould, they will start more strongly into growth than if over-dried by exposure to the atmosphere. At this season the flowers are especially useful in floral decorations of a large character, where delicate or fragile blossoms are not nearly so effective; and the Dahlia, moreover, will last in a perfectly fresh condition for some length of time, even without inserting its stalks in water—a great gain where, as in the case of harvest festivals, school treats, &c., the decorations have to be extemporised without having recourse to the best preservatives. I have found the following varieties all that could be desired, viz.: Angel of Peace, Bessie, Bijou, Crimson Beauty, Fireball, floribunda, Glow-worm, Golden Canary, Jubilee, Little Bobby, Little Darling, Little Dear, Little Helen, Little Nigger, Little Snowball, Pearl of Lilliput, Prince of Wales, Pure Love, Sacramento, Seppho, Seraph, Sunshine, Tomtit, and Voltaire.—J. GROOM.

Phloxes in Lines and Masses.—Those who have cultivated the Phlox in the shape of single plants in mixed borders, and who have not had an opportunity of seeing them planted in masses of distinct colours or in long lines of one variety, can scarcely conceive how exceedingly effective they are when thus planted. Pelargoniums and other tender plants, so commonly met with in beds and ribbon borders, have but a poor effect when compared with a ribbon border or beds of some of the fine Phloxes now in cultivation. If half the labour were bestowed on our brilliant autumnal Phloxes that is bestowed on some of the tender plants of the day, our gardens would have a much more massive and brilliant effect. Of course reference is now made to the autumnal varieties of Phloxes, which come into bloom in August and last till October. Let any one who wants a hardy and brilliant ribbon border take—1, Phlox Lothair, salmon, shaded with violet; 2, P. Mons. Henricque, brilliant reddish-crimson; 3, P. Venus, pure white; 4, P. Mons. Guldenschng, rosy-violet; 5, P. Spenceri, dark rosy-lilac. These give five lines sufficient for a 10-ft. border, and ranging in height from Spenceri 15 in. to Lothair 4 ft. An excellent front edging for this border is the variegated Periwinkle. In order to grow these thoroughly well, and so as to insure a lengthened period of blooming, the ground should be deeply trenched and well enriched with good manure from the farmyard, and not more than six heads of bloom should be allowed to each stool. Thus treated, when planted in long lines, it is difficult to convey an impression of these and similar varieties.—“The Gardener.”

THE OLD YELLOW PROVENCE ROSE (R. SULPHUREA) AND ROSE CULTURE IN PORTUGAL.

MR. D. T. FISH asks (p. 75) for information regarding the culture of this fine old Rose. I have not tried it on the Brier or the Manetti, because it grows like a Bramble on its own roots in this country; in fact, the only difficulty is to keep it within bounds, as it sends up suckers in profusion. It certainly is very capricious as regards flowering, but the perfect flowers, of which we get good specimens every season, are, as Mr. Fish says, remarkably beautiful. If Mr. Fish should meet with any difficulty in procuring plants on their own roots, I shall be happy to send him a bundle of them next November, and as to culture, I should say, trench and manure the ground (medium soil, that is not too heavy) well, and plant in some snug, sheltered, warm corner. Avoid pruning; if there be too many shoots, cut out some of them altogether, and grub up the suckers, unless they are wanted to fill up vacant spaces. Do not shade from the sun, but mulch and let them have water during hot summer weather. It is quite useless to expect this Rose to flourish anywhere near towns; it requires pure country air. *A propos* of Roses on their own roots, from what I read in THE GARDEN, and in the new editions of the various books on Rose culture, it strikes me a tide is setting in in favour of Roses on their own roots. I have long since come to the conclusion that they are the best for our climate. One has to wait longer for a return of fine flowers, but once the plant is established it lasts for ever, so to say, and its aspect is more natural, and therefore preferable to that of worked specimens. All, or almost all, Roses grow from cuttings planted in the open air in November, and they are fit to plant out the next autumn. Even the common Moss will strike root in this way, but with some difficulty. Still, budding must be resorted to; we are all in such a hurry to see what new Roses are like. The question is, which is the best stock? Briers do not do at all in this climate. Our scorching summer sun plays the “two in whist” (as Canon Hole says in his charming book on Roses) with them. The Manetti does pretty well budded so low down that, without burying the roots too much, you can keep the budded part 2 in. below the surface. They then are in appearance on their own roots, and I believe very often actually become so. However, we have a wild Rose in the north of this country which quite satisfies our wants, and has completely superseded both Briar and Manetti. It throws up no suckers, and the buds on the stock are less apt to shoot forth than those on the Manetti. The growth of the budded Rose on this stock is marvellously strong and healthy, and the stock itself increases in proportion. This stock was discovered and introduced by M. Loureiro, an enterprising nurseryman of Oporto, already well known in France and Belgium as the raiser of many fine seedling Camellias. I cannot say to what species of Rose it belongs, but if Mr. Fish or any of your readers would like to judge for themselves, I can place at their disposal a limited number of young plants. They merely require being planted in some out-of-the-way corner; when established prune severely, and they will produce long, stout shoots, which must be made into cuttings about 12 in. long and planted in the autumn. They will be ready to be budded the following summer. We work them just as one would a Brier—that is, cut off all the new shoots with the exception of one or two (I prefer one) of the best, and bud them.

M. Loureiro finds that *R. sulphurea* succeeds very well on this stock. For climbing Roses we have the Banksian, the best stock possible for the purpose, particularly if worked on Rivers' plau—first Gloire de Dijon on the Banksian, and then the kind you want on Gloire de Dijon. The result with such Roses as Mâchéal Niel, Belle de Bordeaux, Cheshunt Hybrid, Rêve d'Or, M^{me}. Berard, and such like is admirable. C. T.

Lisbon.

Button-hole Roses.—I notice (p. 175) that “A. D.” has a word of praise for Catherine Mermet. It deserves all he says of it; but my two favourite button-hole Roses for the autumn are Celine Forestier, soft primrose, and Boule de Neige, pure white, occasionally slightly tinged with pink on the outside of the petals. These two are perfect in size, form, colour, fragrance, and staying powers, exceeding in the latter valuable qualities almost any or all other Roses.—D. T. FISH.

THE INDOOR GARDEN.

HYACINTH GLASSES.

MESSRS. STEVENS & WILLIAMS, Brierley Hill, Staffordshire, send us specimens of their new Hyacinth and flower glasses, which are fairly well adapted for holding flowers when not in use for Hyacinths.

They are engraved with Fern leaves. We are not sure that it would not in such cases be better not to bring ordinary glass-engraving in competition with the living flowers. In any case it would be well to

offer these glasses plain as well as engraved. We ourselves should greatly prefer them plain. It is much to be desired that some spirited firm would make and introduce to the gardening trade generally some of the good forms of vases in green, blue, and other colours

for holding cut flowers. These may be obtained of some of the good "artistic" house decorators, but at prohibitive prices.

AURICULAS IN SEPTEMBER.

So far, the season has been highly favourable to a fine summer growth, and late-potted plants are making a robust growth, and strong-growing varieties, like C. J. Perry, Robert Trail, Lycurgus, Lord Palmerston, Mrs. Smith, Black Prince, Lord of Lorne, Maclean's Unique, Richard Headly, Imperator, White Rival, Colonel Champneys, Duke of Cambridge, and Mrs. Sturrock, have, what has been termed, a "cabbagey" appearance so vigorous do they look. The dull, cool, moist weather suits Auriculas properly housed in a frame and protected from heavy rains. Very little water has to be given, but green fly has to be kept under, decaying foliage removed, and any other insect pests got rid of summarily. A small green caterpillar is troublesome this season, and if it gets into a plant it soon shows traces of rare predatory activity. I suppose there is such a plethora of insect food this summer, that the birds cannot feast on them fast enough, that is, supposing they are the insect feeders some have represented them to be. Occasional stirrings of the surface are also very necessary to keep the surface soil open and prevent sourness. When the weather is sunny and drying, I let a gentle shower fall on the plants, but nothing in the character of heavy rain. For lack of frame accommodation, I was obliged to place a few plants each of Robert Trail, Mrs. Smith, and General Neill in the open air on a cool border without any protection from heavy rains, and, notwithstanding the excess of moisture, they have made a very fine growth. Some strong seedlings of fair character, similarly treated, have also grown famously. The pots are standing on a well-drained ash bottom and the water quickly passes away. By the middle and end of September the fine summer foliage of the plants will begin to decay. This is simply the operation of a natural law, and the least experienced cultivator need not be alarmed about it; and if the autumn keeps fine and open, the decay of the summer foliage will be succeeded by a fine, healthy, but less gross leafage. As Auriculas are generally pretty active during September, it is necessary a due share of water be regularly supplied while drying influences are about; the needful supply of water depends on the state of the weather and the condition of the plants. Weakly plants should be watered with great care and only when absolutely necessary. The pots in which the plants are growing should be kept clean, and, as before recommended, the surface soil should be kept slightly stirred. The dull close weather is in favour of green fly abounding. An occasional fumigation with Tobacco smoke is the best remedy, and if it be not convenient to do this, it is well to brush the leaves with a soft camel's-hair brush. In stirring the surface soil, the operator should be careful not to lay bare any of the roots. Some of the Auriculas throw up their roots to the surface almost before they make any lateral or downward root development; and all the more care is necessary that they be not disturbed. A little soil should be added in the case of roots so displaying themselves. In all probability the strong growth now being made will excite the plants to flower. It is not uncommon for Auriculas to throw up autumn trusses, and there is reason to think that (for the reason above stated) they will be more plentiful than usual this season. Some sorts have already commenced to do this, and, if any such plants are wanted for exhibition next spring, it will be best to allow the stem to rise out of the heart, and then carefully rub off the buds, leaving the stem uninjured; by this treatment the flow of vigour in this direction will be arrested, the stem will very slowly dry off, and die away without injury to the plants; but it will sometimes happen, if the stem be pinched off near to the bottom, it will rot down to the leaves and peril the safety of the plant. It is a good plan to sow Auricula seed as soon as it is ripe. Last spring was a bad seed season, but a few fertilised pods swelled here and there, and as soon as the seed was ready it was sown. Several seeds have already germinated, and more will follow in succession for a few months to come. By sowing as soon as the seed is ripe a season is almost gained. It is best to sow thinly and leave the plants in the seed pots till early spring, and then prick them out

round the sides of smaller pots to encourage them to grow into size. By the autumn the foremost plants will in many cases be strong enough to blossom, and show something of their probable character.

A 6-in. pot is well adapted for *Auricula* seed. The pots should be nearly one-third filled with crocks, and over these a little coarse soil should be laid before the fine soil is added. A good seed soil is made up of finely-sifted loam, leaf-mould, and some finely-powdered charcoal. This should be put into the pots till within $\frac{3}{4}$ in. of the rim, then pressed down gently till level, and the seed thinly spread over it; then the seed should be pressed into the soil, a piece of glass placed over each pot, and then put away in a cool, shady part of the *Auricula* house or frame, shading from the sun as requisite. If the soil be used a little moist, no water will be required for a few days, but it is best to keep the soil in the seed pots fairly damp. If it gets dry, it is a good plan to place the pots in water up to the level of the soil, and allow it to rise in the soil, and gradually moisten the whole. There is a great amount of interest attaching to the raising of seedling *Auriculas*, especially when the seed is saved from choice flowers, but there are cases in which fine varieties have originated as chance seedlings. D.

MUSSÆNDA FRONDOSA.

THIS singular and beautiful plant belongs to a somewhat restricted family of evergreen shrubs, mostly from hot countries in both the Old and New World. This species is much the handsomest of the genus, and is not like any other plant in cultivation. It produces bright yellow flowers, borne in bunches in form not unlike the well-known *Pentas carnea*, but individually smaller. Yet it is not in the flowers alone in which its beauty consists, but in the large floral bracts or pair of coloured leaves, pure white, that are produced immediately at the base of each bunch of flowers. In size and shape they are similar to the ordinary leaves borne by the plant, but are not persistent, longer than the flowers, which will last three weeks in perfection. The plant is easily managed, and does not require a great deal of room, a large specimen rarely attaining more than from 2 ft. to 2½ ft. in diameter. Its disposition to bloom is remarkably free, as even small examples, consisting of a shoot or two, will flower. The singular combination in colour produced by the pale green of the leaves and the white bracts which, when found on a well-grown example, cover half the surface, and the bright yellow flowers rising immediately above them is at once beautiful and wholly distinct from everything else—so much so as to create surprise that the plant is not more generally cultivated, either by those whose heated glass accommodation is limited, for which the little room it occupies adapts it, or by those who have large stoves or warm conservatories, where a few moderate-sized examples dotted about offer a perfect contrast to the other occupants. It is as readily struck as a *Pelargonium*; cuttings made of the green, half-ripened shoots taken off with about three joints, removing the bottom pair of leaves, will root in a few weeks inserted singly in small pots, drained and filled with a mixture of half-sifted loam, to which an equal quantity of sand has been added, with a thin layer of sand on the surface, covered with a bell-glass, kept moist and slightly shaded, with or without bottom-heat, in a night temperature of 65° or 70°, and a proportionate rise in the day. This heat there will be no difficulty in maintaining about the time (May), when cuttings in the condition above described will be obtainable. As soon as they are found to have formed roots give air, gradually dispensing with the glasses, so as to inure the plants to the air of the house. When they have made two pairs more leaves pinch out the points of the shoots, to induce the lower eyes to break, for although the plant is naturally inclined to assume a bushy form, yet to produce specimens that will branch out and hide the surface of the pots (in which way this and subjects of similar habit always look the best), it is necessary to stop the young plants in their first stages. As soon as they have again fairly broken into growth they will have made roots enough to require a shift; pots 2 in. or 3 in. larger will be big enough; drain sufficiently. It will succeed in either peat or loam, but I prefer the latter, as in it the growth is

more robust, affording an ability when in flower during the summer to bear removal to a lower temperature than where it has been grown, a condition that I have invariably found existing to a greater extent in loam-grown, heat-requiring plants than in such as are cultivated in peat. The loam should be of a good ordinary description, containing a fair amount of good turfy matter, not broken too fine, and with enough sand added to admit of the water passing freely through it. Pot moderately firm, and keep the plants where they will be exposed to the full light with a slight shade in the middle of the day.

This plant, being found in the hot parts of India, requires a brisk heat to grow it freely. Admit a moderate quantity of air during the middle of the day, shutting up so as to enclose a considerable amount of sun-heat, syringing overhead, and at the same time maintaining a genial atmosphere. It must never be allowed to want for water in the soil, for, although not a delicate-rooted subject, and the old wood assuming a hard condition, yet the young shoots are always comparatively soft, and if allowed to flag through an insufficiency of moisture, it has a stunting effect, which limits the growth and in the same proportion the ability to flower. As growth progresses, tie up the shoots to neat sticks, inserted just within the rims of the pots, again pinching out the points about the end of July; then shift into pots 3 in. larger, after which time continue to treat as before until the beginning of September, when dispense with the shading, and by the end of the month cease syringing, giving more air, so as to gradually bring about a state of rest, to still further induce which reduce the temperature; keep through the winter about 60° in the night, and a little more in the day, with just as much water as will maintain the soil in a semi-moist state. By the end of February, raise the temperature 5° day and night, and, as soon as growth has fairly commenced, shift into pots 2 in. larger, using enough sticks to keep the shoots evenly balanced, and again commence syringing overhead. The points must not now be pinched out, as it would delay the flowering. Give proportionately more heat as the days lengthen, with a little shade when the sun is powerful. By the end of April the plants will show bloom, which will be indicated by the appearance of the coloured bracts, which will go on developing until the flowers expand. If kept in the stove they will bloom a second time towards the close of summer; consequently, I should not advise their being moved at this first flowering to cooler quarters. When done blooming do not shorten the shoots, but simply pick off the decayed bracts and flowers, at the same time giving them a good syringing. They will now bear as much heat as that given to the generality of stove plants, and will recommence growth immediately; when two or three pairs of leaves have been made, they will again show flower, which may be expected to arrive at maturity by the latter end of summer, at which time they can be moved to the warmest part of the conservatory; but whilst here, like most other stove subjects, they should not be set where they will be under the influence of external air admitted directly in contact with them. When they are in cooler quarters, give no mere water than is sufficient to keep them from flagging. After the blooming is over, shorten the shoots back to about one-half the length that has been made during the season, and at once return the plants to the stove, where they will again break into growth, although not much progress will be made till spring. Winter as before, and give 2-in. or 3-in. shifts as soon as the plants are fairly in motion in spring. Treat as in the previous season. After the first flowering is over they will be considerably benefited by the application of manure water once a week. Let the autumn and winter management be similar to that previously advised, and when the time for potting in spring comes shake out a portion of the old soil, returning the plants to the same pots, which will be large enough for all ordinary purposes, replacing the old soil with new. As soon as the roots have got fairly hold of the new material, supply manure water regularly through the growing season, by which means the plants may be kept for years in a healthy condition, with simply replacing a portion of the old soil by new each spring.

Most of the insects which attack stove plants will live on this *Mussænda*, although they do not appear so partial to it as some things. The leaves are somewhat thin in texture, and are soon injured by the presence of red spider, but if in the

syringing advised the water is got well to the undersides of the leaves, these will never gain a footing. Thrips and green fly are thus in like manner held in check, but should they make their appearance, fumigate or dip in Tobacco water. Brown scale and mealy bug, where present, must, during the growing season, be removed by brushing and sponging, and when the plants are cut in after the second flowering they should be dipped in, or well syringed with, a moderately strong solution of insecticide.

T. BAINES.

NOTES AND QUESTIONS ON THE INDOOR GARDEN.

Two Good Carnations.—In a large collection of Tree Carnations grown in pots, in Messrs. Veitch's nursery at Chelsea, we noted two which ought to occupy a prominent place in every collection. One named Mons. Baldwin is a tall grower, and bears very large, well-formed, bright crimson flowers, which last on the plants in good condition for two or three weeks. Garibaldi is the name of the other; it is a dwarfier grower, but an equally abundant bloomer, its flowers being, 3 in. across, and of a bright scarlet.—S.

Harrison's Musk as a Window Plant.—Young plants of this in 3-in. pots, placed in a window early in spring, will continue flowering continually, if well supplied with water, until midsummer. They should then be potted into 6-in. pots, and the shoots should be carefully pegged down over the new soil; they will then go on growing and flowering until late in autumn. They require plenty of moisture at the root at all times.—J. GROOM.

— We have employed Harrison's new Musk successfully this season for decorative purposes. Early in the spring months, and even up to midsummer, we found it invaluable in pots for conservatory and house decoration. The most useful sized pot in which to grow it is a 5-in. one, using rich soil and good drainage. It requires a liberal supply of water, and occasional waterings with liquid manure are found to be of benefit to it. I have also used it largely for both beds and borders, and when planted in masses it is most satisfactory, being compact in habit and most profuse as regards bloom. Our beds of it were planted in April, and ever since the early part of May they have been a complete mass of flower. Heavy rains impair their beauty for a day or two, but they soon recover. This Musk flourishes best in a light, rich, moist soil, and if dry weather sets in occasional waterings will be necessary.—R. GREENFIELD, *The Priory, Warwick.*

London-grown Tuberoses.—Like "A.C." (p.210), I experienced some difficulty in growing Tuberoses, but this year I have succeeded fairly well, some of my flowers being 2½ in. long and 2 in. in diameter when expanded. The roots were planted in February, one in a 5-in. pot, plunged in bottom-heat until the pots were full of roots, and allowed to grow slowly on in the greenhouse till May, when they were put out-of-doors whenever the day was warm. Several were allowed to remain out and were well watered until the flower-buds were about to burst. They were then left to flower under glass, rendering the room or house agreeably fragrant. Mine are rather late, and several have not yet flowered; but in the heart of London plants must not be encouraged to grow too fast, as light is very defective, and this year we have had less sun than usual. With care and a little practice I think Tuberoses may be well grown in London.—L. S. B.

The Souvenir de Malmaison Carnation deserves a place in every garden where cut flowers or choice decorative plants are in request. The blooms are extremely large and of a very delicate flesh colour. Young plants are preferable for pot culture; those struck in May from soft side growths, in a brisk bottom-heat flower within twelve months. They should be potted off into 3-in. pots in a compost of fibry turf and dry cow manure, and as soon as they are well rooted transferred to cold frames, in which they are set on coal ashes, the lights being drawn off entirely on all favourable occasions. In August they should be shifted into 5-in. and 6-in. pots, great care being exercised in watering, as if at all soddened or the drainage imperfect the plants are liable to die off. Green fly must be guarded against by fumigation or the use of Tobacco water. During winter they should be kept in a light well-ventilated house with intermediate temperature. Such plants, if successfully handled throughout, develop splendid heads of blooms.

Azalea Duke of Edinburgh.—This very fine English seedling *Azalea indica* was raised by Mr. Parsons, gardener to Captain Blake, at Danebury, Welwyn. It is of free-growing, vigorous habit, with healthy foliage of the usual character. The flowers are very large and stout, very smooth both on the surface and at the margin, and abundantly produced; their colour is a bright rich salmon-red, the upper side of the flower being moderately spotted with deep crimson. The solid, though not heavy, colouring, and the large size of the blossoms, place it in the first rank of ornamental varieties, since it combines effectiveness with floral qualities of a very high order. A first-class certificate was awarded to it on May 3, 1876, when it was exhibited before the floral committee, and no award of that body could be better deserved.—"Florist."

THE FRUIT GARDEN.

MAKING BORDERS FOR FRUIT TREES.

UNFORTUNATELY, the places in this country where the choicer kinds of fruit trees can be cultivated to advantage without some previous preparation of the border are few and far between; indeed, we may say, for a crop of so permanent a nature, any money judiciously laid out in deepening or improving the soil will prove, in the long run, a good investment. If every gardener were allowed full liberty of action, nearly every estate would, we believe, furnish materials for forming good and lasting fruit borders. The very light loams might be intermixed and improved with the moister and more adhesive soils from the neighbourhood of streams or ponds, as the presence of water is usually indicative of more retentive soil; and the heavy land could be made more open and porous by adding the sharp gritty parings from the sides of roads, sand, and the *débris* from old buildings. The latter substance is especially suitable for stone fruits. The cuttings, prunings, and other matters that are constantly accumulating, after being submitted to the action of smothered fire, so as to char them into a black mouldering mass, form a capital compost for lightening heavy soil for fruit trees, as it enriches at the same time that it improves its physical or mechanical condition. In dealing with heavy clays, some of it might with advantage be burnt, and the rougher portions reserved for forming foundations for the borders, and the finer particles mixed with the soil to open and improve it. Fruit trees, as a rule, do well or ill in proportion to the pains and care brought to bear upon them, especially in early life. Half the battle is won when they have received a fair start in good, healthy, suitable soil. Cultivators formerly attached more importance to this than is now the case. Most people now-a-days are seeking for short cuts to the attainment of any given object, and permanency is often lost sight of, or altogether ignored. The advice the Scottish laird—immortalised by Scott—gave to his son, "to be always sticking in a tree" was excellent in the sense in which it was given. But it would appear that it had been acted on literally in some instances in planting fruit trees; for one is constantly seeing or hearing of wall and other fruit trees being in a miserable, unhealthy condition, mainly from want of proper preparation being made for the reception of the trees before they were planted. Far too often, indeed, young trees are planted on the same sites from whence old worn-out trees of the same kinds have only just recently been removed, ignoring altogether the important matter of rotation, which it is even more necessary should be observed with a crop which, if successful, would, even at a low calculation, occupy a position profitably for a quarter of a century, or longer, if the work had been well done, and the after management of the trees had been right.

Many of the best methods of draining fruit gardens and orchards are yet capable of improvement. Land naturally porous, and indeed often too dry in summer, is not unfrequently in a water-logged condition in winter; that must, we think, be inimical to the well-doing of the trees, by retarding or altogether preventing the proper development of the delicate tissues of which the advancing flower-buds are composed. Therefore, all properly made fruit borders should have a drain along the front, with a good clear outfall that would be free in times of flood; in some gardens it would only be in times of sudden downpour in autumn or winter that the drains would be required, and in all cases the sooner all excess of water in the land is passed away the better, as it lowers its temperature so much. In preparing borders for wall trees, width, and in some measure depth, must depend upon the height of the wall. A tree that is expected to cover a large space must be allowed a correspondingly wide root-run. Thus, in most gardens, it has been the custom to allow the wall borders to have the same width as the height of the wall, and it should be over rather than under; and then the front might be cropped with dwarf-growing vegetables or salads. These borders are so valuable for early crops that they cannot be dispensed with. The practice of double cropping is not a good one, as it involves either the speedy exhaustion of the soil, or the regular and constant application of manurial matters, that have a danger-

ous tendency to disorganise the system of the trees; and we have no doubt the lives of many trees have been shortened by the practice, besides the lesser evil of unfruitfulness caused by exuberance of growth. September, before the autumn rains set in, is the best time to make new, or remake old fruit borders. The work can be done more expeditiously when everything works cleanly. Another and more important advantage is, it gives a period for the soil to settle before planting; and it is a great advantage for all deciduous trees to be planted by the end of November.

The proper depth for fruit borders has often been discussed, but so far as my own experience goes, coupled with what I have been able to glean from the experience of others in different parts of the country, for a tree that is expected to live to a good old age, to lead a steady, regular, and consequently a fruitful existence, not excited by stimulants, or unduly crippled by poverty through being confined too much in its feeding bed, 3 ft. may be taken as a good average depth. In some places where the subsoil is very inferior a few inches less will suffice, and the border should also be raised a few inches above the natural level. No doubt good crops of fruit have been grown in shallow borders, but in this case more care and labour are involved; and, unless there be a positive necessity through the subsoil being of a cold, wet character and the neighbourhood low and difficult to drain, a depth approaching to 3 ft. will give the best result, if lasting fruitful powers are sought in combination with fully developed trees. There are various ways of making the bottom of the borders impervious to root action, so as to keep the roots in the prepared borders. Where chalk abounds, 5 in. or 6 in. of it placed in the bottom and rammed down firmly make a fine bottom with a layer of 2 in. of sifted coal ashes on good foundation; or 3 in. of tempered clay placed on top of the clay, and well kneaded and trampled in, and rolled when approaching dryness, also forms a good hard floor. A layer of concrete answers the same purpose, or the bottom may be paved with tiles or bricks laid on cement; in short, the materials that can be most easily obtained should be used in each case. The bottom of the border should have a fall of 1 in. in 8 in. or 10 in. to carry off the water to the drain in front, which should be made at the same time the border is excavated, laying the pipes along its front and a few inches below its level. The soil for the different kinds of fruit will not vary much in the same locality. Peaches should have a good sound loam, neither heavy nor light, with as much fibre in it as possible, and if soil of this quality and texture cannot be had, secure the best and nearest approach to it. From 4 in. to 6 in. thick of the top of a sheep pasture is the soil sought for by the cultivator, and where success is aimed at, it is a mistake to refuse the means to do things properly. Apricots will thrive in rather a lighter soil than Peaches; and Cherries, again, thrive best in soil of a gravelly or a stony nature, rather than heavy or close. Plums, Pears, and Apples succeed very well in well-drained soils of a mellow, loamy nature. All stone fruits do best in soil of a calcareous character, and where lime is not present in sufficient quantities lime rubbish may be added in the mixing of the soil when the border is formed, or a dressing of lime may be given to the borders at any time, and lightly forked in should it be necessary.—“Field.”

The Morello Cherry.—This should be freely planted where fruit for culinary or confectionary purposes is in request. If planted against a north wall it is one of the most certain cropping fruit trees that we possess; in fact, it should occupy a north aspect for several reasons, but more especially because the blossoming season is retarded in spring, and because it offers great facilities for preserving the fruit in a fresh plump condition late in autumn. The fan system of training is that best adapted to the Morello, as it offers the greatest facilities for keeping all parts of the tree stocked with young bearing wood; for, although like the Peach, Morellos will bear on spurs, I find that the young annual growths produce the finest fruits. This is a good time for selecting healthy young trained trees worked on the Mahaleb stock. Having well prepared a good position for them, carefully remove them as soon as the leaves have fallen. Do not overcrowd the wood, and keep it free from fly by means of the garden engine.—J. GROOM.

PLATE CXLIV.

APHELANDRA FASCINATOR.

THIS is the finest of all the *Aphelandras* that have yet been introduced to cultivation; and not only is its inflorescence of the most brilliant description, but when not in flower its ornamental foliage renders it attractive. Like others of the genus, its spikes are terminal and four-sided, and its individual blooms are very large and of a brilliant vermilion.

Subjoined are a few of the best species in addition to that just named, and all of them deserve a place even in the smallest collections:—

Aphelandra cristata, an old inhabitant of our stoves—one, indeed, which has been turned out (in many instances) to make room for inferior plants of more recent introduction. When in good condition, its beauty is, however, always appreciated. During the autumn its four-sided spikes of membranous bracts and bright, rich scarlet flowers are produced in great abundance, the broad, shining, deep green leaves forming a grand contrast.

A. Sintzini.—Like *Fascinator*, this is a recent introduction. Its leaves, which are ovate and deep green above, with the primary veins strongly defined, are deep red on the under sides; the membranous bracts are also red, and the large flowers are of an intensely vivid scarlet.

A. Roezli.—This is an extremely free-blooming plant, even in a small state, yielding its gay flowers in the very depth of winter. Its leaves are oblong in shape, overspread with a silvery shading, especially between the primary veins. Its flowers are bright orange-scarlet, and are produced in long terminal bracts.

A. Liboniana.—This is a rather stronger-growing plant than the preceding, and it is, moreover, a spring flowerer. Its leaves are ovate-lanceolate in shape, intensely deep green with a white mid-rib; the bracts in the spike are bright orange, the flowers being yellow tipped with scarlet.

Amongst other species we may name *A. nitens*, *A. Leopoldi*, and *A. aurantiaca* as being desirable where space for growing them can be afforded.

The *Aphelandras* are stove plants that are particularly useful in the case of those who require brightly-coloured winter flowers. They are nearly allied to the *Justicias*, with which, indeed, the older species were at one time associated. In order to have them bushy and well furnished with leaves down to the pot, quick growth should be encouraged by constant feeding. Where small plants only are required seedlings are best, as it is easy to grow them so as to have flowering plants the same year in which the seed is sown. If larger plants be desired, then these seedling plants should be cut back before starting them into growth, and every season this should be repeated to within two or three buds of the old wood. When well started the young growths should again be stopped, in order to increase, if possible, the number of flower-bearing shoots. If a large stock be required, cuttings taken off with what is termed a heel strike readily, and soon make flowering plants. *Aphelandras* require to be kept very clean; if this be not attended to, thrips, bug, and scale will soon render them unsightly. In order to keep these pests in check the most effectual application is Abyssinian mixture. The best soil for *Aphelandras* is a mixture of two parts loam, one part peat, and one part good leaf-mould, with sufficient sharp sand to make the whole feel gritty when compressed in the hand. This compost should be used in a tolerably rough state, which will prevent its settling down into a hard mass. The drainage must be efficient, and then a bountiful supply of water may be given, which will benefit the plants while growing. After flowering they should be removed to a cool house, and be kept as dry as possible without allowing them to suffer from drought, and they should remain dormant until the time arrives for cutting back and starting the plants into growth. The time for doing this will depend upon that at which their flowers are required, bearing in mind that they are produced very quickly if properly encouraged. G.

[The specimen from which our figure was prepared was supplied from Messrs. Rollisson's nursery at Tooting.]

PROPAGATING.

SHOW AND FANCY PELARGONIUMS.—These may be increased nearly all the year round. Cuttings made of young and tender wood strike root freely and quickly if prepared as shown in fig. 1, and inserted in well-drained cutting pots. The compost should be loam, leaf-soil, and sand in equal parts. Plunge the pots half way up in a brisk bottom-heat, and occasionally sprinkle the cuttings overhead, and shade them from hot sunshine. If the propagating house be a very close one, they will require little or no covering, but they must not be allowed to get so dry as to flag. If an extra stock be required of any sort, it can be obtained by means of pieces of root cut and put in upright, as shown in fig. 2. Pieces $1\frac{1}{2}$ in. long are best; they should just be left peeping out at the surface; then place the
