The Russian figures are not given, but this country which is, I believe, a very good customer of Ceylon cocoa, is I read also greatly increasing its consumption. The increase in the American demand is fabulous, 66 per cent in a year. It is true that 1898 may have been a bad year owing to the war and other reasons, although with us the Boer war is stimulating our consumption, but even then it is a great jump. It is rather curious to note that by "the bag" the increase only shows a rise of 38 per cent. The figures being for New York:—

Imported, 210,272 bags in 1899 against 151,956 bags in 1898.

Consumption, 197,200 bags in 1899 against 140,638 bags in 1898.

This shows the average weight per bag in 1899 was 180 lb. against only 150 lb. in 1898 due to a much larger proportion of Trinidad cocoa (packed in heavy bags) being imported in 1899 than in 1898. From Trinidad direct 44,675 bags were sent last year against 32,952 bags in 1898 and I believe last year a good deal of Trinidads were shipped to the States from the United Kingdom than there were in the previous year.

At the public sales this week, 2,054 bags Ceylon cocoa were offered, and nearly all sold. At the sales alone 1,865 bags changed, and though since the sales holders are asking higher rates than buyers as yet care to give, there is no doubt those who have to buy must give way to the sellers, as there is so very little unsold. Other growths are still coming forward slowly. The "Chemiston" has arrived, however with 3,300 bags of Grenada cocoa which they are trying to get up for sale next week: but it will be a month I reckon (from the reliable information I received from Trinidad) before any such quantities of Trinidads are likely to be received. I think the following are about the fair values of Ceylons today:—Common to fair native 68s to 72s; good native 73s to 79s; fine (native 83s); small, fair to fine (estate) 63s 6d to 77s 6d; ordinary 67s 6d and 68s 6d; medium to fair 76s to 83s 6d; good to fine 84s to 91s. The sales include S, L, in diamond 68s 6d; MAKM 69s; MAK 71s; C in diamond 68s to 69s 6d; HMS & Co. in diamond 140 bags 70s; Kepitigalla 82s 6d and 84s; Ukuwella, Lower Haloya 83s 6d; Hylton 84s; Patharagalla, Ingurugalla, and Maousava 84s 6d; 86s 6d was bid but refused for "Pallie"; Polwatta 85s, sold; Meegama 90s; Yattewatte 90s to 91s.

I should not be surprised before the year was out, owing to the war and the large increase in the general demand, to see cocoa very high; for in all probability the demand during the next three or four months when the crops will be coming in will be large enough to prevent any appreciable increase in the stocks, so that we shall have September come with depleted stocks and the few pickings that straggle in as usual at that time of year. Trinidads now are worth 81s to 83s for good to fine red and Grenadas 72s to 73s 6d. Guayaquil are also higher with very little on hand to offer.—Yours truly,

HAROLD HAMEL SMITH.

I enclose a cartoon I have drawn (I apologise for the quality) showing what I believe to be a very fair idea of the Mincing Lane opinion of last year's Liverpool cocoa market, —H.H.S.

COCOA.

London, E.C., Feb. 2.

DEAR SIR,—Letters received this mail from Trinidad, dated 18th January, still complain of the lateness of the crops, and the stores say it has caused them to have a very poor Christmas. Those, however, who were fortunate enough to have any cocoa obtained good prices, fine estate marks selling as high as \$16 75 locally=84s in London. The weather in most quarters is still too dry, Port of Spain itself seems to be having more rain than the country. The Island had only shipped 3,276 bags to the 18th January (2,503 to Europe, 768 to U.S.A.) against 9,672 bags at the same time last year.

The cocoa sales went off this week very irregularly, the Government being again buyers, however, gave some growths especially Trinidads a very much firmer tone than would otherwise have been the case, but even they were cut out in several lots. This caused Grenadas and Dominicas also to sell well. The demand for Ceylon was the most irregular perhaps; but on the whole, especially as sellers were firm, the lots sold were fully up to valuations. Since the sales the news that some 2,000 bags Java offered on the 31st at Amsterdam had all sold considerably above valuations, also no doubt helped the market, for I was shown a lot of fair red native, mixed break, for which only 70s was bid at the sale, but had now been sold at 73s.

Judging from prices obtained at and after the sale I quote the following rates today for Ceylon's:—Common to fair native 67s to 73s, small fair to good 61s to 69s, mid red 75s 6d to 77s, fair red 78s to 80s, good red 83s 6d to 87s 6d, fine 95s. About 1,400 bags in have changed hands this week. Of other growths Trinidads went steady to 1s higher selling from 79s to 84s. The principal feature in this growth was the sale of some 400 bags good middling to good red 82s, which was only valued at 80s to 81s, Grenadas sold from 69s for fair red to 7s for fine marks. The Guayaquils were nearly all bought in but since the sales about 1,000 bags have been sold at 72s 6d for 73s for Caraquez.

During the week ending 27th, 2,042 bags of Ceylon and Java were landed, and 1,562 bags were delivered, leaving a stock of 8,363 bags. As far as I can see about 800 bags will be offered up next week, when about 5,000 bags, of all growths, principally Grenadas, will be offered—as well as 110 tons of Cadbury's cocoa butter, and 100 tons of Shells.

I hear the Mazzawatte Tea Company are beginning to move into their new warehouses near New Cross, also that they have paid the Customs a cheque for £85,000 odd as duty on some six million lb. of tea.—Yours very truly,

HAROLD HAMEL SMITH.

A PLANTER'S ADVICE TO PLANTERS :
CONCENTRATE AND CULTIVATE ONLY
THE BEST LAND.

Coonoor, Nilgiri Hills, Feb. 9th, 1900.

DEAR SIR,—I find that here and in Mysore the advice contained in the long letter you did me the honor to publish, has been acted on. Poor lands are being abandoned, and the waste of labourers has been reduced. I had a long talk with one of the leading merchants of Bombay (largely concerned in the cotton industry at that city), and find

that they are setting to work—either to reduce wages, or to get more work be done for those at present paid, and the movement has spread to the North of India. I only hope that the action of the Indian planters has spread to Ceylon. If they cultivate highly, and only the best land, they will, of course, economise all along the line; and the key of the whole position, in other words, is the restriction of cultivation to the best land. What often happens here, and at home, is that money is made on the good, to be thrown away on the bad land. The President of one of our Mysore Planters' Associations tells me that my views have been almost universally accepted, except by a few who are entirely in the agents' hands.—Very truly yours,

ROBERT H. ELLIOT.

[We cannot speak of much abandonment of land in Ceylon as yet by our tea planters—"coffee" here is practically a thing of the past altogether—a few corners and a few fields of plantations may have been given up, but that is about all. On the other hand, there is little or no extension in fresh planting for this year; but in regard to "manuring" a good deal is being done, where there is labour, and as it is calculated that if "judiciously" carried out, such manuring means an addition of 200 lb. tea per acre to the crop, we have to face the contingency of heavy additions to our exports, though no doubt a good deal of allowance has been made in the P.A. estimate for 1900 which is 138,000,000 lb. against 129,894,156 lb. actually shipped in 1899. Mr. Elliot, we believe, however, is chiefly interested in coffee and cardamoms? Of the latter, there is not much prospect of extended planting in Ceylon, suitable soil well sheltered being scarce.—Ed. T.A.]

COCONUTS IN FIJI AND MEAT
TINNING.

Feb. 10.

DEAR SIR,—Enclosed are cuttings from *Fiji Times* Editorial of 6th Jan. I cannot help thinking that the estimate of 10,000 acres being planted annually in coconuts by the natives is a gross exaggeration. It is worth enquiring about. The fact that Fiji has started meat tinning shews that cattle have wonderfully increased in numbers during recent years, far in excess of local requirements. The country is well adapted for cattle as I have often told you and they thrive and breed well there.

A large stock-owner in Fiji has just written to me saying he is very glad the tinning business has started and complaining that his fine fat cattle only fetch £5 a head at present time. They expect a heavier copra crop this than last year.—Yours truly,
PLANTER.

While the larger portion of the Windward Islands is almost solely devoted to the raising of coconuts, where something like 10,000 acres are being planted annually by the natives, and every tree preserved and taken care of, the main island, Viti Levu, comprising 2,500,000 acres, is devoted to the raising of sugar cane and fruit.

Another industry to be initiated for the first time in Fiji early this year is the tinning of meat. This would appear to be a step in the right direction and should largely assist stockowners to realise a better

price upon their herds. For some two or three years past New Caledonia has been engaged in the industry, and has been importing cattle from Queensland for tinning purposes, but consequent upon the tick pest at the source of supply the industry has been hanging fire. Once it has been demonstrated that tinning meat as an industry will pay, and the many broad acres which at present remain idle will be devoted to the raising of stock.—*Fiji Times*, Jan. 6.

PLANTERS AND TOPICS OF THE DAY IN CEYLON.

Dikoya, Feb. 10.

SIR,—I write *re* several matters of interest to the planting community.

1. Ceylon Labour Federation.—I have followed with the greatest interest the career of the Federation, ever since its conception was first publicably introduced to the planting community by Mr. L. St. Geo. Carey of the Maturata and Hewaheta Planters' Association. The Federation is "good;" has done "good," and will do "more good;" any shortcomings in the working of it are not due to the Federation; but due to those members, who are too slack or too casual to lay breaches of the rules before the Federation Committees, and yet who will on the strength of what are often imaginary wrongs, run down the Federation, without trying to set right what they know to be wrong. I do not believe there is a man who could show just cause of complaint against the Federation, and though I know many who run down the Federation, just by "summa" talk, I have not yet met a man who could show that he had laid his cause of complaint before the Federation Committee, and yet had cause to complain. Let all members act up to the Federation rules, and prosecute before the Federation Committees all breaches of the rules, and all will be right. I agree with Mr. Lane that previous employers should be communicated with before steps are taken to employ coolies; but I would point out that this is not a Rule of the Federation, and so need not be done; and I feel sure that the majority would be opposed to the recommendatory resolution to that effect, passed by the Federation Committee becoming a rule, thus showing what is actually thought of the recommendatory resolution from a business point of view. That a tundu once given is good should be clearly understood by all Federation members, and what are called "perili" tundus should not be allowed by the Federation. All districts should have their Federation Committees, and no breach of the rules should be passed un-reprimanded.

2. Ceylon S.P.C.A.—Now that the question of supporting this Society is before the Planting Community, we must hope that it will meet with every success. Could not the bigger Associations like the Dimbula P. A., Dikoya P. A., Northern Districts P. A., and Maturata and Hewaheta P. A. appoint representatives in each of the several districts they cover: thus Dimbula P. A., Dimbula and the Agras; Dikoya P. A., Dikoya and Bogawantalawa; Maturata and Hewaheta P. A., Maturata, Hewaheta and Deltota? Increased support means more Inspectors, and Inspectors are men with the time at their disposal, and the

purse of the Society at their backs, and whose duty it will be to prosecute on behalf of the Society. Personal support, both moral and financial, is what the Society wants, and then perhaps we shall see less of the cruelty which is so rampant, like the cruelty in cattle branding, &c., &c. Most planters have no time to prosecute, whereas it will be the Inspectors, duty to do so, and to get more Inspectors, financial help must be given: hence the need of personal interest, throughout the planting districts in the work of the Society.

3. Railways and Labour Supply.—This is a very serious question indeed, and it is about time H.E. the Governor told us what practical steps he had taken to secure a Labour Force, sufficient for the works to be undertaken; so that the anxiety felt as to the possibilities of interference with planters' labour, should be relieved.

4. Rice Averages.—I have looked in vain for January's rice averages in all your issues up to date 9th inst. Could you not always make it a rule to publish the monthly rice averages of each month, during the first week of the following month. Many who, like myself, pay for rice on your monthly quotations, would be glad if you could do this.—Yours, &c.,
PRO BONO PUBLICO.

[Rice averages appeared in the *Observer* of 1st Feb., eighth page.—ED. T.A.]

TEA BUSH ROOTS AFFECTED.

Colombo, Feb. 13.

DEAR SIR,—I send herewith a portion of a tea bush (three-year old) from a high estate, which is dying from the root, and shall feel obliged if any of your readers can inform me the cause of same. Thanking you in anticipation,—I remain, dear sir, yours faithfully,

E.
[The following is the report of the Entomologist.—ED. T.A. :—

The tea bushes just to hand. The roots are covered with some fungus—a white mycelium, which may be the early stage of thread blight. The trees have possibly contracted the disease from decaying roots of jungle trees or even large accumulations of buried prunings.—Yours truly,

E. ERNEST GREEN,
Government Entomologist.

Peradeniya, Feb. 15th.

P.S.—If your correspondents would send their specimens *direct* to this department, they would reach us in a better condition for study. It is very difficult to determine diseases after the plants have dried up.—E.E.G.]

COFFEE PLANTING IN QUEENSLAND.—Another Ceylon planter is added to the list of those who have settled in the Australian Colonies. Mr. Louis Battinson has taken up some coffee land (a few acres planted and some reserve) in the Cooktown division of Queensland and he reports no fungus nor bug, while crops are supposed to average 10 to 12 cwt. per acre; but the country is one where the white man has to labour for himself and where he enjoys it as well. There being a Customs Duty on coffee imported, the local grower has that advantage in his favour. We trust Mr. Battinson will make a success,

PRODUCE AND PLANTING.

ONLY THIS, AND NOTHING MORE.—Three firms in the City, Messrs. Appleton, Muchin, and Smiles, Limited, Messrs. Peck Brothers and Winch, Limited, and Messrs. Joseph Tetley and Co., recently addressed a letter to the Chancellor of the Exchequer requesting him to make an early statement as to the intentions of the Government with regard to the tea duty, and pointing out that great disorganisation of the trade was at present being caused by the large sums of duty being paid upon tea in anticipation of an increase. They have received the following reply:—"Gentlemen,—I am desired by the Chancellor of the Exchequer to acknowledge the receipt of your letter of the 23rd inst., asking the Government to take the earliest opportunity, on the assembling of Parliament, to announce whether or not the tea duty is to be increased in the present year. In reply I am to say that he thinks you will see on consideration, that for obvious reasons no information on such a subject could be given before the introduction of the Budget, for which the time has by no means yet arrived. He regrets to learn that there is any speculation in the tea trade of the kind to which you refer. The unwisdom of such action was proved last year in the case of tobacco. Yours faithfully, L. A. GUILLEMARD."

UNITED STATES TEA IMPORTATION.—The following circular, containing regulations as to the importation of tea, has been issued by the Treasury Department of the United States:—"As tea is now subject to duty, and as the original regulations fixing the penalty of the bond given by the importers thereof at one-fourth the invoice value of the tea was prescribed when on the free list, Article 1 of the Regulations of April 4, 1899, in regard to the importation and inspection of tea under the Act of March 2, 1897, is hereby amended to read as follows: The importation of any merchandise for sale as tea, which is inferior in purity, quality, and fitness for consumption to the standards fixed and established by the Secretary of the Treasury in accordance with Section 3 of the Act of March 2, 1897, is prohibited. Entries of tea will be made upon the ordinary warehouse forms, and the entry will contain the words, 'To be stored at—pending examination under the Act of March 2 1897.' A bond shall be taken from the importer that such tea shall not be removed from the warehouse until released by the collector. This bond shall be under a penalty equal to double the amount of estimated duties on tea, and shall also be conditioned for the payment of all Custom House charges which may attach to the merchandise prior to its being released, exported, or destroyed, as the case may be, under the provisions of the law."

One of the leading Indian Tea Garden Companies in London recently received a communication from a country grocer, with the following modest request: "Have you an Indian or Ceylon tea that you can put in for 5d or 6d duty paid? If so," says this ingenuous correspondent, "send samples and price list." This would-be patron of British planting enterprise should try Hamburg.—*H. and C. Mail*, Feb. 2.

THE BATAVIA QUININE AUCTIONS.

It has now been definitely settled that the course of the present year five auctions will be held at Batavia, at each of which from five to six tons of sulphate of quinine are to be offered. The Bandong factory will therefore require a quantity of bark not less than 500 to 600 tons. At a meeting held on October 12th last, it was stated by the directors of the Bandong works that at that moment they had at their disposal sufficient bark to produce twelve tons of quinine, and during the meeting they secured options from various planters for further parcels estimated to produce nearly fourteen tons more, giving a

total of twenty-six tons of quinine. This does not include any Government bark, so that it appears that there will be ample quinine manufactured in Java to meet the requirements of the auctions. The first auction will be held at Batavia on February 23th. The dates of the other auctions are unofficially stated to be April 25th, June 27th, August 29th, and October 31st.—*Chemist and Druggist*, Jan. 27.

THE TREATMENT OF RUBBER WITH ALUM IN PENANG.

Copy of a letter No. 1799, dated the 29th September 1899, from the Inspector-General of Forests, to the Assistant Superintendent, Gardens and Forest Department, Botanic Gardens, Penang.

I have the honour to say that I have read your letter of the 31st December last, to the address of the Director of the Royal Gardens, Kew, regarding the treatment of rubber during the process of extraction with alum, with much interest. During some rubber-tapping operations which were lately undertaken in Assam much inconvenience and loss of rubber was occasioned by the wet weather. It appears that the treatment adapted by you greatly facilitates the extraction of the rubber in wet weather, and that this treatment in no way affects the value of the rubber. I should feel much obliged if you would be good enough to favour me with a full account of the treatment, as I should like to have it tried in Assam.

Copy of a letter dated 18th November 1899, from the Assistant Superintendent, Gardens and Forest Department, Botanic Gardens, Penang, to the Inspector-General Forests.

I have only just returned from leave, or your letter of the 29th September would not have remained so long unanswered.

The report of the expert to whom the Kew authorities submitted the samples of rubber was that the alum treatment does not interfere with its value. You can either stir in a pinch of powdered alum or dissolve the alum first in water, I prefer the latter. You will find that by this treatment you will get out all the rubber there is without loss of time.—*Indian Forester*.

THE AMSTERDAM CINCHONA MARKET IN 1899.

A review just received from Mr. H. A. van Overzee, of Amsterdam, gives some interesting statistics and other particulars of the bark market at Amsterdam during 1899. The small shipments of bark in January and February caused a considerable rise in the prices at the early sales; in fact the average unit, which in January was about 4.70c., rose in March to about 10.90c., an increase of about 130 per cent. When, however, it was found that the March shipments, and subsequently those of April also, were above the average, and that the previous small shipments were not due to scarcity, but to accidental causes, a reaction set in, and prices gradually dropped with continued large shipments, until in September, 1899, the average unit had come down to about 5.35. After this there was again an improvement, and at the last sale of the year the unit was, on the average, 7.75c. The improvement in the prices, notwithstanding larger shipments, would point to a steady increase in the demand for Java bark.—*Chemist and Druggist*, Jan. 27.

TO ALL PARTS OF ASIA, AFRICA, AMERICA AND OCEANIA.

Seeds & Plants of Commercial Products.

Castilleja Elastica Cervantes.—Orders being booked for the coming crop of seeds available in March and April, selected seed from very old trees. R. N. Lync, Esq., Director of Agriculture, Zanzibar, writes under date 24th August, 1899:—"Please send me 200 seeds of Castilleja Elastica for further trial; the seeds of Castilleja you sent me last August germinated very well." Price and particulars in our Circular No. 32; special quotations for large orders according to quantity; immediate booking necessary to avoid disappointment.

Hybridised Maragogipe Coffee.—A large-beaned superior variety of Coffee in demand; orders booked for the coming crop of seeds, February and March delivery. Price according to quantity on application.

Hevea Brasiliensis. (Para Rubber).—Orders being booked for the coming crop available in August and September, 1900. This is the only crop of seeds in the year. All orders should reach us before the end of July to avoid disappointment, as we have to make arrangements in time; guaranteed to arrive in good order at destination. We have already booked a large number of orders. A Sumatra Planter writes, dated 9th March, 1899:—"I consent to the price of £——per thousand. I herewith order 50,000 upon condition that you guarantee at least 83 % seeds germinating." Plants can be forwarded all the year round in Wardian cases. Price and particulars as per our Circular No. 30. A Borneo planter writes dated, Sandakan, 17th August, 1899:—"The last lot of Para seeds turned out very well."

Ficus Elastica (Assam and Java Rubber).—Seeds supplied by the pound with instructions; price according to quantity. This tree grows equally well in high and low land, in forest and grass land, its cultivation being extended largely by the Indian Government. For price of seeds with particulars as per our Circular No. 33.

Manihot Glaziovii (Ceara or Manicoba Rubber).—Fresh seeds available all the year round; price as per our Circular No. 31. It is superior to Mangabeira rubber and second to Para rubber.

Urceola Esculentia (Burma Rubber) and **Landolphia Kirkii** (Mozambique Rubber).—Seeds and plants, both are creepers.

Cinchona Seeds.—Different varieties.

Sterculia Acuminata.—(Kolanut). Superior quality, seeds and plants; price on application; packed to stand the transit well for several months, a hardy tree, cultivation easy.

Erythrina Litkosperma.—Thornless variety, new crops of seeds ready in December, May and June. Price according to quantity on application.

Seeds and Plants of Cinnamon, Nutmeg, Clove, Sandalwood, Pepper, Cardamom, Vanilla, Arabian, Liberian and Maragogipe Coffee, Cacao, Tea, Coca, Fibre, Medicinal and Fruit Trees, Shade and Timber Trees, Eucalyptus various varieties, also Palms, Bulbs, Orchids, &c.

Our enlarged Descriptive Price List of Tropical Seeds and Plants of Commercial Products for Foreign Countries for 1899-1900 are now being forwarded to applicants in different parts of the world. Also Descriptive Price Lists of Seeds and Plants of Fruit Trees, Bulbs, Tubers and Yams, and Orchids.

"SOUTH AFRICA."—The great authority on South African affairs of 25th March, 1899, says:—"An interesting Catalogue reaches us from the East. It is issued by William Brothers, Tropical Seed Merchants, of Henaratgoda, Ceylon, and schedules all the useful and beautiful plants which will thrive in tropical and semi-tropical regions. We fancy Messrs. Williams should do good business, for now that the great Powers have grabbed all the waste places of the earth, they must turn to and prove that they were worth the grabbing. We recommend the great Powers and Concessionaries under them to go to William Brothers."

A leading Planter writes from *New Hebrides* under date 17th January, 1899:—"I shall like a few more of your Catalogues to distribute through these Islands, as I feel sure many would place themselves in communication with you, did they know where to write for Seeds and Plants."

Our New Descriptive Price Lists of Seeds of Shade Trees for Coffee, Cacao, Tea, Cardamoms, &c., Timber Trees, Trees for Avenues, Hedges Wind and Shelter Belts, Ornamental Trees, Shrubs and Climbing Plants; and Seeds and Plants of Palms, Calamus, Pandanus, Cycads, Tree and other Ferns, Crotons and Dracinas, now being prepared and will be ready shortly.

Agents in London:—Messrs. P. W. WOOLLEY & Co., 33, Basinghall Street.

Agent in Colombo, Ceylon:—E. B. CREASY, Esq.

Telegraphic Address:

J. P. WILLIAM & BROTHERS,

Tropical Seed Merchants,

HENARATGODA, CEYLON.

UPPER MASKELIYA ESTATES CO., LTD.

ANNUAL REPORT.

ACREAGE 31ST DECEMBER, 1899.

	Brunswick and Bloomfield.	Caskie- ben.	Total.
Tea in full bearing ..	446	200	646
Do not bearing ..	7	7	14
Grass, Timber Trees, &c..	72	—	72
	518	207	725

The Directors now submit to the Shareholders the accounts of the Company for the past year.

The crop realized amounted to 329,814 lb. Tea (being 29,814 lb. Tea in excess of the estimate) against 256,032 lb. secured in 1898. The average price realized for all tea sold, including the grant of 10 cents per lb. on green teas, was 42.86 cents per lb. The expenditure in 1899 on capital account amounted to R3,242.96 for new lines, and for additions to machinery.

After writing off 10 per cent on original cost for depreciation of Buildings and Machinery and a sum of R50 for bad debts, the profit for the year amounted to R42,340.17 equal to 12.10 per cent on the capital of the Company. To this falls to be added R624.36 brought forward from 1898, and surplus of R742.95 over the estimated value of 12,020 lb. 1898 crop, making R43,707.48 available for dividend. An interim dividend of 3 per cent was paid on 2nd September last, and the Directors now recommend the payment of a final dividend of 5 per cent, making 8 per cent for the year, and that the balance of R15,707.48 be carried forward to the current season's account.

The crop for this year is estimated at 300,000 lb. tea on an expenditure of R91,305.05 which includes the sum of R12,033 for manuring 310 acres.

The attention of shareholders is drawn to the accompanying notice of an Extraordinary Meeting to be held, to pass, if approved, a resolution empowering the Directors to pay an interim dividend, which power is usually given to Directors and obviates the necessity of calling a General Meeting of the Shareholders solely for that purpose.

In terms of the Articles of Association Mr. A E Wright retires from the office of Director, but is eligible for re-election.

The appointment of an Auditor for the current year will rest with the meeting.

THE COLOMBO TEA TRADERS' ASSOCIATION.

REPORT FOR THE YEAR ENDING 31ST DEC. 1899.

The Committee have pleasure in presenting their report for the year 1899.

From many estates the packages are still very indifferent, especially where local woods are used. Of these, experience shows that Kakuna, Mango, and Imbul are particularly unsuitable.

The outturn of weights is now more satisfactory than last year, but there must always be trouble in the trade in this respect after sampling, so long as estates which do not bulk their teas, simply put in the bare weight stencilled on each package.

The general opinion of buyers is that the outturn of machine packed teas is better than those packed in other ways.

The larger portion of tea sold locally is encouraging, and the quantity shipped to America and Russia is still increasing, as is evidenced by the comparative figures for 1898 and 1899 given below. So far as Russia is concerned, the demand is almost entirely for leaf teas.

The total exports for the year were, as per Chamber of Commerce returns.—

	1899.	1898.
United Kingdom ..	103,851,614	96,133,833
Australia ..	15,606,833	15,126,891
Russia ..	3,949,740	2,714,003
America ..	3,080,002	2,180,188
Other Countries ..	3,309,457	3,614,156
	129,797,646	119,769,071

The following figures show the quantity offered locally in public sale for the last four years, with the average price obtained for complete invoices sold.

	lbs.	Average. cents.
1896 ..	32,083,163	41
1897 ..	33,856,809	37
1898 ..	35,958,819	35
1899 ..	28,377,318	38

The following is the present Committee:—

THE CHAIRMAN OF THE CHAMBER OF COMMERCE.

BUYERS:—Messrs. Tarrant, Henderson & Co., F F Street, Darley, Butler & Co., and Finlay, Muir & Co.

SELLERS:—Messrs. Bosanquet & Co., Whittall & Co., J M Robertson & Co., and Geo. Stenart & Co.

The number of members belonging to the Association is 43, against 44 in the previous year.

The accounts for the past year made up to 31st December, 1899, and submitted to you shew a credit balance of R1,247.51.

BADULLA PLANTERS' ASSOCIATION.

ANNUAL REPORT.

Your Committee have much pleasure in submitting their annual report for the year 1899—the sixteenth since the formation of the Association.

During the year two Committee meetings and two general meetings have been held.

MEMBERSHIP.—Forty-seven estates and three private members are on the roll, being the same number as last year.

FINANCE.—The books of the Association are laid on the table for the inspection of members and show a balance of R156.29 at credit against a balance of R4.53 at the end of the previous year.

ESTIMATE OF TEA CROP 1900.—The estimated tea crop from the district is 4,683,150 lb. as against 4,516,090 lb. in 1899—an increase of 167,060 lb. The total acreage in tea is 15,784 acres of which 11,821 acres are in bearing and 3,963 acres young tea. This shows an estimated yield for tea in bearing of 396 lb. per acre.

TEA.—The season was not a favourable one for tea. The rainfall being short and badly distributed throughout the year. Two periods of severe drought were experienced, viz., February and March and May to September. The latter was the most severe drought experienced for many years. Owing to these abnormal climatic conditions the estimates framed for 1899 were not realized on many estates.

COFFEE.—Fortunately the district is not dependent on this product now. Good crops were harvested on a few estates during the past year, but prices have fallen very low and green bug continues its ravages so that the prospects of this product are far from good.

MINOR PRODUCTS.—Cacao and cardamoms continue to be cultivated in the district. The latter product is being extended considerably.

MAIN ROADS AND BRIDGES.—Your Committee have pleasure in reporting that the improved conditions of the main roads mentioned in their last annual report has been maintained. Your Committee congratulate you on the completion of the extension of the Madulsima cart road to Cocogalla Factory: also on the completion of the very handsome cart bridge over the Badulla Oya at Taldena. Both these important works have been carefully designed and thoroughly well-constructed and will be of great benefit to the general public and to the estates they are intended to serve. Great credit is due to Mr. Christie, the Provincial Engineer, and his staff, for the highly satisfactory state of public works throughout the district. It may well and truly be said that never before have the roads in Uva been in such excellent order as at the present time.

NEW WORKS.—Your Committee are pleased to be able to announce that in response to a resolution passed at the last general meeting of this Association, His Excellency the Governor has ordered that provision for a bridge over the Badulla Oya on the

Badulla-Namunakula minor road be included in the estimates for 1901.

Your Committee trust that the extension of the important road from Taldena to Alutunuwara via Bubule will be undertaken at an early date and a cart bridge built over the dangerous Loggaloya, thus completing this most important and necessary link of connection with the lower portion of the Province.

MINOR ROADS have been maintained in a satisfactory condition throughout the year. The Chairman of the Provincial Road Committee addressed this Association with a view of reducing the number of minor roads in the district, but after full and careful consideration of this matter it was resolved that no reduction of these important lines of communication could be recommended at present.

AGRICULTURAL CHEMIST.—Mr. Kelway Bamber paid two visits to the district during the year. Members of the Association had an opportunity of meeting that gentleman on both occasions and were able to elicit a good deal of important information in connection with tea manufacture, &c., and your Committee look forward with interest to the receipt of Mr. Bamber's report which will doubtless contain much valuable information relative to our chief industry. The thanks of the Association are due to H.E. the Governor for the appointment of a Mycologist.

LABOUR.—The labour supply has been fairly good during the year, but there are indications that demand has overtaken supply and your Committee view with some apprehension the increased demand that must necessarily arise when the construction of the lines of Railway to the North and to Udapussellawa is begun. Your Committee earnestly trust that Government will take steps to recruit from outside the island all labour required for railway construction.

RAILWAY EXTENSION.—Your Committee regret that no progress has been made in the matter of railway extension during the year, but sincerely trust that the construction of a light line from Bandarawela as far as Passara will be undertaken before many years have passed.

BENEVOLENT FUND.—Your Committee regret that hitherto this fund has not received from members the support it deserves. They, however, trust that every member of the Association will become a subscriber to this most important fund during 1900.

IN CONCLUSION your Committee would earnestly impress upon every member of the Association, the necessity for continued efforts being made to obtain such reforms and improvements as may be of lasting benefit to the district.

THE KALUTARA COMPANY, LIMITED.

ANNUAL REPORT,

ACREAGE.	
Tea in bearing ..	518 acres
Tea in partial bearing..	140 do
Areanuts, Grass, Ravines, &c. ..	10 do
	668 do
Forest	416 do
	Total. 1,084 do

The Directors now submit to the Shareholders the accounts of the Company for the past year.

The crop secured was 305,433 lb. Tea against an estimate of 285,000 lb. while 5,833 lb. Tea was manufactured from purchased leaf. The average nett price realized was 36.89 cents per lb. against 33.08 cents per lb. in 1898. The expenditure on the estate amounted to 22.93 cents per lb. which included a sum of R5,347.27 for manuring.

The Rubber trees are growing satisfactorily and the supplies which were found necessary owing to damage by cattle are coming on well. Sinhalese are still prospecting for plumbago, but no definite arrangements have yet been made for working it.

After making full provision for depreciation of Buildings and Machinery, writing off a sum of R1,000

to Coast Advance Reserve Account and paying the interest on the Preference Shares, there remains a balance at credit of Profit and Loss Account on the year's working of R30,147.13, equal to 7.54 per cent on the capital of the Company. To this falls to be added the balance of R3,774.66 brought forward from 1898. During the year under review a further 20 of the Preference Shares were issued, making the total Preferential capital R27,500.

On 28th August last an interim dividend of 2 per cent was declared and the Directors now recommend the payment of a final dividend of 5 per cent, making 7 per cent for the year, and that the balance of R5,921.79 be carried forward to the current season's account.

The capital expenditure for the past year amounted to R10,981.38 on the upkeep of young tea not in bearing and additions to Buildings, including the final payments on account of Withering House.

The estimate of crop for this year from the Company's estates is 333,000 lb. Tea on an expenditure of R75,532.65, including the sum of R5,756 to be spent on manuring, while expenditure on Capital Account is estimated at R6,268.75, for the planting up of 25 acres with Tea and the erection of new lines which are much required.

During the year Mr. J G Wardrop resigned his seat on the Board and the remaining Directors appointed Mr. R S Templer in his place. On Mr. W H Figg's departure from the island Mr. Wardrop was re-appointed. In terms of the Articles of Association Mr. G H Alston now retires from the Board, but is eligible for re-election.

The appointment of an Auditor for the current year will rest with the meeting.

THE RUANWELLA TEA COY., LTD.

ANNUAL REPORT.

ACREAGE.	
Tea in full bearing ..	358 acres
Tea not bearing ..	16 "
Jungle and Wasteland ..	199 "
	673 "
Total ..	573 acres

The Directors have now to submit to the Shareholders the Accounts of the Company for the past year.

The crop secured amounted to only 161,100 lb. Tea against an estimate of 200,000lb. The shortfall is mainly due to the deficiency in rainfall.

The average net price realized was 34.66 cents per lb against 30.90 cents per lb in 1898; the cost delivered in Colombo was 26.58 cents per lb, [which includes the cost of manuring, amounting to 2.22 cents per lb. This high cost per pound is attributable to the small crop.

In view of the fact that the balance at credit of Depreciation Account now represents about forty per cent of the original cost of Buildings and Machinery the Directors do not consider it necessary to write off anything further for depreciation at present.

After transferring the sum of R500 to Coast Advance Reserve Account and writing off a bad debt of R73.67, the profit for the year amounted to R10,543.01, to which falls to be added the balance brought forward from 1898, R1,381.26 and a surplus of R661.46 over the estimated value of 16,690 lb. of 1898 crop. The total available for distribution is therefore R12,585.73, and the Directors recommend that a dividend of three per cent be declared for the past year, and of the balance of R4,635.73 carried forward to the current season's accounts.

The estimated crop for 1900 is 180,000 lb tea on an expenditure of R41,763.93, which includes a sum of R3,616.84 for manuring.

During the year Mr. W H Figg resigned his seat on the Board, and the remaining Directors appointed Mr. G H Alston to the vacancy, who now retires, but is eligible for re-election.

The appointment of an Auditor for the current year will rest with the meeting.

HIGH FORESTS ESTATES CO, LTD.

ANNUAL REPORT.

		ACREAGE.
Tea in bearing ..	588	Acres
Do in partial bearing ..	246	do
Do do 1897 ..	174	do
Do do 1898 ..	132	do
Do do 1899 ..	25	do
	1,165	
Forest and Patna ..	467	do
	1,632	Acres

The Directors now submit to the Shareholders the Accounts of the Company for the past year.

The total crop secured during the year under review was 258,496 lb. tea (being 28,496 lb. in excess of estimate) which realized a nett average of 50.06 cents per lb., compared with 50.76 cents per lb. in 1898. This price may be considered very satisfactory in view of the lower prices which prevailed for good teas during the year.

After making the usual provision for depreciation of Buildings and Machinery and writing off R1,840 which was expended on a survey of a route to Padiapalella in 1897-1898, the year's working shews a profit of R53,564.10, equal to 5.79 per cent on the capital of the Company. To this has to be added the balance of R3,560.47 brought forward from 1898. An interim dividend of two per cent was paid on 28th August 1899, and the Directors now recommend the payment of a final dividend of three per cent, making five per cent for the year, which will leave a balance of R10,874.57 to be carried forward to the current year's working.

During 1899 in addition to the capital expenditure referred to in last year's report, the Directors considered it advisable to start the erection of a new withering house, so that it might be completed in time to accommodate the increased quantity of leaf anticipated from March next onwards. The withering house is practically now completed, and it is anticipated will provide the necessary accommodation required for the increased returns from young tea for the next four years. The total expenditure on capital account amounted to R36,847.80, which included the upkeep of 552 acres not then in bearing and the opening up of a further 25 acres. During 1900 the expenditure on upkeep of young tea and the opening of a further 15 acres is estimated to amount to R15,339, while the erection of new lines and the completion of withering house and the cost of additional machinery will probably entail the expenditure of R7,300. The Directors do not anticipate having to make any further call on the holders of the part paid shares until January 1901, when funds will be required to cover the capital expenditure referred to above.

Little progress has been made in the negotiations for improvement of transport arrangements, but, in view of the Uda-Pussellawa light railway having been sanctioned by the Secretary of State, efforts are now being made to obtain access to that line.

The yield of Tea in 1900 is estimated at 300,000 lb. on an expenditure of R80,789.76.

During the year Mr. E J Young resigned his seat on the Board, and the remaining Directors elected Mr. W J Smith to the vacancy. In terms of the Articles of Association Mr. J G Wardrop now resigns his seat on the Board, but is eligible for re-election.

The appointment of an Auditor will rest with the meeting.

MAHA UVA ESTATES COMPANY, LTD

ANNUAL REPORT.

		ACREAGE.
Tea in full bearing ..	598	Acres
„ in partial bearing ..	12	
„ not in bearing ..	8	
Cardamoms ..	89	
Grass and Fuel ..	24	
	731	
Total cultivated ..	731	
Jungle and waste land, &c.	227	
	958	
Total of Estate ..	958	

The Directors now submit to the Shareholder the accounts of the Company for the past year.

The Tea crop secured, including tea made from 1,744 lb. purchased leaf amounted to 235,916 lb. (or an excess over estimate of 5,916 lb.) while the expenditure was less than that estimated.

The cardamon crop did not quite come up to expectations, and coffee crop amounted to 127 hns., but quality was very poor. The nett average prices realized for the tea and cardamoms sold to date were 39.83 cents and R1.58 per lb, respectively; these prices compare with 42 cents and R1.71 per lb. obtained for 1898 crops.

After making the usual provision for depreciation of Buildings and Machinery, the amount at credit of Profit and Loss Account for the year's working was R25,944.14, equal to 8.65 per cent on the capital of the Company. From the balance of R6,595.39 brought forward from 1898 there falls to be deducted the sum of R28.74, being amount over-estimated for value of 466 lb. Cardamoms unsold at the end of 1898. The total amount available for distribution is therefore R22,510.79. Out of this an interim dividend of 3 per cent was paid on 2nd September last absorbing R9,000 and the Directors now recommend the payment of a final dividend of 5 per cent, making 8 per cent for the year, and that the balance of R8,510.79 be carried forward to the current year's account.

The estimates for this year are 244,050 lb. Tea and 6,000 lb. Cardamoms on an expenditure on the estate of R66,817.71, on which however it is hoped a considerable saving may be made if circumstances are favourable, while R1,150 will be expended on Capital Account in roofing with iron two sets of lines.

The attention of shareholders is called to the enclosed notice of an Extraordinary General Meeting, at which it is proposed to alter the Articles of Association to empower the Directors to declare interim dividends without the sanction of a General Meeting.

During the year Mr. E J Young resigned his seat on the Board, and the remaining Directors nominated to the vacancy Mr. W J Smith, who now retires from the Board in accordance with the Articles of Association, but is eligible for re-election.

The appointment of an Auditor for the current year will rest with the meeting.

CEYLON FISHING CLUB.

REPORT ON THE LAST CONSIGNMENT OF BROWN TROUT OVA RECEIVED.

The Ova in the first layer of the box were found to be in good condition, only five to eight per cent were bad. This is a very good percentage. In the second layer the ova of one side of the layer had to be entirely thrown away as they were quite spoilt and about two-thirds of the other half were used. In the third layer about one-half had to be thrown away and from the other half only about one-third were put out, but these were badly affected with fungus.

This is one of the worst lots we have received, but there was one other lot which was worse or about the same.

The causes for this may, I think, be attributed to the following: (1) Was the ice receptacle kept continually replenished during the voyage? When I took the box into the boat, I found that there was a little ice in the receptacle, not enough for the ova, and I immediately put in some more ice. The boatman who preceded me to the cool room told me that when he went there he found that the ice was just being put in the box.

(2) In the bottom of the box we found that the water which flows from the ice does not flow off rapidly as there is only one hole in the centre of the box and this hole was slightly higher than the level of the bottom of the box. The water could easily contaminate the last layer and it will in turn affect the layers above.

The layers are too long and I think that the weight of the layer presses on the layer beneath and thus crushes the eggs. Most of the eggs were found to be in masses closely joined together and completely spoilt. I think this is to a great extent caused by the weight of the layers above. The layers rest one above the other and when they are fairly heavy press on to the ova in the layer beneath. The rims of the layers are too narrow. The old large boxes had square layers with broad rims and it was impossible for one layer to crush the layer beneath. In case they cannot alter the defect it is advisable to revert to the former boxes as a very large percentage of the ova is crushed by this means.

THE OUTTURN.

The outturn of ova has been very low: only 450 alevins hatched out altogether, out of which 257 died and there are at present only 193 alevins. From the first layer 230 alevins hatched out and from the second layer 170 alevins hatched out. No alevins hatched out from the third layer.

The outturn from the top layers in the consignment for 1899, i.e., since the new boxes were used, were also very unsatisfactory. The death rate has also been very high.

Mr. Elhart then refers to appendix C., page 15 of the report for 1899, also drawing attention to the fact therein mentioned that the top layers did not hatch out.

PLANTING NOTES.

MESSRS. LIPTON, LTD., have secured the contract for the supply of 10,000 lb. of tea through the Ceylon Court Paris Exhibition for use in cup. There were eight tenders, we understand, and the samples were put to severe and repeated tests, and that of the Company named came out first on each occasion.—*British Trade Journal*, Feb. 1.

JAMES FRASER.—In all probability the father of Scotch gardeners has passed away in the person of the late Mr. James Fraser, gardener, who died at Casslehill, Turriff, on the 18th ult., aged ninety-eight years. Mr. Fraser was engaged by the late Dr. Adam, as gardener at Ardmiddle House, Turriff, in the year of the disruption, 1843, and for the long period of thirty-three years he conducted gardening operations at Ardmiddle with great acceptance by his employers.—*Gardeners' Chronicle*, Feb. 3.

THE PETROLEUM TRADE.—On page 613 we give an interesting statement, supplied by Messrs. Delmege, Forsyth and Company, regarding the present position of the world's supply of petroleum. Statistics are offered of the output from America and Russia during the past three years and the course of prices is also shown. All point to an increasing scarcity of the popular oil and consequently to a rise in prices which the poor must feel a good deal in what has now become so indispensable an article in every household.

THE SEASON OUTLOOK IN MADRAS.—The following is the Board of Revenue's telegraphic summary for the week ending the 17th February:—"No rain. Water-supplies are diminishing and generally deficient. Unless protected by irrigation standing crops are deteriorating. Harvest continues to yield indifferent outturn. Pasturage is scanty everywhere, but fodder is generally sufficient and cattle is normal. Prices continue almost unaltered. Four test works in Cuddapah attracted 917 men, 1,551 women and 688 children, total 1,156; also advances given to 350 looms employing 864 men and 668 women weavers."—*Madras Mail*.

BANANAS IN QUEENSLAND.—Brisbane, Feb. 5:—Banana growers in the Cairns district, who are almost exclusively Chinese, recently offered to pay the wages of an Inspector to overhaul their fruit before it left for southern markets, owing to the danger of a cessation of the trade, on account of the number of diseased bananas leaving the colony. This arrangement proved so satisfactory that they have since offered to pay the wages of a second Inspector. The Chinese have also bound themselves to pay a fine to the Joss-house of 1s per bunch for all fruit found infected, and, should this occur frequently, to accept the refusal of the Inspector to pass any fruit from that garden.—*Adelaide Observer*.

INDIAN AND CEYLON ROADS.—Our old friend Dr. Workman, has been writing in "Travel" for February, on "the adaptability of Indian Roads to Cycle Touring." There is one paragraph complimentary to Ceylon worth noting:—

So far as the cyclist is concerned, I should class Indian roads as fair-weather roads. Such as they are, good, indifferent, and bad, he can get over them during the dry season, but I have seen very few roads that apparently could be used for cycling during the monsoon rains. In respect of construction the roads of Ceylon are far superior to those of India, the metalling being more thoroughly done. I was able to ride many hundreds of miles in Ceylon during the monsoon, being frequently overtaken by drenching tropical showers, which flooded the roads, without being detained an hour for them to dry.

THE RAINFALL OF 1899.—The aggregate rainfall during the year just closed was deficient over the whole of England, the deficiency amounting to 6 inches in the Channel Islands, 5 inches in the south of England, and 4 inches in the east and south-west of England. There was a slight excess in most parts of Scotland and Ireland. The mean temperature for the year was in excess of the average over the whole area of the British Islands, the excess being greatest over the southern portion of the kingdom, although it was also very large in the north of Scotland. There was an excess of sunshine over the entire country, amounting to about 350 hours in the south of England, and exceeding 200 hours over the whole of England, except in the north-eastern district. In Ireland the excess was about 150 hours; but in parts of Scotland it was not so large.—*Gardeners' Chronicle*, Feb. 3.

COCOA MACHINE WANTED.—What is most needed, says the United States Consul at Asuncion, in reporting on the Cocoa Trade of Paraguay, is a machine which can remove the pulp and break the hulls of the fruit without cracking the kernel. A number of machines have been invented for this purpose, but as yet none has given satisfactory results. The Agricultural Bank has tried a French apparatus, but the cost is too great to enable it to be generally adopted. In one part of the apparatus the pulp is removed from the boll and this is then passed to another part, where there are three cylinders—one with grooves to hold the cleaned hull, another with longitudinal knife-like projections, and the third with transverse projections. This machine costs about \$850. What is desired here is a machine costing, say, \$35. It must be remembered in building a machine that some of the bolls are large and others small. The kernel, when cracked, becomes unfit for the market.—*British Trade Journal*, Feb. 1.

A SYNDICATE of London capitalists have sent out Messrs. Swinney and Bird, who have previously made considerable explorations in Pahang, with a view of obtaining land for mining purposes. These gentlemen have applied for concessions in more than one district of that State. They are also trying to obtain land in the independent State of Kelantan.—*Perak Pioneer*, Feb. 14.

FARMING IN THE TRANSVAAL.—Says the *Sydney Mail*:—It is popularly supposed in Australia that the Transvaal and adjacent territories will offer a wide and profitable field for the exertions of enterprising men after the war is over. In some respects this supposition will doubtless be realised. But we must not forget that, so far as business was concerned, there were better opportunities for pushing men in Johannesburg than in any other part of the world before the war. Also, wages of good, willing men were very high, and the average earnings of the white population were such as would be considered sumptuous even by Australians. Competition will probably be keen when the war is ended, and it is doubtful indeed if the commercial opportunities of the man without the capital will be as great as before. In another direction there may be good openings for experienced agriculturists. There are sound local markets, and Boer methods are not advanced. For the matter of that, there are not so many advanced farmers in Australia that we can afford a trek to Boerland. The Boer may be a ragged farmer, but he probably works on very cheap lines, and cheap production, however slovenly it may be, is a tough opponent. These are points that could be considered with advantage by Australian settlers later on.

INDIA-RUBBER (MEXICO) (LIMITED).—A meeting of shareholders was held yesterday at Winchester-house to consider what concerted action should be taken to recover the money invested by them in the company. The Chairman entered at considerable length into the position of the company since its incorporation in 1897. He reminded them that the prospectus estimated that the profits for the first year's working would be £70,000, and in the second and third year £80,000 and £120,000 respectively. The fact that during those three years only £275 had been derived from the estates in Mexico seemed to show that there was no foundation for such statements. At the recent action against Mr. Clough at Leeds Assizes the jury found that the statements contained in the prospectus were untrue, and that the defendant had no reasonable ground for believing them to be true in fact. The jury further found that Mr. Clough had been guilty of false and fraudulent representation to the plaintiff. In fairness he had to state that Mr. Clough was prosecuting an appeal, the hearing of which might possibly come on within the next six months. Replying to a question, the chairman said that there were 961 shareholders, representing 80,000 shares. Mr. Burton asked if the persons responsible for the prospectus were possessed of adequate means to recoup the shareholders. The chairman said that there was evidence that they were men of ample means. Eventually, on the motion of Mr. J. Hess, seconded by Mr. Horner, a resolution was passed appointing a committee to co-operate with that elected at the Newcastle meeting, to consult with Messrs. Simpson and Simpson, and counsel, if necessary, as to the best way of enforcing liability against the directors, or others, responsible for the prospectus.—*London Times*, Jan. 20.

JAMAICA TOBACCO.—At Montpelier, the property of the Hon. Evelyn Ellis, an extensive factory for the manufacture of cigars is now in full working, the entire cigar being the product of Jamaica soil. Mr. Ellis has planted out sixty acres exclusively with seedlings of the famous Vuelta Abajo tobacco, obtained from the Botanical Department. The tobacco, cured on the spot, realized high prices in New York.—*British Trade Journal*, Feb. 1.

THE ADVANCE IN RUBBER.—A correction, which arrived too late for insertion, in the advertisement of Messrs. Lynch and Co., (Ltd.), Aldersgate Street, E.C., in last week's issue, slightly alters the reading in reference to india-rubber water-bottles. Instead of "No advance" being made in the price of these articles an advance of five per cent should have been notified. This is occasioned by the increase in cost of the raw material, but Messrs. Lynch intimate that no uniform advance will be made. Each article will be dealt with on its own merits, and they will make reductions and revert to old prices as soon as opportunity arises.—*Chemist and Druggist*, Feb. 3.

QUEENSLAND: DEPARTMENT OF AGRICULTURE. —A great deal of useful information is contained in the Annual Report of this Department, just received. Meantime we quote what is said in the chief report about our old staple:—

COFFEE.—Though this, like rice, is grown upon the coast side of the main range from Cooktown to the Tweed Heads, the tendency is towards cultivation in the tropics, where plantations are now being cultivated upon a commercial scale. It has only been within the last three years that the interest shown in this product has demanded the attention of the Registrar-General from a statistical point of view, but from that time the increase in area has each year shown a fair advance. Taking the last two years for an example, it will be found that in 1897 there were 180½ acres of productive coffee trees and 130½ of non-productive, and in 1898, 199 acres and 233 acres respectively. The figures show an evident advance in the area planted, and the information to hand points to the statistics of the present year being yet more favourable. The imports for 1898 were 170,886 lb., and upon that basis there is room for the use of 602 acres before we overtake our consumption, which, upon the present population of 498,523, is at the rate of 456 lb. of coffee per head each year. The market in Europe, however, is good, and though we may not yet have learned how to offer our goods in the most attractive manner, the opinion expressed by the trade in London upon Queensland coffee is very favourable, and by the time we are in a position to place a fair quantity for export that method of preparing our coffee will have been attained, and we shall be able to compete with those countries wherein coffee-growing has been prosecuted for centuries. The appointment of Mr. Newport as instructor in coffee culture has given an impetus to this branch of tropical agriculture, and as he has also an intimate knowledge of what may be termed allied products, such as spices, the benefits to the farmers of the North will be greater than was anticipated. The death of Mr. E. Cowley, and the exigencies of the Diseases in Plants Act at Cairns has precluded Mr. Newport, up to the present, from giving that attention to instruction he would have wished, for the reason that he was retained in Cairns to supervise the nursery, and to attend to the inspection of fruit. Arrangements have, however, now been made to release him from that detention, and his services will henceforth be at the command of the coffee-grower. A report from him upon this subject is attached herewith.

THE PETROLEUM TRADE.

(Special Report.)

The year 1899 has been one of great revolution in the Petroleum trade, prices having shown very material advance, owing mainly to the many new and large uses which have been found for Petroleum products. Among these, Liquid Fuel for use outside of oil-producing countries is a large factor, while it must not be forgotten that the falling-off in the supplies of the Langkat Company's oil has created a void in the east which the production, certainly not increasing, in Russia and America, has found it difficult to fill.

AMERICAN.—The production of Crude Petroleum in America for the last three years has been as follows:—

1897	2,132,759,000	Imperial gallons,
1898	2,111,034,000	" "
1899	2,058,656,000	" "

The Exports were as follows:—

1897	975,515,000	Imperial gallons
1898	1,034,250,000	" "
1899	1,082,345,000	" "

That the Americans have exported to the utmost possible, in view of the improved prices, is evident from the following table:—

Remaining for home consumption per head of the population:

in 1897	18'16	Imperial Gallons
1898	16'92	" "
1899	14'00	" "

LANGKAT.—The supplies of illuminating oil from this source which, during 1898, reached approximately 5,000,000 cases, and which were expected to reach during 1899 nearly double that quantity of have, during the year, fallen off to such an extent that the monthly production during the second half of the year averaged from 150,000 down to 120,000 cases, and today does not exceed the rate of 120,000 cases per month—thus leaving a large void to be filled.

RUSSIA.—The production of Crude Oil in Russia during the last three years was as follows:—

1897	1,883,810,000	Imperial Gallons
1898	2,216,700,000	" "
1899	2,307,957,000	" "

It must be borne in mind that the fast growing increase of demand for Liquid Fuel in Russia has absorbed a very large proportion of the increase, while the production at Baku is immaterial, seeing that the transport facilities by rail from Baku to Batoum are extremely limited, and during the year were more so than usual owing to the removal of a very large number of waggons by the Government Railway Authorities for purposes of repair. A larger number than usual of interruptions in the Railway were also experienced, while the increasing favour in which Russian Oil is held in Europe, and the consequently increased demand for it, have made a call for a larger proportion of the Oil received in Batoum than usual.

The total exports from Black Sea ports of Russian Oils, including Crude, Refined and Residuum during the past three years, have been as follows:—

1897	57,100,000	Poods
1898	68,701,000	" "
1899	69,738,000	" "

(N. B.—One Pood equals approximately 4'378 Imp: Gallons of Refined Oil).

In Russia, as also in America, although the high level of prices reached has stimulated boring to a large extent, nevertheless production has not been materially increased, as it is stated that by boring their Wells too close together, a new Well robs older ones of their production, and this is evidenced

by the reduction in the number of new spouting wells in Russia.

VALUES.—The values in America have been as follows:—

For Crude oil	Jan. and Feb. 1899	\$ 1'15	per Barrel.
	March to June 1899	1'13	do
	July 1899	1'21	do
	August 1899	1'27	do
	September 1899	1'43	do
	November 1899	1'58	do
	December 1899	1'66	do
	January 1900	1'68	do

In Russia values of Refined oil per Pood were as follows:—

	Free on Rail, Baku:—		
January 1899	23½		Copecks per Pood.
February	22½		do
March to April	16½		do
May	19½		do
June to July	22½		do
August	25½		do
September	24 9-16		do
October	30		do
November	38 11-16		do
December	47½		do
January 1900	55		do

In addition to this continuous but fast increase in values, has to be reckoned an increase in the Railway Tariff from Baku to Batoum of four Copecks, viz; from 12 Copecks to 16 Copecks per Pood, while the premium on waggons paid in Baku has gone from 3 to 13 Copecks per pood, thus bringing practically home the shortage of waggons and transport facilities.

Prices of Russian case oil have increased from 2s 7½d to 2s 8d in April to May up to 4s 4d at the end of the year—the last being a purely nominal quotation, as there were no sellers.

Today's parity for Bulk Oil is 4s 8d per case. The same position continues today, although quotations are considerably higher.

American case oil has steadily increased in value from 5 cents per American gallon in January to 11 cents in December.

OTHER SOURCES OF SUPPLY.—Although other sources of supply than Russian and American were eagerly sought for during 1899, none came to such an advanced state that exports of Refined oil were made. The value of the Roumanian fields is very doubtful, but even if the value should turn out to be considerable, the geographical position is not favourable, and a very large cost would have to be incurred, and a very long time occupied, before the oil could be got to the sea-shore.

Borneo has made giant strides, but the difficulties encountered owing to the nature of the country and the climatic conditions have postponed the actual shipment of Refined oil, but the first cargo is expected to be available this month.

It will be seen, therefore, that while production in America and Russia has been practically at a standstill, there has been no production elsewhere to make up for:—

(1). The larger demand for Petroleum owing to its utilisation for fresh purposes; and (2) the material falling-off in the production in Sumatra. The obvious result was, therefore, an increase in values, which has been very material, and which has checked somewhat the extended use in Asiatic countries of Kerosene, so that the increased demand for Kerosene for native consumption in the Far East which has steadily been experienced during the last ten years, was not continued during 1899—which was felt to be a relief by all connected with the Petroleum trade, as it would only have increased the difficulties which were experienced during that year by all connected with the trade in supplying the demand.

COORG IN 1889-99 :

COFFEE, RAPIDLY DECLINING IN AREA: INDEBTEDNESS INCREASING.

We have just received a copy of Report on the Administration of Coorg for the year 1898-99, which shows that the once favourite coffee district of Southern India is fast entering on "the sere and yellow leaf" stage for that staple. Once on a time, when the worthy Highlander, Donald Stewart, was regarded as "King of Coorg," no coffee district was more prosperous. From the detailed Report we quote as follows:—

COFFEE.—The total area of coffee land was 1,04,545 acres against 1,08,611 acres in the previous year. As explained last year this area includes a great extent of land which, though originally under coffee, is now allowed to remain waste by its owners as not suited for coffee. It also contains a considerable extent of Cardamom lands. Many of these waste lands, however, have been resigned by their holders during the year, the depression in coffee rendering them less saleable than before: hence the falling off in the acreage.

The area of assessed coffee lands held by European and native owners respectively is as follows:—

	No.	Acres.
European Estates	378	32,612
Native	14,639	71,933
Total	15,017	1,04,545

COFFEE.—The coffee crop during the year was 4,558 tons against 2,500 tons in 1897-98. Although the crop was satisfactory in quantity, it, for some unknown reason, turned out to be, as a rule, poor in quality. Owing to this and to a glut of coffee in the market caused by large supplies from Brazil, wretched prices have been obtained and the industry is in a very depressed state.

TEA.—The tea planted in the Sampaji Ghant was not very successful, perhaps owing to the operations being somewhat hurried. Planting is being continued this year with every prospect of greater success.

CINCHONA.—The planting of cinchona has ceased in Coorg. There is a chance, should the present prices continue, of attention being again turned to this cultivation. An application was received for the right to bark some trees on one of the abandoned estates. The right was put up to auction, but only the small offer of R100 received.

Then the Commissioner makes the following remarks:—

The year's harvest was good, but prices ruled low. The coffee crop was also good; 4,558 tons against an average of 3,200 tons. Unfortunately the prices realized have been very disappointing, especially for the poorer sorts, owing to the home market being over tasked by Brazil coffee, and in spite of the good crop the industry is seriously depressed. In Padinalknad, where the coffee crop was bad and coffee itself threatens to die out, with the sanction of the Chief Commissioner, the postponement of half the assessment has been allowed.

It is trusted that the figures given above will not lead Government to believe that Coorg is at present a most prosperous Province. For such is unfortunately not the case. One may try not to take too gloomy a view of the prospects of the Province, but it is impossible not to feel that there is cause for grave anxiety. The Coorgs have been living for the last 20 years on borrowed capital. They have fallen into lazy and extravagant habits, as they themselves admit. They have borrowed on their lands, till they are hopelessly in debt, and cannot raise any more money even at 50% interest. Their families are increas-

ing, but the nature of the country is such that the area of cultivation cannot be increased in proportion. The threatened failure of the coffee industry owing to the competition of the Brazils will also, if it continues, mean poverty to many a hitherto well-to-do Coorg family. The Coorgs are getting poorer and poorer and consequently discontented, and of course they blame Government, not themselves, for all their difficulties. There has been some talk of raising a Coorg Regiment. This is a project which, if carried out, will do good by affording employment to the young Coorg, who now too frequently does nothing but loaf round the toddy shops. But what is really required is some scheme by which the ryot could be given a chance of getting out of debt. At present he is hopeless and consequently reckless.

And on this the Chief Commissioner, Lieut.-Col. Donald Robertson, C.S.I., writes as follows:—

I am afraid we may look in vain for an agricultural revival in Coorg. Not only has there been no improvement since the termination of the period now being reported on, but the general depression may be said to have deepened; for though there will, it is confidently expected, be no famine, the rice crop has suffered in various parts and failed altogether in a few villages, whilst those coffee estate-holders who have been fortunate enough to secure moderate crops, are confronted with a discouraging outlook in respect to prices obtainable in England. Additionally coffee has entirely gone out, once flourishing gardens in large tracts in the West of Coorg containing now nothing but bare poles, and it is only the remarkable tenacity with which the Coorgs stick to their land, even though it may be commercially valueless, which prevents a large decrease in the land revenue demand. I confess that I am not hopeful that it will be possible to adopt immediately any remedial measures for removing the burden of indebtedness. The necessary reform should, moreover, originate amongst the Coorgs themselves. Their country has been pauperized by the introduction of such a ready means of becoming rich as presented itself some years ago in the cultivation of coffee, with the higher style of living which unfortunately resulted, and especially the facility for extensive borrowing which it afforded. It is now extremely difficult to obtain advances on coffee estates, and the Coorgs have nothing else to offer as security; if they mortgage their *sagu* rice lands (*jama* lands being inalienable) they cannot live. I carefully examined the very serious question of local indebtedness at my last visit to Coorg in February of this year, but was enabled to arrive at no satisfactory conclusion. The matter seems to be as yet hardly ripe for Government intervention nor is the situation so desperate as to call for extraordinary measures. There are, I believe, some signs that the Coorg character is slowly undergoing change in a recognition of the necessity for thrifty living and the abandonment of the foolish pride which has operated to prevent the people taking service, whilst it tolerated dissipation and laziness.

The case is one somewhat similar to that which occurred in Uva when coffee failed: the natives who owned coffee gardens were, for a time, hopeless and helpless. But by degrees they have come round and now find other products to grow in their gardens.

RECEIVERS OF JAVA COFFEE in this city have been advised that the coming crops of that description of coffee are growing less satisfactory than heretofore, the flowering in many districts having been insufficient, so that not more than a small half crop for 1900 can be counted upon.—New York *Merchants' Review*, Dec. 1.

THE COFFEE INDUSTRY IN QUEENSLAND.

OPENINGS FOR PLANTERS.

Recent advices from Brisbane point to a marked development as a result of Government encouragement in the coffee trade of Queensland, and information is being circulated which should be of particular interest to small capitalists and others who may be considering the advisability of settling in the Colony, or of migrating from one part of the Empire to the other. The cost of the land would, we understand, vary considerably, according to the conditions under which it was taken up—as a homestead selection, agricultural, farm, or freehold land purchased outright. There is land open for selection all along the Queensland coast. The Brisbane Land Commissioner states that there were 50,000 acres of scrub land on the Blackall Range, within fifty miles of Brisbane, suitable for coffee or fruit growing, and open to selection at 2s 6d an acre as homestead lease to the first persons that came along. A few miles back from the coast at Mackay, Cairns, and other northern ports, freehold land may be purchased from 2l an acre upwards. Excellent sites, sheltered from the strong winds which prevail at certain periods of the year, can be chosen on the slopes of the coast hills, which, from their irregular conformation, are unsuitable for general agriculture, but which are all that could be desired for coffee culture. Should the site chosen be freehold land, it may be put down as a general average that 3l an acre would be the cost of purchase. The cost of cutting and burning off the scrub would not exceed 4l an acre. To grub out the heaviest stumps might take 3l or 4l more an acre, but this operation, to a man of limited means, is, to a certain extent, unnecessary, as the stumps may be allowed to rot away. Digging holes for the plants would increase the outlay by another 4l. The whole cost of preparing the plantation would be about 12l an acre. Taking, for instance, a plantation of thirty acres, the expenditure would be approximately:—Cost of land, 90l; clearing (if heavily timbered) and planting, 360l; farming appliances, say 30; fencing, say 60l; total, 540l. There would be other contingent expenses, a dwelling-house, two horses and other items, the cost of which would depend largely on the settler's taste and disposition; and the expenses of living, keeping down weeds, and tending the young trees for three years, until they began to bear, would also have to be taken into consideration. Of course if he has been accustomed to manual labour, much of the above outlay would be avoidable with the help of one or two kanakas, or a couple of sons fit for field work. Opinions differ as to how many trees should be planted to the acre; the estimates range from 700 to 1100. Experienced planters state that 1,000 are not too many where the soil is rich, the land well cleared, and economy of space has to be considered. At the end of three years the first berries appear, yielding approximately one-fourth of a full crop. In the fourth season about a half crop may be expected, and in the fifth year the trees are in full bearing. Each tree will yield 2lb of parchment coffee, which means for 1,000 trees 2,000 lb of parchment. Taking the mean between the various estimated costs, it may be set down that the cost of picking will amount to ½d per lb of berry from the tree, or to 3d per lb of parchment coffee. During the past few years the selling price of the coffee locally has ranged from 7½d to 12d per lb. As importers pay about 9d per lb for inferior coffee from

Fiji, it seems a fair average to estimate 9d as the ruling price of the local product, and at that figure European merchants have offered to buy Cairns and Mackay coffee in unlimited quantity. This would leave a balance of 6d per lb to the producer, which, at a yield of 2030 lb per acre, is 50l. Out of this return all incidental expenses would have to be deducted. Discounting all the estimates, disregarding the fact that growers in North Queensland have netted from 40l to 60l per acre, allowing for an increase in the expenditure, a fall in the price of coffee, and setting the net gain as low as 20l per acre, then the owner of a thirty acre plantation should find himself at the end of five years in receipt of an income of 600l a year.—*British Trade Journal*, Feb. 1.

MINOR PRODUCTS REPORT.

ANNATTO.—At the auctions good bright Ceylon seed brought 2d per lb, and another lot of 18 bags was bought in at 3½d. Privately, business includes parcel of eight bags Ceylon seed at 2d per lb ex auctions of January 18th.

CINCHONA.—A parcel of 18 bales flat cultivated Calisaya bark catalogued for sale had been sold privately. Of Crowned and grey bark 62 packages were offered, and all sold at from 6½d to 7d for fair brown Huanco quill, and 1s to 1s 1d for good Loxa.

COCA LEAVES.—Fair bright Ceylon leaves, the only kind offered sold at 1s 0½d per pound, and broken ditto at 7d.

EUCALYPTUS OIL.—In auction a parcel of four cases Citriodora, which had been previously offered, were held for 1s 4d per pound. Privately the market is somewhat quieter this week, with small sales at 1s 10d to 2s per pound for B. P. quality.

SPICES.—A good business has been done since our last report at steady to rather dearer prices. At auction on Wednesday the first arrivals of new crop Cochín ginger were offered, and sold at 32s per cwt for good boldish washed rough, slightly monldy. New crop Calicut brown rough was bought in, a bid of 32s being refused; bold rough sold at 35s, and medium native cut, slightly wormy at 51s per cwt. There has been a good demand for Japan, and a fair quantity has been sold privately at 24s per owt. Bengal remains unchanged at 25s. Chillies are firm, a parcel of ordinary Zanzibar sold at 42s per cwt. A very nice lot of East India Capsicums, long red on stalk, sold at 39s 6d per cwt; some dark and mixed being bought in at 35s per cwt. Pimento sold at 3½d per pound for ordinary to fair quality. Cinnamon Chips of good quality are scarce, and were held for 4d per pound. Pepper is dearer, Singapore black is offering at 6d per pound on the spot, and 6½d for forward shipment. Tellicherry was bought in at 6½d. Singapore white was bought in, but sales have been made privately at 8½d to 9 1-16d on the spot, and at 9½d to arrive. There has been a good demand for Penang white at 8 9-16d, and 8½d is now wanted.—*Chemist and Druggist*, Feb. 3.

TROUT OVA FOR NUWARA ELIYA.

Another consignment of 10,000 trout ova of the brown species for the Ceylon Fishing Club was brought from England last month by the German mail steamer "Koenig Albert." The consignment was from the firms of Messrs. Andrews and Andrews of Guildford. Shortly after the vessel's arrival, Mr. Elhart went on board and took charge of the ova, proceeding to Nuwara Eliya by the same night mail train. The ova will be placed in the hatcheries and the results will be awaited with interest, the more so as the last lot got out was not so successful as it should have been.

A NEW RUBBER.

THE HANCORNIA OF ST. PAUL, BRAZIL.
(Circular of Messrs. L. P. Barretto and Son, of
Piritura, Saint Paul, specially translated.)

The rubber furnished by the latex of these trees is a product of the first order equalled only by the *Hevea* of the Para.

In every respect, the *Hancornia* should be preferred for exsive culture. While the *Hevea*, like the *Manihot Glaziovii*, cannot go far from the tropics, under penalty of perishing, or of giving poor results, the *Hancornia* stretches from the equator to the 36th parallel South: it braves the tropical sun as well as the frost of our cold temperate zone.

The *Hevea* require soil rich in humus and in water. They have aquatic roots three quarters of the year. The *Hancornia*, on the contrary, require poor, dry soil: prolonged damp kills them.

Unfortunately, the germinative faculty of *Hancornia* seeds is very short: it fails after 12 or 15 days, and is impossible to send them to Europe. We have striven to find some means of conserving them.

Another difficulty has hitherto hindered the transport of these plants to other regions, namely the nature of the physiological rôle of their "sucker," an essential organ of nutrition during the first age. The least disturbance of this "pivot" or sucker during the first stages or in potting would kill the plants. But we have succeeded, after countless experiments, in overcoming this difficulty, and can deliver thousands of plants in Europe prepared and packed so that they can continue their journey to Africa or Asia. Three kinds are available: 1st, *Hancornia speciosa*, a kind known for some time, giving from 1 to 5 kilo per foot and per year. Good edible fruit; 2nd, *Hancornia* with a globular fruit, new, from the coldest zone of the State St. Paul, and giving from 5 to 10 kilo, good fruit. 3rd *Hancornia* with (pyriform) cone-shaped fruits (*Hancornia Barrettoi*, *Nandin*) recently discovered, from our warmest zone, rejoicing in soil neither too dry, nor too arid. It is the king of rubber trees giving up to 15 kilo of the finest rubber with one incision. Delicious fruit. Plants should be despatched between April and September.

THE ABYSSINIA BANANA MUSA
ENSETE.

We are indebted to the Director of Kew for the photograph of a bunch of fruits of *Musa Ensete*. Flowering examples may now and then be seen in the houses at Kew. The bunch of fruits now figured was forwarded to Kew by a Covent Garden agent, who had received it from the Azores as a "peculiar Palm fruit, which might be obtained in quantity from that island." The diameter of the bunch was 12 inches. The fruits were not mature, consequently they did not contain the large seeds which this species generally produces abundantly. In this respect, and also in the fruit being coriaceousdry, and inedible, *M. Ensete* differs from the *Banana* proper, *M. sapientum*. The soft inside of the "stem" (really the folding bases of the leaves), is, according to the traveller Bruce the best of all vegetables. When hoiled, it has the taste of the best new Wheat-bread not fully baked. Only the white "heart" of the stem is eaten; this is well boiled, eaten with milk or butter, and it is wholesome, nourishing, and easily digested. *M. Ensete* is a native of Abyssinia and equatorial Africa, but it is now widely distributed in the tropics. Young plants of it are used for summer effect in the London parks. According to the *Kew Bulletin*, the total weight of a single plant grown in the tropics is about a quarter of a ton.—*Gardeners' Chronicle*, Feb. 3.

PRODUCE AND PLANTING.

INFERIOR TEA CHESTS.—Grocers not infrequently complain of the bad condition of the tea chests they receive. This is a strong argument in favour of the use of patent tea chests. The grievance was made the subject of a resolution at the Grocers Association to be sent to tea importers. At a General Purposes Committee of the Federation of Grocers' Associations, held at Birmingham last week, Mr. Pitts proposed the following resolution on behalf of the Northampton Association: "That the members of this Association desire to bring before the General Purposes Committee the condition of tea chests as now used (more especially those containing Ceylon tea), green sappy wood being employed in their manufacture, thereby depreciating the value of the tea, and would urge upon the General Purposes Committee the desirability of making advances in the proper quarter with a view of obtaining a remedy." Since the matter was brought to his notice, he said he had made inquiries, and he found that there was a tendency to pack tea in chests made of green sappy wood. The grievance was due to unsuitable timber being used in the manufacture of the tea chests for the Indian and Ceylon plantations. The remedies suggested were that the planters must more carefully select and dry the timber from which they made the chests. The members of his own association were of opinion that there was just cause for serious complaint, as there was considerable loss sustained by the tea dealers and retailers. If this was a grievance then it was their duty to find a remedy for it. They might add to that another grievance—and that was in regard to charges for wrappers on chests and packages. They were charged at the rate of 1s for a chest, and 9d for half a chest, and he held it to be a most unjust charge. It did not cost the importers anything like that amount, and why they should want to make a profit out of the traders in that matter was unaccountable. For his own part he never paid these charges, and he always deducted half the charge, though some members paid the full amount. Mr. James seconded the resolution, remarking that Mr. Pitts's statement, that he only paid half the amount for the wrappers, was a lesson to him, because he always paid in full, and he certainly thought it a most exorbitant charge, and one that should be considerably reduced. Councillor Gower suggested, as a representative of a triplate district, that Mr. Pitts should advocate the use of tin chests instead of wood. Mr. Jump said he had not personally had experience of any of the had chests, but he had noticed that some of the Ceylon chests broke up very easily. The wood seemed to have contracted, and in some cases the tea was slightly damaged. He would suggest that they should bring the matter before the attention of the Indian and Ceylon tea importers in London, and he had no doubt that it would be productive of beneficial results. Mr. Pitts agreed that the resolution should be sent to the various associations of tea importers, and the resolution was carried unanimously.

THE VICEROY'S VISIT TO ASSAM.—If, as cabled from India, the Viceroy is to pay a visit to Assam next month it will be a historic occasion, no previous Viceroy having visited the province. His Excellency, it is said, is going right into the interior, to Gowhatty, for the purpose of seeing the actual condition of the tea plantations.—*H. & C. Mail*, Feb. 9.

TO TEST IVORY FOR GENUINENESS.

As ivory is extensively employed, and costs about six shillings per pound, it has been attempted to substitute a cheaper substance having the same appearance. For about forty years an article has been in use in this industry which has its origin in the vegetable kingdom, being derived from the nut of a palm-like shrub called *Phytelphas macrocarpa*, whose fruit has a very white

and exceedingly hard kernel, which can be worked like ivory. One hundred of these fruits only cost about four shillings. Their use for buttons and small articles offers great advantages, and the "ivory" can be passed off as the genuine article, the resemblance being so great that it is sold at the same price. It can be coloured also just like genuine ivory. M Pasquier, of Liege, now gives a practical method to distinguish the two varieties of ivory. It is the following:—Concentrated sulphuric acid applied to vegetable ivory will cause a pink colouring to appear in about ten to twelve minutes, which can be removed by washing with water. Applied to genuine ivory, this acid does not affect it in any manner.—*The Family Herald*.

THE TALGASWELA TEA CO. OF CEYLON.
(LIMITED)

THE ANNUAL REPORT.

The report of the directors was as follows:—

Approximate acreage of tea cultivated ..	516 acres.
Not weeded	
Cinnamon	50 "
Forest, Chena, &c.	1,473 "

Total 2 039 .

ACREAGE.—In October last 210 acres were taken out of cultivation, upon the recommendation of the Visiting Agent, who reported that the bushes were stunted; and, owing to the large number of vacancies, the yield from this portion of the estate was inadequate as compared with the cost of upkeep and cultivation. This will effect economy in working, without, except very slightly, reducing returns. The area specified in tea is still however nominal, owing to the inclusion of swamps and ravines in acreage statement as retained in cultivation.

The Directors beg to lay before the Shareholders their Twelfth Annual Report with a duly audited statement of the Company's affairs on the 31st December, 1899.

Mr. R. Morison last visited the estate on the 30th and 31st December. His report is attached for the information of the shareholders.

The yield for the year was 148,902 lb., against original estimate of 160,000 lb., and a revised estimate of 145,000 lb., dry weather being responsible for the shortage. It was all sold locally, at an average of 34.92 cents per lb., against an average of 34.71 cents for the preceding year. The demand for Ceylon teas in the local market during the year has, on the whole, been satisfactory, a very noticeable feature throughout having been the good prices made by teas of medium and lower quality.

The expenditure on manure was R4,363.11, equal to 02.74 per lb. of made tea, and was debited to revenue account. After paying for this and writing off the usual depreciation on buildings and machinery, the balance at the credit of profit and loss account is R4,070.96, which, in view of the heavy expenditure on manure recommended by the Visiting Agent, the Directors strongly recommend the shareholders to carry over to a new account, they being strongly of opinion that to declare a dividend in the present position of the company would be suicidal.

The estimate for the coming season is 160,000 lb., and the Directors are fully alive to the importance of keeping expenditure down to the lowest point compatible with efficiency and proper cultivation. The Directors feel assured that the only method of making this property pay is to cultivate highly and to manure heavily, and they are prepared to follow out the recommendations made by the Visiting Agent in his last report relative to the manuring of certain fields.

PLUMBAGO.—An offer of £1,000 with a five per cent royalty was made for an option for six months on the mining rights of the property, but the Board thought the offer insufficient, and it was declined. In view of

possible developments in connection with plumbago, the Directors think it would be advisable for the Shareholders by consent to authorise them to make such arrangements as may be compatible with the interest of the shareholders.

Messrs. W MacGregor and J A Henderson were elected Directors at the last General Meeting; and of the Mr. Henderson retires by rotation, and does not offer himself for re-election, as he is going home. The Directors recommend the appointment of Mr. Morison, the Visiting Agent, in his stead.

The appointment of an Auditor is left to the meeting.

THE VISITING AGENT'S REPORT.

In reply to your post-card asking for an abridged report on Talgaswela, I think that the following might be taken as the expression of what appears to me important at the present times on Talgaswela.

MANURING.—As previously reported, 40 acres of No 1 was manured in June-August, 1899; while 60 acres of the same field, the 22 acre field, and 4 acres of No. 5 had prunings buried along with basic slag. The appearance of all these fields is very satisfactory, and the fields will I think fully justify the cost of manuring by shewing paying returns within the 12 months, if the work is now completed by manuring in the alternate lines to those in which prunings were buried. This work should be done by applying the manure in long narrow holes 6 inches deep up middle of alternate lines, or by forking in up middle of alternate lines. I recommend 800 lb. per acre as follows:—

lb.		per ton.	per acre.
500	W Castor Cake	at 68.88	15.37
130	Basic slag	at 54.63	3.17
85	Sulph. of Potash	at 171.60	6.45
85	Blood Meal	at 152.50	5.79
800			30.81
	Tranp. 6 Appl.		4/10 00

40.81 per acre.

In future working I would very strongly urge the burying of prunings as described in previous reports, each hole having added to it on top of prunings about one-half pound of basic slag. [See report of 30th March, 1899.] The present conditions of the tea bushes is so largely due to want of organic matter in the soil, and that want is a point of such vital importance in the considerations of any of scheme cultivation, that the burying of prunings (the only means available within practical limits for increasing this organic matter) appears to be little less than an absolute necessity. This is emphasized by the fact conclusively proved by chemical analysis that each pruning left unburied deprives the soil of essential fertilizing ingredients to an extent equal to one, two, or three full manurings according to the vigour of the bushes dealt with; in other words, the non-burying of prunings may, in certain circumstances, and at one single pruning, be equal to the throwing away of fertilizing matter represented by six years' outlay in manuring on a liberal scale.

A point of much importance as an aid to any scheme of cultivation which may be adopted is that the actual acreage in tea should be clearly defined. An essential element in any system of manuring is the checking of cost against returns obtained, and this is of course impossible with undefined fields. In such fields data which will clearly shew whether and how much manuring pays is impossible, and any work done must be subject to adverse criticism. Without advocating any elaborate detailing of acres, I therefore think a survey which would place the actual tea in the plan in your fair sized fields such as Mr. Symonds recommended for working purposes is a most desirable thing and necessary if cultivation is to go on.—I am, dear sir, yours faithfully, (Signed) R. MORISON, Neboda, 6th Feb., 1900.

THE CLAREMONT ESTATE CO., LTD.

THE ANNUAL REPORT,

ACREAGE.

	Acres.
Tea in bearing	200
Tea in partial bearing ..	46
Forest, Ravines, &c., ..	90
	336

The Directors submit herewith the Balance Sheet and profit and loss account duly audited for the year ending 31st December, 1899.

The yield for the year was 81,281 lb. against estimate of 85,000 lb. costing 24.54 cts., laid down in Colombo, inclusive of up-keep on the 46 acres New Clearing from which only some 4,000 lb., were secured.

Estimate for 1,900 is 90,000 lb., to cost in Colombo, 25.83 cts.

The Tea was all sold locally realising 34.97 cts. per lb., nett.

Mr. A Orchard retires by rotation and offers himself for re-election.

The election of an Auditor rests with meeting and Mr. Guthrie again offers his services.

In view of the present position of affairs and the near approach of the due date of the Mortgage for £3,500, the directors hope that as many of the shareholders as can attend will come to the meeting.

NEBODA TEA COMPANY, LIMITED

THE ANNUAL REPORT.

ACREAGE :

Tea in full bearing	157 acres.
„ in partial bearing	226 „
„ 2 and rising 2 years old ..	112 „
	495 acres.
Forest and Waste Land	240 „
	735 acres.

The directors submit their report and accounts for the year ending 31st December, 1899.

The total extent of the Company's property is now 735 acres, the previous total of 666 acres having been added to by the purchase of 69 acres of forest and chena near Nanthupana.

The crop secured, namely 184,322 lb tea was sold in Colombo at an average of 35.09 cents per lb., as against 33.33 cents the price obtained for crop of 1898 of 126,940 lb.

The tea in full bearing yielded as follows :—

On Nanthupana	755 lb. per acre average.
On Nehoda	522 „ „

and the cost of production was 22.67 cents per lb. or without manuring, 19.88 cents.

Profit in the year's working amounts to R22,651.62. Of this amount R7,830 was disbursed in November 1899, in payment of an interim dividend at three per cent in the Company's Capital, and the Directors recommend that the available balance, namely R14,821.62 be disposed of as follows:—

In payment of a Final Dividend of two per cent R5,220.00. And the balance to Reserve Account R9,601.62.

In terms of the Articles of Association Mr. Robert Morrison resigns from the Board of Directors, but, being eligible, offers himself for re-election.

The appointment of an Auditor resigns with the Meeting.

HORREKELLY ESTATE COMPANY,
LIMITED.

THE ANNUAL REPORT.

The Directors have pleasure in submitting the accounts of the Company for the year ending 31st December, 1899, showing, after writing off R5,901.95 for depreciation on Buildings, Plant and Machinery, a profit of R19,714.89, which, with the balance of R848.14 brought forward from 1898, gives a total of R20,563.03 available for distribution.

The Directors recommend that a dividend at the rate of 5 per cent on the Capital of the Company be declared. This will absorb R20,000, and leave a balance of R563.03 to be carried forward to 1900.

The working of the estate for the years 1897, 1898 and 1899 compares as follows:—

	1897.	1898.	1899.
Expenditure on Estate ..	R 32,066.69	R 37,014.85	R 36,754.67
& in Colombo office...			
Number of Coconuts produced ..	1,400,835	1,437,885	1,305,429
Quantity of Coir Fibre made ..	Ballots 28,553	35,474	28,324
Two Directors—Messrs. F. J. de Saram and Stanley Bois retire by rotation, and are eligible for re-election.			
The Shareholders have to appoint an Auditor for 1900.			

INDIARUBBER IN QUEENSLAND.

The following from the *Brisbane Courier* will be of interest to those who may contemplate taking up an industry that if carefully attended to may lead to an increase in the articles of production from this colony (New South Wales):—"The news from Cairns that a number of local men are arranging to begin operations in the manufacture of india-rubber is important. The raw article can be obtained from indigenous trees in the shrub, and is said to be of first-class quality. What is perhaps, more important, the supply is inexhaustible. One of the chief values attaching to the recent New Guinea concession was the practically unlimited quantity of rubber there obtainable. To find, therefore, that a similar condition of affairs exist within easy distance of a port like Cairns, is to say the least, encouraging. Then, as regards the industry itself, its outlook is as bright as it possibly could be. The marvellous demand for bicycles of late years has given an immense impetus to the rubber trade, india-rubber being also a highly perishable article is another important factor in the question of supply and demand. The demand will always exist, so the supply must be kept going. There is one consideration, however which these Cairns men will find obtruding on their notice sooner or later. That is the question of cheap labour in collecting the article. This must be considered when it comes to competing with others. In New Guinea, for instance, labour is cheap and on the spot. Here in Australia we have practically none of this native labour. The nearness to a port for shipment may counterbalance this advantage which New Guinea rubber traders would derive from a handy labour supply. Our Department of Agriculture has during the year been trying by a series of articles to direct attention to this industry. It will also place another string on the Cairns bow in raising that town into a place of much importance in the future."

RICE-CROP IN SOUTHERN INDIA.—Here is the latest official summing-up:—

The result is that the estimated outturn amounts to nearly 1,940,000 tons of cleaned rice, which is, on the basis adopted, about 30 per cent. less than what may be regarded as a normal crop and is 29 per cent. less than the estimated yield last year. The bearing of these figures on the question whether there is likely to any exportable surplus available may be judged by the fact that on the balance of imports of paddy and exports of rice during the ten years ending in 1897-98, the Presidency showed a surplus of 23,976 tons of cleaned rice, and during 1898-99 one of 49,251 tons; but this result was only rendered possible by importing on the average 88,365 tons of other food-grains for the ten years, and 74,933 tons during 1898-99. This year there has already been a very large excess of grains exported over that imported, and the yield of the "dry" grains has over very wide areas been comparatively poor. They are, in regard to the food supply of the Presidency, of greater importance than the paddy crop.

TEAS AT PUBLIC AUCTION.

A FAULTY SYSTEM.

The practice of rushing teas through at public auction, and the effect on prices, is dealt with by a writer in the "Products Markets Review," who, under the head of "Combination," refers to certain allegations about which more light is needed. He says: "The recent fall in the price of the lower sorts of teas is currently said to be mainly due to an agreement on the part of a few large buyers to withdraw from the market. As a result of this belief the importers have met this refusal to buy by reducing their offers. In an ordinary state of things this would, no doubt, be a remedy for any combined attempt to affect prices, but in tea it is useless, because the supplies will simply accumulate, there being no means of disposing of them except at public sales. Buyers, therefore, know that, although offers may be scarce for the moment, they are only deferred, and that all wants will be satisfied a little later on. Whether the present alleged combination exists or not, and whether it has had, as is generally believed, so heavy an effect upon the market, we cannot say. At any rate, the allegation brings to light a fresh danger in the present system of public sales. A very few large buyers, as things are, undoubtedly have to some extent the market at their mercy. This should not be the case, and it is simply due to a faulty system. As we have often pointed out in detail, the present plan of forcing off all teas at public sale, and practically directly they arrive, is most injurious to the interests alike of the importers, and of the wholesale trade. It may tend, no doubt, to give a partial monopoly of the market to advertising houses, who must sooner or later recover from the growers some proportion of their 2d. or 3d. per lb. for advertisements, while the rest is charged to the public (a total charge that raises the average price some 20 per cent., and proportionately checks the consumption, again to the detriment of the planter). We hold that the present deplorable position of tea in this country is mainly due to the failure to supplement the public sale system by a proper proportion of sales by private contract, which are absolutely necessary if an article of fancy like tea is to fetch proportionate prices for its various grades and qualities. The reply of the brokers is that a considerable proportion of tea is already offered by private contract; but this is done in a manner which chokes off the bulk of the demand. An offer is made of an entire invoice, consisting of a variety of qualities at once, and the parcels are not subdivided, so that buyers, to get something they may want, have to take perhaps a lot of tea which they have no wish to buy for stock. Surely this is unreasonable, for it really destroys any advantage that might generally be derived from private purchases. It is replied that it would be unwise to let buyers, as it were, pick out the tit-bits of consignments, for the rest of the parcel would suffer. Sellers have, however, a complete safeguard against this in the prices they would accept and there would be no compulsion to sell as there is, more or less, at the present time when goods are put up to public sale. If, instead of withdrawing their supplies, sellers had simply decided to offer the qualities affected by private sale, and at reasonable rates, they would, while breaking down any combination, have at the same time relieved the market. Instead of this, they are only heaping up the supplies. It may be said that a combination might just as well extend to private purchases, and that it does so at the pre-

sent moment, but such attempts at restriction of trade cannot be maintained except under the opening given by the obsolete public sale system. With regard to the currently reported motive for the alleged combination, we can say nothing here, except that if A sins against B, it is rather hard of B to set to work to punish the importer C, who has absolutely no part or lot in the causes of the quarrel."—*H. & C. Mail*, Feb. 9.

PEARL SHELL FISHERIES OF THE DUTCH EAST INDIES.

Shells constitute one of the most important articles of exportation from Macassar. Up to the beginning of this decade they were sought almost exclusively by natives, fishing in the shallow waters in the bays, without using any diving apparatus. In 1893, according to the United States Consular Agent at Macassar, Celebes, an English company sent a schooner and some luggers to the Aroo Islands to try exploitation in deeper waters. This company appears to have had a good measure of success, for its fleet left the archipelago only when forced by a Dutch law of 1894, to the effect that only inhabitants of the Netherlands and Netherlands India, or companies established in these countries and under the Dutch flag, should be permitted to engage in pearl fishing. In 1896 the Eastern and Australian Trading Association of Amsterdam began operations which, however, do not appear to have been successful, for the company liquidated in 1898. In the meantime, residents of Dutch India were beginning to pay more and more attention to the shell fisheries, and Europeans, Chinese and Arabs endeavoured to make arrangements with the native chiefs, in whose territorial waters shells were supposed to be, and who generally granted the privilege of fishing for a fixed sum in cash, or a per centage of the quantity fished. Such contracts, however, were legal only after the sanction of the Governor-General of Dutch India, which has been accorded without charge. Shell fishing is at present carried on on the east coast of the Aroo Islands, on the east coast of New Guinea, on the Halmahera and the islands adjacent, on the east coast of Celebes and the Timor group. An undertaking on a large scale is the Djoempandang Maatschappij, established at Macassar in 1898 with a subsidised capital of £12,000, for fishing in the Timor waters, with a fleet of one schooner and ten luggers. The company has succeeded in securing apparently valuable concessions. The chief market for mother-of-pearl shells is Paris; only small quantities are shipped to London, Hamburg and Amsterdam. There were exported in 1896 about 150 tons; in 1897, 200 tons; and in 1898, 250 tons. There is no doubt that 1899 will show a further considerable increase. Notwithstanding this augmentation, prices have been fully maintained. Aroo shells sell at Macassar at £140 per ton; Timor, Ceram and New Guinea and Celebes shells at £80 to £100. Fishing is allowed during the whole year by the Government, but is occasionally prevented by the monsoons. Besides mother-of-pearl, there are also found in the archipelago cheaper varieties, which are obtained exclusively by the natives and used in Germany and England for button manufacture, etc. Of bunda or black-edged shells there is an export of about 18 to 100 tons yearly. Green snail shells are exported to the extent of at least 100 tons yearly and exports of mussel shells amount to about 30 to 50 tons annually.—*Journal of the Society of Arts*, Feb. 9.

PEABERRIES AND MALE COFFEE PLANTS.

Dr. D. Tomatis, commenting on a paragraph in the May number of this Journal (1899) on the subject of male coffee plants writes:—

"As our Government Botanist, Mr. F. M. Bailey, states, the coffee plant is neither *dicocious* nor *monococious*, but beyond doubt *hermaphrodite* as clearly shown by the examination of its flower. Why should the abundance of *pea-berries* fruit on a tree indicate that it is a *male*? Is not *peaberry* fruit all the same? And still more a *peaberry* seed germinates as readily as a bi-lobed berry. The paragraph says that the cause of *peaberry* fruit is not definitely known. I am surprised at this statement, as it is very easy to find the cause, which is in the poverty of the soil and the dryness of the weather after the blossoming time, as through these two causes the young fruit could not be fully formed, developed, and nourished; hence only one lobe grew, and the germ of the other became abortive and atrophied, and consequently the single lobe or grain grew in a roundish form, and the fruit, being a single-grained berry, is richer in the essential aroma. If the ground be rich, season favourable, tree well trimmed and pruned, and blossoms thinned, very few *peaberries* will be produced."

Reporting on the question raised in the paragraph and in the above letter, Mr. Howard Newport, Instructor in Coffee Culture, says:—

PEABERRIES AND MALE COFFEE PLANTS.

In the accompanying letter on this subject, sent on to me for an expression of opinion, I fail to see where the question arises as to why the abundance of *peaberries* on a tree should indicate that it is a *male*.

On referring to the article in the May issue of the departmental *Journal* quoted by the correspondent, it would seem that the first mention of the idea was in the form of a contradiction. It is later contradicted by the Colonial Botanist, and is in itself a contradiction. The amount of *peaberry* on a tree has nothing whatever to do with the sex of coffee.

Peaberry is the result of the failure, for some reason or other, of its fellow-germ to fructify. There are naturally in the embryo berry two cells and it would appear that under certain circumstances one of the cells, on coming in contact with the pollen, will fructify while the other will not.

That it is so clear on examination of the *peaberry* where the atrophied germ is discernable, and its envelope of parchment skin, folded together, still in its place within the "pulp." The reason why the pistils should convey the pollen to one ovule and fail to fructify the other, is the point that is not thoroughly understood yet, and not the state of the tree in which it is most liable to this condition, as your correspondent seems to think.

The *peaberry* is a mal-formation, and generally takes place when the tree is weak or in a state of low vitality, and this condition may be brought about by unfavourable conditions of soil, climate or cultivation. A tree overbearing will produce a larger percentage of *peaberry* than one with a more moderate crop, even though conditions of soil and climate are as favourable as could be desired.

The shape of the malformed growth is somewhat as your correspondent states. It was thought at one time that it was the production of a special variety of coffee-bush—at any rate, by those who had to do only with the cured article; and there are many yet that still adhere to this fallacy, due chiefly to the fact of its being graded separately.

Pea-berry obtains its higher value in the market chiefly on account of the advantage of its shape in roasting. Being easier to roast uniformly, it is supposed to contain a greater percentage of caffeine or aromatic properties, but this is exceedingly doubtful. Its presence on the tree is of doubtful advantage also. A large percentage of "P.B." grade—indicating, as it does, impaired vitality—although

its price is enhanced, is yet a long way short of the value of the double bean in the normal growth.

As a seed for propagation, "P. B." germinates readily, but repeated experiments have been able to show no advantage in the growth, stamina, or bearing capabilities of its production over that of the bi-lobe; nor does the plant raised from a *peaberry* show any special tendency to produce *peaberries*.

"MALE" TREES.—The coffee-tree is, as is well known, hermaphrodite; it is also well known that in such cases generally the contact of pollen from another tree or blossom obtains better results than its own pollen. It may be, therefore, that the *peaberry* is due, to a certain extent, to continued self-fertilising of the plant or "in-breeding."

It is supposed that the plant commonly called the "male" coffee-tree is due to this cause. However this may be among seedlings in a nursery, there is always found a small percentage of plants that appear with long narrow leaves, eyes closer together than ordinary, and a smaller and more stunted growth altogether.

In cultivating these in the field, it is found they bear very little, although they blossom freely. (I have never yet met with one that did not bear at all.)

The flower is somewhat smaller than that of the ordinary tree, but would structurally appear to be identical. It is supposed that the want of fertility is due to some malformation of the stigma or ovules, since the pollen is perfectly fertile when applied to other blossoms.

This tendency to produce blossom that will not fertilise, yet will fertilise others, has earned for this long-leaved tree the sobriquet of "male" coffee. Whether the presence of such trees in an estate is Nature's own remedy for a too long-continued course of "in-breeding," and is, therefore, of advantage, is a moot point. Generally the plant is considered useless and unnecessary (since the other trees, being hermaphrodite, can do without it), and since it bears so little, is not considered "worth its keep." It is, therefore, usually picked out and thrown away as early as it shows the tell-tale narrow long leaf in the germinating bed or nursery.—*Queensland Agricultural Journal*.

ENGLISH QUININE.

(To Editor "Chemist and Druggist,")

Sir,—On page 231 of your issue of February 3rd you quote from an interview alleged to have been held by a correspondent of the *Commercial Intelligences* with Mr. Elliot, of Toronto, in the course of which he is reported to have said, "We sell more German than English quinine because it is cheaper and purer." Whether Mr. Elliot is accurately reported or not we do not know, but we do know, that our quinine always passes the Codex Français test easily, whereas a reference to a German list will show that this quality is charged 2m. per kilo more than Ph. Ger. 11, which is the ordinary German quinine of commerce.—We remain, dear sir, yours truly,

HOWARDS & SONS.

Stratford, near London, E. Feb. 8.

—*Chemist and Druggist*, Feb. 10.

NOTHING LIKE RUBBER.—It has been suggested that the soldiers in South Africa should be supplied with india-rubber sleeping dresses for outdoor sleeping in the wet and cold nights of South African climate. A trooper, who procured a piece of very thin india-rubber sheeting and put a drawing string through the top of it, found the advantage of such an article as a night covering. It kept him as warm and dry as possible, and when folded up he wore it during the day time round his waist, where it looked like a belt.—*India-Rubber Journal*, Feb. 5.

Correspondence.

To the Editor.

NOTES ON CEYLON BOTANY:—NO. I.

DEAR SIR,—With reference to the cuttings from the *Pioneer* re Indian Botany, which you have kindly sent me for perusal, I think the history of Ceylon Botany will bear an interesting comparison with that of our neighbouring continental flora, inasmuch as the former dates back to a somewhat remoter period.

The Sinhalese, as a race, have been credited with being "natural botanists," and supposed to have possessed in pre-European times some systematic classification of their plants, as so many of their vernacular names would, indeed, seem to indicate. Those of us who have had any acquaintance with plants in other countries cannot but be struck with the comparatively intimate knowledge which the Sinhalese have of their native plants and their uses, as well as with the wealth of vernacular plant-names, which, unlike so-called English names, have the merit of being usually descriptive; many of the botanical names of Ceylon plants are, in fact, mere Latinisations of the vernaculars; as, for instance, *Elephantopus* Sinhalese "Et-adi," meaning elephant's footprint; *Kokoona* ("Kokoon" of the Sinhalese); *Ipomoea Pes tigridis* ("Divi-adiya" tiger's footprint); *Naravelia* ("Uara-vel" of the Sinhalese) &c. A fact which also suggests the precedence of Ceylon over India in early botanical operations is, that so many plants which are as common on the Indian mainland as in Ceylon are named *Zeylanica*. But

"What though the spicy breezes
Blow soft o'er Ceylon's isle"

and figure conspicuously in its ancient history, the earliest record of scientific interest in regard to the Flora of Ceylon, dates from about the middle of the 17th century. Thus the credit of pioneer botanical work here, as in India, belongs to the Dutch, the Portuguese having left no testimony of any special interest being taken by them in the botany of the island.

Prior to 1660 a Mr. Hartog was sent on a botanical expedition to Ceylon by Dr. Sherard, a leading botanist of his time; but the results of this undertaking are not of much consequence. The first important contribution to the knowledge of Ceylon Botany was made by Mr. P. Hermann, a distinguished scientist of his period and a medical officer of the Dutch East India Company by whom he was engaged in 1670-77 to "describe the plants and spices growing in the island." This was about twenty years before the advent of the *Hortus Malabaricus*, the first published record of Indian Botany. It may easily be imagined that Hermann's task was beset with many difficulties, the interior of Ceylon being then dangerous and practically impenetrable to Europeans, but he succeeded in making a dried collection of plants comprising about 660 species, chiefly in the neighbourhood of Colombo and Galle. This nucleus herbarium, having changed many hands in Europe and been "lost for about half a century," was ultimately purchased by the celebrated Sir Joseph Banks for 75 guineas, and is now an important botanical relic in the British Museum, London.

Hermann supplemented his specimens with manuscripts and drawings intended for publication;

but unfortunately the scientific world of his age did not gain by his labours, the result of which was not published till 1717 (22 years after Hermann's death) in the form of *Museum Zeylanicum*, an 8vo. volume with the plants arranged alphabetically under their native names with Latin descriptions. This may be said to be the foundation of the Botany of the East Indies.

A second collection made by Hermann, combined with Mr. Hartog's material already referred to, furnished the basis of the *Thesaurus Zeylanicus*, a 4to. volume issued in 1737 by Professor J. Burman, an enthusiastic botanist of Amsterdam. This was a creditable production in its time, containing 110 well-executed illustrations, with the vernacular names arranged alphabetically above copious Latin letter-press.—Yours truly,

X. Y.

NO II.

DEAR SIR,—Some years later, in 1745, Hermann's herbarium fell into the hands of the illustrious Swedish botanist, Chas. Linnæus, who after two years' careful study of its contents published in 1747 his *Flora Zeylanica*, a small 8vo., in which Ceylon plants are for the first time arranged on the famous sexual system invented by Linnæus himself and which bears his name. This book contains in Latin, a concise view of the progress of Botany from the restoration of learning in the 16th century. The great author has expressed himself thus on the vegetation of Ceylon:—"A delicious climate has granted to this island plants of such variety and value, that scarcely any soil can vie with it for the abundance of its aromatic productions. The pastures are scented with basil (*Ocymum*, 'Maduru-tala' of the Sinhalese) and its wood with cinnamon, cardamoms and flowers of the most exquisite colour, structure and fragrance."* The fact that Linnæus in his epoch-making book, *Species Plantarum* (1753), referred to the Ceylon species as *types*, renders Hermann's herbarium of special scientific value.

Dr. C P Thunberg, the celebrated botanical traveller, and Danish Physician, whose name is commemorated in the beautiful genus *Thunbergia*, visited Ceylon in 1777-80, and was followed in 1782 by Dr. J G Koenig, the "Father of Modern Indian Botany," who made an important collection of plants in the lowcountry, which he afterwards bequeathed to Sir Joseph Banks and it is now in the British Museum.

Whether in the cause of science or of the system of Government monopoly which was then in vogue, it is recorded that the Dutch had about the middle of the 18th century commenced an experimental garden in Slave Island, worked by slave labour—hence the name "Slave Island" of today. But this venture had apparently but a short existence.

Thenceforward for three quarters of a century scientific interest in the Botany of Ceylon seems to have languished. With the advent of British rule in 1796 it was recognised that a proper acquaintance with the vegetation of the island was necessary for the due development of its resources, and that the best means of inciting a desire for such knowledge, as well as of introducing and experimenting with new and useful products, was by establishing a duly equipped Botanic Garden.

Accordingly a site was chosen at Peliyagoda, on the Kelani River, and in 1799 Mr. J Jonville

* This passage is probably Heber's justification for his "spicy breezes."—ED. T.A.

was appointed Superintendent of the first Botanic Garden in Ceylon. Formerly Jonville was "clerk for Natural History and Agriculture;" being a versatile man and an artist, he made a valuable collection of plants, with drawings, which is now in the British Museum. In 1810 the Botanic Garden was transferred to Slave Island, the site being named Kew (by which name it is still known), in honour of the well-known London establishment of that name.

To give the new institution a practical as well as scientific character, it was in 1812 put under the charge of a qualified "Resident Superintendent and Head Gardener," viz: Mr. William Kerr—a shrewd Scotchman and a pioneer of Botany in the East—who was transferred from an appointment in China. Kerr brought with him, it is said, a number of Chinese and Japanese plants, though obviously but few if any of these could have thriven in a climate like that of Colombo. He, however, introduced successfully into Europe several interesting plants from the Far East, and his name is commemorated in the beautiful shrub *Kerria Japonica*. In pursuance of his love of exploration, Kerr was the first botanist, if not the first white man, to ascend our famous Adam's Peak. At that time, over a great area of what is now cultivated and domesticated, the jungle held sway in

Savage pride and dignity,
Proclaiming right of native liberty,

so that malarial fever was rampant, and Kerr succumbed to it in 1814, after a residence here of only two years. During his short regime the honorific title of Royal Botanic Gardens was bestowed on this department, and in 1813, the site in Slave Island being found too limited in extent and liable to floods, he secured the transference of the botanical establishment to Kalutara, the situation chosen this time being a sugar estate of 600 acres, which also proved unsuitable for a Botanic Garden.

X. Y.

THE CEYLON ANACONDA.

DEAR SIR,—Could you kindly inform me as to what part of Ceylon is the Anaconda snake found. Dr. Annandale's English Dictionary (1886) says of Anaconda: "The popular name of two of the largest species of the serpent tribe, namely a Ceylonese species and a South American species, both growing to a length of over 30 ft."—Yours truly,

PYTHON.

[The Ceylon Python or Roek Snake is thus referred to in "Tennent's" Natural History:—

The Python.—The great python* (the 'boa,' as it is commonly designated by Europeans, the "anaconda" of Eastern story), which is supposed to crush the bones of an elephant, and to swallow the tiger, is found, though not of such portentous dimensions, in the cinnamon gardens within a mile of the fort of Colombo, where it feeds on hog-deer, and other smaller animals.

The natives occasionally take it alive, and securing it to a pole expose it for sale as a curiosity. One that was brought to me tied in this way measured seventeen feet with a proportionate thickness: but one more fully grown, which crossed my path on a coffee estate on the Peacock Mountain at Pussilawa, considerably exceeded these dimensions. Another which I watched

* Python reticulatus, Gray.

in the garden at Elie House, near Colombo, surprised me by the ease with which it erected itself almost perpendicularly in order to scale a wall upwards of ten feet high.

The Sinhalese assert that when it has swallowed a deer, or any animal of similarly inconvenient bulk, the python draws itself through the narrow aperture between two trees, in order to crush the bones and assist in the process of deglutition.

—ED. T.A.]

CEYLON FISHING CLUB.

TWO INTERESTING LETTERS.

The following two letters were read at the meeting of the Fishing Club held on Tuesday, at the Hill Club, Nuwara Eliya:—

Calsay, Nannoya.
The Hon. Secretary, Ceylon Fishing Club,
Nuwara Eliya.

DEAR SIR,—I emptied my Rainbow trout pond, and turned 14 into Ambavela stream yesterday. A few I have kept in a pond at this Bungalow. This is a disappointing result out of 76 fry put in on the 27th of April last. The trout were in good condition, and were from 5 to 7 inches.—Yours faithfully,

G. G. ROSS CLARKE.

North Cove, Dec. 22, 1899.

The Hon. Secretary, Ceylon Fishing Club,
Nuwara Eliya.

DEAR SIR,—On Dec. 11th, I emptied the large stewpond on the Horton Plains, and captured 130 fish, ranging in size from 2 to 6½ inches. Thirty were turned into the river close by and 100 were carried down to the lower water and turned into Tryers' Pool and adjacent water. They were all strong fish. I have reason to believe that some of the fry escaped from the pond shortly after they arrived and I have seen young fish in the stream below the pond that would correspond with the size they should have reached. I shall be obliged if you will send me a cheque for Rs2.75 being the amount I paid for shrimps and food for the fry.—Yours truly,
(Signed) T. FARR.

A CEYLON TEA REPORT FOR 1899 has just reached us from Messrs. Tarrant, Henderson & Co. We quote one paragraph:—

Taking the year as a whole, it has been a favourable one for producers. The average price throughout for tea has been good. The unfortunate element, however, in connection with the industry, is the fact that demand has more and more continued to run upon lower grade teas. The craze in every part of the world appears to be for "Teas for Price," to the neglect of better grades. This is extremely unfortunate from both a producer's and a consumer's point of view, and is due very largely to the large distributing and advertising firms competing with one another and advertising blends at very low prices. This is much to be regretted, as the larger proportion of lower grades of Indian, Ceylon and China teas are quite characterless, and can give but little satisfaction to the consumer, while the better classes of tea, as a rule have a distinctive character and flavour, and people who have once tried them do not care to go back to the rubbish put before them by the trade. We may say without hesitation, that the difference between teas selling at 7d a lb. and 9d a lb. in Mincing Lane, in point of intrinsic value at present, is quite 6d per lb. so that it is unfortunate that the public do not realise that by paying a little more for their tea they would get so much better value.

PASSARA PLANTERS' ASSOCIATION.

SEVENTH ANNUAL REPORT.

CHAIRMAN.—J J Robinson.
SECRETARY.—W S Taylor.

COMMITTEE.—(Passara). J J Robinson, W S Taylor, G K Deaker, J C Tribe, R A Hope, J B Cotton, J Duncan. (Madulsima). J M Mason, R Webster, W M Kelly, F Hall, R Gatehouse. (Monaragala). J H Betts, J H B Cockburn, S J Sparkes. (Kandy). Chairman, Secretary and G K Deaker.

HOSPITAL VISITORS.—(Badulla). G K Deaker, James Duncan. (Lunugala). R Gatehouse, F Hall.

THIRTY COMMITTEE.—G K Deaker.

REGISTER.—The number of estates on the Register is 42; compared with the last year there is a decrease of two.

MEETINGS.—During the year under review, there have been four Committee Meetings and four General Meetings; these have been very well attended, which goes to show the interest taken by members in the affairs of this Association.

FINANCE.—The Books of the Association are laid upon the table for the inspection of members, and your Committee have much pleasure in bringing to your notice that the amount standing to the credit of the Association with the Bank of Uva amounts to R413'56. Last year's accounts were duly audited by Mr. Cotton.

TEA CROP.—The Estimate for the current year of 1900 is 3,298,800 lb. off 8,395 acres in bearing and 1,852 not in bearing. This gives an average for tea in bearing of 393 lb. per acre and speaks well for the climate and general suitability of this part of Uva as a tea producing country. Prices have been fairly maintained throughout the year and your Committee would impress upon you the many advantages to be derived from placing as much Tea as possible on the local market. The weather during the year was most abnormal, and much against the growth of leaf; we passed through two severe droughts and though the actual fall of rain for the twelve months was satisfactory, yet the distribution of this was calamitous.

COCOA.—Your Committee regrets that the outturn of Crop for this product for the year has been very disappointing and would attribute this serious decrease of crop to the ravages made by the canker and Pod disease which so virulently attacked the Caraccas. Mr. Carruthers treatment as laid down by him, as well as also various other experiments, have been tried, but with very indifferent results; and your Committee view with every satisfaction the late appointment made by His Excellency the Governor of Mr. Carruthers as official Mycologist to the Island. Your Committee take this opportunity of expressing their gratitude to His Excellency for thus moving in this matter and probably saving an industry which is now going through such a precarious crisis. Your Committee view with pleasure the formation by the Parent body of a Cocoa Committee and hope this step will lead to much usefulness and that a fair proportion of the funds at the command of the Kandy Association will now be set apart for furthering the interests of cocoa growers, who, so far, have not had the pecuniary assistance which they have every reasonable right to expect.

COFFEE.—Your Committee would congratulate the fortunate owners of Arabian coffee upon the fine crop gathered during the year; the weather for this product was everything that could be desired with the result that the returns for 1899 have been excellent.

OTHER PRODUCTS.—A considerable acreage has been planted under Rubber and Coconuts in the Monaragala district and the growth of the same gives great promise for its future success, which will probably lead to further extensions.

ROADS AND BRIDGES.—Your Committee have every reason to feel proud with the progress made in the matter of roads and bridges during the year under review. The Wellaraya-Mupane cart road has its

bridges now completed and the wheel tracks metalled throughout. The last bridge completed, namely the Kirinde Oya, was a work of great magnitude and reflects the greatest credit upon the officers in charge. The Madulsima grant-in-aid cart road is now open for traffic as far as Dunedin Factory and is much appreciated by the estates at that end of the district. It having been pointed out to the Government by your Association that the breadth of the Kumbalwella-Passara cart road was insufficient for up and down traffic, room has been found in this year's Supply Bill for widening the road at intervals every quarter of a mile. Your Committee have been urging Government to construct a cart road from Passara to Aliput in the interests of the large native population residing in that neighbourhood, who at the present moment have no profitable means for transporting their produce to the nearest market. Your Committee are given to understand that the present Government Agent as well as two former Uva Government Agents have already urged the necessity of a cart road being constructed to connect these two points. The Association is further to be congratulated upon the endeavours made by their worthy representative on the Provincial Road Committee for the great improvements on our Minor Roads, especially in the obtaining of a grant whereby the Nukkala and Hulanda Oya rivers are to be bridged. Arrangements have been made with the Government which provides for the P. W. D. Bungalow at Namunakula being now opened to the public as a resthouse. Your Committee are also pleased to state that there is every probability of a new resthouse being erected close by the cart road at Buttale (Hospital). The endeavours made by your Committee urging the Government to construct a hospital at Mupane, we regret to say, have so far failed, but they yet believe that the Government will realise that the health of the native community is of greater importance than the consideration of the extra outlay involved in erecting this very desirable and much required building.

UNOFFICIAL POLICE MAGISTRATE.—Mr. J M Mason was made an U P M and J P for the Province of Uva on the representation of your Association to Government which doubtless will be much appreciated by our Madulsima members. A considerable amount of crime was unfortunately observable at the commencement of the year, especially round about the Lunugala district, but thanks to the prompt measures taken by our worthy Government Agent, it was speedily stamped out.

LABOR.—Your Committee view with a certain degree of alarm the tightening of the labor market and the consequent substantial increase in the advances now being given out. This doubtless is greatly owing to the heavy public works about to be commenced by Government, who, so far, have stood aloof from importing their own labor, preferring to engage the planters' cooly; if this continues, your Committee much fear that the results of this policy will be disastrous to our enterprise.

TRAMWAY.—Your Committee view with much satisfaction the sanction given by Government for the construction of the Kandapola Light Feeder line, as, in the event of this scheme proving profitable our Light Feeder Line from Bandarawela via Passara to Badulla has been promised next attention by Government.

MR. BAMBER.—This gentleman officially visited the district twice during the year and your Committee look forward with great interest to his forthcoming Report, which it was expected, would have been in our hands ere this.

THE RELATIONSHIP BETWEEN THE PARENT BODY AND THE THIRTY COMMITTEE.—Your Committee are of the opinion that the time has now arrived for these two important bodies to be separated and each possess their own Chairman, as they feel that the duties are too onerous to be discharged by the one officer. It seems unfair to expect one Chairman to devote

the necessary time that is required in attending to the business connected with these two important bodies.

GOVERNMENT OFFICIALS.—In conclusion, your Committee take this opportunity of asking you to express your thanks to our worthy Government Agent, Mr. Baumgartner, for the very great interest he has always shown for advancing the prosperity and development of this province: Your thanks are also due to the Provincial Engineer and his staff for all they have done for us during the year.

HIS EXCELLENCY THE GOVERNOR.—Your Committee take this opportunity of congratulating His Excellency Sir West Ridgeway upon his complete recovery from his late serious illness and feel sure they are only echoing the voice of this Association in heartily welcoming him back to the Colony.

CEYLON CONTINGENT.—Your Committee wish here to record the pride they feel, in that four gallant members from this Association have joined the Contingent which is now on its way to fight for our Queen and country; we heartily wish them "God Speed" and a safe return back amongst us.

PALMERSTON TEA COMPANY.

ANNUAL MEETING.

The Directors have now to submit their Fourth Annual Report and Accounts being those for the year ending 31st December last. The yield of Tea during the period has been 208,828 lb., costing cts. 28.08. as against cts. 29.55 last year, and realising 45.63 as against 46.12.

As will be seen from the accounts the net profits for the year amount to R23,727.24 after writing off the sum of R5,318.10 for depreciation on Factory and Machinery. An interim dividend of 2½ per cent was paid on 7th August absorbing R10,250, and the Directors recommend that a final dividend of 3 per cent be declared, making a total of 5½ per cent for the year and leaving a sum of R1,177.24 to be carried forward.

Mr. W Sandys-Thomas visited the estates in Jan. and found everything generally in a satisfactory condition. A copy of his report is annexed for the information of the Shareholders.

In terms of the Articles of Association Mr W Sandys-Thomas now retires from the Board but is eligible for re-election.

The appointment of an Auditor for the current year rests with the Meeting.

By order of the Directors,
BOIS BROTHERS & Co.,
Agents and Secretaries.

ACREAGE OF THE ESTATE.

	Queens-land.	Palmerston.	Total.
Tea in Bearing ..	254	205	459
Young Tea ..	4	—	4
Total Tea ..	258	205	463
Jungle ...	19	—	19
Timber ..	—	7	7
Grass, &c. ..	4	—	4
Total Acreage ..	281	212	493

	Lbs.	Per Acre.
Yield off Queens-land ..	116,099	456 lb.
Palmerston ...	93,584	456 "

Total off 459 Acres Tea .. 209,683 lb. 456 lb.

Expenditure per pound of tea as per Reports is as follows, after deducting Capital Expenditure on buildings:—

Queensland ..	28.21
Palmerston ..	27.07

N. B.—Included in Queensland is the sum of R4,700 spent on Manure, which is equal to 4cts. per lb. on Queensland Tea.

It is curious that the yield off the two Estates should be the same per acre. Palmerston with manure will, I am sure, increase in yield more than Queensland has done as the soil is better, except on small patches here and there where Palmerston is poor.

MANURING will be continued on Queensland and commenced on Palmerston, on Queensland about 70 acres will be tackled, and on Palmerston about 40 Palmerston will also do about 15 acres with cattle manure.

CAPITAL EXPENDITURE. On Palmerston none is required during the coming year, but on Queensland a new Roller is wanted.

The cost of Tea per pound after deducting the expenditure on capital account for buildings, i.e., R4,131, comes to 28.08, as compared with 29.55 in 1898 and 32.18 in 1897.

Both Estates are in good order throughout. Coolies are sufficient on Queensland, and on Palmerston the extra 30 coolies wanted will soon be supplied. The estimate for 1900 is as follows:—

Queensland ..	125,000 lb.
Palmerston ..	98,000 "
Total ..	223,000 lb.

AUSTRALIAN OYSTERS' CULTURE.

Australian oysters are cheap and plentiful, being retailed in Sydney at from sixpence to one shilling per plate or bottle. The consumption is enormous, lasting throughout the year, and amounting to several millions of bivalves annually. The whole of the New South Wales coast is admirably adapted for oyster culture. The climate, the nature of the coast line, with its innumerable inlets and creeks, and the natural existence in several varieties of the bivalve itself, all combine to mark its suitability for the culture. At the present time, for the purpose of oyster culture, the Colonial Government grant leases of the foreshores of tidal waters, which may be defined as between the mean high and mean low water mark. The rental is 20s. per annum for every 100 linear yards. The maximum length for which a lease may be obtained is 2,000 yards. There is but little doubt, says Mr. Coghlan, the New South Wales Government Statistician, that the establishment of "parcs," like those which may be seen along the coasts of France and Belgium, where oyster culture is conducted on scientific principles, would be remunerative, as the demand for this delicacy is great, and continually increasing. There is, indeed, a wide field for remunerative employment in this direction, and experts in the art of oyster culture would find every possible facility placed at their disposal. During the year 1897, 14,701 bags of oysters were obtained from the tidal waters of the colony, being a satisfactory increase on the takes of previous years; while in addition to this supply, 2,767 bags of oysters were imported from other colonies, their value being set down at £3,103. In 1898 the quantity imported was 7,110 bags, value £5,322; of which 6,236 bags came from New Zealand, 550 bags from Queensland, 282 bags from South Australia, 30 bags from Victoria, and 12 bags from Tasmania. A bag of oysters contains 3 bushels, and at the beginning of 1899 the price per bag of good oysters in Sydney ranged from 35s. to 40s.—*Journal of the Society of Arts, Feb. 9.*

COTTON IN THE FAR EAST.

ALTHOUGH the first Cotton Mill Company started in Ceylon had to be wound-up, and although on the adjoining Continent most of the once flourishing Cotton Mills are having a very trying time of it, yet there are places in which the cotton mill industry continues to yield fair returns. Indeed, it is in the very ability of Japan and China,—which were till lately the best market, if not for cotton goods generally, at any rate for yarn,—to compete with the old centres of the mill industry, that a special danger now lies. Skilled labour is nowhere cheaper than among the Yellow Races; and it may be doubted whether apter learners and nimbler fingers for delicate work can be found anywhere in the wide world. It is in the readiness with which mechanical knowledge is acquired in the Far East, and in the conversion of the consumer into the producer that Lancashire has found its greatest drawback. The Indian mills were trouble enough with their command of cheap labour, and they undoubtedly compelled contentment with smaller profits than were at one time reaped; but so long as the millions in the Far East remained customers, there was no ground for alarm. Now, the spinning and weaving industry has made considerable strides in Japan which is becoming less and less a purchaser of the cotton goods and yarn which it formerly absorbed in large quantities. It is, however, from China that experts apprehend the greatest danger. Foreign capital has done somewhat to give the industry a start; but now the local capitalist has begun to see prospects of profit in the industry! And what wonder, if the three foreign-owned mills in Shanghai are able to declare dividends varying from $3\frac{1}{2}$ to 7 per cent, without working full time? It may be that the work done is chiefly in the coarser yarns, but these are said to be superior to those turned out in both Bombay and Osaka, and the native capitalist in starting on his own account. The uneasiness of Bombay is, therefore, easily understood.

SUGAR IN QUEENSLAND.

The total quantity of sugar exported from Queensland for the seven months ended January 31, amounted to 96,825 tons as compared with 119,668 tons in the corresponding period of last year.—*Sydney Mail*, Feb. 10.

Dr. W Maxwell, a Honolulu sugar expert, who has just completed his investigation of the sugar industry in Queensland, as well as a number of prominent gentlemen connected with the industry, were entertained at Parliament House by the Premier and the members of the Ministry.—*Ibid*.

PLANTING NOTES.

PLANTING ON THE JOHNSTONE RIVER, WESTERN AUSTRALIA.—A settler, writing on 1st February, reports :—"We have both small patches of coffee, but not in bearing yet. This district goes in for nothing but sugar and bananas; rice, arrowroot, pines and lemons are being tried; tobacco is a failure owing to blue mould on young plants."

FREE EXPLOITATION OF VANILLA, &c.—The official journal of Costa Rica publishes a decree authorising the free exploitation of sarsaparilla and vanilla, as well as of all other vegetable products found in national forests, except timber.—*B. and C. Druggist*, Feb.

CHEAP TEA WANTED!—One of the leading Indian Tea Garden Companies in London recently received a communication from a country grocer, with the following modest request: "Have you an Indian or Ceylon tea that you can put in for 5d or 6d duty paid? If so," says this ingenious correspondent, "send samples and price list." This would-be patron of British planting enterprise should try Hamburg.—*Planter*, Feb. 24.

AMAZONIA RUBBER AND TRADING COMPANY (LIMITED).—The directors, in their annual report to December 31 last, submitted at the general meeting held yesterday, state that the net profit for the past year amounted to £3,299, whereof £1,171 has been absorbed by the interim dividend paid on July 25, 1899. The directors now recommend £1,527 to be paid in completion of a dividend at the rate of 20 per cent. per annum on both preference and ordinary shares for the year ended December 31, 1899, £250 to be placed to reserve fund, and £349 to be carried forward.—*London Times*, Jan. 31.

TOBACCO GROWING IN IRELAND.—A prospect of a new industry for Ireland has been opened up by the Irish Agricultural Organising Society, which has shown that tobacco can be profitably grown at Donaghpatrick, in County Meath. The experimental crop raised has been cured and manufactured, and is now being sold by an Irish newspaper at $4\frac{1}{2}$ d. per ounce through the post. Competent judges have pronounced the Irish weed an excellent smoking tobacco, and the whole cost of production was but 4d. per lb. Allowing for duty at 2s. 8d., this tobacco, sold at 5s. per lb., would show a profit of no less than £264 per acre. The revenue authorities are strongly opposed to the cultivation of tobacco in the British Isles, and an experiment made some years ago on Mr. Faunce de Laune's estate, in Kent, was most unfavourably regarded. It would be a curious coincidence if the two chief importations of Sir Walter Raleigh should combine for the benefit of the distressful country.—*Daily Chronicle*, Feb. 9.

PETROLEUM EXPORT STATISTICS.—The export statistics of petroleum during the past three years show some notable changes in foreign requirements. The export movement reached its maximum in 1897, with a total of 994,297,000 gallons, the succeeding year showing a falling off of 7,817,000 gallons, and last year a further shrinkage of 35,456,000 gallons. Foreign writers have attributed this decrease entirely to the increased competition of Russian oil, but a closer study of the production and movement from various sources of supply proves that the decrease in the exports of American petroleum are not due to direct competition with the Russian product. The production of petroleum in Sumatra, Roumania and Galicia has made rapid strides during the past few years and the product of these sections has displaced just so much oil which would otherwise have been supplied from America or Russia, or in part from both of these petroleum producing countries.—*Oil Paint and Drug Reporter*.

ON TOMATOES.

[BY AN EXPERT.]

"LYCOPERSICUM ESCULENTUM" otherwise tomato, sometimes called love apple, a singular name surely. Most readers doubtless know the tomato belongs to that brilliant natural order the Solanaceæ, than which, very few natural orders are of greater economic importance. The potato, tomato and the brinjal will be quite sufficient to fix its great importance to mankind, and then there is the chili: by the fates what would India be without its chilies? Now the tomato is just one of those excellent things that somehow or another India is very backward in growing: and of all countries on the face of the earth, the one it ought to be abundantly grown in, by reason of its excellent and very well recognised action on the liver and spleen, and general dietetic value. Personally, and notwithstanding Dickens's famous tomato sauce, I am of opinion the cooking of the tomato is a mistake. Plucked when just barely ripe, cut up and eaten just as one would apples, the tomato is delicious, with a fine, firm and crisp flavour, and then in the form of a well concocted salad it is matchless. But it is important the tomato be gathered when just barely ripe, nicely coloured and no more. When quite ripe it rapidly develops a characteristically mawkish flavour that is not nearly so agreeable, at least to my taste, which is a long and extensive one with tomatoes. Furthermore, it is good practice to gather tomatoes, not more than two-thirds ripe, as it greatly helps heavily laden plants to perfect the entire crop. And they finish the ripening just as well off the plants, to the considerable relief of the remainder. As a proof of what tomatoes will do in this way, I may say as I write I have about a maund slung up to the roof of my room, a few beauties of perfect form, would weigh over a pound each, but they are green—there is just a snispion of whitish coloured green, which is the first intimation of colour coming on: under the simple influence of the fire in the room, they will slowly colour. I cannot say the flavour will be so good as when allowed to two-thirds ripen out of doors. But when I commenced to write this paper there was frost and ice out of doors, and so a knowledge of this ripening of tomatoes off the plants, enabled me to enjoy my maund of tomatoes in spite of destroying frost and ice outside.

Now why on earth does not India produce at least one million maunds of tomatoes every year? Why indeed a million maunds, why not ten? It is easy of accomplishment if the "how to do it" is known and of that there shall be no excuse before I leave the subject. The tomato is one of those things that have fallen into the hands of the hybridiser and the raiser—and the hybridiser and raiser is one of the most undoubted and greatest benefactors of his race; and so it comes about that to-day we have not those ngly, ridged and furrowed, crumpled-up fruits of olden times, but on the contrary brilliant-coloured, beautifully formed fruits of perfect outline, handsome as exhibition apples. The consumption of tomatoes for London alone goes into tons daily and one mammoth grower alone turns out some dozen tons a week and that too from glass structures, of which he had some time ago considerably more than a hundred of great length. Now if we take into account the high cost of labour, the numerous rates and taxes and the great value of the land, which is no distance from London, and the considerable cost of such an array of glass structures, this one man alone must have spent enough to purchase many square miles of land in India. And it pays too, not however by reason of long prices, nothing of the kind, that is the point I wish to emphasise—it is simply due in the main to the scientific culture, and the enormous crops; such as one never sees in India. Hence I want to point the way for the Indian gardener to go and do likewise, without all the heavy expenditure of glass, high price labour, &c; and with the model winter climate of India on the plains the tomato should be everywhere abundant and

cheap and should pay the producer and the consumer very well indeed.

I hear some reader say "Oh! but anybody can grow tomatoes" and that is quite true: they will grow themselves, in fact, if you only plant them—but however is not the way to produce either quantity or quality; and it is quantity combined with quality that pays in most things. We will therefore set aside slipshod methods, and come to a simple yet scientific method that will give exceptionally fine fruits and plenty of them.

VARIETIES.

I may say at once the varieties are very numerous, but by no means so numerous as the perusal of half a dozen seedsmen's catalogues would lead you to suppose. We all have our little failings; and your seedman is nothing lacking. Hence it comes that some tomato is one seedsmen's "conqueror," another's "*ne plus ultra*," or Robinson's "Invincible," and as a simple matter of fact this tomato is Brown's, Smith's and Robinson's leading line in tomatoes: a very fine thing you will find it described, and it is probably quite true; but if you buy it from the three it is a hundred to one you will get one kind of tomato. Here is a practical illustration. Some eleven years ago a very fine tomato was brought out, called Empress of India; I have grown that tomato ever since, and it is very fine: even today, brilliant in colour, beautifully shaped, and fine in quality, and large. Now I find some difficulty in finding Empress of India in the lists; it has undoubtedly slipped out of a lot altogether, but another kind is pretty general and variously termed perfection: that I have grown and I find it simply my true friend Empress of India Tomato, and about a quarter of a hundred of other kinds grown are largely synonymous. The tomato grower will do well therefore to select a real good type and stick to it, and prove the improvements so-called one or two at a time, and on no account be deluded into a multitude of varieties.

SEED SOWING.

Having made a good selection, sow in boxes or pots, I find boxes much the best. The tomato is a considerable time in coming into fruiting from seedlings, therefore sowing should be arranged for in good time, and the boxes may conveniently be about four inches deep. Into the boxes put half an inch of drainage, such as cinders, and on this a couple of inches of good garden soil, of a light sandy nature. Now make up a mixture of fine soil, and thoroughly decomposed manure and leaf soil in equal parts, mix all well together and fill in the boxes to with in half an inch of the tops. Firm regularly and moderately, and make all perfectly level with a piece of planed board, and water down the soil. They are now ready for sowing, which should be done carefully. The tomato seed is a large one, and it will be much the best plant to place each seed separately about half an inch apart; in this way every seed will have an individual chance, and come up strong, much superior to a box sown at random, and generally much too thick. Having carefully placed the seed, sift some fine soil over it to depth of two-eighths of an inch, give another light watering, and transfer boxes to some dark warm place, until the seed has germinated, carefully watching the while that the soil in the boxes does not get dry. As soon as germination is seen to be ensuing the boxes may be transferred to the open absolutely free from shade.

PRICKING OFF THE SEEDLINGS.

As soon as the seedlings are strong with a pair of good leaves and another pair in progress, they should be pricked off into other boxes somewhat deeper. Ordinary kerosine boxes cut in half answer well. Here however the previous proceedings should be reversed as regards soil, and the rich mixture of manure, light sandy loam and leaf should go into the box first, and there may with advantage be two-fourths of manure, one of leaf soil and one of loam to the depth of half the box, on top of this any good light friable garden soil will do. Into this mixture, transplant the seedlings three inches apart

shade for a few days and then transfer full into the sun. Attend carefully to watering, and allow the plants to grow unrestrictedly until the boxes are pretty full of roots, in fact what the horticulturist terms slightly root bound. There is a distinct object in this, namely, to induce the plants to show flower much earlier than they otherwise would do so, but the moment the buds can be seen, it will be time to consider their permanent quarters.

PREPARATION FOR PERMANENT PLANTING.

Now the man that can grow good potatoes, should also be able to grow good tomatoes, and if the soil is known to be a good potato soil it will for certain suit tomatoes admirably. For in spite of the very great difference between a potato tuber and a tomato fruit, there is in all other respects a close similarity between the potato plant and the tomato plant, so much so that one can be grafted quite successfully on to the other and *vice versa* and the potato plant will in this way yield a crop of potatoes below ground and tomatoes above it. Furthermore, the tomato, like the potato plant, demands abundance of potash for its vigorous existence; and also like the potato it is a very fine and profuse rooter, therefore hard lumpy soil is ill-adapted to its requirements. The soil should therefore be thoroughly cultivated to the depth of at least a foot or more, and be fine mealy soil, in order that the fine roots may move freely through it and abstract all they require in the early stages of the plants. If the soil is admittedly a good and fertile one, no manure need be added to it in the operation of digging, if however through cropping, or any other cause, the soil is impoverished, a good dressing of thoroughly rotted manure should be added; and if the scrapings of virgin jungle land is available, this is an admirable and valuable manure for the tomato plant.

PLANTING OPERATIONS.

Having thoroughly prepared the soil, and obtained the first indication of flower buds, the plants are now ready for permanent planting, and the exact method to be adopted comes up at once for consideration. The best method of all for the production of fine quality large tomatoes is on single stems, that is to say, one plant, one stem, and therefore no laterals; but this will the better be made clear by an example. Suppose the cultivator selects a piece of ground fifty feet wide, and a hundred long, and plants one foot apart in the lines, and the lines one from the other three feet apart—the plot will require 1,600 plants, and this number may be so planted for single stem plants; or each plant be allowed to carry two, or at the most three stems each, but it comes to much the same thing as the three stems will require room, and there must be a reduction in numbers to allow for this, and the fruits, moreover, are not calculated to come so fine on three stem plants, as on one. I would therefore select the best and most profitable method for exceptionally fine fruits, namely, single stem plants. Accordingly large sized drills, or small trenches may be got out and the first flower buds got as near the surface as possible, in order that the fruiting may begin from the bottom, it may be advisable to lay some plants in slanting to effect this end, which is a very good plan. Any buried stem will be certain to root later on, which is no disadvantage whatever. Suppose this example is carried out, there will be sixteen rows of 100 plants each one foot apart and three between the rows or lines. And this involves a system of training, each plant being grown perfectly vertical. No doubt the best and most economical method in the end is by posts and strained wires; two terminal posts, and one in the centre for each line; but failing this posts may be driven in at intervals six feet long, or more, and by a system of horizontal and vertical lacing of split up bamboo hurdle or gate fashion a substantial training fence be made, and easily taken down, and the wood saved for another season when done with merely leaving the permanent post in the ground, or even these

may be taken up, Having planted the young plants previously soaking the boxes before transplanting and doing the planting well, we come to a thorough system of after management.

PRUNING AND TRAINING.

Now whether the grower elects to have one, two or three shoots to each plant; all else should be regular and systematically destroyed as it appears; with every new point there will inevitably be a couple or three lateral shoots: the moment these are large enough take them out and at the same time secure the plants as they grow to the trellising with a loose tie. In practice this work will be very simple, but it should on no account be neglected at any time; but regularly and systematically attended to, and the lateral shoots taken completely out when quite small; then no other growth can ensue, if it does it must be removed. At intervals all up the main stems there will appear a vigorous bunch of flowers at about nine inches to a foot apart. Now even the best kinds of tomatoes are in the habit of giving some faulty flowers: do not allow these to waste the energy of the plants, but take them out with a fine pointed pair of scissors. This will not be extensive work, but nevertheless should be attended to, and this work will go to the end of the chapter. There will thus be a given number of main stems, and nothing else, absolutely nothing else should be tolerated for a moment. It will happen that some leaves branch out and become very long: these too may be reduced if they crowd each other, taking away one or two pairs of the leaflets. But this must not be overdone, as healthy vigorous foliage is essential to the plants; but the tomato produces such a superabundance under good cultivation I never allow the leaves to crowd each other, and even take some away altogether. When the plants have made good progress and have five or six bunches of developing tomatoes on them, the important question of manuring and feeding comes in.

MANURING.

The time has now arrived to give the plants a heavy mulch of thoroughly rotten manure, available as immediate plant food. The roots will very speedily come for this manure, and eventually fill it with a regular network of roots. It should be laid on three or four inches thick, and as more and more tomatoes are produced, this manure will be of the greatest possible value. Should the plants become in any way dryish, give a good soaking of water, or better still weak liquid manure, and have the manure slightly trodden at the same time in order that the goodness may be squeezed out. And should the weather continue, rainless the plants may be watered once a week in a similar way. Treated in this way the manure immediately becomes available for the fruit, and practically that alone, and this method will be found far superior in results to heavily manuring the ground in the first place, which is mainly provocative of a rampant growth that serves no purpose, but on the contrary produces long jointed growth, and demands a great deal of extra pruning. These are the two great factors in successful tomato culture namely, a rigid system of pruning and strict confinement to main stems, and powerful manuring expressly and solely for the benefit of the fruit as distinguished from the plant itself, and by this method, moreover the fruit ripens in regular order commencing from the bottom, and continuing upwards until the plants become no longer profitable. A most important point is to see the manure is of real value and very thoroughly decomposed. In proportion as it is so will be seen its effect on the character of the fruits.

A CALCULATION.

Now estimates are proverbially dangerous things, like prophecies very much, but I am going to venture on a modest one, that is, for certain within the practicable, provided this method of culture is faithfully carried out. And we will carry the quoted

example through: a plot of land 50 by 100 feet; plants or single stems, total number 1,600 at three by one foot planting; five seers of tomatoes per plant—and all of the finest quality be it noted; five by 1,600—8,000 seers of tomatoes, at four annas per seer gives Rs.2,000. But I have in mind that my readers are not ready-made experts. There is much of routine only possible from keen enthusiastic experience, and so I'll reduce this estimate for the planter and the amateur by fifty per cent—that is, the yield, and call it 2½ seers per plant at Rs.1,000. Now I am absolutely at a loss to know how the grower is going to spend Rs.500 by way of expenditure on this culture and everything connected with it to the sale of the produce, but it is conceivable he may do so. Still he has cent per cent profit and that should satisfy the most exacting. This is exclusively applicable to the plains. I would here warn the hill gardener against any heavy speculation in tomatoes, because he has to grow through the monsoon season and that is quite another thing, as I happen to know to my own cost very dearly.

EXAMPLE.

In 1897 I was going to make a small fortune, and had 4,000 plants all grown as detailed here. They got through the rains pretty well, until nearing the end of September, and hung like ropes of onions, to the extent of very many maunds; hundreds of the fruits weighing over a pound each, of faultless shape, and with the colour just developing in all directions. Then there came quite unexpectedly over a foot of rain in twenty-four hours, and I was congratulating myself on how well they had stood the downpour, when lo, on the third day, black spots appeared; on the next day it had developed fifty per cent and ere a week was up, the entire crop was an absolute mass of disease, a total failure and a dead loss.

CONCLUSION.

Like the potato the tomato plant will not thrive in a wet or swampy soil, neither is excessive moisture at any time a blessing. It delights in a well drained, friable, easily worked soil, abounding in potash salts. It may not be generally known that tomatoes are excellent things for cleaning metal with, and taking out stains, &c, due to the potash absorbed by the fruits from the soil. I should suppose too that it is the potash they contain, that accounts for their excellent action on the system, at least to a considerable extent. It is therefore an excellent medicine and delicious food, far too little understood and appreciated in this country, and should, I venture to think, be recommended and extended in its culture everywhere, seeing, as I have endeavoured to show, that it could be produced on the plains above all places in quantity and quality, and very far from being a non-profitable crop if the best form of culture is once understood.—*Pioneer*, Oct. 9.

DESCRIPTION OF FERTILIZER MATERIALS.

Indirect Fertilizers.—A stimulant or indirect fertilizer is one which does not in itself furnish directly to the soil any needed plant-food, but whose chief value depends upon the power it possesses of changing unavailable into available forms of plant-food. The stimulants or indirect fertilizers which have been most commonly employed are lime, gypsum and common salt.

Gypsum, or land-plaster, known also as calcium sulphate or sulphate of lime, in some manner aids the process of nitrification, by which ammonia and the nitrogen or organic matter are converted into nitric acid and nitrates. It also acts upon the insoluble forms of potash and other elements of plant-food, converting them into soluble and available forms; it is of value on certain soils to certain crops, such as clover, peas, lucerne and similar plants.

Quicklime or burnt lime, or calcium oxide, commonly called lime, produces changes in both the

physical and the chemical character of soils. Freshly burned lime acts chemically upon soils by decomposing vegetable and mineral matter already present in the soil and changing them into forms which are available as food for the plant. Thus, lime acts upon insoluble mineral substances containing potash, etc., and converts them into soluble forms. Lime aids in the decomposition of animal and vegetable matter, such as vegetable mould, stable manure, etc. and tends to convert them into available plant-food. In using lime, care should be taken not to use too large quantities at a time, and, ordinarily, it is best to use it in connection with liberal applications of nutritive fertilizing substances. Lime can be used to advantage on freshly drained swamp-lands and also on lands newly cleared.

Common salt has an indirect fertilizing value which is mainly due to the fact that it has the power of changing unavailable forms of plant-food, especially potash, into available forms.

Danger of Using Stimulant Fertilizers.—It should be kept in mind that these stimulant fertilizers—that is, gypsum (or plaster) lime, and salt,—are not used for the plant-food contained in them; hence, as used, they do not furnish needed plant-food. The chief value of their use lies in the fact that they can change unavailable into available forms of food-plant. It can readily be seen that, when stimulant fertilizers are used exclusively for a term of years, the soil each year loses nitrogen, potash and phosphoric acid, which are not replaced. The inevitable result of such treatment is the exhaustion of these important food constituents from the soil. This affords an explanation of the question often raised now as to why the application of lime does not give such results in crop yields at present as in former days. When lime was the only fertilizing material added to soils for years in succession, it was possible to produce increased crops, so long as there was in the soil enough compounds of nitrogen, potassium and phosphorus to be rendered available by the action of the lime. When, therefore, these forms of plant-food were largely removed, there was nothing for the lime to act upon, in order to increase the supply of available food material. The lime furnished needed no food, but simply helped the crop to use more rapidly the store of plant-food present in the soil.

Direct Fertilizers.—Direct fertilizers contain forms of plant-food, which contribute directly to the growth and substance of plants. Such materials may contain either nitrogen, or potash, or phosphoric acid compounds, or any two, or all three of these forms of plant-food.

Nitrate of soda, known as "Chili saltpeter," is found in large deposits which have been formed in the rainless regions of Chili and Peru. Good commercial nitrate of soda contains from 15½ to 16 per cent, of nitrogen.

Sulphate of ammonia is formed from waste materials produced in the manufacturing of illuminating gas or coke. Sulphate of ammonia contains about 25 per cent. of ammonia, which is equivalent to about 20½ per cent, of nitrogen.

Cotton seed meal is the product formed by removing the oil from cotton seed by pressure, after which the material is dried and ground. Cotton seed meal contains about 7 per cent. of nitrogen, 3 per cent. of phosphoric acid, and 2 per cent of potash. The hulls of the cotton seed also possess considerable fertilizing value.

Tobacco stems are the refuse from tobacco factories. They contain usually from 5 to 8 per cent. of potash, 2 to 3 per cent. of nitrogen, and a small quantity of phosphoric acid.

Dried blood consists of blood obtained from slaughtering animals; it is prepared for market by evaporating, drying and grinding. The color varies from red to black. Dried blood contains from 10 to 15 per cent. of nitrogen.

Dried fish, scraps and ground fish consist of refuse from fish-oil works and canneries; it is dried

and ground for market. Dried ground fish, of good quality, contains from 7 to 8 per cent. of nitrogen together with as much or more insoluble phosphoric acid.

Meat-scrap, tankage, etc., are slaughter house refuse, dried and ground. Good tankage contains 10 per cent. or more of nitrogen and often 10 per cent. or more of insoluble phosphoric acid.

Nitrogenous guanos are formed in dry regions. The Peruvian guano was rich in nitrogen, containing 7 per cent. or more. They usually contain 7 to 12 per cent. phosphoric acid and about 1 per cent. potash.

Bones consist mostly of calcium phosphate of lime, which constitutes from one-half to three-fifths of the weight of the bone. The remaining portion is a soft, flesh-like substance commonly called gelatin. It is distributed throughout the entire mass of bone, and is rich in nitrogen. When bones are burned, the nitrogenous matter is driven off and only the mineral portion or phosphate of lime remains. Bones, such as are used in making commercial fertilizers, contain 4 to 5 per cent. of nitrogen, and from 20 to 25 per cent. of phosphoric acid, about two-thirds of which is insoluble and approximately one-third available.

Bone-ash is made simply by burning bones in the open air. The nitrogen is lost in burning, and the chief constituent is insoluble calcium phosphate, equivalent to 30 to 35 or more per cent. of phosphoric acid for the most part insoluble.

Bone-black, known also as bone-charcoal, is extensively used in refining sugar. After it has been used several times, portions becomes useless for refining purposes, and are then sold as a fertilizer. It is made by heating bones in closed vessels; the fat, water and nitrogen are driven off, and the bone-black remaining consists mainly of insoluble calcium phosphate and carbon or charcoal. Good bone-black may contain 30 or more per cent. of phosphoric acid mostly insoluble.

Bone-meal goes under various names, such as ground bone, bone-flour, bone-dust, etc., Raw bone-meal contains the fat naturally present in bones. The presence of the fat is objectionable, because it retards the decomposition of the bone in the soil, while fat itself has no value as plant-food. The presence of easily decaying nitrogen compounds in bone hastens, in the process of decomposition, to dissolve more or less of the insoluble phosphate. Bone-meal should contain from 3 to 5 per cent. of nitrogen, and from 20 to 25 per cent. of phosphoric acid; about one-third to one-fourth of the latter appears to be in readily available condition. Raw bone-meal generally contains somewhat more nitrogen (1 to 2 per cent.) and rather less phosphoric acid than steamed bone-meal. The fineness of the meal affects its value; the finer the meal the more readily available it is for plant-food.

Phosphoric Guanos, or Rock Guanos—Guanos generally consist chiefly of the dung of sea-fowls, though the term is applied to other animal products. They are generally found in beds resembling earthy deposits. The guanos which are called phosphatic contain little or no nitrogen. Their phosphoric acid is generally in the insoluble form. These guanos come mainly from certain islands in the Pacific Ocean, and from Caribbean Sea and West Indian Islands. The phosphoric acid in guanos is very variable, ranging from below 15 to over 30 per cent.

Rock phosphates are known under several different names which generally designate the localities from which they come, as South Carolina Rock, Florida Rock, Tennessee Rock, West India Rock, etc. Other forms of mineral phosphates are known under the names of apatite, coprolite, phosphorite, which are found in various places in America and Europe, and some of which are used in making commercial fertilizers. The rock phosphates are extensively used in making acid phosphates. When ground to a very fine flour-like powder, rock phosphates are called "floats." Rock Phosphates contain usually from 25

to 30 per cent. of insoluble phosphoric acid and some as much as 35 to 40 per cent.

Acid phosphates are known under several different names, such as superphosphates, dissolved bone, dissolved rock, dissolved bone, black, etc. Acid phosphates are formed by treating some form of insoluble phosphate of lime, as rock-phosphate, bone, bone-ash, etc., with sulphuric acid. By this treatment there are formed soluble phosphate of lime and gypsum (sulphate of lime) in nearly equal proportions. Superphosphate made from rock phosphates may contain from 12 to 18 per cent. of available phosphoric acid.

Thomas slag, also known under several other names, such as basic iron slag, Thomas scoria, Phosphate slag, etc. It is a by-product formed in the manufacture of iron and steel from certain kinds of iron ore containing phosphorus compounds. It usually contains between 19 and 20 per cent. of total phosphoric acid, with 6 to 7 and more per cent. of available phosphoric acid.

Cotton seed hull ashes were produced in the Southern State of America at the cotton seed-oil factories, where the hulls, after being removed from the cotton seed, were used as fuel. Such ashes contain from 15 to 25 per cent. of potash, in addition from 7 to 10 per cent. of phosphoric acid. This material is not commonly found now.

Kainit is the most common products of German potash mines. It is a mixture of several different compounds, containing 11 to 13 per cent. of actual potash, together with about 35 per cent. of common salt, also magnesia salts.

Mariate of potash, also a product of the Stassfurt mines, is the main source of supply for potash for commercial fertilizers in our market, and contains 50 to 53 per cent. of actual potash.

Sulphate of potash is a product of the German mines. The product found in the market contains from 48 to 51 per cent. of actual potash.

Sulphate of potash-magnesia is known also as double manure salt or low grade sulphate of potash. This material comes from the German mines and contains 26 to 28 per cent. of actual potash. It also contains 23 to 36 per cent. of sulphate of magnesia.

Carbonate of potash-magnesia contains about 18 per cent. potash and 19 per cent magnesia, both as carbonates. It is practically free of chloride. It is also a product of the German potash mines.

Wood-ashes contain more or less potash, which is present chiefly in the form of carbonate. The amount of potash in commercial wood-ashes varies from below 4 to 7 per cent., the average being under 5 per cent. Wood-ashes also contain between 1 and 2 per cent. of phosphoric acid.

The following are inferior sources of nitrogen. They are very slowly available, and should be used only where immediate effects are not sought. In some states the fertilizer laws either prohibit the use of these substances in fertilizers or demand that these goods shall be specified when used in making mixtures.

Hair is obtained from slaughter houses; it is often mixed with dried blood and other forms of animal matter. It contains about 15 per cent. of nitrogen.

Hoof-meal and bone dust are by-products containing 10 to 15 per cent. nitrogen and about 2 per cent. phosphoric acid. They are sometimes treated with superheated steam or with sulphuric acid, the treatment rendering the nitrogen compounds more readily available.

Leather scraps and leather-meal are waste products of various factories. When treated with superheated steam and dried or roasted, they can be finely ground. They contain 7 to 8 per cent. nitrogen.

Farm-produced Fertilizing Materials.—Stable or farmyard manure consists of the soil and liquid excrements of animals fed on the farm, mixed with straw and wasted products of the farm.

Horse manure is difficult to mix thoroughly with litter on account of its being very dry. It is called a "hot" manure, because, on account of its loose texture, it easily undergoes decomposition or ferment.

tation, producing a high degree of heat. On this account it is very liable to lose more or less of its nitrogen in the form of ammonia.

Sheep and Goat manure is quite dry, and is commonly the richest of farm-produced manures. Like horse manure, it undergoes fermentation easily and is classed as a "hot" manure. It is similarly very liable to lose ammonia.

Pig manure varies greatly in composition, but is generally rich as compared with other farm-produced fertilizer materials, and contains considerable water. In decomposing, it produces but little heat, and is, therefore, called a "cold" manure.

Cow manure contains, as a rule, less fertilizing materials than any of the producing manures. It contains a large amount of water, and, in decomposing, generates little heat.

Poultry manure contains a comparatively large amount of all the different forms of plant-food, being especially rich in nitrogen and potash. It undergoes fermentation readily, and loses nitrogen unless properly treated with absorbents or preservatives.

Generally speaking, manures produced from working or fattening animals contain 90 to 95 per cent. of the fertilizing constituents contained in the food. In the case of animals which are neither increasing in weight, nor giving milk, the amount of fertilizing materials in the manure will be nearly equal to that contained in the food eaten. The foregoing statements pre-suppose that all the dung and urine are saved, a supposition that is not often true, considering the manner in which stable manure is commonly treated.

Perhaps the elements of manures least understood is the humic matter, of which ordinary manures contain from 16 to 20 per cent. The litter used in bedding stock furnishes much of this, and the quantity depends upon the nature of the material used.—*Journal of the Jamaica Agricultural Society.*

MOCHA COFFEE.

The American Consul at Aden discusses, in a recent report, a statement which is frequently made; and which has been repeated quite recently, that no genuine Mocha coffee reaches the European or American markets from the Arabian ports. The Consul says this statement is quite erroneous, for the books of his own Consulate at Aden, and of the Consular Agency at Hodeida show that over 5,000,000 lb of Mocha coffee were invoiced from these places to the United States last year, not to speak of the quantity sent to Europe. But it is said that, though nominally shipped from Arabian ports, it is really coffee grown elsewhere, and then shipped to Aden to be reshipped as Mocha. This suggestion is also erroneous, as appears from a letter from the British authorities at Aden on the subject. It is true that parcels of coffee from Java, Singapore, and other places are landed in Aden, but, according to the official communication above mentioned, these parcels are bonded in the warehouses of the owners at Maala, and the key lodged in the trade registration department. "When the owner desires to export, a peon of the department is sent with the key to count the bags and bring them to the wharf. As the merchant or owner can have no access to his goods unless accompanied by the peon of the department the transfer of the inferior bean to Aden for mixing with that of Mocha or Harrar is hardly possible." The consul adds that an examination of the Customs authorities' reports shows that foreign coffees are promptly re-exported to other ports, being landed at Aden for transhipment only; while the precautions in Turkish Arabia to prevent mixing are equally stringent. No doubt Mocha coffee is mixed with inferior beans in

Europe, and sold as genuine Mocha, but it is hardly possible that an importer buying in an Arabian port could get anything but genuine Mocha or Harrar coffee.—*Chamber of Commerce Journal.*

BARK AND QUININE FLOURISHING.

Even the smallest buyer of quinine, be he a pharmacist, should be interested in the commercial course of that most important of all drugs—quinine. The year 1899 has been a remarkable one in the history of both the crude bark and the finished alkaloid. Java, which has for years left every other country far away behind in the supply of cinchona, has this year again beaten its record. It has exported about twelve and a-half million pounds of bark, nearly all to Amsterdam, where it has been bought up chiefly by quinine manufacturers who will be able to make from the quantity named 625,000 pounds of quinine and other cinchona alkaloids. Think of it, ten million ounces of quinine practically all sold in a single year. This is not all the world requires in a twelvemonth, but the remaining fifth or fourth of its needs are met from India, Ceylon, Africa and South America.—*B. and C. Druggist, Feb. 2.*

AMSTERDAM BARK MARKET.

At the auctions to be held in Amsterdam on the 15th instant 4,606 packages of ledger, official, and hybrid barks will be offered, as well as 513 cases, 625 bales and 89 serons of succirubra, making a total of 5,833 packages, containing 513,644 kilogramme (say 505 tons) of bark, equivalent roughly to 25½ tons (nearly 900,000 ounces) of quinine sulphate. The first hand stock of bark in Amsterdam on January 23rd was 2,606 packages of Government property and 7,246 packages of private bark, a total of 9,852 packages, including that to be offered at the auction on the 15th instant. The shipments from Java for January are reported to be 660,000 English lb.—*British and Colonial Druggist, Feb. 2.*

A NEW "RUBBER PLANT."—The *Semaine Horticole* of January 13 publishes an illustration and a figure of a new species of Ficus, signed F. Eetveldiana, L. Linden. It is a moderate-sized tree, growing in the Belgian Congo. The leaves are on long slender stalks, the blades cordate oblong. It will form a fine shade tree in the tropics, and grows rapidly under cultivation.—*Gardeners' Chronicle, Feb. 10.*

LUPINS FOR GREEN-MANURING.—A *Bulletin*, by J. Burt Davy, from the University of California, has been issued with the above title. The author gives a bad character to all species of this plant, saying that:—"The Yellow Lupin is considered much more poisonous than the large White, and the Perennial Lupin less so than any other species. In using any species for forage, great care must be taken not to use much at a time, especially of the seeds, and not to use a Lupin ration without intermission. In the event of any cases of "lupinose" appearing, the use of Lupin should be abandoned entirely. Lupin should never be used exclusively in a ration. For forage purposes the Lupins, therefore, do not appear to offer any advantages over other leguminous crops, except as winter growers, and they are certainly more or less dangerous, and not to be recommended indiscriminately."—*Gardeners' Chronicle, Feb. 10.*

AGRICULTURAL AND INDUSTRIAL CONDITIONS IN PARANA, BRAZIL.

Of the three great southern states of Brazil (Rio Grande do Sul, Parana and Santa Catharina), Parana is the least developed. Its area is 85,438 square miles, and its present population, exclusive of the Indians, is about 250,000, 55 per cent of which is colored.

Topographically, the state may be divided into two zones, representing the strongest possible contrast; the littoral zone, situated between the Atlantic ocean and the mountain range which runs from north to south, parallel with the shore—the Serra do Mar; and the mountain zone extending west from there to the Parana river. The narrow strip along the seashore, as a rule, is swampy and unhealthy, the temperature varying between 10° and 35° C. (50° to 95° F.). The altitudes of the table-lands vary from 200 to 1,200 meters (656 to 3,936 feet). The sanitary conditions are very favorable, except where, as in Curitiba and Lapa, the soil and water are, for want of proper drainage, poisoned by sewage. The climate is excellent. The average temperature is 17° C. (62° F.) for the sub-tropical part of Parana; in the table-lands the thermometer sometimes (in July) falls below the freezing point.

The harbor of the state—Paranaguá (with Antonina)—is connected with Curitiba, the capital and distributive centre, by a railroad, which constitutes a masterpiece, not to say a miracle, of engineering, and on its way up the mountains (over 3,000 feet) leads through scenery of unparalleled beauty and grandeur.

It is to be regretted that none of the many pleasure-seekers, travellers, tourists, artists, and students who annually migrate from the United States to France, Italy, Egypt, Germany, and Switzerland find it convenient to visit this beautiful and highly interesting American country, which could be made so easily accessible.

The railroad leading from Paranaguá to the interior (Compagnie Generale de Chemins de fer Bresiliens) was built, with French capital, by the celebrated Brazilian engineer Teixeira Soares. It comprises the following sections: East from Paranaguá to Antonina, 16 kilometers (9.9 miles); west from Paranaguá to Curitiba, 102 kilometers (63.37 miles); and from Curitiba to Serrinha, 71 kilometers (44 miles); thence north to Ponta Grossa, 107 kilometers (66.48 miles), and south to Rio Negro, 89 kilometers (55.3 miles). There is a branch from Restinga to Porto Amazonas (over 12 miles) connecting the railroad with the Iguassu and its tributaries along which the more important colonies are situated. The development of the Iguassu valley is yet in a very primitive state, but this district is destined to have a great future.

The Iguassu river, a tributary to the Parana, is about 800 miles long, but 220 miles are navigable—the section between Porto Amazonas to Porto da Uniao. Although the latter is at present only a little village of about 1,000 inhabitants, there is no doubt in my mind that it is one of the future big cities of Parana; that ere long it will be a large railroad center, outgrowing Curitiba, and will control the trade of the most important part of this promising young state. The construction of a railroad from the coast of Santa Catharina through the rich and very populous German colonies Blumenau and Joinville, northwest to a point connecting with the Rio Grande and Sao Paulo road (now in course of construction) and the Iguassu region is a question of a few years; and both these lines will have to touch Porto da Uniao, which place will also be the terminal point of the proposed extension of the Parana trunk line from Restinga Southwest along the Iguassu. After those railroads are completed, trade and commerce along the Iguassu region and within the fertile plateaus in the west of the state will be rapidly developed, and the bulk of the import and export trade of Parana will probably move by way of the Santa Catharina ports—Itajahy and Sao Francisco—more cheaply and quickly than by way of Paranaguá-Curitiba.

Parana, like the two other south Brazilian states, is crippled for want of capital and proper immigration. Since emigration from Germany has practically ceased, the progress of southern Brazil is retarded.

Serious mistakes were made in the colonization of Parana. Until recently, immigration into Brazil was largely subsidized by the state and the national governments; but it seems the men who had charge of that function were not careful enough in the selection of the material with which they colonized. Large sums of money were wasted and undesirable elements brought to the state in great numbers. Guided by the fear that any one class of immigrants might become too influential by concentration of its forces, some of those formerly in charge of the colonial system located the ninety colonies in such a way as to put the most heterogeneous elements into the closest proximity, intersecting small parcels of one nationality with small parcels of another—Austrian Poles with Russian Poles and Italians, Germans with Russian Poles, Italians with Prussian Poles, etc. Thus the colonial map of Parana presents the aspect of a German-Latin-Slavonic crazy quilt, a fact which is not conducive to a homogeneous development of the commonwealth.

Of the 250,000 inhabitants of the state, about half are natives of Brazil, 40,000 are German, about 40,000 are Italian, 35,000 are Polish (Austrian, Russian, and Prussian), and the rest are of Spanish, French, and other origin.

The import trade is almost exclusively in the hands of the Germans. It amounted in 1897 to \$1,000,000 in foreign goods and about \$175,000 in domestic goods. There were imported 362,000 kilograms (798,000 pounds) of coffee from Santos and Rio; 46,000 kilograms (101,400 pounds) of tobacco from Bahia; large quantities of dried beef and tongues from Rio Grande do Sul, Argentina, and Uruguay; canned goods and preserves from Germany, either direct or through dealers in Rio. Of manufactured articles, there were imported from Germany machinery, rails, iron, hardware, barbed wire, porcelain, china, earthen ware, lamps, pharmaceutical preparations and implements, cutlery, clothing, gent's furnishing, leather and leather ware, shotguns and revolvers, glass-ware; from the United States, druggist's supplies and coal oil; from Norway, 837,000 kilograms (1,845,300 pounds) of pine wood. Importation from France has almost entirely ceased. The cotton piece goods were imported from England, which country also furnished the entire supply of coal.

The export during 1897 consisted chiefly of yerba mate (Paraguay tea), some hard wood, and an experimental shipment of hides and horns to France. Two-thirds of the yerba mate exported (\$1,500,000) went to Argentina and Uruguay and almost one-third to Chile. Unfortunately, none was exported to the United States. For various reasons, the import of mate into the United States ought to be encouraged. From my observation and personal experience, I feel justified in recommending its use as an excellent stimulant and nerve tonic. It is preeminently a temperance drink, and the temperance societies in the United States could do a very useful work by helping to popularize it. Yerba mate, or Paraguay tea as it is called abroad has all the stimulating and sustaining qualities of Chinese tea or coffee, without the detrimental effect caused by their constant excessive use—affection of liver and kidneys, irritation of the nervous system etc.—and it is very cheap. The great masses in Uruguay and Argentina including the famous gauchos (cowboys) of the great prairies, who drink it constantly instead of water, tea, or coffee, hardly ever use alcoholic stimulants. Intoxication is a rare occurrence there. It is almost incredible what hardships they undergo and how vigorous they are, while often for a successive number of days they use nothing to sustain them but mate.

Aside from the sanitary benefits, in helping to develop the mate industry in Parana, we would secure commercial advantages of great importance. The natural resources of the state of Parana are very

considerable, but as yet, little has been done to develop them. Only a comparatively small part of the state is under the influence of civilization; commerce is in its infancy, and the few industries represented in the state (16 mate-mills, 7 small breweries, 3 foundries, 12 barrel factories, some little soap-making shops, a few tanneries, and a furniture factory in Curitiba) are all in a very primitive condition. The only exception is a large match factory in Curitiba, which is well equipped and does a very profitable business.

Although the soil on the highlands is fertile, containing excellent grazing land, and the climate very favorable, the animal industry—cattle, hog, and sheep raising—is very far from what it ought to be. For want of systematic care and regeneration, the cattle are degenerating and the pastures are neglected. During my travels through the interior of Parana, I found, even in districts with large herds of cattle, milk or fresh butter a rare luxury. They would rather go without milk than trouble themselves to milk the cows.

Agriculture and horticulture are in the same state of inertness, suffering from want of capital, deficient means of transportation, bad roads, and scarcity of help.

A very laudable effort to create a new industry, not only in the state of Parana, but throughout Southern Brazil, has been made by a teacher, Mr. Emil Schenk, of Curitiba, who is working hard and successfully to establish rational bee culture. He travels, lectures, and publishes a paper to propagate this work, for which there is an excellent field throughout southern Brazil. I have induced Mr. Schenk to introduce American hives, implements, and machinery appertaining to apiculture. They have given good satisfaction and will undoubtedly, in the course of time, help to secure numerous orders for the specialists (in Ohio) from whom they were bought. Mr. Schenk deserves the fullest encouragement for his intelligent and public-spirited devotion to this good cause.

Commercially and industrially, there is no trace of American influence in the state of Parana; it is therefore doubly gratifying that American intellectuality is represented, highly and ably represented, in another direction—popular education. This report would be incomplete if it did not mention the splendid service rendered to the cause of humanity, Americanism, and good education by the two ladies who conduct the Presbyterian mission school in Curitiba—Miss Mary P. Dascomb and Miss Elmira Kuhl. For over a quarter of a century they have devoted their high qualities of heart and mind to the mission work in Brazil, and came pioneering to Curitiba over ten years ago. Their school now contains three hundred pupils of all nationalities and is prosperous and successful beyond anticipation.

EUGEN SEEGER.

Consul-General at Rio de Janeiro. Washington, October 17, 1899.

MOTH ESSENCE.

According to the *Neueste Erfindungen und Erfahrungen*, the following makes a splendid moth preventer:—

Take of Spanish pepper...	...	100 parts
----- Turpentine oil	50 "
----- Camphor	25 "
----- Clove oil	10 "
----- Alcohol, 96 per cent	900 "

Cut the Spanish pepper into little bits, and pour over them the alcohol and oil of turpentine. Let stand two or three days, then decant and press out. To the liquid thus obtained add the camphor and clove oil; let stand a few days, then filter and fill into suitable bottles. To use, imbibe bits of bibulous paper in the liquid, and put them in the folds of clothing to be protected.—*Nat. Drugg.*

KEW'S FAMOUS GARDENS.

It is almost impossible to imagine a pleasanter retreat on a hot summer day than the Botanic Gardens at Kew. From the time that Sir William Hooker became Curator of the Gardens they have flourished exceedingly. Sir William, who died in 1865, was succeeded by his son, Sir Joseph Hooker; the present Director is Mr. Thiselton-Dyer, C.M.G., F.R.S.

There is nothing quite like Kew in all the wide world. It forms the botanical centre of the British Empire with its fifty or sixty Governments. There is only one British Empire, and there is only one such institution as Kew Gardens—nothing quite like it anywhere. It is not merely that the Gardens are very large and exceedingly beautiful, though in both these respects Englishmen may well be proud of them. They have a total area of nearly 250 acres, a staff of nearly 200 hands—to say nothing of a good many first-rate hands among them—somewhere about three or four acres of glass, and to keep it all going involves a yearly outlay of £20,000. That which meets the eye or comes within the ken of the ordinary visitor to the Gardens is only a part, and by no means the most important part, of the establishment.

It is a huge BOTANICAL CLEARING HOUSE, a centre of exchange, a wealthy and munificent nursing-mother for all the minor establishments of the kind throughout the British Empire; it is a depot to which they can confidently apply whenever they want instructions, or plants, or seeds; it is a fountain head of information for anybody who needs it; and though, naturally enough, Kew gives the first place in its consideration to the British possessions, is on terms of friendly open-handed intercourse with all the world, freely exchanging its treasures with any public garden anywhere under the broad canopy of heaven.

In the sanctum of the Director there are cupboards full of correspondence in all sorts of languages, and from all parts of the world. Ceylon, it may be, finds its coffee plantations being ravaged by disease, submits a specimen of the mischief going on to the experts of the physiological laboratory here, and asks for advice. A merchant in the City has received from some odd corner of the earth samples of an unfamiliar fibrous plant, or one which it is believed may yield a new vegetable dye. He can go to Kew and learn all about it—what the plant is, where it grows, and whether it has already been utilised, and with what results. India some year's ago had no cinchona tree from which to extract the invaluable quinine. Kew suggested that it might very well be grown there, and sent out a stock of plants, and now India yields enormous quantities of quinine. The same has been done for other British dependencies, and quinine, which at one time fetched sixteen shillings an ounce, sells now for four or five.

It is always spring and it is always summer and autumn in one part of the world or another, and all the year round there keep coming into this great central depot parcels of seeds and growing plants cunningly packed in Wardian cases, many of the most dainty and delicate of the denizens of earth's fairest regions turning out on the tables here perfectly fresh and flourishing after travelling perhaps many thousands of miles from the other side of the world. The invention of the Wardian case—an invention only about fifty years old—has greatly facilitated the transmission of growing plants between England and the Colonies, and helped to disseminate fruits and flowers and "economic" plants generally throughout the world. The young nurslings are enclosed in a box, well watered, and tightly shut down under glass, and many of them will thrive better in this limited space than they are found to do afterwards in the magnificent great glasshouses of Kew Gardens.

Plants by the way, do not always take kindly to these great conservatories. They sicken and pine, and it is found necessary to maintain at Kew a small cosy structure, familiarly known in the Gardens as "the hospital." In the great houses it is extremely difficult to maintain the atmosphere at an equable and genial temperature. The plants suffer from the inrush of cold winds through the opened doors, and from the impact of the heated air on the under side of their leaves, but perhaps some day the prisoners in the glass-houses at Kew may have their homes warmed in the manner adopted for sick prisoners at Wormwood Scrubs, where the cells are heated by hot air carried in at the top and sucked out at the bottom. This would warm the upper sides of their foliage just as the sun does, and no doubt be better for them. As it is, the more delicate plants frequently have to go into hospital, or they would die, as indeed many of them do outright.

At the south end of the Gardens is the Great Palm House, which was built in 1845, at a cost of £23,000. It is 362 feet long, 100 feet broad and 66 feet high, and contains nearly an acre of glass. Inside it is easy to imagine oneself in a tropical forest. Palms, tree-ferns, and others of like kind flourish here: and the visitor may note the date-palm, the betel-nut, the coconut, the upas-tree, the bamboo, the cotton-plant, the coffee-shrub, the tamarind and the clove. East of the Palm House is the lake, and westward stretches an avenue through the Arboretum nearly three quarters of a mile long. This is known as Syon Vista, the Duke of Northumberland's estate being within view on the opposite bank of the Thames.

The famous RHODODENDRON WALK, which is one of the chief sights at Kew, runs parallel with the Thames, and is situated near the north-west corner of the Arboretum. The variety of colour here displayed—seen at its best, perhaps, in June—is to those only acquainted with the somewhat stunted shrubs common in private gardens, a relation of unexpected beauty. In its way, the Rhododendron Walk is as famous as is the avenue of horse-chestnuts in Bushey Park, though it has not attained the dignity of being identified with any particular Sunday. The Arboretum used to be separated from the Botanic Gardens proper by a wire fence; and until a few years ago, to the unscientific male visitor, the chief distinction lay in the fact that in the former smoking was permitted, whereas in the Gardens it was prohibited.

The "ARBORETUM"—the original Royal Pleasure Grounds—is a kind of nursery in itself. Here for the past two centuries, experiments have been made in the acclimatisation of trees and shrubs from various foreign countries, and all our parks and public gardens have been enriched and beautified by the additions that this portion of Kew Gardens has made to our botanical wealth. At one extremity of the Arboretum there is a considerable plot of ground parcelled out in squares snugly shut in by thick hedges of privet and holly. Here are nourished thousands of young foreigners, by-and-by to be planted out in the open grounds, but, at present, too delicate to stand our biting winds. Near this nursery are the filter beds, by which all the water supplied to Kew Gardens is filtered. It is drawn in from the Thames to the great lake in the Arboretum, pumped up into the filter beds, then forced up into tanks in Richmond Park, and thence supplied to Kew by gravitation.

To distinguish it from others, the MUSEUM at Kew Gardens is known as museum No. 1. Consisting of three floors and Italian in style, the building faces the Palm House, the large and picturesque lake lying between the two struc-

tures. The Museum was begun in the early fifties, and it was extended in 1881, so crowded had it become with the vegetable economic products and preparations of scientific interest sent for exhibition within its walls. Food, drugs, fibres, timber, are among the varied and carefully classified specimens, and in some cases the processes of manufacture are illustrated. It has been well said that the aim of the authorities is to explain in this Museum everything of interest to botanists which the plants, while alive, cannot set forth.

So many are the attractions of these beautiful Gardens that it is difficult to select any particular house for special notice. Popular favour has indicated the Water-lily House as certainly one of the most interesting. It is situated near the large Palm House already referred to, by the pond at the south end of the Gardens. The tank is 36 feet in diameter, and contains many rare varieties of water-lilies. From centre rises a very fine Papyrus plant. In addition to the numerous lilies, the Sacred Bean of Egypt, the Telegraph Plant of India, the Sensitive Plant, and other curiosities, are to be found in the house, which is well calculated to arouse the interest of even the most ignorant visitor. The famous Victoria Regia Water-lily, of which so much is heard, grows in another building.—*Cassell's New Penny Magazine*.

MINOR PRODUCTS REPORT.

ARECA NUTS.—Offered, 117 packages. Sold, 37. These were cheaper, a drop of 5s to 7s being experienced. The prices were from 15s 6d to 17s 6d.

COCOA LEAVES.—Offered 5 packages. Sold 5. Ceylon leaves of Huanoco character sold at 1s 0½d, and broken small at 7d.

CITRONELLA OIL.—Offered, 4 packages. Sold 0. These were bought in at 1s 1d.

CINNAMON.—In auction, on Wednesday, 254 packages were offered and 23 sold at 3d for wild without reserve.—*B. and C. Druggist*, Feb. 9.

CINCHONA.—The Nederslandche Veem cinchona department at Amsterdam report the shipments during January, 1900, from Java to Europe, at 615,000 Amst. lb against 509,800, 1899; 956,000, 1898; 390,000, 1897; 970,000 1896; 657,000 1895; and 893,000 1894. The total amount of bark to be offered at the Amsterdam auctions on February 15th, weighs 513,644 kilos., containing 23,504 kilos. quinine sulphate, with an average percentage of 5.04 per cent., against 5.30 per cent in the January auctions, and 5.38 per cent for the ten auctions of 1899.

COCOA BUTTER.—For the 70 tons offered at Amsterdam on Tuesday, there was a brisk demand. The auctions opened at 94½c, advancing rapidly to 120½c, the average price being 105½s per half-kilo. Twelve tons of Helm brand sold at 100c to 105½c, and 4 tons de Jong at 100c to 100½c, while 5 tons Mignon were bought in. In London auctions 110 tons Cadbury's brand sold at 1s 4½d to 1s 5½d per pound, the average being a fraction over 1s 4½d against 1s 5 9-16d in January.—*Chemist and Druggist*, Feb. 10.

INDIA-RUBBER is produced by the landolphia of Africa, and the French have made large plantations of it, but there has been a difficulty of getting the gum from the bark as well as from the leaves. M M Arnaud and Verneui, in a paper to the Academie des Sciences, Paris, describes a new method which extracts good rubber from the bark.—*Globe*, Feb. 9.

TEA &c. NOTES FROM WYNAAD.

(From a Correspondent.)

Wynaad, Feb. 25.

FORMER CEYLON MEN.

Since you published your last "Notes" from this district, we have lost two of our most popular and respected residents, who were formerly in your island:—Messrs. Stewart Robinson and W. Q. Wright. The former had gone home for a year, "on private affairs," while failing health compelled Mr. Wright, to seek a change to England, under medical advice. Both gentlemen took a prominent part in all local athletic gatherings, and their friends look forward to their return with favorable anticipations. On the other hand, we have had the pleasure of welcoming Mr. W. Parry from Ceylon, the proprietor of the "Sentinel Rock" estate at Vellera Mulla.

"OUR GROWING TEA INDUSTRY"

in South Wynaad continues to make most satisfactory progress, all the clearings planted in 1898, having come on extremely well, with a minimum of vacancies; while the lands opened in the past monsoon, bid fair to equal the former in every particular. Another fine factory has been added to those previously erected in the country, Messrs. Parry & Co. of Madras, having added such a building to their splendid Pioneer Tea Company's block, at Vellera Mulla last season. Dr. George Watt, Reporter on Economic Products to the Government of India, who paid a brief visit to South Wynaad, towards the close of last year, was especially impressed with the capabilities of the district, in soil and climate, for the profitable cultivation of tea, and highly eulogised the older fields which he was afforded an opportunity of inspecting. Dr. Watt appears to have formed the opinion, that when the older tea already opened, as well as that more recently planted in Wynaad, reaches full bearing capacity, that the average yield will rival the most productive tea districts in India; at the same time he is credited with having discovered and identified the 203th blight with which the tea bushes in Asia are attacked, but up to date, local proprietors do not appear to have been disquieted by this new enemy, and as most of the tea in Wynaad has been planted in detached blocks, with fallow lands dove-tailed in between the gardens, there is reason to assume that an epidemic is less likely to overrun the country, than where an unbroken stretch of the tea bush obtains.

PRICES.

At the same time the opinion is held by competent judges, that the prices realised by Wynaad teas, during the last 12 months, are by no means as satisfactory, as was to be expected from a country which has been so highly eulogised for its advantages in the profitable growth of tea.

In connection with this subject, it is a singular coincidence, that the breaks of tea sold in London, from gardens under the immediate control of Wynaad planter whose experience of tea manufacture is covered by the last quinquennium, have *generally*, if not *invariably*, secured higher prices, at the same sales, than the produce of properties,

solely under the ægis of experienced Ceylon tea planters who have settled in this district. The following quotation from a South Indian journal conveys a fair impression of this subject:—"Wynaad is represented by 'Chulika,' 'Richmond' and 'Kanombyle,' as also by 'Perrengodde,' 'Erramacullee' and 'Perindotty.' The first three properties teas all realized an average of over 8d for considerable breaks, while the latter trio are quoted at 6½d, 6½d and 6½d respectively. The former group are entirely supervised by old Wynaadians, while the last-named are bossed by Ceylon men." "Perindotty," in these figures, boasts "wooden spoon," as its produce *invariably* figures at the foot of the lists. But as the managing proprietor, who came over here in 1896 publicly asseverates, that his domain returns an annual yield of 500 lb. of made tea per acre, which he places f.o.b. for 4d, and disposes of in Mincing Lane for 6½d on the average, while he successfully "places" all his coarser grades of tea locally, amongst native buyers at 5 annas per lb., his ambition would appear to be satiated and he is to be congratulated on the result, in so far as his own balance-sheet is affected; but, to the dispassionate on-looker, it is obvious that as long as the public sale-lists of Wynaad teas are weighted with produce of the class under reference (Perindotty), the average for the district works out at a figure, which conveys an imperfect impression of the capabilities of Wynaad for growing high-class teas. A well-known resident in Ceylon, who has enjoyed the widest opportunities of forming an accurate opinion on these topics, holds the view, that under really skilful manufacture, Wynaad teas should average fully 2d per lb. in excess of the usual sale prices! In the contiguous Nilgiri district of Wynaad, some very fine young tea has been planted within the past two years, while the older fields have been described as equal to anything of the kind in S. India, sales from such properties averaging up to 9d in London.

HOW TO DEAL WITH LABOUR.

There is one point to which the attention of Ceylon men, who may contemplate settling in the Wynaad, should be specially invited, viz., to the unwisdom of taking the law into their own hands, in dealing with local labourers where the standard of work accomplished by the latter falls below what they have been accustomed to look for, in your island, where the discipline in force is entirely different from that ruling in this part of India. Irrespective of the view held by the Wynaad planters, that it is distinctly cowardly for an Englishman to strike an Indian cooly labourer simply for indifferent work, planters who resort to such drastic methods will soon realize that they will not merely drive away their labour, but lose the capital invested in enlisting such people, with the result that their properties will be overrun by weeds, and they themselves will have earned an equivocal notoriety, which is likely to prove a formidable handicap for the residue of their stay in the country. We have a couple of such instances unfortunately in South Wynaad, to substantiate these views.

COCONUT PLANTING ON N.-W. COAST OF CEYLON.

MARAWILA, Feb. 27.

The drought has been broken this month by two falls of rain we had on the morning and eveing of the 25th inst., measuring .85 cents of an inch. The rain was very welcome and was eagerly sucked up by the parched and dry soil. The price of copra and coconuts is keeping up. There seems to be a great demand for the former in Colombo, and agents of some members of the De Soysa family are buying up all they can and at high prices. The copra trade at Madampe and Chilaw is almost entirely in the hands of Chetties, who are very disinclined to sell the stuff locally even at tempting prices. The results of the drought of last year are apparent not only in small crops, but in lower outturns of copra and desiccated stuff per thousand nuts. Those who are paid at the mills for their nuts according to the outturn, find the outturn less than of the previous crop.

PLANTING NOTES.

"KEW'S FAMOUS GARDENS"—are graphically, as well as popularly, described in our daily and T.A., and certainly not too much is made of what British dependencies all round the world owe to Kew.

CEYLON TEA FOR AUSTRALIA.—The following from the Report of Messrs. Tarrant Henderson & Co. is not very reassuring:—

The following extract from a Melbourne circular explains the position, and shows plainly how Ceylon teas have lost ground during the past year:—"The most noticeable feature of last year's trading as regards this market has been the increased demand for Indians, at the expense of Ceylons. If Indians should displace Ceylons to any appreciable extent, the present demand for Chinas will most assuredly continue, if not increase, as a larger proportion of the milder flavoured Foochow teas would be required by blenders to counteract the more astringent properties of Indians, as compared with what is needed when Ceylons are more largely used. Demand runs principally upon teas up to 8d. Ceylons, owing to high costs and poor quality, as compared with Indians, have gone very much out of favour. The latter throughout the year have shown excellent value. Chinas have experienced a steady market, demand being entirely for clean liquoring sorts from 5½d to 6½d, which has been fully supplied." The foregoing, we might say, does not apply to Australia only, but it also applies very largely to the United States, Canada and Russia, whilst to Europe generally, shipments have been disappointing.

Ceylon Rainfall.

THE P. W. D. METEOROLOGICAL OBSERVATIONS OF JAN. 1900.—We append a Monthly Return of rain from which it will be seen that the highest fall was at Naulla in the Eastern Province, 21.40 inches and the lowest at Kayts in the Northern Province 0.38 inches.

THE VALUE OF THE PHILIPPINES.

AN ADDRESS BY SENATOR BEVERIDGE OF INDIANA.

"Mr. President, the times call for candor. The Philippines are ours forever. 'territory belonging to the United States,' as the Constitution calls them. And just beyond the Philippines are China's illimitable markets. We will not retreat from either.

"China's trade is the mightiest commercial fact in our future. Her foreign commerce was \$285,733,300 in 1897, of which we, her neighbor, had less than 15 per cent, of which only a little more than half was merchandise sold to China by us. We ought to have 50 per cent, and we will. And China's foreign commerce is only beginning.

"The Philippines command the commercial situation of the entire East. Can America best trade with China from San Francisco or New York? From San Francisco, of course. But if San Francisco were closer to China than New York is to Pittsburg, what then? And Manila is nearer Hongkong than Havana is to Washington. And yet American statesmen plan to surrender this commercial throne of the Orient where Providence and our soldiers' lives have placed us. When history comes to write the story of that suggested treason to American supremacy and therefore to the spread of American civilization, let her in mercy write that those who so proposed were merely blind and nothing more.

"But if they did not command China, India, the Orient, the whole of the Pacific for purposes of offence, defence and trade, the Philippines are so valuable in themselves that we should hold them. I have cruised more than 2,000 miles through the Archipelago, every moment a surprise at its loveliness and wealth. I have rodden hundreds of miles on the islands, every foot of the way a revelation of vegetable and mineral riches. No land in America surpasses in fertility the plains and valleys of Luzon. Rice and coffee, sugar and coconuts, hemp and tobacco, and many products of the temperate as well as tropic zone grow in various sections of the archipelago. I have seen hundreds of bushels of Indian corn lying in a road fringed with banana trees. The forests of Negros, Mindanao, Mindora, Puanan and parts of Luzon are invaluable and intact. The wood of the Philippines can supply the furniture of the world for a century to come. At Cebu, Rev. Father Julio Segrera told me that forty miles of Cebu's mountain chain are practically mountains of coal. Pablo Majla, one of the most reliable men on the islands, confirmed the statement. Some declare that the coal is only lignite, but ship captains who have used it told me it is better steamer fuel than the best coal of Japan. I have a nugget of pure gold picked up in its present form on the banks of a Philippine creek. I have gold dust washed out by crude processes of careless natives from the sands of a Philippine stream. Both indicate great deposits at the source from which they come. In one of the islands great deposits of copper exist untouched. The mineral wealth of this empire of the ocean will one day surprise the world. I base this statement partly on personal observation, but chiefly on the testimony of foreign merchants in the Philippines who have practically investigated the subject and upon the unanimous opinion of natives and priests. And the mineral wealth is but a small fraction of the agricultural wealth of these islands.

"And the wood, hemp, copra and other products of the Philippines supply what we need and cannot ourselves produce. And the markets they themselves afford will be immense. Spain's export and import

trade with the islands undeveloped, was \$12,175,549 annually. Our trade with the islands developed will be \$125,000,000 annually; for who believes that we cannot do ten times as well as Spain? Consider their imperial dimensions. Luzon is larger and richer than New York, Pennsylvania, Illinois or Ohio. Mindanao is larger and richer than all New England. Manila, as a port of call and exchange, will in the time of men now living, far surpass Liverpool. Behold the exhaustless markets they command. It is as if a half dozen of our states were set down between "Oceania" and the "Orient," and those states themselves undeveloped and unspoiled of their primitive wealth and resources. Nothing is so natural as trade with one's neighbours; the Philippines make us the nearest neighbours of all the East; Nothing is more natural than to trade with those you know. This is the philosophy of all advertising. The Philippines bring us permanently face to face with the most sought customers of the world. National prestige, national propinquity, these and commercial activity are the elements of commercial success. The Philippines give the first; the character of the American people supplies the last. It is a providential conjunction of all the elements of trade, of duty and of power. If we are willing to go to war rather than let England have a few feet of frozen Alaska, which affords no market and commands none, what should we not do rather than let England, Germany, Russia or Japan have all the Philippines? And no man on the spot can fail to see that this would be their fate if we retired.

"The climate is the best tropic climate in the world. This is the belief of those who have lived in many tropic countries, with scores of whom I have talked on this point. My own experience with tropical conditions has not been exhaustive; yet speaking from that experience, I testify that the climate of Iloilo, Suln, Cebu and even of Manila, greatly surpasses that of Hongkong."

"Here, then, Senators, is the situation. Two years ago there was no land in all the world which we could occupy for any purpose. Our commerce was daily turning toward the Orient, and geography and trade developments made necessary our commercial empire over the Pacific. And in that ocean we had no commercial, naval or military base. Today we have one of the three great ocean possessions of the globe, located at the most commanding commercial, naval and military point in the eastern seas, within hail of India, shoulder with China, richer in its own resources than any equal body of land on the entire globe, and peopled by a race which civilization demands shall be improved. Shall we abandon it? That man little knows the common people of the Republic, little understands the instincts of our race, who thinks we will not hold it fast, and hold it forever, administering just-government by simplest methods."

In closing the Senator said: "Mr. President and Senators, adopt the resolution offered that peace may quickly come and that we may begin our civilizing, saving, regenerating and uplifting work. Adopt it and this blood shed will cease when these deluded children of our islands learn that this is the final action of the representatives of the American people in Congress assembled. Reject it, and the world, history and the American people will look where to forever fix the awful responsibility for the consequences that will surely follow such failure to do our manifest duty. How dare we delay when soldiers' blood is flowing."—*American, Manila, Feb. 10.*

THE AGRICULTURAL MAGAZINE, COLOMBO

Added as a Supplement Monthly to the "TROPICAL AGRICULTURIST."

The following pages include the Contents of the *Agricultural Magazine* for March:—

Vol. XI.]

MARCH, 1900.

[No. 9.

THE COCONUT INDUSTRY IN CEYLON.

immense development there has been in the coconut industry:—

ALTHOUGH the coconut palm has been cultivated and has flourished in the Island for centuries, its products did not until recently take as prominent a part as might have been expected among exports. The explanation is that the palm is slow of growth, taking from five to fifteen years, according to the character of the soil, to come into bearing, and not being in full bearing till ten to twenty-five years. In these circumstances, European capital which expects quiet returns such as coffee, cacao, tea, and cardamons yield, has not been largely attracted to it; and the experience of European planters in the Northern and Eastern Provinces, where only very small profits were derived owing to the difficulties of transport, was not such as to encourage investors. What the native plantations yielded, lessened by the enormous claims of home consumption, was therefore practically all that reached the market and was available for export and for manufacture at the hands of British merchants. Within the past ten to fifteen years, however, there has been an immense development of cultivation, partly through the growth in knowledge and enterprise of the Ceylonese themselves, and partly through the appreciation by Europeans of the fact that, though the returns from coconuts are low, they are surer than from any other industry, and that as an investment there is nothing to equal palm cultivation. The following figures from the exports statistics of the Island will show at a glance the

	1861.		1898.	
	Cwt.	Value. Rs.	Cwt.	Value. Rs.
Coconut Oil ..	83,605	1,010,430	435,983	6,694,306
Do Poonac ..	No record.		216,629	897,426
Copra ..	27,279	183,630	506,277	6,328,462
Coir ..	43,163	303,640	183,931	1,767,345
Desiccated Coconuts ..	Not established		116,433	2,342,971
	Gals.		Gals.	
Arrack ..	393,325	267,870	65,902	153,064
			Nut.	
Coconuts ..	—	79,960	12,027,714	541,247

The foregoing figures show not only the great advance made by every product of the coconut palm since 1861, but also the new uses to which the nut and its products are put. Thus, in 1861, either there were no exports of poonac (the kernel refuse after oil is expressed) or they were so small as not to be worth recording. Now they are sent away by thousands of hundredweights to various parts of the world, chiefly Europe, to fatten stock. The trade in desiccated coconuts is of very recent growth, and the exports have found a place in the commercial tabular statements only since 1891; now the kernels of about 40,000,000 nuts are annually deprived of their moisture after being sliced in desiccators, and packed in lead-lined boxes are sent to all parts of the world, including France, to be used for confectionery, &c.

The above items, however, do not exhaust the list of the products of the coconut palm sent away from the island. There is a trade in cadjans (or thatch) and mats made of the leaf, in coir mats and rugs made of the husk, in laths and rafters made of the wood, and in a variety of articles, useful and ornamental, made of the shell. Altogether the value of the exports of the products of the coconut palm cannot be far short of 19 million

rupees a year or 30 million francs. Nor, again, does this represent in any way the value of the coconut industry to the Island. It is the only great agricultural product whose home consumption is even larger than the export trade. It is impossible to state accurately the value of the products of the coconut palm used by the people of the country, in the construction of their houses and huts, in domestic utensils, in trade implements, in food, in drink, in medicine, in the absolute necessities of tropical life, in luxuries, but, even on the moderate calculation that a family uses $1\frac{1}{2}$ nut a day, the 700,000 families of which the $3\frac{1}{2}$ million people in the island may be said to consist, would consume 383 $\frac{1}{2}$ million nuts. A calculation of the exports of last year showed that nearly 400 million nuts were sent away in the husk, in the shell, as oil, and after desiccation; so that the production of the Island cannot be less than 800 million nuts.

It is estimated that, including dwelling gardens, about 700,000 acres (280,000 hectares) are planted with the coconut palm. This acreage, at 75 trees to the acre and 20 nuts to the tree, should yield 1,050 million nuts; but a large number of trees are reserved for toddy drawing, and the distillation therefrom of the spirit known as arrack. The value of the arrack consumed in the Island (over a million gallons) has been computed in a recent official paper at R7,629,067, and of this sum the Government now receives R3,000,000 a year, or one-eighth of the total revenue, by the sale of the monopoly of retailing the spirit to "renters." The importance, therefore, of the coconut industry to the people and to the country is beyond controversy; and the growth of the industry is steadily maintained.

PRACTICAL HINTS TO HORSE OWNERS.

By A. CHINNAH, G.B.V.C.

INTRODUCTION.

Ever since I started practising I have observed that it is very difficult to explain anything based on the rational practice of Veterinary science to a client who is not a horseman. Empiricism is all that is known to such. The empiric is always ready to put down anything and everything rational. The battle between empiricism and rationalism will (as in the case of human medical practice) go on till people are forced by bitter experience to abandon the former for the latter.

As these hints are mainly intended for laymen, it is my desire to avoid technical language as much as possible, but if such terms are unavoidable, they will be explained in footnotes.

CHAPTER I.—STABLES.

Situation.—The stables should be located on a spot well raised from surrounding land, so that the floor will be as free as possible from moisture. It is important to see that no hindrance to the proper circulation of air is possible, and there is no reason why the stables should not be as well constructed and well placed as the master's

residence, in point of aspect, situation and proper elevation. The distance from the other buildings to the stable should be at least 50 yards.

Floor.—Many horse owners in Ceylon favour granite or cement floors for their animals. The preference to this kind of floor is no doubt because it could easily be kept clean. The disadvantages of such flooring are, however, great, and hence their use should be discontinued. Brittle hoof, sand crack, sprains, &c. are the diseases that are brought about by such hard floors.

The best and the cheapest flooring for a horse's stable should be of earthy material, which is a poor conductor of heat and cold. Again, an animal when standing stamps his feet a good deal, and if this goes on on stone or cemented floors, the concussion is greatly felt; but when the texture of the material used is of a yielding nature, it is modified to a great extent. For the tropics a clay floor is the best, and it should be made as follows:—

For the top layer (to a depth of 6 or 8 inches) two parts of fine clay mixed up with one part each of sand and lime should be used. But the lower stratum should be made of good cabook or clay.

The clay or cabook should be spread over a depth of one foot, without any water being added and rammed in with a block of wood. After a day some water should be sprinkled over in the evening. The next morning more earth should again be rammed in and watered in the evening, and on the third day the same process should be repeated. The top layer (the composition of which is given above) should be spread over then, and treated after the same fashion for about three days, and then allowed to dry for three weeks, so that one full month is required to make a floor.

A floor made in this way will be found most satisfactory, but to keep it in good condition is very difficult, unless it is well looked after.

There are some animals that never stale unless they are taken out of the stable. This is an excellent habit, and one which should, if possible, be inculcated. The practice which is sometimes adopted of catching the urine in a bucket or chatty is a good one, but if this is not carried out earth should be sprinkled over the wet ground to absorb the moisture, and the spot brushed clean. The spots stained during the night should be scraped and then filled up with powdered clay, and patted down smooth. A box-full of dry earth should be kept in a corner of the stable for this purpose.

The slope of the stable should not exceed 1 in 80; if above that it produces sprain, weakness of the loins, &c.

(To be continued.)

MODERN AGRICULTURAL SCIENCE.

The *Nineteenth Century* for November last contains an interesting and instructive article referring to a series of useful Agricultural Experiments, which are calculated to throw a good deal of light on agricultural practice:—

Some eighteen years ago the two founders of that New Soil Science were attracted to the study of soil bacteriology. One of them was

Mr. John Hunter, F.I.C., F.C.S., Chemical Analyst and Lecturer on Agricultural Chemistry and Brewing Science. The other was Professor McAlpine, Lecturer on Botany and Botanical Adviser to the Highland and Agricultural Society of Scotland. The discoveries of Pasteur and other investigators as to the paramount importance of having the right crops of yeast plants in the production of beer were doubtless the means by which Mr. Hunter was led to recognise the equally great importance of having in the soil the right crops of soil bacteria. The nodules on the roots of the leguminosæ were first investigated by Messrs. Hunter and McAlpine, and, as the results of a careful series of investigations and experiments, they demonstrated the fact that the bacteria in these root nodules did possess the power of absorbing the "free nitrogen" of the atmosphere and rendering it available for the use of the plant. The discovery of this property on the part of the nodule bacteria is usually ascribed to Hellriegel, but years before Hellriegel announced his discovery in 1836, Messrs. Hunter and McAlpine were teaching the same fact to their students, as the lecture notes of any of their students at that time can testify. After investigating the nature and functions of the bacteria in the root nodules of the leguminosæ, Messrs. Hunter and McAlpine proceeded to carry out a series of investigations in regard to the nitrifying bacteria. At an early stage of their investigations they found there were several well-defined sets of bacteria concerned in the work whose final end is nitrification. They succeeded in isolating and cultivating the nitrous germs, and they also isolated what they believed to be the nitric germ, but in the case of the latter germ they were for a time puzzled to find that they could not from it, in any ordinary culture media, produce nitrates. By a happy inspiration they remembered the plan by which Napoleon was able to secure from the old mortar in the Paris stables a supply of nitrate for the manufacture of gunpowder, and they accordingly added a small supply of mild lime in the form of garden wall mortar to the culture media, with the result that the nitric germs produced nitrates speedily enough. These experimentors knew well enough before then that caustic lime would destroy the soil bacteria, and they therefore taught that the old plan of applying a heavy dressing of four to six tons per acre of hot lime was a huge mistake, while on the other hand a small annual, or at the outside biennial dressing of lime compost to the surface soil, where bacterial life was most active, was essential in successful and scientific manuring. They also found that these lime compounds in the surface soil served a further important use by preventing the soluble silicates being taken up by the roots of the plant, as these soluble silicates were taken up by the lime, and still more readily by the magnesium obtained from the lime, and then formed insoluble silicates which were retained in the soil, and did not diffuse into the plant, so that there was produced a non-silicated stem, or in the other words a cellulose stem, which would bend without breaking in the wind, while the non-silicated straw was much superior in value to the silicated straw.

They ridiculed the old idea that soluble silica built up in the tissue of the plant gave strength and solidity to the stem, and they pointed out that silica was, to all intents and purposes glass, so that straw with a backbone of silica was a brittle substance which was very liable to be broken and lodged by the wind, and moreover was of very inferior feeding value. They also found that just as in the manufacture of beer or whisky, or in fact in any process of fermentation, great quantities of carbonic acid were produced, so through the operations of the soil ferments great quantities of carbonic acid were produced in the soil, and one great function of subsoil drains was to provide an outlet for the great amount of carbonic acid produced in the soil through the operation of the soil ferments. The same line of reasoning went to show that the commonly accepted doctrine as to capillarity required to be recast, and in fact that the whole of the old system of agricultural science as taught in the text-books commonly used, required to be pulled down and built up anew on a biological basis.

(To be concluded.)

THE SOLUBLE MINERAL MATTER OF SOILS.

BY THOMAS H. MEANS,

Assistant in Division of Soils U.S. Department of Agriculture.

If a piece of granite be exposed to the weather for a long time, changes will be noticed gradually taking place. The rock will whiten and finally fall to pieces, leaving a coarse powder without the slightest resemblance to the original rock. If the rock is weighed, it will be found that some of the material composing the rock has disappeared. This process of the breaking down of rocks has been going on for ages unnumbered, and to-day nearly all of the rocks are covered with a layer of rock powder or soil. While the rock is breaking down, or weathering, as it is termed, mosses and lichens begin to grow, and, as they die and give place to other plants, their remains decay and leave in the decomposing rock the black coloring matter which is called organic matter, and which in certain stages of decomposition is called humus. When the rock is all broken down and the organic matter, together with the humus, is mixed with the rock powder, there remains what is termed a soil.

Many chemists have studied this weathering of rocks and the formation of soils, and all of them agree that in the process large quantities of the materials in the rocks are so changed by the weathering that they are rendered more or less soluble in water; then as the rainfall penetrates the rock and the rock powder, this soluble matter is gradually dissolved and washed out, accounting for the loss in weight of the decomposing granite.

Dr. George P. Merrill, of the United States National Museum, has examined a large number of rocks and soils, and has determined that rocks lose by solution from 10 per cent to as much as 98 per cent of their weight in passing from the solid rock to soil, that is to say, in the formation of an acre of soil one foot deep from 200 to 86,000 tons of the rock are removed by solution.

Rocks are composed of various materials, some of which in decomposing or weathering yield large quantities of soluble matter, while others yield little or no readily soluble matter; so that the rock is not dissolved as a whole, but the chemical action of weathering so changes some minerals that parts of them are made soluble. Thus feldspar, a common constituent of many of our rocks, is not soluble in water, but as weathering goes on under the atmospheric conditions, the mineral whitens, breaks down, and the insoluble kaolin (clay) and silica (sand) are left, while potassium carbonate is washed out in solution. On the other hand, quartz, the most common of all minerals, does not change during the weathering, but simply breaks up into finer particles of sand, very little of which is removed by solution.

With the formation of the soil this process of solution and removal does not cease, but as long as water is in contact with the soil grains there are chemical changes taking place and salts are being dissolved. Pure water will dissolve as much as one per cent of some of our soils, but the average amount dissolved will be much less than this, probably nearer one-tenth of one per cent.

The soils, like the rocks, are composed of various materials, and the water dissolves these just as it did the minerals of the granite. Some of the minerals contain plant food, some do not, and when all of the minerals containing plant food are dissolved and washed away, the soils become sterile and will not support plant growth. Plants need only a very small amount of mineral food at one time, but this small amount must be supplied throughout the growing season.

A number of chemists have made chemical analyses of the matter dissolved by water in various soils. They have shown that all of the minerals are more or less dissolved by the water, and that the solutions contain all of the mineral ingredients of a plant. The important plant foods, phosphorus, nitrogen, and potash, are present in small quantities in the solution, while lime is present in a much larger quantity in most soils. Should the plant foods be present in solution in large quantities, the first heavy rain would wash all out that were dissolved, and their value would be lost. The examination of large numbers of samples of drainage water has shown that phosphoric acid and potash are only washed out in small quantities, while nitrogen is removed nearly as fast as formed within the soil.

It was noted many years ago that a soil possessed the property of decolorizing solutions and of rendering foul water pure. This is well illustrated in our common custom of digging wells; the deeper the well the purer the water and the less liable to contamination from surface impurities. This simple fact of the power of sand or soil to take the coloring matter out of manure extracts was noted by chemists, who found, on further examination, that the phenomenon was much more general and of a far larger interest than was first supposed. It has been found that all soils possess this property to a greater or less extent. They remove soluble matters from solution and gradually release them again, so that at no time is any large quantity of matter present in solution. When a solution of potassium nitrate is poured through a soil the potassium is in a

large measure absorbed and retained, while lime takes the place of potash in solution and is washed out as the nitrate of lime. Soils, in other words, decompose the salts and retain the alkaline portion (potash, soda) with the phosphoric acid, while the acid portions (nitric, muriatic, sulphuric, etc.) are removed with part of the alkalies and lime.

The great importance of this fact to the agriculturist can readily be seen. When a mineral fertilizer is applied to a soil, instead of being all dissolved and remaining in solution to be washed down into the subsoil by the first heavy rain, the plant foods are absorbed by the soil and gradually supplied for the use of the plant roots.

During a study of the soluble matter of soils in the Division of Soils several new methods and new apparatus have been used, and the results obtained have been of much interest to those engaged in agricultural research as well as to the practical agriculturist.

The soluble matter of soils may be classed under two general heads, (1) soluble mineral matter and (2) soluble organic matter. Under the first head are classified all salts and soluble compounds derived from the decomposition of rock or mineral parts of the soil. Under the second head are classified all soluble matter derived from plant and animal remains. The study has been confined almost entirely to soluble mineral matter, and only this class of soluble matter will be considered here.

There are three conditions in which a salt can exist within a soil, (1) insoluble; (2) soluble; (3) absorbed—physical and chemical absorption. Of these three conditions the first, in which the salts are insoluble, is of importance as a reserve, for there exists in this condition all of the undecomposed minerals with their stores of plant food. The term insoluble is used in a relative sense, for all the minerals are soluble in water to a slight degree. These minerals are constantly being decomposed, thus yielding their store of plant food in a more available condition for plant growth and furnishing supplies for continued fertility for a long or short time, accordingly as the soil contains much or little plant food locked up in insoluble form. In the second condition, in which the salts are actually in solution, they are, of course, in a condition in which the plant can most readily use them.

The absorption of salts has been briefly discussed in an earlier part of this paper. The condition of absorbed salts is one which has received much attention in recent years. There are two kinds of absorption, chemical and physical. The chemical absorption has already been treated in another paragraph, and the description which follows refers to the physical absorption. Any solid body placed within a solution has the power of absorbing or condensing upon its surface matter which is in the solution. These salts when absorbed or condensed seem to have little effect upon the growth of the plant. They are very slowly given up by the solids to the solution again as the soil is leached. Such physical absorption or condensing action varies with the condition of the surface, that is to say, whether it is rough or smooth, compact or porous, and it also varies with the extent of the surface.

Some salts seem to be more readily absorbed than others. In order to test the relative absorption of various salts which are found in soils, some experiments have been conducted upon the rapidity with which various salts could be washed out from a soil, in which there was no chemical action, but in which the salts were physically condensed, or absorbed bodily, much as a sponge absorbs water. The relative time of washing out the various salts was as follows.—

Relative time of leaching salts.

	Minutes.
Calcium chloride ...	1
Sodium chloride ...	2
Magnesium chloride ...	2
Potassium chloride ...	4
Ammonium chloride ...	8

In this experiment there is the foundation of some of the most important principles regarding the removal of any accumulation of salts. It is seen that the calcium salt was most readily washed out, while the ammonium and potassium salts were the hardest to wash out.

A LETTER ON RABIES.

DEAR SIR,—The following observations should be of interest to your readers, as cases of rabies may be said to be of daily occurrence in Colombo.

This formidable disease has a terrible importance, since it annually claims human victims in considerable numbers.

The symptoms induced by it are very painful for both onlookers and friends of the sufferer to witness.

There are two forms of rabies, the dumb and the furious. The cause is through inoculation by a previously rabid animal. In the early stage there is rise of temperature and all febrile symptoms. The dog seeks hiding places for itself.

In the dumb form of rabies the animal's eyes are dull, while there is a general distressed appearance, dark-coloured tongue and pendulous tongue and lower jaw. In this form the disease runs its course with special rapidity and paralysis supervenes. Face, back and hind limbs are successively invaded until at last the animal becomes completely paralysed.

There is gastric derangement and in some instances spasm of the digestive organs. The animal may collect straw, bedding, stones, &c., and press on it with a view of relieving these spasms. In one case in which I performed a post-mortem examination I observed an abscess formed on the belly which I attribute to the abovementioned fact.

In the early stage of the disorder there is increased sexual excitement and bitches are much less liable to be bitten than dogs. The howl of the mad dog, if once heard, will never be forgotten, and any description must necessarily be insufficient to convey its true character. It is an imperfect bark, followed by incomplete howls. The dog licks and bites himself and especially at the seat of inoculation, which is very irritating.

Any strangeness in the behaviour of a dog must be observed with suspicion. It is remarkable that in rabies the owner is the last person injured.

In the furious form the paroxysm of rabies is well-marked. The animal lies quietly when not excited; it dozes or sleeps soundly, but, if awakened, rises in a fury. "The wrath of the patient varies in different individuals and stages of disease; it either assumes the form of a blind fury, prompting the dog to fly at and worry any strange object, such as a stick inserted through the bars of his cage, or there seems a sort of 'method in his madness' which has been considered an 'instinctive desire to propagate the affection,' thus dogs are the special objects of aversion, and cats too excite the animal to fury, but later herbivora and then men come on the list of those to whom he will do mischief. It is remarked that in the case of rabid herbivora the greatest fury is felt toward dogs, and this is sometimes seen in the case of human beings. The fury is preceded by a period of strange restlessness, a quickness and irritability of the temper, and sometimes a remarkable amount of treachery. The animal is dull but watchful, and a very characteristic symptom is a tendency to snap at flies or other real or imaginary objects, after watching their course for a little time, as though to obtain a favourable opportunity for the act of aggression. While dozing between the paroxysms the animal often starts up suddenly and wildly."

After the febrile stage in the dumb form, the animal becomes paralytic, but in the furious form he is so much stimulated that he could traverse enormous distance. The pace adopted is a slow, dogged sort of trot; at first the animal may go from side to side, biting everything and anything he meets in his track, but soon he goes straight forward, attacking when opposed, and so it is essential that when we notice a rabid dog we should keep out of his path. Latterly the dog becomes exhausted, paralytic and dies.

Rabid animals drink water freely till the loss of swallowing power seen in the later stages. Even then he will endeavour to slake his insatiable thirst. The term Hydrophobia is a misnomer. There is profuse salivation only in the early stages, not lasting more than a couple of days, and there is vomiting in the early stages. Foreign matter such as straw, hair, &c., are accumulated in the pharynx and stomach. It is due to the perverted appetite. Male dogs are most often affected. It is essential in this connection to mention that the saliva of a rabid animal, not necessarily through a bite, falling on the abraded surface of the body is quite sufficient to communicate the disease.

Neither man nor domesticated animals (quadrupeds or birds) are capable of resisting rabies inoculation. Any rabid animal, not only a rabid dog is capable of transmitting the disease to man and other animals.

Dog bites are generally inflicted on the legs except in the case of children, for they are more often bitten in the hands or face. A bite on the face takes a shorter duration to develop the symptoms and a bite inflicted over a protected part, unless such protection is very thin (such in thin trousers or cloth) there is very little likelihood of getting the virus.

The muzzling of dogs, especially during an epidemic of this nature, is very necessary, especially

in the case of the pariah dogs whose home is on the streets. The muzzling should be slackened when the epidemic passes away, for a watch or hunting dog, and in fact any dog is no dog with a muzzle on.

Yours truly,

A. CHINNIAN,

Veterinary Surgeon.

Mango Lodge, Colombo, December 22nd, 1899.

THE CLASSIFICATION OF FIBRES.

(DR. DODGE.)

Among the many wants of man there are two which in all ages and in every clime have been regarded as necessities—food and the covering of the body. The first is an absolute essential to life; the second, an adjunct either to comfort or appearance. In supplying the second necessity man has used the bark, stems, leaves and roots of trees, shrubs, vines, grasses and the fibrous growth often provided by nature to protect their fruits during the period of development; he has employed the skins of animals, their shorn hair or wool, and, lastly, the cocoons of the silk-worm. At first vegetable substances could scarcely have been employed, for primitive man was satisfied with the skin of an animal girded about his loins; but in time, with the dawn of creative intelligence, the filaments of bark and wool and hair were rudely twisted into threads and coarsely woven. These fibres twisted again into larger threads, as fish lines, when knotted together formed fish nets, with which he was enabled to secure food, or a number of these threads wrought together made him cordage. His wants increasing as his inventive faculties were more and more developed, and as he became more intelligent, he felt the need of various utensils in the domestic economy, and pottery, trays and baskets were fashioned from clay, from twigs of bushes or trees, from rushes and the leaves of palms and similar plants. And when canes or overhanging cliffs and rock shelters ceased to be his protection from the elements he learned to build huts and to tatch them with palms and grasses. Having now entered upon a domiciliary existence and new wants being created, mats and screens were woven from seeds and sedges or from strips of palm, and primitive man had entered upon a kind of barbaric civilization. Aboriginal man is primitive in all ages, and the age of his particular race and his environment fixes the scale of his civilization. If, in the early Stone Age, he threw across his shoulders or girded above his loins the skin of an animal slaughtered for food, it was because such rude dress satisfied his simple wants in this direction. And there are native tribes in Africa and Australia at the present time with no higher desires as to their raiment and who still dress in skins, and African Tribes who still adhere to Adam's costume—not fig leaves, but a girdle of evergreens and creepers or a leafy branch, as in the Obbo Tribe. But the economic uses of plants were bound to be learned by savage man in time, and skill was early acquired in preparing them for use. We find, therefore, among the uncivilized races all over the world that many species of

fibre plants have become most useful for utensils, cords, and clothing which civilized man with all his intelligence and inventive genius cannot afford to employ commercially. It is true that the recognized commercial fibres represent those best adapted for use, and that many of them like flax, hemp, and cotton must be classed with the fibres of antiquity. They have established their places because they have been proved to be the best for the purposes for which they are employed and the others can only be considered as their substitutes or as simple "native" fibres. We have therefore two natural groups of fibres—the commercial species with their substitutes which are soon enumerated, and the vast group of the so-called native fibres, many of which might fitly be termed emergency fibres, because they are extracted and used at the moment when needed. These so-called native fibres are also interesting, however, and through our knowledge of some of them, or when a species finds its way to the outside world, a new commercial fibre now and then is brought to light. They are legion when taken collectively, and therefore in enumerating the many species found in the countries of the globe, it is very easy to secure a list that can only be stated in four figures.

We have seen that different forms of cellular structure compose the fibres derived from dicotyledonous and monocotyledonous plants, as well as the seed hairs, or other hairs, from certain species of both divisions of the vegetable kingdom. In general terms, therefore, fibre is composed of bundles of bast or fibro-vascular tissue in the form of long flexible filaments, such as flax, hemp, or manila, or of hairs such as cotton, capable of being twisted or spun into threads or yarns, to be subsequently manufactured into cordage or fabrics. In the economic employment of fibrous vegetable material it is often the case that the fibre bundles are not separated or sub-divided into such delicate filaments as compose the cleaned fibres of flax and hemp, but are used in a conglomerated mass, or even in a more primary form, as the whole stems of seeds or grasses, as in matting manufacture, where both fibrous substances and the cellular tissue and woody waste is used without further preparation than drying. Or, still broader differentiation is found in the employment of palm leaves torn into strips or the woody stems of such plants as the willow and sumac, which are coarsely woven or plaited into baskets and similar objects. These fibrous substances, however, are not always utilized by subjecting them to the operations of twisting, spinning, plaiting or weaving, but are employed in a mass as upholstery material for the stuffing of cushions, mattresses, and the like. Beginning with true fibrous material, such as tow or the waste from scrubbing flax, hemp, &c., and the seed hairs of the many plants known as cotton and silk cotton, and coming down through the list we discover the use of mosses, leaves, and even finely sub-divided wood shavings or 'excelsior' as forms of stuffing or packing material. The last named are not fibre, though on account of their economic employment they are regarded as the substitutes of fibrous substances. Therefore, in considering the many species of plants which are employed for so many different uses in the industrial economy, one species oft-

times being utilized as a cheaper substitute for another, in order to show their relations, both botanically and economically, a division into classes is necessary, that the place and value of each form of fibre may be readily recognized. Several classifications will be found in the works relating to this subject, but after reviewing the 1,000 or more species of vegetable fibres and fibrous substances comprised in this catalogue, a new scheme of classification, considered chiefly from the economic stand-point, has been devised, and is presented as both simple and natural.

DETERMINATION OF AGE BY TEETH IN DOMESTIC ANIMALS.*

Horse.—The horse has 24 temporary teeth. The male has 40 permanent teeth; the female 36 or 40. The smaller number is more usual in females, due to the lack of the tusks. The temporary teeth consist of 12 incisors and 12 molars; the 4 centre front teeth, 2 above and 2 below, are called pinchers; the next 4 are called intermediates or lateral, and the next 4 corner teeth. The permanent teeth consist of 12 incisors, 4 tusks, and 24 molars. The dental star is a yellowish ring appearing next the enamel on the table or crown of the tooth. The following table shows approximately the changes of the teeth with age:—

- 3 to 10 days: Temporary pinchers and 3 molars cut.
- 40 to 60 days: Temporary intermediates or laterals cut.
- 6 to 9 months: Temporary corner teeth cut.
- 19 to 25 months: Leveling of temporary corner teeth.
- 2½ to 3 years: Pinchers replaced by permanent teeth.
- 3½ to 4 years: Intermediates or laterals replaced.
- 4 to 4½ years: Tusks cut.
- 4½ to 5 years: Corner teeth replaced.
- 5 to 6 years: Leveling of lower pinchers.
- 7 years: Leveling of permanent intermediate.
- 8 years: Dental star and notches in pinchers.
- 9 years: Dental star in intermediates.
- 10 years: Dental star in corner teeth.

Cattle.—Cattle have 20 temporary and 32 permanent teeth. The temporary are 8 incisors in the lower jaw and 12 molars. The permanent teeth are 8 incisors and 24 molars. Cattle have no incisors in the upper jaw. The table for cattle is as follows:—

- At birth: Temporary incisors appear.
- 5 to 6 months: Teeth decayed on border.
- 6 to 7 months: Leveling of pinchers.
- 12 months: Leveling of first intermediates.
- 15 months: Leveling of the second intermediates.
- 18 months: Intermediate incisors become stumps.

* Exact correspondence of the condition of an animal's teeth with its age is, of course, not to be expected. It is only hoped that the tables here given, and approved by the United States Bureau of Animal Industry, will aid in forming a reasonably accurate opinion in any actual case.

- 2 years: Permanent pinchers cut.
- 2½ to 3 years: Permanent first intermediates cut.
- 3½ years: Second intermediates or laterals cut.
- 4 years: Corner teeth replaced.
- 5 to 6 years: Leveling of permanent pinchers.
- 7 years: Leveling of first intermediates.
- 8 years: Leveling of second intermediates.
- 9 years: Leveling of corner teeth.
- 10 to 12 years: Dental star in pinchers and intermediates.
- 13 years: Dental star in corner teeth.

Sheep.—Sheep have 20 temporary and 32 permanent teeth. The table for changes is as follows:

- 1 month: Milk incisors appear.
- 3 months: Milk incisors decayed on border.
- 15 months: Permanent incisors cut.
- 2 years: First permanent intermediates cut.
- 33 months: Second permanent intermediates cut.
- 40 months: Corner teeth cut.

Hogs.—Hogs have 28 temporary and 44 permanent teeth. The table for changes is as follows:

- At birth: Temporary corner incisors cut.
- 1 to 2 months: Temporary central incisors cut.
- 3 months: Temporary lateral incisors cut.
- 9 to 12 months: Permanent corner incisors cut.
- 12 to 15 months: Permanent central incisors cut.
- 18 to 20 months: Permanent lateral incisors cut.

EVERYDAY HINTS FOR POULTRY KEEPERS.

ASHES UNDER THE ROOSTS.

Among the very best materials to spread under the roosts in the poultry houses are sifted coal or wood ashes. While they do not absorb as much ammonia as dried earth does, they answer the purpose well enough if used in sufficient quantity.

HOW TO KEEP EGGS FOR HATCHING.

As much as possible eggs for hatching should be kept so as to prevent the evaporation of moisture through the pores of the shell. If the eggs have to be kept any length of time, I have found it a good plan to place them in a box with plenty of bran; some people prefer that the large end of the egg should be upwards.

A BREED SUITABLE FOR MARKET.

Those who wish to raise compact, heavy, finely-trained broilers or fowls for market should try Dorkings. A cross of a Dorking cock on large hens, especially Brahama's or Cochin, makes not only a heavy carcass, but an attractive one. Young hens in laying, excel in quantity, though perhaps their eggs are inferior for hatching purposes.

EGGS FOR HATCHING PURPOSES.

It is advisable to keep eggs intended for hatching above the freezing point, as when thoroughly

chilled the germ is either killed or so badly injured that the chick dies in the shell, or immediately after it is liberated. The egg should be turned once a day, to prevent the yolk setting and adhering to the shell.

NEW QUARTERS FOR POULTRY.

One mistake in poultry-keeping is in running the hens on the same plot of ground continually. It is stated that they will not do as well in the same quarters after running there a few years. That has been the experience of many, and they come to the conclusion that some cheap, but warm, shelter should be made, and every few years removed to an entirely new spot.

CLEANSE YOUR HOUSES.

Spray the hen houses with kerosine, says the "Rural Australian." This is better and cheaper than whitewash. A spraying bellows will soon pay for itself. The spray penetrates every crack and crevice, and it is so fine that a very small quantity of kerosine serves for a given surface. This method of cleansing hen houses is cheap and effectual.

CUT THE WINGS.

It will do a hen no harm to have her wings clipped if she is a tramp, and it will prevent her from visiting the garden as often as usual. The proper way is only to cut one wing. The two longest or flight feathers may be left, cutting all the shorter ones. When her wings are folded the shortened feathers will not be seen.

DON'T STARVE THE FOWLS.

Hens that are starved seldom lay, and hens that are made and kept too fat never lay. The way to be sure of eggs is to strike a happy medium between the extremes, and keep them in good condition. It is not often that poultry need stimulants, and when they do it is from a lack of good attention, pure water, clean food, and clean quarters. It is not often that disease in any form attacks well-kept poultry yards.

SOFTSHELLED EGGS.

In the majority of cases softshelled eggs are caused by the hens being too fat. To remedy this stop feeding corn, and furnish wheat, oats, and barley. If the cause is simply a lack of lime, place old plaster, pulverized bones, or crushed shells, where the hens can pick at them. A little air-slacked lime can be put in the drinking water until the evil is remedied. Crushed bones, green or dry, is an excellent egg-producing food.

THE VALUE OF DRY LEAVES.

A correspondent in an American paper advises the readers to gather fallen leaves before they get wet and sodden, and store them in a dry place. There is nothing like dry, dead leaves in the poultry-house or shed. The hens will scratch them over and over again, until they (the leaves, not the hens) are worn out, and the exercise the

hens get in scratching is what they need to keep them in good health, while necessarily confined to their limited winter quarters.

THE CAUSE OF MANY DISEASES.

It is not cold so much as dampness that brings about disease in the poultry-house. A duck will stay in the water half the time, and be perfectly healthy, but compel them to remain in a house on nights in which the floor is damp, and in a little while they will show the effects of it. Chickens can stand a hard rain occasionally, but a house that is damp and full of bad odours is a regular death-trap, and a breeder of diseases. Half the diseases of poultry are directly traceable to damp houses, and compelling the chickens to roosts where the air strikes them through cracks and crevices.

CHANGE THE FOOD.

Variety of food is absolutely essential to hens; but that is not a good arrangement of the variety which provides corn this week, bran next week, oats the next week, and wheat the following week. These are all good, but should be given at proper periods of the day, rather than during the several weeks of the month. Corn affords heat, and is fat-producing, and should be given sparingly the last thing in the evening so as to supply nourishment and warmth during the cold winter nights. The bran, with table scraps thrown in and all mixed with warm water, is best in the morning, and the wheat and oats should be in places where the fowls can scratch for them during the day.

FOUR FACTS.

In his work on poultry, Mr. Lewis Wright states the following are four facts gathered as the result of careful experiment and enquiry:—"1. The eggs of a young pullet are generally longer and more pointed at the small end than those laid by the same bird either later in the season or the next year. 2. These early pullets' eggs will produce, on an average, about the proportion of six cockerels to four pullets. 3. Eggs laid early in the season by older hens are also, as a rule, perceptibly longer and more pointed than those laid later in the season. 4. It is well known that cockerels oftener predominate in early broods and pullets in later ones.

NATURAL AND ARTIFICIAL RAISING.

The opinion is gradually gaining ground that chicks raised by hens are superior to those brought up in a brooder, says the "Farmer." It makes but little difference whether they are hatched under a hen or in an incubator, but no brooder has yet been made that will approach the hen for comfort. The fact that the hen that steals her nests, hatches and raises more chicks than those that receive so much attention is argument sufficient in favour of the hen over the brooder. One trouble with many persons is, that they continually annoy setting hens in making them comfortable. This is especially true when the eggs are high-priced. An old, setting hen is a good deal like Little Bo-Peep's sheep:—"Leave them alone, and they'll come home, carrying their tails behind them."

CREAM CHEESE.

GENERAL ITEMS.

The following recipe is taken from the *Agricultural Gazette* (London):—

Take one gallon of sweet cream in a glazed earthenware vessel, heat to a temperature of 68 degrees to 70 degrees. If taken from a separator allow cream to stand from four to six hours to ripen. Add 15 to 20 drops of Hansen's rennet diluted with a little water; stir this in for 10 minutes, afterwards covering the vessel, and allow it to stand for 24 hours undisturbed in a temperature of 60 degrees; after this time it should be coagulated about the consistency of Devonshire clotted cream, and should be turned into a cloth and hung inside a vessel to drain in a circulating atmosphere of about 60 degrees. The cloth should be of coarse huckaback towelling, as it is thick enough to retain the cream and at the same time allow the whey to drain. The draining should continue for 18 to 20 hours, and during this time the cream should be scraped two or three times from sides of cloth to facilitate the separation of moisture. After this it should be turned into a fresh cloth and placed under weights of from 8 lb. to 12 lb. until dry enough for moulding, which generally takes from 8 to 10 hours. Before moulding, salt should be added at the rate of 1½ oz. to 2 oz. to the quantity.

On the same subject a lady writes to the *Cape Agricultural Journal*—

When in England I was for several years in the habit of making these cheeses three and four times a week.

This was not done at a public dairy, but was carried out on a fairly large scale on a farm then occupied by my husband.

I had several small wooden vats, about 6 inches long, 4 inches broad, and about 2½ inches deep. Small holes were bored in the bottom of the vats to allow the moisture to escape.

In the bottom of the vats was placed a strainer which had previously been wrung out in hot water—as hot as possible. After adding a small quantity of salt the cream was placed on that strainer, and another strainer (similarly prepared) was put on the top, laying it on the cream.

These strainers were changed night and morning, the fresh ones having of course undergone the scalding process, and this practice was continued until the cheese had arrived at the proper consistency. The time would necessarily vary according to the weather, but I usually looked for results after about three or four days.

The suggestions given in the *Journal* as to the addition to the cream of new milk, sugar, and rennet evidently refer only to the making of what is termed a new milk cheese, but that is a wonderfully different article from a *pure cream cheese*, which is indeed a great delicacy, and one which, in a climate such as that of South Africa, ought to be able to command very remunerative prices.

[We should like to see some of our upcountry dairies try cream-cheese making, for which there should be a demand; it might perhaps turn out to be more remunerative than butter making. Soft cheeses are made in India and sell fairly well.—*Ed. A.M.*]

In answer to a Northern correspondent *re* rice bran as a food for stock, we are enabled to give an analysis of the bran, which we extract from the *Jamaica Agricultural Journal*:—

Analysis of a sample of Jamaica Rice Bran.

Moisture...	10.54
Oil	4.33
*Albuminous bodies	8.91
Carbohydrates, &c.	43.09
Woody fibre	20.50
†Ash	12.63

100.00

This would form excellent ration for stock but for the large proportion of woody fibre, which is entirely indigestible. The proportion of protein (nitrogen) is fair, somewhat less than cornmeal, but only half what wheat bran contains. The fat or oil exists in better proportion to the protein and carbohydrates for our conditions than in corn or cornmeal. Still, unless this rice bran could be sold at one-fourth the price of wheat bran, it could not in any way supersede it on account of the proportion of the indigestible fibre which is an objection to its constant use as a single ration. If mixed to the extent of one-third with some strong condensed food such as cotton-seed meal, and the bloodmeal used for poultry or beanmeal, it might form a cheap and suitable ration for cattle, pigs, or poultry.

The *Danish Milk Times* has the following:—The question has been asked, "Ought milking to be done in a quick or slow tempo?" To answer this a series of trials have taken place in Germany, one of which we herewith publish. On the farm where the trials took place were the same lot of cows—five in number—alternately milked by an elderly woman, who milked very slowly, and by a very able young milkmaid, who finished her work in a very much shorter length of time. The following figures give the milk-yield from the same number of cows, milked at the same time of day, in pounds:—

No.	Slow Milking.	Quick Milking.
1	32	38½
2	34½	51½
3	50	68½
4	40½	43
5	44½	50

As an explanation of this enormous difference it is said that by the quick milking the milk-glands were influenced so as to give a larger quantity of milk.

MALARIA PREVENTED BY LIME.—The opportunities afforded Chief Wiley, of the Chemical Division, United States Department of Agriculture, have led him to the conclusion that the liberal application of lime to all centres of infection would prove of immense benefit, by promoting the vigorous development of nitrifying organisms, thus securing a rapid destruction of organic matter and the conversion of the nitrogenous part thereof into nitric acid or nitrates; and thus it is that lime may indirectly prove valuable in dis-

* Contains nitrogen.

† Including silica.

infesting and destroying the germs of malaria in general and yellow fever in particular. Briefly, it may be said, lime promotes vigorously the decay of organic matter, chiefly by furnishing a neutral or alkaline environment in which the nitrifying germs, which are most active in the destruction of organic matter, exercise their most important functions.

THE LEGEND OF THE ORANGE BLOSSOM.—The wearing of orange blossoms at weddings is accounted for in various ways. Among other stories is the following very pretty legend:—"An African king presented a Spanish king with a magnificent orange tree, whose creamy, waxy blossoms and wonderful fragrance excited the admiration of the whole court. Many begged in vain for a branch of the plant, and a foreign ambassador was tormented by the desire to introduce so great a

curiosity to his native land. He used every possible means, fair or foul, to accomplish his purpose, but all his efforts coming to naught, he gave up in despair. The fair daughter of the Court gardener was loved by a young artisan, but lacked the dowry the family considered necessary in a bride. One day, chancing to break off a spray of orange blossoms, the gardener thoughtlessly gave it to his daughter. Seeing the coveted prize in the girl's hair, the wily ambassador offered her a sum sufficient for the desired dowry provided she gave him the branch and said nothing about it. Her marriage was soon celebrated, and on her way to the altar, in grateful remembrance of the source of all her happiness, she secretly broke off another bit of the lucky tree to adorn her hair." Since the plant was first introduced into Europe it has been customary for a bride to wear a few sprays of the orange blossom in her hair or somewhere on her wedding dress.

No. 10.

A SKETCH OF THE HISTORY OF INDIAN BOTANY.*

BY SIR GEORGE KING, K.C.I.E. LL.D. M.B. F.R.S.

THE earliest reference in literature to Indian plants are, of course, those which occur in the Sanskrit classics. These are, however, for the most part, vague and obscure. The interest which these references have great as it may be, is not scientific, and they may therefore be omitted from consideration on the present occasion. The Portuguese, who were the first Europeans to appear in India as conquerors and settlers, did practically nothing in the way of describing the plants of their Eastern possessions. And the first contribution to the knowledge of the Botany of what is now British India was made by the Dutch in the shape of the 'Hortus Malabaricus,' which was undertaken at the instance of Van Rhee de, governor of the territory of Malabar, which during the latter half of the seventeenth century had become a possession of Holland. This book, which is in twelve folio volumes and is illustrated by 794 plates, was published at Amsterdam between the years 1686 and 1703, under the editorship of the distinguished Botanist Commelyn. Van Rhee de was himself only a Botanical amateur, but he had a great love of plants and most enlightened ideas as to the value of a correct and scientific knowledge of them. The 'Hortus Malabaricus' was based on specimens collected by Brahmins, on drawings of many of the species made by Mathæus, a Carmelite missionary at Cochin, and on descriptions originally drawn up in the vernacular language of Malabar, which were afterwards translated into Portuguese by Corneiro, a Por-

tuguese official in Cochin, and from that language finally done into Latin by Van Douet. The whole of these operations were carried on under the general superintendence of Casearius, a missionary at Cochin. Of this most interesting work the plates are the best part; in fact, some of these are so good that there is no difficulty in identifying them with the species which they are intended to represent. The next important contribution to the Botanical literature of Tropical Asia deals rather with the plants of Dutch than of British India. It was the work of George Everhard Rumph (a native of Hanover), a physician and merchant, who for some time was Dutch consul at Amboina. The materials for this book were collected mainly by Rumphius himself, and the Latin descriptions and the drawings (of which there are over one thousand) were his own work. The book was completed in 1690, but it remained unpublished during the author's lifetime. Rumph died at Amboina in 1706, and his manuscript, after lying for thirty years in the hands of the Dutch East India Company, was rescued from oblivion by Professor John Burman, of Amsterdam (commonly known as the elder Burman), and was published under the title of 'Herbarium Amboinense,' in seven folio volumes, between the years 1741 and 1755. The illustrations of this work cover over a thousand species, but they are printed on 636 plates. These illustrations are as much inferior to those of Van Rhee de's book as the descriptions are superior to those of the latter. The works of Plukenet, published in London between 1696 and 1705, in quarto, contain figures of a number of Indian plants which, although small in size, are generally good portraits, and therefore deserve mention in an enumeration of botanical books connected with British India. An account of the plants of Ceylon, under the name 'Thesaurus Zeylanicus,' was published in 1737 by John Burman (the elder Burman), and in this work many of the plants which are common to that island and to Peninsular India are

* From the Report of the Sixty-ninth Meeting of the British Association for the Advancement of Science held at Dover in September, 1899.

described. Burman's book was founded on the collections of Paul Hermann, who spent seven years (from 1670 to 1677) exploring the Flora of Ceylon at the expense of the Dutch East India Company. The nomenclature of the five books already mentioned is all uni-nominal.

Hermann's Cingalese collection fell, however, sixty years after the publication of Burman's account of it, into the hands of Linnæus, and that great systematist published in 1747 an account of such of the species as were adequately represented by specimens, under the title 'Flora Zeylanica.' This Hermann Herbarium, consisting of 600 species, may still be consulted at the British Museum, by the trustees of which institution it was acquired, along with many of the other treasures possessed by Sir Joseph Banks. Linnæus's 'Flora Zeylanica' was followed in 1766 by the 'Flora Indica' of Nicholas Burman (the younger Burman)—an inferior production, in which about 1,500 species are described. The Herbarium on which this 'Flora Indica' was founded now forms part of the great Herbarium Delessert at Geneva.

The active study of Botany on the binominal system of nomenclature invented by Linnæus was initiated in India itself by Koenig, a pupil of that great reformer and systematist. It will be convenient to divide the subsequent history of Botanic science in India into two periods, the first extending from Koenig's arrival in India in 1768 to Sir Joseph Hooker's arrival in 1848; and the second from the latter date to the present day.

The pioneer John Gerard Koenig was a native of the Baltic province of Courland. He was a correspondent of Linnæus, whose pupil he had formerly been. Koenig went out to the Danish Settlement at Tranquebar (150 miles south of Madras) in 1768, and at once began the study of Botany with all the fervour of an enthusiasm which he succeeded in imparting to various correspondents who were then settled near him in Southern India. These friends formed themselves into a society under the name of 'The United Brothers,' the chief object of their union being the promotion of Botanical study. Three of these brothers, viz. Heyne, Klein and Rottler, were missionaries located near Tranquebar. Gradually the circle widened, and before the century closed, the enthusiasm for Botanic research had spread to the younger Presidency of Bengal, and the number of workers had increased to about twelve, among whom may be mentioned Fleming, Hunter, Anderson Berry, John Roxburgh, Buchanan (afterwards Buchanan-Hamilton), and Sir William Jones, so well known as an Oriental scholar. At the first it was the custom of this brotherhood merely to exchange specimens, but gradually names began to be given, and specimens, both named and unnamed, began to be sent to Botanists of established reputation in Europe. Many plants of Indian origin came thus to be described by Retz, Roth, Schrader, Willdenow, Vahl, and Smith. Rottler was the only member of the band who himself published in Europe descriptions of any of the new species of his own collecting, and these appeared in the 'Nova Acta Acad. Nat. Curiosorum' of Berlin. A little later Sonnerat and other Botanists of the French Settlement at Pondicherry sent large collections of plants to Paris, and these were followed at a considerably later date by the collections of Leschenhault. These French collections were described chiefly by Lamarck and Poiret. Hitherto Botanical work in India had been more or less desultory, and it was not until the establishment in 1787 of the Botanic Garden at Calcutta that a recognised centre of Botanical activity was established in British India. Robert Kyd, the founder of that Garden, was more of a gardener than a Botanist. He was, however, a man of much energy and shrewdness. The East India Company was still in 1787 a trading company, and a large part of their most profitable business was derived from the nutmegs and other spices exported from their settlements in Penang, Malacca, Amboina, Sumatra, and other islands of the Malayan Archipelago. The Company were also in those days the owners of

a fine fleet of sailing vessels, and the teak of which these ships were built had to be obtained from sources outside the Company's possessions. The proposal to found a Botanic Garden near Calcutta was thus recommended to the Governor of the Company's settlements in Bengal on the ground that, by its means, the cultivation of teak and of the Malayan spices might be introduced into a province near one of the Company's chief Indian centres. Kyd, as a Lieutenant-Colonel of the Company's engineers and as Secretary to the Military Board at Calcutta, occupied a position of considerable influence, and his suggestion evidently fell on no unwilling ears; for the Government of Bengal, with the promptitude to accept and to act on good advice in scientific and semi-scientific matters which has characterised them from the day of Kyd until now, lost no time in taking steps to find a site for the proposed garden. Colonel Kyd's official proposal was dated June 1, 1786 and, in a despatch dated August 2, Calcutta Government recommended Kyd's proposal to the Court of Directors in London. Posts were slow and infrequent in those days, and the Calcutta Government were impatient. They did not wait for a reply from Leadenhall Street, but in the following July they boldly secured the site recommended by Colonel Kyd. This site covered an area of 300 acres, and the whole of it with the exception of thirty acres which were subsequently given up to Bishop Middleton for an English college, still continues under cultivation as a Botanic Garden. Kyd died in 1793, and in the same year his place as Superintendent of the Garden was taken by Dr. William Roxburgh, a young Botanical enthusiast, and one of Koenig's 'United Brotherhood.' Roxburgh had studied Botany in Edinburgh, where he was a favourite pupil of Dr. Hope. Desirous of seeing something of foreign countries, he made several voyages to Madras in ships belonging to the Honourable East India Company. In 1776 he accepted an appointment in the Company's Medical Establishment, and was posted to the town of Madras, where he very soon made the acquaintance of Koenig. Roxburgh was shortly after transferred to a remote district, a good deal to the north of Madras, then named the Northern Circars. The station of Samal-cotta, which formed Roxburgh's headquarters during his sojourn in the Circars, stands on the edge of a hilly region possessing a very interesting Flora, and this Flora, he explored with the greatest ardour; and as part of the result of his labours an account some of the most interesting of its plants was published in London, at the East India Company's expense, in three large folio volumes under the title 'The plants of the Coast of Coromandel.' This was Roxburgh's earliest publication on a large scale. The first part of this book appeared in 1795, and the last not until 1819, i.e. five years after the author's death. The increased facilities afforded to Roxburgh after his transfer to a comparatively well-equipped institution like that at Calcutta induced him at once to begin the preparation of descriptions of all the plants indigenous to British India of which he could procure specimens. And so diligently did he work that, when he was finally driven from India by ill-health in 1813, he left complete and ready for publication the manuscripts of his 'Flora Indica' and of his 'Hortus Bengalensis' (the latter being an enumeration of the plants in cultivation in the Calcutta Garden). He also left admirable coloured drawings (mostly of natural size) of 2,533 species of plants indigenous to India. Seldom have twenty years yielded so rich a Botanical harvest! Dr. Roxburgh was thus the first Botanist who attempted to draw up a systematic account of the plants of India, and his book, which is on the Linnæan system, is the basis of all subsequent works on Indian Botany; and until the publication of Sir Joseph Hooker's monumental 'Flora of British India' it remained the only single book through which a knowledge of Indian plants could be acquired. Roxburgh was immediately succeeded in the Calcutta Garden by Dr. Buchanan, Hamilton, a man of many accomplishments, who had travelled from Nepal in the North to Ava and

Mysore in the South, accumulating materials for a Gazetteer of the Honourable Company's possessions. Dr. Buchanan was a Zoologist as well as a Botanist. He had published a valuable account of Mysore, Canara, and Malabar, and had collected materials for a work on the Fishes of India, besides having accumulated a large Herbarium, part of which may now be consulted at the University of Edinburgh. Prior to his death Buchanan-Hamilton had begun to write a learned commentary on Van Rheedé's 'Hortus Malabaricus.' Many of his Nepalese collections were described in 1825 (a few years before his own death) by Don in his 'Prodromus Floræ Nepalensis.' Buchanan-Hamilton remained only one year at Calcutta, and in 1815 he was succeeded by Nathaniel Wallich, a native of Copenhagen, who, prior to his appointment to the Calcutta Garden, had been attached as surgeon to the Danish settlement at Serampore, twenty miles higher up the Hooghly. Wallich remained Superintendent of the Calcutta Garden for thirty years. In 1846 he went to England, and in 1854 he died. During his tenure of office in the Calcutta Garden, Wallich organised collecting expeditions to the then little-known regions of Kamaon and Nepal (in the Himalaya), to Oudh, Rohilkund, Sylhet, Tenasserim, Penang, and Singapore. He personally undertook in fact a botanical survey of a large part of the Company's possessions in India. The vast materials thus collected under his own immediate direction, and the various contributions made by others, were taken to London by him in 1828. With these were subsequently incorporated the collections of Russell, Klein, Heyne, Rottler, Buchanan-Hamilton, and Roxburgh. And by the help of a band of distinguished European Botanists, among whom may be named De Candolle, Kunth, Lindley, Meissner, Nees von Esenbeck, Von Martius, and Bentham (the latter in a very special manner), this vast mass of material was classified and named specifically. A catalogue of the collection was prepared by Wallich himself (largely aided by Bentham), and sets of the named specimens were distributed to the leading Botanical institutions in Europe, every example of each species bearing the same number. No description of the whole collection was ever attempted, but many of the plants belonging to it were subsequently described in various places and at various times. So extensive was the Wallichian distribution that, amongst the names and synonyms of tropical Asiatic plants, no citation is more frequent in Botanical books than that of the contraction 'Wall. Cat.' Besides the naming and distribution of this gigantic collection, Wallich prepared and published, at the expense of the same liberal and enlightened East India Company, his 'Plantæ Asiaticæ Rariores,' in three folio volumes with 300 coloured plates. He also contributed to an edition of Roxburgh's 'Flora Indica,' which was begun by the celebrated Dr. Carey of Serampore, descriptions of many plants of his own collecting. But the task of publishing his discoveries in this way proved beyond his powers, as it would have proved beyond those of any one who had only 365 days to his year, and less than a hundred years as his term of life! Carey and Wallich's edition of Roxburgh's 'Flora Indica' was brought to an untimely conclusion at the end of the *Pentandria Monogynia* of Linnæus. Wallich also began an illustrated account of the Flora of Nepal under the title 'Tentamen Floræ Nepalensis.' But this also came to a premature end with the publication of its second part.

During much of the time that Wallich was labouring in Northern India, Robert Wight; a botanist of remarkable sagacity and of boundless energy, was labouring in Southern India, chiefly in parts of the Peninsula different from those in which Koenig and his band had worked. Wight was never liberally supported by the Government of Madras, and it was mostly by his own efforts and from his own resources that his collections were made, and that his Botanical works were published. The chief of the latter is his 'Icones Plantarum.' This book consists of figures with des-

criptions of more than two thousand Indian species. A good many of the plates are indeed copies from the suite of drawings already referred to as having been made at Calcutta by Dr. Roxburgh. The rest are from drawings made by native artists under his personal supervision. Ample evidence of the extraordinary energy of Dr. Wight is afforded by the facts that, although he had to teach the native artists whom he employed both to draw and to lithograph, the two thousand *Icones* which he published and described were issued during the short period of thirteen years, and that during the whole of this time he performed his official duties.

Besides this *magnum opus* Wight published his *Spicilegium Nilghirensis* in two vols. quarto, with 200 coloured plates. And between 1840 and 1850 he issued in two vols. quarto, with 200 plates, another book named 'Illustrations of Indian Botany,' the object of which was to give figures and fuller descriptions of some of the chief species described in a systematic book of the highest Botanical merit, which he prepared conjointly with Dr. G. A. Walker-Arnot, Professor of Botany in the University of Glasgow, and which was published under the title 'Prodromus Floræ Peninsulae Indicæ.' The 'Prodromus' was the first attempt at a Flora of any part of India in which the natural system of classification was followed. Owing to various causes, this work was never completed, and this splendid fragment of a Flora of Peninsular India ends with the natural order *Dipsacæ*.

The next great Indian botanist whose labours demand our attention is William Griffith. Born in 1810, sixteen years after Wight, and twenty-four years later than Wallich, Griffith died before either. But the labours even of such devotees to science as were these two are quite eclipsed by those of this most remarkable man. Griffith's Botanical career in India was begun in Tenasserim. From thence he made Botanical expeditions to the Assam valley, exploring the Mishmi, Khasia, and Naga ranges. From the latter he passed by a route never since traversed by a Botanist, through the hooking valley down the Irrawadi to Rangoon. Having been appointed, soon after his arrival in Rangoon, surgeon to Pemberton's Embassy to Bhotan, he explored part of that country, and also sent collectors into the neighbouring one of Sikkim. At the conclusion of this exploration he was transferred to the opposite extremity of the Northern frontier, and was posted to the Army of the Indus. After the subjugation of Cabul, he penetrated to Khorassan. Subsequently he visited the portion of the Himalaya of which Simla is now the best-known spot. He then made a run down the Nerbudda valley in Central India, and finally appeared in Malacca as Civil Surgeon of that Settlement. At the latter place he soon died of an abscess of the liver brought on by the hardships he had undergone on his various travels, which were made under conditions most inimical to health, in countries then absolutely unvisited by Europeans. No Botanist ever made such extensive explorations, nor himself collected so many species (9,000), as Griffith did during the brief thirteen years of his Indian career; none ever made so many field notes or wrote so many descriptions of plants from living specimens. His Botanical predecessors and contemporaries were men of ability and of devotion. Griffith was a man of genius. He did not confine himself to the study of flowering plants, nor to the study of them from the point of view of their place in any system of classification. He also studied their morphology. The difficult problems in the latter naturally had most attraction for him, and we find him publishing, in the 'Linnæan Transactions,' the results of his researches on the ovule in *Santalum*, *Loranthus*, *Viscum*, and *Cycas*. Griffith was also a cryptogamist. He collected, studied, and wrote much on Mosses, Liverworts, *Marsiliaceæ*, and Lycopods, and he made hundreds of drawings to illustrate his microscopic observations. Wherever he travelled he made sketches of the most striking features in the scenery. His

habit of making notes was inveterate; and his itinerant diaries are full of information not only on the Botany, but also on the zoology, physical geography, meteorology, archæology, and agriculture of the countries through which he passed. His manuscripts and drawings, although left in rather a chaotic state, were published after his death under the editorship of Dr. McClelland, at the expense of the enlightened and ever-liberal East India Company. They occupy six volumes in octavo, four in quarto, and one (a 'Monograph of Palms') in folio.

Another Botanist of much fame, who died prematurely in 1823, after an Indian career of only nine years, was Dr. William Jack. In 1814-15 Jack accompanied Ochterlony's army to the Nepal terai. He was transferred in 1818 to the Company's Settlement in Sumatra under Sir Stamford Raffles, and during the four years of his residence in Sumatra he contributed to Botanical literature descriptions of many new genera and species which were published in his 'Malayan Miscellanies.' His collections, unfortunately, were for the most part lost by an accident, but those which were saved are now in the Herbarium Delessert in Geneva,

(To be continued.)

COTTON CULTIVATION.

The following is the translation of an article specially contributed to the *Egyptian Gazette* by M. Y. K. Agathon, farm manager to H. E. Boghos Pasha Nubar:—

In accordance with your laudable desire to point out to land owners who grow cotton the means which science and agricultural experience show to be necessary to fight against or at least attenuate the disastrous effects which the scarcity of water this year might occasion, I will here trace some of the means which each might employ. My own personal opinion with regard to the bad condition of the Nile, is that a large number of land-holders will lose the whole of their cotton crop.

In order to allow the cotton plant to resist without water for a reasonably long time I would give the following bits of advice to cultivators:

1. On sweet lands (*Ard Helou*), it is necessary to plough well into the ground. For this purpose European ploughs might be employed. If these are not available, the native plough (*Mihrat Beledi*) may be dragged over the furrow which has already been opened by the same instrument. The effect of this deep ploughing will be to allow the roots of the cotton plant to penetrate rapidly into the sub-soil, which, being always damp, will furnish the water necessary for cultivation.

It has often been remarked in Europe, especially in the south of France, in Italy, and in Algeria, that during years of drought good crops were always obtained on lands which had been deeply ploughed, whilst on those superficially ploughed the crop was almost nil.

2. Sow cotton seed as soon as the climate of the region allows of it, as the plant, sown in time and not suffering from scarcity of water in the first phases of its vegetation, will send out numerous and deep roots which might well resist the dearth of water when the time of drought of long duration comes.

3. Dress and weed out the cotton fields as often as possible. It is usual to give three second dressings to the cotton plant during its vegetation, but I think that this year five and even six second dressings should be given. A popular adage has it that "two dressings are worth one watering or one dressing is equivalent to half a watering." This dictum is quite right as by dressing the earth we destroy the capillarity of the soil, the effect of which is to "pump" its humidity. On clay lands in Lower Egypt, in about ten days after irrigation the earth cracks and shows fairly wide crevices; the strong

rays of the sun penetrating into these crevices quickly evaporate the little humidity which the soil possesses, but when the earth is dressed frequently, these crevices no longer show, and owing to the solar rays in June and July—the most critical time for cotton—not having any more hold on the sub-soil, the humidity which remains there prevents the drying-up, and, in consequence, the death of the plant.

4. When in June and July it is known that owing to the programme of rotation the cotton-fields will remain for 40 or 50 days without water on estates where there are chips or reeds, I would suggest that after irrigation the surface of the soil should be covered with a light bed of chips or reed. This bed would form a sort of shade, the earth begin no longer uncovered, the evaporation of the soil would be prevented, and the water given with the last irrigation would allow the plant to vegetate about fifty days without watering.

5. The digging of sakieh wells might render great services on lands where water may be obtained pretty abundantly to a depth of five to six metres. Half a watering furnished by the sakieh might in certain cases save the crop, which otherwise would be lost without fail. I have myself just had recourse to this means. At Seguine near Mehallet Roh at a depth of six metres the water spouted out, like the creater of a volcano, and in less than half-an-hour the whole of the well, whose holding capacity was 300 metres, was filled with water.

These are a few means which I modestly put before Egyptian cultivators. The country, happily, does not lack in enlightened agriculturists much more qualified than I am, and if each of them, in the interest of the public, would indicate through the medium of the Press the means, other than those I have given here, of remedying the disastrous effect of the scarcity of water, he would assuredly render an inestimable service to the country. I trust that your confères of Alexandria and Cairo will follow your laudable example and will themselves make an appeal to the enlightenment of agriculturists to save the country from a disaster without precedent in the history of Egyptian Agriculture in this century.—*Egyptian Gazette*, March 3.

BURNING WEEDS.

It is a mistake to let weeds go to seed in the garden or around the farm, under the impression that they can be destroyed if gathered in the fall and burned. In the first place, the job is apt to be forgotten until most of the weed seeds have been scattered. Even if a weed is burned its seeds may not be destroyed, unless a hot fire of brush is first made and the weed seeds are thrown on a mass of burning coals. If weeds are piled in heaps they burn slowly, and, as the seed falls to the ground it is protected from burning by the stratum of carbonic-acid gas that is found at the bottom of a slow-burning fire.—*American Cultivator*.

A LOUSE-PROOF ROOST.

The accompanying diagram from the *American Agriculturist* depicts a rattling good idea for protecting hen-roosts from invasion by lice or ticks, which are becoming so troublesome in many parts of this Colony. The plain is simply to suspend the roosts with wire, as recommended a little time ago by Mr. McCue; but, instead of using, as he suggests, a bit of kerosene rag, get an old jam tin soldered on to each wire, forming a cup which can be kept filled with crude or pure kerosene, or even greasy water. The same arrangement might be used for hanging safes, to prevent the inroads of ants.—*Agricultural Gazette*.

WEED-KILLER—Mr. White, a florist, of Worcester, was proceeded against on January 16 in the Queen's Bench Division by the Pharmaceutical Society for selling a weed-killer containing arsenic, he not being a person permitted by law to distribute poisons. It appeared that the florist did not keep the weed-killer in stock, but sent on any orders he might receive to the manufacturers, who executed the order, and gave him a commission. The county court judge of Worcestershire held that the defendant, White, was, within the meaning of the Act, not the seller of the weed-killer. This decision was appealed against by the Pharmaceutical Society but the court, without hearing counsel for the respondent, dismissed the appeal, and upheld the decision of the county court judge. The Society will have to be more careful in operations.—*Gardeners' Chronicle*.

COFFEE IN QUEENSLAND.

REPORT OF THE INSTRUCTION IN COFFEE CULTURE.

SIR,—I have the honour to submit my Report. Having reported myself at your office on my arrival from India on the 10th of January of this-year, I commenced my duties by leaving Brisbane on the 21st, and proceeding, under your orders, to Cook own, with the object of working my way southward through the coffee-growing districts as far as Mackay, and compiling a report on the industry.

It so happened, through force of circumstances that I shall give in detail later, that I was prevented from carrying out the programme originally intended, and, instead of being able to return to Brisbane in a position to draw up and submit to you a detailed report upon the industry in the whole colony, I only got as far as Cairns on my southward journey, and have remained here since.

At Cooktown I was enabled, by the courtesy of Mr. Jas. Dick, to go round the district somewhat, and to see what land there was under the cultivation of coffee, and also to judge of some of the soils and lands in their vicinity during the week I spent there. I much regretted that I could not then spare the time to see the Bloomfield district as well as the McIvor lands, which, from what information I could gather, and judging by the nature of the land, climate, and soil that I was able to see, would seem to be well suited to the cultivation of coffee—even more so than the vicinity of Cooktown.

Coming further south, I had to miss Port Douglas, including the Mossman and the Daintree districts, in both of which places coffee is being cultivated.

Judging by the letters I have received appealing for information and advice from these parts, it would seem that a visit there as soon as may be would be of advantage to the industry and benefit to the growers.

The rainy season coming on, it was desirable that I should push through with the larger centres, and visit the rest later on when time allowed.

I arrived in Cairns on the 4th of February, and from that date until my receipt of your telegram of the 8th March, requesting me for the time to confine my attention to other duties, I was assiduously visiting the coffee-growers and their estates, giving what information was required, demonstrating, to the best advantage in the short time I could spare to each, the necessary works that were due for execution at that time of the year, pointing out errors and omissions, explaining the theory and advantages of as well as the practical reasons for adopting the correct and more modern methods of cultivation, and making notes and collecting matter for the report to be submitted to yourself.

It will be seen, therefore, that my work in connection with coffee culture in this colony since I joined the Department has extended over a few days in January and but little more than the month of February—roughly speaking, for some forty days in all.

Being the only officer of the Department in the North, and on the spot when the last overseer of the Kamerunga State Nursery passed away, I was asked to take over charge pending the appointment of another overseer. Before this could be settled, the new regulations respecting the inspection of fruit and plants exported from this port came into force, and this complicated matters. The work of inspecting imported plants and fruit not being heavy, the appointment of inspector under "The Diseases in Plants Act of 1896" had until then been attached to that of overseer of the Nursery. The new regulation, requiring the examination of all bananas leaving this port for Victoria, made the work very much heavier; and there being no one else then available competent to carry out the examination for the minute signs of fruit fly in its initial stages, I was requested to do this work also. This necessitated my presence in Cairns on nearly every day in the week and on

the wharf frequently until late at night. These matters have now been arranged, however, by the transference of the sub-overseer of the Mackay Nursery for work on the Kamerunga Nursery, and by the appointment of an independent inspector for the port of Cairns under the Diseases in Plants Act. I hope, therefore, while still making this my headquarters and the centre of my operations, to be free after this for work in connection with the coffee industry, I trust also that my headquarters will be permitted to remain in the centre of the coffee-growing districts and the scene of my operations.

In the short time I have hitherto been able to devote to my industry I have visited the districts of Cooktown, and, in Cairns, of Hambledon, Kuranda, Myola, and Atherton. I have not been able to finish the districts of Cairns yet, there being many more estates and growers to visit, including among them the two largest growers in the colony—the Hon. De Molyns and Messrs. Cutten Brothers.

I have visited 43 separate coffee-growers, representing some 200 acres of coffee. Many of these have only small areas, but I would submit these are as important as the larger growers, for it is on the success of the smaller ventures that the larger estates are opened and the large and prosperous industries built up.

With regard to statistics, I regret that I cannot as yet give any, since I have been able to go over so little of the land under the cultivation of coffee. As I go round I hope to be able to compile statistics. Those given to me, on my asking for them, in the Department's offices in Brisbane, showed some 283½ acres for 42 growers. This included Cooktown, Cairns, Nelson, Cardwell, Port Douglas, Daintree, Mackay, Yeppoon, St. Lawrence, and the Buderim range. Whereas I have visited more growers representing in aggregate two-thirds of the area mentioned, in the districts of Cooktown and Cairns (in part only). I therefore am of the opinion that when I can give exact statistics both the extent of the industry and the number engaged in it will be larger than the Department and the public are aware of.

With respect to soils and climates, I have seen only a small portion of the colony as yet, and it would be impossible for me to make any but the most general statements until I have been able to thoroughly go into the whole matter, and have seen and appreciated the conditions to be found in all parts. Bearing in mind this fact, I can still say that both the soils and the climates obtaining in this country are infinitely superior to those in which coffee is grown in many—and indeed most—of the coffee-growing centres of the world.

Labour.—This also is a question that needs careful consideration, and, having had to do with the matter of labour for coffee culture in other countries, I feel the more diffident in making any statement until I have been enabled to take up the subject and make myself thoroughly conversant with all its details. Without losing sight of this fact, I am of opinion, from what I have seen, that while undoubtedly a difficulty (of what magnitude I cannot yet say) it would seem to be much less than many are inclined to think and make it.

The cultivation of coffee has hitherto practically been carried on only in countries where labour is cheap; consequently it has obtained for itself a name as an industry that cannot be successfully worked without an unlimited supply of cheap labour. Sufficient consideration has not been given either to the reduction of the amount of labour necessary for the work or to the choosing of soils and climate where the bearing capabilities will be so favourable as to counteract a comparatively more expensive labour supply. Those intending to invest capital in coffee cultivation, having little or no practical experience of it themselves, rush to countries where labour is cheap, and there put up with conditions of climate and soil that are frequently exceedingly poor. In this country the conditions of climate are exceptionally favourable, and of soil such that very few coffee-growing countries can in any way compete with. I am therefore inclined to think that

economy of labour, by adopting modern and better methods of culture and thus reducing the cost of production; careful and scientific curing, allowing the produce to take its place as a high-grade article and bringing into competition its analytic qualities, which are high; together with the infinitely greater bearing capabilities that coffee here has over that of other countries, will enable Queensland coffees to compete favourably in the world's market, in spite of a disadvantage respecting labour.

The Market for Coffee.—There would seem to be a fear amongst some of the growers that owing to the recent drop in prices there will be no sale for coffee produced. In reply to this, and without going into details of imports and local sales, I would point out that the drop has been principally in the medium and low-grade article. Sir Frederick Able, in a letter that has already passed through your office, corroborates this when he says, speaking of the coffee market at the time of the arrival in England of the consignments of Queensland coffee sent last season: "Prices are depressed for all *except* the finest coffees."

So long as the coffee sent to the London market is a well cultivated and well-cured article, and therefore takes its place as a high-grade coffee, there is no doubt whatever about there being a ready market for it. Prices of low grades may possibly remain low, and even have a tendency to drop, but high grades will always sell well. Roughly speaking, about two-thirds of the world's output of coffee is low grade and only one-third high grade, and the low grades must make way for the finer coffees.

It has been remarked—and printed and published also—that the fault of Queensland coffees is in the *curing*, which means that while its analytic properties are high it is otherwise a poor sample. From what I have been enabled to see, this is undoubtedly so, but this is only half the truth. The root of the matter lies in the cultivation. A badly-cultivated sample will not, even with the best and most scientific curing, give the same profits that a well-cultivated sample will do, because in almost all cases it will have cost too much in production.

A coffee produced at 6½l. or 7d. per lb. and sold at 7d. or 7½d. does not pay to cultivate, or the profit is so small that the investment does not give even fair interest. When by good cultivation the cost of production is lowered to 4d. or 4½d., and the same article (putting better curing on one side for the time being is sold at 7d., or 7½l. the difference, amounting to £28 a ton, is readily appreciated.

By cultivation it must be understood that methods, times, and seasons are meant. The most excellent work—be it weeding, draining, pitting, digging, forking, staking, topping, pruning, handling, mulching, manuring, or even picking—if not done by good methods or at the right time and seasons, so as to save and economise labour as well as to give the greatest amount of benefit to the plant, amounts to bad cultivation, since it means enhanced cost of production.

For instance, a hauling in the second year costing very little, would mean not only quicker and cheaper handling and a saving of labour in the third year—the two works together costing less than only the one operation in the third year—but enhanced stability and sturdiness of the tree, better and stronger wood, a direction of energy into the right channel and more, as well as a better sample of crop in the third and subsequent years.

The subject of statistics, soils, climatic conditions, markets (both local and open), values of present samples of coffee, methods of culture in vogue and modernised, the labour question as affecting the industry, the classes and varieties of coffee in the colony, &c., &c., I would request your permission to allow to stand over until I can make myself better acquainted with the conditions obtaining in the colony.

It will be evident to you that it would not be reasonable to go into details of such matters after only forty days' observation, and that statements respecting them should be applicable to the whole colony; whereas, with the limited time I have been able to devote to the colony, any remarks I were to record

must necessarily either be evolved from hearsay or unconsciously biased in favour of what I have been able to see. I would request that I be allowed to compile a full and detailed report either during the year or, should my other duties hinder an early drawing up of such a report, in time to be included in the departmental report for 1899-1900.

I would also suggest that it would be of advantage to the industry in general if I were to monthly submit an article on one of the many details of culture for the publication in the *Departmental Journal*, so arranged that they could be subsequently embodied in a pamphlet which could be issued as a bulletin for use of resident growers in a compact form, or for newcomers who intend opening out in coffee.

Since my work in connection with the industry has been, for the unavoidable and unforeseen reasons above mentioned, stopped temporarily, I have received many letters asking for advice and information, and also for visits to different parts. I have endeavoured to give what instruction I could by letter, and a good deal of my time has been so occupied. Giving instruction by letter, however, on very vague data, to be applicable to districts and conditions I have not seen, necessitates the mentioning of so many different methods necessary for as many possibly different conditions of climate, soil, &c., that a great deal of inapplicable matter has unavoidably to be recorded, and a great deal of time wasted.

I have already had correspondence with and also been interviewed by several newcomers, who, hearing of my arrival and appointment, wish to invest in and open up in coffee.

Information has been asked for from time to time by the Department both for different parts of the colony and for outside, and duly given, and an article published in the *Agricultural Journal*.

HOWARD NEWPORT.

TRIAL OF FLORIDA VELVET BEAN.—Mr. F. A. Hunter of Halfway Creek (country of Clarence), reports having tried a plot of velvet bean alongside a plot of cow-pea. The seeds were shown in November. "The growth of the velvet-bean is enormous, covering a row of corn that is close with one mass of vine, while the cow-peas are only just running." In reference to this matter Mr. Valder remarks that while the Florida velvet bean is undoubtedly of great value in the Northern districts, it could not compare with the cow-pea for districts as far south as the Hawkesbury, for instance.—*Queensland Journal*.

RIVAL TEA ENTERPRISE: CEYLON AND INDIA.—Whether the climate of Calcutta is inimical to any exertion over and above what is absolutely necessary for the actual carrying on of business, we cannot say, but one thing is certain, and that is that we are laggards in the race compared with our Ceylon brethren. Ceylon has been spending its money freely, and pushing its teas in all directions, with an amount of life and vigour which is bound to ensure success. We have done nothing like so much in comparison. We may some day have a rude awakening from our lethargic somnolence. Although we imagine we are slumbering in safe security and have no cause to fear any rivalry, we shall later on, probably, find Ceylon in fixed possession of markets which we should have captured long ago. When we read the reports of what the Ceylon planters are doing, and note how very energetically they are working to extend the consumption of their teas the world over, we cannot but help being struck with the want of energy and push we are displaying, in comparison, in our efforts to extend the consumption of our teas. The facts are so patent that further comment is superfluous.—*Indian Planters' Gazette*, March 17.

MICA-MINING IN BENGAL.*

DIFFERENT KINDS OF MICA, SIZE OF SHEETS
AND VALUES.

By A. Mervyn Smith, M. Inst. M.M.

Position.—The mines described are situated between 85 deg. to 86 deg. 30 min. east longitude, and 24 deg. 25 min. to 25 deg. north latitude. The country is made up of a series of parallel ranges of low hills some 400 ft. above the surrounding country and 1,200 ft. above sea level. The direction of the ranges is east and west nearly; they form the boundary between the Hazaribagh district on the south, and the Gaya and Monghyr district on the north, being part of the Bengal Presidency, India.

Geology.—The country is made up of gneiss, grading into mica schists, tourmaline schists, hornblende rocks, quartzites, and a coarse felspathic rock resembling conglomerate with intrusive dykes of fine-grained diorite. The hornblende rock closely resembles the diorite, and weathers into similar rounded boulders. But this variety passes into a much coarser kind, in which "blebs" of white felspar are so close-placed as to give it a "banquet" appearance. The mica schists are strongly developed in this area, and are made up chiefly of white mica (muscovite) with here and there a little black mica (violet) and red mica (lepidolite). This rock is highly schistose, breaking up into thin laminae, and consists chiefly of small plates of mica, cemented together, with a slight admixture of felspar and quartz. It is this rock that contains the lodes that yield the mica of commerce. The gneiss and other foliated rocks have a nearly east and west strike (about 5 degrees north of east and south of west), and underlie to the north at an angle of about 75 degrees. These rocks are classed in Indian geology as among the younger gneisses.

Pegmatite Veins.—Running with the bedding of the schists, from east to west, are numerous veins of granite (pegmatite) varying in width from a mere thread to 20 ft. The schists are in places faulted or thrown out of their normal strike. The pegmatite veins are subjected to the same "faulting," and frequently at the point of "faulting" short north to south veins or "cross courses" of great width have been formed.

The veins are made up of amorphous masses of quartz, large crystals of pink felspar (orthoclase), and crystals or "books" of mica (muscovite). The quality of the vein varies with the nature of the adjacent rock. Near to the quartzites, the vein stuff is nearly pure quartz with little felspar and mica. Where the adjacent rock is highly felspathic, pink felspar crystals are the chief constituents of the lode; while we may look for a large predominance of mica, where the including rock is mica schist. This fact is of importance, as a knowledge of this peculiarity of segregation in the vein matter enables the miners to discriminate between the spots that will yield more or less mica.

In addition to these three chief constituents of the pegmatite veins, the following accessory minerals are sometimes found—tourmaline, garnet, tin-stone and columbite. The tourmaline is at times strongly developed. Near to the tourmaline schists, large massive crystals of black tourmaline are not infrequent in the lode, and occasionally crystals of tourmaline penetrate the mica books across the planes or lamination and destroy the value of the sheets.

The pegmatite veins in this district are apparently of aqueous origin and due to segregation. The following are some of the data pointing to this conclusion. 1. In many places the veins die out in depth and in length. 2. The vein matter partakes of the quality of the including rock, quartz, felspar, and mica predominating as the lode traverses rocks containing these minerals in excess. 3. The crystallisation of the vein matter varying within very short distances not being at all homogeneous, as one would expect in an igneous dyke. In places the crystals of mica are 2 ft.

long, 18 in. wide, and 9 in. thick. Within a few hundred feet of either side of this spot the mica books are small and worthless.

Ages of the Mines.—The zone of mica-bearing rock has been worked for centuries by the Hindoos. Mica is largely used by them for ornamental purposes, such as inlaid work, tassels, flower, toys, and banners.

The large clear plates are much used by native artists for portrait painting, as being extremely durable and not affected by heat or damp and impervious to the attacks of insects. The waste mica is ground to a coarse powder, and after being mixed with starch is applied to cheap cotton cloths to give them a sheen.

The great marts for mica for native consumption are Patna and Delhi. Dr. P. Breton, who visited these mines in 1826, found as many as 5,000 people at work at different mines. In 1849 Dr. McClelland gives the output as 100,000 maunds (a maund being 82 lb.). In 1863 the statistical account of Bengal says 10,000 maunds were exported.

The Native Methods of Mining.—The native mines are of the most primitive kind. Open cuts along the outcrops of the pegmatite veins where books of mica are seen in any quantity. These cuts are continued down 20 ft. or 30 ft. till the sides become dangerous. No timbering is used to keep the sides from falling in, and frequently accidents happen and the miners are buried beneath the fallen walls of the reef. Where exceptionally rich stuff is met, and the vein-stuff is decomposed and soft to some 50 ft. or 100 ft. inclines are put in, and follow down the rich shoots of mica in a most tortuous course, zig-zagging about from side to side with the "leads" of rich ground. Long lines of women, near to each other and placed in double row from the water level to surface, hand out earthen pitchers—called "gurrahs"—to one another; the full pitchers are handed up one line and the empties down the other. As many as seventy women are sometimes placed to remove the water from a mine not 35 ft. deep in perpendicular depth. The incline, of course, was much more than this in length.

Where the reef is highly felspathic and of large size, decomposition extends to a quite hundred feet or more, and it is here that their largest mining operations are carried on. In order to ventilate the inclines and draw out the mica, perpendicular shafts, about 2 ft. in diameter, are put in. The author counted as many as thirty of these circular shafts along the strike of the reef, and within a few feet of each other.

The miners are a local tribe called "Bandathis"; the men, women and children all working at the mine, when they have no agricultural work in the fields. Work is only conducted in the dry months (November to May). Immediately the rains set in they return to the tillage of their fields. Work is only conducted in the day, beginning about 8 a.m., and giving over at dusk. When the veins are hard, yet sufficiently rich to pay for the labour, large fires are kindled against the face of the lode, and when the vein stuff is sufficiently heated, water is thrown on to it, when the sudden cooling causes the rock to shrink and crack. In these cracks wedges of soft iron, locally manufactured from the magnetic iron ores common in this neighbourhood, are driven and large boulders detached. The exposed books of mica are chiselled out and taken to surface. The books of mica are split into sheets of about $\frac{1}{2}$ in. in thickness. All the rough edges and flaws are trimmed off by means of a sharp sickle (called "hasawah"), and then sorted according to colour and size. The sheets are in some cases very large, 24 in. by 18 in. being the largest in this district. In the Itakuri Mine, Nellore district, Machas, plates 60 in. by 40 in. have been obtained.

Present Method of Work.—It is only within very recent years that Europeans have taken to the mica industry. Mining is still conducted on purely native methods described above; and although 250 mines are at work in this district, on not a single one is machinery of any kind used, and certainly on none of the properties visited by me this year (1898) was there the least attempt at European methods of mining. The same wasteful, slow, and laborious system practised by the natives for hundreds of years

* Paper read before the Institution of Mining and Metallurgy.

is still in vogue. Men are sent out during the rains to search for likely-looking outcrops of mica. The mica-schist being softer than the other members of this series of rocks, is eroded into valleys—the more quartzose beds making the ridges of hills. A certain amount of alluvium and talus from the adjacent hills covers the valleys.

After exceptionally heavy rain this surface deposit is washed off, and with it the decomposed felspar of the pegmatite veins, having exposed tufts of partially decomposed mica. The natives call these tufts "foo-foo" and believe that they grow during the rains, as they cannot account for their exposure at surface after a heavy shower, where there was nothing apparent before the rain. Having discovered several of these "foo-foo" spots, these are marked off for mining operations as soon as the dry season begins. Parties of men, women, and children are set to work on those outcrops, and the books of mica dug out, packed in loads of about 30 lb., and brought in at dusk to the central store.

Here several skilled men are seated on the floor trimming the mica before it is packed away for market. Before each man is a stout peg, driven firmly into the ground and protruding about 18 in. The books of mica are first split into plates about 1 in. in thickness, the mica easily splitting into laminae of any thickness. The trimmers are provided with sharp sickles, and the point of this knife is used for opening the sheets. Imperfect laminae are now peeled off the plates till both surfaces show a clean, even face. The plate is supported against the side of the peg, and the sickle drawn downwards to trim off the jagged ends and irregularities along the edge of the sheets of mica.

After trimming, the plates are sorted for the European market, the United Kingdom and America being the chief buyers. The sheets are first sorted according to quality, four kinds being recognised by the dealers.

1. Ruby mica, hard and tough.
2. White transparent mica.
3. Discoloured and mica.
4. Black mica and flawed.

If 8 represents the value of ruby mica, 4 would be paid for white, 2 for discoloured, and 1 for black and flawed sheets of equal size. The sizing is as follows:

Special Sheets Measuring more than 50 Square inches.

No.	1.	2.	3.	4.	5.	6.
No. 1.	Sheets of from	36 to 50	square inches.			
" 2.	"	24	36	"		
" 3.	"	16	24	"		
" 4.	"	10	16	"		
" 5.	"	6	10	"		
" 6.	"	4	6	"		

Quoting from a recent sale sheet at an auction in London, the following prices were realised:

Best Ruby.	Per Pound.
Number.	s. d.
1	6 8
2	4 0
3	2 0
4	1 0
5	0 4
6	0 2

Specials bring as much as £1 per lb, according to size of sheets.

The sheets are trimmed irregularly into any shape they will take to clear them of flaws. Should square rectangular, or diamond-shape sheets be wanted, a special rate has to be paid for these to allow for the great waste.

The sheets are packed in boxes of 1 cwt., and transported on carts to the nearest railway station, 100 miles distant. From thence they go to Calcutta, and are shipped to London or the United States of America.

Market and Output.—During the year 1895-6, 8,913 cwt. of mica were exported from India, of which the mines under review contributed 8,835 cwt., valued at R995,000 or £66,000. The yield of the mines may be placed at double this figure, one-half being require

for the Indian market, and that chiefly of the inferior kinds.

The export trade is a growing one, as the following figures will show:—

Exports.	1892.	1893.	1894.	1895.	1896.
	cwt.	cwt.	cwt.	cwt.	cwt.
Bengal..	2,298	3,310	4,843	5,126	8,835

Hard, sound, ruby mica is much used for the doors of glass and steel furnaces where extreme heat is required. The mica is not affected by the extreme heat, and thus enables the workmen to look into the furnace and watch the crucibles of molten matter. Thin sheets are made into chimneys for incandescent gas burners, also for fire screens and for electrical purposes, as mica is an extremely bad conductor of electricity.

A method of cementing sheets of mica into a card board has been recently patented in Germany, and this cardboard is used for coating boilers, mica being a nonconductor of heat. It is also manufactured into helmets for fire-brigade men, packing for fireproof rooms, etc. Thinner sheets are made into envelopes for wrapping valuable documents.

Quantity of Mica Available.—At present India yields the bulk of the mica consumed in the Arts, and of this quantity nearly all comes from the district described. The pegmatite veins in this locality are numerous and of large size, and are in places extremely rich in mica, nearly one-third of the vein-stuff being of this material. The quantity of mica available is practically inexhaustible. The present method of mining is wasteful in the extreme and fully nine-tenths of the mica extracted from the mines is injured and rendered unfit for export. Thousands of tons of waste mica are to be seen at the mouths of the mines and at the dressing floors. Probably the new patented method of cementing mica into cardboard may create a market for this. There cannot be the slightest doubt that when European methods of mining are introduced, the cost of production will be materially reduced, the waste will be much less, and a better quality of mica will be secured. At present only the decomposed, or partially decomposed, vein-stuff is mined. Here the mica must also undergo a partial decomposition, but, of course, not to anything like the extent of the felspar. In the hard vein-stuff the mica is hard and tough, and this class of mica commands a better price.

Some of the veins yield black mica (biotite). This is largely used as a drug by Hindoos and Mohammedans. Reduced to a powder, it is supposed to be very efficacious in cases of dysentery. The sheets of mica are at times very queerly marked. In places one-half of each sheet will be muscovite and the other half biotite, the line of division between the two colours being a perfectly straight line, and there being no apparent change beyond the colour in the uniformity of the sheet. Other sheets, again, are marked with a chequered pattern in black lines, the lines being due to magnetite. Again, there are dendritic inclusions of white quartz between the laminae. All markings take from the value of the sheets. The most esteemed colours are pure ruby, amber, light green transparent white. There is also a silver white, which the natives prize for inlaid work.

A demand for indian mica has lately sprung up in the United States of America. In 1895 the quantity taken was 1,900 cwt., while in 1896 it was 5,076 cwt. Indian ruby is found to answer the purposes of furnace work better than the locally obtained mica.

[Altogether, the export from India in 1897-98 was 11,603 cwt. and from Ceylon in 1897 it was 166 cwt. —Ed. T.A.]

Riches.—It was a saying of Plato, that the only certain way to be truly rich is not to have more property, but fewer desires. For whoever is always grasping at more avows that he is still in want, and must be poor in the midst of affluence. Here is a philosophy which many of us can contemplate complacently.—*Journal of the Jamaica Agricultural Society.*

ORANGES: HOW I MANAGE TO HAVE RIPE ONES.

The following communication was sent to the Director of Public Gardens, who kindly forwarded it to us as likely to be of interest:—"All through the year this is the way I did it. I had an orange tree in my kitchen garden last year in full bearing, and when the fruits were about the size of a pigeon's egg I went to work and took off all leaving 30. I then dug a trench 18 inches deep around the tree just under the outer leaves where the rain falls and had the trench filled with pen manure, and then covered up, thus forming a ridge about a foot high around the tree, and shortly after the tree began to blossom on one side only, and put out 38 oranges on one branch. Shortly after I saw more blossoms appear on the next branch to the young fruits, and 21 more came out. Since then the tree has been constantly blossoming and fruiting out young oranges, one course after another right around the tree, I was however careless in noting what month it was last year when I started the work, all I know is, the first 30 oranges were ripe in December the 38 were ripe at the end of March, and the 21 I am eating now; and I am able to show any man to-day four different sizes of fruit, and blossoms on the tree also. I don't know if this is an exceptional case, being the first tree I have tried, but I think its worth mentioning and also worth trying.—E.A.K, Little London, P.O."—*Journal of the Jamaica Agricultural Society.*

WATTLE CULTIVATION.

A NEGLECTED QUEENSLAND INDUSTRY.

There are many portions of the mountainous parts of Queensland of which it is often remarked that the land is apparently fit for nothing—that it will not feed the proverbial goat; that the undergrowth of young gums and wattles will not even allow a dog's bark to travel. From a purely agricultural point of view, such country is undoubtedly useless as farming land; but there are few "bad lands" in the colony, provided they do not consist of sandy, swampy "wallum" country, on which something of value will not grow. Take the gravelly ridges so frequently met with on the coast. They are unsuitable for maize, which will produce on good lands from £6 to £8 per acre, but they are the ideal home of the Sisal hemp, and of the mauritius hemp, which will produce £40 per acre. In like manner, the ridges and gullies of the Main Range are a favourite habitat of the wattle tree, which will yield from £25 to £30 per acre. During the winter season, the eye of the traveller amongst the ranges is delighted with the beautiful, feathery, yellow bloom of countless wattle-trees of different varieties.

Three varieties have been planted for the purpose of obtaining tan bark, but these only two are of commercial value. The third was an unfortunate introduction, and in New Zealand formed a large part of the earlier-laid-out plantations. It is comparatively worthless. This is the *Acacia dealbata*.

The second best is the Golden Wattle (*Acacia pycnantha*), the bark of which yields a large per cent. of tannin. But this does not form a large-sized tree, and from its habit of growth, throwing out many stems, more like an immense bush than a tree, it is more troublesome, and consequently more expensive to strip than the Black Wattle (*Acacia decurrens*), which grows to a respectable size and forms a good straight barrel. Wattle-bark is extensively exported from Tasmania and New Zealand. The price has fallen to £5 15s. per ton, whilst formerly the bark in bundles fetched £12 per ton. But it will pay at the lower price, once a plantation is established. It takes about nine years before a full return can be obtained.

The wattle, whilst doing well on poor soils, has no objection to a richer one, provided it be well drained. Hence on the naturally drained slopes and

valleys of the ranges, plantations may be formed with almost a certainty of success. Bush fires will naturally do much damage, but the effects of these may be minimised by judiciously planting—leaving breaks between the blocks.

Inspector Clifton, of Auckland, New Zealand, describes the wattle plantations at Wairangi. He says the usual procedure in forming a wattle plantation is to fell and clear the scrub, plough, and work down roughly with disc harrows, and sow during the month of October.* Scald the seed, and sow at the rate of 1 lb. per acre. A great advance on this is to drill in 3-lb. of seed with 1 cwt. of bonedust. Trees so treated are, at two years, equal to those of four years' growth sown without manure.

The cost of wattle-planting may be estimated as follows:—

Clearing and burning, per acre...	£	s.	d.
Ploughing	0	7	6
Discs harrowing, one stroke	0	1	3
Sowing	0	0	9
Seed, 1 lb.	0	2	0
Harrowing	0	1	0

Total £1 0 0

To this, with advantage, may be added—

Second ploughing, at 6s. per acre..	..	6	0
Bones, 1½ cwt., at £5 10s. per ton..	..	8	3

Total.. .. . 14 3

The returns may be estimated at—

Per acre—10 tons of green bark=	£	s.	d.	£	s.	d.
5 tons dry, at £5 15s. per ton..				28	15	0
Expenses—						
Shipping 10 tons, at £1 per ton		10	0			
Weighing, carting, and strong 10 tons at 2s. 6d.		1	5			
Railage, about 5s. on 5 tons		1	5			
				12	10	0
				£16	5	0

From this has to be deducted rent, interest, &c.

Wattle-growing in New Zealand for the production of tannin bark occupies an area of about 4,500 acres in the Auckland district. The black Wattle (*Acacia decurrens*) is the only variety planted.

Wattle plantations do not increase greatly, mainly owing to the length of time which elapses before a full return can be obtained. There are, however, many settlers in Queensland, who have from 5 to 500 acres of poor open land, where scarcely any clearing is needed, and on which they might in spare moments put in a few hundred trees which would come in to benefit some members of the family. We know of farmers who have occupied their land now for nearly forty years, and the portion of hungry, waste, untouched land lies hungry and waste to this day. Had this been planted ever so roughly with wattle-trees of the right kind, they would have been enjoying an income of at least £10 per acre for thirty years, and at the old prices that income would have reached £30 per acre.

At Lucindale (S.A.), Mr. Newman recently read a paper on Wattle Cultivation before that branch of the Bureau of Agriculture. He said had great confidence that this could be made one of the most profitable industries of this district, as the soil, climate, and the facilities for delivering the bark at a seaport are all that can be desired. He saw part of a plantation east of Adelaide stripped; the yield being 4 tons per acre, and enough small wattles being left to make another good yield in two or three year's time. The price obtained for the bark

* The scrub here alluded to is not the dense vine scrub with which we are familiar in Queensland, Ed. Q.A.J.

was £5 4s. per ton in the field; the price paid for stripping was £1 5s. per ton, which included cutting the trees down and packing them in heaps; the landowner receiving £4 per ton clear, equal to £16 per acre. The land was of poor quality, being very stony and sandy. During the past ten years he had experimented in wattle growing in this district, and proved that they can be grown on almost any land that is over 3 feet above the level of the winter flood waters. A few months ago he stripped a wattle seven years old that gave over 1 cwt. of bark fit for market. Trees of that size standing 20 feet apart each way would give over 5 tons per acre. That trees was grown on a limestone ridge (red soil), and he had them of nearly equal growth on the fern hills (white sand). As there are thousands of acres of open fern land in that district almost useless for grazing, and eminently suited for wattle-growing, he would strongly urge leaseholders to give that industry a trial. Such land is leased at from 3d. to 2d. an acre annually. About four years ago he planted 1 acre of fern land, and now estimates the wattles on it to be worth £8 to 10. Although the wattle has never been systematically cultivated at Mount Benson, in the Kingston district, still it grows there over a considerable area, and last season no less than 1,200 tons of bark were stripped and sent to market, the price received ranging from £3 15s. to £4 per ton; and as stripping costs £1 per ton, it means £1,200 being distributed amongst the labouring classes of the district, and about £3,500 amongst the landholders and teamsters. The bark grown at Mount Benson is deficient in tannic acid, consequently a lower price has to be taken. Where only a small area is to be planted, he found the following a good plan:—Commence at one side of the field, using a double-furrow plough, strike out the length of the piece to be planted, then mark out back again parallel with the first furrows and about 8 feet away from them, and so on through the field. Then take 1 lb. of good seed for each acre, place in a vessel and cover with boiling water, and allow them to soak for twenty-four hours, then drop them regularly along the ploughed stripes and cover with a harrow. The next year it will be necessary to thin out the plants in the rows to the required distance. Where large areas are to be cultivated it would save time and labour to have a box fitted to the back of the plough with a roller through it, and worked by a belt which the rear wheel, and so made to drop a seed or two at each revolution, and a small harrow attached would complete the planting in one operation. One team should do 8 acres a day. About every 5 chains it is advisable to leave a strip 16 feet wide unplanted for the purpose of drawing furrows in summer to check a possible fire, and later on as a roadway for carting out the bark. He could not recommend broadcast sowing, as there is so much more labour in ploughing all the land, and the work of thinning out the young plants is very much greater. He would strongly advise that only seed of the true broad-leaf wattle should be planted, as it is doubtful whether it will pay to grow any other variety, the bark of which will be worth quite 20 per cent. less. Horses may be allowed the free run of a wattle paddock, but cattle should be kept out altogether, and sheep should not be allowed in until the tops of the plants are out of reach, as they are very fond of the young shoots. He felt certain that if the bark had no market value it would pay well to plough fern hills, and sow 3 or 4 lb. of seed per acre broadcast, and keep all stock out for three years, by which time the wattles would provide a very large amount of feed for either cattle or sheep.

DOBBI'S WATTLE-BARKING MACHINE.

This lately invented machine readily stripes the trees close up to the leaves far higher than could be stripped by hand. The speedy operation of the machine shows to special advantage on wattles from the thickness of walking-sticks up to 3 inches in diameter, indicating that where the crops of wattles

were so abundant as to require thinning out, and were too small to strip by hand, it would pay to use the machine. It has been regarded as being quite evident that the machine would reduce the cost of stripping by at least 25 per cent. Moreover, by using the implement, stripping could be commenced much earlier and carried on much later in the season than is possible by hand. The machine itself has the appearance of a substantial roller mangle, the rollers being either metal or covered with metal. One man can carry out the whole of the operations; but it would apparently be still greater economy for two or even four men or boys to operate in conjunction with one another. In using the machine the wattles pass between the revolving rollers, thus receiving pressure upon two sides, which cuts top and bottom, and causes the bark to spring from the complete circle of the stem in two halves. It would appear from this that a very valuable addition has been made to the wattle-bark industry.—*Queensland Agricultural Journal.*

INDIARUBBER CULTIVATION.

BY SCIENTIFIC AGRICULTURE.

Malaya is the peculiar home and habitat of the guttapercha tree, but of late the cultivation of the Indian rubber tree has been recommended, and in parts even taken up by our planters. We need not go into the chemistry of the composition of the two substances, gutta and caoutchouc, but we may observe that the former tree is of slow growth and cannot be tapped in the way as rubber trees, owing to their having closed sacs, and not communicating tubes, containing the latex, and hence have to be almost destroyed or cut down to get at the commercial sap. Their natural order in Botany, too, is different from those trees which yield caoutchouc. Caoutchouc, or the true India rubber, is found in a number of orders, as the Moraceæ, Apocynaceæ, and Euphorbiaceæ. Some of these grow into magnificent trees, and others are mere climbers and vines. All these have the latex-holding tubes in the inner bark, some communicating with one another more freely than others and some yielding more than others. Of those, however, which have hitherto mostly entered into commerce, or which have hitherto yielded the most caoutchouc, only four varieties may be noted: the *Castilloa*, or panama rubber, the para rubber or *Hevea brasiliensis*, the Ceara rubber or *Mamhot glaziovie*, and the Assam rubber or *Ficus elastica*. Of these four, the two last may be neglected by us, as the Ceara rubber tree does not seem to thrive in Ceylon, nor produce much, and the other, or Assam rubber, though it thrives, gives only a small yield. At the same time, it ought to be mentioned for both that a machine lately invented by Mr. Biffen, of Cambridge University, so does away with the labour and processes needful to separate and consolidate the rubber from the latex as to obviate the defect of small yield to a considerable degree; and it ought to be mentioned, for Assam rubber, that it is—possibly only in shallow soils—a great surface feeder, with great roots running in all directions for great distances half above-ground, and that all these roots, like some African varieties, yield the rubber. And for this reason, as well as that the tree thrives here, and we believe has already been begun to be cultivated, we may append two notes regarding it that may prove useful for planters. The first is that in congenial leaf-mould, shaded forest-soil in which there is a superabundance of moisture, any branch or twig simply cut down and thrown about will take root. The other is that the seeds, which should be fresh, should be sown in sheltered boxes or pots during the wet weather, the soil being composed of one part of half-and-quarter-inch brick pieces, one part of half-inch charcoal, and one part leaf-mould with a little dry cow-dung well ground; this last for top-dressing. The watering should be carefully managed, otherwise the seed and seedlings are rooted out and washed

away. Hence the necessity of keeping them under shelter from heavy rains. The boxes and pots should receive some light, and should never be allowed to get quite dry. From those nurseries the plants should be potted out singly when sufficiently high. There remain, thus, only two varieties, the *Castilloa* or Panama rubber and the *Hevea Brasiliensis* or para rubber; to which we may confine our remarks. And here it may be observed that only till within three or four months back the latter, or para rubber was supposed, from its furnishing quantity for quantity, more and purer caoutchouc, to be the best to plant; whereas now, owing to Mr. Biffen's invention and the very much larger yield of latex—ten times as much in Ceylon—as well as fever and more simple incisions being necessary—thus immensely reducing cost and labour—the former, or *Castilloa* (Panama rubber) has come to be more thoroughly recommended for planters. Hence it is we see that most of our planters who directed their attention to this rubber cultivation have gone in for the para rubber. These will now see that it is the *Castilloa* or Panama rubber which should be cultivated by them. In fact, in regard to this cultivation, which tree, which mode—as annual crops of seedling plants and twigs or as trees—and with machine and other inventions revolutionising past ideas, all are in such an unfix'd, at the same time, progressive state that one object of this paper is to set this fact before our planters not only to enable them to be on the *qui vive*, but for them to adopt due caution and act calmly and not hastily. Of late years, there has been a great increase in the demand for rubber, prices have gone up and the subject has gathered round it quite literature of its own. Indeed, there is even a journal devoted to it, call the *India Rubber World*. Chemistry and mechanical invention, too, here, as in other similar products, have come in to aid in the manufacture, as we may term it, of the caoutchouc from the sap or latex, cheapening the production of the article, and taking up varieties of plants that were unprofitable before, or otherwise aiding in its production from twigs, &c. Indeed, it may or may not be known that Singapore itself at the present moment has a manufactory for expressing the juice or latex from leaves and twigs, which whether it be caoutchouc, or "viscin," to be further dealt with by chemists in Europe—is exported to Germany. And if to be further dealt with by German chemists—or whether it be not "viscin" but the true latex—there is here, in our very midst perhaps, the actual solving of the most difficult and most nearly interesting point that remains yet unsolved in Ceylon. In any case we may proceed with our general preliminary observations. As we have said above, things must be proceeded with cautiously. As yet, the India rubber can only be recommended as a minor or by-product of a plantation. The chemical quest that is proceeding may usher in a new era of extracting the rubber from annual crops instead of having to wait eight to ten years for a tree to be sufficiently grown to be tapped. Experiments are now being carried on in London and Trinidad to secure rubber from year-old plants of the *Castilloa elastica*. (We may note here that this is not the same as *Castilloa markhamiana* which seems to be the kind in Ceylon.) To quote from an article in the *India Rubber World*:—"It has been found that seeds sown broadcast over a prepared field will yield an abundant crop of young trees, which, at about a year old, can be cut and sent to a factory where, with ordinary machinery, eight per cent. of fine rubber can be extracted from the young shoots. This young tree crop, at present prices, would return an estimated profit of \$200 to \$400 per acre." This extraction of the rubber from young shoots has been done in the chemical laboratory, and it only remains to apply to the chemical production of rubber on a large scale. Besides the *Castilloa elastica* there are also a number of other varieties that may be named as yielding latex from leaves and twigs, such as the *Alstonia macrophylla*, which grows in Ceylon, and the *Alstonia plumosa* of Fiji.

It has to be observed, too, that the rubber trees vary in their produce, just as most other plants, with change of habitat. These things will have to be observed and noted with respect to the Peninsula, and hence as well as for a variety of other strong reasons, it is to be regretted there is no proper Agricultural Department or Royal Experimental Gardens in a select locality, in the Federated States. Altogether, therefore, we may be sure that the cultivation of the rubber tree will enter on new phases in the near future. Root-tapping of some varieties may be more largely utilised; there may be annual young crops, the preparation of rubber from leaves and twigs, and the utilisation of a number of at present neglected plants by chemistry—all these are not only possible but probable. It may also be observed that in the matter of rubber, too, as in that of coffee, Brazil may be said to be the principal determining factor. The annual output of rubber all over the world, and which is all consumed, is put down at over 100,000,000 lb., and of this nearly half comes from Brazil, while most part of the rest also comes from Central America. Lagos, in Africa, has also lately taken a lead in the supply, while the great interior forests of the Dark continent, which have not yet been brought into the market, are also known to contain rubber trees of varieties.—*British North Borneo Herald*.

COFFEE HYBRIDS.

The *Revue de Cultures Coloniales*, in its last issue to hand, publishes an interesting note on "The Sterility of Coffee Hybrids" from the proceedings of the Agricultural Society of Kediri (Java) with an annotation by M. Maximo Cornu.

M. H. van Lennep, President of the Society, premising that it was desirable to discover whether by hybridisation it was not possible to obtain a race of coffee plants producing good fruit of superior quality, resisting *hemileia*, prolific and easy of multiplication by grafting is reported to have said, "How often, in looking at a superb hybrid coffee plant, have you not noticed, with regret, that a great part of the berries are empty and what few beans remain are altered and, by the fact, of inferior quality? It follows that hybrids afflicted as they are with these two faults, form a disadvantageous and little remunerative cultivation.

The bad quality of coffee gathered from these hybrids is above all attributable to insufficient fecundation. It is the more annoying as in general hybrids are distinguished by vigorous vegetation, a fine appearance, superb foliage on which *hemileia* does not seem to take hold, and a regular flowering, after which the plant fruits abundantly.

"It is thus with all the hybrids known, so far as I know," continues M. van Lennep, "and for this reason none have yet taken a serious place in cultivation. The problem has become urgent since the extension of vermicular disease (*maladie vermiculaire*) rendered impossible the replacement of individual Java plants dead of that disease by plants of the same species. The roots of the Liberian plant; and certain hybrids alone resist *vermicular* (vermicular disease).

Liberian coffee not being of easy sale, the idea arose of grafting Java coffee on the roots of Liberian, but the problem is not yet solved in that manner. "In practice," says M. van Lennep, "the operation of grafting is easy enough, the joining easily effected, the coffee is of good quality, but at low elevations at least, the development of the young trees does not seem vigorous enough, the grafted plant becomes feeble, and subject to *hemileia*; and taking everything into consideration, I hesitate yet to believe in the future of Java coffee grafted on Liberian roots. In elevated altitudes I cannot speak from experience.

How different is the aspect of hybrids grafted on Liberia! From the beginning, the development is so

vigorous that sometimes the graft appears more vigorous than the stem; there is every indication of great vital force, *hemileia* does not appear at all, the joining is perfect.

But, as I have said above, the hybrids which I have seen show a large proportion of empty berries or of beans imperfect and spoilt. I possess different hybrids; there are some which produce, so to speak, not a single healthy bean. Most of my plants, flourish vigorously, their foliage is fine, every year they are surcharged with fruit; without exception they furnish berries with soft pulp, equally easy to delup with Java coffee. For some years it was believed that the hybrid "Klein Getas" (van Riemdsijk) constituted a happy exception and produced at the same time beans abundant and healthy. I recognise willingly that the berry of that hybrid is a little more valuable than of the others which I know, and that the development of the plant is perfect. Nevertheless, it is not free from the great general fault, it gives too many sterile berries, "loos boon," and too many imperfect beans, nearly without selling value.

However, since variations are observed between hybrids, that is to say, that some furnish fewer abortive beans than others, I think it is justifiable to hope that the hybrid is susceptible of improvement. Further, that it is not impossible to obtain some day a hybrid that reunites the desired qualities—a well constituted bean and a vigorous growth.

There would be nothing for it, therefore, than to continue to propagate by means of grafts upon Liberia."

In the rest of his discourse M. van Lennep insisted upon the point, that in order to increase the chances of attaining the desired end, it would be necessary not to abandon hybridisation to the chances of nature, but to undertake, on the contrary, methodical experiments in artificial hybridisation. M. van Lennep had projected the creation of an establishment specially directed to that research, but the necessary official sanction was not obtained.

M. Maxime Cornu, the eminent *Professeur du Museum*, has kindly communicated to us, says the *Revue des Cultures Coloniales*, the following observations apropos of the preceding note:—

"Botanists have long recognised the general sterility of hybrid plants; they have also considered that sterility was a fundamental character of hybridity; but the experiments of certain scientific men, and above all the repeated operations of horticulturalists (who work without troubling themselves with theories) have shown that that proposition is too absolute.

"The illustrious Darwin was remarked that fertility among hybrids is a character which is acquired in successive generations obtained by the force of successive sowings.

"That method is a lengthy one, but continued with science and sagacity, it may give important results. It should, however, be assured, in the first place, that the hybrid taken in hand really merits so much persevering attention, that it possesses beans of sufficient quality as well as a complete resistance to *hemileia*.

"Hybrids are far from necessarily possessing similarity between themselves; they may differ enormously one from the other and present altogether distinct individualities. They possess, in divers degrees, the characters of the parents; but these characters are sometimes mingled, sometimes juxtaposed. One may then hope, one day to obtain a form of hybrid which possesses the qualities of the two parents, for example, the robustness of *Coffea liberia* with the fine flavour of the *Arabica*. We should not be discouraged therefore.

"In order to assure ourselves, hybrids should be observed in large numbers in a systematic manner, and studied individually. It is necessary to make reiterated experiments."

M. Cornu considers these experiments should be taken in hand by Government, as private persons have neither the leisure nor the facilities for such lengthy and uncertain operations.—*Planting Opinion*.

HOUSEHOLD HINTS.

SWEET Potatoes make fine potato-chips if used just as common potatoes are. To fry them after they are cooked, cut in slices, dip in eggs and bread crumbs and fry as oysters. To make croquettes of sweet potatoes, take three teacupfuls of mealy baked potatoes, a table-spoonful of butter, a teaspoonful of lemon juice, the yolk of one egg, a gill of milk and salt and pepper to taste. Work all together thoroughly with a fork, then form into round cakes, dip in egg and crumbs and fry in smoking fat. If sweet potatoes are boiled for dinner, boil half a dozen more than will be needed and then prepare them with a hot dish for tea, in the following way:—When cold, peel them and cut into long slices, about half an inch in thickness. Place the slices on a shallow dish that has been well-buttered, dredge lightly with flour, sprinkle over them two table-spoonfuls of sugar and half a teaspoonful of ground cinnamon, then a little more flour and last of all some bits of butter and a cupful of milk. Cover and cook in a moderate oven until done, then remove the cover and brown slightly. A sweet potato pie is a fine thing if rightly made and the following is a good recipe:—Mash enough boiled potatoes to make a cupful. To this add a heaping table-spoonful of sugar, one of butter, a pinch of salt, half a teaspoonful of lemon juice and a cup and a half of milk. Bake with one crust and put a meringue over the top in the usual way, being sure to add a few drops of lemon juice to it.

AN EASY WAY TO CLEAN BLANKETS.—Shave a bar of pure soap thin, put it in a small saucepan, cover well with water, and set over the fire to melt. Stain through a colander into a tub half-full of rain water, to which add half a pound of powdered borax. Stir this mixture thoroughly, and put two or three blankets in; let soak over night. In the morning stir the blankets with a stick, lifting up and down, but do not rub. When clean, and free of stains, press the suds from them, and put into a tub of clean luke warm water, rinse and pour off the water, add more, and rinse until clean. Then shake a squeeze, but do not wring. Hang the blankets on a strong clothes line, and let dry. When ready to take down, fold, sprinkle with powdered borax to keep away moths, and lay in a drawer or box. Blankets thus washed will not shrink, and will remain white and soft until worn out.

CINNAMON has a marked antiseptic power. Even the scent of it is said to be fatal to microbes. A decoction should be taken freely by persons living in places affected with typhoid fever or cholera.

VIRTUES OF BUTTERMILK.—The growing practice of utilizing the waste products of all manufactures has brought out the fact that butter milk possesses many unsuspected qualities. A medical paper says its reputation as an agent of superior digestibility has become firmly established. It is, indeed, a true milk peptone—that is, milk already partially digested, the coagulation of the coagulated portion being loose and flaky and not of that firm, indigestible nature which is the result of the action of the gastric juice upon sweet cow's milk. It is of great value in the treatment of typhoid fever, and, being a decided laxative, it may be turned to advantage in the treatment of habitual constipation. It is no less valuable in kidney troubles, from its diuretic qualities. It is in great request for the treatment of diabetes, either alone or alternately with skimmed milk, and in cases of gastric ulcer and cancer of the stomach it can often be retained when no other food can. Chemical analysis shows that in its nature it greatly resembles koumiss, with the exception of which it is the most grateful, refreshing and digestible of the products of milk. Moral, make your own butter and drink the butter milk.

SOME GOOD COOLING DRINKS.—CURRANT SBRUB.—To one pint currant juice add three pints cold water and sugar to taste; chill with ice. LEMON TEA.—Squeeze all the juice from one lemon, add sugar and

stir till dissolved, then put one scant tablespoon to each cup of tea (cold,) lay a thin slice of lemon in the cup, and if this seems too strong, add cold water till it suits, and of course some ice. Russian Tea.—Place two cubes of loaf sugar in a cup half filled with cracked ice, add a slice of lemon and fill up with cold tea. Ginger Punch.—One quart cold water, one cup sugar, half cup orange and the same amount of lemon juice, half lb. ginger. Chop ginger, add water and sugar, boil 15 minutes, add fruit juice, cool, strain and dilute with water and cracked ice, Fruit Punch.—One quart cold water, two cups sugar, half cup lemon juice, two cups chopped fruit, one cup orange juice. Boil water, sugar and fruit 15 minutes, add fruit juice, cool strain and dilute with ice water. Lemon Syrup.—Roll the lemons, then press the juice into a bowl, take all seeds out. Remove the pulp from the peels and cover with water and boil a few moments, then strain the water with the juice of the lemons. Allow one lb. of white sugar to every pint of juice, boil 10 minutes and then bottle. Put a tablespoon or two of this in a glass of water with cracked ice and you have a pleasant cooling drink.

* * * * *

How to REMOVE STAINS.—Tea and coffee usually readily yield to the purifying influence of boiling water poured through the fabric so, too, do some fruit stains. An application of lemon juice and salt, with good sun exposure, is an old and in many instances an effective remedy. Green stains usually can be removed by dipping in alcohol, and an application of paste made of cream of tartar wet up with water will remove them when alcohol will not. So, too, cream of tartar and water will remove iron mold spots, drying on the grass in the sun. If one application does not remove, repeat. Soaking in sour milk over night will usually remove ink stains, while the juice of a rice tomato is useful in removing stains from the hands. Kerosene will clean many stains from old cloth, brass or copper. Surfaces that would be marred by sand soaps can often be nicely cleaner with kerosene, followed by an application of hot soap suds. But the stand by when all other remedies fail to successfully remove stains from white fabrics is javaly water. It is easily made, and once used no housekeeper will be without it. The formula is as follows:—Four lb. bi-carbonate of soda, and lb. chloride of lime pour over the soda, one gallon of boiling water, place over the fire and boil 15 minutes, then stir in the chloride of lime until thoroughly dissolved. Allow to cool and settle, then strain through cloth, bottle and set aside to use. To remove stains, wet the stain in cold water, dip up and down until the spot disappears, then wash as usual. Do not use on colored materials, as it will destroy color. It will remove ink stains better than any other preparation we ever tried. One teacupful of this liquid to a boiler of water whitens garments that have grown yellow from disuse.—*Journal of the Jamaica Agricultural Society.*

CHEMISTRY AND AGRICULTURE.

The following paper was read before the Farmer's Conference at the Agricultural College, Gatton, Queensland, June, 1897:—

IMPORTANCE OF CHEMISTRY TO AGRICULTURE.

“Professor Warrington, in a lecture recently delivered before the University of Oxford, draws attention to the great difference in the position of agriculture at the present day and a hundred years ago. He says—

A hundred years ago agriculture was an art, having only few points of contact with natural science. At the present time both the materials and the operations of agriculture have been so far examined and elucidated by patient scientific investigations that we may now give the title of agricultural science to this edifice of true theory

This is undeniably true, but agriculture will always remain an art if we consider that art deals with practical ways and means to accomplish certain things. Science again gives us the explanation of these ways and means, so that really art and science have to work hand in hand to maintain agriculture in its present eminent position.

The science which helped agriculture more than any other is undoubtedly chemistry.

No other science, electricity perhaps excepted, has made such wonderful progress in the present century as chemistry; and there is hardly, in the present time, any occupation or industry in which chemistry does not play an important part.

Let us briefly consider what chemistry is. You all know that man, with all his science and wonderful appliances, has never and will never succeed in creating matter, any more than he can destroy existing matter.

All the bodies which surround us, the air we breathe, the food we consume, the clothes we wear, the earth on which we grow our crops, are all composed of a few distinct constituents, which at present cannot be further decomposed and which are called the elements.

Only a few of these elements exists in nature in an uncombined state. The most of them are combined in such a wonderful manner that no one would suspect such combination, judging only by the ordinary senses. Who would, for instance, suppose that starch, cane-sugar and cotton are simply composed of carbon and of water.!

The science of chemistry has to come to our aid to tell us the nature of these combinations, and which elements take part in their formation.

Chemistry further tells us in which manner we can force the elements or combinations to unite and to form new bodies.

Chemistry also proves that all things are formed out of pre-existing matter. A plant which grows is not a creation but simply a transformation of other existing bodies. Again, when a plant decays in the ground, or when a tree stump is burned, the bodies which took part in their formation are not lost by simply transformed into other bodies, which, in their turn, will again be assimilated by other growing plants.

Emerson, in one of his essays on farming, says—
Who are the farmer's servants? Not the Irish, nor the coolies, but geology and chemistry, the quarry of the air, the water of the brook, the lightning of the cloud, the castings of the worm, and the plough of the frost.

That chemistry is to be the servant of the farmer is now universally recognised, and consequently we find amongst the staff of Agricultural Departments a large number of chemists.

In the United States a very great number of agricultural experimental stations and agricultural colleges exist, and I may mention that, for instance, at the New York Agricultural Experimental Station out of a total number of 16 officers 7 are chemists; at the South Dakota Experimental Station, and also at the Virginia Agricultural College out of 8 officers 3 are chemists; and at Alabama Agricultural Experimental Station 4 out of 11. In the Southern Colonies, besides, the agricultural colleges and experiment farms with their staff of experts, exist agricultural laboratories with chemists in charge and several assistants.

The work to be carried out at an agricultural laboratory is very large and of a varied nature, and consists chiefly in the following:—

- Analyses of soils,
- Analyses of waters, chiefly irrigation waters.
- Analyses of manures.
- Analyses of foods and food-stuffs.
- Analyses of dairy products.
- Analyses of plants, fruits and grains.
- Experiments with wheats and testing them as to milling qualities, &c.
- Practical experiments in the field,

Investigations about stock-poisoning.

Experiment and analyses of insecticides.

Preservation of meal and other products.

Experiments and investigations in agricultural industries, as sugar, wine, tanning, &c., &c.

The value of soil analyses to the farmers has been much discussed. Some authorities deny all value, and others again put too much faith in it. The truth must lie somewhere between these two extremes.

Chemical analysis alone is very often misleading, and I have analysed soils which, according to the analysis, should be first-class soils; but which as a matter of fact would not grow anything on account of their heavy clayey nature. This adverse property would, of course, have been found out by the mechanical analysis, which at the same time would point out that these soils could be improved by draining or green manuring.

Very often the analysis of a soil shows its deficiency in certain necessary constituents.

It is principally the want of nitrogen for which many of our soils in Queensland suffer, and this perhaps, has to be attributed to adverse climatic conditions. The advantages of green manuring have been known for a very long time, but the scientific explanation of the fact that nitrogen is assimilated from our atmosphere by the help of the root-nodules of leguminous plants is only a recent discovery made by Professor Hellriegel. The active agents of this wonderful process are *Bacteria* found in these root-nodules.

Our farmers will find no cheaper or better way of supplying this want of nitrogen to their soils than by green manuring with leguminous crops; and the cow-pea (*Dolichos sinensis*), introduced from America by Professor Shelton, seems especially suited for this purpose, and yields excellent crops in different parts of this colony.

A crop of cow-pea grown in the Mackay district could be ploughed under after eight weeks' growth. This crop weighed 9.7 tons, (vines and roots) per acre, and supplied to the soil per acre 2.87 tons organic matter, 150 lb. of nitrogen, 35 lb. of phosphoric acid 96 lb. of potash; these ingredients representing a manuring value of £ 5 per acre.

The analyses of waters, chiefly water used for irrigation purposes, is important, as very often the water during its passage through the earth may take up constituents which are detrimental to plant life.

The analyses of artificial manures is undoubtedly part of the most important work of the agricultural chemist.

It is of the greatest importance to the farmer to know if he really receives value of his money spent in manures, and it is a great pity that the fertilisers Bill, regulating and controlling the sale of manures, was not passed by the last session of Parliament.

The farmer cannot afford to experiment with various manures, and in the choice of his manures he should be guided by the analyses and by practical results obtained at experiment stations.

Another important branch of the analytical work is the analysis of dairy products, foods for our own consumption, and feed-stuffs or fodder for our cattle.

Interesting experiments can be made with regard to the preservation of fodder in silos, which would show how far the nutritious value of the fodder is influenced by storage.

With regard to the testing of wheat, a large amount of work has been done in the New South Wales Agricultural Department by Dr. Cobb and Mr. Guthrie.

Of course it will be necessary to repeat these experiments with our own wheats. Over 300 varieties have been sown at the College farm. All of these will need testing, and this will involve a great deal of work during the coming year.

A great many interesting investigations can be carried out with regard to stock-poisoning, and to the yield of some of our native plants in volatile oils, valuable extracts, gums, resins, &c.

Very important also are experiments and investigation in our Agricultural industries, in which chemistry plays an important part. Amongst the foremost of these, stands our sugar industry.

The chemist is not only necessary for the cultivation of the cane crop by trying to improve its quality and quantity, and regulating and controlling the cutting of the cane, but he is also the principal man in the mill in order to control the losses and direct the process of manufacture. Other industries—as, for instance, preservation of meat, butter, and other products for export—will also come more or less under the control of the agricultural chemist.

But let us not forget that analysis alone cannot decide everything, and science alone is not sufficient for successful farming.

Experience and practice are absolutely necessary. The chief aim of the Agricultural College about to be started, is to teach our youths both the practice and science of agriculture, and thus to turn out useful, practical farmers, who can direct and investigate the why and wherefore of the necessary practical work by the elements of science."

[In the discussion on this paper it was stated that there was a general opinion among farmers that fertilizers put on land were apt to be largely carried away by draining—especially such chemical as nitrate of soda. Drainage waters had been analysed after such application and had been found to contain a large amount of fertilizing materials. Green manuring was strongly advocated and a dressing with "Cow-Pea" was stated to have a manurial value of £5 per acre.—J. H. H.]—Extract *Queensland Agricultural Journal*, July, 1897.

BARNYARD MANURES: WHAT THEY DO FOR THE SOIL.

BARNYARD manure and other vegetable matter decomposing in the soil have more or less indirect action as a manure in that they are instrumental in decomposing the insoluble mineral compounds with the result of making potash and phosphoric acid more available. Their action in this way, however, is only secondary and of minor importance. The leading articles used to improve the physical condition of soils are barnyard manure and other coarse residues of plants (such as straw, cow peas, velvet beans and green crops plowed under for manure) lime and ashes. Of these, barnyard manure and other material of its class, improve the water holding power of sandy soils because of their property of holding large quantities of water in themselves in much the same way that a sponge absorbs and holds water. Thoroughly mixed with clay soil they assist in making it, more porous and open. It thus becomes more permeable to air, less retentive of water and less liable to cake on drying. Vegetable matter has also a warming influence on soils. Because of its dark color it makes them absorb heat more readily and by assisting the escape of water in clay soils reduces the cooling effect of the very large amount of evaporation which otherwise takes place. The purpose of barnyard manure and litter is improving the physical condition of soils will be best served by applying that which is more coarse and straw-like to clay soils. Lime and ashes improve the physical condition of sandy soils by binding the particles together and, especially the ashes, by filling the spaces between the sand grains with its fine particles. They improve the physical condition of clay soils by making them more porous and open.—*Journal of the Jamaica Agricultural Society*.

ROSE CULTURE IN TURKEY.—We learn from a Constantinople authority that in order to encourage the cultivation of Roses, and thus to assist in the production of perfumery (attar) through out the empire the Minister of Agriculture has distributed 100,000 Rose-trees, of good variety, to agriculturists in seven of the Turkish provinces. In addition to this, loans on easy terms will be made to such producers as require new apparatus and stills, or these will be sold at the lowest possible prices to such as prefer to purchase outright. This assistance does not come too soon.—*Gardeners' Chronicle*.

RUBBER IN BOLIVIA.

Sir Martin Conway has just been lecturing before the Society of Arts, on February 2nd, on some of the Undeveloped Resources of Bolivia and from this we quote a very interesting chapter, as follows:—

It is only since 1878 or thereabout that the existence of rubber in the eastern forest region has been known. Legislation was passed in consequence of the discovery, defining the manner in which these lands may be acquired. A small annual rate per *estrada* must be paid to the Government, and the lands taken up must be registered with a map of the area. The annual rent may at any time be commuted at a fixed rate, after which commutation the land becomes the freehold property of the purchaser. If the annual instalments are not paid the land lapses to the Government. Thus the Mollendo rubber forests ought now to be owned on an indefeasible title, and many of them are so owned. The titles of others are defective, either because there has been irregularity in the payment of rent, or from mis-description in the deeds of registration. The map accompanying the register often includes a very much larger number of *estradas* than the claimant has scheduled or paid for; and this of necessity, for no one can count or correctly estimate the number of *estradas* in an area which has not been explored in detail. Again, the maps themselves are inaccurately surveyed. Thus a multitude of questions may be made subject of dispute. In other cases, I am told, persons have obtained legal possession of a number of *estradas*, patched about, and now claim to own all the land included between those *estradas*. The question of title is therefore one that in any particular case needs close investigation on the spot. Up to the present time, however, none of these titles have been contested, and it does not appear to be the interest of any individual to contest them, whilst the chief interest of the Government is to induce men of capital to work the forests, introduce immigrants, develop lines of communication, and so increase the general trade and prosperity of the country. It is not likely, therefore, that the Government will attempt to upset titles even if they are not absolutely satisfactory, provided that the forests in question are properly worked.

Time fails me to speak of the COFFEE, COCOA, AND COCOA PLANTATIONS of the sugar estates, and the vine-yards. I can only deal very briefly with the india-rubber forests. In the great eastern plain and low hills that flank the Rio Beni, and still more in the little explored districts to the north and north-east, are immense rubber forests, whose exploitation on any large scale is for the future. It cannot be undertaken profitably until the route to the Amazon is opened up and made easy. Some rubber goes that way, but the difficulties and distances are very great. That the day for this region will come may be prophesied confidently, for the enormous and ever increasing demand for rubber made by modern electrical and other industries, renders the development of increased sources of supply a very important matter. From a recently issued United States Consular Report on the Resources and Trade Opportunities of the Amazon Valley, I quote the following important passage:—

"I have learned that some accounts which have been written concerning RUBBER, although not entirely misdealing, have not been quite accurate. The impression created by the narratives of previous travellers who have been up the Amazon is that the rubber production is on a constant and endless increase. It is not generally believed, but it is nevertheless a fact, that the output is not likely to increase to any marked degree unless a much larger force of rubber gatherers is sent into the forests than has been employed during the

past year or two. This is the opinion of the best informed rubber-plantation owners. Reports that the supply of rubber trees is inexhaustible are largely overdrawn. It is true that there is no fear of immediate scarcity of rubber, and perhaps there will not be for the next 50 years. It is believed in well-informed circles that hereafter there will be a gradual but steady shrinkage in the rubber product, unless the present force of rubber gatherers is largely increased, because in the first place, the trees conveniently located near the banks of the rivers are naturally the first to be worked and in consequence are becoming exhausted from constant tapping, the milk extracted being weaker each year; hence the shrinkage in such rubber is very great. In the second place, the rivers have all been worked inland for a distance of about three miles from their banks, and, in order to reach the so-called unexplored rubber forests still further inland, it will require much more time and necessitate three times as strong a force. Owners of rubber farms inform me that milk drawn from rubber trees five years ago possessed twice the strength contained in that extracted from the same tree today. The islands near Para are all over-worked. Good judges can easily recognise rubber drawn from overworked trees by its peculiar colour."

If, therefore, the supply of PARA RUBBER does not show signs of increase, the importance of developing other sources of supply becomes obvious. The following observations upon the forests of so-called Mollendo rubber are the result of my own observations and enquiries, in which I was much helped by Mr. M. Martindale, an English gentleman, whose acquaintance I made in La Paz, and whose long experience of the country was unreservedly placed at my disposal. I have recently heard of his tragic death. He was killed by the fall of a tree in the Mapiri forest.

In the European markets a certain brand of india-rubber is sold under the name of MOLLENDO RUBBER. Of course no rubber trees grow at or anywhere near the Peruvian port of Mollendo on the Pacific coast. The name applies merely to the rubber which is shipped from that port. All the Mollendo rubber comes from the Bolivian province of Larecaja, the forest-clad valleys of Mapiri, Tipuani, Coroico, Challana, Zongo, &c., which descend north-eastward from the Bolivian Cordillera Real. The rubber is brought over various passes to the Bolivian Puna, shipped from Chililaya on Lake Titicaca by steamer to the Peruvian port Puno, and carried down by the Arequipa railroad to Mollendo. All Mollendo rubber comes from the valleys above mentioned, and all the rubber produced in those valleys is exported through Mollendo. The statistics of the rubber exported from Mollendo thus form an impartial record of the production of the Cordillera valleys.

The following are the statistics of the Mollendo rubber exports for a series of years:—

Year	lb.
1893-4	37,587
1894-5	80,734
1895-6	251,341
1896-7	292,121
1897-8	491,087

The statistics of the year 1898-9 have not come to my hands, but the output was very much larger than in the preceding year, and the industry is gradually developing. The quality of Mollendo rubber, as judged by its price, is nearly equal to that of Para rubber, which is the best in the world. In the year 1898, Para rubber in the English market varied in price per pound from 3s 5½d to 4s 4½d, whilst Mollendo rubber varied from 3s 4d to 4s 1½d. Considering the importance of india-rubber at the present time, it appears likely that some account of this little known forest region may be of general interest.

It must be borne in mind that the area under discussion does not include the Rio Beni and the region of the plains about it. The rubber that comes from the Beni is carried away to the eastward, and emerges into the light of commerce as Para rubber. It is only the forests of the lowest eastward Cordillera slopes that are comprised in the Mollendo district. The rubber trees there are stated to be of the *Siphonia elastica*, a large forest tree, approximately as big as an average English elm. These trees are self-planted. They grow in clumps, or *estradas*, of from 100 to 150 altogether, and these clumps rise well above the other forest trees, and can be seen from afar, so that the richness of any area can be judged by a general oversight from a commanding position.

In most parts of the world RUBBER-PRODUCING TREES grow in a swamp, a condition which renders rubber forests direfully inimical to human habitation. In this respect the Mollendo rubber forest is fortunate exception, for by all accounts it is not unhealthy; so, at all events, I was informed by an Irishman and a German, both of whom had spent the best part of from ten to twenty years in the forest. There are, of course, unhealthy places, but the forest is not generally unhealthy. The reason is that the trees do not grow on level swamps, but on the sloping sides of deep valleys or *quebradas*. For moisture they depend upon the almost constant cloud that hangs over them, and is formed by the cold air pouring continually down from the adjacent snowy Cordillera. This cloud is a geographical feature, and its lower limit appears to be the exact boundary of the Mollendo rubber forest. The upper boundary is a contour line at approximately the 3,000 feet level, above which altitude the tree will not grow.

The main valleys in the rubber zone are traversed by navigable rivers. The difficulty of transport begins at the upper limit of navigation, whence the rubber has to be carried by toilsome tracks over the high passes of the Cordillera. At present there are no roads and no mule-paths worth mention. There are a few tracks traversable by mules with difficulty. The best are the Mapiri and Tipuani trails which converge on the town of Sorata after surmounting passes of 16,000 feet altitude. The part of the forest which has thus far been best opened out is the area worked by these trails. Up to the present, therefore, Sorata has been the chief centre of the industry. The Challana and Zongo forests will not be properly worked till better tracks have been made over the two passes north and south of Mount Condoriri and down the respective valleys. Such mule tracks could be easily made at a relatively small cost. When that preliminary work is done the production of Mollendo rubber will rapidly increase.

At present the main impediment to the development of the industry is not the difficulty of carrying out the RUBBER, but of carrying in the necessary supplies; for it is important to remember that the forest region is practically uninhabited, and the amount of cultivation is very small. A tropical forest left to itself produces little food for man. At one or two points by the river banks, where gold-washing is carried on, there are small Indian villages; but the inhabitants are fully occupied, and have no time to spare for winning the rubber. Both labour and food have therefore to be imported from the high Bolivian plateau by the same route that the rubber retraces on its way to export.

We are thus brought to consider the important question of LABOUR. In the department of La Paz there are reckoned to be over 300,000 Indians, most of whom inhabit the high plateau region. These people are agricultural labourers who work, under a kind of manorial system, for what corresponds to a very low rate of pay, a starvation wage, in fact. They cannot be described as an industrious folk, but they are extravagant, and their

extravagance of expenditure on festivals¹ and especially on festal raiment of a costly and gorgeous character, leads them to temporary emigrations from home, to which they are also frequently driven by dire necessity. They are wont under such circumstances to pledge their labour in advance, and their extraordinary honesty makes the avoidance of their pledge an event of extreme rarity. Employers needing labour secure the services of agents who visit Indian villages, and either directly or through the corregedores or presidents of the villages, enlist the required workmen. Payment is generally made in advance, for the Indian has to leave money with his family and to provide himself with food for the time of his absence in the forest. He transports the food either on his own back or on that of his donkey, and sometimes he takes his wife and family with him. He contracts either to work for so many days or to bring out of the forest so many pounds of rubber. The time spent by him on the journey to and fro is not paid for. In the case of a mine or other enterprise that has been running for some time, a certain number of Indians become habituated to working for it, but they generally do so only for portions of the year, returning at stated intervals to their homes for the purpose of pursuing the cultivation of their lands. All depends upon how the Indians are treated by their employers. If they are well treated they will return and bring others with them, even without payment in advance, if provisions are supplied to them at the place of labour. The system is not a very satisfactory one, and is not capable of indefinite extension, though undoubtedly if the forests were worked on a large scale, and the Indians were well treated and punctually paid, a change in their habits might be brought about. It is not, however, probable that the forest region could ever be colonised by plateau Indians, the difference of climate and level between the two countries being so strongly marked. Whenever an organised attempt is made to exploit the splendid forests on a large scale, foreign labour will have to be imported, and it will be necessary to seek Chinese coolies in San Francisco, or Italians from Buenos Ayres, or to fetch Hungarians from Europe. Such colonists would live in the forests and would cultivate the ground as well as work the rubber trees. Their labour would be supplemented by that of Indians, but a steadier industry would be the result.

THE METHOD OF EXTRACTING RUBBER

is one of the simplest crafts in the world, and can be learnt by the most ignorant in no time. The process is as follows:—The workman, starting out very early in the morning (for when the sun is high the trees cease to bleed), carries with him a number of little tin cups, called *tichelas*. Arriving at a tree, he makes one or more small incisions in the bark, and below each attaches one of the tin cups by pressing it into the soft bark. The number of incisions that can be made in a tree at one time is variously stated. A strip of the bark all down the tree, one-third of the circumference in width, must be left unbroken, or the tree will be liable to bleed to death. The cup, of course, collects the drops of sap that bleed from the wound in the bark above it. Ultimately the wound in the bark is covered by a film of dry sap, which also is afterwards collected. The workman proceeds from tree to tree, attaching his cups, till he has tapped from seventy-five to one hundred and fifty trees in his *estrada*, according to his industry and the nature of the ground. After the hour when the sap ceases to run the man goes round again, carrying a tin vessel with a cover, into which he pours the milk that has run into the *tichelas*. When all the *tichelas* have been emptied, the man returns to his *barraca*. Some collectors tap the trees in the morning and return to collect the milk in the evening, whilst others tap in the evening and collect in the morn

ing: At the *barraca* the collector lights in his hut a fire of palm-wood, with which the nut of the Montacu palm is mixed, if it can be obtained. He places a funnel over it to collect the smoke, and then, taking a kind of small wooden paddle (something like a squash racket bat) in his hand, dips the broad end into the milk, which covers it with a thin layer. He now holds the paddle over the fire in the smoke, turning its faces alternately to the heat. The layer of milk is thus rapidly smoked and coagulated into hard cured rubber. The paddle is then dipped into the milk again and the process repeated until a large cake has been formed. When the cake has reached a convenient size it is slit down the sides and stripped from the paddle. The figure-of-8-shaped lumps thus formed are ready for export. They still contain about 7 per cent. of water which gradually dries out in the next few mouths, and for which allowance must be made in weighing. In the Mapiro district, it is usual to cure the production of each day separately, so that each collector's work can be controlled. Moreover rubber so cured can be easily tested for cleanliness and purity. Lower down the Amazon the custom is to smoke one day's rubber on top of the previous day's, making larger *bolachos*, into which dishonest workmen more easily introduce stones and other adulterations.

THE AVERAGE AMOUNT OF RUBBER which one collector produces on one day is very variously stated. On the Lower Amazon 7 lb. daily is the figure quoted, on the Upper Amazon 21 lb. daily. In the Mollendo district the lower of these figures does not appear to be reached under present management. To this cured rubber must be added the scraps and remnants called *sernambi*, which include the cicatraces of the incision of the bark, the cleanings of the *ticholes*, &c. The amount of the *sernambi* is equivalent to about 10 per cent. of the smoked rubber; its price is from 15 to 20 per cent. less than the price of smoked rubber.

The *pica* or RUBBER-HARVEST is collected twice a year in the Mollendo forests, from April to July, and from October to March. It appears that a single tree can only be tapped during three months of one year, and then needs nine months' rest. If thus treated, and if a good broad strip of bark is left untapped from bottom to top, the health of a tree does not seem to be interfered with. For how many years it is possible to go on tapping a single tree we do not yet know. There is a tree in the *barraca* Cristina, in Senor Violand's San Antonio estate, which was stripped of all the bark on one side, and yet had yielded milk from the remaining bark during six *picas* in six successive years; the tree still retains a thoroughly healthy appearance. It is certain that the life of a tree, though annually tapped, is a long one, and exceeds the fifteen years which are required for the growth of a tree from seed, so that the forest may be perennially tapped, and will give a fairly constant yield when thoroughly opened up and worked. This, however, implies that the trees are carefully handled; the yield of a mishandled tree falls off. The average yearly output of a fullgrown tree is variously stated. Some put it as high as 7 lb.; no one puts it at less than 3 lb. of cured rubber (after 10 per cent. has been deducted for drying).

THE COST OF PRODUCTION in Bolivian dollars for 100 lb. of Mollendo rubber in the Mapiro forest is as follows:—

Paid to contractor per 100 lb	Dols.	73.00
Loss in weight, 10 per cent.	7.30
Freight from the forest to Sorata town	5.00
Commissions and road tolls	60
Cost of administration	10.00
Sacking, packing, commission, and freight to Chililaya on Lake Titicaca	2.20
Freight, insurance, and incidental expenses to London	12.00
		110.10

Or reckoning the Bolivian dollar at 18d., the cost of 1 lb. of Mapiro rubber put in London is 19.32d.

From the books of two other forest owners in the same neighbourhood I find a slightly higher cost, 20.16d. per lb. The present price of this rubber in London has now risen, as above stated, to 4s. 1½d. per lb.

Coming now to a consideration of the possible SUPPLY OF RUBBER to be drawn from the Mollendo forests, we enter a region of conjecture, for of course the trees have not been counted nor even the number of *estradas*. A part of one estate has been recently proved to contain 6,410 *estradas* (961,500 trees), when, according to the original estimate, the whole estate contained only 500,000 trees. Five million trees may be taken as the lowest probable limit of the number of trees, whilst they may not improbably turn out to reach 10,000,000 or even more. Now in the year 1897-8 the amount of Mollendo rubber exported was 491,087 lb. which at 3 lb. per tree, represents the yield of only 163,695 trees, and the same number of days' labour at 3 lb. per man per day. If one Indian is taken as working for three weeks, this represents the labour of only 7,795 Indians out of a population of 300,000 in the department of La Paz. At the lowest reckoning, therefore, the output of Mollendo rubber might be increased 30-fold without planting a tree. How is this development to be attained?

Without going into financial questions concerned with any possible purchase of the estates and concentration of them under single management, a few essential features of the problem may be pointed out. To begin with, the first necessity is to make good mule roads over the high passes that lead from the town of Sorata and from the Bolivian plateau to the chief eastern valleys and down those valleys to the forests. These roads would, of course, be very useful to the gold miners, coffee planters, and others whose work leads them to the eastward. They are, therefore, rather work for the Government than for the rubber-forest proprietors; but the Government is poor and cannot afford to make them. If made at all, in the immediate future, the forest proprietors must make them. The main roads having been made, it is necessary to cut forest tracks from one *estrada* to another, as only the *estradas* easily accessible have yet been touched. This implies additional labour, wise oversight, and intelligent exploration.

At present all the food consumed by the rubber collectors has to be carried in to the forests from Sorata or the plateau—a great waste of labour. It would be perfectly easy to raise any quantity of food in the hot valleys, which are of the richest natural fertility; but such cultivation implies preliminary colonisation. As already stated it would be impossible to colonise these low, hot valleys with Indus from the Tibet-like plateau. Chinese coolies are the class most suited for such work. They could be obtained very easily from San Francisco. A nucleus of such men, who would soon become expert in working the rubber forests, would enable the industry of rubber collection to be far better organised than it is today, and opportunities of theft would be reduced. Large areas in these valleys which do not carry rubber are suitable for coffee plantations, and such plantations as do exist produce the finest coffee of South America, and some of the finest in the world, so that here also important future developments may be expected. What is true of coffee is true also of cocoa, for which a large local market exist among the Indians of Bolivia. Such developments of the rubber industry imply, not merely concentration or co-ordination of proprietorship, but skilled administration and scientific experience, which could only come in the wake of capital. At present everything is done experimentally, or by rule of thumb.

The Bolivian Government would certainly favour such an enterprise providing that roadmaking and

colonisation were an essential feature of it. With their help the business of recruiting Indian labourers would be greatly facilitated, for the village corregidores have much influence over the Indians, and can promote or hinder their enlistment or turn them in one direction or another very much as they please. Under any circumstances, however, the future of this region of tropical valleys, descending from the eastern face of the snowy Cordillera Real of Bolivia is certain to be prosperous, and its development will attract much attention.

From the Discussion which followed the reading of the paper, we quote as follows:—

THE BOLIVIAN MINISTER said: The production of rubber was even more important than the figures quoted would indicate. Sir Martin Conway spoke of 1,000,000 lb. as the export from Mollendo, but that did not include that exported by way of the Madera river, which was so considerable that it brought the total export in 1898 up to 3,100,000 kilos., or in value about £1,100,000.

MR. R. KAYE GRAY confirmed what had been said by the Bolivian Minister and Colonel Church, that the greater part of the rubber from Bolivia came down the Madera; the quantity which came down *via* Mollendo was insignificant. He had been to Lake Titicaca, but could not pretend to know the district. It was certainly a great advantage to have railway communication as far as the lake: but as that stood at an elevation of 13,000 feet and all produce had to be taken to that height, that route did not seem well fitted for commercial purposes. Some years ago he met Mr. Martindale, who was much interested in trying to develop the rubber industry on the eastern slopes of the Andes, and in discussing the matter with him he came to the conclusion that the labour question, including transport, was the chief difficulty. Still, Mr. Martindale had been able to do something, and the rubber was certainly very good, fetching about 2d. a pound less than the finest Para, and 3d. less than what was known as Bolivian rubber. The inferior quality and scraps probably did not pay for carriage. Being interested in rubber, and finding it very difficult to turn out electric wires and waterproof garments with Para rubber at 4s. 5d. lb., he should rejoice at any development of the production of good rubber.

MR. R. H. BIFFEN asked if Sir Martin Conway could assure him that the rubber trees he had spoken of were really the *Siphonia elastica* of the Amazon, because from the description given, it hardly seemed likely. As known in the Amazon valley, that species always grew on soil which was flooded part of the year, and when transported to Ceylon, where the situation was somewhat similar to that described in Bovilla, the trees did badly, and the yield fell off very much.

SIR MARTIN CONWAY, in reply, said he was not a botanical expert, and unfortunately the specimens he brought home were lost *en route*, so that he could not get them identified. The statement was based on the report of the British Consul, Mr. St. John, who visited Bolivia three or four years ago, and he said that he got his information from an expert, but he could not ascertain his name, and could not therefore affirm positively that the identification was complete. But it grew under conditions practically similar to a swamp, inasmuch as there was rain falling daily from a permanent cloud. It was a very unusual climate, if not quite unique. The amount of Mollendo rubber exported was not quite insignificant, for it amounted to over three million pounds; over half a million came from the small district over which alone he had an opportunity of examining, near Sorata. Of course the great forests in the neighbourhood of the Beni river could produce a vastly greater quantity than the little district he had mentioned, and its full de-

velopment could only result from the opening up of the Amazon route. As for railway development generally, there was the line from Antofagasta to the shore of Lake Titicaca, and the whole area alongside it was very rich in minerals. Sicasica, half-way between Ururo and La Paz, was also a rich mineral district, but it produced practically nothing, for lack of means of transport. Even fuel had to be carried up if the mines were to be worked. He did not believe there would ever be a trans-Andean Railway. It had, however, only cost a few hundred pounds to make the mule tracks necessary to work the little district he had referred to. With regard to labour, there were plenty of Indians, but you cannot get them to stay at work more than three weeks at a time, and therefore it was very difficult to organise the proper cultivation of the rubber industry. It could only be done by importing colonists, who would not only look after the rubber, but cultivate the ground and provide their own food. —*Journal of the Society of Arts*, Feb. 2.

HOW TO PUSH CEYLON TEA ON THE CONTINENT OF EUROPE AND ELSEWHERE.

THE TRI-LINGUAL LETTER ON TEA;

OUR tri-lingual letter on "Ceylon Tea"—of which the "Thirty Committee" has given 10,000 copies to Commissioner Renton for use on the Continent of Europe, attracted a good deal of attention during our recent visit to central and northern France and Belgium, as also among London City merchants dealing in tea with the Continent. It may be of interest in view of the "Thirty Committee"'s order, to recapitulate some of the English opinions kindly given to us when we were trying to improve the circular letter; and at the same time to publish certain information respecting tea generally which should be of interest to tea planters. We first quote a sentence from the letter of Mr. Herbert Anderson, of the Dimbula Company:—

I thank you for yours of November 20th, enclosing copy of circular letter for the Continent, which is very much to the point, and ought to answer the purpose, especially as it shows how the revenue may be increased by absorbing our teas. Mr. Anderson was good enough to point out a couple of misprints in our figures which were at once corrected. Mr. H. K. Rutherford was good enough to write:—

You are indefatigable in your exertions to advertize Ceylon, and this latest idea of having your article on Ceylon Tea translated into the continental languages is a very happy one, as it should undoubtedly draw attention to the advantages to be derived by foreign Governments in lowering the duty on tea. I return the paper and cannot suggest any alteration as it puts the matter in a very telling way. Messrs. Fredk. Huth & Co. (Tea Department) 27, Mincing Lane, wrote:—

We have to thank you for your very interesting circular, the distribution of which on the Continent would be probably of assistance to the trade in general, but scarcely to the benefit of Ceylon teas only, as the dealers and packers no doubt will continue to buy such teas that suit their taste and pocket.

We now turn to a long communication sent to us on the eve of our departure from England, by a well-known London merchant connected with the Indian tea trade.

THE TEA CAMPAIGN IN AMERICA AND THE CONTINENT.

From the long letter of a London merchant closely connected with the Indian tea trade, we quote largely as follows and also give our reply to the same:—

Since I was in Colombo four years ago, I have had the *Weekly Observer* regularly, and came to the conclusion long ago that it would be a good thing for both of us to meet. I have always recognized the honest and good tone of your paper, in contrast to that of some special subject papers, the desire of which seems to be always to conceal the truth and write only what is likely to be palatable to their readers. There were a great many things in your letter of 6th October (published in your paper of 26th) which I should have liked to discuss with you, but which it is most difficult to deal with in correspondence without being tediously long.

TEA DUTY AND CONSUMPTION.

Now to take up your tri-lingual paper on Ceylon Tea. It will no doubt have some effect if it gets a good circulation, especially in German-speaking communities and in Russia. I do not quite agree with your argument that the increased consumption of Tea in the United Kingdom arises from the reduction of the duty,—at least so far as relates to the adoption of a uniform duty of 6d per lb. on 1st June 1865, afterwards reduced to 4d per lb. on 1st May 1890. There has no doubt been a very material increase in the consumption, but it has been a uniform and steady one practically throughout this century, and to my mind the increase has arisen very largely because of the higher and more extravagant scale of living which the last half-century has brought about. Tea 50 years ago was to a great extent a luxury of the rich; today it is a necessary of the poor. Then a very material point in the question of increased consumption is the fact that not only has the first cost been reduced, but the distributive costs and profits have gradually been materially cut into, and consequently the retail selling prices are remarkably low, in fact, they are so low that I do not believe the abolition of the existing duty would have a great effect in giving a further stimulus to consumption, although of course, if the price were lower there would probably be a great deal of waste. I look upon the average consumption per head of the population as having now nearly reached its possible maximum, because an average allowance of 6 lb. per annum amounts to a great deal in the liquid equivalent. I consider that the higher average shown by the Australian and New Zealand Colonies does not mean more liquid tea. A great part of it goes in waste because of the rough-and-ready way of the colonial and because of the method of making. Besides, in those Colonies the consumption is almost entirely the lowest class of tea which can be got from China, India or Ceylon, the liquid equivalent from which is often not more than half what the Irish people get from high-class Indian Broken Pekoes, which do not cost double the price per lb. In proof of my argument that the increased use of tea in this country arises largely from the more extravagant living of all classes, I would refer you to the increase in the consumption of

nearly all those goods which pass through a general grocer and provision dealer's stock, also of butcher meat.

Now as to forcing Tea on countries where it is not consumed at present. I am always amazed at the calmness and the confidence of many of your planters in regard to such things. I should say that if you took an average citizen of Europe who had never tasted beer, wine, spirits, tea or coffee, and experimented upon him, he would in all probability pronounce tea to be the most nauseous of them all. The more I travel among foreign peoples, the more I am convinced of the fact that the use of tea is very much indeed a matter of acquired taste. Children are gradually brought up to it and get to like it, but it is very difficult to convert adults from another beverage. You doubtless have seen in Italy the very infant at the breast being offered a sip of the sour wine of the country, and in Germany the tiny children drinking their lager beer with their parents, while in Russia you see them in family groups round the samovar. It seems to me somewhat like trying to stop Niagara to attempt to convert whole nations from the customs of centuries and a great deal of harm has been done in Ceylon and India by overproduction of tea, based on the idea that because the United States of America contain 90 million people (roughly presumed to be Anglo-Saxon, but really a nondescript horde representing all the nations and ways of living of Europe) there was a reserve ground of consumption there which in time might be expected to equal that of Great Britain. During the last 10 years I have over and over again protested against the use of the parrot-cry "Capture the American market," on the ground that there was no American market of material consequence. To begin with, the people of the United States are coffee-drinkers wherever they use hot liquid beverages. A certain proportion are drinkers of the pale, thin, pungent Green Teas of Formosa and Japan, while only a small proportion (principally immigrants from this side, or their descendants) are drinkers of Black Tea. The only market for us to capture was this Black Tea market, and we have been getting it all the time by the displacement of China Tea. It has come to us in a natural way, firstly by the constant inferiority of the China production, and secondly by the serious fall in the cost of Indian and Ceylon Teas, which have gone down to a level that China cannot compete with, in fact, the fall in prices has done far more for us in North America, in Russia and in Persia, than all our efforts of special missionaries and commissioners. The latter have too often only disturbed and interfered with the ordinary course of trade in the usual channels.

"I do not think we can ever make much headway in any of the Latin countries or in any of the Green Tea-using districts, or in Germany and Austro-Hungary, but I have no doubt that we can make good progress in all the higher latitudes of Europe, particularly in Russia. As to Russia, it seems to me the most gross presumption on the part of some of your people to suggest to the Government of that Empire the reduction or the abolition of duty. It is merely a revenue duty, not a protective one (except in so far as encouragement is given to Russian vessels and to the development of certain new trade routes) and if we can get our Tea in on the same terms as the ordinary China Tea, I have no doubt whatever that we will gradually over-

come the conservatism of the large Russian distributors, as we had to do formerly with those in Great Britain, thus bringing about a gradual transition from the use of China Tea to that of Indian and Ceylon. The high retail selling prices of Tea in many European countries are merely caused by the fact of the very limited demand, and merchants there are largely of opinion that a reduction would not have any material effect upon increasing the consumption, the latter being a question of national taste.

"The whole of the Ceylon men are so comparatively new to the Tea business, that they are continually making discoveries of matters well-known to firms like my own, and it is a pity that they do not allow themselves to be rather more influenced than they are by some of the previous traditions of the Tea trade.

"I have not left myself much room to deal with your editorial of 26th October, and I would just say that the sending of Tea to other centres such as Manchester and Glasgow has been tried over and over again. I have had as much as 5,000 chests in stock in bond in Glasgow at one time, but the practical conclusion I have come to is that you must have one ruling market, and unless you wish to suffer heavily by being at the mercy of a limited outlet of buyers, you must have your Tea available to offer in that ruling market."

REPLY.

It will be seen that our correspondent does not require to use the prayer "Gie's a gude conceit o' one's-self," in regard to some of his opinions. From a reply, written to him by us on board ship we quote:—

"I have your long and interesting letter; but, I do not agree with you on several points. The way in which I have myself seen the use of tea increase among the French (the least likely of people to be converted) gives me great hope for the whole Continent of Europe and the United States. In 1878, the year I first visited Vichy, and saw a great deal of Paris and its people, under the auspices of a relative, Dr. MacCall, founder of the well-known Mission in Paris and other leading towns, when I enquired for tea. I was always referred to the "Pharmacy." I found a change for the better on my next stay in 1887; but now in 1899, there was not a greener in Vichy (nor I may add in Paris) who did not hold tea; and much more, not a café or restaurant where they did not give it to you, if asked for, at any hour of the day; and *still more*, I saw French families of an evening frequently with the tea pot and cups before them, in place of coffee or wine, at the restaurants. Then, as to the United States: can you tell me why the tea-drinkers from the United Kingdom, who have gone by the 100,000 or 1,000,000 to the States, during the past 50 or 60 years, have become coffee drinkers? Simply, because they could not get the beverage to which they were accustomed at home, or rather the quality of tea from which to brew it. I crossed the Pacific in 1884, with the largest buyer of Japanese tea for the United States and he admitted that every pound was artificially 'faced' with deleterious stuff to give it the required colour, and that it would be far better if his countrymen drank pure Ceylon tea; but, he added, their taste won't change in my time (he was an oldish man) and I don't mind your using my opinion. Well, gradually, but surely, the Americans are being won over to English breakfast tea: the figures show a steady increase, and if only there had been no war tax on tea, the increase would have

been greater.—You mistake my argument in the circular letter as to Russia: M. de Witte, the Finance Minister, has, for some years, been trying to improve the condition of the people by getting them to drink tea in place of intoxicating drinks—he has been opening tea-houses under official auspices, or directly encouraging others to do so. Now my point is, that with so heavy a duty it is impossible for the bulk of the people to afford to buy good tea. The duty in Russia *now* is what it was in England when Queen Victoria came to the throne—2/1 a lb. The English duty is now 4d; but the revenue has lost nothing, but has rather benefitted. Now surely, for Russia to begin reducing gradually, should lead to the same result:—increased consumption and increased revenue. As a matter of fact, Russia has a differential duty, in favour of 'overland' teas, which is not fair to tea sent through Odessa. [This has since been rectified.] As regards the burdens on tea in London—between ship and retailer—don't you think an Association of all tea producers is required to investigate and reform the matter thoroughly? Tea seems to be placed at a great disadvantage as compared with coffee."

WANTED A TEA-GROWERS' ASSOCIATION. LARGE BREAKS DEPRECATED.

JOCATIVE PROPOSAL TO ABOLISH BROKERS!

In regard to the closing remark in our last instalment, emphasizing the need of an Association of tea producers to watch over their interests, we have the following strong expression of opinion from another London merchant connected with Ceylon tea—an opinion which planters would do well to note and endeavour to act on:—

"I think a TEA-GROWERS' ASSOCIATION is badly wanted, and that if it were properly representative of Indian and Ceylon (British) tea-growers, it would be of much advantage to the industry. The mere fact that the growers had organized their forces would have a wholesome influence on the Docks' Committee and Buyers' Association. Nearly every industry has its Association to protect its interests, and why not tea growing, as well as tea distributing and tea warehousing? The one weak point, as regards growers, in the tea draft fight was that their forces were much of the 'undisciplined-mob' order."

BIG BREAKS—WAREHOUSE CHARGES— ABOLISH BROKERS.

Finally, from a source whose identity for obvious reasons is not to be revealed, we have the following rather extraordinary if not amusing deliverance:—

"Very large breaks are not a good thing for the producer. They are only wanted by the big brokers and buyers in London to save themselves trouble. Breaks of moderate size bring the best competition in Public Auction.

"The warehouse charges will probably be at once reformed here, and there is another reform which I have jocularly suggested for many years, but I would on no account like my name to be associated with it, because so many of the Tea Brokers are intimate personal friends. I consider that as business is conducted now-a-days, there is absolutely no need of either selling or

buying brokers in the London market. Teas should never be printed in sale unless the owners are prepared to take the value offered by the trade on the day they are selling them, therefore all that is necessary is one public auctioneer to knock down the lots mechanically and a clearing house to collect the proceeds in accordance with the conditions of sale. The whole of this work could be done for a trifling percentage on the value, in fact what goes now for lot money and selling expenses might cover it, and 1½ per cent. upon the total value of the Tea sold would be saved to someone."

Do away with the brokers! The time has scarcely arrived for that. Ceylon planters would rather vote for doing away with the *Blenders* and giant Tea Dealers?

TRAVANCORE TEA ESTATES COMPANY, LIMITED.

The following is from the report of the directors submitted at the third annual ordinary general meeting of shareholders, held at the office of the company on Feb. 21. :-

The directors have to submit the general balance-sheet and profit and loss account for the year ending September 30, 1899, duly audited. The net amount at credit of profit and loss account, including balance brought forward at September 30, 1898, after providing for general expenses, income-tax, &c., is £2,264 0s 8d. Dividends on the preference shares paid December 31, 1898, March 31, and September 30, 1899 (less income-tax), amount to £2,682 10s; less set aside in last account, £536 10s; leaving to carry forward to next year the sum of £118 0s 8d. The results of the past year's working have not materially differed from those of the previous year, as there was no appreciable difference in the amount of crop harvested. The average price for the teas sold in London was 7-18d per lb, as against 6-80d, and the rate of exchange 1s 4½d, as against 1s 4-3-32d for 1898. The tea crop was 390,885 lb, as against 382,661 lb in 1898, the yield being 342 lb per acre off a plucking area of 1,146 acres, as against 392 lb per acre the previous year off 975 acres. The coffee crop amounted to 280 cwt. In addition to the factories on Bon Ami and Pambanar, factories have been erected on the Mount and Munja Mully Estates, and these latter are expected to be in working order this month. A factory is now in course of construction on Kolie Kanum Estate, and these five establishments, when complete with machinery, will meet the requirements for the manufacture of tea from the 3,312 acres, of which only one-third of the acreage was in bearing last year. Debentures have been issued to the extent of £33,100, and a further issue will require to be made to bring the tea planted into bearing, and to complete and equip the factories. Mr. W. MacKenzie retires on this occasion from the Board, but being eligible offers himself for re-election.—*H. & C. Mail*, Feb. 16,

THE BOMBAY TEA ASSOCIATION, LD.

The ordinary general meeting of the shareholders of the above association was held for the first year at their premises in No. 26, Church Gate Street, last month, when a dividend of Rupees 7-1-2 per share was declared. The well-known

millionaire and Banker, Mr. Purnmull Gulji Singanee, was elected one of the additional directors, and Mr. Fazulbhoy Joomabhoy Laljee, who retired by rotation, was also re-elected a director.

The directors in their report state that owing to the plague, and other unfavourable circumstances which resulted in dislocating and paralysing business of all sorts:—Your directors thought it advisable to suspend all active operations in reference to getting more shares of the company taken up by the public, and to wait till better times come. In the meanwhile your directors think that the result achieved so far is encouraging, and they believe there is a good field for a company like ours, and that if properly managed as they feel sure it will be under the careful and tactful supervision of their agents, Messrs. Morton Maju and Company, it will result in much benefit to the shareholders. It is with satisfaction that your directors state that in spite of adverse circumstances, additional shares to the value of Rupees 26,500 have already been subscribed.—*Times of India*.

PUBLIC SALES FOR TEA: THEIR ADVANTAGES.
—We said the other day we should touch on other aspects of the public sale system for tea than that of the capability of the buyer, big or small, for combination with a view to lowering the demand, or for any other action with a similar purpose in view. But a correspondent now sends us a few remarks which so exactly sum up the situation as it appears, we believe, to most Colombo buyers that we have no hesitation in giving them prominence:—"To a certain extent it must be true that a big (very big) buyer has the market at his mercy. But what alternative would the seller suggest? Do without the big buyer?—and see where his prices would go! You have only to see what happens even in Colombo if, say, Russians are not buying much,—why the market is not nearly so 'brisk' and prices *may* shew a decline! But it would be unfair to say the Russians were combining to bring prices down. It is a far more galling thing than that, to them—namely, absence of orders! To my mind, the public sale system suits buyer and seller better than any other. It advertises the sellers' goods and gives the buyer the opportunity of seeing and tasting a good variety and making his choice in a way that he wouldn't have by private contract. I doubt whether the enormous quantities of Indians and Ceylons which are sold in London could be handled in any other way but by public auction and if I were a broker I should certainly want more than one per cent brokerage if I had to 'worry round,' selling everything privately. With regard to offering a whole invoice privately, without the option of dividing, I should not blame the seller because in selling privately he does not know whether, if one buyer will take the leaf teas, another will take the broken. Public auction obviates all this, as all the buyers are represented in the room and the various grades are easily divided amongst the various interests. In my opinion therefore the only system possible for dealing with the huge sales in London is that of public auction, believing as I do that in the long run it suits buyer and seller best."

PLANTING COFFEE, COCONUTS RUBBER, &c. IN THE STRAITS.

SELANGOR PLANTERS' ASSOCIATION.

ANNUAL REPORT FOR 1899

In presenting their Seventh Annual Report, your Committee have to announce that 65 members are now on the roll of the Association, being only two less than last year, although seven names have been removed from the roll during the year through closing of estates, departure from the State and resignation. The attached statistics show an increase under cultivation of 1,172 acres, but of labourers of all nationalities a decrease of 178.

PLANTING PRODUCTS.—(a) **COFFEE.**—Estimates have for the most part been realized, but the depression of prices, complained of in 1898, continued during the past year, and the following list of prices realized for coffee during 1899:—viz., January \$18.25, February \$18.50, March \$18, April \$16.50, May \$16.65, June \$16.75, July \$16, August \$15.50, September \$15.85, October \$16, November \$18, December \$20.50: an average of \$17.20 per picul for the twelve months—shows that there was no margin for profit; in fact, your Committee consider that the present good order of Selangor Estates is very creditable considering above prices, and that it has been a good, though trying, lesson to planters generally. During the year, until December, there was almost no demand for Liberian coffee in the European market, but since then there has been a distinct improvement.

There has also been a decided improvement in the quality of our coffee, owing, no doubt, to better machinery and greater care in curing, and your Committee hope that every member of the Association will do his utmost to help in this respect, so that still greater improvement may be reported at the end of 1900. Although some 300 acres under coffee were abandoned during the past year, it is satisfactory to know that the acreage cultivated under coffee by Europeans has not decreased, being about the same as at end of 1898, as for every acre of bad land abandoned there has been an acre of good land brought into cultivation. Mr. Heslop Hill has taken great trouble in procuring statistics which show that we can produce coffee in the Straits cheaper than it can be produced in Brazil, and this, taken with the fact that late London reports maintain that the demand has almost equalled the supply, make your Committee consider that the present outlook is more hopeful than it has been for a long time past.

(b) **PARA RUBBER.**—The low prices for coffee during 1899 stimulated the cultivation of this product very considerably, and no less than 1,600,000 imported and locally grown seeds were put into nurseries in Selangor, which have produced, say 1,000,000 healthy plants, all of which either have been or are being planted out. On all estates in Selangor where Para Rubber has been planted, it is doing extremely well, and, at present, it seems as if rubber was going to be one of the leading products of the State. There can be no doubt that we have much to learn about rubber, and it is satisfactory to report that through the representations of the U. P. A., F. M. S., the Federal Malay States Government have voted a sum of \$1,000 in the 1900 estimates for the purpose of carrying out experiments with rubber and other products. There has also been some discussion about sending a practical man to report on Para and Castilloa Rubber in the countries where they are grown, and there is every likelihood that this will be done by the planting community even should Government not see their way to help. The planting of Para Rubber seed at stake has not, as a rule, proved a success,

and even young plants are so liable to be eaten off by rats, crickets, and other pests, that the best and safest plan seems to be to plant stumps as thick as a man's forefinger, and cut long. The white ants (termites) are Para Rubber's worst enemy, and your Committee hopes that any successful experiments in destroying these or any other pests will be reported to them.

(c) **GUTTA RAMBONG.**—This rubber is indigenous to the Straits Settlements and up to the present does not seem to have received as much attention as it deserves from Planters. It grows luxuriantly and gives an enormous yield at from 10 to 12 years old (probably earlier) and no doubt the new coagulating machine will act on its milk in the same way that it does on that of the *Castilloa Elastica*, as reported in the Ceylon Botanical Gardens Reports (making it equal to the best Para). Up to last year it was rather difficult to get plants or cuttings which found a ready sale at from 15 to 25 cents each, but each plant put out for the last three years has been yielding 30 fold, and there are now thousands of rooted plants available at from 4 to 5 cents each, which is a very reasonable price. There should be about 500,000 plants available for next year, though probably not all for sale, as some planters are planting out all they can produce.

(d) **CASTILLOA ELASTICA.**—It has been almost impossible to procure seed of this rubber, but those plants already in the country are doing extremely well, and a large quantity of seed has been booked for 1900.

(e) **COCONUTS.**—A large acreage has been planted during the year, chiefly in the Coast Districts and the Kuala Selangor Oil Mill has been working steadily and turning out excellent oil and cake. The company have planted 200 acres this year. The growth of the coconut in Selangor has been pronounced by experts from Ceylon to be finer than anything in that island. This product is well worthy of attention.

(f) **RAMIE.**—So far, the only extensive experiments carried out with this product are those of Mr. C Baxendale on the Jugra Estate, Kuala Langat, which we hear reported on favourably and we hope soon to learn that he has proved the cultivation a success.

(g) **MINOR PRODUCTS.**—A very considerable area has been planted with plantains and kladi in conjunction with coffee and rubber, and both are favourably reported on as more than paying all expenses of upkeep on the land. During the year an attempt was made to establish a trade in plantains with Western Australia, but, on enquiry, the business proved to be so small that nothing came of it. We believe another effort is being made in the same direction, but have not yet heard with what result.

CINCHONA: CABLEG'S MS

AMSTERDAM, Feb. 15.

At the auctions of cinchona bark held today, over 6,000 packages were offered, of which 5,814 sold at an average unit of 10.65c per half-kilo. against 8.90c paid at the January auctions. The following were the approximate quantities purchased by the principal buyers:—English and American factories, who purchased the equivalent of 7,430 kilos. quinine sulphate; Brunswick factory, 2,629 kilos; the Mannheim and Amsterdam factories 5,201 kilos. the Frankfort-on-Maine and Stuttgart factories, 2,448 kilos; and various buyers, 3,408 kilos. The prices paid for the manufacturing bark ranged from 12c to 93c per half-kilo, and for "druggists" from 10½c to 86c per half-kilo. The tone was very firm.—*Chemist and Druggist*, Feb. 17.

TEA: KNAVESMIRE ESTATES CO., LD.

THE ANNUAL REPORT.

Your Directors have now to submit Accounts and their Report for the year ended 31st December, 1899.

The Accounts close with a balance of R17,483 54 at credit of Profit and Loss account, and the Directors recommend that a final dividend of 2½ per cent be declared, making with the interim dividend of 2½ per cent already paid, a total of 5 per cent for the year.

The dividend will absorb R10,375, and leave a sum of R7,108 54, which it is proposed to carry forward to the new season.

The crop for the year has turned out very short, only 244,636 lb having been secured against the reduced estimate of 300,000 lb. This shortfall is almost entirely due to the very severe drought experienced at the beginning of 1899 when the Estate suffered much, and never seemed to flush freely during the remainder of the year. Following this drought, the S.W. Monsoon set in very early with strong wind and too much rain, so that no sooner had the bushes recovered from the effects of the dry weather, than they were checked again by the wind and rain; in fact there was very little good flushing weather during the whole year. Over and above these unfavorable conditions, the Superintendent was hampered by having to transport his leaf to neighbouring factories during the busiest months of the year, owing to the new factory not being completed; the transport of material for the building also taking up a good deal of labor, so that during the month of April a little leaf was lost, although nothing to account for the great shortage of crop, the greater part of which occurred during the latter six months of the year.

Expenditure per lb. of made Tea is heavy, being 26-14 cents per lb., but this is accounted for partly by the short crop, and partly by having to pay neighbouring estates to manufacture our tea, and extra transport, &c., while the new factory was in course of erection.

To cover this, however, a sum of R16,184 82 was provided by the balance due on a Loss of Profit Policy, and if this sum be deducted from the estate expenditure, the cost of production becomes reduced to 19 53 cents per lb., which is less than the tea would probably have cost under ordinary circumstances. The net value of the crop was 35 74 cents per lb.

The Estate is in good order and well supplied with labor. The estimate of crop for 1900 is 300,000 lb. of made tea at a cost of 21 55 cents per lb., which includes the cost of opening up a new clearing of 15 acres.

The old factory which was destroyed by fire has been replaced by a larger and better building with more up-to-date machinery. The new factory is complete in every respect, and well up to the requirements of the Estate. The amount spent on the new building and machinery over and above recoveries from the Fire Insurance Company is R17,506 72, which amount has been provided for out of the revenue of the Estate.

In terms of the Articles of Association, Mr. Wm. Anderson retires, by rotation from the Board of Directors, but is eligible for re-election.

The appointment of an Auditor for 1900 rests with the meeting.

TEA: THE RAYIGAM COMPANY, LD.
THE ANNUAL REPORT.

Acreage:—

RAYIGAM.	
Tea in bearing ...	362 acres.
„ partial bearing ...	264 „
„ not in „ ...	69½ „
Forest ..	504½ „
Total ...	1,200 acres.
ANNANDALE.	
Tea in bearing ..	250 acres.
Forest	8 „
Grass	38 „
Total ...	296 acres.

The Directors herewith submit their Report and Balance Sheet with Profit and loss accounts for 1899. After writing off R4,838 38 for depreciation on Buildings and Machinery and R1,319 12 being the balance outstanding for preliminary expenses, there remains a balance of R9,779 63 available for distribution, out of which the Directors propose to pay a 5 per cent dividend absorbing R30,000, and to place R9,000 to a reserve for making provision for the reduction of the mortgage loan, carrying forward a balance of R7,9 63.

The crops of tea from both estates considerably exceeded estimates, that of Rayigam being 299,395 lb. exclusive of bought leaf, and of Annandale 92,846 lb.

The net prices realised for Rayigam and Annandale Estates teas respectively were 33 82 cents and 44 22 cents per lb. The teas were all sold locally.

The estimate of crop for the current year for Rayigam is 320,000 lb. as against 250,000 lb. for last year, and for Annandale 94,000 lb., as against 82,000 for last year.

Mr. Gordon Frazer having gone on leave, Mr G E Woodman was elected a Director to fill the vacancy on the Board during Mr. Frazer's absence from the Island.

Mr. Albert Rosling retires from the Board of Directors by rotation, but being eligible offers himself for re-election.

The election of an Auditor for 1900 rests with the Meeting.

THE CLYDE TEA ESTATES COMPANY, LD.

THE ANNUAL REPORT.

Acreage:—

Tea in full bearing ..	434 acres.
Young Tea ..	112 „
Jungle, &c. ...	169 „

Total.. 715 acres.

Your Directors beg to submit their Report and accounts for the year ending 31st December, 1899.

During portions of the year unusual droughts were experienced, a serious shortfall in crop resulting therefrom.

The quantity of tea made was: from estate leaf 173,040 lb. and from bought leaf 7,225 lb., against estimates of 235,000 lb and 5,000 lb. respectively.

The yield for the year equals 400 lb. of made tea per acre in full bearing.

The cost of estate tea, including transport but exclusive of manuring was R45,302 45, or say 26 18 cents per lb. The net amount realized for the total crop (180,265 lb.) was R64,402 53, an average of 35 73 cents as compared with 33 50 cents per lb. in 1898.

The expenditure on manuring during the year (R5,111 60) has been charged against revenue, and the following additional sums have been written off:—

R1,000 being balance of preliminary expenses.
R3,233 58 for depreciation in value of buildings and machinery at 2½ per cent and 10 per cent respectively.

The available balance is R7,637 09, from which the Directors recommend payment of a dividend of 2½ per cent absorbing R6,750, and leaving R887 09 to be carried forward to next account.

Under the Articles of Association, Mr. F M Laurie retires from the Board, and being eligible offers himself for re-election.

The shareholders have to appoint an auditor for 1900.

TEA: THE UDABAGE COMPANY, LD.

THE ANNUAL REPORT.

Acreage:—

215 acres in full bearing.
84 „ 3 years old.
36 „ 2½ „
164 „ 1½ „
499 acres cultivated.
641 „ available reserve.

1,140 acres more or less.

The Directors beg to submit to the shareholders the accounts for the year ending 31st Dec., 1899.

The crop secured amounted to 141,430 lb. made tea against an estimate of 145,000 lb. and realized R46,599.10 or an average of 32.94 cents per lb. against an expenditure of R34,687.06 or an average f.o.b. cost of 24.52 cents per lb. The cost of production for the year has thus been reduced by nearly cents per lb. while the average price realized is better by fully 2 cents per lb.

The balance at credit of Profit and Loss Account is R5,422.77 after providing for interest on advances for extensions and development of the Company's property amounting to R11,293.34. A new factory is in course of construction, and it is expected will be fully equipped and in working order shortly.

The estimate for the current season is (including 7,500 lb. of tea from bought leaf) 165,000 lb. made tea, and it is anticipated with the increased facilities for transport from the estate and an improvement in manufacture afforded by the new factory and machinery better results may hereafter be shewn.

Mr. Gibson in his last report dated 9th February, 1900, states that the latest clearings are making excellent progress and will be a fine sheet of tea, and that the estate is in every respect in a satisfactory condition.

Mr. Thos. Hudson retires from the Directorate in terms of the Memorandum and Articles of Association, but is eligible for re-election.

It will also be necessary to elect a Director in place of Mr. G. J. Jameson who is leaving the island temporarily.

The appointment of an Auditor rests with the meeting.

TEA AND CACAO: THE KANDYAN HILLS COMPANY, LD.

THE ANNUAL REPORT.

Acreage:—

Tea in full bearing	320 acres
„ in partial bearing	32 „
„ in planted in 1897	58 „
			410 acres
Cocoa	90 „
Reserve land	810 „
			1,310 acres

The directors have the pleasure to present their Report for the season ended 31st December, 1899, together with a statement of accounts, duly audited for the same period.

The tea crop for the year including purchased leaf amounted to 177,027 lb. the quantity secured from the estate itself being 164,945 lb. against an estimate for the season of 130,000 lb., while the cocoa crop resulted in a yield of 110 cwt. 0 qr. 4 lb., which is about 20 cwt. less than the quantity expected at the beginning of the year.

The nett price realized for the tea was 35.70 cts. against 36.23 cts. in 1898. and the cocoa sold at an average of a little over R47 per cwt. all round.

The f.o.b. cost of the tea after allowing for expenses in connection with outside leaf works out at a little over 23 cts. a lb. which shews a very large reduction on the rates of previous years, and it includes the cost of sufficient manure for a 30 acres field about to be gone over.

The profit and loss account after providing for the debit balance of last year (R6,957.76) together with interest and other charges shows a sum of R9,535.74 to credit of the account which it is proposed to deal with as follows:—

6 per cent. dividend which will absorb	R7,500 00
Carried forward to next account	2,035 74
	R9,535 74

The financial position of the Company has been placed on a satisfactory footing by the issue of debentures to the value of R50,000, carrying interest

at seven per cent. per annum, all of which were subscribed for by the shareholders.

The new season's estimates are based on a crop of 160,000 lb. of tea and 130 cwt. of cocoa, besides which there will again be some transactions in outside leaf.

The expenditure including the cost of manuring 100 acres of tea is computed at an f.o.b. rate of a little over 26 cts. a lb., and the cocoa crop works out at R29 per cwt.

The capital outlay in connection with the new season is estimated at R17,790, and provides for a Pelton Wheel installation which has been rendered necessary by the continued scarcity of fuel. It further includes the cost of a new siccoco and finishing off the extension to the factory, besides opening of, and planting with tea, another 25 acres of the reserve land. The balance of the money raised on debentures will be available for these improvements to the property.

Mr. J. N. Campbell retires by rotation and is eligible for re-election. Mr. G. J. Jameson, who was elected in place of Mr. Macindoe on his leaving for England also retires, and it will be necessary to elect a director in his place.

The appointment of an auditor rests with the meeting.

TEA: THE KIRKLEES ESTATE CO., LTD.

THE ANNUAL REPORT.

Acreage 31st December, 1899:—

Tea in full bearing	..	310 acres.
Tea in partial bearing	..	70 „
Tea not in bearing	..	48 „
New clearings about	..	10 „
Timber and cardamoms, about	..	105 „
Uncultivated land	..	174 „

Total 717 acres.

The directors have now to submit to the shareholders the accounts of the Company for the past year.

The crops secured were 130,888 lb. Tea, 1,251 lb. cardamoms and 35 22-32 hushels coffee, while 7,809 lb. Tea were manufactured from purchased leaf. The price realized for the tea was 39.80 cents nett per lb. as against 39.33 cents in 1898, while the cardamoms sold for Re. 1.49 per lb. nett, as against Re. 1.62 per lb. in 1898.

After making ample provision for depreciation of buildings and machinery and setting aside a sum of R1,500 as a further provision to cover any possible loss of Coast advances, the profits for the past year amounted to R8,590.48, to which falls to be added the balance of R1,484.84 brought forward from 1898, less R8.10 realized short of the estimated value of cardamoms belonging to that year's crop.

An interim dividend of 3 per cent was paid on the 28th August last, and the directors now recommend the payment of a final dividend of 6 per cent. making 9 per cent for the year, and that the balance of R1,067.22 be carried forward to the current season's account.

The crops for the current year are estimated at 150,000 lb. tea and 2,000 lb. cardamoms, on an expenditure of R44,286.59.

In accordance with the articles of Association an issue of 350 cumulative preference shares of R100 each was offered to the shareholders by the directors in their circular dated 26th October last, but only 47 shares were applied for. The directors have however been able to place elsewhere 200 shares, and have decided not to issue the balance at present as negotiations for the purchase of Beckington Estate have in the meantime fallen through. Payment has now been made for these shares and the loan of R25,000, appearing in the annexed accounts, was paid off on the 13th February.

In terms of the articles of Association Mr. G. H. Alston retires from the office of director, but is eligible for re-election.

The appointment of an auditor for the current year will rest with the meeting.

CEYLON HILLS TEA ESTATES CO., LTD.

THE ANNUAL REPORT.

The Directors have now to submit their fourth annual report and the accounts of the Company for the year ended 31st December, 1899.

The crop secured was 425,603 lb. as against 389,649 lb. in 1898, and the cost of putting it on the market was 31.68, realising 36.36 per lb., as against 33.04 and 33.90 cents respectively in 1898.

While the yield was again short of expectations, it is satisfactory to notice an increase of 36,000 lb. over 1898, and the Directors would emphasize the fact that the hope expressed in last year's report, that the ground lost in 1898 would be recovered in the following twelve months, has thus happily been fulfilled to an appreciable extent, and this in the face of continued abnormal and adverse conditions.

The estimate for the current year is put down at 468,500 lb. made Tea, and Mr. Galton, when sending in his January report, says that prospects for the first six months of the year are extremely good.

Debenture interest has been paid for the half year ended 30th September, 1899, and the next payment will be due on March 31st next.

It will be noticed that the debit balance of R3,962.99 as on 31st December, 1898, has been reduced to R2,417.11 during the last year, the profit made in 1899 having thus been R7,545.88.

Mr. Galton reports in January that estates and buildings are in a generally satisfactory condition, but that labour is not so plentiful as he would like, though he hopes to get fresh labourers from the coast in March-April. Coast advances stand at R11,888.05 on 31st December, 1899, as against R16,913.67 the year before.

The Directors have decided to again relinquish their fees, and the Agents and Secretaries have agreed to respond with a like amount.

It will be noticed that the Company's form of accounts has been altered in so far as the amount written off for depreciation is concerned, the original cost of factories, buildings and Machinery being shown on the one side and the total amount written off for depreciation on the other.

In terms of the articles of association Mr. F. Liesching retires from the office of Director, but is eligible for re-election.

The appointment of an Auditor for the current year will rest with the meeting.

WAREHOUSE CHARGES FOR TEA.

If the London dock and warehouse-keepers think that the slight concession recently made in regard to their charges on tea will satisfy tea growers and importers they are under a false impression. A slight reduction is better than nothing, but in this instance it can only be regarded as a fore-taste of further reform in the same direction. Feeling on the subject is strong, and the position is aptly described in the following comments which we take from the *Investors' Review* of February 10th:—

The writer in the *Review* says: "The 'ring' of warehouses known as the Tea Clearing House has informed the Indian Tea Association that the committee of the Clearing House have decided to recommend a reduction in the bulking and taring charges, and this recommendation has been duly confirmed. As near as possible the reduction appears to be some 25 per cent., the charge for bulking and taring packages of 90lb. to 129 lb.—the average weight—being now 1s 1d. per package as against 1s 5d. in former days. To have obtained a concession at all is equivalent to an admission that the agitation on the part of tea importers was well founded; but no one should imagine that the grace now bestowed will meet the needs of the case. Indeed, it is really very

little in the nature of a concession, for it has been made rather with a view to meet new conditions produced by the events which followed the 'draft' dispute. The effects of that disastrous dispute still hang over the tea market, with the result that the dealers demand that every package of tea that has been re-bulked in London shall be tared. The cost of this operation was so great that the warehouses have met the market by reducing these charges. Apart from this matter, the abatements now granted will not weaken the agitation, because many of the energetic companies will obtain no benefit from it. A company that has paid particular attention to the bulking of its tea in India or Ceylon, and has so arranged it so that an average tare will always suffice for the buyer, does not require to undergo this combined bulking and taring charge. This is the move now made, merely a little inducement offered to the companies to go back to the old slovenly ways, when such matters as bulking and equality of tares were ignored. We therefore imagine that the committee of the Indian and Ceylon Tea Association which is sitting upon this matter of warehouse charges will not be content with such a small crumb dropped from the rich table of the warehouse-keepers, but will press for a substantial reduction in all important charges, particularly the working charge and the rent. Independent testimony has satisfied all those connected with the tea industry that a reduction in the charges is reasonable and equitable, and if such concessions are not granted responsible men in the trade are quite prepared to carry on the struggle to the bitter end. The warehouse-keepers had therefore better agree to an amicable adjustment of the points in dispute whilst there is time, for if no redress is granted, the subsequent action of those interested in a reduction would cause a far greater decline in rates than is even hinted at now."

There are also some comments written in a similar strain in the *Produce Markets Review* of the same date.—*H. and C. Mail*, Feb. 16.

THE LONDON COCOA MARKET.

(By Harold Hamel Smith.)

London, E.C., 16th Feb., 1900.

In spite of the Government being in the market this week, prices, generally speaking of cocoa went easier, though to what extent it is puzzling to know as the reports vary in a somewhat remarkable degree. Some say Trinidads and Ceylons are steady, and others that they are down 2s to 3s. The truth is, as I think you will see by the prices I quote below, that of Trinidads the best marks were decidedly steady, but "middling" and "good middling" red sold at lower rates compared to 81s 6d and 82s for some "Belle Fleurs" sold last month. It is this class of Trinidads that went low this week say at 78s and 79s. As to Ceylons, except perhaps for the better qualities which seemed to be in less demand, and hence met with rather poor competition, the prices realised I think compare favorably with those of the previous week, and if it still sold at somewhat irregular prices, it was with an upward tendency this time instead of a downward one.

7,908 bags of all growths were offered at Tuesday's sale, of which some 4,000 bags sold, or about one-half. Trinidads sold up to 84s 6d for fine marks say Sta Rosa Scheult at 83s and San Jose Degannes at 84s 6d whilst "good middling" and "good red" as "Las Hermanas"

sold down to 78s. Grenadas went 1s lower, and in some cases perhaps even a little more, for only two lots sold at 72s, the bulk of the "fine red" which had been selling at 72s to 74s, only realising 70s to 71s. This week the Government did not buy any Gre adas, but were purchasers of about 700 bags of Trinidads at prices varying from 79s to 81s 6d. Or Ceylons nearly 2,000 bags were offered of which 731 bags were sold, at 60s to 63s 6d for "smalls," 78s to 83s fair to good red, 85s 6d to 87s for fine red. Native cocoa sold at 66s for common and 67s to 70s 6d for fair to good. The demand for this growth is evidently dull this week for I have not heard of any more having been sold since the sale, but I still think "very fine bold" red with a light break, would fetch a fancy price.

Cocoa butter is quoted a little higher in price being 1s 5½d today.

Stocks still run very low, the stock of all growths being only 74,943 bags against 91,152 bags last year, and 113,918 bags in 1898, of these 7,400 late Ceylons, 15,172 Trinidads, 9,727 Grenadas and 25,241 bags Guayaquil.

From all accounts I am of opinion that this year's supply of Cocoa, will be nearly as large as that of 1899. The Guayaquil crop may not be quite so heavy, but the small difference will be more than compensated by increased receipts from Africa, and perhaps Bahia, especially African where I hear the increased cultivations are beginning to tell up. This is just as well for with the consumption increasing as it is we shall want every pound of last year's supply, if, indeed, it will be sufficient to prevent prices a little later, going higher.

PADDY CULTIVATION: ITS COST AND PROFIT.

LARGE PROFITS?

(FROM A WYNAAD POINT OF VIEW.)

In view of the decline in values of coffee and tea in the European markets, as well as of the circumstance that a considerable extent of land suited to the profitable growth of rice is to be found in proximity to blocks which are under coffee and tea in India, it will be instructive to glance at the advantages resulting from utilizing such blocks for raising an article of consumption which lends itself so readily as a means of supporting the labour engaged, not merely on the tilth itself but in that devoted to the major products named above.

There are practically two methods by which rice, *i. e.*, paddy can be successfully grown, namely, through indigenous labour, and by means of imported coolies.

The former are accustomed as a general rule in South India, to be remunerated in kind, a man receiving for a full day's work approximately 4 lb. of paddy, a woman 3 lb., while one anna in cash is disbursed weekly to such of the former as may have worked for not less than six days in the week; and twice a year all hands expect to be presented with a couple of large coarsely woven white cloths, on the recurring anniversary of the two principal festivals, in March-April and in August-September. On the other hand, imported coolies are paid at the rate of 4 and 2½ as each daily.

It may be taken for granted, speaking broadly, that the average value of paddy in Southern India is R2 per maund of 82 lb., and upon this hypothesis the scale of wages payable to the imported labourer, 4 as per man) is more than double that earned by his indigenous confidre.

In framing an estimate of the outlay connected with paddy cultivation, it will consequently be fairest

to strike an average, and debit the account with day labour at an all round scale of 3as. per diem.

Before scrutinizing the cost of cultivating paddy lands or bhil tracts it should be assumed that the ryot possesses upon a 30 acre block a herd of at least 40 buffaloes, the accruing manure from which will suffice to liberally fertilize the whole, once every second year (one-half of the holding being so treated annually), while the services of the animals are utilized (1) for ploughing, and (2) for threshing, *i. e.*, for treading out the grain.

Paddy, on the average, requires about four months to mature, but upon some tracts, two harvests can be annually raised. The following statement furnishes a schedule of the outlay incidental to cultivating 30 acres of wet land for a period of about eight months:—

	R
1 Herding 40 buffaloes at 6 annas per diem	90
2 Cost of 30 maunds of seed grain ..	60
3 Ploughing each acre six times (prior to seed sowing, a man taking three days to do the work each time, also labour for "bundling" the land ..	200
4 Sowing the seed ..	30
5 Application of manure ..	15
6 Reaping ..	30
7 Threshing and winnowing the grain ..	90
	455
Value of Harvest representing a yield of 15 maunds per acre, amounting to 450 mds. at R2 ..	900
Value of straw ..	100
	1,000
Deduct Expenditure ..	455
Balance of profit ..	545

The yield of paddy varies considerably and ranges from 10 to 30 fold, but in this statement a return of only 15 fold is provided for, a result which may confidently be anticipated where the work of supervision is intrusted to capable hands.

From these figures it will be obvious that on ordinary land of the extent named properly manned and otherwise treated a return of 15 fold yielding a net profit of over 115 per cent. accrues, or deducting the pay of a native supervisor, 100 per cent. profit remains to the cultivator.

One maund of paddy properly cleaned and winnowed yields about 50 lb. of raw rice, the value of the latter as a marketable commodity being governed by the particular class of grain from which it was raised.

But assuming that an average is struck between the best quality and the commonest description of rice, a rupee purchases about 18 lb. of the latter, so that a rateable yield of 15 maunds per acre is equivalent to a crop of more than 750 lb. of rice worth R41-10-8.

These calculations are based on practical experience and may be thoroughly relied on as a moderate estimate of the probable profits accruing from the cultivation of paddy or boidings at an elevation of 2,400 feet above sea level and enjoying an annual rainfall approximating 80-120 inches, fairly well distributed.

Ryot.

—Planter, February 24.

BRITISH NEW GUINEA.

AN AUSTRALIAN CEYLON.—This is the term applied to New Guinea by the Australians. The new colony, we learn, is at last to be thrown open to white colonisation, not through the agency of a British syndicate, but by the direct action of Government Administrator, Mr. Le Hunte, with the concurrence of the Australian colonies concerned. The terms on which land may be acquired after a certain date for settlement purposes have been issued, and it is prob-

able that the career of British New Guinea as an Australasian colony will commence simultaneously with the proclamation of the Australian commonwealth. The new colony, it is claimed, possesses many of the features on which the prosperity of Ceylon is based, and offers many advantages to the semi-tropical agriculturist, the general character of the climate being not unlike that of Northern Queensland. When British New Guinea became part of the British Empire, European settlement other than at a few points of the coasts could not be attempted with safety on account of the savage character of the natives, who naturally regarded the white man as an intruder. But like the Maoris of New Zealand and the inhabitants of Fiji, they are a singularly intelligent people, and, under the kindly yet firm rule of Sir William Macgregor and his successor, have learned to respect and confide in the sway of the white man. There is not the slightest risk incurred by a settler, unless he disregards official advice and seeks to penetrate the yet unexplored portions of the colony. The country is exceedingly mountainous, and as the more elevated regions become more and more accessible they will afford a ready means of escape from the summer heat of the low lying country. So far as can be ascertained, the country is one immense forest, abounding in valuable timber, and broken in places by vast alluvial plains, formed by the deposits of rivers in flood. The natives are mostly of settled habits, having large villages kept scrupulously clean. The native manufacturing industries include pottery and rope making, but the Papuans are an imitative race, and speedily acquire a knowledge of the use of tools and the simpler industrial arts. The Government of British New Guinea has for some time been engaged in securing places suitable for the beginning of European settlement, a large portion being bought from the natives. Each locality has the natural makings of a plantation—good soil, a plentiful supply of water, and accessibility from the coast. Each lot will be sold at a nominal price, subject to conditions intended to prevent its being secured for purposes of speculation. At present it looks as if gold-mining, sugar-growing, and cattle-raising are destined to become the leading local industries, but there are many branches of semi-tropical agriculture which can be successfully introduced, especially tea, coffee, and rice. Several varieties of sugar-cane indigenous to the colony are said to be disease-proof, while the ease with which luxuriant crops of bananas, yams, coconuts, mangoes, sweet potatoes, and other agricultural products are obtained by the natives fully illustrates the capabilities of the soil. There is a Customs tariff imposed, with numerous exemptions, for revenue purposes, but at present the whole of the New Guinea trade is in the hands of Queensland firms. As the development of the infant colony proceeds the Solomon and other island groups will inevitably become more or less influenced.—*H. & C. Mail*, Feb. 16.

COCOS-KEELING ISLANDS.

ALL-BRITISH CABLE MAY BE LANDED ON ONE OF THE GROUP.

The fairyland in the Indian Ocean, which is known as the Cocos-Keeling Islands, and belongs to a Scottish chieftain of the name of Ross, third monarch of the name, is suddenly assuming quite a new importance in the world.

The Cocos-Keelings are coral islands of the south-west coast of Java, which Clunies Ross the first found unoccupied three-quarters of a century ago, and colonised with a few Scots and some coolies. According to a Colonial Office report issued on Saturday the islands shipped away last year 800 tons of copra, the produce of four and a half million coconuts at £14 15s. a ton.

There are 615 people on the islands, and a school with two pupils—"rather above the average

attendance," remarks the Commissioner; but the younger generation of the Ross family are taught English two hours daily by Miss May Ross. There are no police, and there is no need for them. The natives seemed to the consul more like the laboring class of Europeans bereft of alcoholic liquors and released from the struggle for existence than like natives without religious restraint.

They build good European boats under the instruction of the Ross dynasty, and they do not undervalue themselves. They are surprised, indeed, why the British Government does not give them men-of-war to build.

The home of this simple little community is likely to become a part in the "all-British cable" scheme via the Indian Ocean to Australia. The cables at present pass through Java, which is Dutch; but the Eastern Extension Australasia and China Telegraph Company proposes to land a cable on one of the Cocos Islands. The Commissioner, who is very enthusiastic about the scheme, says Mr. Ross is prepared to grant the concession. He adds, urging the connection of the Far East by an Indian Ocean rather than a Pacific cable: India would be connected by an all-British cable. Then, taking an even more ambitious view of the possibilities of the case, he adds: It is probable that even without a subsidy a cable connecting Zanzibar with India, Australia, and Java, by way of Seychelles, Chagos, Cocos, and Christmas Islands, would become a commercial success if worked in conjunction with the African Trans-Continental line. If the tariff from Europe to Zanzibar was 1s. 3d. the rate to India might be lowered to 2s. 3d.—*Morning Leader*, Feb. 15.

MINERAL PHOSPHATES WANTED IN AUSTRALIA.—The Government of South Australia offers a reward for the discovery of payable deposits of mineral phosphates. The amount is £500 if found on Crown lands, and £250 if on private property. The discoverer will be entitled to a lease of 21 years of 648 acres of land. The conditions are that the deposits are readily accessible by rail or port; that the deposit is sufficiently abundant, and is available to the farmers at a payable price; and that the product is of good, marketable quality, averaging not less than 40 per cent of phosphate of lime. Half the amount will be paid when 200 tons have been produced, and the remainder when the second 200 tons have been produced.—*Melbourne Leader*.

CAMPHOR is an infallible remedy for chicken lice. When you make your nest and put in your eggs, at the same time place in the nest with the eggs, one camphorated ball, which is sufficient for the entire incubation, and your hen and little chicks will leave the nest free from all kinds of vermin. When you have placed the little ball in the nest, you need not bother any more. It will evaporate and get to be very small toward the latter part of the incubating, but never mind, it has done its work. It is a good idea to keep one of the balls in the nest where the hens lay, as it keeps them from having scaly legs as well as keeping them free from vermin. The camphorated ball is a little white ball and can be had from almost any drug store. I buy penny squares in Kingston, instead of the ball, and half a one is effective in the layers' nests.—*Journal of the Jamaica Agricultural Society*.

THE SEYCHELLES.

The Acting Administrator's report on the Blue Book for the year 1898 has just been published by the Colonial Office. Mr Brown's report shows a satisfactory state of affairs, the revenue having been the largest ever collected in Seychelles, and in excess of the expenditure by R39,791. The exports, less coin and bullion, amounted to R1,278,382, and the imports, less coin and bullion, to R889,041. The large increase in both exports and imports is due to the large vanilla crops of 1897 and 1898. Vanilla valued at R748,810 was exported in 1890.—*Commercial Intelligence*, Feb. 17.

THE BANK CLEARING-HOUSE" AND LOCAL BUSINESS.

The figures we append show an enormous increase in the mass of local business during the past fifteen years:—

	R.		R.
1885-86	51,740,748	1890-91	83,607,049
1886-87	55,530,720	1891-92	98,358,939
1887-88	64,921,478	1892-93	105,914,810
1888-89	74,072,097	1893-94	128,112,905
1889-90	76,791,733	1894-95	133,812,072
		R.	
	1895-96	171,677,240	
	1896-97	171,429,740	
	1897-98	192,136,477	
	1898-99	169,991,275	
	1899-00	195,467,028	

Since the "clearing house" was established, we have had the means of obtaining reliable statistics which indicate the steady revival of business and prosperity, mainly through the rise of the tea industry. Still, it would never do to attribute all the increase in the clearing-house figures to the growth of local trade. True, the value of our imports and exports show much improvement in the interval, as may be seen from the following comparison (the figures for 1898 being the latest published):—

	Imports.	Exports.
1885	R 45,132,340	R 35,782,400
1898	97,893,058	85,372,622

Increase R52,760,718 R49,590,222
The increase here is also very notable; but at the same time a good deal of allowance must be made for the gradual change in the modes of business in Colombo. Far more cheques are used by natives and planters now than in "days of old." Chetties and planters were notorious for dealing almost universally in rupees—and of course a great deal is done still in payment of coolies—whereas now cheques are readily accepted by the carpenter or other artificer, the cart contractor, rice-dealer, &c., &c. In 1885, we were slowly emerging from a period of great depression; the old Oriental Bank had collapsed the year before and its successor had by no means secured general confidence. Now we have five first-class Banks all doing a large business and all therefore contributing handsomely to the sum-total of the "clearing-house."

VISIT OF A JAVA PLANTER TO CEYLON.

We have had a call from Mr. Bley, a planter in the Samarang division of Java, and who has been out there for the past 22 years without ever visiting Europe. Mr.

Bley has had a great variety of experience in his day, as a Sugar, Coffee, Tea, Liberian Coffee, Cacao, Nutmeg, Pepper, Kapok and Cinchona planter. Now he confines his attention chiefly to Liberian coffee with some Arabian, and cinchona with tea. Mr. Bley has enjoyed a fortnight in Ceylon very much, more especially in visiting Kandy, Peradeniya, Galaha, Mariawatte, Dimbula, Nuwara Eliya, Ragalla, and Bandarawela. Mr. Bley would at once describe Nuwara Eliya as the remains of an old volcanic crater, so like is it to many such spots in Java. He finds that the cost of labour in Ceylon is a little more than he pays in Samarang, where, however, nearly all is done by piece-work. Mr. Bley states that he is troubled with a bad disease in his cacao in Java, which he has nowhere seen in Ceylon. It has not yet been scientifically described. Mr. Bley left for Europe last month by the N.D.L.S. "Königin Luise": we wish him a pleasant trip and visit and that he may return re-invigorated. Mr. Bley confirms our opinion that the people of Holland and adjacent Germany are beginning to drink tea very freely. Java, he thinks, will never become a great tea-growing country.

THE BRITISH ASSOCIATION.

The Report of the British Association for the Session of 1899 held at Dover reached us by a recent mail. It is a bulky volume of well-nigh 1,000 pages, besides lists of members, &c., and, of course, contains the latest in "Science." The only plan or plate is the "plan of Dover Harbour" as prepared to accompany their paper by Messrs. Coode, Son & Matthews. This bears considerable resemblance to the Colombo Harbour with two openings—one of 800 and the other of 600 feet. The area of the Admiralty division is 610 acres at low water; of the Commercial harbour 75 acres—together 685 against 640 acres for the Colombo harbour.—After the present "Notes on Ceylon Botany" are done, it will be interesting to reproduce "A sketch of the History of Indian Botany" by Sir George King, in our *Tropical Agriculturist*. Mr. Parkins' paper on Rubber, given in our Manual, is summarized; as also briefly "Notes on Indiarubber" by R.H. Biffen, Cambridge, and this summary we give as follows:—

Notes on Indiarubber, by R. H. BIFFEN, Cambridge.

Starch and caoutchouc appear not to occur together. Caoutchouc occurs as small particles in latex, and coagulation begins with their running together. Certain reagents will bring this about; but it is better to avoid all chemical processes, any of which do harm. Two physical processes are now being used. (1) The latex, mixed with water, is strained and churned; the thick cream which rises to the surface is pressed through rollers and converted into rubber. (2) The author's process consists in separating the rubber with a centrifugal apparatus. Details are given in the paper regarding the chemical properties of the different kinds of rubber obtained from *Hevea*, *Castilloa*, *Manihot*, *Ficus*, *Hancornia*, *Kickxia*, *Artocarpus*, and *Clusia*. The author also raises some questions of theoretical interest with regard to possible relations between caoutchouc, starch, and resin-bodies, and indicates lines for further inquiry.

CINCHONA AND QUININE.

These important staples are again in an interesting position, few knowing exactly what their immediate future on the market will be, and, opportunely, Messrs. C. M. & C. Woodhouse, the Mincing Lane cinchona-brokers, have issued a pink circular about them this week. After reviewing the markets during 1899, and tracing the market fluctuations month by month, they give reasons for the quite unlooked-for results which occurred last year. They say:—

In the first place, the rise in quinine caused the markets of Europe and the United States to be swept for supplies, and dealers, &c., were induced to part with their stocks to take advantage of the higher prices obtainable in London, with the consequence that the stocks in London have been increased by about 1,000,000 oz. This is, however, an operation that cannot well be repeated, and the trade everywhere must be proportionately bare of stocks. On the other hand, we might have expected the rise in prices to have checked the consumption to some extent; but, as far as consumption can be gauged from the exports of quinine, &c., from Germany, this does not appear at all to have been the case, but rather the contrary, for 210,900 kilos. (7,381,500 oz.) were shipped, against 200,900 kilos. (7,031,500 oz.) for 1898. Again, it was natural to anticipate that a unit value of about 11c. per half-kilo. would have induced the planters in Java and elsewhere to take advantage of the rise and hurry their bark to market, and thus the total supplies of bark would have shown a large increase over previous years; but this has not been so, as the total exports from the principal producing countries show no increase, even allowing for the quantity manufactured in Java and exported in the form of quinine. Further, the returns of the Java bark offered at auction in Holland show that there is a much larger proportion of succirubra and other barks of low analysis as compared with previous years.

The three main facts to be adduced from the above statement are (1) that less bark was shipped from Java last year (5,583,400 kilos, against 6,945,400 kilos in 1898); (2) that the exports of quinine from Germany increased by 381,500 oz.; (3) that there is an increase of 997,000 oz. in the London stock of quinine. In regard to the future of cinchona, Messrs. Woodhouse quote from Mr. Standen's report made after his visit to Java, and his opinion confirms their views that "consumption has at last overtaken production." The circular concludes with statistics of Java bark, and a three-years' summary of imports and exports of bark for United Kingdom and Holland, from which readers are left to draw their own conclusions. This year has opened with a very firm market for cinchona, and the tendency, both in London and Amsterdam, is towards higher prices. The London stock of bark is the smallest since 1894—viz., 16,099 packages; on the other hand, Amsterdam has a larger stock—viz., 14,387 packages, against 12,263 packages last year. Ceylon and British India are now sending us greatly reduced quantities, the imports last year being—Ceylon, 618,921 lb., against 975,784 lb., and British India, 2,000,000 lb., against 3,090,000 lb. So far this year there have been no shipments at all from Ceylon, and Java has sent but little—615,000 Amsterdam lb. for January. Another consideration is that the first Amsterdam auctions this year were small, as also was the one held on Thursday, so that another advance in the unit is extremely probable. This Messrs. Woodhouse surmise.

Since the beginning of the year quinine has been in a strong position, and all indications point to a still higher market in the future. There have already been three advances on the part of makers, from 1s 3½d to 1s 6d without engagement, the latest advance being made on Tuesday, when the makers of B. & S. and Brunswick quinine added 1d. This advance, coming as it does immediately before the Amsterdam auctions, has puzzled the second-hand holders, but it is entirely due to the good consumptive demand and abundance of orders. The second-hand market has also been fairly active, the bulk of the transactions

being for March delivery, commencing at 1s 3½d in January, and rising to 1s 5½d, which figure has been paid this week for March delivery. The quinine-auctions to be held in Java on February 28 are expected to influence the market, and if they are successful the shipments of bark to Europe are bound to diminish, for Java's idea is to make and export quinine, and ultimately to keep all the bark they can.

We have confirmation of what we have said regarding the decreased output of cinchona in India in an important circular which we have received this week from Mr. J. E. O'Connor, Director General of Statistics, Calcutta. This shows that, during the thirteen years ending 1898-99, the area under cinchona in India has fallen from 14,491 acres to 7,591 acres. At the end of the last official year, of the 7,591 acres of land under cultivation, nearly 82 per cent was situated in Southern India, the remainder being in Bengal; the latter comprising 1,373 acres in and near Darjeeling. Most of the area in Southern India is in the Nilgiris (4,531 acres), and there are 1,173 acres in Travancore, and smaller areas in Mysore, Malabar, and Coorg. In Bengal, the cinchona plantations, which are the property of the State, cover 1,303 acres. In the Madras Presidency, on the other hand, the industry is mainly in private hands, the State plantations covering only 874 acres. There has been a substantial decline in Bengal as well as in Madras, and in Coorg the cultivation has been almost entirely abandoned. The number of trees in permanent plantations has fallen in the same period from 28½ millions to about six millions, of which a little over four millions were classed as mature. Mr. O'Connor attributes the decline in cultivation to a fall in the price of quinine. He gives statistics showing the amount of bark collected and exported from Southern India (Madras and Bengal) from 1885-86 to 1898-99. For the past five years they were:—

	Bark Collected.	Exports (lb).
1894-95	2,027,629	1,737,318
1895-96	2,039,881	939,938
1896-97	1,491,506	321,478
1-97-98	1,692,439	3,056,769
1893-99	997,001	1,361,539

The Bengal and Madras Medical Departments use between them at least 1,200,000 lb. of bark per year for the manufacture of alkaloids and galenical preparations, and are purchasers from private planters. These Departments are a factor in the cinchona problem which is not generally reckoned with. The figures which we give indicate that they use about a twelfth of the world's present output of bark, which is reckoned at 16,000,000 lb., or 3,000,000 lb. less than a decade since. The fact should be specially noted that the Indian Government has come into the open market as a buyer; not for much—still, a buyer.—*Chemist and Druggist*, Feb. 17.

PLANTING NOTES.

SUGAR IN QUEENSLAND.—The report of Mr. Maxwell, a Honolulu sugar expert, deals comprehensively with the three districts of Bundaberg, Mackay, and Cairns. He thinks that the climatic conditions largely favour the industry in Queensland, particularly in maximum rainfall occurring during the hot weather, but speaks strongly of soil exhaustion in various portions of the colony. He also deals with the ratoon question, and considers continued growth without replanting conducive to many pests and diseases. He regards many portions of each district as suitable for irrigation, and condemns the system of extreme maceration in the manufacture of sugar. Three experimental stations should, he says be established—one in the Cairns district, one in Mackay, and the third at Bundaberg, the last named to be the chief experimental station.—*Sydney Mail*, Feb. 17.

WANTED: A LOCAL TEA STANDARD.—We have had the red-leaf tea sample sent us some days ago on our table; but it remains quite "sweet"—although very "coarse" ("a coarse kintra piece of wark") and the Brokers assure us the infusion was sweet and wholesome in this case; but that there are far worse teas sold sometimes in the local market and that "Merchant" and his colleagues (as members of the Tea Traders' Association) should make it their special duty to form and establish a "standard" below which no teas should be admitted into local sales or for export shipments.

"DO AWAY WITH THE BROKERS."—We omitted giving our correspondent, who is responsible for this "counsel of perfection," some of the reasons which render action in that direction very undesirable at the present time. It is well-known that leading broking houses act as great checks on the large blending houses in their buying of tea. The brokers take the trouble to distribute many samples in independent directions and before the sales they are the recipients of very numerous orders to buy, which often act as a great check on the big dealers, not allowing them their own way, but rather provoking a free and active competition.

BOTANICAL DISCOVERIES.—The "Colonial Garden" established at Vincennes last July is already, says the *Morning Post*, rendering important services to the French Colonies. M. Dybowski, the director, informed an interviewer that he was at present engaged in studying the ko-sam plant, which had been found to be a marvellous remedy against the dysentery prevalent in hot countries. A discovery made at the garden was that the *eucomia almidides* contains 28 per cent. of gutta-percha. Plants have been sent to Tonquin, Annam, and North Africa, and it is confidently hoped that very important results will be attained. Incidentally M Dybowski found that the bark of indiarubber trees contains 5 per cent. more rubber than the leaves and branches. All the Governors of the French rubber producing Colonies have been informed of the fact. The bark has hitherto been thrown away.—*British and Colonial Druggist*, Feb. 9.

ROYAL TREES.—In the vicinity of Frogmore there is a large number of ornamental trees scattered about the well-kept lawns. Amongst these are a *Salisburia adiantifolia*, planted by Princess Victoria Eugenie and Prince Maurice of Battenberg on the Queen's eightieth birthday; a deciduous Cypress, about 85 feet high; *Retinospora obtusa anrea*, planted by the Empress Eugenie, March 5, 1880; *Tsuga Pattoniana*, planted by the Queen of Denmark on December 1, 1875, about 13 feet high; *Abies lasiocarpa* (concolor?), planted by Princess Thyra of Denmark on December 1, 1875; *Abies Nordmanniana*, planted by H.R.H. the Duchess of Edinburgh on March 11, 1874; *Cupressus Lambertiana*, planted by the Prince of Wales on March 24, 1864; *Thuya gigantea*, planted by H.R.H. Princess Louise of Hesse on July 1, 1864; another of the same kind, on the opposite side of the path, 55 feet high; another Maidenhair Tree (*Salisburia adiantifolia*), planted in 1754; *Thuya gigantea*, planted by H.S.H. Princess Hohenzollern on March 16, 1857. Close to the manseoleum is a practically good-looking deciduous Cypress, and a fine *Cedrus Deodara* and *C. atlantica*. *English Arboricultural Transactions*, vol. iv., part 2, p. 207.

SUGAR FROM THE ALOE.—The *Kolar Goldfield News* says the famine-stricken people in India, in 1877, were seen to dig out the core of the aloe and boil it for consumption as food. The product was found to be exceedingly sweet, and the question is asked whether the aloe plant could not be used as a source of sugar. A gentleman is said to be buying land to the extent of 2,000 acres in the Kolar district for growing aloes.—*British and Colonial Druggist*, Feb. 16.

"OIL OF CHINESE (AND JAPANESE) WOOD" is extracted from the grains of a tree called *Aleurites cordata*, or in Chinese *Ying fu tung*, which grows in rocky places, especially in the provinces of Hunan, Hupeh and Szechuen. The oil is used for making lacquer and waterproof oilcloths. It can be employed instead of linseed oil in painting, but for this purpose, according to the *Farben Zeitung*, it should first be boiled with a little oxide of zinc, minium or litharge, the temperature being kept over 200° Centigrade.—*British and Colonial Druggist*, Feb. 16.

LABOUR AND EXCHANGE IN INDIA AND CEYLON.—We direct attention to the incisive letter which we publish elsewhere from Mr. R. H. Elliot, of Mysore. The writer takes a gloomy view of the planters' future, more especially from the belief that "exchange" will be further forced up; but this, we can scarcely believe,—nor can we at all think that there would be the least hope of obtaining bounties in the planters' interests. But Mr. Elliot's writings are always suggestive and well worth reading.

CAUCASUS TEA.—According to a British Consular Report the tea grown in the Caucasus is inferior in quality and flavour to the Indian, Ceylon and Chinese teas; and the prices obtained have not been encouraging. There is great difficulty, in procuring labour, and the expenses connected with tea planting are so high as to render profits dubious, especially in competition with Indian and Ceylon teas. And for the present at any rate, if the Consular Report can be relied on, Indian planters should feel re-assured about danger from the Caucasus. However the Russian Government, as stated in *Capital* of 1st instant, is undertaking experiments in tea cultivation in the Caucasus, and is offering favourable conditions to those embarking on it; and perhaps in time the situation may be changed for the better.—A. K.

PLANTING IN THE STRAITS.—**COFFEE, RUBBER AND COCONUTS:**—The annual report of the Selangor Planters' Association—the greater portion of which we reproduce on page 671—is a most instructive document and puts the position of our neighbours in the Straits in a very clear light. Altogether the 70 estates represented have 15,537 acres in cultivation, the crop estimated for 1900 (we suppose of coffee) being 25,636 piculs, and the labour return shewing 2,877 Tamils, 401 Chinese, 1,016 Malays and Javanese. Much useful work has been done by the body, of which Mr. W W Bailey is Chairman and Mr. Tom Gibson Secretary, besides what appears in our quotation; and we can only extend all good wishes to our brethren at the Straits, and say how pleased we are to see the Veteran pioneer Mr. T H Hill still to the fore.

TO ALL PARTS OF ASIA, AFRICA, AMERICA AND OCEANIA.

Seeds & Plants of Commercial Products.

Castilloa Elastica Cervantes.—Orders being booked for the coming crop of seeds available in March and April, selected seed from very old trees, R. N. Lyma, Esq., Director of Agriculture, Zanzibar, writes under date 24th August, 1899:—"Please send me 200 seeds of *Castilloa Elastica* for further trial; the seeds of *Castilloa* you sent me last August germinated very well." Price and particulars in our Circular No. 32; special quotations for large orders according to quantity; immediate booking necessary to avoid disappointment.

Hybridised Maragogipe Coffee.—A large-beaned superior variety of Coffee in demand; orders booked for the coming crop of seeds, February and March delivery. Price according to quantity on application.

Hevea Brasiliensis. (Para-Rubber).—Orders being booked for the coming crop available in August and September, 1900. This is the only crop of seeds in the year. All orders should reach us before the end of July to avoid disappointment, as we have to make arrangements in time; guaranteed to arrive in good order at destination. We have already booked a large number of orders. A Sumatra Planter writes, dating 9th March, 1899:—"I consent to the price of £—— per thousand. I herewith order 50,000 upon condition that you guarantee at least 33 % seeds germinating." Plants can be forwarded all the year round in Wardian cases. Price and particulars as per our Circular No. 30. A Borneo planter writes dating, Sandakan, 17th August, 1899:—"The last lot of Para seeds turned out very well."

Ficus Elastica (Assam and Java Rubber).—Seeds supplied by the pound with instructions; price according to quantity. This tree grows equally well in high and low land, in forest and grass land, its cultivation being extended largely by the Indian Government. For price of seeds with particulars as per our Circular No. 33.

Manihot Glaziovii (Ceara or Manicoba Rubber).—Fresh seeds available all the year round; price as per our Circular No. 31. It is superior to Mangabeira rubber and second to Para rubber.

Urceola Esculenta (Burma Rubber) and **Landolphia Kirkii** (Mozambique Rubber).—Seeds and plants, both are creepers.

Cinchona Seeds.—Different varieties.

Sterculia Acuminata.—(Kolanut). Superior quality, seeds and plants; price on application; packed to stand the transit well for several months, a hardy tree, cultivation easy.

Erythrina Lithosperma.—Thornless variety, new crops of seeds ready in December, May and June. Price according to quantity on application.

Seeds and Plants of Cinnamon, Nutmeg, Clove, Sandlewood, Pepper, Cardamom, Vanilla, Arabian, Liberian and Maragogipe Coffee, Cacao, Tea, Coca, Fibre, Medicinal and Fruit Trees, Shade and Timber Trees, Eucalyptus various varieties, also Palms, Bulbs, Orchids, &c.

Our enlarged Descriptive Price List of Tropical Seeds and Plants of Commercial Products for Foreign Countries for 1899-1900 are now being forwarded to applicants in different parts of the world. Also Descriptive Price Lists of Seeds and Plants of Fruit Trees, Bulbs, Tubers and Yams, and Orchids.

"**SOUTH AFRICA.**"—The great authority on South African affairs of 25th March, 1899, says:—"An interesting Catalogue reaches us from the East. It is issued by William Brothers, Tropical Seed Merchants, of Honaragodda, Ceylon, and schedules all the useful and beautiful plants which will thrive in tropical and semi-tropical regions. We fancy Messrs. Williams should do good business, for now that the great Powers have grabbed all the waste places of the earth, they must turn to and prove that they were worth the grabbing. We recommend the great Powers and Concessionaries under them to go to William Brothers."

A leading Planter writes from *New Hebrides* under date 17th January, 1899:—"I shall like a few more of your Catalogues to distribute through these Islands, as I feel sure many would place themselves in communication with you, did they know where to write for Seeds and Plants."

Our New Descriptive Price Lists of Seeds of Shade Trees for Coffee, Cacao, Tea, Cardamoms, &c., Timber Trees, Trees for Avenues, Hedges Wind and Shelter Belts, Ornamental Trees, Shrubs and Climbing Plants; and Seeds and Plants of Palms, Calamus, Pandanus, Cycads, Tree and other Ferns, Crotons and Dracinas, now being prepared and will be ready shortly.

Agents in London:—MESSRS. P. W. WOOLLEY & Co., 33, Basinghall Street.

Agent in Colombo, Ceylon:—E. B. CREASY, Esq.

"A FARMER'S EVERY DAY LIFE."

"A FARMER'S EVERY DAY LIFE"—is the title of our "Cosmopolite's" latest contribution to our columns, given below. It is written at our special request and we know few men so able to do justice to the theme owing to a very wide experience, keenness of observation, and facility of expression, not to speak of the saving grace of humour which is so often visible. As a former Australian and New Zealand pioneer and bushman, an ex-Colombo merchant and still more, as an ex-Rangala planter, before taking to farming in Aberdeenshire, it must be seen that "Cosmopolite" has travelled over a wide field and that the conclusions he now lays before us cannot have been formed in haste, but are the mature results of much experience and observation. Practically the question discussed is that of a country *versus* a town life, and it is one that must come home very closely to planters in Ceylon, who may be intending shortly to seek retirement in the United Kingdom, or may be looking forward to such a consummation at no distant date. It must be extremely difficult after an active planter's life out here to settle down in town or suburbs with nothing, but a few hundred square yards of garden of one's own to traverse or overlook. "Logie" (Sir Græme Elphinstone) felt it so badly, albeit his residence was in the country, that he returned once more to "planting" and is now in the Malayan peninsula. Others who have gone "home" to settle down, have been very glad to get back to Ceylon on any terms, that is to secure a charge if possible; and if not to make a home on their own account. Now "Cosmopolite" comes forward and preaches that the proper course for the retired planter is to follow his example and become a farmer. Of the healthfulness of the life there can be no denial, and really that ought to count for an immense deal if there be children and a full household to think of. But, in our experience, gentlemen farmers—practical and hard-working as any Ceylon planters let us say—in Ross-shire and Morayshire, always grumble unless they can show a handsome percentage of profit on capital laid aside every year, without making proper allowance for the extremely healthful life enjoyed, or even for the economy in education and other items experienced, as compared with the colonist who has to see his family broken up and separated. Still, it cannot be denied that there are cases where even practical farmers have not been able to make both ends meet; where, indeed, they have had to dispose of their farming interest to prevent the disappearance of their capital altogether. We have two or three ex-Ceylon planters—hard-headed Scots even—who have come within this category,—men who like "Cosmopolite" would any day prefer

To hear the lark sing
To the mouse cheep,

—to live and work in the country, rather than be shut up in town or suburb and dawdle between their city brokers or agents and their club—an extremely disagreeable life surely to a man in the full vigour of life and who is

willing to be useful in his day and generation. But how are such men to be recommended to take to "farming" if it cannot be shown to "pay"—not in the sense of the 8-or-10-per-cent.-profit-sharers; but to the extent of covering actual annual outlay and household expenses? Now, we trust "Cosmopolite" is going on in the further instalments of his Paper, with practical advice calculated to help Ceylon planters who may wish to follow his footsteps, to enable them to choose the right sort of farm to stock it properly and to choose suitable subordinates and to shew, generally, how to make "a fair start." Perhaps, too, we may have successful "farmers" in England, Wales, the South of Scotland and even Ireland (all Ceylon planters we mean) who may supplement "Cosmopolite's" letters with specimens of their own experience and then, to finish up, we must endeavour to get contributions from a planter-settler in Tasmania, New Zealand, New South Wales or Victoria, the United States or Canada, and why not in South Africa? In this way "Cosmopolite," who is capable of criticising all such productions, will have started us on the way to much information of a varied and useful if not valuable character. A "Tea-farmer's" life in Ceylon can scarcely be considered a permanency in the vast majority of districts, and especially if there be a family. "What should come next" is therefore a matter of much practical interest at all times, and we trust "Cosmopolite" and other retired Ceylon men will help us to answer it.

A FARMER'S EVERY DAY LIFE.

IN NORTH BRITAIN:—No. I.

(BY COSMOPOLITE.)

Surprise has often been expressed that so many retired planters, merchants and civil servants from the East take, on their return to the mother country, to the glorious, most ancient but (by the British Government) most neglected profession of farming. With regard to planters one can see some reason in this choice: because having been accustomed to an out-of-door existence, they pine for a continuance of that same; but in the case of the others, it surely must be a matter of heredity—derived by them from the blood of their great ancestor, the original farmer Adam.

As a rule these amateur farmers, transported from the palm-fringed isle of the Eastern wave, or the banks of the Ganges, do not prove exceptionally successful in their new walk of life; but to a certain extent they seem satisfied with the healthy occupation they have undertaken, and do not complain more grievously than do professional farmers who have from infancy upwards grumbled as only a British farmer is entitled to grumble.

But having met many of these late-in-life agriculturists, I have been much distressed to find that they fail to see the humours of a farmer's life which blend with the numerous troubles and trials which beset these labourers in the corn field; and I have often felt inclined to draw attention to some of those amusing incidents which I, for one, cannot avoid seeing in my every-day life, and which

adds so much to the pleasure of living in this beautiful world of ours.

It is just 40 years since I began

A FARMER'S CAREER

and, although for a time, I took up the rôle first of Colombo merchant, and then that of a Rangala planter, the time came when I once more returned to my old love,—my old profession,—in the wilds of Buchan, where the East wind blows its best, and the cattle, sheep and turnips are unequalled in the world.

I know that the *Observer* is read regularly by farmers from our Eastern Empire, and also, of course, by planters who are still in the land of sunshine and tom-toms, but who intend at some future time, to adopt a farmer's life in the old country and in the hope that these notes of mine may catch their eyes. I intend giving some plain facts from a farmer's life in Scotland, as seen by one who knows life in the East as well as in our Australian Colonies, and I trust that some of those who can see nothing but drudgery in a farmer's life may learn from my experiences that there is much of pleasure and amusement even in a bucolic existence which one can easily assimilate, if not a perpetual victim to those gloomy views which generally accompany a disordered state of the liver. And now having made these remarks by preface, let me commence a description of that life which I am leading, hoping my remarks may be of some interest to those Ceylon men now farming at home, and to those planters who, in the near future, intend to beat their paper umbrellas into scythes, and their pruning knives into sheep-shears.

There are many, especially of late years, who have given up country life and gravitated to the towns, giving as their reason for so doing that the life they had been leading was so deadly dull compared with the pleasant and joyful existence to be had in the cities.

But there is another side of the question which these renegades from the country seem to have overlooked, and I am just the one that can point it out to them, for I have lived 20 years in various cities in different parts of the world, and spent nearly twice as long a period in country districts, at home and abroad. With such practical experience to guide me I have come to the conclusion that

THE ENJOYMENTS OF A TOWN LIFE

are but small in comparison with the disagreeable irksomeness of civilization. To say nothing about the smells, noises, bad water, indifferent gas and a score of other unpleasant peculiarities of city life, there is the chronic state of ill-health in the children of the town, and the normal condition of ill-nature peculiar to all house-keepers. If a city man is detained later than usual at his club, or some other important place of resort, the look which he receives from his wife on his arrival at home, not to speak of her language, distinctly shows an active state of that lady's liver. If he is half an hour late for dinner, he is greeted with the question: "How do you expect servants to stay if you can't come

home in proper time?" Exciting passages of that sort would never do with me; I would promptly go on strike. What is a paltry half hour to me, who was once three days' late for my dinner, and then had to eat it raw, as I could get no fire lighted, owing to everything being soaking wet with rain!

No, no, the pleasures of town life are as Dead Sea fruit—so sweet and delicious to the eye, so bitter and nauseous to the taste. My own school fellows, that I meet, who have spent their whole lives in a city, seem to me to have been dead from their birth, whilst those who have been resident in the country appear to have been very much alive all the time townsfolk never get any exercise worth calling by that name, for what they have consists principally in driving their own trap, or riding on the top of a fiery, untameable tram car. But ask the planters of Ceylon or the farmers of Britain how they account for their exceptionally good health, and they will reply that it is all owing to

THE WALKING

they have to do; for walking helps the general tone and improves the temper. People with thick boots, and the sense to wear them, generally have even tempers. There is nothing like walking ill-temper off: never mind what sort the weather is, go out and half tire yourself, and then hang up your water-proof and you will find yourself in a calm, forgiving mood unknown to people who stick in the house. Don't think I am mad: "Allah created the English mad"—but not the Scotch, and I have walked a good many tens-of-thousand of miles in my day, and know what I am writing about. Of course, we have much to growl about, farmers always have. If we have not got too much rain we have got too little, and if the rain comes just as we would wish it to, instead of being thankful for present mercies, we cast our prophetic eye into the future and declare that there will be a drought or a deluge next month. Farmers can never see a blight prospect, they are not built that way, and gloom and despondency are their portion. Of course, there are exceptions to every rule, and I claim to be one of the exceptions to this, for I do not go about the country with my jaw hanging below the lowest button of my waistcoat, as I remember some planters doing, in the days when coffee leaf-disease was rampant. And I know other farmers also who are quite content with things as they are, although, naturally, we would prefer better prices and a more generous Government, and these are the sort of agriculturists I would recommend farmers from the East to copy.

There are some people, however, who are never content—for example, a neighbour, who had been present at a very intellectual lecture which was given in our village, lately; when I asked him if he had not enjoyed and felt edified by it, replied:—"Weel I dinna ken that, but twa days' rain wud hae deen us a hauntle mair guid."

It has been asserted that the gloom and despondency, which is inherent in most farmers, is caused by the

BAD WHISKY

they drink. Not that they drink much, they cannot afford to do so, but there may be some truth in the assertion, for the whisky which is retailed to the farmers at markets and fairs, and which I have sampled, seemed to me to be a deadly poison, and went down my throat like a torchlight procession. Of course, I know that the average farmer is ill to please, and we had an example of this, only lately, in our own county. Lord Aberdeen, one of the most generous landlords in the kingdom, erected a magnificent fountain, in the village of Tarves, for the benefit of his tenantry; but these, instead of being grateful, assembled in a body, and pelted the unoffending fountain with stones. Doubtless had his lordship laid on whisky to the fountain, instead of *agua pura*, his tenantry would have exhibited rather different feelings than they did.

In this, the month of February, how pleasant it is to sit at

ONE'S "AIN FIRESIDE,"

listening to the howling of the wind in the chimney, and watching the snow flakes covering up trees and hedges, and lying twelve inches deep all over the face of the country, and to know that everything on the farm is secure, the stock housed and comfortable, and enough of turnips pitted and straw thrashed to last through a two-months' storm at any rate. I know that all Buchan farmers cannot be in this equable frame of mind, because there are some men who will never learn a lesson, but will continue year after year the unprofitable occupation of digging under the snow for turnips, which are, after all, injurious as food to the health of their stock, and the pulling of which is injurious to the temper of their men. For my part, with 100 loads of turnips pitted in the month of November, as I make a point of doing, I feel comfortable and ready for any emergency.

The heavy snowstorm, which has been raging for the past ten days, will do a lot of good, as it will clear the atmosphere of the wicked microbes of influenza, hooping cough, measles, &c. which have been rampant in all the towns and villages: whilst in the country it has put a stop to the epidemic of ploughing-matches which has been prevailing during the past two months.

THE CHAMPION PLOUGHING MATCH

of the district was held in a field adjoining my farm, when 42 ploughmen with their teams faced the music. Of course I graced the field with my presence, in spite of a perfect deluge of rain, which, however, seemed to create no inconvenience to the performers, who continued to plough away, without either coats or waist coats, and doing most excellent work in spite of wind and wet.

One of the judges impressed me very much with the thorough manner in which he performed his duties, bending down and examining every "furr," and calculating the depth, breadth and the levelness with the greatest care. Strange to say he was not an agriculturist but a tailor by trade, from a neighbouring village; dressed like a ship's cook in his shore togs, or a south sea missionary in uneasy circumstances, and his attitude, at times, reminded me of the

Sphinx crouching in the desert; composed, intense, repressed in manner: whilst, every now and again, from his statuesque throat there proceeded a hoarse cough,—and little wonder, considering the drenching nature of the day. It was a stirring scene, and fully 1,000 spectators were present from near and far; for the day of the Champion Ploughing match is one of the red-letter days of the district, and one on which the farm hands all get a holiday.

At some ploughing matches I have heard bitter complaints from the competitors against the heat and brightness of the day, these declaring that they were "blin' fu' wi' sun." But no complaints of that kind were to be heard on this occasion.

Dog-fanciers who were on the ground had a rich treat in the sight of an animal that appeared to me to be half terrier—the other half no breed at all—just dog. I have seen a similar breed of dog in those kennels of Oodispattu from which the

RANGALLA BOYS.

were wont to draw fresh couples for hunting the wily *mozel*. Report said that the Committee allowed this rare specimen of the canine race into the field, as a special attraction, without any payment whatever.

Had I been an artist I would have immortalised the scene, giving prominence in my picture to the Sphinx-like judge and the cross-bred dog.

CHINA TEA.

THE exports of China tea, in the season just closed, show a considerable increase, more especially to Europe and Russia in Asia:—

CHINA TEA—CLOSING OF SEASON.

The Season being finished, this is the final Circular. The total Export as per Customs Returns is:—

	1899-1900.	1898-99.	1897-98.	1896-97.
	lbs.	lbs.	lbs.	lbs.
Europe	*16,174,605	†12,976,578	‡12,607,188	‡2,994,298
Australia and New Zealand	6,094,660	5,818,934	4,447,217	6,208,357

"AN AUSTRALIAN CEYLON" is the latest title for New Guinea, just as "New Ceylon" was for North Borneo. With Australian capital and backbone so near, British New Guinea should go ahead rapidly under a liberal régime.

NEW TROUT-FISHERIES.

The following extracts from a paper in *Black-wood* for February (by John Bickerlyke) will be read with interest by many in Ceylon where so much is done to introduce Trout into our streams :—

At a time when agricultural land is in many places unproductive of income, while trout-fisheries, more particularly those in the neighbourhood of big towns, will fetch enormous rents, the utilisation of ponds, lakes, and streams as fisheries is well worthy of consideration by all land-owners who have water of any kind on their estates. There is a popular belief—like many others, a mistaken one—that trout cannot be reared except in running water. As a matter of fact, there is hardly any piece of unpolluted water, stagnant or flowing, in which trout may not be raised, provided the fish can obtain, either in the water itself or from the hands of the keeper, a sufficient supply of food.

But while a stagnant pool may be made a rearing-ground for large, lusty trout, it should be well understood that for these trout to naturally increase their species running water is necessary. This fact, however, need be no obstacle in the way of trout-culture; for where the fish in any pool cannot increase naturally, it is an inexpensive and simple matter to keep restocking the water from other sources.

In many large lakes trout, salmon, pike, perch, and eels live together on fairly amicable terms, each taking toll of the other, with the result that while trout are not plentiful, they are, on the other hand, very large and, as a rule, in splendid condition. There is, however, one great disadvantage in having trout with coarse fish in the water—the trout do not rise well. They may be taken by trolling all through the season, but if they rise at all, it is only when the may-fly, or green-drake as it is called in Ireland, brings them to the surface.

Exactly the same state of affairs may be found in rivers where coarse fish abound. The greater the number of coarse fish, the larger the trout, and the fewer the opportunities of the fly-fisher. These facts point very strongly, and indeed unmistakably, to the necessity for abolishing coarse fish from those rivers and lakes in which it is desired to have free-rising trout.

I would like here incidentally to comment on the mistake so many fly-fishermen make of returning to the water what they term out-of-condition trout. When black-looking, lanky fish of a foot or so in length are caught, particularly if about the middle of May is passed, the best thing to do is to knock them on the head, for they will surely be old or diseased, and are better out of the river.

In addition to taking out the coarse fish, the shallows of the stream should be harrowed and made as clean as possible—a process which may be repeated with advantage every summer. If there are any lay-bys where black, stinking mud has collected, the filth should be altogether removed and spread on the land. It makes excellent manure. Light-coloured, clean, sandy mud, on the other hand, harbours the larvæ of waterflies and other fish food, and should not be wantonly disturbed. Large, reed beds, as I have said, are better put out of the way, for they are cover for pike. I do not mean by this the wholesale cutting down or sweeping away of all rushes, reeds, sedge, and weeds. A reasonable quantity of these growths is necessary to serve both as shelter for the trout and breeding and resting-places for the thousand-and-one small creatures on which the trout feed.

As trout, after they are introduced, will be found spawning in the autumn and winter, great care should be taken to leave the bed of the river, and the mud at its sides, carefully alone during that season. Nothing is more fatal to the healthy hatching of the eggs than disturbance of any kind, or the dirtying of the water, caused so often by men wading in the river, netting, dredging, and similar operations. I have not the least doubt that works and repairs carried on at mills during the spawning

season entail the loss of thousands of prospective trout. The sediment in the dirty water sent down settles on the redds (gravelly shallows where the trout have been spawning) and chokes the eggs. A trout egg is a most delicate thing. It may be said to breathe in the water, being full of tiny pores from which carbonic acid gas is given off. If these pores are choked with the sediment deposited from the stream, the embryo within the egg is asphyxiated by its own carbonic acid gas which it is no longer able to get rid of. For this reason a trout-egg so near hatching that the eyes of the young fish can be seen, if placed in still water, will die in a few hours, the water immediately next to it quickly becoming charged with poisonous carbonic acid gas. The owner of a trout-stream should therefore use his utmost endeavours to maintain the purity and flow of the water during the spawning season. Once the fish are hatched and feeding, the sediment, and even a certain amount of sewage pollution, matters little. Indeed, in sewage-polluted rivers trout often thrive exceedingly, though they are unable to breed; and of this the Wandle, near London, is a remarkable instance.

Ponds and lakes into which no water flows are as useless for breeding fish as a polluted river; but such sheets of water may be treated in much the same way as the stream. In the first place, the coarse fish should be removed. Next, if the bottom is muddy and capable of being cleaned, the cleaning should be done, except in places where it is desirable to cultivate weeds, and with them the food of trout. When the water is ready for them trout should be turned in from time to time.

The sheets of water not included in the terms "river" and "stream," which are likely to yield the best results, are those which have naturally a gravelly bottom, with aquatic growths near the edges, and here and there rocks; and, secondly, pools which are capable of being emptied. These latter are mostly of artificial construction, and, as a rule, have been brought into existence, at some time or another, by means of a dam thrown across the course of some small stream, the object often being to obtain water-power. Even though the bottom be of mud, trout will thrive; but it is most desirable to occasionally draw off the water, dry the pond, and expose it to the air for a few months. The fish-culturists of Catholic times, when there were no means of transit for sea fish, and fast-days had to be provided for, used to grow a crop on the bottom of their ponds from time to time. The earthy bottom having been sweetened and purified by light and air, water was turned in, and fish introduced. The example is one to be followed.

Sheets of water which I should deem entirely unsuitable for trout are those which are very shallow, and in which the temperature rises considerably in hot weather. If there is a stream flowing through such a piece of water, and a considerable growth of weeds among which the trout can take shelter from the sun, then fish may thrive; but be it well understood that trout must have shelter, either under overhanging banks, in deep water, under weeds, among rocks, or behind old camp-sheathing. The reason why so many amateurs fails in their attempt to rear trout-fry is that they place them in quite shallow ponds of small area, exposed to the full light of the sun—ponds in which the temperature of the water varies considerably and quickly.

Lastly, I come to a consideration of the varieties of trout which may be introduced. This depends in a large measure on the locality and the food-supply, natural or artificial. In Sir Thomas Wardle's famous pool in Staffordshire an immense quantity of trout of various kinds are kept in a healthy condition in a pool of probably not more than an acre in extent. The growth of weeds is considerable, and the supply of water-snails, shrimps, and other natural food seems almost unlimited; but in addition the keeper throws in half a bucket or so of fish food every day, which is readily taken by the rainbows, fontinalis, Loch Leven trout, farios, and hybrids inhabiting the pool.]

I have no hesitation in saying that for ponds and other enclosed waters, where the temperature in winter is not a very low one, there is no variety of trout so excellent as the rainbow (*Salmo irideus*)

variety *Shasta*). These fish grow extremely fast; they are most beautiful in appearance; they fight and play as gamely as a sea-trout, and on the table they are far superior to *Salmo fario*, our own brown trout, or yellow trout, as it is called in Scotland.

What would be the result generally of placing rainbow-trout in rivers is not known, the experiment has not been tried in any river on a sufficiently large scale to test the suitability of the fish for unenclosed waters. It is feared that they would migrate and be lost, as was the case with the fontinalis. But from an experiment tried in the Dove, it seems that the fish in such a stream have remained until the third year of their age; and their continuance in the beautiful Derbyshire river seems probable, provided there is a sufficient quantity of food for them, and the water does not at any time get too cold. It may be taken as an axiom that fish which grow large quickly, eat greedily. To put such fish (among which rainbows may be classed) into a stream containing little food is decidedly a mistake. They are sure to disappear, not necessarily in consequence of migratory tendencies, but merely in search of food. A few rainbows have, so I understand, been placed in the Test, and many have been caught.

Having stocked our stream, loch, or pond, the question of preservation has to be seriously considered.

Last year Sir Herbert Maxwell was largely responsible for a bill introduced by Lord Balfour of Burleigh on behalf of the Government, in the House of Lords, where it passed its third reading. According to its provisions trout would have been protected from anglers and netsmen between October 15 in one year and February 28 in the year following, both dates inclusive. To sell or expose trout for sale between these dates would also have been an offence. I most earnestly beg all who value the sport of trout-fishing to support this measure, which will surely lead to a better stock of trout and improved sport for all classes of anglers.

THE CEYLON LORIS OR SLOTH.

PHOTOGRAPHED IN FIVE ATTITUDES—
AWAKE AND ASLEEP.

We have received from Mr. W L H Skeen one of the most interesting set of photographs it has ever been our fortune to gaze upon. They are illustrations of the habits of that strangest of Ceylon animals, the "loris." Mr. Skeen had considerable difficulty in taking the shy little creature so often; but he managed to get five successful representations within four to five hours of different positions, and these shew (1) the loris in full activity climbing a tree with his owl-like face and bright protruding eyes most keenly observant; (2) loris resting between two branches, but still "wide-awake"; (3) loris in same attitude, but dropping off to sleep; (4) loris fast asleep—and doubled up; (5) loris sleeping in a suspended attitude. We can imagine how the heart of Frank Buckland or any similarly enthusiastic naturalist would be charmed with Mr. Skeen's most faithful and most interesting reproductions. Tennent has two fair engravings in his "Natural History"; and this is what he says of the "loris" (specimens of which we have seen occasionally hawked round Colombo for sale):—

The only other quadrumanous animal found in Ceylon is the little loris,* which, from its sluggish movements, nocturnal habits, and consequent inaction during the day, has acquired the name of the "Ceylon Sloth." There are two varieties

in the island; one of the ordinary fulvous brown, and another larger, whose fur is entirely black. A specimen of the former was sent to me from Chilaw, on the western coast, and lived for some time at Colombo, feeding on rice, fruit, and vegetables. It was partial to ants and other insects, and was always eager for milk or the bone of a fowl. The naturally slow motion of its limbs enables the loris to approach its prey so stealthily that it seizes birds before they can be alarmed by its presence. The natives assert that it has been known to strangle the pea-fowl at night, to feast on the brain. During the day the one which I kept was usually asleep in the strange position represented on the last page; its perch firmly grasped with both hands, its back curved into a ball of soft fur, and its head hidden deep between its legs. The singularly-large and intense eyes of the loris have attracted the attention of the Singhalese, who capture the creature for the purpose of extracting them as charms and love-potions, and this they are said to effect by holding the little animal to the fire till its eyeballs burst. Its Tamil name is *thavangu*, or "thin-bodied;" and hence a deformed child or an emaciated person has acquired in the Tamil districts the same epithet. The light-coloured variety of the loris in Ceylon has a spot on its forehead, somewhat resembling the *namam*, or mark worn by the worshippers of Vishnu; and, from this peculiarity, it is distinguished as the *Nama-thavangu*.

CINCHONA:

IN SOUTH AMERICAN FORESTS.

BY J. M. VARGAS-VERGARA, F.C.S., ETC.

(Abstract of a Paper read before the London Section of the Society of Chemical Industry, on Jan. 8.)

The recent rise in the price of cinchona bark has led to hopes that South America might again compete with India and Java. In former years, when Colombia exported cinchona, very few barks gave more than three per cent of sulphate of quinine, and fairly good samples contained 1.5 and two per cent.

The cinchona fever almost completely exhausted the Colombian forests, and trees now to be found in the woods cannot be more than twenty years old.

As the collection of the bark in bygone days was a very profitable business, samples were often mixed with all sorts of rubbish. The Quineros were not very particular as to the quality of bark, their chief aim being to obtain as many bales as possible, without any consideration as to its content of alkaloids. Hence the author is unable to determine whether there has been a favourable change in the constitution of the bark, or whether the increase in the yield of quinine is due to the extra care with which the extraction is now made. The following are some of his figures:—

	Quinine	Quinine Sulphate.
Tuna (Dona), wild ...	4.20	5.72
Cuprea (Bucaramanga), wild	2.26	3.00
Ledgeriana trunk, cultivated	4.08	5.57
Do twigs do.	0.85	1.17
Succirubra trunk do.	4.91	6.70
Do. twigs do.	3.87	5.27
Ledgeriana (old) do.	4.78	6.53
Do. (new) do.	4.86	6.68

The Colombian barks from the cold Andes are, according to Mr. Vergara, much richer in quinine than in the older times, and the cinchonidine has almost disappeared from these barks.

The ledger, old and new, presents a curious fact, the old is the same bark as the new, but has been kept under unfavourable conditions, being exposed to the rain, wind and sun during some years, so that the owners thought this bark had become completely useless. However, on analysing it proved equal to the freshly gathered bark.—*B. and C. Druggist.*

* *Loris gracilis*, Geoff.

THE TONACOMBE ESTATES COMPANY OF CEYLON, LTD.

THE ANNUAL REPORT.

The acreage of the Company's Estates is as follows:—

Tea in bearing ...	494	acres.
Tea not in bearing ...	96	"
Tea seed bearers ...	3	"
<hr/>		
Cardamoms in bearing ..	87	"
" not in bearing ...	14	"
<hr/>		
Reserved Forest	24
Fuel Trees	11
Chena and Patana	1,151
<hr/>		
Total ..	1,880	

The total quantity of Tea secured during the year was 188,078 lb. which has been sold at an average of 42.74 cents per lb. net.

The total Cardamom crop was 9,791 lb. which realized R1.76 per lb. net.

The total expenditure on working account amounted to R59,407.19.

During the year the permanent improvements on capital account include the erection of a set of 12 room lines, the purchase and erection of a new Rapid Roller, and the completion of the tatts on the ground floor of the new extension to the Factory.

The balance available, after providing for depreciation, amounts to R27,800.21, and the Directors propose to pay a dividend for the year at the rate of 5 per cent., absorbing R14,000, to place R13,000 to the credit of Extensions account, and to carry forward R800.21 to next account.

In pursuance of the Policy indicated by the Directors in their Report for 1898, Ten Debenture Bonds of £100 sterling each have been redeemed, the Debenture issue now standing at £6,000.

The cost advances have been still further reduced from R8,193.58 on 31st December, 1898, to R5,125.98 on 31st December, 1899.

The crops for 1900 are estimated at
200,000 lb. Tea,
9,000 lb. Cardamoms,
against an expenditure of R64,122.50.

During the year Mr. Cumberbatch and Mr. Figg resigned their seats on the Board, and Mr. R S Templer and Mr. G H Alston were appointed in their places.

Of the Directors the Hon. J N Campbell retires by rotation, but is eligible for re-election.

The appointment of an Auditor for the current year will rest with the meeting.

CEYLON GAME PROTECTION SOCIETY.

ANNUAL REPORT.

The last annual report was laid before a general meeting held at the Hill Club, Nuwara Eliya, on 7th February, 1899. Since that date three general meetings have been held, viz., on 17th May in Nuwara Eliya, on 24th May in Kandy and on 16th Sept. in Nuwara Eliya and one Sub-Committee meeting on 17th November in Nuwara Eliya. In addition to this a branch meeting was held in Nawalapitiya with the sanction of the Hon Mr. Lee, Mr. P R Shand, being the moving spirit and Mr. Bailey, late Government Agent, C.P., presiding.

The attendance at the meetings generally has been very poor, but at the last general meeting a small working Sub-Committee was elected, to discuss correspondence and though only one Sub-Committee meeting has yet been called it is clear that the work of the Society will now be pushed through in a much more satisfactory manner. In this connection I might mention that the thanks of the Society are due to the Secretary of the Hill Club for his

invariable courtesy and kindness in placing a room at the disposal of the Society when appealed to by the Hon. Mr. Lee.

BUSINESS.

One of the first subjects brought up for consideration by this Society was a resolution by Mr. Gordon Reeves that this Society ask for donations from visiting sportsmen. An amendment, that Government be asked to impose a tax on visiting sportsmen, was carried, but Government would not agree to impose the tax. During the past year numerous wealthy sportsmen have visited this Island and have enjoyed good sport and the following three donations to the Ceylon Game Protection Society have been received by the Hon. Mr. Lee:—

From Comte Antoine Kharenhuller and Hans Bechinie	£	R.	c.
From Comte de Raveneau and Comte de Martin Prey			80 00
From Mr. Paul Niedeck			100 00

—making in all R203.50, so that the Society does not meet with due recognition by the wealthy sportsmen who enjoy the result of the Society's work. Some definite tax *should* be imposed on visiting sportsmen

PROTECTION OF ELEPHANTS.

The Society asked Government to prohibit the capture of elephants or to raise the license for capturing an elephant from R10 to R100.

The Government met our request half way, by raising the license to R50.

The Society also asked Government to remit the amounts received for game licenses to the Society. This, Government said, they were unable to do, but at the same time they have raised the amount allotted for watchers at the Yala Sanctuary by an additional grant of R500 per annum and are going to allow two watchers in the Nuwara Eliya district at R180 per annum each. Watchers to be chosen by the Ceylon Game Protection Society. The Society has been paying for four watchers in the Sabaragamuwa Province and for two in the Nuwara Eliya district. The four watchers in Sabaragamuwa are said by the Balaugoda Ratamahatmeya, Mahawalatenne, to be doing good work. The watchers in the Nuwara Eliya district are commonly derided as being useless, and are accused of accepting bribes, &c., but I am of opinion that there is a marked decrease in poaching and even if the watchers do accept bribes, as most low-paid natives will do, still the mere fact that they *have* to be bribed must have a deterrent effect on poaching. It is almost impossible to check the watchers' movements though the Hon. Secretary makes an effort to do so by making him produce his book for superintendents to write their names in on his visiting the jungles in the neighbourhood of their properties.

Last year this Society asked Government to prohibit the shooting of sambar and deer in the forests lying along the ridges in the neighbourhood of Nuwara Eliya, the Elk Plains and the Horton Plains, at an elevation of over 4,000 feet, in fact where running to the knife can be and is indulged in. His Excellency the Governor issued the necessary prohibition, but the limits of the prescribed country are not very clearly defined and the result has been that some dissatisfaction has been expressed by sportsmen living in the hill districts where no elk packs are kept. I think this matter should be represented to Government and the limits of the prescribed country clearly defined.

His Excellency at the request of the Society, has graciously given permission that recognised packs of hounds be allowed to hunt in the forest reserves, on condition that each master of a recognised pack, register his name in the office of the Assistant Conservator at Nuwara Eliya. The prohibition of the export of deer and sambar hides which lapsed on 31st December, 1899, has been extended for another five years.

I learn from the Collector of Customs that the shipments of buffalo and other hides are always carefully examined and now and then deer and sambar hides have

been discovered mixed up with the other hides and the whole shipment has been confiscated. On 8th September, 1899, the Society was courteously and considerably invited by the Hon. the Collector of Customs to inspect a shipment of deer and sambur horns about to be shipped. A few Committee members of the Ceylon Game Protection Society who were able to attend did so with very interesting results. Though the proportion of apparently shed to apparently "cut" i.e., killed horns, was satisfactory from a game protectionist's point of view, unfortunately the Inspecting Committee were convinced that a very large proportion of the so-called shed horns were what is vulgarly called "faked" being really "cut" horns.

There is small doubt that there is a tremendous illicit slaughter of game. The number of game licenses issued in the past year were 361, of which 175 were taken out by Europeans, leaving 186 among natives. This small number is proof that the low-country Headmen do not exert themselves sufficiently to check illicit killing of game. The repeated efforts of this Society to get a reform in the Game Ordinance which would put a stop to the indiscriminate slaughter of deer and sambur in the low-country, have not been hitherto successful, chiefly due, I think, to the fact that the members themselves are not agreed as to what is the best scheme. The Sub-Committee, however, drew up a scheme and issued it in the form of a circular to the Committee members for suggestions and the replies will be laid before the general meeting and it is to be hoped that some definite scheme may be elaborated for presentation to H.E. the Governor for his approval. That a reform in the present Game Ordinance is necessary, is allowed by the Government Officials themselves.

The country lying between Yala River and the Kumbukan Aar was proclaimed as a sanctuary, on 22nd February, 1899. The Government Agent, Southern Province, asked the Ceylon Game Protection Society for help towards paying for extra watchers during the close season, as it was then that poaching was rife. The Ceylon Game Protection Society granted them R500; but it was gratifying to learn that Government had allowed an extra grant of R500 and our contribution was returned to us. The thanks of this Society are due to that thorough sportsman, Mr. A. F. Brown, Conservator of Forests, for looking after the sanctuary, it being in charge of the Forest Department.

It is a common idea that Government Officials, as a rule, are more or less opposed to the interests of the Society. Far from this being the case, I am glad to say that the Ceylon Game Protection Society has invariably met with the greatest courtesy and assistance whenever it has been in the power of the officials referred to to give it, and from His Excellency the Governor downwards there is a decided wish to further the Protection of Game, should a really workable scheme be laid before Government; and the object of the Society should be to formulate such a scheme.

Subscriptions and Finances:—The total number of members on the roll is 231, of these 60 have not paid their subscriptions for 1899, and of these 60, 15 have not paid for 1898. At a general meeting in Kandy, held 24th May, seventeen members being present, it was decided to raise the subscription from R5 to R10. As there were only 17 members present and as the resolution did not, of course, refer to subscriptions for the current year, the Hon. Mr. Lee took upon himself to inform members that the subscriptions for 1899 was R5 as before and received over sixty letters protesting against raising the subscriptions. At the general meeting Mr. J. Wickwar is bringing forward a resolution that the subscription remain at R5. As a glance at the balance sheet will show the funds are in a satisfactory state and with the additional help of R360 for watchers in the New in Elna district, the present year should see us doing more in the

low-country as it is there that illicit slaughter is quite unchecked. I annex balance-sheet, which shows a balance to credit of the Ceylon Game Protection Society of R1,857.99 exclusive of say R300 due by members.

NORTH C. DAVIDSON, Hon. Secretary, C.G.P.S.

NORTH C. DAVIDSON, Hon. Secretary, C.G.P.S.
28th February, 1900.

COCOS-KEELING.—There are on the Island some magnificent specimens of *Ciclus Elastica*. The trees are about 10 years old—*British and Colonial Druggist*, Feb. 16.

VITICULTURE IN NORTH CEYLON.—The appended paragraph reminds us of an omission in discussing products available for our dry Northern regions. The late P. A. Dyke showed how the vine could be successfully grown on a small scale in Jaffna. Why should not the country from Anuradhapura Northwards suit it as well as Uruguay? The sooner Mr. Willis has an experimental pioneer vineyard established the better:—

THE VINE IN URUGUAY.—From a recent report by the Uruguayan Bureau of Agriculture, we learn that in the Carelones department, in 1896-97, there were 230,200 American Vines in nurseries, and 1,617,800 at the end of August last. The number of Vines transplanted and growing were, for 1896-97, some 149,000, and for the year ending in August last 196,334. The amount of Grapes produced in the department increased last year to 383,530 kilogrammes—showing that the pest of the phylloxera had actually increased the production, owing to the restoration of vineyards and the augmented acreage devoted to their culture. In the department of Monte Video the plants in nurseries, in 1896-97, were 1,288,800 of the American variety, and 2,826,100 in 1899. The Vines transplanted in the former period were 262,900, and in the latter term 104,300. The smallness of the latter figure, compared with the former, is due to grafting—there having been 12,700 Vines grafted in the nurseries, and 379,782 in the vineyards. The production of Grapes in 1897-97 was 938,403 kilogrammes: for last year the production was 1,481,740 kilogrammes. It will thus be seen that the joint vineyards have improved in production, notwithstanding the plague of the vine-lice, and this improvement is due to restoration of Vines and increase in number of vineyards.

Correspondence.

To the Editor.

NOTES ON CEYLON BOTANY.

NO. III.

DEAR SIR,—Kerr was succeeded in 1816 by Mr. Alexander Moon, a zealous botanist whose ingenuity and industry did much to advance Ceylon Botany. After eight years' habitual study of the local vegetation, with but few opportunities, a scanty library, and no assistance, Moon published in 1824 his *Catalogue of Ceylon Plants*, a 4to volume containing over 900 indigenous and a number of exotic plants. This is the first book on Ceylon plants which gives specific names, the system of binominal nomenclature having been invented by Linnæus, a few years after writing his "Flora Zeylanica," which contains generic names only. Moon's Catalogue was a creditable work; it contains numerous notes of reference and a useful "Introduction to Botany," which being also ingeniously translated into Sinhalese is specially suited to local students; whilst appended is a Sinhalese Supplement, the names being arranged alphabetically in Sinhalese characters. In 1821 Mr. Moon selected the site, and formed the nucleus, of what has since become one of the most famous Gardens in the world, viz., the Royal Botanic Gardens at Peradeniya. Moon was an indefatigable botanical collector, and the magnitude of his collections may be estimated from the fact that they amounted to "ten cart-loads." Moon died in 1824 from fever, and to his memory has been dedicated, amongst others, the genus *Moonia* (now referred to under *Chrysogonum*) by Dr. Walker-Arnott. To the latter well-known botanist, though more particularly connected with the Botany of peninsular India in collaboration with Dr. Wight, must be given the credit of having elucidated many Ceylon species. In 1836 he published descriptions in Latin, of a collection of Ceylon plants made by Col. Walker, referred to below.

Although Peradeniya rapidly became the recognised centre of botanical activity, a spirit akin to botanical ardour was inspired in other quarters, and in 1824 the Ceylon Literary and Agricultural Society, the forerunner of the present Ceylon Branch of the Royal Asiatic Society, established an Experimental Garden at Fort Macdonald in Uva, which however had a short and unimportant history.

The next Superintendent of the Peradeniya Gardens was Mr. James Macrae, appointed in 1827, whose name is commemorated in *Dendrobium Macraei*. He added considerably, especially in orchids and grasses, to the herbarium collections of his predecessors, and supplied copious specimens and information to Dr. Lindley in England for his "Genera and Species of Orchidaceous Plants," an 8vo. dated 1830-40. Following in chronological order, a name worthy of honourable mention amongst the ranks of amateur botanists in Ceylon is that of the enthusiastic collector Col. Walker, Military Secretary in Ceylon (afterwards Brigadier-General in India) from 1820 to about 1837 who with his wife, a gifted delineator and painter, made one of the most valuable collections of Ceylon plants ever got together. This collection, now believed to be in possession of the Royal Gardens at Kew, furnished the material, as already referred to, for a 4to. volume by Dr. Walker-Arnott entitled *Pugillus Plantarum Indiae Orien-*

talis, published in 1836. Mrs. Col. Walker's "Journal of an ascent to the summit of Adam's Peak" (in 1833) forms interesting reading in the *Companion to the Botanical Magazine* for 1836, Vol. I., as does also her account of an extended tour made by herself and her husband in the Southern Provinces in 1837, which is given in Vol. II. of the *Journal of Botany*, 1840.

In 1830 the Peradeniya office seems to have been again vacant, and was apparently not filled till 1832 by the appointment of Mr. J. G. Watson, who, being specially interested in orchids, made a dried collection of that family, discovering amongst others the ground orchid *Acanthephippium bicolor*. He however held office for only five years, and appears to have had two or three successors during the next five years.

The specific name "Championii" distinguishing several Ceylon plants, is in honour of Capt. Champion of the 95th Regiment, who was stationed here from 1838 to 1847, and afterwards killed at Inkerman in 1854. Champion made an extensive collection of indigenous plants, and was recognised as an authority on local botany, his advice and instruction being sought for and esteemed.

Mr. J. W. Bennett, F.L.S., Assistant Government Agent at Matara, having a taste for botanical pursuits, wrote in 1842 a 4to volume on the *Fruits of Ceylon*; whilst in 1844 Mr. Simon Casie Chitty contributed to the literature of Ceylon Botany in the shape of a *Botanical Dictionary*, a 12mo. intended to contain the names of all the plants of the Tamil flora, with their synonyms." X. Y.

NO. IV.

DEAR SIR,—The gradual increase to the herbarium at Peradeniya and consequently to new species, had in the course of 10 or 12 years, rendered Mr. Moon's Catalogue out of date, and the want of a revised edition was felt. Dr. Wight, the celebrated Indian botanist, and author of the voluminous *Icones Plantarum, &c.*, when on a visit to Ceylon in 1836 undertook at the suggestion of Governor Sir R. W. Horton to supply this want. Accordingly all the material available at Peradeniya was duly despatched to him in India. The work could not have been deputed to better hands; but these—however, unfortunately for Ceylon—proved to be already too full, and the large quantities of dried plants were returned to Ceylon after an absence of eight years, without the object in view having been accomplished. To assist in the execution of this undertaking, Dr. George Gardner, shortly after his appointment in 1844 as Superintendent of the Peradeniya Gardens, was sent over to India to join Dr. Wight at Coimbatore, where he remained for a few months. Under the *egis* of Dr. Gardner, who had already made himself famous by his explorations in Brazil and elsewhere, the history of Ceylon Botany may be said to have entered on a new era of activity. Gardner soon proceeded to travel all over Ceylon, collecting and describing native plants—and publishing the novelties—chiefly in the Calcutta "Journal of Natural History," for the botanical editorship of which he was principally responsible. His enthusiasm as a collector may be judged from the fact that whilst recruiting health for a month on the Nilgiris he collected and dried about a thousand species on his "own account." Gardner's energetic career was, however, cut short by an apoplectic fit at Nuwara Eliya in March 1849, four years after his arrival in the island.

As powerful patrons of the cause of Botany—the grammar to successful Horticulture and Agriculture—the genera *Anstrutheria*, *Carria*, and *Mackenzia* (*Strobilanthes*) are worthy of reference, since they commemorate respectively Mr. Philip Anstruther, late Colonial Secretary of Ceylon; Sir W. O. Carr, F.L.S., late Chief Justice; and Rt. Hon. J. A. Stewart-Mackenzie, Governor of Ceylon from 1837-1841, who himself made an important collection of Ceylon plants which he afterwards presented to the Kew Herbarium.

Succeeding Dr. Gardner in 1850, Dr. G. H. K. Thwaites, F.R.S., arrived in Ceylon early in that year to take up the duties of the post which he worthily and uninterruptedly held for over 30 years, never having once left the island after his first arrival, so great was his devotion to his work. Thwaites had an early and special love for cryptogamic botany, which in Ceylon he soon extended to the phanerogamic flora. In 1858 was commenced the publication of his *Enumeratio Plantarum Zeylanicæ*, which was completed in an 8vo. volume in 1864. The cause of economic botany also found in him a strong promoter, and during his administration the branch garden at Hakgala was founded in 1860, and that at Heneratgoda in 1876, each with the object of introducing and experimenting with products suitable for the respective districts represented; whilst one must also attribute to him in a great measure the establishment of cinchona cultivation in the island, the introduction of both the Para-rubber and Ceara-rubber tree, and of Liberian coffee. The genus of Algae *Thwaitesia* was dedicated to him, and this was supplemented in 1867 by the foundation by Sir Joseph Hooker of the beautiful epiphytic genus *Kendrickia*, representing the third of Thwaites' names.

Dr. Thwaites was elected F. R. S. in 1864, and made C. M. G. in 1878. He died suddenly in Kandy in 1882, two years after his retirement, and a handsome cenotaph memorial was erected to him in 1885, in a prominent part of Peradeniya Gardens, by public subscription, a similar recognition of services having already been accorded to the memory of his predecessor Dr. Gardner, in the form of a cenotaph in the Gardens. There is a memoir of Dr. Thwaites, with portrait, in the *Tropical Agriculturist* Vol. XIV, and a short notice of the life and death of Dr. Gardner in the "Journal of Botany" for 1849.

Succeeding Mr. Hartog, who held for three years (1874-77) the newly created office of Assistant Director at Peradeniya. Mr. (now Dr.) Daniel Morris, who is at present Imperial Commissioner of Agriculture for the West Indian Colonies, remained in the same capacity for two years. He was followed in 1880 by Mr. Marshall Ward, now an eminent Professor of botany in England, who was appointed for about a year only in the capacity of Cryptogamist for the purpose of investigating the coffee-leaf disease, *Hamuleia vastatrix*.

X. Y.

NO. V.

DEAR SIR,—In Ceylon,

"Where spring perpetual leads the laughing hours," the pursuit of botany has offered fascination to ecclesiastics as well as civilians. The genus *Gleniea* has been so named by Sir Joseph Hooker in honour of that zealous botanist Rev. S. O. Glenie, F.L.S., who, being resident in the Colony from 1859 to 1871 as Colonial Chaplain and Archdeacon, made large collections of indi-

genous plants, chiefly in the Eastern Province, sending them with notes to Dr. Thwaites for incorporation in the "Enumeratio."

Few amateur botanists have cultivated a taste for botanical pursuits with more signal success than the late Mr. W. Ferguson, F.L.S., officer of the Survey Department and brother of the eminent editor Mr. A. M. Ferguson, C.M.G. Besides numerous papers and correspondence on botanical as well as zoological subjects, he issued in 1850 a unique and instructive book on the *Palmyrah Palm*, an 8vo. pamphlet now very scarce. The *Scripture Botany of Ceylon* formed the subject of an interesting pamphlet by him in 1859, followed by an account of the *Timber Trees of Ceylon* in 1863, *Ceylon Ferns and their Allies* in 1881, and a brochure on *The Grasses of Ceylon* in the same year. The study of low vegetable organisms had also an attraction for him, and his collection of Algae was incorporated in 1887 in the *Catalogue of Ceylon Algae* by Mr. George Murray, F.L.S., of the British Museum. Sir Joseph Hooker, Sir Emerson Tennent, Drs. Thwaites and Trimen, all acknowledged their "copious and mutually instructive communications" with Ferguson; and, as is a customary compliment to men of repute, Sir Joseph Hooker dedicated the genus *Fergusonia* to him.

Mr. W. Ferguson had a worthy contemporary in Mr. George Wall, F.L.S., who published in 1873, for private circulation only, his *Catalogue of Ceylon Ferns*, a 4to vol. which was followed by his *Check List of Ceylon Ferns* in 1879. Cryptogamic botany was his favourite pastime, and his private collection of Ceylon ferns was very large. The tower of the Victoria Commemoration Buildings in Kandy, now opened, has been erected to the memory of Mr. Wall, by the Planters' Association of Ceylon.

The present state of knowledge of Ceylon Botany owes undoubtedly more to Dr. Trimen, who succeeded Dr. Thwaites in 1880, than even to the labours of his illustrious predecessors. Assuming the duties of head of our Botanical Department at the age of 35, with an already established reputation in Europe as a botanist, he by his great acquirements and steady devotion to science rendered yeoman service to the botanical world generally for 16 years, his death, truly in harness, occurring in October 1896. From the outset the reorganisation of his department upon more modern and utilitarian principles received his special attention, simultaneously with the investigation of the local flora, collecting and describing new species and elucidating ones hitherto imperfectly understood. He was an authority on Quinology, and in 1883 was engaged by the Madras Government to report on certain problems connected with the Cinchona industry of the Nilgiris. In 1886 he issued his *Systematic Catalogue of Flowering Plants and Ferns Indigenous to Ceylon*, an 8vo. now out of print; whilst in 1888 he published his *Hortus Zeylanicus*, being a classified list of plants grown in the Royal Botanic Gardens at Peradeniya. As co-author of the voluminous and standard work *Medical Plants* by Trimen and Bently, he was *au fait* in medical botany, which he turned to good purpose by establishing in Peradeniya Gardens a Botanical Museum, containing collections of native and foreign drugs, fibres, timbers, grains, curiosities, &c. Branch-gardens were founded by him at Anuradhapura and Badulla in 1883 and 1886 respectively. The pages of various scientific journals, more particularly the *Journal*

of Botany, of which he himself was editor from 1870 to 1880, were frequently enriched by Trimen's contributions on Ceylon Botany, and "no less than fifty papers" stand under his name at the Royal Society, of which he was a distinguished Fellow. His *magnum opus* is, however, his *Flora of Ceylon*, which, unfortunately for the Colony, he did not live to finish. The completion of this work has, happily, been undertaken by the veteran Sir Joseph Hooker of Kew, Dr. Trimen having completed the first three volumes, with an atlas of plates, which bring the book as far down as Balanophoraceæ in the order of Bentham and Hooker's *Genera Plantarum*. Sir Joseph has creditably accomplished his task, the fifth and last volume being now finished. The plan of Trimen's *Flora* is acknowledged to be a model of what such floræ should be, it being, as far as completed by him, characterised by the critical insight and terse lucidity which always distinguished the author.—Yours truly, X. Y.

NO. VI.

DEAR SIR,—Though the real value of Dr. Trimen's "Flora" cannot well be estimated, more especially as Thwaites' "Enumeratio"—though superseding preceding works—is of use to botanists only, an idea of its merit may be inferred from the fact that "one principal object of the work is to enable observers to ascertain the name of any plant they may find growing wild;" afterwards learning "all that may have been written about it, appreciating its relationship with other plants, tracing its geographical limits, and intelligently investigating its properties and uses." In 1896, shortly before his death, Dr. Trimen contributed to the "Journal of Botany," Vol. XXXIV, *A Preliminary List of Maldive Plants*, with notes, based on a collection of plants sent him from the Maldive Islands, it being his intention to write later a *Flora* of these islands. Trimen's name is perpetuated in *Ficus Trimeni* and others; a tree of the last-named species forms a handsome object in Peradeniya Gardens. Vol. XXXIV of the "Journal of Botany" is dedicated to this *savant* and the same volume contains a memoir and a portrait of him.

In any account of the Botany of Ceylon it would be unjustifiable not to make reference to the compilations of Mr. J. Ferguson, F.R.C.I., &c. the capable and esteemed multi-editor of 38 years' standing. In 1881 he started the *Tropical Agriculturist*, a monthly magazine devoted to the interests of tropical agriculture and inevitably touching botany and horticulture; whilst amongst his other labours are his compilations on the *Coconut Palm* (*cocos nucifera*) second edition in 1898; *All About Tobacco*, 1890; *All About Spices and Fibres*, 1888; *Areca nut* (*areca catechu*) 1897; *Tobacco*, 1889; *Coffee Planters' Manual* (latest edition), *All About Rubber*, 1899, &c.

With reference to the economic aspects of Botany in Ceylon, it is worth mentioning the unparalleled rapidity with which both the Cinchona bark and Tea industries developed in the island. The yearly export of the former (now but a few hundred thousand pounds) reached from 50 lb. in 1869 to nearly 16 million pounds in 1887; whilst that of tea rose from 23 lb. in 1873 to almost 130 millions in 1899, the estimate of export for 1900 being 140 millions.

Ceylon Tea

Who could estimate the virtues of that drink,
Which made not one, but many thousands think,
And write such works as made the vulgar stare,
And filled the world with disputations rare.

Before concluding this brief and incomplete bibliography of Ceylon Botany it is imperative to refer to the notable Sinhalese family of Natural History Artists, the de Alwises, who by their hereditary talent for drawing and painting connect the present day with practically the inception of Botanic Gardens in Ceylon. The late Mr. H. de Alwis, Mudaliyar, served as writer under Moon in 1818 at Kalutara, being, after the removal of the Gardens to Peradeniya, appointed Botanical Draftsman, a post which he held for 38 years. In 1839 his services were solicited and secured by Dr. Wight for three months at Madras to assist in the botanical drawings for the great work *Icones Plantarum Indiæ Orientalis*. In 1861 Mr. de Alwis retired on pension which he enjoyed for the record number of 33 years. The orchids *Alwisia tenuis* and *Taniophyllum Alwisii* have been named after him by Dr. Lindley. Mr. de Alwis was succeeded in 1865 by his son William (made Muhandiram in 1896) who, being still in office and with the gift of his father admirably developed, has added largely to the series of botanical drawings started by his father almost at the beginning of the century. He has painted from nature the Lepidopterous Insects of Ceylon, which with a few additions were published in 1880-87 in three 4to volumes by F. W. Moore, F.Z.S., who supplied the text and in mistake put his own name to the plates. Mr. Alwis's drawings were of such high character that pecuniary assistance from the Ceylon Government was given for this work. The Rev. M. J. Berkeley, F.L.S. and C. E. Broome, F.L.S., in their *Fungi of Ceylon* (published in *Journal of the Linnæan Society*, vols. xi, xiv, and xv) accord their appreciation of Mr. W. de Alwis's "exquisite drawings of the fleshy fungi of Ceylon" by naming after him the fungus *Hygrophorus Alwisii*.

The selection in 1896 of Mr. J. C. Willis, M.A., F.L.S., as head of the Ceylon Botanical Department and so succeeding the line of illustrious Directors preceding him, has been fully justified in the result. Mr. Willis has given the results of his investigation in the remarkable family of Podostomaceæ in a paper before the British Association at Dover in 1899. Since his appointment he has energetically carried on the extension of his department on scientific and practical principles, securing the establishment in the Gardens of a new Research Laboratory, and the appointments on his staff of an expert Entomologist and a professional Mycologist.

X. Y.

EXPERIMENTS IN MANURING TEA IN CEYLON.

DEAR SIR,—I see you take notice of Messrs. Tarrant, Henderson & Co.'s Circular, especially as regards the results of manuring, which the compilers show. The results are poor, and it does not require a manuring expert to advise the proprietor of No. 2 field to abandon that field.

The proprietor of field No. 3 must have had the cockles of his heart warmed when his manuring brought forth 426lb instead of 250; but he must have felt less jubilant when he found a second dose of manure reduced his bearing to 372lb. Perhaps the third manuring will land him at the original amount—250lb.

I have read hurriedly Mr. Kelway Bamber's report on tea soils, and as in scavenging carts in cities you have often a man in front ringing a large bell, I think our well-

known manuring expert should have an Elwood Helmet presented to him by Ceylon proprietors, on which the following words (page 74) might be lettered in gold—"That the present crop in Ceylon could be increased by one-third or more there is little doubt, and this without the employment of very expensive, though perhaps somewhat, stimulating manures. But what would be the effect if new markets and demand did not keep up with the supply?"

In these days of so many subscription lists, terribly costly though they are, I however don't mind adding my mite for this charitable object, the gold lettering of the Elwood Helmet to be presented to our manuring expert.—Yours truly,

170,000,000LB EXPORT.

"HAS CEYLON THREE ROBINS?"

DEAR SIR,—My question is in the heading. Tennent's "Natural History," page 241, speaks of "the rich and melodious tones of their clear and musical calls. In the elevations of the Kandyan country there are a few, such as the robin of Neura-ellia (*Pratincola atrata*) and the long-tailed thrush (*Kittacinela macrura*) whose song rivals that of their European namesakes; but far beyond the attraction of their notes, the traveller rejoices in the flute-like voices of the Dayal-bird (*Copsychus saularis*) called by Europeans in Ceylon the 'Magpie Robin.' This is not to be confounded with the other popular favourite, the Indian Robin (*Thamnomia fulvicata*) which Edgar Layard said "is never seen in the unfrequented jungle, but always near the habitations of men." Who will describe for me then the distinctive appearance of each bird, in simple clear language so that I may identify the

(1) Indian Robin.

(2) Dayal bird or Magpie Robin.

And (3) the Robin of Nuwara Eliya.
and oblige.—Yours truly, NEWCOMER.

[We quote as follows from Legge's big book on Ceylon Birds:—

(1) INDIAN ROBIN.—*Thamnomia Fulvicata* (The Black Robin). Adult male. Length 6.2 to 6.4 inches; wing 3.0; tail 2.5; Iris brown; bill, legs and feet, black. Entire body, except the abdomen, glossy blue black; this, with the under-tail coverts, is fine chestnut; wings and tail coal-black; a large patch on the wing formed by the lesser and median coverts, white. This familiar little bird is a general household favourite in Ceylon, frequenting the vicinity of human dwellings, perching on walls and roofs, resorting even to the verandahs of bungalows. In the Northern and Eastern parts, where it is abundant, and likewise in many portions of the interior, it is by no means restricted as Layard supposed, to the neighbourhood of houses, but is found in all open rocky places, in newly burnt clearings, and in cultivated chenas, and in the Central Province it affects stony patnas and bare hill-sides. It is most animated in its movements, carrying its tail erect and jerking it up with a corresponding strutting down of its wings when giving out its pretty warble. It passes much of its time on the ground, darting about after flies and insects, and moving hither and thither with a short jerky flight. It consorts in pairs, but the young brood remain a long time with their parents, thus forming after the breeding season a little troop of three or four.

(2) *COPSYCHUS SAULARIS*. (THE MAGPIE ROBIN.) Adult male. Length 8.0 to 8.5 inches; wing 4.0 to 4.1; tail 3.5. Iris dark brown; eye-lid neutral brown; bill black; legs and feet plumbeous brown or blackish leaden, claws black. Head, neck, chest and upper surface with the scapulars glossy blue-black; quills and tail black; secondary wing-coverts, outer webs of tertials, under surface from the chest, under wing-coverts, three outer tail-feathers entirely and the next pair, except on the inner margin pure white; thighs white, black posteriorly. The white wing-coverts and outer webs of the tertials form a broad longitudinal band on the wing when closed.

The Magpie Robin is universally distributed throughout the whole island up to an altitude of 5,500 feet; there is no spot in the lowcountry, save the solitudes of the damp southern and western forests, where it may not from time to time be observed.

(3) THE NUWARA ELIYA ROBIN.—*Pratincola atrata*. (The Hill Bush-chat.) Adult male. Length 5.9 to 6.2 inches; wing 3.0 to 3.25; tail 2.25 to 2.4. Iris hazel-brown; bill, legs and feet black. Above and beneath coal-black, slightly brownish on the lower part of the breast; tips of the rump-feathers, and all but the terminal portions of the tail-coverts, the median and innermost feathers of the greater wing-coverts, together with the centre of the abdomen and under tail-coverts, white. Not infrequently one or two white feathers about the nape exist, and the amount of this colour on the rump and lower parts varies somewhat.

The Hill-Chat is only an inhabitant of the upper mountains and even there its limit is markedly defined.

ROUND THE WORLD FOR CEYLON TEA: IN THE FROZEN NORTH.

Mount Stephen, Rocky Mountains, Jan. 27.

DEAR SIR,—The last time I wrote you was on the banks of the Atbara River squatting on the sands under the piercing rays of a tropical sun, with my faithful Soudanese servant "Hassan" in attendance, and Teck making a feed on rushes before taking his master back to Berber.

As I now write the surroundings are somewhat different. Here I am seated in the Canadian Pacific Railway Pullman Car "Montana," which forms part of the train, which with two engines is slowly creeping up the steep gorges of the Rocky Mountains which are covered with snow many feet deep, and the thermometer forty degrees below zero. In an hour we hope to be at Mount Stephen Station which is 5,296 feet above the sea; the highest point in Canada as yet reached by the iron horse. At this time of year few passengers cross the Rocky Mountains, today I am the only occupant of the Pullman Car, which has sleeping accommodation for thirty-four passengers fitted up with electric light, steam pipes to regulate the heat, large smoking room, lavatories, &c., These cars are so heavy, and well balanced, that even when running at a high rate of speed, I have no difficulty in writing with my typewriter. Leaving San Francisco on the 21st inst. by the Northern Pacific Railway, a distance of 1,500 miles which is covered in three days and three nights brings you to Vancouver, the Western terminus of the Canadian Pacific Railway. The growth of this city which now numbers 26,000 inhabitants, has been very rapid, and only dates back to 1886. The city has many fine stone buildings, streets are lit by electric light, and paved with wood blocks and asphalt. Electric cable cars run to all parts, and past the doors of the twelve banks which this new city can boast of.

The climate of Vancouver is wet and mild; snow may be seen on the mountains which surround the city for five months of the year, but it is seldom that it falls in the city.

The distance from Vancouver to Halifax (which is the terminus of the railway on the Eastern coast) is 3,666 miles, the journey occupies a week; the passenger only changing cars once. Leaving Vancouver the scenery is very beautiful, as the train winds its way along the bank of the Fraser River, which is known throughout the world for the large numbers of salmon that are caught every year, canned and shipped to all parts of the world.

On waking the following morning the scenery is very different, the train which the day before was covering some sixty miles an hour, is now creeping slowly up the sides of steep gorges through which torrents of icy water are rushing; on either side stand gigantic cliffs towering hundreds of feet above, covered with ice and snow. At noon we reach Glacier House, and stop for lunch. Last year the fall of snow at this particular point registered fifty feet. Facing the station stands the "Great Glacier" only half a mile distant, an amazing sight, as you will imagine when I tell you that this field of perpetual ice covers some 200 square miles, some hundreds of feet in thickness. To the left of the "Great Glacier" rises Mount Sir Donald, a naked and abrupt pyramid to a height of a mile and a half above the station. This stately monolith was named after Sir Donald Smith, now Lord Strathcona, Agent-General in London for Canada, the man who has offered to equip and transport to South Africa 400 picked Mounted Infantry at his own expense; the cost of which I have heard will exceed two hundred thousand pounds sterling. Leaving Glacier House the train continues its winding route steadily climbing up the sides of the steep gorges, now and again diving through long snowsheds, which have been built where it was found impossible to keep the line clear of snow. During the winter months hundreds of men are employed in removing the snow off the line in these parts.

As I am writing we are steaming out of Mount Stephen Station, above which stands Mount Stephen towering 8,000 feet above the valley, to the left is seen a huge green glacier 800 feet in thickness. The cold here is more than a typewriter can describe; and as darkness has set in I think bed the best place, leaving my letter to be continued tomorrow.

Moose Jaw, Jan. 28.—Rising at 9 a.m. I found the train travelling at a good pace along the great prairie plateau which extends for some thousands of square miles to the north and east of the Rocky Mountains, which are now out of sight. In winter this great prairie is enveloped in snow and ice; in summer it is covered with rich grass, not a tree to be seen. At the stations where we stop, Indians board the train and offer milk and buffalo horns for sale. This race who in the past were renowned for their powers in hunting big game, and for their brave and fierce methods of fighting, are fast becoming extinct. Tomorrow we enter the more civilized regions wherein summer farms covering thousands of acres may be seen under wheat. In the evening we arrive at Winnipeg, where I will stay for two days before continuing my journey to the East Coast, *en route* for Paris. This afternoon the Conductor took compassion on my solitude and

began to give a detailed account of what I would and would not see as we went farther East; I soon brought him up with a round turn, by informing him that "this was my eighth journey across this track in the past seven years."—Yours truly,
R. VALENTINE WEBSTER.

LABOUR IN INDIA AND CEYLON.

Coonoor, Nilgiris, Feb. 23.

SIR.—There are upwards of 3½ millions of people now being relieved by the Government of India in connection with the present famine, and as the population in this year is increasing at the rate of six millions, or two per cent per annum, and this rate will continue in larger numbers every year, it is evident that famines in the future will become more and more costly. That financial difficulties must ensue is evident, and just as the previous difficulties were met by forcing up the exchange, so will future financial embarrassments be met by the same expedient with the view of reducing the home charges. There are two reasons why it is certain that the same expedient will be resorted to—the fact that the unpopularity necessarily accompanying fresh taxation will be avoided, and the still more influential fact that the officials, who are really the rulers of India, will gain largely by still further raising the rate of exchange. That they will seize the first pretext for doing so in the future as readily as they have done in the past, no one can doubt, who has the smallest experience of human nature. The planters of India and Ceylon will have to face two serious facts—the fact that they have been placed at a great disadvantage in competing with their rivals in the other silver-using countries, and the fact that there is every prospect, I might almost say certainty, of their being placed at a still further disadvantage. Does any one believe, or can it be for one moment supposed, that the producers of India and Ceylon and the capitalists who work in conjunction with them are blind to these facts? That they are not so is proved by the facts which appeared in the leading article of the *Ceylon Observer* of Feb. 7, which tells us that in 1899 (when it was certain that the Government would adhere to its fatal currency policy) the cooly immigrants fell off by about half, while the departures exceeded the arrivals by 13,000. And that both producers and capitalists are rightly judging the situation, we have ample evidence in India where wages are being reduced, and advances too, all of which indicates what everyone knows, namely, that extensions have been stopped, and that land is being thrown out of cultivation, being either wholly abandoned, or put into an inferior state of working. There is only one thing that can arrest this decline, and that is the granting of such a Bounty on exports as will place producers in the same position which they occupied previous to the closing of the mints. The producers would be thus placed on a secure footing, confidence would at once be restored both to them and to the capitalists, and India and Ceylon would soon exhibit the same signs of progress which they did previous to the closing of the mints, and about up to the time when it was certain that they would not be reopened. The proposed step would probably call for a further raising of the exchange, but this would be all in favour of the proposed measure, ere the officials would gain on their home remittances,

and they, as we know, are masters of the situation both in India and, in the shape of the India Council, at home. The Secretary of State may be reckoned on as being usually in the hands of the Council, and the Governor-General as being in the hands of the Secretary of State when the adoption of any new policy is concerned. Parliament, I need hardly say, is absolutely out of the count.

In conclusion I may remark that nothing could (vide p. 464 of "Gold, Sport, and Planting") be more certain than that the first effect of the currency measure would be a diminution in the demand for labour, and if it did not sooner occur it was partly because it was not generally believed, that the Government would persevere with its currency policy, and partly to a vague hope that the second Currency Committee might reverse the decision of the first, for which indeed there was some ground as the witnesses were nearly all against the policy which has been carried out, and a change from which it is now hopeless to expect.—Obediently yours,

ROBERT H. ELLIOT.

THE LONDON COCOA MARKET.

London, Feb. 23.

DEAR SIR,—As usual when the new crops of Trinidad and Grenada Cocoa first arrive in any quantity, the pressure to sell being out of proportion to the desire to buy, has caused a drop in prices, which is unwarranted by the present state of the market; for with a good demand which is sure to last, the stocks are very small being only 79,203 bags, against 90,435 bags in 1899, 113,918 bags in 1898, and 139,538 bags in 1897, and there are outside influences now at work creating an exceptional demand which were altogether absent in previous years; and even if the supply this year proves to be as large as that of 1899, which it is generally believed will be the case, the South African War will keep the Government active buyers for another six months at least (Monsieur Jean Bloch, the Polish author of "The Theory of Modern Warfare," estimates it will take a year to see the matter properly through) and the American and continental demand is expected to show as large an increase in the coming year's consumption as they have done in the past one, which makes me convinced that by June those who are now anxious sellers will see the mistake they have made; for, if they do not show a firmer tone than they are now doing, we shall have good middling to good red Trinidads at 73s and Fine Grenadas at 65s before the end of April. As during the last two years there has been a tendency to handle fine Trinidads more judiciously, this grade is not likely to show a great drop, if indeed they do not go higher, as is the case just now, for whilst good middling red is now selling at only 78s against 82 and 82s 6d three weeks ago; one of the fine marks sold last week at 84s 6d against only 82s 6d in Jany. Ceylon Cocoa it is true often fluctuates independently of Trinidads, being used more for confectionery, for which purposes its finest marks fetch fancy prices, and also because up to now the bulk of the crop has been sent exclusively to London, which, forcing the best buyers to come together from all parts of the world as Russia, America, Spain, and even Mexico when her crop is short, causes a keen competition resulting in high rates which would never be obtained if she sent her cocoa to every market under the sun that buys it, as Trinidad is so fond

of doing, and which is a great mistake, for not only does it, as I have already said, prevent buyers coming together in one common centre, but the cocoa is often shipped entirely to one buyer who having it all to himself squeezes the prices down to the utmost limit he can before he forces the owner to ship it elsewhere, and sell at a better rate.

At the sales this week 6,783 bags of all growths were offered including 419 Trinidads, 1896 Grenadas, and 800 Ceylons. Of these the Government bought 214 bags of Trinidad at 78s and 78s 6d, 167 bags of Grenada at 69s to 70s and 76 bags Machala Guayaquils at 73s 6d. The sales went off with good demand at slightly lower rates for Grenadas, and Dominicas, for out of 2,500 bags offered 1800 bags sold; Grenadas at 65s 6d for common to 71s 6d for fine, and Dominicas at 65s 6d to 67s. The Ceylons nearly all sold, (707 changed hands at the sales) at 68s for native, 62s 6d to 66s 6d for smalls—70s to 77s for middling to fair—and 80s to 86s for good to fine red. Since the sale the demand has been quiet as there is expected to be big sales next week. The West India mail had nearly 4,000 bags of Trinidads alone, which they are trying to get up in time, whilst of Ceylons the cocoa by the "Duke of Buckingham" and if possible by the "Awa Maru" will be offered.

The receipts from Guayaquil are still large, and up to now in excess of last year's, being 36,710 quintals since 1st January against 26,400 quintals last year, and 33,000 quintals in 1898. Cocoa butter is firm: sales have taken place at 1s 5½d and 1s 6d is now asked.—Yours truly,

HAROLD HAMEL SMITH.

TEA: LONDON CHARGES ON.

Kandy, 27th Feb.

SIR,—I herein enclose copy of letter received from the Secretary, Ceylon Association in London, on the subject of the reduction of Bulking and Taring Charges in London.—I am, sir, yours faithfully,

A. PHILIP.

Ceylon Association in London, 61, and 62, Gracechurch Street, E.C., 9th Feb. 1900.

A. Philip Esq., Secretary, Planters' Association, Kandy.

DEAR SIR,—Referring to my letter of 26th ult: I beg to forward copy of a second letter from the Tea-clearing House Committee, dated 5th instant, from which it will be seen that for the present it is not proposed to make any reductions except in respect of the Bulking and Taring rate.—Yours faithfully, (Signed)

WM. MARTIN LEAKE, Secretary.

Tea Clearing House Committee, 21, Mincing Lane, 5th Feb. 1900.

The Secretary, the Ceylon Association in London, 61, and 62, Gracechurch Street, E.C.

DEAR SIR,—Referring to my letter of the 23rd ult. I am directed to inform you that the reduced Bulking and Taring charges therein set out, have now been confirmed and will apply to all teas bulked and separately tared on and after the 1st March next.

This alteration is a considerable reduction and the Committee trust it will enable the Importers to make desired arrangements with the Trade in respect of the taring of the teas. The Committee, however, regret that in view of the heavy expenses pressing upon their trade they are unable at present to make further alterations in the rates.—I am, dear sir, yours faithfully, (Signed) GEO. T. POCOCK, Secretary.

MINOR PRODUCTS REPORT.

ANNATTO SEED.—A bid of 3d per pound for fair bright Madras seed is likely to be accepted for a parcel of 13 bags. There was little on offer today compared with previous sales.

CINCHONA.—Our Amsterdam correspondent informs us that the Vriessveen cinchona bark department reports the shipments from Java to Europe from January 9th to February 12th, 1900, at 715,000 Amst. lb.

CINNAMON OIL.—Leaf oil sold at 1½d per oz., subject.

COCA LEAVES.—In auction fair green Ceylon leaves realised 1s per pound for one bag. The shipments from Java from July 1st to November 30th, 1899, have been:—

	1899	1898	1897	1896	1895
Bales 202	445	496	335	509	

Dark green Huanoco leaves are offered at 1s 4d per pound, c.i.f. and light green Truxillo at 1s 1d.

QUININE.—The exports of quinine from Java during November, 1899, were in one consignment of 133 cases to the United Kingdom (opt. New York). The shipments from July 1st to November 30th, 1899, were 655 cases, against 614 cases for the corresponding period of 1898.—*Chemist and Druggist*, Feb. 17.

DEATH OF AN OLD CEYLON
PLANTER.

Our obituary includes the name of a well-known former planting resident in Ceylon, but who has latterly been tea planting in Natal, Mr. John Fraser. He was in his day a very strong man; but after enduring all the worries and trials appertaining to the life of a coffee estate proprietor in one of the wettest parts of Lower Dikoya and then fighting away till he got the estate into tea and became Superintendent where he had been proprietor, his health broke down, and a succession of abscesses on the liver undermined his constitution; indeed the late Dr. MacDonald was amazed at his repeated recoveries. A time of great weakness, however, arrived; and on our advice, "Aberdeen" Fraser went to Carlsbad, and came back in four months looking and feeling as well as ever he did in his life,—a marvellous case of the waters taking effect when a man was very far gone indeed. No one could persuade Mr. Fraser not to go back to "Aberdeen" estate and he worked there for two or three years in good health until he moved to Brae estate, Matale—a still wetter region if possible!—and there also he did good work and kept well. After some years, there came the offer through a brother to go as Manager of a Tea place in Natal, and Mr. Fraser has been in the "Garden Colony" since January, 1897, well-pleased with his work: but here again he had a narrow escape of poisoning at the time his brother James, who was visiting him, fell a victim. It is, perhaps, therefore, no wonder that the end has come to Mr. John Fraser in his 60th year. We do not know if he was touched by the war or had trouble therefrom; but in his day, certainly Mr. John Fraser of Aberdeen, Brae and Natal, had his full share of battling with misfortune and with physical ills, while he always showed an example of putting "a stout heart to a stey brae." Mr. Fraser has left a son in Ceylon, now Manager of Nicholoya, Matale. To him and other relatives, we tender sympathy on this sad event.

BOTANY AND THE INDIAN FOREST
DEPARTMENT.

AN APPEAL.

(To the Editor "Indian Forester.")

Anent the letter of Dr. Schlich in *Nature*, copy of which appears in your issue of December last, regarding the above subject, every Forester, it is thought, of some standing and experience, will agree with almost everything he has said in answer to Sir George King, with this exception: that it is not believed that the lack of knowledge of botany displayed by most Indian Forest officers is due so much to the want of well equipped systematic botanical instructors at Coopers Hill as Dr. Schlich alleges. With the botanical instruction now acquired at the College, Forest officers, it is felt, should have been able to increase their knowledge of the subject in India if a real interest had been taken in the subject originally; what is needed it seems is that men must be recruited for the Indian Forest service from among those who are botanically inclined, and to attract such men, botany as even now taught, must not only be made compulsory, but placed in the forefront of the subjects for the entrance and after examinations of the College. By forefront is meant that a much larger number of marks should be given for botany than for any other subject.

As far as can be ascertained the large majority of men who have joined the Imperial Forest Service during the past 10 or 11 years have relapsed into administrators pure and simple, and little difference is apparent between their present qualifications and those in the Indian Civil or Police. In fact as far as external appearances go their previous training might, to all intents and purposes have been the same, originally as the training of the former.

A modification in the present system of marking at Cooper's Hill therefore is suggested in the manner explained, and more constant practical instruction in botany should be imparted to the students while at the College. Examinations, chiefly oral, should also be held in this branch of their studies, as well as in Forest organization, while on tour. The latter subject is doubtless very valuable, and needs much attention but it can be acquired and improved upon in India to a very great extent because of officers being forced *nolens volens*, to study it. Working plans in fact can be drawn up by any educated Forester with the aid of Dr. Schlich's admirable works, and with a little previous practical continental experience such as most Foresters obtain. And if it could be ruled that no Forest officer of less than seven years standing should be a working plans officer so much the better.

Sir George King has done a service in drawing attention to the want of knowledge of even elementary botany among Indian Foresters, and a discussion it is hoped in your columns will now follow, bearing on his remarks as reproduced by Dr. Schlich. The Forest Department is still practically in its infancy and by a discussion among men now out here, who have almost completed their time and who would be capable of giving an opinion as to how best to remedy the unsatisfactory state of things (as unsatisfactory they must be termed), some valuable suggestions might be thrown out which would be of use to the authorities at home in coming to a decision in the matter.

It is true, that we do not require men to be only botanists; but those who enter the Forest service should display a greater leaning towards the study of trees, shrubs and small plants than the large majority especially from Cooper's Hill now do. D. C. O.

25th January, 1900.—*Indian Forester*, February.

TREES.—The Government of India have sanctioned the expenditure of sums not exceeding Rs.1,000 in each case for tree planting in Wana and in the Tochi Valley.

QUININE.

Mr. Martin mentioned the labours of Richard Spence, Pritchett, John Weir, Robert Cross, Charles Ledger, De Vrij, and others who were pioneers in the establishment of cinchona-cultivation in Java, India and Ceylon. He then called attention to the superior quality of the *Ledgeriana* variety of *Cinchona Calisaya*, which yields from 9 to 10.5 per cent of quinine,* with 10½ to 11½ per cent of total alkaloids.

The cultivation of cinchona in India, and the preparation and sale of cinchona febrifuge there, were next referred to, the methods of cultivation also being briefly noted. From this the author proceeded to mention the principal facts in respect to the discovery of quinine and other cinchona alkaloids, and described some of the methods for manufacturing quinine which had been published. He then submitted the following short descriptions of salts of quinine:—

ACETATE.—Rather more soluble in water than sulphate.

ARSENATE AND ARSENITE.—Recommended by some doctors as more powerfully antiperiodic than the other salts; contains twenty-nine per cent arsenious acid, and 69.4 per cent quinine.

BITARTRATE.—Sparingly soluble in water, and has, therefore, little taste. In a number of prescriptions by a West-end physician I observed quinine sulphate and citric acid frequently prescribed; one day I questioned him as to why, when he told me that it was the most useful salt of quinine to administer to patients having a tendency to acidity.

FERROCYANIDE.—Said to be most efficacious.

HYDRIODIDE.—Alterative, tonic and antiperiodic, used in scrofulous affections.

HYDRIODIDE, ACID.—Soluble 1 in 20.

LACTATE.—Soluble 1 in 20; used for hypodermic injections.

HYDROBROMIDE.—Excess of hydrobromic acid given to lessen cinchonism sometimes caused by large doses; contains 76.6 per cent.

HYDROBROMIDE, ACID.—Well adapted for hypodermic injection.

HYDROCHLORIDE.—Richer in alkaloid than sulphate (81.8 per cent); antiseptic; powerful germicide, 1 in 800 stopping growth.

HYDROCHLORIDE, ACID.—Most soluble salt of quinine (1 in 1); contains 72 per cent.

HYDROCHLOROSULPHATE.—74.3 per cent alkaloid.

HYDROCHLOROCARBAMIDE.—Urea quinine; not rich in alkaloid

PHOSPHATE.—For rickets associated with stomach-affections; contains 76.2 per cent.

SALICYLATE.—Contains 70.1 per cent alkaloid: useful in rheumatic gout.

SULPHATE.—This salt is the most used of any; contains 73.5 per cent alkaloid; wherever quinine is ordered by the physician it is universally understood to mean this salt.

SULPHATE, ACID.—Soluble 1 in 11 water, and contains 59.1 per cent alkaloid only.

TANNATE.—Useful for intermittent neuralgia; only 20 per cent alkaloid in it; almost tasteless, and covered with chocolate, is given to children.

TARTRATE.—Used in India for hypodermic injection.

VALERIANATE.—Is of no special value for the antispasmodic purposes for which some give it; contains 73 per cent alkaloid.

* This is incorrect; the following are some of the percentages in Ledgeriana bark offered at the last cinchona auctions at Amsterdam, the figures representing quinine sulphate 2.3, 3.1, 4.1, 5.2, 6.2, 7.3, 8.6, and 10.6, with many percentages between these figures. Occasionally a bark yielding as much as 12 per cent of quinine sulphate comes into the market, but the assumption that Ledgeriana bark yields a minimum of 9 per cent is erroneous: the average is about 5 per cent, and the highest known 14.5. It is particularly to be noted that these percentages do not refer to the alkaloid quinine, but to quinine sulphate of the British and other Pharmacopœias. Most materia medica textbooks fall into the same error as the writer of this paper.—Ed., C, and D.

Finally the physiological action of the alkaloid was discussed, and some reference made to the prices that had been paid, the highest since 1874, when quinine sulphate was 9s per oz, being 16s 6d in 1881, and the lowest 8½d for the German sulphate.

Mr. Hyman, in opening the discussion, said he thought it curious that artificial quinine had never been synthesised except from cinchonidine, although all kinds of ways had been tried. With reference to the dose of quinine sulphate, he mentioned that the one usually taken in the tropics was much higher than that in England, 10-gr. doses being quite usual.—*Chemist and Druggist*, Feb. 17.

PRODUCE AND PLANTING.

TRY KASHGAR.—In his very interesting and instructive book, "Innermost Asia; Travel and Sport in the Pamirs," just published by Mr. Heinemann, Captain Cobbold has something to say about trade with Kashgaria which will interest tea planters. The Government might do much to facilitate British and Anglo-Indian trade with Kashgar, the commercial centre of innermost Asia. Only removable obstacles stand between tea planters of India and an enormous market in innermost Asia. The British acquisition of Chitral gives the Indian Government an opportunity of establishing commercial routes easily and speedily traversible.

TEA IN BOND.—At a recent meeting of the Grocers, Provision Dealers, and Oilmen's Association, a letter was read from a member asking whether, in the event of there being any increase of the tea duty, such increase would be charged on any duty-paid tea lying in bonded warehouses at the time. In the course of the discussion it was stated that Messrs. Densham Brothers had received a letter from Mr. R. T. Prowse, secretary to the Customs, stating that "the Board feel bound to withhold assent to the retention of tea in bond after duty has been paid on it. . . . It is quite intended to exercise all the powers we may find ourselves to be possessed of to prevent the wholesale retention of duty-paid stock in bonded warehouses." It was resolved to call the attention of every member of the Association to the importance of bearing in mind that this decision of the Customs applied, of course, to all dutiable articles. The following is the correspondence referred to:—

Letter to the Mazawattee Tea Company:

"Office Inspector, Customs, London, February 14, 1900.—Gentlemen,—With reference to a recent large payment of duty on tea by you, it has been reported that on the 6th inst. there still remained 11,460 packages of tea in various duty-paid warehouses in London, of which delivery had not been taken, although duty had been paid. I am desired by the Commissioners of Customs to ascertain from you what steps are being taken for the withdrawal of these packages from bonded premises with as little delay as possible.—I am, gentlemen, your obedient servant, (signed) J. FLEMING, Office Inspector."

"Eastcheap, E.C., February 15, 1900.—

Dear Sir,—We are in receipt of your letter of yesterday's date, and in reply beg to state that we have spared no effort to keep strictly to the regulations which your Board enforces. Immediately on payment of our big cheque steps were taken by us to clear out of the bonded warehouses without delay the various parcels represented by our payment, and up to the date mentioned by you—viz., February 6—we had removed nearly 45,000 packages, or four-fifths of the bulk. Had it not been for the exceptionally severe weather the whole of the tea would have been cleared. We feel sure that you will realise the magnitude of the task imposed by your regulations of clearing over five million pounds of tea from bond within a few weeks.—We are, dear sir, yours faithfully, THE MAZAWATTEE TEA COMPANY, LIMITED.—H. and C. Mail, Feb. 23.

TEA IN CEYLON:
EXPORTS IN PROPORTION TO AREA
PLANTED.

IS IT WELL TO MANURE TEA
ON VIRGIN SOIL?

THE question has lately been raised in practical quarters as to whether the export of tea from Ceylon of recent years has kept up with the extension of planted land. We have heard a decided negative given, and the explanation offered that, apart from actual abandonments of unprofitable fields, much tea on poor land had fallen off in yield and that, even if manured, such poor tea failed to respond for more than one or two seasons and then fell back into a worse state than before, more especially if a stimulating fertiliser had been used. In these days of almost universal belief in the virtue of manure—properly selected and adapted of course,—it is somewhat refreshing to meet with practical men who are not only doubtful, but sceptical of the advantages of manuring from the proprietor's point of view, if a series of years be taken into consideration. Given a decent soil with a carefully planted field of hardy hybrid jat in a suitable climate; and "leave well alone" would be their motto. "Content yourself with an average 400 to 500 lb. yield; do all justice in careful pruning, weeding, tillage, burying prunings with a little lime perhaps; and leave the rest to Providence,"—is very much their idea of what is right. "No doubt," they add, "by manuring you can increase your yield by from 25 to 40 per cent. for some years; but your trees suffer in the long run and the yield eventually falls off."

Now as regards a problem of this kind, no doubt a good deal will be learned from the forthcoming Report of Mr. Kelway Bamber, in which, of course, the virtues and effects of manure for tea plantations are most fully discussed. Nor is this done simply from the point of view of the Laboratory and Analytical Chemist. For, Mr. Kelway-Bamber has had a special advantage in visiting every tea district in the island, in getting the fullest information respecting typical estates in each, and in profiting by the experience and observation of many of the shrewdest and most successful of our practical planters, an incalculable gain to the scientist however advanced he may be in his own Department. Nevertheless for the purpose of answering the problem now raised, we should think it preferable if scientific attention had been directed to two typical and therefore old plantations—one of which had never been manured, while the other had had systematic if not continuous applications. Now, for the former, we should be inclined to suggest, above all others, the Loolecondera estate with perhaps the oldest continuously bearing tea in the island. We have been accustomed to get reports at intervals from the manager of this estate for embodiment in our "Handbook and Directory." The latest was courteously furnished by Mr. G. F. Deane on 20th May, 1898, when he wrote as follows:—"Replying to your letter of 17th, the oldest field of

tea" (30 to 32 years of age) "on Loolecondera is still looking remarkably well and continues to give yields varying from 400 to 500 lb. made tea per acre per annum. It last year received a heavier pruning and cutting down than it ever had before and looks all the better for it. The ground is a network of roots and the stems of the bushes are very thick. This tea is now some 30 years old, is very wind-swept in the South-west monsoon and has, I believe, never been manured." There is one exception (and but one only, we believe) to the last clause: in July, 1891, (about a year before his death) Mr. James Taylor, who first planted the tea on Loolecondera, reported to us:—"The field is as good as ever, giving about the same crops: it was manured once only with castor cake in the beginning of 1885." The one exception may surely be said to prove the rule in the case of Loolecondera if the tea of this field still continues up to the mark at 32 to 34 years of age? Now, it ought to be of great interest to have a special report on this unmanured estate, giving, from a scientist's point of view, the reasons why the tea is still in such good heart, with yields if anything increasing, or at any rate, steady year by year. Surely there is encouragement in the case of Loolecondera to proprietors of tea fields formed out of virgin forest, to follow the same course of careful cultivation without manuring? Of course, the lesson might be still more instructive if Mr. Kelway-Bamber were to find a similar estate where an opposite, or "manuring", policy had been adopted from an early age, with a better result in crops and with trees—at 25 to 30 years old—if such there be in Ceylon—even healthier and more vigorous than those of Loolecondera.

We are leaving out of view here the case of tea planted on old coffee estates, or on land otherwise used up or washed out. There, the choice may be: "manuring" or "abandonment." The question we propound is in respect of tea estates formed out of virgin land, doing well and in good heart, or if showing any slackness, only of a few months' duration, due to seasonal influences.

We must now leave this subject, to revert to the more particular and statistical enquiry raised in our opening sentences, namely, Has the Ceylon export (or crop) of tea of late years increased in proportion to the area of young tea coming into bearing? This demands a very careful examination of the figures in our Handbook—more than we are prepared to give today—but before closing for the present, we should like to lay two sets of figures before our readers, making the following contrast:—

In 1888, the total area planted with tea was, as near as we could make out, 183,000 acres, (of course, most not in bearing) the total export of tea that year was 24,381,296 lb.

In 1898—six years after—the area had risen to 273,000 acres: the total export to 84,406,064 lb.—an increase of 90,000 acres under tea and 60 millions lb. more tea exported.

Six years later, in 1899, we have an estimated area under tea of 375,000 acres—an increase of 100,000—while the total export of tea reached to 129,854,156 lb. (above the estimate, but) an increase of less than 45½ millions over 1893. We are aware that this is a very rough mode of instituting a comparison, and that much importance cannot be attached to our figures in support of any theory. Still, their suggestiveness is undeniable; and if they lead some of our "tea" authorities among proprietors, visiting agents, managers and thoughtful mercantile observers, to ponder the subject-matter, our purpose will be fully served.

AGRICULTURAL DEPARTMENT IN JAMAICA.

The Report of the Committee respecting the Establishment of an Agricultural Department and an Experimental Station, has appeared. We quote:—"For the organization and management of this Department there should be constituted a Board of Agriculture. It should have the same sort of control over the whole Department that an ordinary Head of a Department would have, subject to the usual control of the Government over all Departments, and subject also to the fixing by law or by the Government of any functions of any Branch of the Department. The Board should consist of:—(1) The Director of Public Gardens, *ex officio*. (2) The Agricultural Chemist, *ex officio*. (3) A person appointed by the Governor on the nomination of the Managing Body of the Agricultural Society, (4) Six members appointed by the Governor and holding office during his pleasure, one of whom should be an elected member of the Legislative Council. Of these six members two should retire annually in the order of their appointment, but be eligible for re-appointment. (5) The Commissioner of the Imperial Agricultural Department of the West Indies should be *ex officio* a member of the Board to enable him to attend the meetings of the Board on his visits to the island. The Chairman of the Board should be annually appointed by the Governor from among the members of the Board. The Governor should have power to give leave of absence to any member of the Board, and to appoint a person to act in his place during his absence. Provision should be made for paying the travelling expenses of country members of the Board in attending meetings. The Board shall meet at least once monthly, three members to be a quorum. The present Secretary of the Agricultural Society should be the Secretary of the Board. The powers and duties of the Board should be:—(1) To correlate and re-distribute the work of the subordinate Branches as opportunity offers, and to create new agencies and direct new efforts in any line of Agricultural progress. (2) To make arrangements for the carrying out by any Branch of the Department of instructions received from the Government; or for the discharging of any duties imposed upon the Board by Law affecting Agriculture. (3) To consider and report to the Government upon any matter affecting agriculture seeming to the Board to need consideration or action. (4) To be the channel of communication between any Branch of the Department and the Government. (5) To receive the annual estimates of the different Branches, to consider, to alter if necessary, and to confirm them, and to forward them to the Government, together with

estimates for its own expenditure. The Chairman of the Board should be the accounting officer for the direct expenditure of the Board; and some member of the present Staff of the Department under the Director of Public Gardens should be the Clerk in charge of the accounts. (6) To make its own annual report to the Government, and to forward to the Government the Reports of the subordinate Branches of the Department, either separately or incorporated with its own report." Dr. Morris concurs in all this and a great deal more, for instance:—"The Departments and Agencies to be brought into immediate organic relation with the Board, and to have their work more or less combined under the Board for Agricultural purposes are:—(1) The Department of Public Gardens. (2) The Government Laboratory. (3) The Agricultural Society. (4) The Experiment and Teaching Station to be created at the Hope University College though not a Department will require to be brought into close relations with the Experiment and Teaching Station. The management of the Teaching Station should be under the general control of the Board, but the detailed carrying out of plans should be under the direction of a body to be called 'The Station Committee.' This Committee should consist of:—(1) The Director of Public Gardens. (2) The Principal of University College. (3) The Agricultural Chemist. (4) The member of the Board nominated by the Agricultural Society. (5) Any other specially qualified person whom the Board, after receiving the advice of the Station Committee, may appoint."

HOW TO REDUCE THE CEYLON TEA CROP:

A PRACTICAL SUGGESTION.

March 10.

SIR,—With reference to "Tea Farmer" 's letter (see page 708) I beg to put before you a scheme for curtailing our crop by 10 per cent. *without* resorting to the need of letting our estates "lie fallow," etc., and, moreover, one which will affect all growers equally.

In short the idea is to raise the present "cess" to one or two cents per lb. and utilize the revenue secured to pay for the tea withdrawn from export or sale locally.

(1) For argument, say, the output is 100 million lb. for 1900.

(2) Prices are supposed to have "touched bottom," *i.e.*, are only equal to cost of production.

(3) Granted that a shortage of 10 per cent. will *more* than raise the average price a like amount, when

(4) No further expense for "booming" Ceylon tea will be necessary.

Now, the present "cess" at one-fifth cent per lb. on 100 million lb. produces R200,000 revenue; and at one cent per lb. do. R1,000,000 do.

This would purchase—

3 million lb. tea at 33½ cents per lb.	
4 do do	25 do do
5 do do	20 do do

and, should we submit to two cents per lb. cess, would purchase six, eight or ten million lb. per annum.

Each estate would be obliged to provide for sale, at the price fixed, an *average* break assessed as regards quantity by the "Thirty Committee," C.P.A., and the tea so secured would be destroyed or used as manure at their discretion.

The total intermediate loss to the producer would be about three cents per lb., but the nett ultimate gain—granting that the above conditions (1 to 4) hold good—would be five to ten cents per lb. at the end of the year.

The above may or may not be practicable, but it is, I believe, an original theory and could be put to the test if the condition of the Tea Industry becomes desperate.—I am, yours truly,
PLANTER.

CEYLON TEA EXPORTS: CAN THEY BE REDUCED?

A correspondent puts forward (see above) an original and, possibly, practical—though, we fear, not practicable—scheme for reducing the total export of tea. Theoretically, there is not a great deal to be said against it; it raises the “cess,” it is true, but the extra charge will, according to “supply and demand”, find its way back in to the pockets of the producer, in the shape of an extra 5 to 6 cents a lb. at the end of the year! This would be a correct enough method of arguing, if only the details of the scheme had to be considered *per se*. But there are inevitable and, we feel certain, insuperable objections:—

(1.) Small as the present tea-cess is, there are murmurings beginning to be heard against its imposition at all. The work accomplished by means of the Cess Fund, it is argued, has gone so far, that it can go on now by itself without further commissions and commissioners. We do not share this opinion, but it exists; and the wholesale raising of the cess would meet with instant opposition.

(2.) It is not likely that the Ceylon planters will produce tea with the off-chance of its being destroyed or used as manure!

(3.) If Ceylon, by a united effort, agreed to any such monster—we will not say “monstrous”—plan, is there any guarantee that India will not step in and increase supplies by an opposite kind of effort; and the whole machinery of raising prices will be instantly upset? We believe there is none, and that the “putting to the test” of “Supply and Demand”’s scheme would be considered far too hazardous an experiment ever to receive a trial.

Passing to the wider question of tea-producing as affected by the rise in the tea-duty, we find it is the belief locally that the producer must suffer considerably, owing to the accumulation of stocks in the hands of big buyers, stocks accumulated in anticipation of the extra 2d. From arrivals from home today, however, we learn that several brokers in London had been giving their opinion that the market would right itself very shortly after the new duty was fixed. The big buyers might play their game for a few weeks; but the balance would soon be regained and prices resume their equilibrium, on the higher plane created by the extra duty. For ourselves we do not foresee any long-standing danger to the tea-growing industry, following on the larger Customs levy. That there will come a period

when the lowest of low prices will be reached and awhile maintained, we may well believe; but the tea industry has passed through worse crises before and should weather this as successfully as the rest.

INDIAN TEA ASSOCIATION: SCIENCE AND PLANTING.

Calcutta, 27th Feb. 1900.

Extracts of Proceedings of a Meeting of the General Committee held this day:—

Present:—Mr. H. C. Begg (Vice-Chairman), Mr. G. G. Anderson, Mr. W. Brown, Mr. G. Kingsley, Mr. G. A. Ormiston, Mr. M. R. Quin, Mr. A. Tocher, Mr. R. R. Toynbee, and Mr. T. Traill.

SCIENTIFIC OFFICER.—Enclosed with Mr. Tye’s letter, dated 9th February, was a copy of a letter dated 5th February from Dr. J. Augustus Voelcker, Consulting Chemist to the Royal Agricultural Society of England, regarding this appointment. In this letter it was stated that the gentleman selected by Dr. Voelcker for the post was Mr. Harold B. Mann, B.Sc. (Victoria University), F.I.C. Mr. Mann was formerly a student at the Yorkshire College, Leeds, and took his B.Sc. degree at Victoria University, (Owen’s College, Manchester), with first class honours in 1892. He became Le Blanc Medallist in the same year. Mr. Mann subsequently gained a Research Scholarship of the Commissioners of the 1851 Exhibition and went to Paris, studying fermentation at the Pasteur Institute under Professor Duclaux. He had subsequently been employed by the Royal Agricultural Society of England. His appointment was strongly recommended by Dr. Voelcker. It was understood that the London Committee had appointed Mr. Mann to the post, and the arrangements to be made on his arrival were now considered.

Considered letter, dated 19th February, from Messrs. Duncan Brothers & Co., regarding the refusal of the Conference Liners to pay claims for loss or damage which occurs in their hands in the case of tea in metal packages. Messrs. Duncan Brothers & Co. considered that the Liners were not entitled to condemn all metal chests in this way, and they suggested that the point should be kept in view when the time arrived for any new Steamer Agreement. The Committee agreed with Messrs. Duncan Brothers & Co. that the Liners were not entitled to condemn metal chests in the manner indicated. They did not, however, see their way to take action beyond drawing the attention of the London Committee to the point in view of any future new agreement with the Conference.

Considered note, dated 10th February, by the Chairman regarding the provision of samples of Indian Tea for exhibition in the Economic Court of the Indian Museum. This subject was last referred to in the proceedings of the meeting of the Committee held on 1st August. The arrangement then suggested, whereby a representative collection of samples from the several Tea producing districts should be exhibited, had been carried out by the Committee. It appeared, however, from more recent correspondence with Dr. Watt, the Reporter on Economic Products to the Government of India, that this did not meet his requirements. He had informed the Chairman that he desired to have for the Court—(1) Samples from all, or as many as possible, of the gardens of the chief Agency Houses. (2) Tea chests of all descriptions—Country-made, Japanese, Swedish, &c. (3) Models of machinery of all available types. Dr. Watt

proposed to group the gardens of each Agency House together; and to label each sample with the names of its garden, and of the garden Agents.

Before taking any action in the direction of asking members of the Association to supply samples upon this system, the Committee directed the Secretary to ascertain from Dr. Watt an approximate idea of the number he had space for. They rather inclined to the opinion that the space required for samples from all the gardens of the chief Agency Houses might be greater than Dr. Watt anticipated.—*Indian Planters' Gazette*, March 3rd.

THE PROSPECTS OF TEA : CONSUMPTION IN FOREIGN COUNTRIES. THE CHECK ON OVER-PRODUCTION AND LOW PRICES—? "A TRUST."

The London merchant, largely interested in Indian tea, whom we have already quoted, (see page 669) writes on 23rd February:—"I duly received your letter of 14th December written on board the 'Rome.' We can only await developments of foreign consumptions. There is no doubt whatever a tendency among certain French people, where they are brought into close touch with the English or are influenced by the fashionable tendency to ape English ways, to make use of tea; but the French are a very conservative people, and it seems to me that the tea habit is foreign to their ways and therefore unlikely ever to become a prominent factor in their national life. I have been in pretty close touch with the various movements made in the last twenty years by the Indian tea people to promote a greater consumption of tea in Paris, and so far I can only characterise the business as practically of no mercantile importance.

"As to the immigrants from the United Kingdom into the United States not having continued the traditions of their fathers, I must say I am not at one with you in tracing the reason for this. The climate to my mind explains a great deal, and the character of the tea consumed follows fairly well-defined geographical lines. In New England and all the older states there has always been a fair consumption of black tea, and the people there have followed the other Anglo-Saxon people in passing more or less gradually from one black tea to another, that is China has been displaced by the Indians and Ceylons. Japan tea has made its way largely from the western seaboard since the opening up of the various routes of trans-continental railroad, and it has made a business for itself quite independent of the old black tea trade. There is no doubt that some people in California and the States nearer the West may have been induced to drink Japan whose parents or who themselves, prior to emigration, had used old-fashioned China teas in the home country; but you must recollect that the consumption per head of tea in the old country fifty years ago was very low in comparison with the present figure, and more on a level with the present figure in the United States. You must bear in mind that the term English breakfast tea is merely an inclusive title for all black teas, and was in use as descriptive of China congo before any Indian or Ceylon

teas were imported, and although the two latter teas have been gaining ground in America, it has been principally because of the displacement of China tea; and I must say I am doubtful whether there has actually been any increase of recent years within the United States itself in the use of black teas.

"As to Russian duty, your argument that a reduction in the rate would lead to the use of better,* tea is not justified by what has happened elsewhere. At present Russia consumes largely of the very finest tea the world produces. Canada, where there is no duty, and the United States, where the duty is recent and probably temporary, take the filthiest rubbish the law will allow to enter. Great Britain, where the duty is a very small one, takes lower and commoner tea all the time, the rage for cheapness and not for quality seeming to pervade the whole life of the people.

"The existing Associations in London of Tea Producers have so far achieved little but trouble. Had we not had a vast over-production of tea in both India and Ceylon many of the grievances that are made so much of, would never have been felt, and I think those Tea Associations would have served a much more useful purpose had they endeavoured to pass 10 years ago a self-denying ordinance as to increased acreage,† instead of checking things at the fountain head in that way, they have made repeated trouble for the distributive section of the trade whom they affect to regard as their natural enemies, while they really are their best friends. It is all very well to try to eliminate the middle-man, and in the tea trade a good many such have been effectually abolished, so that producers and retail distributors are very closely brought together indeed now. What is the result? The powerful retailers are combining in a way that the old-fashioned dealers never could have combined, and I see very little hope for the future of tea production unless it is all forced into one gigantic Trust on the model of recent industrial developments in the United States."

COCHIN MARKET REPORT.

COCHIN, 10th March.

C. N. OIL.—Some contracts were placed in the bazaar in the early part of the week at R87 to R87/8 per candy but latterly rates dropped and the market closes today rather weak at R87 with ready sellers for prompt delivery.

COIR YARN.—A moderate demand exists for weaving qualities, for shipment to Europe. There is also some enquiry for shipment to Calcutta. Rates may be quoted at R35/60 per candy.

COPRAH.—Rassi—R52/53 per candy.—*Cochin Argus*, March 10th.

* Our idea was better Ceylon tea for the rich classes and a larger quantity of ordinary teas for the middle classes.—Ed. T.A.

† Our correspondent should remember that the worst sinner in this respect was a great proprietor or capitalist interested in Indian tea estates, who some years ago showed in print, a vast field for extending tea consumption in Europe and America, as justifying a large extension of planting in Ceylon and Southern India.—Ed. T.A.

CEYLON COCONUT PALM INDUSTRY AND EXPORTS:

PAST, PRESENT AND FUTURE.

In reviewing the exports of coconut palm produce for last year, we calculated that they represented a falling-off of the equivalent of about 59 million nuts, as compared with 1898; and that represented in value about 1½ million rupees. We are not surprised, therefore, that the Horrekelly [Coconut Estates] Company, which declared a dividend of six per cent for 1898, was able to divide only five per cent among its shareholders for 1899. As good coconut property is believed to yield larger returns than are indicated by these dividends, we gather from the summary of proceedings sent to us for publication, that the Directors are to consider whether means cannot be adopted by better manuring, to increase the yield of the plantation. Meanwhile, we observe that there has been an improvement in the exports during the past two months; and we have been making inquiries to ascertain whether this improvement generally, can be expected to continue, with the result noted down as follows for the information of our readers.

In the first place, no safe deduction, can be made from the figures for the first two months of the year. The prices offered for nuts and copra at the end of last year were not such as to favour large transactions; and with the season of short crops on, holders were not in a hurry to part with what they had in hand. Then the South African War had a disturbing effect on trade generally, and on the freight market in particular. Much of the coconut produce sent forward, so far, this year probably represents last year's crop; and it will not be safe to calculate on a continuance of the excess over last year's figures which the export tables shew. The decrease last year, as compared with the previous year, was largely due to the two droughts in February-March and June-July, which told seriously on crops. But the effects of those rainless months are indicated only partially in last year's outturn of crop. This year's crops, too, must show a falling-off, as it takes almost a year for a nut to set and mature; and the effects of the June-July drought will be felt in the crops to be picked till the middle of this year. To add to the trouble, the North-East rains have been scanty, and complaints are rife of the severity of the drought now prevailing towards the Madampe and other coconut growing districts. Under these circumstances we fear, not only that no excess over last year's outturn of coconut palm produce is to be expected; but even that there will be a positive falling-off from the not too satisfactory exports of last year—unless young plantations just coming into bearing add materially to the year's outturn of crop. It is of interest to note the increase over last year which the exports for the past two and half months show. To take the figures up to 12th instant,—of coconut oil there has been sent away as much as 90,572 cwt, which is in excess of the quantity shown in any of the three years past, and nearly treble that for

1897. So with copra: 87,901 cwt is close upon double the figures for the last two years which witnessed a revival of the trade, and nearly nine times the exports for the corresponding period of 1897. High prices ruling for copra explain the rapid pushing forward of supplies. In desiccated coconut, however, there is a decrease of about 78,000 lb. compared with the same date (12th March) of 1899, when 1,781,790 lb. were sent off; but this quantity is 358,849 lb. less than that for 1898. Coconuts in the shell, too, for which high prices prevail, number over 1,872,000 against 1,120,000 exported last year, and nearly 1,733,000 in the year before. If our apprehension that this year's crop of coconuts will fall short of last year's crop prove true, better prices than last year's should prevail, if the demand, as is likely, continues brisk.—Since the foregoing was written we have cheering accounts of a break in the drought; but we fear much damage to crops has already been done, especially in the Northern Districts.

THE USE OF NETTLE FIBRE.

The American Consul at Glauchau (Germany) reports that nettle fibre has of late come greatly into favour in the manufacture of fine yarns and tissues. In Germany, there are factories which use these fibres both in spinning and also for ulterior purposes. In nettle-spinning alone, over 10,000 spindles and some hundred workmen are employed. The raw material is imported almost exclusively from China, whence 661,500 to 802,000 pounds are annually sent to Germany. Nettle fibre produces one of the finest tissues obtainable from any known kind of vegetable fibre, and in view of the importance which this seems likely to attain in connection with the weaving industries, it is intended to introduce the cultivation of nettles, if possible, into the Cameroons. The idea is to prepare the products of this experimental culture at the place where they are obtained, and test them in German factories. Should favourable results follow from these experiments, it is intended to organise nettle-growing enterprises on an extensive scale.—*Indian Review* (March.)

PLANTING AND THE INDIAN CURRENCY.—Mr. John Logan, in the *Madras Mail*, backs up Mr. R. H. Elliot as to the evil effects on planting (coffee especially) of the new currency. Here is the comparison:—

Land went up to fabulous prices, as high as R200 per acre being given at public auction for forest land. Prices were good and money flowed freely into the country, and the revenue went up by leaps and bounds. In the labour market, the demand was far in excess of the supply, which was scarce and dear. This happened before our Government began to tinker with the currency. What is the obverse of the picture now after we have had four or five years of a sound and stable currency? Prices of land and produce have gone down lower than they have been for years. I have seen good land sold at less than R5 per acre. Labour has been so plentiful that the best Canarese coolies have been driven from the door, and of course, is cheaper. The coffee industry in the hands of the natives has collapsed, while the voice of the rich sowcar is silent in the land.

ROEBERRY TEA CO. OF CEYLON, LD.

THE ANNUAL REPORT.

	ACREAGE,	
Tea in bearing	... 542	acres
Planted in 1896	.. 127 $\frac{1}{4}$	"
Do. 1897	.. 46	"
	<hr/>	
	709 $\frac{1}{4}$	
Cardamoms	.. 4	
	<hr/>	
	713 $\frac{1}{4}$	acres in cultivation.

The Directors have now to submit their Fourth Annual Report and accounts, being those for the year ending 31st December, 1899. The yield of Tea during the period has been 179,176 lb. costing 30.32 cent per lb. as against 39.94 cents last year, and realizing 40.46 cents as against 39.94 for the same period.

On a reference to the accounts it will be seen that the sum at credit of Profit and Loss Account, including the sum brought forward from last year, is R9,541.15 after allowing for Depreciation on Factory and Machinery; and out of this sum the Directors recommend that a dividend at the rate of 3 per cent be declared, absorbing R9,000.00 leaving a sum of R541.15 to be carried forward to the current year.

Crop has again been short owing to excessive drought, the rains having been late in setting in after the dry season, but it is hoped, with increased plucking from the young Tea now coming into bearing, 200,000 lb. may be secured during season 1900.

Mr. W Sandys Thomas visited the Estates on 18th, and 19th December last, and found things generally in a satisfactory condition.

The retiring Director is Mr. E Hamilton, who is eligible for re-election.

The appointment of an Auditor for the current year rests with the meeting.

CEYLON PROVINCIAL ESTATES CO., LD.

THE ANNUAL REPORT.

The directors have the pleasure to present their Report for the year ended 31st December 1899 together with a statement of Accounts for the same period, which have been duly audited.

The season has been a favourable one for the growth of leaf, and the crop has amounted to 488,904 lb of Tea as compared with 430,951 lb last year. This is considerably in excess of the Estimate, and shows an average yield of 560 lb per acre in bearing.

Prices, too, have been well maintained, and the average is 44.62 cents per lb against 42.73 last year.

The cost of production has at the same time been moderate and works out at 24.35 cents per lb which includes 2.25 cents per lb for expenditure on manuring operations. Last year the cost was 26.10 cents including 1.50 cents for manure.

The Working Account closes with a surplus over expenditure of R103,221.09 as against R76,371.16 last year.

Out of this an interim dividend amounting to R19,980 at 3 per cent has been paid, and R15,000 has been absorbed in paying off £1,000 from the Glassaugh Mortgage in order to get permission to remove the Factory and Machinery from that division of the property to Aadneven where the new Factory for Glassaugh is now situated. Interest on Mortgages amounts to R9,900.15, and after providing for Bonus to Superintendents and other items, there is a final balance of R51,227.66 standing at credit of Profit and Loss Account.

On the other hand, it will be seen by the Balance Sheet that our liquid Assets, or available funds amount to only R33,887.03. The difference is accounted for by the capital and mortgage money having been insufficient, to the extent of R17,340.63, to provide for the extension and improvements to property of late years.

The Directors recommend, therefore, that a final dividend of 5 per cent be declared, making a total of 8 per cent for the year. This will absorb R33,300, leaving R587.03 to be carried forward to next season, besides placing the above mentioned sum of R17,340.63 to Extension account which, with the capital and mortgage money, now equals the amount locked up in property, etc. It is to be observed, however, that, had it not been for the stipulation of the Glassaugh Mortgage about the old Factory on that Estate, we should have been able to make a dividend of 10 per cent for the year, and something over.

The balance of £5,000 due on the Glassaugh Mortgage has been replaced by a new Mortgage for R75,000 resulting in advantages to the Company.

The Estates are reported to be in excellent order and although Blights have been prevalent at certain periods of the year, the crops show that their attacks have not, so far at all events, affected the yield or impaired the vitality of the bushes.

The Estimates for the new season point to a yield of 455,000 lb of tea costing 26.70 cents to produce, and this expenditure includes a liberal allowance for manure and cultivation generally.

A fresh survey has been made of Brownlow, with the result as given below. Glassaugh has also been surveyed, but particulars have not yet been received.

	Glassaugh.	Brownlow.
Tea in bearing	.. 426 $\frac{1}{2}$ acres	423 acres
„ partial bearing	.. 34 $\frac{1}{2}$ „	80 „
„ young	.. 40 „	— „
	<hr/>

Scrub and Waste	.. 15 „	13 „

Total ... 532 acres 585 acres

Mr. Auderson retires from the Board on this occasion in terms of the Articles of Association and is eligible for re-election.

The appointment of an Auditor for 1900 rests with the Meeting.

THE CEYLON TEA AND COCONUT ESTATES COMPANY, LIMITED.

THE ANNUAL REPORT.

ACREAGE :

TEA.—In bearing	.. 265 acres.	
In partial bearing	165 „	
		430 acres.
Coconuts	558 „
Rubber	35 „
Grass, Forest and chena	213 „
Cinnamon	21 „

Total...1,257 „

The Directors have now to submit to the shareholders the accounts for the past year.

TEA DIVISION.—The crop secured amounted to 78,933 lb., being about 29,000 lb. under the estimate which is accounted for by the very dry season that has effected most of the estates in the district, and part of the tea having been attacked by Grey Blight (though no permanent damage has been done by it) necessitated the pruning down of about 70 acres, which was not estimated for. The nett average price realised was cents 36.43 against cents 37.34 in 1898.

COCONUT DIVISION.—This crop was over 200,000 nuts short of the estimate, entirely owing to the unusually dry season. The total crop gathered during 1899 was 541,912 nuts, of which 1,460 were sold on the estate at the average of R30 per thousand nuts. The remainder were made into copra—candies 421.0 2-8, and sold at a nett average of R44.20 per candy, as compared with 493 candies in 1898 which, realised an average of R44.76.

During 1899 the Directors considered it advisable to enlarge the withering accommodation of the factory, in consequence of the increased quantity of leaf anticipated this year, and for the same reason they have also purchased a new Rapid Roller and a large Down-Draft Sirocco.

The estimates for this year are, Tea, 184,000 lb. against an expenditure on working account of R42,518'50, which includes the purchase of 50,000 lb., green leaf from other estates. Coconuts,—600,000 nuts on an expenditure of R14,100. These estimates include R7,180 to be expended on manuring.

After making the usual provision for depreciation of buildings and machinery, the result of the year's working shows a loss of R5,993'30.

Messrs. W H Figg & J A Henderson having resigned their seats on the Board, Messrs. G H Alston & H Tarrant were appointed to fill the vacancies.

In terms of the Articles of Association, Mr. G H Alston retires from the Board of Directors, but is eligible for re-election.

The appointment of an Auditor for the current year will rest with the meeting

In view of the amount still owing to the bank the Directors regret that they cannot recommend the payment of a dividend, but would suggest that R10,000 be transferred to an extension fund account and the balance of R1,818'86 carried forward to the current year's accounts.

Capital expenditure during 1899 amounted to R8,268'57, of which R4,054'62 was expended on completion of electrical transmission installation and the balance on the upkeep of acreages not in bearing, and on necessary additions to Machinery and Buildings.

Crops for the current year are estimated at 366,000 lb. tea, 120 cwt. cocoa and 200 lb. cardamoms, on an expenditure of R111,855 29, while expenditure on capital account is estimated at R3,500, principally on upkeep of acreage not in bearing and the erection of new lines on Hayes Estate.

In terms of the articles of Association Mr. W. D. Gibbon now retires from the office of Director, but is eligible for re-election.

The appointment of an auditor for the current year rests with the meeting.

THE UNION ESTATES COMPANY OF CEYLON, LIMITED.

THE ANNUAL REPORT. ACREAGE.

	Tea in full bearing.	Tea not in bearing.	Cocoas.	Cardamoms.	Total Cultivated.	Grass, Jungle and Waste Land.	Total.
Hayes Group	518	3	—	25	546	1,665	2,211
Dea Ella	248	—	91	—	339	147	486
	766	3	91	25	885	1,812	2,697

The Directors now submit to the Shareholders the accounts of the Company for the past year.

From the 1st September the Directors arranged for a four years' lease of Longford estate, which is 256 acres in extent, 142 acres of which are under tea. The terms arranged are that this Company undertakes to pay from time to time as they fall due, the assessments due by Longford estate for the construction of the Anningkande-Hayes road, which amount to R2,841'11, or say a little over R700 per annum.

This estate has for many years been managed by the Superintendent of Hayes and its tea manufactured at Hayes Factory at a price which left a fair profit to the Company. Had the estate passed into other hands this profit would have been lost, which at the above rental will still be earned by the Company.

The tea crops secured amounted to 82,330 lb. (including 18,332 lb. purchased leaf) on Dea Ella, 219,778 lb. on Hayes, and 12,963 lb. on Longford during four months, while 9,641 lb. and 32,469 lb. were manufactured for other estates. The average prices realized were 36 cents for Dea Ella and 38'65 cents per lb. for Hayes and Longford teas, which were sold together under the Hayes mark on an all round average of 37'96 cents per lb. as against 34'32 cents in 1898. The cocoa crop on Dea Ella amounted to 95 cwts., which sold at an average of R40'25 per cwt., while the small crop of Cardamoms from Hayes realized Re. 1'12 per lb. nett.

The road to Hayes Factory has now been opened for some time and has been of great service to the estate. The plant for electrical transmission of power to the factory has worked most successfully during the year.

After writing off to coast advance reserve account the sum of R1,500 as a provision for doubtful advances and the sum of R165'07 for bad debts, and transferring to depreciation account on the usual scale, the sum of R10,306'91, (which is equal to 3'22 per cent on the capital of the Company,) the nett profit for the year amounted to R11,456'76, equal to 3'58 per cent on the capital of the Company. To this has to be added the balance of R275'39 brought forward from last year and R86'71 surplus over estimated proceeds of crop unsold at end of 1898.

THE ESTATES COMPANY OF UVA, LD.

THE ANNUAL REPORT.

CREAGE :

	Tea in full bearing.	Tea in partial bearing.	Tea not in bearing.	Total Tea.	Other Products: Timber, Grass, Forest and Waste land.	Total.
Dammeria Group	515	60	29	04	30	556
Battawatte and Forest Hill	413	178	..	591	..	164
Gampaha	455	78	57	590	45	231
	1383	316	86	1785	75	951
						2311

The Directors now submit to the Shareholders the accounts of the Company for the past year.

The crops secured were as follows, 530,695 lb. tea, 495 bushels coffee, about 143 lb. cardamoms and 54 cwt. cocoa. During the year 54,891 lb. tea were manufactured for other estates on Gampaha, while it was necessary, owing to want of withering space, to manufacture elsewhere 8,590 lb. of Battawatte tea. The new withering house on Battawatte is now completed and there is ample space to deal with the crops for some time to come. The cart road through this estate is now finished, and difficulties of transport are in consequence considerably lightened.

After writing off for depreciation of buildings and machinery on the usual scale the sum of R17,638'19 (equal to 2'48 per cent on the capital of the Company), and a small irrecoverable coast advance of R24'33, the profit for the year was R24,519'05, equal to 3'45 per cent on the Capital of the Company. There falls to be added to this the balance brought forward from 1898, R9,842 10, and a surplus of R43'89 over the estimated proceeds of produce unsold at the end of 1898. The Directors recommend the payment of a dividend of 3 per cent for the year, and that the balance of R13,090 04 be carried forward to the current season's account.

During 1899 the expenditure on Capital Account amounted to R29,753'03; the erection of the new withering house on Battawatte cost R15,581'34, the contribution on account of the construction of Forest Hill cart road amounted to R1,053'84, and the balance was expended on the opening of 15 acres on Gampaha, the upkeep of acreage not in bearing and on small additions to the buildings and machinery and erection of new lines.

The crops for the current year are estimated at 581,000 lb. Tea, 50 bushels Coffee, 60 cwt. Cocoa and 150 lb. Cardamoms on an expenditure of R181,417'85.

The expenditure estimated on Capital Account is R12,853 for upkeep of acreage not in bearing and additions to machinery and buildings.

During the past year Mr. W H Figg resigned his seat on the Board and Mr. F G A Lane was elected to the vacancy.

In terms of the Articles of Association Mr. G H Alston now retires from the office of Director, but is eligible for re-election.

The appointment of an Auditor for the current year will rest with the meeting.

UVAKELIE TEA CO. OF CEYLON, LD.

ANNUAL GENERAL MEETING.

THE REPORT.

The Directors have now to submit their Report and Accounts for the year ending 31st December, 1899

The crop amounted to 152,660 lb. tea, costing 26 82 cts. per lb. against 138,995 lb., costing 30 82 cts. in 1898; the profit on the Working Account being equal to 9 30 per cent on the Capital of the Company.

After estimating the unsold tea at a safe figure, the crop has realized 41 67 cts. per lb. against 45 10 cts. in 1898.

After paying an interim Dividend of 3 per cent and writing off 7½ per cent for Depreciation on Buildings and Machinery, the profit amounts to R12,287 30, and the Directors recommend that this amount be disposed of as follows:—

That a final dividend be paid of 4 per cent (making 7 per cent for the year) absorbing ..	R9,600 00
That a sum be carried to Reserve, of	2,000 00
That a Bonus be paid to the Superintendent, of	500 00
and that the balance of	187 30
	R12,287 30

The Estimate for the current year is 155,000 lb. tea to cost R47,045 16.

In terms of the Articles of Association Mr. W D Gibbon retires from the Board, but being eligible, offers himself for re-election. It will also be necessary to appoint an Auditor for 1900.

BRAZIL COFFEE NOTES.

The continued rains throughout the coffee districts have greatly benefited the growing crop. The ripening of the fruit from the abnormally early flowering is being delayed, and the general condition of the crop is said to be much improved.

Telegrams from Paris on the 23rd and 24th state that the French government will impose double duties on Brazilian coffee, should this country impose special duties on French products. A tariff as destructive to the interests of both countries, would therefore appear to be imminent.—*Rio News*, Jan. 15.

PLANTING NOTES.

THE "AGRICULTURAL LEDGER."—1899—No. II. *Xylia Dolabriformis*. (Iron-wood of Pegu). A Revision of the article on that subject as given in the Dictionary of Economic Products, with special reference to the timber, and the employment of the refuse wood as a tanning material.—received.

JAVA TEA.—An Amsterdam circular by this mail gives the total sales of Java tea there during 1899 at 5,293,770 half-kilograms (1 1-10 lb.) at an average of 37½ cents (of a florin) per half-kilogram. This is equivalent to 5,823,147 lb. and the average to about 34½ cents, or say a little over 8d, per lb.—The imports in 1899 seem to have been rather less than in 1898. A certain quantity is still taken of "China tea": a merely trifling quantity of "British-Indian" tea.

TEA PLANTED AND EXPORTS.—Our figures in article on page 697, require a little supplementing, in order to make the comparison more instructive. In 1888, of 183,000 acres planted, about 81,000 would not be in bearing or under three years; in 1893, of a total of 273,000, about 53,000 not in bearing; in 1899, of estimated area of 375,000 acres, say 45,000 acres not in bearing.

CACAO PROSPECTS.—In his report on the London market (see page 676) Mr. Hamel Smith speaks of "increasing cultivation in Africa" which will give crop this year sufficient to cover an increasing demand. Now, we should like to know more exactly where cacao cultivation is being systematically and extensively carried on in Africa? There may be a very little in Nyassaland, Uganda and German East Africa; but we take it the West Coast is meant; and yet we cannot suppose Congo land, or any British dependency is seeing much cacao planted?

PARA RUBBER.—Exports of rubber from Para were valued at £7,600,000 for 1897 and £7,700,000 in 1898. For 1899 they are likely to have reached £8,000,000 or about £14 per head, a rate equalled but by very few other countries and probably excelled by none—not even the Australian colonies or Uruguay. The *Brazilian Review* remarks:—In a country that produces so much with so comparative, little labour there must be plenty of money to spend and even to waste. So if there are any young and enterprising men in search of a Golconda so long as they don't mind the heat or a little feverishness they can't do better than try Para and if they don't make their pile it must be because they "have not the method of making a fortune."

TEA CROPS AND THE INCREASED TEA DUTY.—Says "*Indian Gardening*":—"Any fear of the future could only arise from an increase in production, which we see no reason to apprehend. In the year just past the exceptionally favourable season in Cachar, Sylhet and the Dooars accounted for the unexpected increase in production, those districts being responsible for nearly the whole of the eleven million pounds of surplus. But the fact that the last season was an exceptionally favourable one relieves us from the anxiety that the districts named will again improve on these figures. They will do well if they equal them. Assam has been practically stationary for the last two seasons at 62 to 64 million pounds. Her estimates have been accurate and we may accept them. The other districts may be disregarded; they cannot do very much towards upsetting the figures. Therefore we think there is every reason to conclude that the Indian tea crop has reached its limit for the present, and the increase of the duty will no doubt make planters chary of extending cultivation or entering upon any operations which will increase the load on the British market. At present figures we may consider ourselves safe. Ceylon, we notice, has estimated for an increase of 8,000,000 lb., which they trust to work off. It is possible that the increased duty may interfere with their anticipation, and we trust that their foreign markets propaganda will be unusually successful to relieve the British market of their surplus."

AN ELEPHANT INQUEST IN LONDON.

Last Sunday afternoon (Feb. 18), while a concert was being held at the Crystal Palace, an elephant belonging to a circus which had been performing there broke from its fastenings and killed its keeper. It then brushed through various partitions of wood and glass, and appeared in the main building, where a great number of persons were listening to the music. It did not attempt to hurt any of the crowd, though it broke off with its trunk the uplifted arm of a statue, probably under the idea that this represented a man about to strike. After some time it allowed itself to be secured by another elephant. It was then decided to kill the animal, and after a dose of poison had failed, a London gunmaker was sent for as executioner and shot the animal dead.

On the following Wednesday an inquest was held on the body of the man. If it had been one of the trials of animals held by jurists in the middle Ages for the exhibition of legal subtlety, the evidence in favour of the elephant could not have been more clearly put. Mr. Sanger, its owner, admitted that the animal had once before killed a former keeper; and he gave the facts which led to the death of the second. The facts speak for themselves. The first man had been discharged by Mr. Sanger fifteen months previously for gross brutality to the animals. He came back and asked to be employed again. This was granted, and he was taken on, not as a keeper, but as a labourer. The very first time he went into the stable the elephant, though it was quite dark at the time, instantly recognised the man's voice and

AT ONCE CRUSHED HIM TO DEATH

against the stall. That the creature had acted only in a panic of horror at the reappearance of a tormentor was so well established at the previous inquest that it was retained in the menagerie. It was exceptionally docile, and was taken through towns and villages all over England. Why then did he kill the second keeper? Because this man, after his Sunday dinner, declared that he would "pay out" the elephant for striking him with its trunk. He actually took a lance, one of those taken from the Arabs in the Soudan. (Those who have seen the trophies taken from the Mahdi's followers, now kept in the United Service Institution, will realise what a horrible weapon this was.) Followed by another keeper also armed with a lance, he proceeded to "prod," —i.e., pierce the chained elephant. The tortured creature after backing as far as it could, "at length rushed forward to escape the lance, broke its chains, threw down the keeper and trampled on him." If the elephant had been a man and had been put on his trial afterwards, would it be too much to anticipate that the verdict would have been one of justifiable homicide? All these facts, it is worth remembering, were sworn to on oath. They leave a very unpleasant impression as to the management of the "elephant herd" in this country. It is perfectly clear that the animal was in each case influenced by resentment caused by the cruelty of one individual. Male elephants, apart from their occasional attacks of frenzy, are not as unaccountably docile and submissive as the females, and most accidents which do occur in their long lives are due to the gradual forgetfulness of this difference of sex and temper by men who are so accustomed to witnessing the unhesitating obedience of the one that they make too great demands on the forbearance of the other. At the present

time the Indian Government, with the exception of a few males kept for parade, only employs female elephants for this reason; even so it is believed that the pay or pensions of mahouts is calculated with reference to the conviction that they pursue

A DANGEROUS TRADE.

The native princes, on the contrary, keep male elephants in large numbers for purposes of State, and it is among the attendants of these animals that "accidents" most commonly happen. Experience, as well as common report, which declares that every elephant kills a mahout in its lifetime, shows that in far the greater number of cases the person attacked is the animal's own attendant. This at first sight seems a contradiction to the general behaviour of animals in captivity, or even in domestication. Generally speaking, they are specially attached to the person who feeds them and gives them exercise, and if disposed to be savage, vent their anger on strangers. There are a few instances on record of horses attacking their grooms, but this, as a rule, is only because the attendant happened to be the only person near when the animal was in a bad temper. The only domestic animals which habitually attack their attendants are the bulls kept for stock-breeding in England, which are responsible for most intentional homicides caused by animals in this country.

The grounds for the ill-will which the elephant often harbours towards its Indian mahout lie partly in the animal's temperament, partly in the character of these men. As most elephants behave with propriety to their drivers, we must believe that either the greater number of the mahouts do their duty by the beasts, or that the latter are exceptionally forgiving. But there must be more than mere hearsay in the general belief that the mahouts commonly steal and appropriate a very large part of the elephant's allowance of food, that they are in consequence often half-starved and hungry, and that the men use their steel-hooked and spiked "ankus" in a very merciless way on animals which are often not in condition to do the work which is set them. As the

COST OF AN ELEPHANT'S KEEP

is from £4 to £8 per month, in proportion to the food given him a proportion and quality which is fixed in reference to the work to be done, the margin for stealing is very great, being reckoned between the minimum necessary to keep the animal alive on low diet, and that required for keeping him in fine condition on the march in a campaign, when he is allowed extra rations, and even a bottle of rum per diem. No other animal is clever enough to know that overwork and underfeeding are probably caused by the direct agency of the man who maintains him. But it is pretty certain that the extraordinary intelligence of the elephant does enable it to put two and two together, and to conclude that the person who gives him little food ought not to punish him for not being up to his work. In any case the elephant bears no gratitude to the man who, if he can, gives him starvation rations, and is his daily slave-driver; and as long as native usage holds that "the driver and three generations of his family shall live on the beast he is paid to nourish" it must be expected that the animal will occasionally try the experiment as to whether the next generation can possibly be worse than its present tormentor. It is sometimes forgotten that an elephant may live for seventy or eighty years, or even longer, in the service of man, and that in the unchanging East he may, through this long life, be farmed as

a kind of property by the same family of ma-houts; that the brutality of the father, if he be a brute, is learnt by the children and grandchildren, and that, if the wretched elephant is in bad hands, he has to put up with practically two of our working lives of ill-treatment and semi-starvation. The wonder is, not that its temper occasionally goes amiss, but that it does not "break out" oftener. The inference is that the natural temper of the elephant is almost the best and most easy going of that of any beast. All Hindoo traditions and folk-lore agree in this. The elephant is the type of *bonhomie* and easy geniality. It is this belief which encourages its "public" to take liberties with it on which they would venture with no other animal whatever. Perhaps the gentlest of our giant domestic animals are the big shire horses. But no one would expect them to lie down on being pressed with a sharp-pointed goad, or to do work on insufficient food, when ridden and managed by a creature no longer in proportion to their bulk than a monkey, armed with a sharp and painful weapon. Yet the shire horse has no memory for injuries and is at least as docile in his way as the elephant.

There is no doubt that the

POWER OF MEMORY

which the elephant possesses beyond all other beasts, and of reasoning, in which it is supreme, makes its ill-treatment especially dangerous, a danger which is only mitigated, but not removed, by its good nature and extreme patience. Though no one imagines that our English elephant herd is half-starved by the white attendants there is no doubt that these men do not infrequently incur the ill-will of their charges. By long familiarity and constant control the men gradually forget that the creature has a will of its own, and that it has both memory and a power of resentment. They also seem to lose all consciousness of the enormous strength of the beast they manage. Many of the men come to regard them as being as much under control as a traction engine, which only needs the turning on or off of taps to make it advance or recede. As a rule, their only instrument of discipline is a whip; but with this and plenty of shouting and scolding they can "get on the nerves" of an elephant very effectively. In a circus, and it is always in circuses and travelling menageries that these accidents occur, the men who attend the elephants often ride them in performances, and make them perform tricks. A good deal of hurry, some roughness, and occasional punishment are inevitable in these performances, all of which the animal carefully remembers. One day it has a fit of temper, or turns sulky—they will sulk for hours—and then the keeper is attacked. Circus elephants have also a trick of killing people "accidentally." By a movement backwards, or to one side, they will quietly jam a man up against the wall of a stable or a shed. One of the elephants at Olympia did this some years ago, and the first keeper killed by "Charlie" met his fate in this way. It should also be remembered that the elephant is one of the most nervous of all beasts, that one at the Zoo died of sheer fright caused by a thunderstorm, and that a highly nervous temperament of this kind may easily be worked into a frenzy by excitement following ill-treatment. But this is not the fault of elephant temper.—*Spectator*, Feb. 24.

CINNAMON: THE LONDON QUARTERLY SALE.

The news to hand by mail touching the first quarterly sale of cinnamon this year in London must be very cheering to proprietors of estates. While tea is having its weekly ups and downs, cinnamon seems to be holding its own, if not actually forging ahead, notwithstanding unprecedentedly large shipments. During a visit of a couple of days to the Southern Province and a drive of some 20 miles in the country inland between Galle and Dodanduwa, we were greatly surprised to see how freely cinnamon cultivation is being maintained and extended; and the experienced manager of Baddegama assured us that an annual rent of from R25 to R30 an acre can now be got for cinnamon gardens which perhaps had so far not cost more than R50 in outlay per acre. We saw, when reviewing the exports for last year, what immense strides the spice had taken, both in quills and chips, excluding altogether from consideration the wretched fraud separately catalogued as wild cinnamon; and we expressed a natural fear lest heavy shipments coupled with the disturbance which adulteration and spurious spice might create, might lead to a fall in prices. That our apprehensions were rather wide of the mark, we learnt by wire three weeks ago, when a steady market with better prices for fine qualities, and a slight fall for inferior bark, was reported. The information brought by the mail is even more satisfactory than the commercial telegram foreshadowed.

The quantity of plantation spice offered was 1,650 bales, or about the same quantity as in February last year, when the catalogues showed 1,649 bales. We regret to find this comparison omitted in the Report we append; but the usual form has had to be varied in more particulars than one. The natural objection of shippers to their carefully made up bales being undone in London, and rebaled at two or three times the cost of sorting, baling and stencilling here, has led to a great deal of cinnamon being described in the catalogues as "unworked" in London. A further distinction has had to be introduced between "plantation" and "wild" spice; and to find space for these changes, there have been omissions, which we regret, in particulars referring to previous sales. The Report which we published last December on the November auctions, did not distinguish between plantation and wild spice, but merely informed us that the offerings were 4,450 bales of both sorts—an unprecedentedly large catalogue. Of this immense quantity, the proportion of genuine spice was by no means small; and although as much as 1,200 bales of this were cleared in the room, the tone of the sales was reported dull. It is not a little then that, with a full average quantity, the sale last month should have gone off well, the leading marks fetching late rates, and "A S G P" realising exceptionally high prices. This mark represents Golua Pokuna Estate in the Kadirane District, whose produce, under excellent management, has always topped the market; but from 1s 6d to 1s 9d per lb for the first three qualities is

quite a record, and must recall old times. Last November, when "worked" cinnamon of fine quality was in small supply, 1s 5d to 1s 8d were the highest prices, and they were satisfactory; while in February, 1899, the prices were 1s 2d to 1s 5d. So that the figures obtained last month may well be described as exceptional. Nor had "unworked" spice cause to complain, considering the fullness of the offerings. The prices they realised, and the quantity that found buyers in the room, point to the continuance of the demand for good honest spice, as heavy sales are frequently effected after the auctions. Even more satisfactory than the top prices obtained for fine bark, is the news that there was no demand for what is aptly described as "wild rubbish." The last was the second public auction at which wild cinnamon (if such it is) was neglected; and we trust soon to hear that there has been a cessation of disturbing shipments of what is veritable rubbish. How anything fetching 1½d to 1¾d per lb can pay shippers, we fail to see; but care will have to be taken by local buyers that "wild" spice, failing to command a market as such, is not mixed with plantation spice, and an outlet be found for it in that way; It is to be noted that, though the Chamber of Commerce gives no quotation for wild spice, exports have not altogether ceased yet, and last week saw a shipment of chips to the United Kingdom.

We quote as follows from the Report of Messrs. Forbes, Forbes & Co., Ltd. on the February sale:—

CINNAMON.

London, 27th February, 1900.

The first series of public auctions of the year took place yesterday, when about 1,650 bales Ceylon plantation were offered, together with about 1,500 bales wild Ceylon, and a large quantity of low bark &c. The supply of plantation quill was in excess of demand, about half only finding buyers.

The "worked" spice 150 bales met good competition, and the leading marks averaged late rates, except the fine quill A.S.G.P. in estate mark, some lots of which realised exceptionally high prices. The 1,500 bales "unworked" ordinary to medium sorts met a fair demand, some 700 bales being sold at prices, on the whole rather in favour of buyers. "Worked" firsts 1s 5d to 1s 9d; seconds 1s 3d to 1s 7d; thirds 1s 1d to 1s 6d; fourths 8½d to 11½d per lb. "Unworked" firsts 9d to 1s 2d; seconds 8d to 11½d; thirds 6d to 11d; and fourths 4d to 9½d per lb. For the "wild" rubbish there was no demand, a few bales only being sold at 1½d to 1¾d per lb. Of 4,600 packages wild bark, and chips about 1,700 bags sold, wild at 1d to 1½d; middling to good chips 2½d to 4d and quillings up to 10½d per lb.

Stocks of Ceylon 4,109 bales against in 1899 5,239; in 1898 4,193 and in 1897 2,700 bales. There are 2,871 bales of "wild" Ceylon in warehouses. Of wild chips bark &c., 10,067 packages, and ordinary chips 2,736 bags.

The next sales will be held on 28th May.

PLANTING IN THE CAPE COLONY.—The Forestry Department is undertaking the planting of Conifers for timber. At present a quarter of a million is annually paid for imported wood, mostly coniferous.—*Gardeners' Chronicle*, Mar. 3.

SALE OF ESTATES.

PITA RATMALIE GROUP OF ESTATES,
HAPUTALE, PURCHASED BY CEYLON
TEA PLANTATIONS CO., LTD.,
FOR £40,000.

The name of Colonel Lillie was "familiar as a household word" among the early proprietors of estates in Ceylon. Like so many other military officers on the spot, he in the "thirties" and "forties" picked up some choice land between Kandy and Ramboda; but he also later, through his agents, secured a very valuable block in Haputale which became known as the "Pita Ratmalie and Pitarat Lillie estates," covering 1,603 acres in all. The management was for many years in the hands of "Dick Wyllie" and latterly of Mr. A. I. Kirk. Of course, the worthy proprietor, Colonel Lillie, has long been dead and his property out here has been held by trustees, for whom Messrs. Geo. Steuart & Co. are agents. Besides the Haputale estates just sold, they still hold Nayapane estate in the Pussellawa district.

It is an extensive investment, the purchase money being stated at £40,000 and will afford scope for some of the reserve money of this prosperous Company. The bargain would seem to be a good one for the Company, even if the large area of coffee is not regarded as a stable industry; for the total figures are given as follows:—

Tea	466 acres.
Coffee	294 "
Grass and Timber	35 "
Jungle	808 "

Total .. 1,603 acres.

The tea is very good, and the large reserve of jungle is described as of fine soil, high elevation (5,000 feet and upwards) and most of it well sheltered, so that it alone ought to be worth a considerable proportion of the purchase money. If the coffee is in good heart and can be kept up by liberal cultivation and attention to enemies (now chiefly "bug" we suppose) the purchase may at once give some good crops to the Company. In any case this transaction indicates much confidence in the future of our staple, tea, and of high-grown tea in particular. We congratulate Mr. H. K. Rutherford, as Managing Director of the C.T.P. Company, on this latest addition to its properties.

EXPERIMENTS IN THE GROWTH OF SUGAR BEET.—At a recent meeting of the Sugar Beet Committee of the Central Chamber of Agriculture, Colonel Victor Milward, MP in the chair, it was decided to make arrangements for a series of not less than 20 experiments in the growth of sugar beet in different parts of Great Britain and Ireland during the forthcoming season, each experimental plot to be at least one acre in extent. It is proposed that of the 20 experiments about 12 should be in England, four in Scotland, and four in Ireland. As in certain cases previous experiments have demonstrated the value of sugar beet for the feeding of stock, independently of the value of the root for the manufacture of sugar this point will be specially kept in view in connexion with the proposed experiments of the present year.—*London Times*, Feb. 23.

Correspondence.

To the Editor.

TEA CULTIVATION AND MANURE.

DEAR SIR,—Where do you get tea estates upcountry formed out of “virgin soil” except perhaps “High Forests”? There can only be about 100 acres of such soil on Loolcondera. It was, as a whole, long before planted in coffee.* In the lowcountry, of course, there are estates that fulfil these conditions and have been some time now in tea—sixteen years at any rate—such as Kanangama in Delhiowita, in the Kelani Valley. Mr. Taylor of Loolcondera, told his friends, of whom I was one, that manuring only gave increased crops in the ratio of what the land naturally gave when first opened. An estate that never paid from its commencement without manure, would never pay by the application of manure, for such application would be costly and give no remunerative return. *Ex nihilo nihil fit.*

My impression is, and I know it is shared by others, that tea planted in new clearings now, with the best seed available, does not give so quick or so good returns, as young tea planted, say ten or twelve years ago.

It is quite possible that Mr. Fraser's imitators will not get the same returns from their manuring as he did—though no doubt he will give them the best advice possible—because he commenced manuring trees that had been planted with tea seed in its prime, and the atmosphere was not poisoned by the immense area of tea now planted all over Ceylon taking up the same ingredients in their cultivation and throwing out the same excreta and gases.

I met an intelligent planter the other day, who told me that he had been recommended to bury his prunings, because by leaving them on the surface he lost in three prunings what could only be given him by an ordinary manuring. He said: “Well, my estate soil is alive with white ants. They will soon eat all my prunings and migrate elsewhere: don't they take the chemical ingredients of my prunings with them, and may they not in the laboratory of their stomachs evolve poisonous excreta that will produce some beastliness on my tea that may affect its price, or my bushes that may affect the bearing?” “My dear friend,” said I, “get Mr. Bamber's opinion on the subject; let him analyse your prunings, your white ants, previous to and after gorging on your prunings, and mention my name, so that the fees you will have to pay the worthy Analyst will be credited against my guarantee.”

Is it the case that the wily planter, now that he has from the P.A. in Mr. Kelway Bamber's pamphlet the analyses of the soils on typical estates and Mr. Bamber's prescription for the manure needed for such estates, is quite satisfied to use such manure,

and so Mr. Kelway Bamber's “occupation is gone” as a soil analyst?! OLD HAND.

[Surely “Old Hand” will admit that the whole of the tea in the Nuwara Eliya and Kandapola districts was planted direct on forest-land—so with a great deal in Upper Dimbula, Upper Dikoya and Maskeliya, and what about Balangoda? In fact, there are few districts, even in the Central Province, where some reserves of “forest” have not been planted within the tea era.—ED. T.A.]

THE NEW TEA DUTY AND PLANTERS.

DEAR SIR.—So 2d. extra tea duty is to be our war burden. The producer can ill afford it, let it be shared by the consumer and the dealers. Instead of manuring let the growers allow to lie fallow for a year a quarter of the cultivated area, and we shall then bring down on their bended knees, the wily blenders and mammoth dealers. Knock down our export 20,000,000 lb. instead of raising it 30,000,000 by manure and 10d will be the Ceylon average.—Yours truly,

TEA FARMER.

[Most satisfactory of results; but who is to nock down the export—or rather the “manuring”? “Who will bell the cat” by declaring who may, and who may not indulge in Manure?!—ED. T.A.]

THE NEED OF ADVERTISING ALL ESTATES FOR SALE.

Upcountry, March 16.

SIR,—How is it that the fact of large estates in Ceylon being for sale is sometimes, kept so quiet, in place of being generally and freely advertised? We all remember Lipton's great bargain in getting poor Downall's estates from Messrs. Antony Gibbs by private negotiation, for £25,000—when, had the places been advertised, there were those in Ceylon at the time who could raise £30,000 or more to secure so fine a group. Now it is another Haputale group sold for £40,000 and I have heard one gentleman at least, who could easily have paid the amount, say “A very good bargain—had I known of the places being for sale, I should certainly have made an offer”—and perhaps a better one!—Your truly,

THE AGRICULTURAL SCHOOL.

ANNUAL PRIZE-GIVING.

On Saturday, March 31, the annual prize-giving of this institution was held in the presence of a large gathering presided over by Mr. S M Burrows, Director of Public Instruction. Much pains

had been bestowed to decorate the main hall and the long corridor leading to it, and the effect presented was most pleasing. A well constructed pandal was put up at the entrance, bearing the inscription "Welcome to Mr. S M Burrows, Director of Public Instruction." Among those present were:—Lady and Miss Grenier, Mrs. Ferguson and Misses Williams and Macdougall (of Madras), Mrs C Drieberg, the Very Rev Father Collin, Rev Brothers William, Edmond and Cassian, Messrs J Harward, E Elliott, Jas Pieris, Jacob de Mel, W Arthur De Silva, Mrs North, Mr Scott Given, Mr Francis Beven, the Misses Beven and Drieberg, Dr and Mrs J B Drieberg, Mrs Bawa, Arthur Bawa, Dr Chinniah, Morgan de Saram and the Misses Bawa, Messrs B W Bawa, Allan Drieberg, the Misses Barber, Mrs H O Beven, the Misses Vanderstraaten, Mr. R H Ferguson, and many others.

Mr. BURROWS called upon Mr Drieberg, the Superintendent of the School, to read

THE PRINCIPAL'S REPORT.

I have much pleasure in offering a hearty welcome to our new Director, who is present for the first time at a public function connected with this Institution.

Let it be admitted that such enthusiasm as Mr. Green (the founder of this School) showed in matters Agricultural was rare, and that the School

suffered for lack of interest on the part of his successor, when it is seriously proposed to dissociate this Institution from the Educational Department. I venture to think that so sweeping a change is ill-conceived at the present time, when we have as our head one who is so eminently fitted to be Director, both of Education and Agriculture, who may be expected to avoid the mistakes which the founder of the School (like all pioneers) was bound to make, and to pursue an enlightened policy based on his experience of the country and a knowledge of the requirements of the people.

During the last few weeks, in addition to the usual annual report, I have, at the request of the Director, prepared a special memorandum dealing fully with the school, its past, present and future. But you will, I feel sure, prefer to read these documents when they appear in print, or to call for them whenever it may suit your convenience, rather than that I should take advantage of your kind presence here today to intrude them upon your attention. I shall therefore occupy very little of your time. I will not repeat the recommendations which I have from time to time offered in previous reports, for making this institution serve its object more worthily. I must say, however, that I have begun to be a little hopeful of some of these recommendations being carried into effect, if the sympathy of the head of a department counts for anything. And this is naturally a source of satisfaction after years of unsatisfied expectancy. There are, moreover, rumours of a special Committee having been appointed to deal with the school—a circumstance which is calculated to strengthen our hope that some definite measures for the good of the school will soon be decided on.

As regards numbers, our largest number on the roll last year was 22, and the average for the year 16.

These are rather below the normal: the full complement being 25 and the usual average 20. The decrease is to be attributed to the uncertainty attaching to the future of the school. Indeed, the wonder is that, under present conditions, our numbers are what they are. In India, with greater inducements for the study of agriculture, and with prospects of employment to trained students, there are instances of the attendance at agricultural classes being far more disappointing. Were we only half as fortunate as our sister institutions in India as regards financial aid, provision for a thorough course of training and inducements offered to students, the School of Agriculture will be rather a different institution to what it is.

On the results of the final examination held last November, three students became entitled to the first class certificate of merit granted by the Department.

Veterinary training continues to form part of the School course and already three old boys of the school have fully qualified as veterinary surgeons, while two others have lately been appointed stock-inspectors. The present Government Veterinary Scholar is J E Fernando—also a late student of the school—who left for Bombay at the end of last year to prosecute his studies at the Veterinary College there. He succeeded Veterinary Surgeon Chinniah, who, with commendable enterprise, started practice in Colombo on his own account—a departure which, I believe, he has no reason to regret.

The other institutions (the existence of which few persons are aware of) located in this building are the Government Training and Practising Schools and the School of Forestry. But of these I have no excuse to say anything today. The Government Dairy, however, is more intimately connected with the School of Agriculture, and I am able to report that it has been working satisfactorily during the past year. We have now in the Dairy 82 cows, 72 calves and seven bulls, or a total of 161 animals.

The net profit from the Dairy on last year's working was nearly R2,500, while that from the Model Farm exceeded R3,000. In addition to this a sum of R4,337 was realized by the sale of stock, principally young stock bred on the farm. The Dairy has now paid back to Government the sum of R11,500 advanced for working of the concern; over and above which it has refunded a sum of nearly R13,000, against an initial expenditure of R19,539 on buildings and equipment. But then our stock-in-trade was at the end of last year reasonably estimated to be worth R13,500, a sum which, I think, the most cautious speculator would be willing to give for it. But, while all this is very satisfactory, the School of Agriculture of which the Dairy is an offshoot, derives no advantage by the prosperity of the latter.

It is a pleasure to me to be able to count Mr. Harward among the speakers this evening. The short time he acted as Director was more than sufficient to impress us with his worth, and for his continued interest in this institution we are most grateful.

I must not omit to acknowledge our indebtedness to Mr. J W C De Soysa, who with traditional liberality, continues to present the handsome prize which the late Mr. Charles De Soysa first offered for competition among our students.

Finally, I have the pleasant duty of thanking you, ladies and gentlemen, for your encouraging presence here today, for, I say it regretfully, our friends are all too few.

The prizes were distributed by the Chairman:—

THE PRIZE LIST.

SENIOR FORM:—1, English, E W Jayatilleke; 2, Mathematics, G S Jayasinghe; 3, Agriculture, G S Jayasinghe; 4, Science, P C Fernando; 5, Practical Chemistry, G S Jayasinghe; 6, Veterinary, E W Jayatilleke.

JUNIOR FORM:—1, English, M D S A Wijenaik; 2, Mathematics, C S Fernando; 3, Agriculture, M D S A Wijenaik; 4, Science, M D S A Wijenaik; 5, Veterinary, C S Fernando; 6, Dairying, M D S A Wijenaik.

The following are the winners of the certificates:—E W Jayatilleke, G S Jayasinghe, P C J Fernando.

THE CHAIRMAN'S SPEECH.

The CHAIRMAN said, after some introductory remarks, that in Ceylon the very best reason for making a speech was that one practically knew nothing of the subject on which he was speaking. (Laughter.) He had been appointed on a great and awful Committee sitting to discuss the future of the Agricultural School. The Committee was composed of men whose very titles would fill them with awe, and if he divulged any of their

secrets he would probably be condemned to death by sealing wax or choked to death by red tape. Therefore, his hands were tied in that direction entirely. It was impossible to say what the future of the Agricultural School would be. But he would like to say something of its past. It was the hobby of a very old friend of his—Mr. H. W. Green. Mr. Green was a man on whom the vials of criticism were freely poured. People were very ready to criticise and to show how much better they could have done a thing themselves. But there was this to say of Mr. Green—unlike certain other people, he attempted to do something. But few people realised what he had in mind, and when he started the Agricultural School people said he was trying to do an impossible thing—to improve agriculture in Ceylon! Personally, he (Mr. Burrows) did not believe it was impossible. There were various methods of doing it, and people might differ very widely as to the best methods to adopt, but the best way to set about it was to make some effort in some direction. Mr. Green did make an effort, and he deserved intense gratitude for the effort he made. And that brought him (the speaker) to the obvious conclusion that the gentleman to whom was entrusted the carrying out of Mr. Green's ideas deserved the fullest measure of praise. It was not easy to carry on an institution to which help had not always been given. The School of Agriculture, however, had not wanted the energy and perseverance of Mr. Drieberg. Those advantages had been most fully and ably offered. Mr. Drieberg could look back on the fact that he had trained 25 or 30 men who had taken to the career that was predestined for them and they were thoroughly creditable to the training they had received. Those present should all join in congratulating Mr. Drieberg most heartily upon the admirable work he had done in the school.

MR. HARWARD'S COMMENTS.

Mr. HARWARD said that during a short tenure of the office of Acting Director of Public Instruction, it was a great pleasure to him to be very constantly, for different reasons, within those premises. In fact he became nearly as familiar with them as with those of the Royal College. It was true he did not go there with any knowledge of the subject of Agriculture proper, nor with any ideas to suggest to the Superintendent of the School. Mr. Drieberg was, however, kind enough to go very fully into the question of what his school course was, and how the time of the students was occupied, and he had formed the idea,—and still had the idea—that so far as his opportunities went, and so far as means allowed and the existing constitution of the school admitted, he was doing his very best for it. He also received intimation from the public press and elsewhere that considerable changes were contemplated with regard to the school, and that, in fact, even a Commission was sitting, which was deliberating as to its future destiny. Of the verdict of that Commission he knew nothing, but he hoped they might regard the present state of the School of Agriculture, so far as Agriculture itself was concerned, as being in a chrysalis state, and that something further would be done for it which would enable it to put forth wings and assume the splendours of the butterfly, and let them hope, when it was in that condition also it would be associated with the able management of Mr. Drieberg. (Applause.) One thing was certain,

and that was that the School had not had a fair chance in the past. He did not mean to say there would have been anything necessarily defective in the ideas with which it was started, but funds had not been forthcoming for the full carrying out of those ideas, and changes had been introduced from time to time which had prevented the carrying out of any one consistent idea. In estimating in any way the work of that school, they must not lose sight of the fact that it had formed a centre round which a very large amount of useful work had been done in other subjects than those of Agriculture, strictly speaking, and by Mr. Rodrigo, the Manager of the Dairy, and he had no hesitation in saying, that its existence had been of very great service to the School had served as a centre, to which was to be attached a Forestry Class, which had also done excellent work. It had been of great use also to the Department of Public Instruction by providing a local habitation to what was of very great use to the Department, namely a small Government Training School, and he might add that those who had been trained in that school had derived very useful knowledge of Agricultural principles, by being associated with that building. Ceylon was essentially an agricultural country. Living in Colombo they were apt to lose sight of that fact. They saw very little of agriculture in Colombo. The eyes of the people were rather fixed on trade and commerce and things in the way of manufacture, and were apt to lose sight of the fact that Ceylon was essentially an agricultural country, and was dependent for its prosperity mainly on agriculture of various kinds. It ought to be an axiom, that an Agricultural School or College ought to be one of the educational institutions of the island. (Applause).

PRACTICAL AGRICULTURE.

Mr. E. ELLIOTT said he had simply come there, being naturally interested in the occasion, and to hear what had been doing in the School for the last few years. Some years ago he addressed them on a similar occasion. He was then a Government Agent. He was now a *Goiya*. (Laughter.) He had practical experience for the last three years of growing a considerable extent of paddy, and he had had, like a great many pioneers, to buy his experience. He had no reason to regret what he had done, and he hoped that before long he would be able to satisfy men of business of the soundness of the venture he had embarked on, and he was sure there would be a good many people, erelong, who would regret that they did not go in for coconuts and other low-country products. Of course, there was a great difference between the practical growing of a large area—he had 500 acres of paddy—and the theoretical growing of two acres, under an instructor. One could not repeat on a large scale the immediate results of what was practically horticulture. What he had seen of the students educated in that school convinced him that they were very satisfactory men. Several in the Eastern Province worked with him, and he was at present assisted very ably by a gentleman—a relative of the superintendent and bearing the same name. That gentleman had been most useful to him as an assistant, and the practical education which he had received in that school had been of most valuable assistance to him, and would be, he trusted, of still greater value in time to come. He (Mr. Elliott) could quite sup-

port the view which Mr. Harward had enunciated, that the Agricultural School had been a decided success, though working under considerable difficulties for a number of years past. He had also had several communications with Mr. Drieberg who had given him various hints and assisted him in getting various kinds of paddy, etc., and he was glad to be able to publicly acknowledge all that had been said of him on that occasion. He trusted that the new scheme, that was under consideration for improving the school would include some arrangement for giving the school a good large piece of decent land. They could not do much on the adjacent cinnamon land. What they wanted was a plot of 50 or 100 acres of land, which they could practically cultivate on a respectable scale and make experiments on. Experiments, of course, cost money, and people who were working for profits could not afford to make experiments as fully and exhaustively as a Government institution could. All over America there were Government farms, kept up at Government expense, where all sorts of things were grown and all sorts of manures were tried, and the results published. That was what was wanted in Ceylon, not only as regards paddy, but even with other products. The native cultivator, after all, was not such a bad cultivator as some people thought. He was no modern agriculturist it was true, but he had generations of experience and tradition, which stood him in very good stead. If he had had more time he might have put together some more ideas. Living as he did, in the jungle, did not train him to public speaking. (Laughter.) As Mr. Drieberg had said, he hoped, if there was any change, that it would not be of such a nature as to take the school out of the fostering care of Mr. Burrows. (Applause.)

THE MAYOR'S FORECAST: CATTLE DISEASE MAY BE STAMPED OUT.

Mr. PRICE (Mayor of Colombo) proposed a vote of thanks to the Director of Public Instruction for so ably presiding at that meeting. They had all listened with much pleasure and gratification to his eloquent address; and equally to the speech which Mr. Harward had given with his accustomed ability, and similarly to the practical remarks which fell from Mr. Elliott. None of them who lived here and there settled in this country could affect to ignore the importance of agriculture, and he had listened with attention to the report which Mr. Drieberg read at the outset of the proceedings. One point specially attracted his attention, and that was what he said—and others touched on afterwards—with reference to the education of Veterinary Surgeons. That was most important as they all knew. He specially recognized the importance, because a short time ago—a few months ago—he was considering and elaborating with the aid of Mr. W A de Silva, a scheme for quarantining all cattle imported into Ceylon from India, the object in view being to stamp out all cattle disease. At first they thought that if they obtained money and elaborated a scheme and obtained the necessary legislation to enable them to inspect and quarantine every head of cattle imported from India, they might be confident they would then succeed in eventually stamping out cattle disease in Ceylon. However he went to work slowly, on purpose, and after discussing it with officers of greater experience, they came to the conclusion that the measure proposed was a good one; but, he thought

that it would not be sufficient, because there were centres of affection in Ceylon where the disease had to be stamped out. To stamp it out they wanted a trained staff of Veterinary Surgeons. If the School of Agriculture trained Veterinary Surgeons, and if the authorities in Colombo, where the school was in progress, provided a scheme of quarantine that could be elaborated, he saw every prospect of a most material benefit accruing to Ceylon, namely the total stamping out of cattle disease. He commended the idea to the head of the School and to the head of the Department, and he felt they would all endorse his proposal that they should pass a vote of thanks to the Director of Public Instruction for presiding on the occasion. (Applause.)

Cheers were given for the chairman, Mrs. Burrows, Mr. Harward and Mr. and Mrs. C. Drieberg, and a musical entertainment, in which several amateurs took part, concluded the interesting and instructive proceedings.

(From the "Ceylon Observer.")

The periodical function at the Agricultural School which took place in the school hall on Saturday was a pronounced success. Mr. Drieberg's report, which we published in our issue of that evening, was eminently encouraging; and its contents, taken as a whole, appeared to us scarcely to justify the note of, we might almost say, despondency with which it closed. Yet it is perhaps too true that expert agricultural training in new and improved methods of cultivation has not yet acquired that popularity which the sterling work accomplished by both present and past students of the School already, fully merits. It is, indeed, to be hoped that the "Committee now sitting on the future of the school," as Mr. Burrows put it, has in mind some such scheme of extending the experimental scope of the Institution as that which the third speaker, Mr. Edward Elliott, suggested—namely, to grant for the school property (probably near Kandy) something like 50 to 100 acres on which sufficiently extensive and instructive scientific work could be done. Mr. Elliott spoke as an experienced paddy cultivator, one, too, who had had personal contact with students from the school and who bore testimony to their practical worth.

Mr. Burrows on Saturday gave another specimen of his remarkable powers as a skilful as well as lively speaker. "Skilful" is scarcely sufficient—"brilliant" would be more suitably applied to portions of his rapid speech which were filled with robust humour. Mr. Burrows knows how to be immeasurably entertaining while telling you nothing at all; and this is anything but a fault in an official who is barred from unfolding state secrets. But his audience can sometimes barely keep up with him. Speaking on his pledged secrecy with regard to the verdict of the Committee on the Agricultural School he brought out the following:—"If I were to reveal to you one morsel of their verdict, I suppose I would be condemned to death by sealing-wax, choked up with red-tape, or swept out of existence by whatever other form of electrocution the Government are accustomed to use." But

his listeners had not properly assimilated this rich mouthful before the speaker had got on to more serious stuff, and neither laughter nor applause were forthcoming in time!

Of the other speakers we have already referred to Mr. Elliott. Mr. Harward once more gave a clear, concise and instructive speech which was specially welcomed as from one who knew more about the Agricultural School, perhaps, than any one present—the Principal, of course, excepted. And that Mr. Harward should publicly state his conviction that all he had seen went to show that Mr. Drieberg had "done his very best" must have been the most gratifying testimony to the zealous, enthusiastic and indefatigable head of the only Government Agricultural Institution in our island. The Mayor closed the prize-giving proper with a short speech, referring especially to the progress of Veterinary science and practice in the island through the medium of the school. The rest of the proceedings partook of a social nature.

PRACTICAL HINTS TO HORSE OWNERS.

BY A. CHINNIAM, G.B.V.C.

(Continued.)

Partition.—There are many materials that are used for partitioning stables. The best of them is a brick wall partition. The next in order comes thick wooden planks. I have noticed in some stables cadjan partitions and thin board partitions, but these are frequently the causes of accidents. But any material may be used which answers the purposes, which is durable and is a bad conductor of heat or cold. Whitewashing the walls should be periodically done and glaring colours should be avoided as far as feasible. A light blue or green tint is to be preferred. Tarring the walls is resorted to by some stable owners, and this is undoubtedly a good thing, especially in stables where there are more than one animal. In cases of contagious diseases such

walls are less liable to contamination. In big stables it is usual for the sake of convenience to have temporary partitions slung upon on chains or iron bars; in such establishments these partitions are less costly and are of great practical use when carefully managed.

Space.—The space allowed for a single horse should not be below 12 feet by 12 by 16 feet. The passage into the stable ought to be broad and high, and if doors are used they must be very simple in construction and should always open outside. If bars be used they must be strong and so fitted as to be easily removed.

Roof.—A tiled roof is probably the best. If galvanized iron is preferred it is very essential to have a wooden ceiling so constructed as to allow the free circulation of air between the roofing and the ceiling.

Ventilation.—The ingress and egress of atmospheric air must be well regulated. It is an undoubted fact in the animal economy that the proper ventilation forms one of the main features that go to contribute to the health and comfort of the creature. This is in many cases ignored, and hence the animal suffers from mange and other skin diseases, inflammation of the eye membrane, &c. The door or the entrance to the stable is of course the chief means of ventilation.

In addition to the door there must be a window opposite to the door and at a height just above the head of the animal. And just below the window there should be a floor ventilator. Square pieces 2 x 2 feet of earthenware ventilators are generally used. In some instances galvanized iron is used. Let any material be used, but care must be taken that the free passage of air does not become interrupted, while at the same time there should be no possibility of reptiles creeping in. Floor ventilation is invariably neglected in Ceylon, but it is of the greatest importance as being the means of carrying off the heavy foul air which otherwise requires a high temperature to make it rise to the level of the window or upper ventilators. Further, it dries up the floor and keeps the stable sweet.

The Window.—It is necessary as already stated to have the window just above the head of the horse. It should also be so constructed as not to admit of bottles and other articles being placed on the ledge. I have heard instances where the horses were burnt to death by such lamps placed on the window ledge falling on the bedding. The wings of the windows should be made to move horizontally on two sockets, so that it may open and close according to the direction of wind.

THE CLASSIFICATION OF FIBRES.

(Continued.)

In this arrangement I have separated the fibrous substances derived from plants into five groups, according to their use in the plant economy, as well as in relation to part of the plant employed. The first and third groups follow the natural division of the two great vegetable kingdoms into exogenous and endogenous plants; the second group confined wholly to the first division, but only fibrous in a sense; the fourth group pertaining to both, but more largely confined to the first division,

while the fifth group is comprised of low orders of plants that are not fibrous at all, but which are chiefly used as cheap substitutes of better packing materials. The classification is as follows:—

A. FIBRO-VASCULAR STRUCTURE.

1. Bast Fibres.

Derived from the inner fibrous bark of decotyledonous plants or exogens or outside growers. They are composed of bast cells, the ends of which overlap each other so as to form in mass a filament. They occupy the phloem portion of the fibro-vascular bundles, and their utility in nature is to give strength and flexibility to the tissue.

2. Woody Fibres.

(a) The stems and twigs of exogenous plants, simply stripped of their bark and used entire, or separated into widths, for weaving or plaiting into basketry.

(b) The entire or subdivided roots of exogenous plants, to be employed for the same purpose or as tie material, or as very coarse thread for stitching or binding.

(c) The wood of exogenous trees easily divisible into layers or splints for the same purposes, or more finely subdivided into thread-like shadings for packing material.

(d) The wood of certain soft species of exogenous trees after grinding and converting by chemical means into wood pulp, which is simple cellulose, and similar woods more carefully prepared for the manufacture of artificial silk.

3. Structural Fibres.

(a) Derived from the structural system of the stalks, leaf stems, and leaves or other parts of monocotyledonous plants or inside growers occurring as isolated fibro-vascular bundles and surrounded by a pithy spongy, corky, or often a soft succulent cellular mass covered with a thick epidermis. They give to the plant rigidity and toughness, thus enabling it to resist injury from the elements, and they also serve as water vessels.

(b) The whole stems, or roots or leaves or split and shredded leaves of monocotyledonous plants.

(c) The fibrous portion of the leaves or fruits of certain exogenous plants when deprived of their epidermis and soft cellular tissue.

B. SIMPLE CELLULAR STRUCTURE.

4. Surface Fibres.

(a) The down or hairs surrounding the seeds, or seed envelopes of exogenous plants, which are usually contained in a husk, pod, or capsule.

(b) Hairlike growths or tomentum, found on the surfaces of the stems and leaves or on the leaf buds of both divisions of plants.

(c) Fibrous material produced in the form of epidermal strips from the leaves of certain endogenous species, as the palms.

5. Pseudo-fibres, or false fibrous material.

(a) Certain of the mosses, as the species of Sphagnum for packing material.

(b) Certain leaves and marine weeds, the dried substance of which forms a more delicate packing material.

(c) Seaweeds wrought into lines or cordage.

(d) Fungous growths, or the mycelium of certain fungi that may be applied to economic uses, for which some of the true fibres are employed.

The bast fibres, derived from the bark of exogenous plants, such as trees, shrubs, the climbing vines, herbaceous vegetation generally, are clearly defined, and the fibres of all species of such plants, when simply stripped, are similar in form as to outward appearance, differing chiefly in colour, fineness and strength. An example of a fine bast fibre is the ribbons or filaments of hemp, and of a coarser form, the bast from the linden or cedar. A variation in form should be noted in the lacebarks and the paper barks, where the bundles of fibres which interlace may be peeled off in the form of thin, flat strips. The woody fibres are only fibrous in a broad sense, as their cellulose is broken down and all extraneous matter removed by chemical means, as for the manufacture of paper pulp or of artificial silk. The greater number are merely wood in the form of flexible slender twigs or osiers that are useful for making baskets; or the larger branches may be split or subdivided into strips, withes, or flat ribbons of wood for making coarser baskets. The softer woods still further subdivided give the product known as excelsior, which can only claim a place in a list of fibre plants, because it is a substitute for upholstery or packing material. Structural fibres are found in many forms, some of which may be enumerated as follows:—The stiff, white or yellowish fibres forming the structure of all fleshy-leaved or aloe-like plants, as the century plant, the Yuccas, Agave, and pineapple or the leaf trunk of the banana, as an example, rival hemp of commerce; the coarser bundles of stiff, fibrous substance which gives strength to the trunks, leaf, stems (mid-ribs and veins), and even the leaves of palms, a good example being *Piassaba*, derived from the dilated margins of the petioles of a palm, where they clasp the stem, these are made into thin strips which afterwards split into smooth, cylindrical fibres. Another example is the stiff fibres extracted by maceration from the "boots" or bases of the leaf stems of the cabbage palmetto, or the shredded leaves of the American fan-palm, known as *Crinvégétal*. Other familiar examples may be noted in strips rattan, the fibrous material derived from bamboo, from the cornstalk, the flower stems of broom corn, and from reeds sedges, and the true grasses. Still another form is the fibrous mass surrounding the fruit of the coconut, known as coir, and as a curious example may be noted the fibre from pine needles, a notable exception of a structural fibre derived from an exogenous plant, the fibrous mass filling the sponge cucumber being another.

MODERN AGRICULTURAL SCIENCE.

(Concluded.)

But, every thing comes to him who waits, and at last the time came when the doctrines of the New Soil Science could be tested under the most favourable conditions. The post of land agent on Lord Rosebery's Scottish estates became vacant, and Mr. Drysdale, the gentleman who was appointed to that highly-responsible post, was an old pupil of Mr. Hunter's. Mr. Drysdale was wholly unfettered by any feeling of blind loyalty to orthodox doctrines in agricultural science, and, after carefully examining for

himself the later developments in the New Soil Science, he came to the conclusion that it was desirable to have these new ideas put to the test in actual farm practice. He accordingly commenced experimenting on a small scale in various fields, and with such satisfactory results that, with the cordial approval of Lord Rosebery, it was decided to extend the work. In the Spring of 1895, therefore, a thoroughly well-equipped experimental station was established on his Lordship's farm, at Dalmeny Park, with Mr. Hunter as scientific adviser, the practical work being under the personal supervision of Mr. Drysdale himself. Part of the station was devoted to testing the relative productiveness of different varieties of grain, potatoes, &c., another part was devoted to bacteriological research work, and the remainder of the station was worked as a miniature farm on the four-course rotation, each section being subdivided into sixteen plots, which were all differently manured on a regular system. A good-sized volume would be required to detail the results, which have been most consistent throughout, obtained at this station in the last four years, during which time the station has been annually visited by hundreds of deeply-interested agriculturists. A few of the more notable results, may, however, be briefly summarised. In the first season the beneficial results of a small dressing of ground lime were so marked that the system of applying to every field on the farm an annual dressing of 4 cwts. of lime was commenced, and has been continued ever since. In order that the small dressing should be equally distributed over the soil, Mr. Hunter procured ground lime, *i.e.*, ordinary burned lime shells mechanically ground to a fine state of division. At first this ground lime was applied in the compost form, but the second year's experience showed that it was equally effective and less costly when applied direct in the hot state when the land was being worked, the small quantity of hot lime applied being insufficient to injure the nitrifying and other soil organisms, besides being rapidly converted into the carbonate form when worked into the soil. It was also found that when the lime required by the nitrifying and other soil organisms was thus supplied, the plots which had received their nitrogen in the form of sulphate of ammonia showed much better crops, alike as to quantity and quality than were obtained from plots which got their nitrogen in the form of nitrate of soda. Mineral superphosphate, supplemented in the case of the potato and root crops with fermented bones, proved the most satisfactory form of phosphate. The Dalmeny experiment also emphasised the importance of potash for every crop, particularly the leguminous, potatoes, and root crops. With a moderate dressing of farmyard manure, supplemented with 4 cwts. ground lime applied at the working of the land, and followed by 4 cwts. superphosphate, 1 cwt. fermented bones, 2 cwts. of kainits and 1 cwt. of sulphate of ammonia, the Dalmeny Home farm produces crops which are the admiration of all who see them. Another most important branch of investigation was in regard to the destructive pest of finger-and-toe in turnips,

a pest which had previously baffled the skill of experimenters. The Dalmeny experimenters knew that a heavy dressing of caustic lime would kill the germ of finger-and-toe, but it would also kill the nitrifying and other advantageous soil organisms, while, on the other hand, a small dressing of 4 cwts. per acre would be insufficient to kill the disease germ. They therefore steered a middle course so as to avoid the Scylla on the one hand and the Charybdis on the other, by applying one ton of ground lime per acre when the land was being ploughed in the autumn, and another ton per acre when the land was being worked in the spring. In this case they rigidly avoided the use of dissolved phosphates and used undissolved phosphates supplemented with 8 cwts. kainit and 1 cwt. sulphate of ammonia. This treatment proved a complete success, and the root crops grown by this system on infested soil were found to be sound and good, while those grown on the same soil under different treatment were so rotten as hardly to be worth removing. It was noted, however, that though this treatment was successful in eradicating the disease, the crop was decidedly smaller than that grown on uninfested land to which only a tenth of the same amount of lime had been applied. A word in conclusion may be added as to the far-reaching effect of the Dalmeny experiments. When these experiments were commenced, ground lime for agricultural purposes had never been heard of, whereas now there are at least six lime works where extensive grinding 'plant' is kept hard at work to supply the ever-increasing demand for that substance. Since the principles of the New Soil Science have been put in successful practice at Dalmeny, the scientific authorities, who at first had branded these principles as absurd heresies, have changed their tune, and in the recently-published volume of the Highland Society's Transactions, the chemical adviser of that society has unreservedly declared his acceptance of these new doctrines. Great credit is due to Lord Rosebery for not only providing the means of carrying on this important research work, but also for throwing his home farm and experimental grounds open for the inspection and information of agriculturists.

[Note by the Editor *Agricultural Magazine*.—"Years before Hellriegel announced his discovery in 1836, Messrs. Hunter and McAlpine were teaching the same fact to their students, as the lecture notes of any of their students at that time can testify." As a student both of Mr. John Hunter, one of the extra-mural teachers of Agricultural Chemistry, and Professor McAlpine, the popular lecturer on Botany at Minto House, we can fully endorse the above from our personal experience as well as from our 'lecture notes,' and it gives us very great pleasure to press the claims of our old teachers in Edinburgh to the discovery, as indeed we did in the pages of the *Agricultural Magazine* as soon as we read of "Hellriegel's discovery" shortly after our arrival in the Island. To us the "new theory" was familiar enough from acquaintance gained in the class-rooms at Edinburgh."]

THE SOLUBLE MINERAL MATTER OF SOILS.

By THOMAS H. MEANS.

Assistant in the Division of Soils U.S. Dept. of Agriculture.

(Concluded.)

If in the piece of granite referred to in the beginning of this paper the rain water had not been allowed to wash out the soluble matter as it was formed, there would have been found a quantity of white salt in the rock powder and in the resultant soil. If the quantity of this white salt had been great, as much as 2 or 3 per cent of the weight of the rock, it would have been difficult or impossible to get a plant to grow in the soil. This has been the experience the world over, that plants will not grow in a soil that contains too much soluble matter.

In arid countries there is not sufficient rainfall to remove all of the soluble matter as it is formed in the decay of rocks and soils, and the result is an accumulation of salts within the soil. In still other parts of the country, where more rain falls, the salts may be washed out, but the solution runs down into inclosed basins having no connection with the ocean, and there evaporates, depositing the salts. In either of these cases plants suffer when the amount of salts reaches a certain per cent. It can safely be said that few crops can flourish when soluble matter amounting to one-half of 1 per cent of the weight of the soil is in solution around the soil grains when the soil is saturated with moisture. As the water of saturation weighs from 25 to 75 per cent of the dry weight of the soil, it will be seen that crops will not thrive when the solution contains more than 1 per cent of the soluble matter. When the concentration of the soil solution reaches this per cent, the leaves of alfalfa turn yellow, wither, and die, just as the plant would do if drought prevailed.

In arid regions where the amount of rainfall is small, the amount of water which leaches through the soil is not sufficient to wash out all of the soluble matter. For this reason the amount of soluble matter in the western soils exceeds the amount of soluble matter in the eastern soils of the United States. The following table shows the relation between the amounts of soluble matter in the soils of different parts of the country:—

Relative amounts of salts in soils.

Kind of soil.	Locality.	Per cent soluble matter.	Pounds soluble matter per acre-foot.
Prairie ...	Kansas, Nebraska	0.033	1,155
Limestone ...	Virginia, Maryland, Pennsylvaniam, Kentucky	.017	595
Gneiss ...	Virginia, North Carolina	.077	245
Truck ...	Maryland, Virginia, North Carolina	.006	210
Subtropical.	Florida	.0012	42

The prairie soils throughout the West show large amounts of soluble matter, and they are exceedingly productive when enough rain falls to keep the soil in a moist condition. Of the soils of the humid regions, those formed from limestone show the greatest percentage of soluble matter. In general,

it will be found that in the humid regions of the United States the percentage of soluble matter depends upon the size of the soil grains. The soils of the humid regions vary much in size of grain and extent of surface exposed on these grains upon which the water may act. The following table shows the relation in a general way between the texture of the soil and the percentage of soluble matter present.—

Relation between texture of soils and percentage of salt.

Kind of soil.	Locality.	Relative extent of surface of gr. ins.	Percentage of salt.
Florida soils	1
Truck	5
Limestone soils...	Maryland	...	18
Do	... Pennsylvania...	...	33
Do	... Kentucky	...	55
Do	... Virginia	...	56

It will be seen from the table that the soil which had the greatest extent of surface for the water to act on (or, in other words, the soil which was made up of the finest grains) had also the greatest percentage of salt which was soluble. It is a well-known fact, also, that the general agricultural value of a soil varies in nearly this same ratio, that is to say, a heavy soil is better for general farming purposes than a light, sandy soil.

There is another point of difference between the humid and arid soils which is of general interest as well as of general importance. The soils of the humid regions contain much more soluble matter than the subsoils, that is to say, the greater part of the soluble matter is concentrated within the surface foot of the soil. About 50 per cent of the rainfall of the humid regions either washes over the surface of the ground or else washes through the soils and skins down below the subsoil to appear at a lower level and be carried off by streams into the ocean. This has been going on for ages, and the amount of soluble matter left is very small, only sufficient to supply the plant roots.

The absorbing action of the soil grains retains the greater part of the salt as it becomes soluble within the surface foot of the soil, and it is here used by the plants. Below this, in the subsoil, in the region where the action of weathering is reduced to a minimum, the amount of soluble matter found is very small.

In the arid regions, where the rainfall is not sufficient to keep the soil continuously moistened to any great depth, and where the air is drier and evaporation much more rapid, the proportion of the rainfall drained from the land by the rivers is much less, in some cases less than 10 per cent, and in nearly all cases of Western rivers less than 25 per cent. Thus, with a small rainfall, very little water leaches through the soil, and therefore very little soluble matter is washed out.

In fact, in most of our arid prairies the soil is never wet from the surface to a depth of more than 5 or 6 feet. When the rainfall soaks down to the subsoil it carries with it some of the soluble matter which is in the soil. This soluble matter is absorbed by and condensed upon the grains of

the subsoil, and when the water is again brought to the surface of the ground by the evaporation of the soil water, part of the soluble matter remains in the lower layers of the soil. Then, if an examination is made of the prairie soils as they normally occur, more soluble matter will be found in the subsoil than in the soil, while in the humid regions the conditions are just the reverse.

BORACIC ACID AS A FOOD PRESERVATIVE.

Boracic or boric acid and its sodium salt Borax are now extensively used for the preservation of liquid and solid foods such as milk, butter, cream, fish and meat that a short account of them should prove of general interest. We are indebted for our facts to an instructive paper on this subject by Prof. Brünlich, F.C.S.

In all preservatives sold, boric acid and borax are the chief ingredients. Analyses of some of these preparations are given below:—

Preservitas contained:

Water	...	34.50	per cent.
Soda	...	5.58	"
Boric acid	...	47.39	"
Salt	...	9.33	"
Saltpetre	...	3.00	"
		<u>99.80</u>	

Sal praeservare contained:

Water	...	34.30	per cent.
Soda	...	4.96	"
Boric acid	...	51.80	"
Salt	...	8.52	"
		<u>99.58</u>	

Preservative contained:

Water	...	37.70	per cent.
Boric acid	...	40.60	"
Salt	...	20.16	"
Saltpetre	...	3.03	"
		<u>101.49</u>	

Preservative contained:

Water	...	39.30	per cent.
Boric acid	...	57.26	"
Soda	...	4.35	"
		<u>100.91</u>	

The effect of boric acid and borates on man and animals has been studied by a great number of scientists, but the results of their investigations are by no means conclusive. Some of the investigators—for instance, the French Commission appointed to study the influence of boracic acid on the human system—found that it could be taken for a considerable time without injurious effects. More recent experiments proved that small doses of boric acid, or borax, have no injurious effects, whereas larger doses produce distinct physiological disturbances—a danger will consequently arise if boric acid is used indiscriminately as a preservative. The Medical Officer for Health for East Kent, Dr. M. K. Robinson, has

shown that a serious outbreak of illness, by which five out of the seven inmates of a house were suddenly attacked, was due to a repeated addition of a preservative containing boric acid. Milk was at once suspected, being not only taken by itself, but also with tea and in a blanc-mange. It was found that the cook added preservative to the milk, which already contained boric acid when delivered by the dairyman. The result was that, by using the preservative twice, over-doses of boric acid had been administered. The remainder of the blanc-mange was given to nine fowls, of which five died; the rest suffered badly, but recovered. Dr. Robinson states that the addition of the drug should be regarded as an injurious adulteration. If such results, he says, can be produced in the case of adults, it is not unreasonable to presume that infants cannot take with impunity long-continued doses in their staple food. The opinion is general among physiologists that all preservatives, when effectual, either from their nature or quantity, in so injuring the micro-organisms which bring about fermentation or putrefaction of food as to inhibit their action, also injure those persons who consume such food. If a preservative substance can so influence the proto-plasmic integrity of bacteria and other low forms of life as well as of the higher forms like ordinary plants, it is difficult to conceive that the same basis of life-tissues in animals, especially that of the mucous membrane of the alimentary canal, should not also be injuriously affected, to say nothing of those beneficial bacteria concerned in the digestive processes. In 1897, a "Lancet Special Sanitary Commission on the use of Antiseptics in Food" was appointed, and consulted eminent members of the medical profession, as, for instance, Sir Benjamin W. Richardson, Sir Henry Thompson, Dr. Lauder Brunton, Dr. Pavy, Dr. E. J. Allen, and others on the subject. In spite of a great difference of views expressed by the various authorities, they all agree in stating that the antiseptics taken continuously in food, in sufficient quantity, are injurious to health, and they all insist that the name and the quantity of the antiseptic used should be stated on a label attached to the article when sold. Some of the medical men demand a restriction on the amounts of preservatives used; others again wish for a complete prohibition of the use of antiseptics. By the laws of Germany, France, Belgium, Switzerland, Italy, and most other countries, the addition of preservatives to goods is absolutely forbidden. In England, although an Adulteration Act has been in existence for a long time, no direct action to prevent the use of antiseptics has been taken; and only recently, since 1898, numerous convictions have been obtained for the addition of boric acid to milk and butter at a great many places.

The *National Provisioner*, Chicago, 4th, 11th, and 18th February, reopens the question under the heading, "Is Boracic Acid Deadly?" and numerous evidence is given to show that the drug is not deadly, which no one hitherto had tried to prove. But nothing new is brought forth, and some of the statements, as, for instance, that 10,000,000 lb. of cured meat treated with borax are eaten annually in Germany, and over

100,000,000 lb. in England, have to be taken with more than the proverbial grain of salt, considering that the adulteration law is carried out so very strictly in Germany.

The conclusions to be drawn from the foregoing remarks are very simple. Sooner or later the use of boracic acid (although it is not a deadly poison) as a preservative will be everywhere greatly restricted, if not entirely prohibited. There is not the slightest doubt that milk, butter, meat, fish, &c., can be preserved without the use of drugs. Cold storage is the simplest modern method of preservation of foods, and is applicable with equal advantage on a small or on a large scale. If, with cold storage as preservative, a previous scrupulous care as to cleanliness, inspection of meat and dairies, modern processes, such as pasteurization, &c., go hand in hand, our products such as meat, butter, and other foods can compete successfully with the products of other nations in the world's market.

GENERAL ITEMS.

Too much care cannot be exercised in taking up a young tree for the purpose of transplantation. If it be taken up roughly many of the young feeding roots will be destroyed, and without these the necessary amount of sap cannot be supplied to the branches and buds, yet the tree will continue to evaporate a large amount of water. The consequence of this evaporation and failure of supply is that the tree will often fail, or will remain for a long time a sickly, struggling object, unless assistance is given by removing sufficient branches and buds to compensate for the loss of roots. In any case, the damaged roots should be cut off clean with a sharp knife. In taking up the young tree, first remove all the surface soil down to the root system. Then dig a trench round it at some distance from the extremities of the roots. If the weather be dry, it is a good plan to water the roots copiously, to cause the soil to adhere. Then, with a sharp spade, cut under the roots and loosen the ball of earth from that below. The tree may then be safely removed, the tender roots having received very little damage: and if it be carefully replanted, success will be almost assured. In the latter process, the roots should be spread out evenly on a loose bed, and the soil pressed firmly upon all the fibres, thus excluding air as much as possible. The depth at which the young tree is planted will depend upon the nature of the soil in the new location. If the latter is of the same quality as that from which the tree was taken, then the depth should be the same; but if the soil is heavier than the former, then the plant should be set shallower in the ground; and on the other hand, if lighter, then it should be planted deeper. On finally filling in the hole, the surface soil should be fine and light, because moisture can then not escape by capillarity.

Tomato diseases have become very common of late years, and it therefore behoves every grower of this popular fruit to be able to recognise the early symptoms of various troubles, so that

remedies may be applied before the diseases have obtained a strong foothold. Root knot is generally caused by ellworms, which form galls, or irregularly swollen diseased growths on the roots, resulting in the wilting and death of affected plants, which should be burned, the soil in which they have been grown being either carefully burned or sterilised with quicklime. The sleeping disease of tomatoes, caused by an internal fungus parasite, is surely indicated by the drooping of the leaves successively from the base of the plant upward, increasing day by day, and sometimes accompanied by discoloration. At this stage the woody parts of a split root show a dingy yellowish-brown hue, more pronounced five or six hours after being cut open. Infested plants should be burned, and the soil in which they have been growing cleared out and sterilised by being mixed with quicklime. In cases of tomato-blight, the fungus-infested foliage shows rusty, yellowish spots, and the edges of the leaves often curl downwards before the foliage shrivels and dies, leaving the stems bare. Spraying with Bordeaux mixture directly the first indications of disease are observed, and the removal of the badly affected plants, are effective remedial measures. The tomato-rot-fungus generally attacks only over half-grown fruits, the first symptoms being the appearance at the blossom end of a small black spot, rapidly increasing in size until half the affected fruit is sunken, black, and destroyed, the injury usually extending uniformly from side to side across the tomato. The crop also suffers from a physiological trouble, a kind of tomato dropsy, visible in swellings on both leaves and stems, and in the curling of the former. This disease results from an excess of water in the tissues of the plant, and is encouraged by insufficient light, and by injudicious watering, especially in dull weather.

A method of fertilising fruit trees in vogue in Holstein is suggestive, and not unworthy of a trial. The trees, it is said, receive no cultivation, and the fruit is large, sound, and produced

in abundance. Every two years a few holes are dug in the ground about 4 or 5 feet from the trunk of the tree, and about 1 foot deep, closer and shallower in the case of young trees. These holes are filled with liquid manure about four times during the winter months, and for young trees this is diluted with water. If there is more liquid manure than is wanted, it is distributed over the surface of the orchard, using an old street sprinkling-waggon for the purpose. There is no reason why manure water should not be used once or twice after it is seen what the crop is likely to be; of course, not affording any at that season to trees not bearing a crop, or which are carrying only a few fruits, as to dose them would be to encourage, probably, an unnecessary growth of shoots. But in this matter, the cultivator must be guided by the condition of the trees and of the soil.

A noteworthy milking record has been established by the Red Poll cow *Crocus*, which belonged to the famous Norfolk dairy herd at *Whitlingham*. She gave birth to her third calf on May 11, 1890, since which date she continued uninterruptedly in milk till September 28, 1899, a period of over nine years, her milk yield in the last week of her life being at the rate of 43½ lb. or nearly 4½ gallons. During the nine years four months that she was continuously in milk she yielded altogether 50,428 lb., or nearly 23 tons of milk. Over the last five years the average quantity of butter fat in her milk was as high as 4.3 per cent. Her live weight when sent to market, after being on grass feed for the last six months of her life, was 10 cwt. 1 qr. 11 lb. In the nine years since her last calving she gave something like 45 times her own weight in milk, and her average production during that period was 5,403 lb. of milk, or considerably over 500 gallons per annum. For a moderate sized cow this is a remarkable performance which has aroused much interest amongst the breeders of Red Polls.

“PIONEERS OF THE PLANTING ENTERPRISE IN CEYLON.”

(Third Series.)

ARTHUR SINCLAIR, F.L.S., F.R.C.I.,

PLANTER AND VISITING AGENT IN CEYLON.

[THE STORY OF HIS LIFE AND TIMES AS TOLD BY HIMSELF.]

N a snug, little farm-house at King Edward, Aberdeenshire, I was born one dreigh day in December, 1832. My earliest recollection is a ploughing match, or “love darg,” by the neighbours on the occasion of my father retiring to Turriff, an adjacent township :

“ A wee bit placie nestlin’ doon
Wi’ burns and hills and wide aroon ;
It’s hardly what you’d ca’ a toon,
Oor native Turra.

But little placie tho’ it be,
It’s dear to many mair than me,
And prood are we to say that we
Were born and bred near Turra.”

SCHOOLS.

Here I was sent to school at the age of five. Albeit letters were not of the first importance at Mrs. Cruickshank’s establishment, knitting was her forte, and she insisted upon all her pupils of both sexes being proficient in this art, a technical education which has not as yet proved eminently useful to me, but who knows? The day may come, as it did to Robt. Knox, to whom the knitting and hawking of caps led to the opportunity of his escaping from Ceylon.

I graduated in my seventh year and entered the Parish-school, then ably conducted by the Rev. John Clark; and here I soon took a fairly good position. At the end of my third year I got to the front, or “McCulloch class” next to the village lad of pairs—‘gas Johnie’ who by the way still survives as the Rev. Dr. Duncan, the esteemed mimster o’ Trinity Congregational Church, Aberdeen. In my tenth year my school education virtually ended, untoward circumstances followed, which henceforth deprived me of the dominie’s aid, my father removing again to a bleak country district, where the school and schoolmaster belonged to a type so poor and primitive as to be quite a revelation to the village-bred boy who found nothing in common with the “heather peepers of Blacklaw.” Two things went very much against my grain, the one was the carrying of a peat daily to school, and the other was the committing to memory of that profound document said to have been compiled “for those of weaker capacity,” though to this day, I am bound to confess it is beyond mine. My parents were descended from an old Jacobite stock, at this time still rather at a discount, and although they would have offered no objections to my learning the Shorter Catechism, they would not enforce it. So left to the freedom of my own will, I decided to have none of it. In Turriff school I had been

allowed to repeat the Church of England Catechism with a few other "whistle kirk" bairns; but this enlightened dominie was horrified at the bare suggestion, and taking me aside, lectured me on the iniquity of belonging to such a sect, and said no creed containing such words as "Holy Catholic Church" should ever be repeated in his school! I ought to mention that this was in 1843, when there was a great upheaval amongst the Presbyterians, and any one whose "effectual calling" was not in the orthodox form, was looked upon with grave suspicion.

And here I may say ended my schooling and began my education such as it was and is. Scotland had doubtless a very admirable system of education and theology, and it was perhaps more my misfortune than my fault that I did not profit by it.

READING INDISCRIMINATELY.

Thrown upon my own resources, I read indiscriminately every book in my father's house, at least such as seemed to me at all interesting or intelligible. Blair's Sermons and Boston's "Fourfold State" hardly came within that category; but I found a perfect treasure in the gentle and scholarly James Hervey, whose "Reflections on a Flower Garden" I read and re-read with intense delight; planted a little flower-garden for myself, and on summer eves sat therein poring over my Hervey. Never had the tranquil and talented Rector of Weston-Favel a more devout disciple. Never had I seen a book better fitted

"To form the taste and raise the nobler part,

"To mend the morals, and to warm the heart."

There was no mere affectation in my love for this author; for on my first visit to Aberdeen the only "fairin" I purchased for myself, was six more volumes of Hervey, containing his delightful *Theron and Aspasia* and his defence thereof against the objections of John Wesley. Looking back from to day, it seems strange pabulum for a boy of 13; but it was the first book to really influence me, and so deeply interested was I in my treasure, that as I walked home from Aberdeen I could not help sitting down occasionally by the wayside to dip into it. The classical footnotes, however, sadly puzzled me, and awakened in me an ambition to dip into, Latin, which I did with more diligence than success; for my knowledge of Latin—never studied methodically,—amounted to little more than a string of roots, tenses and long words which, however, proved of use in after years. With French I was more successful, reading and writing the language with tolerable ease, though never able to speak it very fluently or intelligibly. The same may be said of my English; probably one of the many drawbacks of so-called self-education. I also tackled Trigonometry and Land Measuring with very fair success,

A GRAND DISCOVERY.

About this time I made a grand discovery. Speaking to a young ploughman, he remarked: "I say, min, I could gie ye a richt book for naething if you'd tak oot the lave o't." He had begun taking it out in parts, but found the bookman's calls came at inopportune times, when he felt more in need of tobacco than literature. I closed with this offer, and the boy boasted how cleverly he had sold me, and freed himself of the tax of 1s. per month. The book turned out to be Oliver Goldsmith's works, a perfect treasure and godsend to me; not so much for the matter as the manner in which it was said. I at once became charmed with a style of English I had never before seen or heard, and soon I became so thoroughly saturated with it, that to this day I can scarcely scribble a line without first thinking "how would Goldie have said it." No other writer—with the exception, perhaps, of Thomas de Quincey,—ever fascinated me so much. Both may have been eccentric, but certainly gifted and inspired to a marvellous degree. The beauty of the prose-poems and neatness of the humour was such as I had never before met with, while the descriptive notes of the latter, such as the scene of Catalina's travels, is—as I discovered in after life—drawn with wonderful fidelity.

BOTANICAL STUDIES.

Goldsmith was followed by "Rhind's Vegetable Kingdom," then looked upon as a sort of companion to "Animated Nature," and this book fixed my fate. Though not written like a "fairy tale," the Vegetable Kingdom was presented in a sufficiently attractive form to make plants, both wild and cultivated, from henceforth my chief hobby. The speedwell's peeping eye shed a new light from the hedgerow, the buttercups by the burnie brink became something more than buttercups to me, while exotics in the garden and window, even the familiar lupins, calceolarias and fuchsias had a life-history which it was a delight to trace, and I dreamed even then of visiting them someday in their own native habitat.

Rhind in due course was followed by Humboldt, whose "Geography of Plants" greatly interested me, and whose footprints on the slopes of the Andes I then dreamt of perhaps coming across. Meanwhile, though looked upon as rather an erratic and somewhat "dowie lad," I was not lazy; indeed, my little garden was already looked upon as an oasis in a wilderness of moorland farms, and a neighbouring farmer seeing my industry, gave me off a corner of a field measuring perhaps quarter of an acre,

which I tackled with as much diligence as any Chinaman, getting up by 4 a.m. and working till late at night.

"BOTRYTIS INFESTANS" OR POTATO BLIGHT.

The year was 1846, the summer one of the loveliest of the century. A little burn rippled past the ground in which by way of relaxation I bathed, caught trout and culled the *Nymphæa* from its margin; but my special pride was a plot of potatoes: the grand old blue kidney, nowhere now to be seen. No coffee planter ever saw with greater interest his first 100-acre clearing burst into blossom. Early one July morning I got up to watch the flowers expanding, when I observed what seemed drops of soot upon the tender green leaves. It looked like the work of some malicious miscreant, but no footprints were there, and I felt fairly puzzled. Next morning there were still more "soot drops," and every day during the week added to the mystery, till at length the haulins began to blacken, and a sickening smell greeted me as I approached my precious plot. I was only 14 years of age, but I shall never forget my first great discouragement as a planter; and when a quarter of a century afterwards I saw coffee attacked with a similar blight, I could not help remembering my early sorrow and fearing how little science could do for us.

Like the Ceylon planter of the "seventies," however, my horizon gradually expanded to other plants and products. I now sought and found congenial employment in a Nursery-garden to see how the various plants were propagated and learn the mysteries of grafting, budding and hybridising. He was a rough, unkindly fellow, the foreman, but a perfect workman; and I have seen few gardeners who could handle the knife, the rake or spade like old T—, but he had no taste or respect for science.

"See that you take that horse gowan out by the root," he said to a fellow-creeper who hadn't just come from a botanical class. "You mean the *Leontodon taraxacum*, sir?" said the youth wishing perhaps to air his learning. "Ah! I see," said the foreman sarcastically, "you're a bit of a botanist." "Ay!" was the reply, "and I can draw a little too." "D—n you, draw that barrow out of my way?" was the rough rejoinder.

TRAINING FOR TROPICAL AGRICULTURE.

For eighteen months I laboured here; the work was hard but interesting enough. Yet, the plants were only native trees or hardy flowers from temperate latitudes, and I, longing to make the acquaintance of exotics from warmer regions, now apprenticed myself to a garden where there were

good hot-houses, preparing, like many a better man, for what was to follow. I well remember my first little tropical acquaintance, viz., the *sensitive plant*. How I marvelled at the curiosity and never rested till I knew of its native home, and had read everything that was known about it, little thinking that in after years, it, as a troublesome weed, would cost me thousands of rupees to keep it down. Through the *Balsam (Impatiens)*, *Nepenthes plumeria* and the *Gloriosa superba*, I was first introduced to Ceylon. I was in my element, and my special hobby and delight was in tracing every exotic I came across, to its original home, a labour which gave me much pleasurable reading.

FIRST EFFORTS AT WRITING.

In four years I had reached the top of my ambition as a gardener, and with the wide world before me began to look towards the Tropics for a more congenial field. I had already begun writing for the local press. My first accepted article being on "Evergreens," a contribution which led to the life-long friendship of Mr. Wm. Alexander, Editor of the Aberdeen *Free Press*, and one of the kindest, purest-souled men I ever intimately knew.

About this time I was introduced by Mr. Geo. Dalrymple to Sir John Cheape, who, during a visit to Lady Elphinstone, came to consult me with reference to sending out certain varieties of Rhododendrons to Ceylon. "Will they grow in Ceylon?" enquired Sir John. "Unquestionably," was the reply. "How do I know?" "Well, I have just been reading Dr. Hoffmeister's delightful book in which he says that Rhododendrons not only grow wild at Nuwara Eliya and other upland districts, but on the very top of Adam's Peak he found a gorgeous display of blooms." Sir John was good enough to seem interested in me, and told me all about his estates near Kandy, managed by Mr. Mortimer, "a most capable man," he said, "though he had not the educational advantages you seem to have had" (save the mark!)

FIRST THOUGHTS OF CEYLON.

The excellent work by Dr. Hoffmeister was one of the first and certainly one of the best books on Ceylon I ever read.

A splendid young fellow was Dr. Hoffmeister, travelling Physician to H.R.H. Prince Waldemar of Prussia, the first German Prince to visit Ceylon. No keener, more observant botanist ever landed at Galle, and the fidelity of his description of the vegetation and natives, seen *en route* for Colombo, has rarely been excelled. The reception by Sir Colin Campbell, the journey to Kandy, thence *via* Pussellawa, where the brothers Worms were found planting their first clearings, and onwards to Nuwara Eliya and Badulla, where they were royally entertained by Major Rogers, is all graphically described. Dr. Hoffmeister was no sportsman, but while the Prince accompanied the Major on sundry shooting excursions, he contrived to extract great delight from his botanical rambles. The poor young physician and scientist (he was only 25) accompanied the Prince to India, where he collected much interesting and valuable information. Unfortunately, Britain was at the time embroiled in one of her inglorious border wars, and the Prince wishing to see fighting, went to the front, his faithful physician by his side. The latter was killed on the spot, and the sorrowing

relatives had only the melancholy satisfaction of publishing the admirable letters which, with the appendices addressed to Baron Von Humboldt, form this most interesting volume.

GEO. E. DALRYMPLE.

The George Dalrymple mentioned above was uncle to "our Logie;" he also had been in Ceylon for seven years, during which time he had worked himself up into a leading position in a Kandy Firm. A tall and very handsome, beardless youth, he was popular with all classes and an especial favourite with the young military officers stationed at the Central Capital. One afternoon a bit of a lark was proposed, and no sooner said than done. Young Dalrymple was dressed as a lady, as near as possible *a la mode*, the next step was on to a high dog-cart, and one of the officers to drive "her" round the Lake; the chief object being to attract the attention of and arouse the jealousy of a certain Mrs. S——, who had recently begun to trot out two daughters.

Few in the present day of globe-trotters can imagine the consternation such a simple event caused in the early "fifties."

Round and round rode the handsome pair, and none was more critically interested in the new arrival than Mrs. S——. Most unfortunately, in turning a corner for the third time, right opposite her bungalow, the horse shied. Up went a wheel on the parapet and over went the occupants! With a shriek ran Mrs. S—— to the help of "the lady," the screeching daughters behind her, but were shocked and thunderstruck to get hold of a top boot!

The next upshot was that Master George got a badly broken thigh which rendered him a cripple for life, and as such was ordered home. We all thought he had been injured while out hunting elephant; but Dr. Charsley, who attended him, gave me the true version of George's mishap. On returning home he started a Flax Works, but falling into the hands of Aberdeen Jews the project failed, and he went out to Australia where he did some good exploring work. I had thought of accompanying him, but at the last moment he said "No, you would be throwing yourself away, Ceylon is the place for you," and he offered to recommend me to his friend Simon Keir. Meanwhile, the following advertisement appeared in the *Aberdeen Journal*:—"Wanted for Ceylon, a young man of liberal education, with a knowledge of Agriculture. Applicants in own handwriting must state age, where educated, and how employed hitherto, good references required." I answered this and was the successful applicant.

START FOR CEYLON.

So, early in February, 1858, I sailed in the good mahogany ship "Albemarle," 400 tons burthen, my fellow-passengers being Ellis, Tindall, Wernham, Bruce, Hay, and the brothers Rossiter:—all gone now excepting one of the last-mentioned and myself.

The events of the four and half months, such as they were, were they not too fully chronicled in the *Aberdeen Free Press*.

We reached Colombo on the 10th June, a memorable day, of which Padre Ellis, as long as he lived, kept up the anniversary, by writing to me, often in pawky verse, of which the following is a sample:—

"Here's health, milk and meal
To an honest hearty chiel,
Deil eadge them in a creel
Wha doesna wish us baith weel,"

ARRIVAL AND PECULIAR RECEPTION AT
"OBSERVER" OFFICE.

Our reception in Baillie Street was peculiar. I had been asked by my fellow-passengers to write and publish a letter of thanks to Captain Collett for his considerate and unremitting kindness to us during the long voyage. Consequently, our first call in Colombo was at the *Observer* Office. Dr. Elliott sat in the Editorial chair, and after glancing over the MSS, said in his loud cheery voice, "We shall be *delighted* to insert this;" but, and again he looked at us up and down, with a twinkle in his eye; then leaning back in his chair simply *roared*:—"Come here, Ferguson, and look at this," and the handsome head of a man in middle-life looked over the screen. "*Sample of passengers per Albemarle*," he said pointing to us, and they both laughed in ready chorus; while we, reddening with chagrin and surprise, drew back at the strange and unexpected reception. An explanation soon followed. Our names had been sent in by the Wharf clerk with the prefix "*Misses*," instead of "*Messrs.*" and all Colombo was on the *qui vive* to see the batch of young ladies, newly arrived!

Fred. Wernham and I were hospitably received by good genial Sylvester Richmond, whose hearty laugh was a grand entertainment in itself. Next evening found us in Kandy introduced to those keen coffee dealers, Sandy Brown and old Gerrard, the latter by this time in shady circumstances, but full of anecdote; the point or moral of his reminiscences, however, was not very edifying or encouraging to newcomers. Poor old rake! he evidently imagined he was having a ruse out of the raw arrivals, little thinking how minutely they weighed and appraised him.

ON THE HILLS.

My destination was Rangalla, a district that stood A1 in coffee planters' estimation, and Battagalla, which was acknowledged at that time to be the finest hill estate in the island. Mr. Duckworth, the fortunate proprietor, resided there and received me with great kindness. His father—one of the merchant princes of Liverpool—I had visited before leaving England, meeting the young student brother, now Canon Duckworth. Battagalla was indeed an ideal estate, combining good soil and shelter with a glorious view of the rich lowcountry beyond, 350 acres bearing at the rate of fully 15 cwt. per acre, an ample labour supply, rising prices, and altogether the prospects were as bright as ever they were before or since in Ceylon. Sir Henry Ward had just been up dining and complimenting the "spirited gentlemen of the district" for having made "a beautiful bandy-road of 9 miles from Teldeniya to their splendid estates."

The second day's tappal brought me a kindly letter from A. M. F. telling me he had just seen Capt. Collett with an armful of papers from Aberdeen containing my contributions on the voyage, and concluded by hoping I wouldn't send all the fruits of my pen to Aberdeen-awa, and here began another long-cherished friendship. Few outdoor occupations could be more attractive than Coffee planting in the "fifties." Coolies were more docile than they now are, the surrounding Sinhalese less corrupted and more respectful. The busy crop season was soon over and then came ample leisure, the interesting process of pruning, the beautiful blossoming time when bumper crops were estimated, after which those so minded could readily be spared for a sporting trip to Bintenne. Monotonous as the work seemed to many, to me it was a daily delight, albeit the climate had its drawbacks.

DYSENTERY.

We had just entered upon a wet cycle, and the surroundings during the S.-W. monsoon were decidedly damp. There were no bungalow fireplaces in those early days, no flannel shirts, the rains blew through the weather-boarding, and the bed-sheets had frequently to be wrung out before retiring. As a believer in hydropathy, I did not dream of the danger of this; but the result was, in the words of Dr. Charsley, "a rattling case of dysentery." Few Europeans escaped in those days: my colleague Mr. Greig had to seek a drier climate, while I was carried into Kandy—30 miles—by coolies, and was for some time despaired of. The kindness and skill of Dr. Charsley* and attentions of Dr. Symons and Mr. Sprout can never be forgotten, particularly during convalescence, when they took me for drives to Peradeniya Gardens, where Dr. Thwaites did so much to encourage and gratify my taste for plants. It was during one of those visits that I saw the first cuttings of cinchona ever introduced into Ceylon being planted in a propagating frame. Meanwhile, poor Mr. Duckworth had been left alone in the midst of crop, attempting work for which he was thoroughly unfitted: the wet coffee lay 5 feet deep on the barbecue, the smoke from which could be seen for miles around.

The weather, however, hardened up by the end of December, and with the aid of a clever adaptation of Clerihew—erected by our friend A. Greig—we struggled through the wet coffee, and by 1st March had the satisfaction of seeing Miner Cader cart away the last load to Colombo, over 20,000 bushels from about 300 acres in full bearing.

W. N. D.

Mr. Duckworth, though not a planter, was a gentleman of refined tastes, and managed to employ his time in a very interesting, if not very profitable, manner: a musician of no mean order, he could paint passably and even dabbled in verse, would often send a messenger to call me from a distant corner of the estate to hear or see his latest effort, and if I could but suggest a word or a half note by which a line would go more smoothly, he was more pleased than if I had added another cwt. per acre to the crop. "Don't go away," he would say, "tiffin is coming, and what do we pay kanganis for but to look after coolies," as if he had yet to learn, that kanganis were merely stuck on stones to warn the coolies of durai's approach.

PLANTING AND PLANTERS 40 YEARS AGO.

Forty years ago the planters were a comparatively small body, about 400 all told. The S.D. was treated with more consideration than he probably is now; relations with the Proprietor were most cordial, and seldom indeed did the S.D. † abuse the confidence or dishonour the position he was encouraged to occupy. In after years, I occasionally did come across something different. Once when making enquiries regarding the capabilities of an applicant for a situation, his employer wrote:—"My only reason for parting with him is that he is apt to get too d—d familiar; the sort

of fellow who slaps you on the back when you go to visit him." This man did not get the appointment.

Then there was "R.B.T."s man to whom he gave a certificate merely stating: "I hereby certify that the bearer requires to be taken down a considerable peg." And there is the other side, when the too exacting P.D. ordered his Superintendent to remove at once to the lowcountry and open some lands he had recently bought, to which the planter demurred as the place was known to be *hot and sickly*. "Hot," said the irate proprietor, "Superintendents ought to be ready to plant coffee in h—l if we so desire them". "*May be*," retorted the cautious Scot, "but I'm thinking it won't be necessary." "*Why?*" "Because you will doubtless all be resident proprietors there."

At the time I speak of, Mr. Duckworth had a visit from the redoubtable Andrew Nicol. "A.N." and "W.N.D." were old friends or rather the descendants of old friends, for individually, truth to tell, there was little love lost between them. "A.N." though in some respects less accomplished, had much more energy than the somewhat phlegmatic "W. N.D." over whom, moreover, he possessed a considerable influence, and at this time managed to arrange for the transfer of my services to his own employ, with a view, it was thought, of my succeeding Jas. S. Martin who was looking forward to a trip home.

MY FIRST MOVE.

Meanwhile, I was sent to reclaim a half-abandoned estate in Matale East, the wholly abandoned Superintendent of which had been carried into Kandy suffering sadly from "D.T."

Kabroosa had a history, dating from the famous rebellion of 1848, when every bungalow in the district was sacked with the solitary exception of this one. The Matale Volunteer Corps had not yet been formed, and the "dorainar" of the day finding it necessary to be in Kandy on urgent business, the estate buildings were the more easily looted. The conductor on *Kabroosa*, however, was a bit of a strategist: he mustered a score of stalwart coolies, took them to the bungalow, dressed them in dori's clothes as far as they went, and seating them on chairs in the front verandah, armed each with an open *Observer*, and fearlessly awaited the approach of the enemy. By and by Appuhamy keeked out from the jungle on the opposite side of the stream, but seeing such an array of Mahatmayas beat a hasty retreat to Warriapola where the decisive battle was fought, resulting, sad to say, in one English Sergeant being wounded. The Government of Ceylon very properly pensioned this conductor.

MY NEIGHBOURS.

My near neighbours here were Wingate, a genial gentlemanly man, as were also the brothers Hope, always happy except when visiting the wind-blown wattie over the hill, where even the grindstone had to be staked and tethered to the ground!

Robt. Mitchell, on the adjoining estate, was a rather unpolished piece of granite, but the soul of hospitality, whose Sinhalese employer on his periodic visits invariably got drunk on champagne. "You must find those visits rather costly," I ventured to remark one day. "Oh! no," said Bob, "I just charge it to manning."

Poor Paul Macrac, on the opposite side of the stream, was then a fine active specimen of a hielan' man, more at home in Gaelic than in English—a

* Our friend has forgotten to mention, how the first evening Dr. Charsley saw him in Kandy, he thought so seriously of his case that he said:—"If you have any little matters to put right, any important letters to write, I would advise you to see to them now.—Ed. P.A.

† Sinna Durai—*anglice* "little master" or Assistant, —Ed. T.A.

good planter, but his great delight was to dine the district, and his one after-dinner song, "*Robie Tamson's Smiddy*" was always ready and well-rendered. Poor Paul and Poor Bob! both came rather to grief in the end; good useful men, but had not the moral stamina to stand an attack of *Hemileia*.

Over the ridge on Dangkale swaggered, though more economically, our friend Christie, while John Gray on Cattaratenne remained a Buchan loon, pure and simple to the end of his days.

Kabroosa had just given its record crop, and its condition, in the words of Billy Rudd, was one of "*Veeds, Vips and Walking Sticks*." I did my best to renovate the totum. True, I let light into the matted bushes, and when expostulated with, remarked with a certain air of native conceit, that I did not to go to Matale or even come to Ceylon to learn pruning.

"Never cut a primary," said the orthodox coffee planter. "Till it requires it," I added. Nevertheless, though dead branches no longer bear, they do give a certain amount of shelter to young shoots, and had I known the full force of the monsoon on these hills, I might have used the knife more sparingly.

Here I remained about 18 months, meanwhile opening and planting *Owelle*, one of the first of the Lower Matale estates and still flourishing in the list of that most prosperous of Companies, The Ceylon Land and Produce, Limited.

It was while planting here, that drowned out of my talipot hut, I rode for shelter to *Suduganga*, and thereby first made the acquaintance of Hugh Blacklaw, which led to a friendship of now 40 years, which stood the test too of seven years of official visiting! When Mr. Martin went home, I returned to Rangalla to manage Galleboda and Lovegrove estates; and it was while here I awoke one morning to find myself famous, or infamous, as the suspected writer of the notorious "*Young Scotsman letters*:" otherwise this period passed away without any striking incident.

WM. FERGUSON, F.L.S.

By the time Mr. Martin was ready to return, I had accepted a situation in Sabaragamuwa. In passing through Colombo I first met that genial soul, *Wm. Ferguson*. Who in the "fifties," "sixties," or "seventies," could visit Colombo without meeting and making the acquaintance of "W.F.?" And who that once enjoyed with him a ride round the gravets in his well-known and well-worn trap, could ever forget it? Kept more for use than ornament, his equipage was ever at the service of visitors, and to hear him talk of the trees and flowers by the wayside was a lesson in botany, while few professors could impart information with such success or delight to his listeners. Less of a litterateur than his gifted brother, he was in his own department unique in Ceylon. Let one but ask the name of the meanest little creeper in the hedgerow, and at once the trap was stopped, the horsekeeper sent for a handful, and "now let me tell you a story about this plant" he would begin; and for 10 minutes or more the story would flow in such idiomatic English with just a slight dash of highland accent. After such an object lesson, that *IPOMEA* would be for ever familiar to you. Or let any luckless native be found hacking a branch from a favourite tree and then listen to the castigation of the Vandal. "W.F." would not swear, he would not strike, but in fluency of cutting hard words, O'Connell would have been

nowhere! The poor Yahoo trembling from top to toe would slink away. Meanwhile, we also would be moving on, and the intercepted story would begin again where it was left off. Altogether a more interesting and lovable man than Wm. Ferguson never lived in Ceylon. All who loved plants loved "W.F.," and the love of plants and flowers is the secret of success in Ceylon. "I never met but one man who hated flowers," said the late Editor of the *Spectator*, and this poor prejudiced creature was a Plymouth Brother, who believed that flowers were cursed with the ground, owing to the disobedience of Adam and Eve!

EN ROUTE FOR RAKWANA.

The journey through the ancient Province of Sabaragamuwa was not so easily accomplished forty years ago as it now is. No Rakwana Defiance with spanking horses went up and down the Madampe hill at eight miles an hour. Only the weary hired and unwilling hack, upon which it was a feat to ride in three days, over the 90 miles of rough roads, portions of which were frequently flooded; indeed Chas. Shand was reported to have said he "once walked 10 miles under water." The Resthouses were poor. *Awissawella* might be looked upon as the *ultima thule* of civilisation, and even it did not strike me as very cheerful, the first thing pointed out being a spot at the end of the verandah where lay the bones of a predecessor.

At Ratnapura I found old "T.P.,"* busy with a gang of jail-birds digging for cat's-eyes, without much apparent success, judging from his looks. The natural beauty of the Gem City greatly charmed me, though verily, beyond the planting of a few *Crotons*, *Poinsettia*, *Hibiscus*, *Datura*, and a couple of Nutmeg trees, man had done but little to beautify the scene with exotics.

At Pelmadulla the sorry screw and I arrived wet and weary enough. "Do you know anything about an estate called Everton?" I asked of the old appu who stood in the door of his inhospitable-looking shed. "No, sir, only that all gentlemen who go there get sick and die" was the grim reply, the fact being that my three immediate predecessors got ill, of whom two died on the way to Colombo. No doctor nearer than 90 miles, and yet the poor Durais died!

IMPRESSIONS, AND NEW FRIENDS.

Hoping for better things I hastened onward and upward, finding Everton—the "Kabragalla" of the Sinhalese—for a wouder, bathed in sunshine. Here I pitched my camp and remained for five years, enjoying the ample elbow-room. I visited within a few months every hill top in the district, and carefully taking my bearings, got to know the locality better than most natives.

Rakwana had long been somewhat stagnant; "the first planted coffee," as Sir Henry Ward said, "was thin and bare;" but there were sheltered pockets of good soil which, judiciously opened, paid the planter well. I selected about 1,000 acres, and opened three estates, all of which ultimately did well. It was a lonely scattered district. At that time we were only five Europeans all told, David Mitchell, Joe Bennison, M. Moss, Reid and myself.

David, the father of the district, was one of the gentlest of men, albeit clothed in a somewhat rough exterior, hospitable to a fault, scrupulously

* Tom Power, C.C.S.

honorable in all his dealings, and tender-hearted as the most motherly woman, never in a hurry and inclined to be somewhat prosy; yet, one rarely wearied in waiting for the completion of David's story. Joe, too, was as good a fellow as ever dropped an H. or entertained a neighbour, and no better planter ever mustered coolies in Rakwana. M. Moss, though he kept his grus cleaner than his estate, was all round a gentleman and a sportsman to be depended upon in any emergency. Poor Reid was a waif frae Buchan, whose splendid penmanship was his only redeeming qualification. Such were the lords of a district 60 miles in circumference, sparsely inhabited and very partially cultivated. Yet in this "Wilderness of the Peak" I contrived to spend some of the pleasantest years of my planting life. Just as on board-ship we get to know men more familiarly than it would be possible in a crowded city, I became intimately associated here with two men who had a considerable influence on my after-life—men whom I elsewhere might never have had the same chance of knowing.

W. HAY WODEHOUSE AND. J. W. BIRCH.

The first and best was Mr. Haye Wodehouse (C.C.S.) whom I met at the Ratnapura resthouse on the way up, and was so struck with his courteous, kindly bearing to all around him, so different from the average John Bull who bullies appus and kicks kudrakarens that I reported him on my arrival at Rakwana as the most amiable man I had ever met.

"Ah!" said David with a kindly twinkle, "let us invite him up," which we did, and for two years I saw much of the Temple Lands Commissioner, who frequently stayed with me for a week, and whom I as frequently accompanied on many of his pilgrimages through village lands; in the intervals many scores of letters passing between us. Son of Canon Wodehouse, a family of stupendous pedigree, Wodehouse was a highly polished, scholarly aristocrat with all the advantages I had most lacked, yet he was pleased to discover many affinities in our reading tastes. We agreed to take out on joint account some of the best magazines of the day, and much of our correspondence related to the different writers and their styles. This of itself was an education for me which I greatly appreciated.

My other friend, J. W. Birch (C.C.S.) was in many respects the very antipodes of W. H. W.—Wodey always dignified and leisurely, whether dressed for dinner or enjoying his matutinal pipe, was ever the pink of propriety. B. was ready, rough and careless of his toggery, but an energetic, clever man of outstanding ability. W. inclined to be lazy, but always suave and kind to the meanest cooly! B. simply indefatigable, could work day and night and lick a dozen Sinhalese into shape before breakfast. "Does not know the word difficulty," said Sir H. Robinson.—W. scrupulous in statements and refined in his language; B. would swear till all was blue, and illustrate his after-dinner yarns with the most monstrous of Rougemont-like fables; and "if you don't believe me ask —" he would say, — being a relative and another well-known economist of truth. Both W. and B. were men whom it was interesting and profitable to know, far above the average in administrative ability, while as letter-writers the best I ever came across, never too busy to reply to a note, yet never like the fussy man asking to be excused while he did so.

Dear Wodey has slept soundly in Borella for the past 30 years; but the last visit I paid in Colombo two years ago was to his grave. "Poor Colonial Birch," as H. S. O. Russell was wont to call him, was assassinated in Perak.

Mr. Russell, by the way, who acted for sometime as Agent at Ratnapura, was altogether a different type from Birch! He ruled the district with a dignified hauteur—slow, sarcastic, but very choice in his language. In the most polite way he could make his belted peon tremble with fear, as he deliberately exclaimed when very angry, "You son of a — misguided woman!" An admirable administrator, however, the district was never more conscientiously ruled than in his day; no shady gem-pit digging, no broken heads by H. S. O. R., and the day soon came when he was promoted to the Central Province.

CALLED TO THE C.P. AS V.A.

About the same time I also had "a call"—as the ministers say—and selecting Kandy as my centre, entered upon the busiest portion of my life; travelling as V.A. over the length and breadth of the island for the next ten years, almost continuously in the saddle. It may be thought that the wilds of Sabaragamuwa was not a very good training ground for an Estate Inspector in the C.P., but as a matter of fact, my planting experience was acquired in Aberdeenshire. What I had chiefly to learn in Ceylon was the nature of the different localities on an island where every few miles give a change of soil and climate. Coffee-planting in rugged but richly-cropping Rangala was quite a different matter from the culture of the same plant in the leafy dales of Dimbula; and estates in poor patchy Sabaragamuwa required more careful treatment than those in the more happy-go-lucky Haputale. This experience I had now ample opportunity of acquiring. Beginning with a modest dozen estates, they gradually increased upon my hands, till at the end of my second year I had three times that number, and in a few years more the numbers rose to 100 or about one-twelfth of the island's extent of Coffee, and my duties were not merely to report on the condition of the estates, but to direct the cultivation and estimate the crops. Those were the days before *Homileia vastatrix*.

My remuneration was now over £2,000 stg. per annum, equal to that of the Lord Bishop!

RETIREMENT.

And yet I retired at the age of 40! Some remain the year too many; peradventure others retire prematurely; but who knows? There was much to induce me to stay; but the superior attractions of Aberdeenshire prevailed.

As showing the cordial relations between a V.A. and his Colombo Agents in the seventies, the following letter from a leading firm may suffice:—

"Colombo, 14th October, 1873.

"Dear Sir,

"In now relinquishing your valuable services, we beg to reciprocate sincerely the good feelings expressed in your letter, and to assure you that the intercourse carried on between us, has afforded us the utmost satisfaction in every way. "The able and conscientious nature of your Reports has been much appreciated by our Constituents both here and in England, and we feel satisfied that their several properties have benefited much by the good directions you have been able to give to the Superintendents in charge.

"We remain, &c.,

"GEORGE STEUART & CO,"

James Sangster Martin, for whom I acted fourteen years before, now undertook a portion of the work I left. James was the elder brother of the equally well-known John, perhaps the more intellectual of the two; but both were first-rate planters, indeed none better ever came to Ceylon.

I had scarcely reached Aberdeen when I got a wire that J. S. M. had died of dysentery. It was in the end of May (1874), the trees were bursting into leaf. I had not seen a summer for sixteen years, and not feeling disposed to re-sume my duties at once, I gave up all idea of returning to my post!

Now for the next ten years I extracted as much enjoyment out of life as perhaps ever falls to the lot of ordinary unambitious mortals; but at the end of this time I fell amongst thieves, and as misfortunes rarely come single, the *Hemileia* must needs play havoc with securities in Ceylon at the same time, so that I began to look abroad again for investments and occupation, resulting in a trip to *Tasmania*, an adventure often talked of with friends now gone, R. B. T., J. S. M. and others.

PROSPECTING IN TASMANIA.

Of my experiences there have I not written fully to the *Observer* under the heading "In search of a Home." My prospecting during these three years cost me over £2,000, money not by any means wasted, as I gained in return a more thorough knowledge of this beautiful, if in many respects over-rated and sadly misguided island than many of the natives possess, and learned to appreciate better our own bountiful native land on which there is yet ample room.

Calling in passing and repassing upon my first love, Ceylon, I found her more interesting and beautiful than ever.

"HOW I FOUND MY WATTIE."

The old *Wattie* on which I lived and reared a family, though now uncultivated, was not abandoned, hundreds of tree and flowers—escapes from the Botanical Gardens—grew there where

they never grew before; the fruit trees I planted thirty years ago, jak, mango, coconut and lime, now waxing old and bearing heavily. The sensitive plant, with its clover-like blossoms, covered the walk like a carpet, a walk made just eighty years ago to enable Lady Barnes to enjoy the view. The sweet little yellow *Thunbergia* peeped with its dark eye from amongst the weeds by the wayside, while its rich mauve-flowering relative, the noble *Laurafolia*, hung in festoons from the arms of the gaunt cotton tree. The flowers on the huge Sapu trees scented the air, while the indigenous Guava—from which the district derives its name—*Pera(deniya)*—was in many places an impenetrable thicket, Lantana only—once so luxuriant—now decaying, and being supplanted by a sunflower, also from S. America. The *Bougainvillea* with its rose-coloured braets, hides the crumbling ruins of the godowns, while the *Inga Saman* trees which, on the recommendation of Dr. Thwaites in 1870, I transplanted from the garden now throw a grateful shade over the old bungalow, looking so inviting and with its sunny memories doubly interesting. The view from the verandah greener and richer than of yore; the old sugar estate—an abandoned common in the sixties—now a splendid sheet of luxuriant and valuable tea. Why should Primrose Hill not be again utilized? Why should the lost *wattie* not be regained? The desire was natural and in process of time was gratified. Yet one cannot live upon a wealth of wild flowers or on the distant view however lovely:—

"Such wealth is but a name
That leaves our useful products still the same."

The next step was to replant the totum, which I did very successfully; and while the tea, &c., was growing, I made sundry excursions into other parts of the world, the most notable being Peru* and Australia as elsewhere described; but my home in Ceylon—preserved as a winter resort—is still my favourite stand-by.

* See "In Tropical Lands: Recent Travels to the Sources of the Amazon, the West Indian Islands, and Ceylon"—by A. Sinclair, F.R.C.S., etc.—"Ceylon Observer" Book Store, Colombo.

A SKETCH OF THE HISTORY OF INDIAN BOTANY.*

BY SIR GEORGE KING, K.C.I.E., LL.D., M.B., F.R.S.

(Continued from page 619.)

Somewhat similar to Griffith in temperament and versatility was the brilliant Victor Jacquemont, a French Botanist who, at the instance of the Paris Natural History Museum, travelled in India for three years from 1829 to 1832. During this period Jacquemont collected largely in the Gangetic plain. He then entered the North-West Himalaya at Mussonrie, explored Gharwal and Sirmur, ascended the Sutlej to Kanawar and Piti (at that time unexplored), visited Cashmir, and returning to the plains, crossed Northern Rajpntana to Malwa and the Deccan. He finally reached Bombay with the intention of returning to France. But at Bombay he succumbed to disease of the liver, brought on by hard work and exposure. His remains, after having lain in the cemetery there for fifty years, were, with that tender regard for the personality of her famous sons which France has always shown, exhumed in 1881, and conveyed in a France frigate to find a permanent resting-place in the place of Jacquemont's birth. Jacquemont's collections were transmitted to Paris, and his plants were described by Cambessedes and Decaisne, while his non-botanical collections were elaborated by workers in the branches of science to which they respectively appertained, the whole being published in four volumes quarto, at the expense of the French Government.

The roll of eminent Botanists who worked in India during the first half of the century closes with the name of Thomas Thomson, who collected plants extensively between 1842 and 1847 in Rohilkund and the Punjab, and again still more extensively during a Government mission to the North-West Himalaya and Tibet which was continued from 1847 to 1849. During this period Dr. Thomson explored Simla, Kanawar, Piti, Cashmir, Ladak, and part of the Karakoram. His collections, which were large and important, were transmitted to the Botanic Garden at Calcutta, and thence in part to Kew. They formed no insignificant part of the materials on which the 'Flora Indica' and 'Flora of British India' were founded. Dr. Thomson also published an account of his travels—an admirable book, though now jostled out of memory by the quantities of subsequently issued books of Himalayan travel and adventure.

About the year 1820 a second centre of Botanical enterprise was established at Seharanpore, in the North-West Provinces. A large old garden near that important town, which had been originally founded by some Mohammedan nobles of the Delhi Court, was taken over by the Honourable Company, and was gradually put upon a scientific basis by Dr. George Govan, who was appointed its first superintendent. Dr. Govan was in 1823 succeeded by Dr. J. Forbes Royle, and in 1832 by Dr. Hugh Falconer. Dr. Royle made collections in the Jumna-Gangetic plain, in the Lower Gharwal Himalaya, and in Cashmir. He was distinguished in the field of Economic rather than in that of Systematic Botany, his chief contribution to the latter having been a folio volume entitled 'Illustrations of the Botany of the Himalaya Mountains.' His valuable labours as an Economic Botanist will be noticed later on. Hugh Falconer was an accomplished palæontologist who devoted but little of his splendid talents to Botany. His great contribution to palæontology, the value of which it is almost impossible to over-estimate, consisted of his exploration and classification of the tertiary fossils of the Sewalik range. Falconer was transferred to the Calcutta Garden in 1842. He was succeeded at Seharanpore by Dr. W. Jameson, who explored the Botany of Gharwal, Kamaon, and Cash-

mir, but who published nothing Botanical, his chief energies having been devoted to the useful work of introducing the cultivation of the China tea plant into British India, and this he did (as will afterwards be mentioned) with triumphant success.

During the first half of the century, a considerable amount of excellent Botanic work was done in Western India by Graham, Law, Nimmo, Gibson, Stocks, and Dalzell, the results of whose labours culminated in the preparation by Graham of a List of the Plants of Bombay, which was not, however, published until 1839 (after his death); in the publication by Stocks of various papers on the Botany of Scinde; and in the publication by Dalzell and Gibson in 1861 of his 'Flora of Bombay.' It is impossible in a brief review like the present to mention the names of all the workers who, in various parts of the gradually extending Indian Empire, added to our knowledge of its Botanical wealth. It must suffice to mention the names of a few of the chief, such as Hardwicke, Madden, Munro, Edgeworth, Lance, and Vicary, who collected and observed in Northern India, and who all, except the two last mentioned, also published Botanical papers and pamphlets of more or less importance; Jenkins, Masters, Mack, Simons, and Oldham, who all collected extensively in Assam; Hofmeister, who accompanied Prince Waldemar of Prussia, and whose collections form the basis of the fine work by Klotzsch and Garcke (*Reis. Pr. Wald.*); Norris, Prince, Lobb, and Cuming, whose labours were in Penang and Malacca; and last, but not least, Strachey and Winterbottom, whose large and valuable collections, amounting to about 2,000 species, were made during 1848 to 1850 in the higher ranges of the Kamaon and Gharwal Himalaya, and in the adjacent parts of Tibet. In referring to the latter classic Herbarium, Sir Joseph Hooker remarks that it is 'the most valuable for its size that has ever been distributed from India.' General Strachey is the only one who survives of the splendid band of collectors whom I have mentioned. I cannot conclude this brief account of the Botanical labours of our first period without mentioning one more book, and that is the 'Hortus Calcuttensis' of Voigt. Under the form of a list, this excellent work, published in 1845, contains a great deal of information about the plants growing near Calcutta, either wild or in fields and gardens. It is strong in vernacular names and vegetable economics.

The second period of our history begins with the arrival in India in 1848 of Sir (then Dr.) Joseph Hooker. This distinguished Botanist came out in the suite of Lord Dalhousie, who had been appointed Governor-General of India. The province to the exploration of which Sir Joseph directed his chief attention was that of Sikkim in the Eastern Himalaya, the higher and inner ranges of which had never previously been visited by a Botanist, for Griffith's explorations had been confined to the lower and outer spurs. The results of Sir Joseph's labour in Sikkim were enormous. Towards the end of his exploration of Sikkim he was joined by Dr. Thomas Thomson, and the two friends subsequently explored the Khasia Hills (one of the richest collecting grounds in the world), and also to some extent the districts of Sylhet, Cachar, and Chittagong. Dr. Thomson subsequently amalgamated the collections made by himself in the Western Himalaya with those made in Sikkim by Sir Joseph individually, and by them both conjointly in Eastern India; and a distribution of the duplicates after the fashion of the Wallichian issue, and second only to it in importance, was subsequently made from Kew. The number of species thus issued amounted to from 6,000 to 7,000, and the individuals were much more numerous than those of the Wallichian collection. The immediate literary results of Sir Joseph Hooker's visit to Sikkim were, (1) his superbly illustrated monograph of the new and magnificent species of *Rhododendron* which he had discovered; (2) a similar splendid volume illustrated by plates founded on drawings of certain other prominent plants of the Eastern Himalaya which had been made

* From the Report of the Sixty-ninth Meeting of the British Association for the Advancement of Science held at Dover in September, 1899.

for Mr. Cathcart, a number of the Civil Service of India, and (3) his classic 'Himalayan Journals'—a book which remains until this day the richest repertory of information concerning the botany, geography, and anthropology of the eastern Himalaya. A remoter result was the appearance in 1855 of the first volume of a 'Flora Indica,' projected by himself and his friend Dr. Thomson. The first half of this volume is occupied by a masterly introductory essay on Indian Botany, of which it is hardly possible to overrate the importance. This remarkable essay contains by far the most important contribution to the Physico-Geographical Botany of India that has ever been made, and it abounds in sagacious observations on the limitation of species and on hybridisation, besides containing much information on the history of Indian Botanical collections and collectors. The taxonomic part of the book was cast in a large mould, and the descriptions were written in Latin. Unfortunately the condition of Dr. Thomson's health and the pressure of Sir Joseph's official duties at Kew made it impossible that the book should be continued on the magnificent scale on which it had been conceived. After a period of about twelve years Sir Joseph, however, returned to the task of preparing, with the aid of other Botanists, a Flora of the Indian Empire, conceived on a smaller scale and written in the English language. His proposals for this work were accepted and officially sanctioned by the Duke of Argyll while he was Secretary of State for India. The first part of this great work was published in 1872 and the last in 1897. In the execution of this great undertaking Sir Joseph had the assistance of Mr. C. B. Clarke, who elaborated various natural orders; of Mr. J. G. Baker, who worked out *Leguminosæ* and *Scitamineæ*, and of Sir W. Thistelton Dyer, Messrs. A. W. Bennett, Anderson, Edgeworth, Hiern, Lawson, Maxwell Masters, Stapf, and Gamble. The greater proportion, however, of the book is Sir Joseph's own work, and noble monument it forms of his devotion and genius.

Since the date of Sir Joseph Hooker's visit to India, by far the most important Botanical work done in India has been that of Mr. C. B. Clarke. Rather than attempt to give any appreciation of my own of Mr. Clarke's labours (which would be more or less of an impertinence), I may be allowed to quote from the preface to the concluding volume of the 'Flora of British India,' Sir Joseph Hooker's estimate of them. Referring to all the collections received at Kew since the preparation of the 'Flora' was begun, Sir Joseph writes: 'The first in importance amongst them are Mr. C. B. Clarke's, whether for their extent, the knowledge and judgement with which the specimens were selected, ticketed, and preserved, and for the valuable observations which accompany them.' Mr. Clarke has published numerous papers on Indian Botanical subjects in the Journals of the Linnæan and other societies. He has issued as independent books monographs of Indian *Compositæ* and *Cyrtandraceæ*, the former in octavo, the latter in folio, and illustrated by many plates; and he is now engaged on his *opus maximum*, viz. a monography of the *Cyperaceæ*, not only of India, but of the whole world; and to the completion and publication of this every systematic Botanist is looking forward with eager anxiety.

During the second half of the century Dr. Thomas Anderson, who was for ten years superintendent of the Calcutta Garden, collected much; and he had just entered on what promised to be a brilliant career of Botanical authorship when his life was cut short by disease of the liver, contracted during his labours to establish the cultivation in British India of the quinine-yielding species of cinchona. Dr. Anderson was also the earliest Conservator of Forests in Bengal. Sulpiz Kurz, for many years Curator of the Calcutta Herbarium, also collected largely in Burma, and besides many excellent papers which he contributed to the 'Journal of the Asiatic Society of Bengal,' he prepared for Government an excellent manual entitled 'The Forest

Flora of Burma.' This was published in two volumes in 1877. Other collectors in Burma were Colonel Eyre (in Pegu), Mr. Brnness (at Ava), and the Rev. Mr. Parish, to whom horticulturists are indebted for the introduction to Europe of the beautiful orchids of this province. And in this connection must be mentioned Mr. E. H. Man, C.I.E., who, although not himself a Botanist, has given for many years past the greatest possible help in the Botanical exploration of the Andaman and Nicobar groups of islands, our first knowledge of which was, by the way, derived from the collections made by the naturalists of the Australian and Danish exploring expeditions. A large book on Burma, which contains a good deal of Botany, was published by an American missionary named Mason, who resided for the greater part of his working life in that country. General Sir Henry Collett, who commanded a brigade during the last Burmese war, also made most interesting collections in that country, the novelties of which were described by himself in collaboration with Mr. W. Botting Hemsley, of the Kew Herbarium, in the Linnæan Society's, 'Journal' some years ago. Sir Henry Collett also collected much in the Khasia and Naga hills, and in the portion of the North-Western Himalaya of which Simla is the capital, and on these latter collections, together with the materials in Kew Herbarium, Sir Henry is now elaborating a local Flora of Simla. The preparation of a local Flora for an Indian district is an entirely new departure, and the publication of Sir Henry's book, which is to be well illustrated, is looked forward to with much interest. At rather an earlier period, Dr. Aitchieson, C.I.E., was a diligent collector of the plants of the Punjab and of the North-Western Frontier. Some results of his work are to be found in his 'List of Punjab Plants,' which was published in 1867, and in various papers which he contributed (some of them in conjunction with Mr. Hemsley) to the Linnæan Society and to the Botanical Society of Edinburgh. In Dr. G. Henderson's book on Yarkand there are also descriptions of some plants of the extreme North-Western Himalaya and of Western Tibet. Mr. (now Sir George) Birdwood also made some contributions to the Botany of the Bombay Presidency.

Five officers of the Indian Forest Department, viz. Dr. Lindsay Stewart, Colonel Beddome, Sir D. Brandis, and Messrs. Talbot and Gamble, C.I.E., have within the past thirty years made important contributions to the systematic Botany of India. Dr. Stewart collected largely, and published in 1869 his 'Punjab Plants,' a book which gives a very imperfect impression of his acquirements as a Botanist. Sir Dietrich Brandis issued in 1874 his admirably accurate 'Forest Flora of the North-West Provinces of India,' illustrated by seventy excellent plates. Between the years 1869 and 1873, Colonel Beddome issued his 'Flora Sylvatica of the Madras Presidency,' illustrated by numerous plates. He also published, between 1869 and 1874, a volume of descriptions and figures of new Indian plants, under the title 'Icones Plantarum India Orientalis.' Colonel Beddome is the only Indian Botanist of note, except Griffith, Mr. C. B. Clarke, and Mr. C. W. Hope, who has written much on Indian Ferns. His two works, the 'Ferns of Southern India' and the 'Ferns of British India,' published, the former in 1863 and the latter between 1865 and 1870, practically give a systematic account, together with excellent figures, of the whole Fern Flora of India. Of these excellent books a condensation in a popular and abridged form has also been issued. The fourth Forest officer who has published contributions to Systematic Botany is Mr. W. A. Talbot, whose 'List of the Trees, Shrubs, and Woody Climbers of the Bombay Presidency,' gives evidence of much careful research. And the fifth is Mr. J. S. Gamble, who besides amassing at his own expense probably the largest private collection of plants ever owned in India, has published a systematic account of the Indian *Bambuseæ*, a tribe of grasses which, from the

peculiarity of many of the species in the matter of flowering, had so long been the bane of the Indian agrostologist. Mr. Gamble, in his monograph, gives a description and a life-sized figure of every one of the Indian species. Of this monograph (which forms a volume of the 'Annals of the Botanic Garden, Calcutta') Sir Joseph Hooker writes (at p. 375, vol. vii. of his 'Flora of British India'): 'It is indispensable to the student of the tribe by reason of its descriptions and admirable plates and analyses.' Mr. Gamble has also published a Manual of Indian Timbers. A Forest officer who has ever ready to help in Botanical work, but who never himself published, was Mr. Gustav Mann, for many years Conservator of Forest in Assam, but now lost to India by his premature retirement. Other Forests officers, who have done, and are still doing, good botanical work in their various spheres, are Messrs. Lace, Heinig, Haines, McDonell, Ellis, Oliver, and Upeudra Nath Kanjilal. Mr. Bourdillon, Conservator of Forests in the Travancore State, is also an enthusiastic Botanist and collector.

In the Madras Presidency Botanical work has been carried on during this second half of the century by Noton, Perrottet, Metz, Hohenacher, Schmidt (on the Nilgiris), Bidie, and Lawson. By the efforts of the latter two a second public Herbarium was established in Madras (the first having been broken up many years ago), and in this second Madras Herbarium are to be found many of the collections of Wight, besides those of the other Madras Botanists just named.

In the Bombay Presidency the only public Herbarium is at Poona. This is of recent origin, and owes its existence to the devotion of four men, viz. Dr. Theodore Cooke (late Principal of the College of Science at Poona), Mr. Marshall, Woodrow (until recently Superintendent of the Garden at Guneshkind and Lecturer in Botany in the Poona College), the late Mr. Ranade (a native gentleman), and Dr. Lisboa (a medical practitioner in the Deccan)—all four enthusiastic Botanists. The amount of Government support given to this Herbarium at Poona has hitherto been very inadequate. It is to be hoped that greater liberality may be extended to it now that a stranger to the Bombay Presidency has just been appointed to its charge in the person of Mr. George Gammie, hitherto employed in the Cinchona Department of Bengal.

Reference has already been made to the Botanic Gardens at Seharunpore and Calcutta. But to complete this sketch, and especially in order to give a clear idea of the apparatus at present existing in India for carrying on the study and practice of Systematic Botany, it is necessary again to refer to them. On the retirement of Dr. Jameson in 1872, Mr. J. F. Duthie was selected by the Secretary of State for India as Superintendent of the Seharunpore Garden. Mr. Duthie is still at Seharunpore. During his tenure of office he has added to the Herbarium previously existing there (which consisted chiefly of the collections of Royle, Falconer, and Jameson) a magnificent collection of his own. Mr. Duthie has published a valuable book on the 'Field and Garden Crops of the North-Western Provinces,' and another on the Grasses of the same area. He is now engaged on the preparation of local Floras of the North-Western Provinces and of the Punjab.

The Calcutta Garden at the Date of Sir J. D. Hooker's arrival in India in 1848 was under the temporary charge of Dr. McClelland, who soon made way for Dr. Falconer, who, in 1855, was succeeded by D. J. Thomson, and he in turn by Dr. T. Anderson in 1861. Mr. C. B. Clarke acted as Superintendent during the interregnum between Dr. Anderson's lamented death in 1870 and my own appointment in 1871. The Garden and Herbarium at Calcutta have been most liberally supported by the Government of Bengal. By funds thus supplied the Garden has been remodelled and improved; the Herbarium has been housed in an excellent fire-proof building (erected in 1883), and the collections of which it

consists have been greatly increased. The chief items of these after acquisitions have been the large contributions of Mr. C. B. Clarke; of Dr. D. Prain, for many years Curator of the Herbarium, and now Superintendent of the Garden and of the cinchona plantation and factory; of Mr. G. A. Gammie, formerly one of the staff of the cinchona plantation and now Lecturer on Botany in the College of Science at Poona; of Mr. R. Pantling, Deputy-Superintendent of the Cinchona plantation, who, in addition to dried specimens of the orchids of Sikkim, contributed nearly five hundred drawings, most of which have been lithographed as the illustrations to a book published in the 'Annals' of the Garden as the 'Orchid Flora of Sikkim;' of Mr. Kunsler, a collector in the Malay Peninsula; and last, but by no means least, of a trained band of aborigines of Sikkim named Lepchas who possesses keener powers of observation of natural objects, more patience, sweeter tempers, and, I am bound in fairness to add, dirtier clothes than any race I have ever met—black, yellow, or white! In addition to their liberal grants to the Garden and Herbarium, the Bengal Government, twelve years ago, sanctioned the publication, at their expense, as occasion might offer, of monographs of important families or genera of Indian plants. These monographs are printed in quarto, and they are, with one exception, profusely illustrated by plates drawn and lithographed by Bengali draughtsmen. The series is known as 'The Annals of the Royal Botanic Garden Calcutta,' and it has now reached its eighth volume, the ninth being in active preparation. These 'Annals' have been contributed to by Dr. Prain (my successor at the Calcutta Garden) by Dr. D. Douglas Cunningham, Mr. J. S. Gamble, Mr. R. Pantling, and myself.

About ten years ago, it occurred to the Supreme Government of India that it might be to the interest of Science if the four Botanical establishments at Calcutta, Seharunpore, Madras, and Poona were to be formed into a kind of hierarchy under the designation of the Botanical Survey of India, without removing either the officers of the four institutions to which they were attached from the financial or general control of the local administrations within which they are respectively situated, the Supreme Government making a small contribution of money for the purpose of exploring little-known districts and making itself responsible for the cost of a publication called 'The Records of the Botanical Survey.' The four institutions just mentioned continue, therefore, to be paid for and controlled by the Governments of Bengal, the North-Western Provinces, Madras, and Bombay, but their Superintendents are placed on the cadre of the Botanical Survey. The published Records of this Survey now extended to twelve numbers, each of which is devoted to an account of the Botany of some parts of the enormous and continually expanding area to be explored.

Such, then, is the machinery by which Systematic and Geographical, as distinguished from Economic and Physiological, Botany is carried on within the Indian Empire. But the work done in India itself by no means represents all that is being carried on in connection with the elucidation of the Flora of the Empire of India. On the contrary the bulk of the work of elaborating the materials sent from India in the shape of dried specimens has always been, and must always be, done in a large Herbarium; and until lately no Herbarium in Asia has been sufficiently extensive. The last word on every difficult taxonomic question must still lie in Europe. A very large number of the Herbarium specimens collected in India have found their way to the various centres of Botanical activity in Europe, and have been described by Botanists of many nationalities. The lion's share of these specimens has naturally come to the two great national Herbaria in the British Museum and at Kew, but especially to the latter. It was in the Kew Herbarium that Sir Joseph Hooker and his collaborators prepared

the Flora of British India. And it is in the Kew Herbarium that are to be found the types of an overwhelming proportion of the new species described for the first time in that monumental work. The Kew Herbarium is therefore to the Indian Botanist the most important that exists. I must apologise for diverging for a moment to remind you what a type specimen is. It is the very one on which an author has founded any species to which he has given a name. And in order to determine absolutely what is the specific form to which the author meant his name to apply, it is often necessary to examine his type. The necessity increases in urgency with the extension of our knowledge of the Flora of the world.

(To be concluded.)

THE CAUSE OF DECAY IN PLANTS, AND THE REMEDY TO GIVE TO THEM NEW LIFE.

BY R. R. HARDING, CURATOR, BOTANIC GARDENS, TOOWOOMBA, QUEENSLAND.

The primary object of this paper is to direct attention to the results of unskilful planting of trees. I will endeavour to show that this is very expensive, and unsatisfactory in the end. When we consider that it takes only a little time longer to plant trees properly, the only excuse that can be given for not doing so is that the persons who plant trees or shrubs are afraid to separate the roots for fear of killing the plant. It would be, as a matter of fact much better to kill it then than to be disappointed in after years. Such cases are numerous in this town and I am often asked by residents here and by others in different parts of the colony, what is the reason for their trees looking so miserable?

Before I give a practical illustration of this, I will go back to the heading of this paper: "The Cause of Decay in Plants." Decay or disease is the antithesis of health, and, as the health of the plant means the correct performance of its functions, disease may be defined to be an incorrect performance of those functions. I believe that of all the various kinds and forms of disease to which plants are liable, none are so general or so fatal as those affecting the roots. In many, perhaps in most cases, it is extremely difficult to say precisely where disease originates and how it is produced. It is only when we see it in some of its intense forms of development that we are aware of its existence.

On the authority of the wisest of men there is nothing new under the sun, yet there are constantly presented to us things that appear, and are to us essentially new. Take the position of a tree. Its position may be said to be unchangeable; the soil, subsoils, atmosphere, and climate may be so far unvarying as to be also unchangeable. On the other hand, the roots of the tree are constantly year by year altering their position, traversing as it were the whole surrounding area in quest of food. Moisture also performs a very important part in the nourishment of the tree and all strata of soil penetrated by the roots are not equally full of moisture, so that when the roots pass through one stratum the tree is well nourished, and on passing through another it is less liberally supplied. Atmospheric influences also materially affect the tree, and as these vary so the growth varies. Insects, too, do occasional injury to trees by eating or poisoning their foliage, hence, as the foliage is good or healthy, or the reverse, so is the growth of the tree good or bad for that or for succeeding years. The mellow, withered, or fallen leaf in early or midsummer is not always a sure indication of a diseased tree, indeed it is always more satisfactory to find an evergreen tree of any kind shed its leaves freely on agitating the tree than that they should tenaciously hold by the tree after they have become withered. The decay or the dying of leaves in some instances, evidently depends on a want of vigour or on partial rot in the roots, but in

a great majority of cases it is produced by injudicious planting and after cultivation. As an instance of this, I may state that last September I was requested to inspect the avenue of camphors growing in the Royal Agricultural Show Grounds. For the past two or three years they had looked very sick, each year getting worse, and they would eventually die if something extraordinary were not soon done to them. Various causes have been assigned for the appearance of these trees by those who have expressed their views upon the subject, but there was no difference of opinion as to their highly unsatisfactory state. Like most other places of similar extent in this part of the Downs, it is evident that the land in the area is not all alike in its suitability for the growth of trees; yet allowing for the difference, those conversant with tree culture will not have long to seek for the cause of this decay, which has been slowly but surely going on. The decline is not the result of old age, nor of the capability of the soil to grow and maintain the trees in a healthy condition, for a closer inspection of similar trees growing only a few yards away, confirmed my first opinion, which was that want of timely thinning and the want of nourishment at the roots, caused by bad planting, were at the bottom of it all. The questions put to me were—"Could anything be done to the trees to give them new life? Was it advisable to plant young trees between them, and when these had made a start to then take the sick ones out? The answer I gave was—"Leave them to me, with power to act, and they will be given new life." I remarked at the time these were planted that they would never make anything else but shrubs, and that only for a time. I examined the roots and foliage thoroughly, and found that three parts of the branches were dead or decaying and the foliage scant and yellow-tinted; but on examining the roots I saw at once the cause of all the evil. The trees in the first instance, had been planted too high; the roots when young had not been spread out; they were simply growing as if they remained in a pot, and those who know the size of these camphors will be surprised at my saying that the roots had not extended more than 6 feet from the stem of the tree, when they should have spread 12 feet at the least. The roots showed up out of the ground 2 feet from the trunk. They had embraced and interlocked each other and on account of the scant foliage, were exposed to the full rays of the sun, and the remark I made at the time of planting was now justified. My first work was to cut out the dead yellow branches, the centre of which was found to be decayed. Then all the inside branches were taken out, the surface of the soil under each tree was forked over very shallow, and outside the spread of the foliage a trench was dug all around the tree. Now this, of course, is the proper place to apply the nourishment, at the mouth of any tree, as here are situated the extremities of the roots, and as these feeding roots spread out beneath the soil pretty nearly to the same extent as the branches above ground, the tree should be fed at the distance of the extremity of the branches above ground from the stem. Here Nature teaches us a lesson: The head of the tree is in the form of a dome like an umbrella; all around the soil is exposed to the rain, and the water penetrates the earth just where the extremities of the roots are situated to receive it. In addition to this, the greater part of the rain which has washed and refreshed the leaves trickles down from the ends of the branches, and reaches the ground in the appropriate spot. In trenching around the trees, immediately where the branches extended, the men were surprised to find no roots. This was nothing more than my practical experience expected, because, if there had been roots there would have been no necessity to do anything to the trees; but here was the mischief. The trees were then thoroughly mulched with half-rotten straw and manure, well covering up the large crinkled roots near the stem with a good coating of it. At the extremities, where the feeding roots should have been in the trench, the richest manure was

placed, but none was forked in. On the 17th March, the caretaker being present, we found that at the extremity of the trenching, and right up to within 3 feet of the stem, the young fibrous roots had formed a mat, and it was impossible to lift the mulching without damaging these roots. Now, what I wish to draw particular attention to is this: When the men started to fork over the surface they wanted to start near the stem. This I objected to at once, and made them keep their backs to it, showing them where the mistake is often made by digging underneath any tree or shrub. Each time you turn over the soil, so many rootlets suffer, because as you proceed you keep on doubling the roots over towards the stem, and this is carried on until the work is finished, when the soil is generally raked back again. Now this is against nature; it is similar to someone doubling your fingers back upon the wrist and leaving them there. The roots are left in that state until the next season, and then the same cruel operation is carried out again, until the roots are diseased by being constantly bruised and broken, when, of course, the tree suffers and begins to decay. The proper way to clean underneath a tree is to start just at the extremity of the branches, keeping your face to the opening until finished. You need not disturb the soil near the stem of a large tree, for do what you will there you cannot improve the growth of the tree; because all roots at that place cannot feed, being too large, but you can throw some of the soil from the first remove round the stem. If you want to prevent decay, feed them just as I have explained that is at the extremity of the feeding roots, and that is just where the rain trickles down from the leaves. A practical man can see immediately what is the matter with any tree that is sickly-looking; if the top of the tree is decaying, it is the fault of the tap-root entering the cold wet ground, and the remedy for this is to excavate and cut the tap-root clean off I say clean, for the least bruise will affect the tree's future growth. If the branches wither and the leaves fall off from the lower branches, it is because the surface roots have been disturbed and doubled back in the way I have already described. There may be some other cause, but that is the chief one. As all plants in this colony are surface rooted, it is advisable not to disturb them by that process. If the rootlets require separating the best way is to get a pointed pick and work from the stem by continuous drawing: this does no harm, and the few roots that are torn up are of advantage to the tree's growth; it separates the mats of roots and draws all towards the feeding point. There is no necessity to throw any soil back, get some mulching and cover all underneath the tree with a good coating. If you have any manure especially good, I have told you where to put it.

I know of one instance where the owner, wishing to prevent the roots of a camphor tree from coming into a bed made around the stem, placed bricks and sheet iron close round the bottom with the object of preventing its roots coming through; but very soon they got beyond this confinement; they turned upwards and now the 2 feet of soil is a mass of fibrous roots, and the tree has splendid foliage.

There is no pursuit wherein so much depends upon the right thing being done at the right time as in this; and in all other pursuits the man of close observation and systematic habits—who is not too proud to learn from any sources, however humble—is the one who will succeed, for there is no better guide than to seek the advice and experience of others and by following the advice tendered it will be the means of preventing decay, and will also give to the plants new life.—*Queensland Agricultural Journal.*

HYBRIDISM IN CITRUS.—The seeds of Citrus often contain more than one embryo plant. Lately Mr. Webber has shown that in hybrid plants of Citrus only one of the embryos shows any trace of the pollen-parent, the true hybrid being derived from the egg-cell, and all the others by adventitious embryos produced from the nucellar tissue of the ovule.—*Gardeners' Chronicle.*

THE STRAITS: DEVELOPMENT OF THE FEDERATED MALAY STATES.

COFFEE, COCONUTS, AND RUBBER IN PERAK.

A representative of a Colombo Paper has had an interesting interview with a resident of the Federated Malay States, who is on a visit to Ceylon, showing the opening up of the country, the introduction of new products and the starting of new industries, all affording splendid opportunities for the investment of capital. The development of the country is gradually taking place, Europeans are settling down, and plantations of new products are being opened, while the mineral resources of the country is also attracting a share of attention. The climate is fine and agreeable, and there is plenty of rain, and the soil is described as very rich. Land can be secured on favourable terms from Government on a long lease at a nominal rent.

The Rev. W. E. Horley, of the Methodist Episcopal Church, an American institution, who afforded the representative the interview, has spent many years in the Malay Peninsula carrying on Mission work at Ipoh, in Perak, while he has also travelled all over the country.

COFFEE.

Regarding the introduction of coffee we were told that the soil is remarkably adapted for its cultivation, and during recent years large plantations were being opened up round about Ipoh by Chinese *towkyahs*, that is men who have made their fortunes in tin mining. At Taluk-anson, about forty miles from the coast up the Perak River, a fine, large plantation, about four to five years old, has been opened by a European Company, and this is now bearing heavily. An older plantation is Waterloo estate in Kinta district, which covers an extensive area, and was planted over ten years ago. With the exception of the first-named estate which is on low land, the others are all on the hills, about 100 miles from the coast. Most of them are now bearing, and the produce is transported by river and rail, being taken to Penang or Singapore by small steamers. The berries are fine and large, and there is no leaf disease, and the trees have a vigorous growth. The price of coffee, however, is at present very low, but notwithstanding this, the native growers keep up their plantations.

COCONUTS.

Coconut cultivation can be said to be quite a new introduction. Up till recently whatever nuts were required had to be imported from neighbouring countries, but now the first clearings are producing crops, while further extensions are in progress. A large clearing at the mouth of the Perak River which was laid down in nuts some four years ago is now in bearing which demonstrates the richness of the soil. The Straits Plantations Co., a European concern, is opening out several thousand acres; while they are also intending to erect oil mills on their premises. The natives are also going in largely for coconut cultivation, and on some of their patches there are trees already in bearing. Several new Companies are being formed for coconut cultivation on a large scale at the mouth of the Perak River; and the industry promises to be an important one in the near future. There are vast tracts of land suitable for coconuts, and only waiting to be opened.

PARA RUBBER

The cultivation of Para Rubber is just attracting some attention, and the product is being planted by both Europeans and natives in different localities. A wealthy Chinaman, with much enterprise, is going in for Rubber cultivation on a large scale at Kotabharu, in the Kinta Valley, which is about 30 miles from Taluk-anson. He is opening out about 5,000 acres, and has engaged a European Manager to supervise the work. Other plantations for this product are also being opened in the Kinta Valley; and large patches among the coffee, on the coffee estates, are to be seen planted with the new product. It is expected that satisfactory results will be obtained in Rubber cultivation.

SUGAR PLANTATIONS.

The sugar industry in the Malay States, like that of the adjacent countries, is an old one. The cane thrives, very well, and in the Malay Peninsula is principally grown in the Krin District, adjoining Lower Perak, on the coast most of the plantations being owned by European Companies, but the cane is now being introduced inland and a large tract of land is being opened up the Perak River, close to Taluk-anson, by Mr. Turner from Province Wellesley. Tamil coolies are felling the jungle, and it is expected to start planting the canes shortly. Almost all the existing plantations have their sugar mills; while it might be mentioned that all the labour employed on the plantations is secured from South India.

CLIMATE AND RAINFALL.

While on the subject of planting it will not be out of place to say a few words about the climate and rainfall. The climate is described as pleasant and healthy, and there is plenty of rain. In fact it might be said to be raining during the whole year with the exception of two months which are hot and dry. The rainfall is pretty evenly distributed through the whole year, and the country well watered. There is said to be very little malaria in the country.

AGRICULTURAL EDUCATION IN
GREATER BRITAIN.

PAPER READ BEFORE THE FOREIGN AND
COLONIAL SECTION OF THE SOCIETY OF ARTS, ON
TUESDAY, FEBRUARY 27, 1900.

By R. HEDGER WALLACE.

There can be little doubt that the interest taken in agricultural education generally is extremely widespread. The subject I find is not discussed by a few authorities alone, but seems to appeal to and attract the attention of the general public also. The title of my paper, I trust, indicates clearly the section or branch of the subject I intend to deal with, and I would ask that it be clearly understood that I do not approach it as an authority, agricultural or educational. My paper can be best described I think, as a compilation, in which an attempt is made to condense, in a form suitable for the general public, a large amount of data obtained from various sources. It is an attempt to answer such a common inquiry as, What are they doing in regard to agricultural education in this or that colony? I have no intention, therefore, of criticising either the work done or methods employed in the Colonies; and may only venture into the domain of criticism when discussing the point whether a suitable training for colonial life can be obtained in this country, or whether it is desirable to take advantage of the educational facilities in agriculture offered in the Colonies. Here of course all citizens looking forward to the settlement in life, either of themselves or of members of their families, meet on common ground.

The subject of "Agricultural Education" generally has within recent years been twice (as far as I am aware) brought before the Society of Arts. First by Mr. J. C. Morton in 1887, and next by Professor Wrightson in 1888. In Mr. Morton's paper no reference is made to the Colonies at all, while Professor Wrightson only makes a passing allusion to Canada in his. Again at the International Congress on Technical Education held in London in 1897, at the invitation of the Society of Arts, there is no detailed reference, as far as I can find to the work done in the Colonies either in the papers read on "Agricultural Education" or in the resulting discussion. Some information however, can be gathered from the papers on technical education. In the period under discussion, I may add, there have been quite a number of papers read and published on "Foreign Agricultural Education" but their survey has been limited to the work done on the Continent of Europe or in the United States, and the Colonies have been left untouched. Yet there is one paper to which I must direct particular attention, namely, the paper by Mr. Henry F. Moore on "Agricultural and Technical Education in the Colonies" read before

the Royal Colonial Institute in January, 1891. This exceedingly interesting and valuable paper, in its references to work accomplished in the matter of agricultural education in Greater Britain, covers the same ground that I do in this paper. In fact I shall attempt a similar survey, but I do it after an interval of ten years, and if a comparison be made, my paper will indicate, I hope, the progress accomplished in the Colonies and dependencies surveyed.

I have already stated that the general public are interested in learning what is being done in the Colonies in regard to agricultural education, and they are also keenly interested in discussions as to whether a suitable training for colonial life can be obtained at home or not. That such questions are really of general interest, and one not limited or restricted to the area in which dry-as-dust authorities and factists profound and demolish the dogmatic assertions of each other, can be readily illustrated by references to our general literature as represented by our ordinary monthly magazines and reviews. I would in this connection refer to such articles as that entitled "Colonial Training for Gentlemen's Sons" in *Chambers' Journal* for 1885, to Mr. Montefiore's "Education for the Colonies" in *Macmillan's Magazine* for 1892, to the article by Frances Macnab on "The Production of Learned Pigs amongst the Poor" in *Temple Bar* for 1896, and to Mr. George J. Holyoske's article on "Emigrant Education" in the *Nineteenth Century* for 1898. The articles I have just named, and many similar ones that could be quoted, support I think, the view that my paper should be addressed to, and primarily intended for, the ordinary man, rather than for the expert. At any rate such is the position I have adopted, and I hope these prefatory remarks will sufficiently explain.

When one surveys the agriculture of Greater Britain it is at once apparent that it can be grouped under two heads, i. e., farming, farms, and farmers: and planting, plantations, and planters. That there is a difference between these two groups will be at once recognised; but to define when or how the distinction is made or can be drawn is by no means an easy matter. Generally speaking, however, it may be assumed that a plantation is a large estate devoted to the rearing of tropical or semitropical crops—such as sugar-cane, tea, coffee, cotton, and tobacco—by the labour of an inferior or subject race. On the other hand a farm can be of any size and is cultivated by the labour of the owner, assisted when desired by the labour of men of his own race, and the crops grown are those of a temperate climate. The distinction between a farmer and planter is so marked that it has been stated (in *The Times* I think) that the tendency or tone of a body of planters is to be exclusive and aristocratic, while on the other hand that of a community of farmers is generally democratic.

The technical education or training in agriculture of a prospective farmer and a planter (we suppose will be readily admitted), ought to differ a good deal, seeing that the work, for instance, of a tea planter in Assam differs wholly from every point of view from that of a farmer in Tasmania. As far as I am aware, however, no such distinction is made in the agricultural training obtainable in this country: Some such specialised training is, I am aware, obtainable at Kew, by gardeners, and a man going out from there to some tropical botanic station has already had some experience in the propagation of tropical plants specially those of economic value. Turning next to Greater Britain there also, unfortunately, we find no facilities are provided for the agricultural education or technical training of the planter, such facilities as do exist in the tropical regions being intended entirely if not exclusively for the benefit of the native race. I believe, however, that under Dr. Morris's scheme of agricultural education for the West Indies opportunities are to be given to the younger generation of planters and sons of planters to study "the scientific problems which underlie the practical work in which they are daily engaged."

There are many in this country, I think, who at some period in their life have had to ask themselves

the question—can a training for a life career in Greater Britain, as a farmer or a planter, be obtained in England? That for a planter is, I should say, practically unobtainable, as the soil, climate, vegetation, and conditions of life and work with us are not the same as in tropical and subtropical countries. Perhaps it is from this very cause that, as Sir William Des Voeux has pointed out, we are said to be most subject of all colonisers to entertaining delusions about tropical cultivation. "The luxuriance," he states, "of the tropical virgin forests appeal to the colonising enthusiast chiefly as indicating possibilities of its succession by equal luxuriance of plantations controlled by planters." In imagination he sees the 'jungle,' 'bush,' or 'scrub' replaced by fields of sugar, cotton, or tea, judging in doing so, of the cultivation and vegetation of the tropics by the conditions common to the temperate zone. As regards planting then it would appear that the only education or technical training available is by the system under which young men are placed out with planters to be taught the management of an economic plant in all its stages, from the seedling in the nursery to the shipping home of the ultimate commercial product.

There still remains a part of the original question to be examined, namely can a training for farming in the Colonies be obtained in England? Those who intend to settle and farm in the Colonies can usually, I think, be divided into two classes—those who have been brought up in rural districts and from an early age have been accustomed to farm and manual labour, and on the other hand those brought up in urban districts unaccustomed to farm labour and often even to labour in any form. In a way, as far as I can gather, this distinction is to some extent recognised in this country. Those who are acquainted and accustomed with the practical work of agriculture can find institutions in England at which they can study simply the science of agriculture. At the same time those who have known acquaintance with the details of agricultural practice will be able to find institutions, where besides studying the theory of agriculture, they will also be instructed as regards its practical details, taking part in all the operations and processes which go to form the yearly cycle in farming. Turning now to the Colonies, what appears to be a general feature there is, that in the agricultural colleges of Great Britain it is assumed that the student who seeks instruction is unacquainted with practical farm work and, therefore, practical work or manual labour must be undertaken or performed by all and is a part of the instruction offered.

The agricultural settler in the Colonies as already indicated may have had a rural or an urban training. It is but natural, therefore, that these two differently trained men should approach the subject of "Agricultural Education" from two different standpoints. In the one case, considering that both the theory and practice of agriculture has to be learnt, it would seem that the most advantageous way to undergo such instruction would be in the college of the colony where settlement was intended. On the other hand one cannot but admit the justice of the other view held, namely, that the practical man who desires to study chiefly the higher scientific problems which underlie the practice of agriculture before he entered upon colonial life, would find it to his advantage to do so in England, where he can command the best teaching talent, material and equipment. Still there is one factor which must not be overlooked by the most practical man who has further benefited by an expensive agricultural education in England, and that is the time and money that must necessarily be spent by him, in obtaining colonial experience in the colony he has chosen. Colonial experience being a term which indicates the knowledge that is absolutely necessary for bringing undertakings entered upon with entirely new surroundings to a successful issue, and it includes experience in "the clearing of bush lands, the preparation of virgin soil for cultivation, the dealing with the heavy timbers of the colony, whether for use or destruction, the varied modes of

cultivation and manuring consequent on the peculiarities of soil and climate and methods of clearing and reaping, the different systems of fencing, the handling of large herds of cattle and flocks of sheep, the local buying and selling of the stock and produce and the treatment of wool, timber, meat, fruit, bark, butter and other produce for export." It will be readily seen therefore that this "colonial experience" is the difficulty that has to be surmounted and, of course, it will be just as readily observed that a training at a colonial agricultural college, theoretically, should give the knowledge and experience usually so much in demand and sought after.

This leads me to what is the main object in this paper—a survey of what our colonies and dependencies have attempted and accomplished in respect to agricultural education. I cannot pretend to be able to give a complete record of what is being done in the British Empire, but I have attempted by correspondence with the chief officials of our various colonies and dependencies, and by a careful study of numerous reports to be found in the libraries of the British Museum, Colonial Office, and India Office, assisted also by the good offices of the various Agent-Generals in London for our colonies, to gather together some authentic information on the subject.

Leaving England, then, and going to the great American continent, the first country there of importance for us is the Dominion of Canada. I have been favoured with a memorandum relating to agricultural education in Canada, which has been drawn up by Dr. Saunders, Director of the Dominion Experimental Farms as follows:—

"Information relating to agriculture in Canada is given to the farming community by both the Provincial and Dominion Governments.

"PROVINCIAL AIDS.

"1. *Agricultural Schools.*—Some of the provinces maintain agricultural schools for the practical education of young men in farming. The Ontario College of Agriculture at Guelph, Ont., is the best of these, institutions in Canada. It is well-equipped well managed, and has been in operation for about 25 years. There a large number of the sons of Canadian farmers receive practical training in their calling. An experimental farm is also carried on in connection with this institution. The full course of study covers a period of three years.

(To be continued.)

LESSONS IN TREE-PLANTING.

A class of blue-books that may be held to fully justify its existence, even in the face of recent criticism, is that relating to road-side arboriculture. As a rule departmental reports on this subject are at once concise, practical and instructive. It seems unfortunate, therefore, that advantages like these should not infrequently be neutralised by dilatoriness in publication. We have just received, writes the *Civil and Military Gazette*, two annual reports on road-side arboriculture in the Central Provinces, one for the year 1898-99, itself a sufficiently belated production, and the other for the year 1897-98. As it happens, the latter is intrinsically even more valuable than the former, and had it seen the light a couple of years ago, as it ought to have done, would doubtless have served important uses. Even at this late hour, however the book is still something better than waste-paper, and it may be that a province like Punjab which itself dabbles largely in tree-planting, can pick up some grains of counsel from the many failures and the few successes of the Arboriculture Department in the Central Provinces during the periods under notice.

The period 1897-98 embraced the worst half of the famine year, and although the closing portion was a time of recuperation, owing to the bounteous crops reaped in the autumn of 1897, still it was not to be expected that lost ground would be regained.

As remarked by the Commissioner of the Jubbalpore Division, "When the crops fail, road-side trees escape attention." The results of the year's operations

were, therefore, unsatisfactory. Planting operations, especially those conducted by private agency, were curtailed, and the maintenance of trees planted in previous years was a matter of special difficulty, owing to the drought that prevailed and the low level of the sub-soil water. But there were probably additional reasons for the comparative want of success. The Director of Land Records and Agriculture, who has watched the working of the present system for a number of years, seems disposed to question whether the allotments are always spent to the best advantage. Making due allowance for the unfavourable nature of the season, he thinks "we want more concentration of our resources, and at present money is frittered away in dribbles to little effect." The annual expenditure of District Councils on tree-planting amounts to about Rs.9,000 per annum, and as this money is distributed with impartiality rather than with discretion, each Local Board gets roughly the useless sum of Rs.100 to spend on twelve months arboricultural operations. As a particularly bad instance of this excessive subdivision of allotments, mention is made of Hoshangabad district, in which an annual sum of Rs.350 is split up to maintain six different nurseries. One, or at most two, nurseries should presumably suffice for all requirements, and by receiving undivided attention and financial support, would probably show much better results. On the other hand, as an instance of wise concentration of resources, Chanda district is cited, in which the entire annual allotment of Rs.300 is to be devoted for the next few years to planting trees on a single trunk road: when the avenues on this road are duly established, and not till then, the District Council will consider other claims. Complaint is also made that the management of nurseries is often conducted in what is described as spasmodic fashion. The Nagpur nurseries, for example, contain 1,257 saplings, all of which have attained a growth of over three feet. When this defect was brought to light, and an explanation called for, the naive explanation was offered that no new plants were put down because the existing number of saplings was deemed sufficient. It had apparently not occurred to the apologist that many of the existing saplings might grow too old for transplantation before funds are available to plant them out on roads, and that what is required is a succession of plants in different stages of growth, the number ready for transplantation each year according, as nearly as possible, with the number actually required for planting out. It is clear that in the absence of some such arrangement arboricultural operations would shortly come to a standstill for want of saplings of the prescribed height, or, what is more probable, money would be wasted on putting down immature seedlings.

As already stated that the number of trees planted by private agency declined greatly during the few years of agricultural depression culminating in the famine of 1897. The only districts in which it was possible to enlist the co-operation of private individuals are Bhandara, Balaghat, and Sambalpur. The assistance rendered in the two former districts was on a small scale, but appears to have been fairly effective. On this subject of tree-planting by private agency, the report for 1898-99 shows that there is much ground for dissatisfaction with the attitude of District Councils. In Nagpur the Chairman of the District Council states that "private plantings show no desire to undertake the trouble of planting and rearing trees on the side of public roads." He, however, admits that the slackness of Local Board members in the matter has a good deal to do with the apathy. The Chairman, District Council of Wardha, remarks: "Private agency has again been found wanting. The history of the year under report is one more illustration of the futility of reliance on this source." The inference to be drawn from these remarks would seem to be that the people of Nagpur and Wardha are less fond of tree-planting than those of more enlightened districts like Bilaspur or Bhandara. But as a matter of fact, this is not at all the case. The Officiating Commissioner of Settlements and Agriculture says: "I know from personal

experience that trees have been planted in the past by private individuals on the sides of public roads, and there are no districts in which rights of ownership in trees are more keenly contested. If the Chairman of the District Council, or the Local Board member of the district, have ever stirred a finger to encourage private enterprise of this kind, there is no evidence to show it in their reports. In other words, where there is apathy at the top, there will be apathy at the bottom.

Now that most districts have come up for increased arboricultural allotments, it is more than ever necessary that the operations should be carried out in a methodical manner. To this end nearly all districts have been induced to frame schemes; but this alone will be of little utility unless more interest is taken in the subject by those responsible. The reports which accompany the statements are annually full of promises of what will be done "next year," but each year come confessions of neglect of rules. Money may be wasted on planting out immature saplings contrary to rule, but nobody is ever brought to book. Responsibility for failures must be fixed before much improvement can be manifested, and the conduct of arboricultural operations of any road should be as much the duty of the overseer or other official in charge of it, as the maintenance of the road itself. In the report for 1898-99 the Officiating Commissioner of Land Settlements says: "The orders of the Administration are contained in a Revenue Book Circular, but have the instructions which it lays down been communicated to the officials whose duty it is to carry them out? Plain instructions should be issued in writing to each official, and neglect to carry them out should entail his punishment. For instance, the gharra system of watering is laid down in paragraph 11 of that Circular; where it has been tried it has been found successful and economical; yet it was necessary to ask for information regarding it in nearly every district, and in many cases it is found that the system has never been tried, although enjoined in the plainest terms." Again, in the matter of enlisting private agency, the Circular prescribes the issue of a preliminary certificate when a tree is planted and of a sanad when it is established. But this procedure is hardly anywhere followed: it is flagrantly ignored. Every body acquainted with the lethargic character of petty landowners realises that it is almost needless to issue a sort of impersonal encyclical urging malguzars to plant trees in their own and the public interests. Individual officers must go to individual malguzars whose fields adjoin public roads, and use persuasive eloquence to stimulate them to plant trees. As long as people are assured that they will receive the fruit of trees which they may plant, and their titles are confirmed by the issue to them of the prescribed certificates and sanads, many will be glad to come forward. The Officiating Commissioner of Land Settlement and Agriculture writes: "I remember cases a few years ago when such persons were denied the ownership of the trees they had planted. This is, I hope, a thing of the past, but unless certificates are issued in such cases, it is not unlikely that some ignorant road overseer may commit the same mistake, thereby effectually discouraging all private planting." This same critic says: "Some of the writers of the reports merely contend themselves year after year with lamenting the absence of private energy in the matter of tree-planting, but they never state what measures were adopted to enlist such efforts, or whether they themselves ever thought about it until the day that a draft report is put up for their signature." No doubt the present time is unfavourable for pressing the subject of road-side arboriculture. With famine imminent in many districts and a falling water-supply, arboricultural operations must necessarily be restricted. But there is no reason why, in such operations as are conducted, rules should be neglected, and neglect go unpunished, and the first essential is that every official in charge should know the rules and appreciate the consequences of neglecting them.—*Indian Agriculturist.*

COCONUTS AND NATIVE DEALERS.

JUDGMENT OF THE CEYLON SUPREME COURT.

Messrs. Justices Lawrie and Browne delivered judgment on March 16th, in the case in which Messrs. William Birch Junior & Co., Ltd., of Manchester, sued I. L. M. H. Mohamad Mohideen of the Pettah. The plaintiffs alleged that the defendant consigned to them 625 bags of coconuts and drew on them a bill of exchange for £150. The coconuts had to be sold at a loss, and the plaintiffs sued the defendant for the recovery of £225—15—10 or its equivalent R3,427.03 due to them on this consignment. In defence the defendant pleaded that he suffered the loss owing to the neglect of the plaintiffs, and admitted his liability to a sum of only £36—17—9. Mr. Dias, A. D. J., held that the loss was due to the plaintiffs' neglect, and condemned them in costs, giving them judgment only for the amount admitted. Their lordships gave judgment for the plaintiffs as follows:—

Mr. JUSTICE LAWRIE:—The defendant consigned a quantity of coconuts to the plaintiffs, a firm of merchants in England. Roughly speaking the agreement was that the plaintiffs should honour a draft for $\frac{2}{3}$ of the invoice price, that they should do their best to sell the nuts at a profit, that they should be paid brokerage and storage &c. and that they should be remunerated for their trouble; but as I read the agreement the consignors should bear the loss if the market fell or the articles did not find a purchaser. The speculation ended in a loss. The plaintiffs are out of pocket and they brought this action for payment. The defence is that the loss was caused by the neglect or want of skill or misconduct of the plaintiffs; that the plaintiffs ought to have sold the coconuts immediately or at least shortly after their arrival for 4s. per 100. They kept the consignment. The market did not rise for months and then so slightly as not to make up for the deterioration of the nuts. That is, fresh nuts were saleable at 4s. per 100 in December and though the price of fresh nuts rose in June or July to 5s. per 100, the price of stale nuts (as these had then become) was hardly 4s. and that the price obtained after so many months keeping was much the same as could have been got when they first arrived. The warehouse and other charges had accumulated, so there was a greater loss than if they had been sold for 4s. in December. Men are wise after the event and wish they sold when the market was higher, or bought when the market was lower. The defendant valued the coconuts at 8s. per 100. That estimate may have been justified by the prices quoted in September before the coconuts were shipped from Ceylon; but it is clear that the high price (8s.) induced many from the East and from the West to import nuts to England, that the market was glutted, the prices fell and 8s. per 100 could not be got after the nuts arrived. The defendant wrote to the plaintiffs to sell, but they did not say what sacrifice they were willing to endure; they did not say sell for less than 8s. If the letters implied that they would take a less price, they did not suggest that they would take half the value stated in the invoice. In my opinion the plaintiffs did not neglect the defendant's interest. At first, perhaps they were too sanguine as to a rise in the price. In January they showed they were not sanguine and they wished to bring the transaction to a close and they sent an account and drew on the defendant. They showed that at the prices obtainable there would be a loss. They asked to be relieved of the business and they were willing to transfer the account. An attempt was made to hand it over to Mr. Scrutton who did not agree to take the consignment over. Finally the plaintiff said that if the defendant did not make other arrangements they would sell for any price they could get. The defendant did not write to prevent this. This speculation in coconuts valued at double their worth was bound to end in

loss which the defendants have to meet. I would set aside and give judgment for the plaintiffs with costs.

Mr. JUSTICE BROWNE:—It appears to me that the learned Additional District Judge in declining to discuss in detail the evidence with regard to the state of the London Market for coconuts from Nov. 1896, when this shipment arrived, until May-June 1897, when they were sold, and in paying no attention whatever (so far as I can see) to the fact that from about the 22nd February until the 4th or 5th March, the defendant had placed the disposal of the shipment with another firm, has omitted matters of serious import in the consideration of whether or not the plaintiffs had failed in any duty or obligation by them to the defendant. The defendant certainly did not put any limit upon the price for which they should be sold in merely invoicing the nuts as at 8s per 100. It is to be noted, however, as to this consignment that the advice thereof preceded their arrival by only a few days, and that the shipment was in the less attractive forms of mixed unspecified sizes, instead of so many bags each of the sizes known in the trade as one, two and three, the first of which may have its subdivisions of large, extra large, and extra selected. Even had he therefore directed or had plaintiffs' broker desired to effect sales "to arrive" or "afloat," I find no reason to believe that such a sale would have been found easily practicable. The evidence as to the market rates shews that after prices of 7s in October and 8s in November there were such heavy stocks in London in December in readiness for the first of the four festivals, or festive seasons specified as those, when trade is most brisk, viz: Christmas, Easter, Whitsuntide, and August. That the highest price here proved to have been possibly obtainable in December sale would have been 4s 6d—5s 3d; but that practically there were no offers when these and other parcels were offered on 9, 11, 16, and 18 December, the nuts having been landed on 5th December, and that it must be taken that 4s—4s 9d was the best price obtainable before their arrival. The result to defendant of any sale that would have been effected then at 4s is shewn by plaintiffs' *pro forma* account of 14th January; it would have placed in plaintiffs' hands £17 16s 7s as against a draft for £150 which defendant had drawn against the shipment and plaintiffs had duly honoured. In spite of their having been offered at those 4 sales by a leading broker in the trade in December within a fortnight after arrival, the District Judge has held that "plaintiffs do not appear to have taken any steps whatever to dispose of them," and suggests that if on their arrival the price was only 4s the plaintiffs should not have honoured the defendant's draft. The consequence of that would probably have been that the Bank which bought the draft would either have simply redrawn upon defendant for the amount and let the nuts be sold to pay freight, or else have sold them with possibly a worse result than the *pro forma* account estimated, and in either case the defendant-consignor would have had no opportunity of seeing whether a less disastrous result could be arrived at ere he "ont his loss." When their broker reported to plaintiffs on the 4th January that there were no offers, were plaintiffs wrong in writing defendant and giving him a chance to make other arrangements? Or should they have sold at that loss? His letters to them of and after 23rd December, to effect speedy sales, had not then arrived, and they stood to lose about £190 upon this first venture of their new client, and had to keep a prudent watch over their own interests. Plaintiffs' manager says "it was unquestionably my duty not to sell in that state of the market," and in *Frazer v. Vanderspaar Withers J.*, remarked, in the absence of authorities on the point, looking at the question from a common sense point of view:—"If a factor has the invoice prices before him and he finds that he can only put the consignment on the market for a price very considerably below the invoice price, it might be argued that he should communicate the fact to his principal who would either instruct him to sell for whatever price he

could obtain, or would demand the return of the goods subject to any lien for honoured drafts drawn against the goods and other legitimate charges." How defendant would have judged of plaintiffs had they so sold, may be considered from the fact that on receipt of their letter he did not wire "sell best possible price," and honor their drafts, thus making his loss then, but elected to try the market further per another agent, who on the 3rd March reported the nuts were then worth only 35s per 1,000, and declined to pay the draft and freight as a condition-*precedent* to their realising the invoice. No member of their firm however gave evidence for what "much better price" they could have sold them for the Christmas market. There is but little evidence (apart from Mr. Isaac's evidence as to sales "to arrive") of what the market rates were in and after March. They seem to have been 3/6—4/3. Even on the 25th March defendant wrote to plaintiffs "If you cannot obtain a better offer, deliver to Messrs. Scrutton. Owing to your non-experience in this line of business I had to suffer the loss." He evidently still believed that a better market could have been and might even then be found, and, in the same faith as he there wrote, has defended this action. But the evidence does not shew that this defence was well founded. One witness examined spoke chiefly, if not entirely of sales to arrive, which are more speculations than "Open Sales" and the other had no transactions in Dec.—May, except one in Feb. which was of assorted nuts and "to arrive." I have pointed out that defendant's general instructions to effect speedy sales were received after the plaintiffs had, as they thought it their duty to do, referred to him for instructions ere sacrificing the consignment at half the price he had anticipated, and I regard his action in desiring to see, could Messrs. Scrutton do better for him, and in not telegraphing or even writing "sell at once" is in itself approbating their having referred to him. I find no ground therefore for the strictures which the District Judge has passed in his Judgment on the plaintiffs. They appear to me to have taken all ordinary measures to bring the consignment to prompt sale, and defendant's loss is attributable only to the market being overstocked. I would set aside the dismissal, and enter judgment for plaintiffs as prayed for with costs.

THE RUBBER INDUSTRY.

At the sitting on Friday, February 23rd., in the House of Commons, Mr. Weir asked the Secretary of State for the Colonies, whether he was aware that the value of rubber imported from the British Central Africa Protectorate through Chiromo amounted during the year 1898-99 to £10,233 18s, as compared with £1,044 17s 6d in 1897-98, showing an increase of over £9,000 in one year; and would he state whether any efforts were being made to regulate the mode of collecting rubber juice, so as to prevent destruction of the rubber vines.

Mr. Brodrick, who replied, said,—Yes, it is so stated in the last report on the Protectorate. Regulations regulating the manufacture and sale of rubber were issued on September 1st last.

MORIB COCONUT ESTATES SYNDICATE, LIMITED.

Registered on February 23rd by Heath and Hamilton, 50, Lincoln's-inn-fields, W C, with a capital of £2,500 in £10 shares. Object, to acquire an estate in the district of Kuala Langat, Selangor, Malay Peninsula, and to carry on the business of coconut and rubber growers and merchants. The first directors (to number not less than three nor more than seven) are to be appointed by the subscribers. Qualification, one share.—*Financial News*, March 2.

CEYLON COMPANY DIVIDENDS FOR 1899.

(AS COMPARED WITH PREVIOUS DIVIDENDS).

The following table has to do with 24 Plantation (Tea) Companies, one for Coco-nuts and three Hotel Companies—28 Limited Rupee Companies in all. And it will be seen that, with very few exceptions, the dividends declared for these Companies for 1899 are better than for 1898. In only two instances do we find a less dividend paid; in six other cases the dividends for 1898 and 1899 are the same; while twenty Companies declare an improved dividend for last year over 1898. Here are the figures:—

THE RECEIPTS FROM THE TEA-DUTY have recently been at the rate of £160,000 per week, or just double that usually charged at the beginning of a year, says the *Grocer* of Feb. 17th. This represents a clearance of about 720 tons per day, or a quantity sufficient to last the public two and a half days. The cold weather has caused a considerable demand for rum. In mild winters 90,000 gallons of that liquor is consumed, for the past few weeks 140,000 have apparently been required to help to counteract the action of frost. Possibly the existence of the suspicion that the duties on spirits will be raised may have something to do with these increased clearances from bond; but as the Budget is two months off, merchants are not likely to lose the interest on the duty for six or seven weeks if they can help it. Cocoa is advancing in popularity at a great rate; for the month of January, 1897, the consumption was 1,082 tons, in 1898 the month's demand was 1,400 tons, in 1899 the quantity was 1,670 tons, last month it had risen to 1,830 tons.

**BIG CEYLON TEA CO.
COOPER COOPER & JOHNSON.**

**DIRECTORS' REPORT—NO DIVIDEND ON THE
ORDINARY SHARES.**

The report of the directors of Cooper Cooper and Johnson, Ltd., for the year ended 30th June, 1899, to be submitted to the ordinary annual general meeting to be held in London on 6th prox. states that the difficulties of effecting the transfer of so many estates and businesses, and their organisation as a whole, have been very great, but the directors consider that the company has now been brought into good and economical working order, with steadily improving results. During the first part of the year under review the management of the estates acquired by the company was not in their hands, but after the transference had been effected and other matters in London settled, Mr. E H Hancock proceeded to Ceylon, on behalf of the company, to make the necessary arrangements for combining and working the estates. The Board, being subsequently dissatisfied with the way in which the Colombo agency was being managed by Messrs. J J Vanderspar and Co., instructed Mr. Hancock to pay special attention to that matter, and eventually particulars of such a nature came to the knowledge of the Board as to render, in their judgment, a change of agency necessary in the interests of the company. This change was made, but unfortunately disputes have arisen on accounts and otherwise, the details of which the directors are unable to go into, the matter being still sub-judice. The non-receipt of the accounts from Ceylon has caused the delay in preparing the accounts of the company. Mr. Hancock spent six months in visiting Ceylon, and making arrangements on the estates, which have already resulted in a more efficient working, by which the cost of the tea has been reduced and a considerable saving effected in every way, and he reports most favourably on the future prospects of both tea and cocoa estates. The amount of tea produced up to 30th June was 2,100,302 lb. and it is estimated that the production for the current year will be 2,322,000 lb. at a reduced cost per lb. The cocoa estates, from various causes, including unfavourable weather, showed disappointing results, but advices received to date show that a larger crop may be expected this year. The wholesale business shows satisfactory results. The business acquired from Messrs Cooper Cooper & Co., Ltd., has been a serious disappointment under the late management, but it is now showing better results under new direction, and there is reason to hope that it will prove a satisfactory source of revenue to the company in the future. The late managing director ceased to control the business in May, 1899, and subsequently resigned his seat on the board. The directors regret that owing to the results shown by Cooper Cooper & Co.'s business, and to the poor cocoa crop, they are unable to recommend a dividend on the ordinary shares for the year ended 30th June, 1899. It will be seen from the accounts that the net profit in working the properties is £23,068. After deducting general expenses and interest £9,001 remains, out of which preference dividends amounting to £6,996 have been paid, leaving a balance of £2,005 to be carried forward. The directors are pleased to say that Messrs. Antony Gibbs and Sons have undertaken the London agency of the estates. It has been decided that 1st April and 1st October are more convenient dates for the payment of preference dividends payable in respect of profits made up to 31st

December and 30th June, and a resolution will be proposed to that effect. Messrs. A A Clark, M P Evans and Clive Meares have retired, and Messrs. G L Davies and Hector F Monro have joined the Board, and the shareholders are asked to confirm their appointment. Messrs. John Young and H A Hancock retire. The former does not offer himself for re-election owing to ill health.

BEES AT KANDY.

It is a strange fact that regularly once a year a swarm of bees form a hive on the huge beam supporting the verandah of the upper story of Messrs. Walker, Sons and Company's premises in Ward Street. The attraction of bees to this particular beam is strange and on Friday last a multitude of them settled themselves once again on this their favourite spot and yesterday morning the unruly hand of some mischievous lad in all probability disturbed the insects which caused great commotion in Ward Street. The bees commenced stinging every passer-by. Several native men, women and boys were attacked and it was amusing to see them running along the streets, many of them with the bees sticking on to their heads or faces. Mr. Elton, Private Secretary of Sir Winfield Bonser, Chief Justice, was one of the victims. He was riding up the street on his bicycle when he was stung by one or two on his face and throwing his cycle aside he ran up to the pavement and fortunately found himself in the Central Dispensary. There the Dispenser applied some soothing remedies and in a few minutes he left the place. He was seen in Court, in the afternoon, however, with marks on his face. It would be to the safety of the passers-by if the bees were smoked out of the place.—*Cor.*

PRODUCE AND PLANTING.

ADVANCE DUTY PAYMENT ON TEA.—The general order of the Custom House Board requiring the immediate withdrawal from the bonded warehouse of goods on which duty has been paid is as follows: "General Order 14, 1900.—Custom House, London, February 19, 1900.—Duty-paid Goods: Prompt Removal from Bonded Warehouses.—The Board, in concurrence with the Board of Inland Revenue, direct that the following paragraph be inserted in the Warehousing Code, after paragraph 489: '489A. The sole purpose for which a bonded warehouse is approved and appointed by the Commissioners of Customs or Inland Revenue is to secure keeping of dutiable goods before and until the payment of duty or exportation, and subject to any permissible operations therein; and the bond taken from the sureties of a warehouse-keeper is to secure the payment of duty upon such goods. It follows that the retention in a bonded warehouse of dutiable goods after duty has been paid thereon is to turn the warehouse to an illicit use. Warehouse-keepers and owners of bonded goods must therefore be made to understand that the payment of duty entails an obligation to remove forthwith from bonded premises the goods in respect of which such duty is paid. Collectors at outports, and the inspectors in London are directed to make this Order known to the several warehouse-keepers within the respective ports and, in order to facilitate this notification the new paragraph will be printed separately for distribution and copies can be had on application in the usual manner to Division II. of the secretary's office.—By order of the Board, R. T. PROWSE." One effect of this general order will be that it will be difficult to cover the risk of any large increase of tea duty by paying the duty and leaving the goods in the warehouse.

THE OUTLOOK FOR COFFEE.—Coffee planters would be glad to hear that there was foundation for the statements made in some quarters that the consumption of the berry was increasing at a rate that threatened to overtake the production. Statistics do not bear this out, however. Messrs. W. H. Crossman

and Bros., of New York, in their circular of the 9th ult., estimate that the Brazil crops of Rio and Santos coffee together will swell to an aggregate of 37,663,000 bags for the four seasons from July 1, 1896, to June 30, 1900, as contrasted with 22,682,000 bags for the same number of seasons between July, 1892, and June, 1896, a growth in the production of about 15,000,000 bags in four years. According to Messrs. Crossman's statistics, the total deliveries of the Brazil description of coffee in the United States during the four seasons ended June next will approximate to 22,807,000 bags in comparison with a previous four years' delivery (1892-96) of 17,432,000 bags, which is tantamount to an enlargement of 5,375,000 bags in one country alone. Turning to Europe for the same period we find that the deliveries of coffee of all kinds (including Brazil) will probably amount to 32,178,000 bags, in lieu of the 26,439,000 bags delivered in the interval prior to 1895-96. The difference in this case is clearly shown to be 5,739,000 bags, but still on the favorable side, and makes the total gain in the quantities of coffee cleared from the stocks on hand in Europe and the United States equal to 11,114,000 bags in the short space of four years. It will thus be seen that, although the increase in consumption is considerable, it falls short by nearly one-third of the extra 15,000,000 bags produced in the corresponding period of time. There is not much chance therefore at present of a failure in the world's supplies.—*H. & C. Mail*, March 2.

THE LONDON COCOA MARKET.

BY HAROLD HAMEL SMITH.

London, March 5.

In comparison with the total business done in cocoa since last mail, this has been quite a "Ceylon week," for of the 4819 bags of all growths offered this week for public sales, 2,163 bags were Ceylons, and of the 2,200 bags sold at and after the sale Ceylons accounted for at least 1,400 of them, so the island has had a good share of attention.

On the whole it has been a quiet week, the sales were made up of 2,163 bags Ceylons, 1,682 bags Trinidad, 363 Dominicas, 300 Guayaquil, and about 300 various. The continued pressure caused a further drop in Trinidads, in the lots sold, whilst some of the bids were very low, and out of proportion to others. The market generally was evidently not wanting this growth as there was an absence of competition when it was offered: middling to good red sold at 75s to 78s, and some marks since the sale realised 80s. The Ceylons received much more attention and sold at 64s 6d for native, 56s to 68s 6d for smalls, 69s to 75s for middling to fair, 76s to 83s 6d good to fine up to 90s for very fine. At times the prices were a little irregular—but on the whole steady, except for the cheaper growths.

The shipments from Trinidad up to the 14th Feb. were only 3,146,000 bags against 6,217,000 bags last years. It is hoped the difference will be much less by July, and what the crop will be after that it is too early to say. Although the Venezuelan cocoa is coming in fairly well just now, it is said that owing to the Revolution, cultivation is neglected, many of the labourers are away, and the bush is growing very high, all of which is bad for the crop.

Thanks to the courtesy of the selling brokers I was able to ascertain that the L R C (Trinidad) cocoa of which I sent you a sample, and which had been here since March 1898 had lost 18 ounces (eighteen ounces) a bag of 1½ cwt. during that period and the charges amounted to 13s 9d per bag. There are 5,210 bags Cocoa (all growths) advertised at present for sale next week.

TEA TWADDLE.

Apparently the increasing popularity of Indian and Ceylon teas in the United States is causing uneasiness among certain sections of the grocery trade which have been vending the Chinese product with profit in the past. There have been many tirades written against the cup that cheers without muddling one's brains; but one does not look for twaddle from persons who are credited with intelligence. Doctor Kellogg, who "runs" a sanitarium at Battle Creek, in Michigan, U.S.A., with branches at Calcutta and Darjeeling, seems to have outdistanced all previous detractors of tea. According to Doctor Kellogg, tea "is a most dangerous drug." He tells of servant girls arrested in the streets of Boston for being drunk and disorderly who had tasted no alcohol, but who had "chewed tea constantly;" also, of an old lady in Minneapolis who drank thirty or forty cups a day and ended her life in a lunatic asylum. But even worse than these cases are those in which tea plays a more silent and insidious part. Among women it produces a kind of mania—"the mania for acting the persecuted saint." Among men, unlike the much-condemned alcohol, it produces fear. "One patient who was suffering from tea poisoning in this way never passed a high building without looking up to see if something was going to fall upon him. Tea is responsible for sleeplessness, and, in fact, most of the ills which flesh is heir to." This is the kind of language one expects from the illiterate. However, tea will go on making its way in public favor so long as men like Lord Kitchener sing its praises as the best sustainer for fighting men.—*Indian Gardening (Calcutta).*

[Similar tactics are employed to win favor for imitation coffee and other articles. It is a wonder that retail grocers will put into stock articles made by parties who persistently and systematically discredit staple and universally used articles in order to create a demand for some cheap and enormously overvalued substitute or rival brand. There is need of reform in this direction. Some makers of gelatine seek to win favor for their brand by discrediting all other makes. Some manufacturers of soap hint that rival makers use stock of an obnoxious character. This sort of publicity leads people to ignore all goods of the class attacked, and thus injures the demand in all directions. The retailers have a remedy within control by throwing out of stock goods made by manufacturers who persistently attack quality.—*Ed. American Grocer.*] Feb 14.

BRAZIL COFFEE NOTES.

Should the French Government impose double its present import duties on coffee, who will suffer most? In our opinion the French people will hardly care to pay the cost, nor will they wish to do without coffee. Brazil will suffer, of course, but less perhaps than France.

The minister of industry has advised the director of the Central railway that he has assented to the petition of the coffee commissarios to be relieved of the obligation of having their coffee sent to a central deposit. They can hereafter take their coffee to their own deposits.

The ship "Somali," which cleared for New York on Thursday, takes a cargo of 82,169 bags of coffee, shipped by Messrs. J W Doane & Co. of this city. This is not only the largest cargo which has ever left this port in a sailing vessel, but is the largest that has ever cleared in any vessel with but one exception. And in the case of the exception, the cargo came partly from Santos, while the "Somali's" cargo was entirely made up here and was shipped by one firm—probably the largest single shipment on record.—*Bio News*, Feb. 6.

THE "TROPICAL AGRICULTURIST":
A COMPLIMENT.

(From Mr. Montague Kirkwood, Japan.)

I have always read that excellent periodical with the greatest interest and consider it invaluable to

all those who desire information of a thoroughly practical nature with regard to agriculture and kindred industries in tropical or semi-tropical countries. If you have not already done so, you would do well, I think, to bring it prominently to the notice of the American officials and merchants and planters, who are now engaged in the development of the Philippines. Should you forward copies to the "President of the United States Commission to the Philippine Islands," you are at liberty to say that you do so "on the recommendation of Mr. Montague Kirkwood of Tokyo, who has furnished Reports to the Commission in regard to the Government of Britain's Dependencies in Asia."

PORTMORE TEA COMPANY OF CEYLON.

Report of the Directors submitted at the Third Annual Ordinary General Meeting of Shareholders, held at 24, Rood Lane, London, E C., on Thursday, 8th March 1900.

The Directors have the pleasure to submit the General Balance Sheet and Profit and Loss Account for the year ending 31st December, 1899, duly audited.

	£ s. d.	£ s. d.
The net amount at credit of Profit and Loss after providing for general expenses, Income Tax, &c., and writing off New Clearings and Withering Shed £166 11s. 6d is		4,393 11 4
To which should be added Balances forward from former years, viz:—1897	116 16 7	
1898	367 5 8	
		484 2 3
		4,877 13 7
An Interim Dividend of 5 per cent was paid September 18th, 1899, amounting to .. 2,000 0 0		
It is proposed to pay a final Dividend of 6 per cent (making 11 per cent in all, free of Income Tax) which will absorb 2,400 0 0		
And to carry forward to next year	477 13 7	

£4,877 13 7

In presenting their Third Annual Report, the Directors have pleasure in recommending a dividend of eleven per cent.

The yield of tea has been 242,740 lb., being at the rate of 510 lb. per acre, the cost of production has been £4,249 15s 9d being at the rate of 4d 201 per pound, and the crop has netted £9,024 10s 1d, being 8d 92 per pound, equal to a profit on the capital of the Company of 11.93 per cent.

The lower price realized for the tea has not been due to any falling off in quality, but to the unprecedented demand for common tea which has existed during the past year and which has withdrawn the attention of the market from higher class teas.

The average rate of exchange for year has been 1s 4 13-64d against 1s 4 5-64d during 1898.

Mr. W. Herbert Anderson retires from the Board by rotation, but being eligible offers himself for re-election.

The latest reports from the Manager in Ceylon describe the estates, buildings, and machinery as all being in good order, and the estimates of crop and expenditure for the current year give promise of continued satisfactory results.

The Directors desire to express their unqualified satisfaction with the manner in which the Manager and the Superintendent of the estates in Ceylon have discharged their duties during the year.—By order of the Board,

SHAND, HALDANE & Co., Secretaries

THE GANGAWATTA ESTATES COMPANY OF CEYLON, LIMITED.

THE ANNUAL REPORT.

ACREAGE:

Tea in full bearing	..	335	acres.
„ partial bearing	..	2	„
„ not in bearing	..	8	„
Grass and Ravines	..	10	„
Total	..	355	acres.

The Directors beg to submit their third annual report and statement of accounts for the year ended 31st December, 1899.

A visitation of blight on some of the best yielding fields has caused a shortfall to the extent of 10,000 lb. on the crop, and the result has been a yield of only 140,025 lb. against 150,000 lb. estimated.

Prices have been slightly better than last year, and the average is 40.16 cents per lb. while the cost of production works out at 27.06 cents per lb. including 2.70 under the head of manure.

The working account shows a surplus over expenditure of R18,343.92 which, after allowing for interest on mortgage, amounts to a little over 9 per cent on the capital. Out of this, however, we have had to spend R3,316.95 for permanent improvements for which there was no capital provided, and that, with an uncovered balance under the head of coast advances, has somewhat crippled our funds. The expenditure on manuring was absolutely necessary, and it is proposed to treat a third of the acreage annually with artificial manure.

An interim dividend of 3 per cent has already been paid, and the Directors now propose a final dividend of the same amount, making 6 per cent for the year.

After payment of this, the balance remaining at credit of profit and loss account will be R3,996.33 subject to deduction for directors' fees, and it is proposed that this should be carried to an extension account against the capital expenditure this season above alluded to.

Mr Hayes reports that the properties are in good order.

The estimate of crop for 1900 is 160,000 lb. and of expenditure R43,060 which includes an outlay of R5,175 for manuring.

In terms of the articles of Association Mr. Anderson retires from the office of director, and offers himself for re-election.

The appointment of an auditor for the current year rests with the meeting.

NAHAVILLA ESTATES COMPANY, LD.

ANNUAL MEETING.

The Directors beg to present their Report for the year ended 31st of December, 1899, together with a Statement of Accounts for the same period, which have been duly audited.

The Tea Crop amounted to 377,376 lb. against an estimate of 345,000 lb. and the Coffee Crop also exceeded expectations, 1,786 bushels having been secured in place of 1,360 bushels estimated.

Prices obtained for the Nahavilla Teas have been very satisfactory, but the Ury Factory shows a falling off from last year, which may have been partly caused by insufficient withering space. Further accommodation has now been provided, but more is still needed to meet the requirements of an improving yield. The general average price for all the Estates combined amounts to over 40 cents per pound.

The cost of producing the teas and placing them on the market is 30.32 cents per lb. and is less than in previous years. The rates, moreover, should continue to decrease as the young fields of tea come into bearing. A distinct improvement has taken place in connection with the working of Galella, but the estate

has still to meet the cost of manufacturing its teas at a neighbouring Factory, and the ordinary expenditure this season also includes a payment of R1,698.36 on account of the new Cart Road.

The total working profit from the four Estates for the year under review, amounts to R50,076.72, which is equal to about 10 per cent on the capital of the Company after allowing for interest on the mortgages.

The Profit and Loss Account, after paying interest on Mortgages and other charges, shows a balance of R50,828.62 at credit. Out of this a sum of R15,239.47 was brought forward from last year to meet previous extensions, and we have spent R24,645.02 under that head this season.

Your Directors recommend that a Dividend of 6 per cent be declared, absorbing R23,790.00; and that the balance, after providing for Directors' fees, and a Bonus to the Superintendents of Nabavilla and Galella which has been omitted should be carried to Extension Account.

The latter account will then be well in funds as regards past outlay, but further extensions are still imperative to the Factories and Machinery on Ury and Nahavilla, even if it be decided not to have a Factory on Galella. The upkeep of a considerable extent of tea not in bearing must be provided for, and there is also much available land which ought to be planted in order more fully to develop the estates. There is, moreover, a large lock up in Coast advances which has to be met, and your Directors will have to consider how capital can best be raised for these purposes. The requirements are judged to be too large to admit of their being wholly met out of revenue without unduly depressing dividends.

The new Season's estimates point to a yield of 420,000 lb. of tea and 750 bushels of coffee against an outlay of R129,564.00, and under normal conditions of weather it may be hoped that these crops will be fully secured.

	ACREAGE.				
	Nahavilla.	Ury.	M. P. G.	Galella.	Total.
Tea in full bearing	...251	209	195	294	949
Tea in partial bearing	72	155	22	—	249
Tea not in bearing	... 50	163	35	3	251
Coffee	...112	41	—	—	153
Forest	... 45	66	5	72	188
Grass, Fuel trees and Patna	... 71	132	84	244	531
Total	...601	766	341	613	2,321

Mr. Anderson retires from the Board of Directors by rotation, and is eligible for re-election.

The appointment of an Auditor rests with the Meeting.

THE CAMPHOR TREE.—In reply to the question, "Is the camphor tree grown in California?" the editor of the *Rural Press* replies thus:—The camphor tree has been grown for many years as a shade and ornamental tree, but no effort has thus far been made to produce camphor upon a commercial scale. At the State University, some years ago, a small sample of camphor was made from the twigs and foliage, and was exhibited at the fairs as a matter of common interest. The trees are very widely distributed over the State of California, both along the coast and in the interior, and everywhere are much admired for their thrifty growth and natural beauty. There are trees, probably nearly forty years of age, sixty feet in height, and three feet in diameter at the base. No large plantations have been made, but only scattering trees here and there.

PLANTING NOTES.

STABLE-MANURE FOR POTATOES.—According to some experiments carried out for the Wilts County Council, a more profitable crop was obtained with the use of stable-mannure, at 5s a load, than with artificials. The stable-mannure undoubtedly enabled the plants to resist the effects of the drought of the last two seasons.—*Gardeners' Chronicle*, Mar. 3.

BORDEAUX MIXTURE AND THE POTATO DISEASE.—According to the experiments made on behalf of the Wilts County Council, the average gain from the use of Bordeaux Mixture as a preventative of the Potato disease amounted to over £2 10s per acre. The application is specially valuable to late varieties. Two applications are generally necessary, the first being most advantageous, whilst no benefit accrued from a third spraying.—*Gardeners' Chronicle*, Mar. 3.

THE "COCONUT" DISPUTE, with the judgments of their Honors Justices Lawrie and Browne on page 731, ought to carry a lesson to local consignors of produce to London who (if Ceylonese especially) are sometimes inclined to think that if they ship and draw on the bills of lading at their own estimation of value, there is an end of the transaction. In the present case, the consignor not only gets nothing for his 625 bags of coconuts; but he will be out of pocket £75 15s 10d, besides the costs of both sides in the case in the District Court and in appeal. Pity such coconuts were ever shipped; but then it is too late to cry over what is irretrievable.

A CURE AGAINST DYSENTERY.—The Colonial Garden in Indo-China, through the good offices of Senator Pauliat, has received some seeds called "Ko-San" by the Chinese and employed by them as a preventive against dysentery. Dr. Mongeot, of Saigon, had the happy idea of utilising these seeds according to the Chinese methods, and the results have been very satisfactory. Out of 879 cases experimented upon, he met with only eight unsuccessful results. Experiments made at the Colonial Garden have shown that the seeds had a powerful physiological action. New experiments will, no doubt, enable the cause to be traced, and the effects of the action determined. If, as everything seems to point to it the utility of this Ko-San seed is confirmed, the plant will be spread all throughout the French Colonies.—*Singapore Free Press*, March, 8.

COFFEE HULLING: DUTCH EAST INDIES.—The coffee planter has always been very desirous of finding a huller which, whilst not deteriorating the bean, would at the same time be able to deal with different kinds of coffee. The problem has now been solved by M. Schaap, one of the planters, who has invented a machine which can hull all the kinds of coffee grown in the colony. At the last coffee planters' congress held at Malany in October, 1898, a prize of 200 florins was voted for the improvement of Schaap's system which could be made lighter, more economical in motive power, and able to treat at least three piculs per hour. Coffee hullers come generally from England and Germany, but on many plantations this work is still done in a very rudimentary way. The U.S.A. are now introducing machines made by the "Engelberg Huller Co." of Syracuse, New York; they are giving great satisfaction and will soon become very widely spread.—*French Official Report from Java*.

COCONUT CULTIVATION IN SELANGOR.—Says the *Perak Pioneer* (March 7th) in an article on the Annual Report of the Selangor Planters' Association:—Under the heading of 'coconuts' the report records the testimony of Ceylon experts, that the F M S product is finer than anything obtainable in that island. This betokens an unmistakable influx of Ceylon coconut planters in the near future. The coconut oil, fibre, and rope industry, are already under development in the Straits and F M States. Hitherto, Rangoon and Calcutta have received a very large percentage of our coconut produce, for the purposes specified. The order of things now existing, promises therefore and very rightly so, to be revolutionized. The sooner the better say we, for, when its products are re-produced in a country, its welfare is undoubtedly on the incline. A mighty industry in the coconut and its products may therefore be safely predicted, for the regions bordering on and contiguous to the Straits of Malacca.

COOPER, COOPER AND JOHNSON.—On page 733 we give the annual report of this well-known Ceylon Company in which it is stated that the concern has now been brought into good and economical working order. *Commerce* however considers it very disheartening reading for the shareholders and adds:—

An addition is made to the melancholy list of industrial companies which have failed to come up to the promises of their prospectuses. They ought to have done well. For not only have they the advantage of growing their own teas, but they sell direct to the consumer, and thus save those intermediary charges which add such a serious burden to the tea trade. The document states that the difficulties of effecting the transfer of so many estates and businesses, and their organisation as a whole have been very great, but the directors consider that the company has now been brought into good and economical working order, with steadily improving results. During the first part of the year under review the management of the estates acquired by the company was not in their hands, but after the transferee had been effected and other matters in London settled, Mr. E H Hancock proceeded to Ceylon, on behalf of the company, to make the necessary arrangements for combining and working the estates. The board being subsequently dissatisfied with the way in which the Colombo agency was being managed by Messrs. J J Vanderspar & Co., instructed Mr. Hancock to pay special attention to that matter, and eventually particulars of such a nature came to the knowledge of the board as to render, in their judgment, a change of agency necessary in the interests of the company. This change was made, but unfortunately disputes have arisen on accounts and otherwise, the details of which the directors are unable to go into, the matter being still sub judice. The non-receipt of the accounts from Ceylon has caused the delay in preparing the accounts of the company. Mr. Hancock spent six months in visiting Ceylon, and making arrangements on the estates, which have already resulted in a more efficient working, by which the cost of the tea has been reduced and a considerable saving effected in every way, and he reports most favourably on the future prospects of both tea and cocoa estates. The amount of tea produced up to 30th June was 2,100,302 lb and it is estimated that the production for the current year will be 2,322,000 lb at a reduced cost per lb. The cocoa estates, from various causes, including unfavourable weather, showed disappointing results, but advices received to date show that a larger crop may be expected this year. The wholesale business shows satisfactory results.

We also reproduce a letter to *The Financial Times* in which the opinion is expressed that it is a case of too much Hancock.

RICE-GROWING IN LOUISIANA, U. S. A.—Japanese Kiushu rice is now grown in the warm prairies of south-western Louisiana. Steam harvesters and thrashers are employed in the culture, and the kinshu is expected to bear the milling better than ordinary rice.—*Globe*, March 2.

TEA BULKING.—We understand that a consignment of some 5,000 chests of tea was recently bulked and tared at the Port Commissioners' godown by the aid of the Apjohn tea-bulker. This is a step in the right direction, and we hope to see the movement grow rapidly.—*Indian Gardening*, March 8.

TROUT CULTURE UP THE THAMES.—The trout eggs in the private hatchery erected by Mr. A. Barrow, at Staines, have now hatched out, and the young trout (Loch Levens) look very healthy. Out of 25,000 eggs put down under one hundred have been lost. The trout when old enough are to be placed in the Thames.—*Daily Chronicle*, Feb. 24.

A NEW FUNGICIDE.—In some French tests a fungicide composed of 3 lb. copper sulphate, 5 lb. copper carbonate $\frac{1}{2}$ oz. of permanganate of potash dissolved in a pint of water and 100 qts. water; is said to have given as good results as the same quantity of Bordeaux mixture, and has the advantage of adhering to the foliage better.—*Planting Opinion*, March 17.

PLANTING IN THE STRAITS SETTLEMENTS.—In Malacca a good tea plantation has been thoroughly established, which finds a local market for its produce. An enterprising syndicate of Chinese has begun to plant rubber largely in that Settlement. In all the Settlements the cultivation of coconuts is progressing. In Malacca a very successful agricultural show was held. It is intended in future that there should be a show every year in some Settlement of the Colony. The Botanical Garden at Singapore continued to aid planters by seeds and advice. This station is a centre for British North Borneo, Sarawak, Labuan, Johore, the Federated Malay States, and even Siam, and there was very keen competition for all the rubber seeds which could be spared. Orders were booked for quite twenty times as much seed as was available.—*Colonial Office Report from Singapore*.

DOES TEA IMPROVE OR DETERIORATE BY KEEPING?—Some say that it improves, whilst others assert that it begins at once to deteriorate unless hermetically sealed. As a matter of fact, provided the tea has been thoroughly dried before packing and then carefully soldered in lead or tin, it will most certainly improve by age. This has been proved by planters time and again: We would remark, however, that even in the most (as we think) thoroughly dried tea there is always a certain amount of moisture retained, which, although imperceptible to us, is perceptible to the chemist or analyst. If the keeping qualities of the tea are to be preserved for any very extended period, the tea should not be packed whilst greatly heated, but allowed to gently cool in some dry place (so that it may not absorb moisture), and then be enclosed in its lead or tins casing, which must be most carefully soldered, so that there may be no possibility of air entering it in any manner whatsoever. Such hermetically-sealed tea will not only keep as long as its casing survives uninjured, but will greatly improve with age. Once, however, its case is opened, its keeping qualities are impaired, and although it may be repacked at once, its contact with the air has deprived it of its properties of resisting deterioration for an indefinite period of time.—*Indian Planters' Gazette*, March 3.

FRUIT CROPS IN QUEENSLAND, 1900.—Acting upon instruction from the Queensland Under-Secretary for Agriculture, the Instructor in Fruit Culture attached to that department, has forwarded to us (under date January 15), the following interesting particulars connected with the fruit crops for the current season:—The last figures available show the following acreage and returns for the following fruits:—

Bananas	..	5264 acres	...	Produce	46,547,090 doz.
Pineapples		1,130	"	"	462,752 "
Oranges		2,272	"	"	1,527,469 "

The prospects of the present crop are as follows:—Bananas. The dry spring has somewhat retarded this crop, but recent rains have greatly improved it. Pineapples will be ready for marketing within a month; there is a good show of fruit on both rough-leaved and smooth Pines, and the recent rains will tend to improve the size, which promised to be small. Oranges are very patchy; some districts promising record crops, whilst others will be less than average. The same remarks apply Mandarins. Passion-fruit has been a good crop, as have also been strawberries and Cape Gooseberries. Mangoes are only a small crop in the southern part of the colony.—*Gardeners' Chronicle*, Mar. 3.

NEW DARVEL BAY (BORNEO) TOBACCO PLANTATIONS (LIMITED).—The seventh ordinary general meeting was held yesterday at Winchester-house. Mr. Sigmund Sinauer presided, and, in moving the adoption of the report, expressed a hope that the shareholders would consider it satisfactory. The company's tobacco, though of good quality, had the fault of being "spotted," and, moreover, the market had not been so favourable as in the previous year. They had received only 1s 10d per lb., against 2s 2½d in 1898, and this difference had affected the profits to the extent of upwards of £12,000. The large quantity reaped showed, however, the capabilities of the plantations for tobacco cultivation. From the balance standing to the credit of profit and lost account, £13,938, including the amount brought forward, it was proposed to pay a dividend of 1s 6d. per share, free of income-tax, and to transfer £4,000 to the reserve fund, leaving more than £1,000 to be carried forward. In addition about £6,000 had been written off for depreciation. The 1899 crop had been housed in the fermenting sheds and would soon be ready for shipment. Although in quantity it might not be quite so satisfactory as the 1898 crop, the quality was better. With regard to the prospects of finding gold on the company's property, he said that owing to the illness of the mining engineer development work had had to be suspended. Arrangements had been made with the British North Borneo Company for an extension of the concession for two years more, so that they had plenty of time in which to conduct operations. Since the engineer had resumed work he had reported that there were indications of something better than he had originally expected to find. A large quantity of conglomerate had been discovered in the sides of the bed of the river, and about 13cwt. of it had been sent home. Experiments on it had been made by three firms. Two of these reported that they could not find gold in payable quantities, but the other had given a more favourable report. The intention of the directors was to have a large quantity of the "stuff" sent home in order that a more thorough test of its value might be made. The shareholders might rest assured that the sum spent on making experiments would not be in excess of that already authorised. Mr. H. Hayman seconded the motion, which was adopted.—*London Times*, Feb. 22.

TEA IN THE ANDAMAN ISLANDS.

CONVICT-WORKED TEA GARDENS;

DEAD LOSS IN EACH CASE.

An experimental tea garden was first commenced in the Andaman Islands in the year 1876, tea seed being planted in nursery beds in February of that year. Lieutenant-Colonel Berkeley took charge of the plantation on the 12th April, 1880, and found, on taking over charge, that the trees had growing very tall, some being as much as eight feet high. The experiment proved a success, and a source of profit to Government at the time. The "Report on the Administration of the Andaman and Nicobar Islands for 1898-99," just published, furnishes us with some interesting information relative to the present condition of tea cultivation in the Andamans. There are three tea gardens: one at Navy Bay, one at Goplakabang, and one at Kalating.

THE GARDEN AT NAVY BAY

was in charge of Mr. A J King during the year 1898-99. He reports that the season was very unfavourable, due entirely to unseasonable weather. The year opened favourably and continued so until the 8th of May. Unfavourable weather was then experienced for the rest of the year, with small breaks. The total area under plant is 301½ acres. No new land was cleared. The whole garden was as well cultivated as circumstances permitted, and portions were manured with cow-dung and castor cake respectively.

The outturn was 48,300 lb. only against 55,021 lb. during the previous year. The shortage was due to the very unfavourable weather experienced during the greater portion of the year, as also to inadequate supply of labour, whereby the necessary cultivation had to be restricted. The cost of manufacture averaged nine annas 2½ pies per lb., against five annas 10 pies per lb. during the previous year and five annas 8½ pies during 1896-97. There was a loss, as was to be expected. The report states that:—"The sale proceeds of 47,236 lb. was a little under six annas one pie per lb. against six annas one pie during 1897-98, so that the net loss per lb. equalled three annas 1½ pie after charging for convict labour and local material in addition to cash expenditure. The profit per lb. during 1897-98 was three pies." The garden being Government property, situated in a penal settlement and worked by convict labour, it matters little whether it yields a profit or not as it is simply a case of taking money out of one pocket and placing in the other. With regard to prospects, Mr. King states that if anything like favourable weather is experienced during the remaining months of 1899-1900, he anticipates manufacturing 64,000 lb. of tea. It is to be hoped, however, that this will again not be at a net loss of three annas per lb. The contract rate at which tea is supplied to the Burma and Madras Commissariat Departments is five annas 11 04 pies per lb. Mr. Minto held charge of the

GOPLAKABANG GARDEN

to the 2nd of February, 1899, when he proceeded on leave, handing over charge to Mr. A J King, who reports that the first eight months of the year under review were fairly favourable. This was followed by heavy rain, which did considerable damage. From December 1898 to the end of March, 1899, the season was most unfavourable, no rain falling. This was the longest and most severe drought experienced for very many years, and to this, and other causes, is due a deficit of 23,745 lb. in the outturn during the year. The chief cause, however, was insufficiency of labour. Thread Blight has also been steadily increasing yearly and causing great damage. The total area of this garden is 187 acres. The garden was cultivated as much as an inadequate labour force permitted. The yield of leaf taken off the nurseries was not good. The crop of tea manufactured was 25,460 lb. against an outturn of 49,205 lb. during 1897-98, showing thus a deficit of 23,745 lb. The cost of manufacturing the year's crop averaged 12 annas 7½ pies per lb. against 5 annas and 6½ pies per lb. during the previous year. The sale proceeds of 13,192 lb. of tea, says the report, was 3

annas and 9½ pies per lb. against 5 annas per lb. during 1897-98, so that the loss per pound was 8 annas and 10 pies, against 6 annas and 3 pies during 1897-98, after charging for convict labour cost of machinery and local material. Comment is superfluous further than to remark that we do not understand why this garden is not abandoned. The total loss on the year's transactions, according to the accounts submitted, was R16,976. Mr. A. J. King held charge

OF THE KALATANG GARDEN

also from the 2nd of February, 1899. This is an indigenous planted garden. The season, on the whole, was unfavourable. The area of the garden is 30 acres only. It was attacked by Thread Blight, which, however, disappeared after a time. The outturn of tea from this garden exceeded its estimate by 4,600 lb. The bushes were regularly clipped throughout the year, and the yield was 21,600 lb., as against an outturn of 16,830 lb. during the previous year. This yield gives for the 30 acres, 9 maunds per acre, a very satisfactory crop. The cost of manufacture was 3 annas and 5 pies per lb. against 3 annas and 4 pies per lb. last year. The sale proceeds of 13,480 lb. was 4 annas and 2½ pies per lb. against 4 annas 9½ pies per lb. during the previous year and 4 annas 9½ pies per lb. during 1896-97, so that the net profit per lb. equalled 9½ pies, after all charges, against a profit of 1 anna 5½ pies per lb. during 1897-98. The report, however, states that—"After deducting these book charges, the account exhibits a loss of R1,052 as compared with a net profit of R625 during 1897-98. This is said to be due entirely to the failure of the Burma Commissariat Department to fulfil its part of the tea contract. Mr. King expects an outturn of 22,000 lb. of tea during 1899-1900 if the conditions are at all favourable. Taken all in all the conditions of the tea industry as at present existing in the Andaman Islands are by no means inviting.—*Planter.*"

PLANTING IN BRITISH NEW GUINEA.

Some months ago two young men asked me to give them some information on British New Guinea and what likely success would attend them on taking up a block of land. Within the last few days I obtained particulars from the Surveyor-General, Queensland, of land now open for settlement, and, as the price and conditions are so favourable, I have extracted from the document the following particulars:—The blocks of land on the south coast of the Central district range from 1,280 acres to 4,500 acres, and I classified as agricultural and pasturage. They are situated on Cloudy Bay, Cape Rodney, Velerupu River, Waipara River, and Kemp Welch River. In the Central district the area of the blocks range from 5,000 acres to 326,000 acres, and are situated on Brown and Laloke rivers, south of Laloke River, Vanapa River, Galley Reach, and Cape Suckling, and are similarly classified as the above. In the Western district only one block of 21,200 acres, on the Oriomo River, of agricultural and pasturage lands is gazetted. The price is subject to arrangement with the Government, but not to be less than 2s 6d per acre for agricultural land, free hold; 6d per acre for pasturage land, freehold; 6d per acre for agricultural land, leasehold; 1d per acre for pasturage land, leasehold. The improvement conditions, also under the same conditions as price, are 2s 6d per acre agricultural land, to be effected within five years; 2s per acre pasturage land, to be effected within five years, exclusive of residential buildings. The latter, in respect of large pastoral blocks, is far too excessive. For instance, on the 326,000-block advertised, which is classified agricultural and pasturage, the outlay would mean something like £40,000, or £8,000 per year. In the present state of progress no individual or company could see its way

to lay out such a sum and expect a profitable return from it. Most of the blocks are on open and undulating country, partially wooded. The climate is not worse than Northern Queensland: in fact, in the upland country the climate is healthy and bracing. I believe there is a good future for British New Guinea, and I hope that the land taken up will be in the hands of Australians only.—*Sydney Mail*, March 3.

PARA RUBBER IN THE STRAITS. A PROMISING OUTLOOK.

TO THE EDITOR "S. F. PRESS,"

DEAR SIR,—I have been asked by the Committee of the United Planters' Association F. M. S. to let it be widely known that a strong feeling exists amongst planters that the time is fast approaching when we should send a representative to Para and from thence to the different seats of the rubber industry in order that when this country is ready to put its own rubber upon the Market, we may be in full possession of all the most up-to-date methods of tapping, of obtaining the maximum output with the minimum of damage to the tree and of curing our produce in such a manner that it will fetch as high a price as any in the markets of the world. It has already been demonstrated that we can grow Para Rubber, that we can get a heavy yield, and that the quality of our produce is equal in value to the best Brazilian. These are now proved facts and there is no doubt that if we avoid all initial mistakes when cultivating and producing on a large scale, are thoroughly coached in our business when we first make our bow to the public and so gain straight off a reputation for quality, a very prosperous agricultural future lies before the Malay Peninsula.

I believe I am right in stating that the Rubber zone is approximately confined to 15° north and 5° south of the equator, and a glance at a map of the world will very soon show how exceptionally well situated we are in every respect by comparison with other rubber producing countries. Easy transport, a labour supply that can be developed until it is sufficient for our fullest requirements, a healthy climate where the white man and the coolie alike can thrive, all these advantages are ours; and I maintain that it rests with us whether we make a success of the great industry which we have inaugurated here or whether by carelessness and ignorance in our initial methods we find ourselves saddled with a reputation which it may take us years to live down.

The Resident-General with characteristic sympathy, has promised the planters the assistance of an expert from Kew, and a substantial sum has been provided for that purpose on the Federal Estimates: no one doubts that the results of this officer's researches will be of enormous benefit to Malayan agriculture generally, but, with respect to Rubber, we believe that much additional good may be done by sending over to Para one of our own men, a thoroughly practical and energetic planter, and, making his experience the basis of our own methods, by steadily endeavouring to improve from that point. In Selangor during the year 1898, no less than 389,500 Para Rubber trees were planted and in 1899 the S.P.A. Annual Report shows a return of 1,600,000. Previous to 1898 a fair number were planted too. Taking 1,000,000 then as likely to arrive at maturity and with a yield of 1½ lb. per tree which we may put at 2s, or say \$1 to allow for a possible fall of 50 per cent in value, we have in this State alone sufficient area planted

to give us an annual return of \$1,500,000, double this for the rest of the Malay Peninsula, and it is abundantly clear that we have already laid the foundations of what may with luck and care become an enormous trade.

It will no doubt be objected that what answers in Brazil may not by any means apply here, but surely it is folly to assume this? We know next to nothing about our subject at present, and very soon most planters will be wanting to begin tapping on a small scale, let us find out then as soon as possible all that there is to be learnt and apply that knowledge to suit local conditions.

It has been estimated that to send a good man to Brazil with 'carte blanche' to travel as he thinks best and to extend his inquiries, if he get the opportunity, to other rubbers besides Para, will cost in all probability not less than \$10,000. In these hard times this is a large sum to raise, and my object in writing is to invite public opinion on the question. If those interested will communicate their views to the press much good may result and when the time comes for us to take definite action, the skeleton of the scheme will already have been framed.—I am, dear sir, yours faithfully,

E. V. CAREY,

Chairman, United Planters' Association,
Klang, 13th March, 1900.

Singapore Free Press, March 17.

CATTLE NOTES.

BY W. A. DE SILVA, V.S.

This little volume (published by the "Ceylon Standard" Press of over 109 leaves), meets a need experienced by many residents in the island, and being compiled for this country; it touches on the questions that constantly arise with owners of cattle. The headings of the chapters will give an idea of the scope of the work:—

Cattle and Buffaloes; Uscerption and Aging. Cattle Food; Cattle Sheds; Handling of Cattle; Signs of Ill Health; Nursing and Attendance; Medicinal Materials; Prevention of Disease and Treatment; Milk Cows.

There is also an Index with the names of medicinal materials in Sinhalese, Tamil and Hindi.

Thirty pages are devoted to the Diseases to which Cattle are liable. The book will be found very valuable in giving simple directions as to treatment in sickness and the proper feeding and care of animals at all times, and should be in the hands of all those who own cattle. Three rupees would be well spent on the volume. As a sample of the style of the book we will quote what is said on the subject of cow-pox:—

An infective fever attended with eruptions in the teats and udder of cows. This is a very mild disease, the fever is not high, and the vesicles that appear on the udder and teats, do not give much trouble; the disease runs its course in from ten to fourteen days. Laxatives, such as a pint of gingelly oil or linseed oil; salines as an ounce of nitre in the water, are useful in the early stages. Milk from cows suffering from this disease should not be used.

PLANTING IN BRITISH GUIANA.—According to the Government Botanist there is an excellent opening in British Guiana for small cultivators. Cacao was formerly largely produced by the Dutch, and, with due selection of situation and soil, few countries are better adapted to cacao cultivation. Rubber cultivation could also be successfully carried on, as already one or more valuable species are found in a wild state.—*Imperial Institute Journal*, March.

Correspondence.

To the Editor.

TEA PRODUCTION AND MANURE:
PATANA SOIL GIVING UP TO
800 lb PER ACRE AFTER 15
YEARS WITHOUT MANURE!

DEAR SIR,—The figures given in the *Observer* (see page 697) certainly leave the impression that the production of tea has not been keeping pace with the increased area under cultivation and yet speaking from my own observation I cannot say I have noticed much falling-off in the returns of the older fields. No doubt in some instances the yield might have suffered, if the land had not been manured, but speaking *generally* of tea growing in soil which had been to some extent impoverished by crops of coffee and cinchona in older days, I find the yield, notwithstanding the age of the bushes, is being on the whole well maintained. To institute correct comparisons and arrive at accurate conclusions one must of course take the returns, not of a particular season only, but over a period of two years, from pruning to pruning and if a shortfall is experienced after *one* pruning, it may be made up for after the next. Much depends on the style of pruning, whether it is light or heavy, and still more on the plucking afterwards. The latter naturally varies according to the class of tea it is intended to produce, and labour considerations are also an important factor. Even should a particular field shew a diminished return, therefore, the chances are that it may have been the result of one of the many causes which go to influence the yield and not to the diminished vitality of the bush itself. As to any *serious* falling-off in the yield of our old tea, I cannot see it, nor do our estate returns which are accurately kept, afford ground for such a conclusion.

People speak of patna tea as giving a record yield after a few years, but I have to do with a large acreage of tea-growing in land of this description and my experience does not agree with those who take that view. As an illustration of what a comparatively poor field of patana (the soil is quartz) will do, it may interest your readers to know that in Badulla district there is a field of tea *15 years* old which has given, without the aid of manure, crops ranging from 420 lb. to 670 lb. per acre ever since it came into bearing, and *this* year the manager is expecting to beat previous records with a yield of *800 lb.* to *850 lb.* per acre all round!!

If common grass land can produce a result such as this, after fifteen years' cropping, unassisted by manure, it cuts away the ground from the feet of those who contend that cultivation is necessary to maintain the productiveness of patana soils. Still your figures go to prove that there is a falling-off *somewhere* and if it is not in the old tea, where is it? I regret to say my personal experience and observation do not provide the material for any satisfactory

reply to this question. Turning to estates with which I am connected, it is only in a very few cases that a systematic falling-off in the yield can be detected and in such fields the returns were *never* good. This is important. In parts of the lowcountry I am told there is a very distinct deterioration in the condition of some of the older fields and I may observe that it is here where I have myself noticed that returns have diminished in individual fields; but there has been nothing so far as I am aware to approach a *general* falling-off in the yield, such as your figures seem to indicate and you may, I am sure, search in vain for any convincing evidence upcountry.

My fear is and always has been, not that there will be any difficulty in *growing* leaf in Ceylon, but that we may not be able to dispose of what we produce, and I think myself that all this heavy manuring which we now hear so much about is a mistake. Individuals who are first in the field may score; but the industry as a whole must suffer, and yet if we do not go ahead in keeping with the times, we shall be left behind,—so what is to be done?

If a certain gentleman who has been very successful with manuring had kept the information to himself, the prospects of the island generally would have been brighter and be none the poorer. But the ball has been set rolling now and where will it stop?

VIATOR.

[Oh, no earthly good trying to keep back information—and such a policy would be worse than useless in the end; for rumour would, as usual, magnify results greatly.—ED. T.A.]

BEE-ROOT SUGAR.

DEAR SIR,—Do you not think the sugar-beet would grow in Ceylon and have you any idea where seeds could be had for an experimental patch? Given sugar in the island, our guava jelly, loquat and other jams might be a profitable industry.—Yours truly,

HOUSEKEEPER.

[Has "Housekeeper" thought of asking for the wholesale price of his No. 1 and No. 2 quality sugar from the Manager of Baddegama estate, Galle?—ED. T.A.]

GUM OFF A TREE.

Anuradhapura, 1st March.

DEAR SIR,—I enclose a specimen of gum picked off a tree, of which I am told many are to be found in the jungles up here.

Please let me know if it indicates in your opinion that Indiarubber may prove an export from these regions when transport is available.

When this tree grows, may not better qualities be cultivated?—Yours faithfully,
G.
—[The gum is the ordinary 'cashew,' not fit for rubber purposes, but it melted very useful for 'gumming,' &c.—ED. T.A.]

TEA ON LOOLECONDERA—ABOUT THE OLDEST IN CEYLON :

INTERESTING PARTICULARS.

Loolecondera Estate, Deltota, March 23.

DEAR SIR,—The *Observer* of 13th and 16th instant containing an article (page 637) and a letter (page 708) referring incidentally to Loolecondera, which you sent me I found most interesting.

With regard to the second heading of your article "Is it well to manure Tea on Virgin Soil?" I would say "Certainly not;" but the yield and quality of the leaf will depend in a great measure on careful and systematic pruning, and of course weeding; and as to burying prunings as far as my experience goes nothing is gained by burying them. I would prefer to leave such on the surface to shade the ground immediately after pruning and thus lessen the shock to the trees in being pruned and denuded of shade at the same time. The prunings being left on the surface also prevent and arrest wash and help to form new surface soil.

The old 100 acres last year gave a yield of 450 lb. made tea per acre, though 20 acres of it were pruned down. The yield would, I believe, be much larger were it not for the extraordinarily high winds which prevail here throughout the S.-W. monsoon.

As to the remark of "Old Hand," about there being no virgin soil here, besides the 100 acres referred to, which was planted with tea,—some 120 acres of forest and 75 acres scrub and patana have been planted with tea here since 1894, beside the old coffee and cinchona land.—Yours faithfully,

G. F. DEANE.

COFFEE AND TEA—AND A HIGHER CURRENCY :

EVIL TIMES APPROACHING IN INDIA ?

Coonoor, Nilgiris, March 16.

SIR,—On the 28th of last month you did me the honour to publish a letter on "Labour in India and Ceylon" in which I pointed out that, from the increasing population and the corresponding increase in the cost arising from famines, the Indian Government must sooner or later be involved in financial difficulties, and that it was certain that in that case the Government would seek relief, as it did before, by forcing up the exchange in order to lessen its payments for home charges. When remarking upon my forecast you say that you "can scarcely believe this," but that it is not only possible but probable, is evident from the statement of the Indian Finance Minister when introducing the Currency Bill—June 1893, and I may remind your readers that he then said "it is not intended to do more *at present* (the italics are mine) than aim at a rate of 1s 4d," so that it is clear that the Government contemplated a higher rate than 1s 4d in the future, and that too without the pressure of any severe financial emergencies. That such emergencies must arise sooner or later is evident, when we come to consider that we have a rapidly increasing population and diminishing means of employment which must, before many years go by still further diminish, as the remaining railways and large irrigation works are completed. It is then not only possible, but in the highest degree probable, and many will be inclined to say certain, that

the producers of India and Ceylon may at no distant time have to face a 1s 6d exchange, or even more, and it is to provide against such a crushing calamity that I suggest that such an amount of bounty should be granted as will us in the same position in competing with our rivals in the other silver-using countries that we enjoyed before the closing of the mints. But you think that there would not be the least hope of obtaining bounties in "the planters' interest." As to this remark I should entirely agree, were the planters interests' solely concerned, because the Government of India has hitherto not only shown an utter disregard of planters' interests; but, as I could amply prove were I not afraid of unduly encroaching on your space, taken pains to refuse them a hearing as regards those points which most conclusively show the evils arising from the currency policy. But where the interests of the cooly are concerned, when his wages are being reduced, and when even at reduced wages there are diminished numbers employed, and therefore the certainty of increased cost to the Government in time of famine, it is a different affair altogether. Unless the planters are placed on a footing of security there can be no security for the labourer. That is an argument which the Government will and must listen to. Formerly the planters stood firmly on an automatic currency which placed him on even terms with his competitors in the other silver using countries. Whereas now he is at the mercy of Government officials who have already placed a burden of 25 to 30 per cent on the back of the producers, and who, as we have seen, will in all probability increase the burden by still further forcing up the rate of exchange. What the effect of this must sooner or later be in the case of tea we can see by the effects produced in the case of coffee. We cannot, of course, prove the fact scientifically. In such matters we can only be guided by reasonable probabilities in making our deduction from the facts. We know it to be a fact that our coffee difficulties have mainly arisen from an immense over-production in South America and other silver-using countries. We also know it to be a fact that this over-production has arisen from the large breadths of coffee planted in the year of, and the year following, the passing of the Currency Act. It is therefore perfectly reasonable to conclude that just as coffee extensions would have been stimulated here, had the Governments of our rival manipulated their currencies, so as to confer on us superior exchange advantage, so has the action of the Indian Government stimulated extensions in the other silver-using countries. Now let us suppose these competing countries had been growing tea as well as coffee, is it not evident that the tea industry of Ceylon and India will be involved in all the difficulties that have overtaken coffee? But wherever coffee can be grown tea can be raised, and it is more than probable, or I may say certain, that tea will be raised in Mexico and the other countries which now compete with us as regards coffee, seeing that our Government has given them, by its currency policy,

every incentive to embark in the cultivation.

The sum of the matter in this. We must either return to our former automatic silver Currency, or India and Ceylon industries must be protected by a Bounty, or they must steadily decline in consequence of the unfair competition to which they are now subjected.

In conclusion I would warn planters that nothing can be got out of the Indian Government by a representation of planting interests. The Indian Government has declared war against those interests by its Currency policy. For the blow it has struck at us, we have only one-third of a blow to deliver in return, and that is by stopping extensions, and throwing out of cultivation, or placing in an inferior state of cultivation, all but the best lands. This will reduce not only the wages, but very largely the numbers of people employed. Such reduction in wages will gradually extend themselves to other Indian industries, so that the whole policy I advocate will hamper the Government permanently by increasing the cost of finances. Mr. Granville Acworth told the Currency Committee that the Government policy would have created a rebellion in any other country. Well we cannot rebel, but we must recognize the fact that the Government has declared war against us and that we must do our best to retaliate in whatever way will at once best serve our own interests and inflict most injury on the Government. One thing at least is certain and that is that if we do not adopt some form of strike the Government will conclude that we are so well off that we could easily afford a one-shilling-and six penny, or even a one and eight-penny rate of exchange.—Obediently yours,

ROBERT H. ELLIOT.

TEA PRUNINGS—BURIED OR UNBURIED.

March 17.

DEAR SIR,—I see in a letter from Mr. E. Ernest Green, the Government Entomologist, in the March *Tropical Agriculturist*, that he thinks it possible that root disease in the tea trees at a high district may be induced by large accumulation of *buried prunings*. What with "Old Hand"'s white ants and the chemical processes that occur in their stomachs after gorging on buried prunings and the attacks of mycelium fostered by said buried prunings, I think I will allow my prunings to lie unburied in future.—Yours truly,

DUFFER.

[A little quicklime added to the buried prunings would save trouble, as per the example of the experienced manager of "St. George," etc., Agras.—Ed. T.A.]

TEA CROPS AND MANURING.

No. I,

SIR,—In looking through your editorial (see page 697) which discussed the subject of manuring,—it struck me that the opinions you quote as to the after effect of manuring hardly seem logi-

cal. One manures; the vigour of bushes increases and the soil improves; but we are told the after-effects will be a falling-off in yield. It would be just as logical to say that children should not be fed on Mellins' and other artificial foods because the child would suffer afterwards. Again a deterioration of quality is spoken of, as the result of manures. Possibly were very stimulating manures used such might be the case, but this lies entirely with the Manager; his commonsense—coupled with the scientific knowledge we now have at our disposal should prevent such occurring. When tea is to be manured for the first time, in many cases, increased yields are undesirable and in fact excepting whenever stimulating mixtures are used, nature sees to this and devotes her time to fostering and creating the rootlets and frames so conspicuously absent, ere allowing her patients to start the work of creating excessive foliage. I have often thought that in many cases, money and time could be saved were manuring operations to be preceded by careful attention to bush and soil, treating the former to careful pruning; bearing in mind the necessity of a healthy sound frame, free from gnarly knots, etc., and sometimes a great change for the better would occur were the roots pruned as well. As for soil, an attempt should be made to improve its mechanical condition and increase organic matter, which can be done by prunings—burying, forking and so forth, and in very steep places a small dose of some organic manure might be applied. Having done all one can in this way; when the time came for manuring everything necessary for economical work would be at hand, instead of the manure lying idle (for want of the necessary chemical balance in soil-life in bush required to render it soluble) and being slowly washed out of the bushes' reach, a healthy growth would start at once.

My personal experience of the effects of using a mixture containing some soluble matter—sulphate of ammonia, etc.—in fields that have been in a fairly healthy condition at the time of application, is that increase of yield has commenced almost at once, accompanied by marked improvement in vigour of bushes. In one field particularly, I made repeated tests—extending from time of application—even about six months, finding the teas made from this leaf, fully equal in every particular to teas made from contemporary fields which was—though I am not quite certain on this point—hardly the case formerly. As far as comparing manured with unmanured property goes, figures may prove anything; but taking into consideration *past, present and possible future* results, one argues against nature in giving a preference to unmanured estates.

As for the last item, *Over-production*, this subject is no doubt a serious one; but more fitted for discussion by the Pessimistical Theorist than the Practical Planter; the latter, as an individual, is hardly likely to reduce, or keep down, yield for the benefit of his neighbours.

SUPERINTENDENT.

No. II.

Peacock Hill, Pussellawa, 16th March.

With regard to your leader "Tea in Ceylon," in *Observer* of 13th instant,—

(1) Has the export (or crop) of tea from Ceylon of recent years kept up with the extension of

planted land? I think that your Directory apparently shows that it has, and that not only has it kept up but that the yield has increased per acre, as I endeavour to show. Beginning in 1883, the first year that the export, exceeded 1,000,000 lb. I find that the exports amounted to 1,665,768 lb. The acreage of tea in cultivation in same year is 32,000, from this I would deduct the acreage planted during the three previous years, as certainly not in bearing, this amounts according to Directory to 25,500 acres leaving 6,500 acres yielding 256 lb. per acre. In 1888, or five years after, the acreage planted is 183,000, deducting as before the tea planted during the previous three years which amount to 116,000 acres there remains 77,000 acres, export for the year is 3,820,723 lb. or at the rate of 309 lb. per acre. In 1893 or after another period of five years, the acreage under tea is 273,000, including 68,000 acres planted during the previous three years, deducting this the result is 205,000 acres, export 82,269,353 lb. or at the rate of 401 lb. per acre. In 1898 there are 364,000 acres of tea, deduct 75,000 acres planted during the previous three years leaving 289,000 acres, exports are 119,769,071 lb. of tea or 414 lb. per acre. Taking 1899 with (an estimated) planted acreage of 375,000, 70,000 acres was planted during the previous three years, subtracting this there remains 305,000 acres with an export according to the Chamber of Commerce returns of 129,894,156, or at the rate of 425 lb per acre, or, put simply, the above comes to the following :—

Year.	Aores of Tea in bearing.	Yield per acre.
1883	.. 6,500	.. 256 lb.
1888	.. 77,000	.. 309 "
1893	.. 205,000	.. 401 "
1898	.. 289,000	.. 414 "
1899	.. 305,000	.. 425 "

Of course an important factor to be taken into consideration with the increase of yield, is when the bulk of the tea in the lowcountry came into bearing, this would give the yield per acre for the whole island a perceptible rise. There is no doubt as yet that the lowcountry tea has not gone back, in spite of sporadic attacks of grey blight.

(2) Is it well to manure Tea on virgin soil?—If the "virgin soil" was suitable for opening in tea, (I exclude patna and cheua lands), and was properly drained when opened it should not require manure for at least fifteen years and I question if there is much tea planted in such land in Ceylon of that age. With regard to those estates you mention "formed out of virgin land doing well, and in good heart, or if shewing any slackness only of a few months duration, due to seasonal influences. Should they be manured?" One would imagine that the obvious answer to this would be no, but that there is something wrong with the tillage which could be remedied without applying manure, though it is now extensively believed, and we have good authority for it, that the systematic burying of prunings—with possibly the addition of basic slag—will do a great deal towards keeping up the yield of tea. Of course, however, if Mr. Bamber is successful in his attempt to impregnate the soil with the lower oxide of iron, in an active condition or so that it can be assimilated by the bushes, and which he shows raises the price of made tea pence per lb. according to the quantity present in the soil naturally, the answer would be "Manure by all means."

GEO. THORNTON PETT.

No. III.

Uva, March 20.

DEAR SIR.—I fully agree with you when you say you think it is a mistake to manure tea planted in virgin soil; it is I think a great error. Manuring, unless we can open new markets for our product, tends I think, to become the curse of Ceylon. The way it is being shovelled in to such fine estates as there are in the Agras, Dimbula, Bogawantalawa and on the Nuwara Eliya side appears to me to be folly. No doubt the people who are doing it do not think so. Manure old coffee estates where the tea is finely grown and is simply at a stand-still, because the soil has become exhausted. Of course another point of view must be taken besides the yield one gets in manuring. It is whether tea regularly manured is less apt to be affected by the blights it is said to be subject to. Personally from what little I have seen I am inclined to think that a well-cultivated estate is not affected so much as an unmanured one. In Haputale, however, it may be said in argument against this opinion and very rightly too, that little or no manuring has been done so far (except on Lipton's group) in this district. I think I am right in saying that so far not a single estate here has had a bad attack of blight, such as has been experienced in some parts of Dimbula and the lowcountry. I think burying prunings with lime or, better still, basic slag, where land is not too steep, an excellent practice. Then six months after, where soil requires, add a mixture to keep the tea up to an average yield of 500 to 600 lb. an acre. Further than this I would not go.—Yours,

LOOK AHEAD.

No. IV.

1883.

183,000 acres ... Yield 133 lb. per acre.
192,000 acres in bearing—crop 24,381,296 lb.
Average yield, including home consumption,
say 240 lb. per acre in bearing.

1893.

273,000 acres ... Yield 309 lb. per acre.
220,000 acres in bearing—crop 84,406,064 lb.
Average yield, including home consumption,
say 390 lb. per acre in bearing.

1899.

375,000 acres ... Yield 346 lb. per acre.
330,000 acres in bearing—crop 129,854,156 lb.
Average yield, including home consumption,
say 395 lb. per acre in bearing.

"Given" a decent soil, etc., etc.—Quite true; but *fortunately* the island does not consist of that, or we should have a crop of 150 to 160 millions. You don't want to increase your crop if you get 500 lb., but what about the 250 lb. per acre places. To live they must manure.

Re Loolecondra.—Remember the old field quoted may give 400 or 500 lb. per acre; but look at the acreage of the whole place and crop. See Wilson, Smithett's yearly circular. I forget the acreage of this field, but I believe under 30 acres. Mr. Bamber, as you doubtless know, visited Loolecondra.

"We are leaving out of view" para.—How big a proportion of whole? You seem to be raising bogies only to knock them down

Table I. shows on your own figures crops gradually increasing on whatever figures you base it.

ERRATA.—On page 753, under heading “The Manuring of Tea,” para 4, line 1, “The similarity of the increase in the field of plot five” should be “*in the yield,*” &c. In the next column, “oxide of magnesia” should be “oxide of *manganese.*”

Each Manager of an estate is the best judge or should be, as to whether the virgin soil estate should be manured. I take it a big proportion of estates have old coffee land and virgin soil; in my own case I am manuring the old coffee land but not the virgin soil at present.

PROPRIETOR.

No. V.

Holmwood, Agrapatna, March 22.

DEAR SIR,—In reply to your query *re* Manuring Tea on virgin soil, I can see no harm in supplying to the soil any mineral ingredient in which it might be shown by analysis to be deficient, and by adopting such a course I think the trees would be built up of stronger constitution; but manuring with the object of forcing an unnaturally large yield, I should consider a very risky proceeding, and therefore better left alone.—Yours faithfully,
W. D. B.

THE MANURING OF TEA.

Colombo, Ceylon, March 23.

DEAR SIR,—Mr. Joseph Fraser sends us today the statistical results which he obtained during the second year of his experiments in manuring, and we take pleasure in annexing a copy of the same.

These statistics are drawn upon the same lines as those published in the *Ceylon Observer* on the 6th April, 1899* and will no doubt prove of great interest to the public generally. Mr. Fraser adds the following remarks:—

“The tea was four years old, and well grown when the experiments began. The field was in Guinea and Mana grass before being cleared for tea. There was no pruning in the first year, but all the plots were pruned in the second.

“The similarity of the increase in the field of plots five, six, seven, and eight in the second year is rather remarkable, though it varied to a certain extent from month to month. You will observe that the manure applied shows a maximum and minimum application of the three fertilising ingredients in the four plots. No. 6 is the most puzzling, as in all my experiments carried out previous to this, in old coffee land tea, a low percentage of nitrogen meant a low yield, and this is borne out by plot No. 3, where the nitrogen was suppressed. The only explanation that suggests itself to me is that in the plots from five to ten inclusive, there were a considerable number of ‘*Albizia Stipulata*’ trees growing naturally in the land. A considerable number of these were cut out when the land was cleared for tea, and a fair number allowed to grow along with the tea. The decay of the roots rich in nitrogen and the fall of the leaflets yearly (the *Albizzias* being atmospheric nitrogen collectors) may have afforded a sufficient supply of nitrogen naturally. The decay of grass roots, would no doubt also have aided in this respect, but then all the plots had these equally. Plots one, two, and three had no *Albizzias* and four only one or two. The general appearance of the bushes in the various plots, as regards health, vigour and succulent growth stand in the order of six, five, seven, ten and four—eight and nine suffered most again from

grey blight and the mite family of insect pests, of all the plots, and indicates that the mixture, as regards potash was not properly balanced, and this might be all the more marked as the *Albizzias* are strong potash feeders.

“Results from the increased profit per acre point of view, are in the order of eight, six, ten, five, seven, nine and four—No. 8 and 6 take the lead as in the previous year, but ten jumps from 7th to 3rd place. The experiments have been again repeated, and will be recorded for another two years.

“I had the soil of plot No. 6 analysed, but as is usual with soil analyses, it helps little to an interpretation of results.”

We further annex copy of the analysis made by Mr. Cochran of the Pitakande soil, and his report on the same and remain.—Dear sir, yours faithfully,
FREUDENBERG & CO.

(Copy)

M. Cochran,

City Analyst's Office, 56, Kollupitiya Road, Colombo, 25th November, 1899.

Analysis of a Sample of Soil from the Pitakande Group, received on the 3rd November from Mr. Joseph Fraser, per Mr. J. Morris.

MECHANICAL ANALYSIS.

The soil which passed through a sieve having 10 meshes to the lineal inch consisted of

	per cent.
Coarse Earth	46.5
Fine Earth	53.5
	<hr/>
	100.0

CHEMICAL ANALYSIS OF THE FINE EARTH.

	per cent.
Moisture	3.650
* Organic and volatile matters	13.050
Soluble in standard Hydrochloric Acid.	
Oxide of Iron	12.143
Alumina and small quantity of oxide of magnesia	21.029
Lime168
Magnesia400
Potash233
Phosphoric Acid128
Silica, Insoluble Silicates and undeter- mined matters	49.199
	<hr/>
	100.00
	<hr/>
* Containing nitrogen156

This sample of soil is rather richer in nitrogen than the sample analyzed in January, while the latter had somewhat more potash and phosphoric acid, and was also richer in lime of magnesia.

The sample just analyzed has more alumina, and also rather more organic matter, but, nevertheless, the dried sample has less moisture than the sample analyzed in January. A drier condition of the atmosphere, when the present sample was prepared, is probably the explanation of this.

With regard to the general characteristics of the soil, it has the composition of a soil that should be fertile for tea; nitrogen, however, being relatively less than the other important constituents.

(Signed) M. COCHRAN, F.C.S.

City Analyst.

THE GOVERNMENT DAIRY AND CATTLE SALES.

March 23.

SIR,—I see an advertisement in the papers that a sale of bulls and cows will take place at the Government Dairy on the 31st instant. This will only give an opportunity to the wealthier men to buy these fine animals, as there will be high competition. I think the Government Dairy is not in want, but in a flourishing condition, and has a balance in its favour. Taking the circumstance to be so, would it not be advisable to sell these animals in the different Korals and out of the way places—the sale to be open to *bonafide* villagers only—and stop the sale for the 31st instant. By this means the breed of bulls and cows in the villages will be greatly improved, and this ought to be the aim of the Government. Or why not distribute stud bulls among the villages by giving them in charge of the Headmen and Mudaliyars.

I hope Government will not lose sight of this suggestion—and a word from your pen will go a great way to help in this cause.—Yours

A CULTIVATOR.

—[Well worthy of consideration.—Ed. T.A.]

PLANTING NOTES.

THE COFFEE MARKET.—Messrs. C. J. Leech & Co. in their weekly report on the coffee market, state that there has been another week of large receipts in Rio, where the rise in exchange would seem to be having the effect of attracting the balance of the crop from the interior faster than would otherwise be the case. In the speculative centres the tone has been weak, the large Rio receipts having unfavourably affected the New York market.—*Home and Colonial Mail*, March 9.

MANURING FRUIT TREES IN HOLSTEIN.—A method of fertilising fruit trees in vogue in Holstein is suggestive, and not unworthy of a trial. The trees, it is said, receive no cultivation, and the fruit is large, sound, and produced in abundance. Every two years a few wholes are dug in the ground about four or five feet from the trunk of the tree, and about one foot deep, closer and shallower in the case of young trees. These holes are filled with liquid manure about four times during the winter months, and for young trees this is diluted with water. If there is more liquid manure than is wanted, it is distributed over the surface of the orchard, using an old street sprinkling-wagon for the purpose. There is no reason why manure water should not be used once or twice after it is seen what the crop is likely to be; of course, not affording any at that season to trees not bearing a crop, or which are carrying only a few fruits, as to dose them would be to encourage, probably, an unnecessary growth of shoots. But in this matter, the cultivator must be guided by the condition of the trees and of the soil.—*Gardeners' Chronicle*.

THE WORLD'S PRODUCTION OF PRECIOUS METALS.—The year 1899 would have been a record-breaker in the production of gold, had it not been for the conditions in South Africa, but it is estimated the production will amount to 968,000 pounds. The Witwatersrand will probably, after peace has been restored, produce 5,000,000 and the other districts in Africa 250,000 ounces, or approximately double the production of 1897. The United States, Australia and Canada also contribute an increase, so that the twentieth century will commence with a yearly production of about 1,614,000 pounds, of a value of \$305,360,000, which means that the output of gold alone will exceed by \$119,000,000 the average production of gold and silver combined in the years between 1866 and 1870. From the discovery of America up to the year 1899, there were produced 32,514,329 pounds of gold.—*Scientific American*.

TO ALL PARTS OF ASIA, AFRICA, AMERICA AND OCEANIA.

Seeds & Plants of Commercial Products.

Castilloa Elastica Cervantes.—Orders being booked for the coming crop of seeds available in March and April, selected seed from very old trees. R. N. Lync, Esq., Director of Agriculture, Zanzibar, writes under date 24th August, 1899:—"Please send me 200 seeds of Castilloa Elastica for further trial; the seeds of Castilloa you sent me last August germinated very well." Price and particulars in our Circular No. 32; special quotations for large orders according to quantity; immediate booking necessary to avoid disappointment.

Hybridised Maragogipe Coffee.—A large-beaned superior variety of Coffee in demand; orders booked for the coming crop of seeds, February and March delivery. Price according to quantity on application.

Hevea Brasiliensis (Para Rubber).—Orders being booked for the coming crop available in August and September, 1900. This is the only crop of seeds in the year. All orders should reach us before the end of July to avoid disappointment, as we have to make arrangements in time; guaranteed to arrive in good order at destination. We have already booked a large number of orders. A Sumatra Planter writes, dating 9th March, 1899:—"I consent to the price of £——per thousand. I herewith order 50,000 upon condition that you guarantee at least 33 % seeds germinating." Plants can be forwarded all the year round in Wardian cases. Price and particulars as per our Circular No. 30. A Borneo planter writes dating, Sandakan, 17th August, 1899:—"The last lot of Para seeds turned out very well."

Ficus Elastica (Assam and Java Rubber).—Seeds supplied by the pound with instructions; price according to quantity. This tree grows equally well in high and low land, in forest and grass land, its cultivation being extended largely by the Indian Government. For price of seeds with particulars as per our Circular No. 32.

Manihot Glazievii (Ceara or Manicoba Rubber).—Fresh seeds available all the year round; price as per our Circular No. 31. It is superior to Mangabeira rubber and second to Para rubber.

Urceola Esculenta (Burma Rubber) and Landolphia Kirkii (Mozambique Rubber).—Seeds and plants, both are creepers.

Cinchona Seeds.—Different varieties.

Sterculia Acuminata.—(Kolanut). Superior quality, seeds and plants; price on application, packed to stand the transit well for several months, a hardy tree, cultivation easy.

Erythrina Lithosperma.—Thornless variety, new crops of seeds ready in December, May and June. Price according to quantity on application.

Seeds and Plants of Cinnamon, Nutmeg, Clove, Sandlewood, Pepper, Cardamom, Vanilla, Arabian, Liberian and Maragogipe Coffee, Cacao, Tea, Coca, Fibre, Medicinal and Fruit Trees, Shade and Timber Trees, Eucalyptus various varieties, also Palms, Bulbs, Orchids, &c.

Our enlarged Descriptive Price List of Tropical Seeds and Plants of Commercial Products for Foreign Countries for 1899-1900 are now being forwarded to applicants in different parts of the world. Also Descriptive Price Lists of Seeds and Plants of Fruit Trees, Bulbs, Tubers and Yams, and Orchids.

"South Africa."—The great authority on South African affairs of 25th March, 1899, says:—"An interesting Catalogue reaches us from the East. It is issued by William Brothers, Tropical Seed Merchants, of Henaragoda, Ceylon, and schedules all the useful and beautiful plants which will thrive in tropical and semi-tropical regions. We fancy Messrs. Williams should do good business, for now that the great Powers have grabbed all the waste places of the earth, they must turn to and prove that they were worth the grabbing. We recommend the great Powers and Concessionaries under them to go to William Brothers."

A leading Planter writes from *New Hebrides* under date 17th January, 1899:—"I shall like a few more of your Catalogues to distribute through these Islands, as I feel sure many would place themselves in communication with you, did they know where to write for Seeds and Plants."

Our New Descriptive Price Lists of Seeds of Shade Trees for Coffee, Cacao, Tea, Cardamoms, &c., Timber Trees, Trees for Avenues, Hedges Wind and Shelter Belts, Ornamental Trees, Shrubs and Climbing Plants; and Seeds and Plants of Palms, Calamus, Pandanus, Cycads, Tree and other Ferns, *Crotoms* and *Dracinas*, now being prepared and will be ready shortly.

Agents in London:—MESSRS. P. W. WOOLLEY & Co., 33, Basinghall Street.

Agent in Colombo, Ceylon:—E. B. CREASY, Esq.

PLANTING IN THE WEST INDIES.

DR. MORRIS'S PLANS.

An agricultural Conference was held in Barbados in January, under the presidency of Dr. Morris, Commissioner of the Imperial Department of Agriculture for the West Indies, who described in his address the experimental work which was being done in the agricultural interests of the West Indies. In the sugar industry, for example, beside the raising of new canes and the cheapening of the manufacture, there was the reduction of the cost of cultivation to be considered, and it was expected that the present costly system of manuring might be modified without affecting the yield. The value of green manuring for fertilising cane lands was to be re-examined, and the cost of cultivation might also be reduced by increased attention to rotation and catch crops, thus growing to a larger extent than at present the food stuffs and supplies imported from other countries. Next to sugar, cacao is the most important production of the West Indies, Trinidad's export of that product showing a steady increase in value year by year. This is an industry that offers good profit to the planter; it requires little labour, compared with sugar, and is adapted for large and small cultivators. At Grenada, St. Lucia and Dominica, where many small growers have already started planting cacao, the Imperial Department will afford advice and assistance by means of travelling instructors, and establish model plots in each district as object lessons in the right methods of cultivation. A new coffee estate of about 200 acres, at an elevation of 2,500 feet, has been opened in Dominica by a Ceylon coffee planter. If this undertaking should be successful, Dominica may regain its former position as the producer of some of the finest coffee in the New World. The first-class coffee grown in the Blue mountains of Jamaica has been little affected by the recent fall in prices. Fruit cultivation continues to expand in Jamaica, and producers throughout the island must at once make arrangements to meet opportunities, which will arise, of shipping large quantities of fruit, when the new direct steamship service shall commence in January next, for it is understood that the owners of the steamers are to be purchasers of produce and not merely carriers. While bananas and oranges will be the principal products taken, there will be an increasing demand for many of the minor products which are at present luxuries in the English markets, and cultivators will do well to extend their plantations, paying the greatest attention to the quality of their produce.—*Imperial Institute Journal*.

THE DELGOLLA ESTATE CO., LD.,
(IN LIQUIDATION.)

The liquidation of this estate by Mr. Munton is now closed, and the result is a loss on realisation of about R135,000 out of the capital of R220,000. The shareholders have, in other words, had about R155½ paid back for each paid-up share of R400. At one time, Delgolla seemed a most promising property, having not only flourishing cacao, but also coconut palms; but the cacao proved a great disappointment after a few years, and a purchaser having been found for the estate, it seemed very wise to liquidate. Mr. John Guthrie has audited the liquidator's accounts and all is now closed.

TEA CROPS AND MANURING.

ONCE again we are indebted to Messrs. Freudenberg & Co. and Mr. Joseph Fraser for the results of the very careful and elaborate series of manuring experiments made by the latter on Pitakandé estate. (See page 751.) This is the second year of the experiments. Planters who file our monthly ought to refer to the May number of last year for the analyses of the average of the several plots, to compare with that of No. 6 plot by Mr. Cochran, given on page 753. Mr. Fraser's own remarks on the results will be specially considered; but it is evident that the observations must be continued for one or two years more, before any very definite conclusions are arrived at.

In this connection we also call attention to a couple of letters arising out of our recent article on "Manuring" and "Overproduction"—see page 751. Some of these are suggestive and useful. Two writers seem to shew that, leaving out "tea not in bearing," the average production per acre has, on the whole, increased. It seems not to be realized that we had a practical purpose in view; we insist that the acreage of tea planted on forest-land, even in high districts, is appreciable; that there are absent proprietors and shareholders who are liable to be carried away by the general cry for "manuring" and that it is worth while to shew such proprietors—getting probably not less than 500 lb. tea per acre—that they ought to leave well alone and take encouragement from the old field on Looecondura. Very different is the case of the estates on which Mr. Fraser has been experimenting; but, on the other hand, we are bound to put his opinion on record, as now sent to us, to the effect that "generally all tea at medium and low elevations will have to be manured if yield and quality are to be kept up, even if planted in virgin soil. The forcing and exhaustive nature of the climate is so great at these elevations, both in regard to organic matter and soluble or available plant food, that the yield sooner or later invariably falls off."

LARGE CEDARS OF LEBANON.—On p. 106 of the *Gardeners' Chronicle* reference was made to these noble trees, from Transactions of English Arboricultural Society, vol. ii. "Dimensions were given of different trees, the one growing at West Wycombe being stated to have a quarter girth of 71 inches, or nearly 24 feet at 5 feet in circumference from the ground, the largest Cedar ever seen by any arboriculturist present when the trees were inspected last August." It may interest those gentlemen, or other readers of these pages, to learn that at Goodwood may be seen, without doubt, the finest specimen in the country. It has one clean stem, the girth at 5 feet from the ground being no less than 29 feet 6 inches. At this point, however, it is where the massive limb commences to divert from the stem. The smallest measurement of the latter taken at 3 feet from the ground, exceeds 25 feet 11 inches. The height is rather more than 100 feet; spread of branches 130 feet. This specimen, together with many others, was planted in 1769. Richard Parker, Goodwood.—*Gardeners' Chronicle*.

CACAO IN SAMOA.

The following (says the *Samoa Weekly Herald*) is taken from advance sheets of a Consular report:—

Cacao is generally planted in rows about 14 feet apart and on hillsides at closer distances. Some planters favour a wider spacing; thus it will be seen that from 180 to 225 trees are usually planted to each acre of ground occupied. During the third year a small crop is produced, but not until the fourth year is the crop of any appreciable value. Each year thereafter, as far as my short experience goes, the crops increase, and at the present time I can not even conjecture how much may ultimately be produced.

On my Papa oloa plantation, after clearing my land of the forest growth, I set out rows of bananas in lines 15 feet apart, and when these were well under way and offering good shade, I planted my cacao with spaces of 15 feet on parts of the land and 18 feet on other portions. Along all the different roads I planted pine apples, and I also devoted several fields to them. I have reserved for pasturage about 8 acres all told, and it may seem astonishing to people outside of Samoa when I say that land has furnished abundant pasturage for six horses, fifteen sheep, and twenty one head of cattle. I can not from memory say just how much fruit I shipped last year from this place to Auckland, nor how many head of cattle I sold out of the natural increase of the place. But I am well assured that my net profits, after paying every expense, were upward of \$1,200. This from 60 acres all told is very satisfactory, considering that all was obtained from catch crops (bananas and pines) planted mostly to shade my cacao, from which, during the next two years, I expect very profitable returns.

During the early months of this year, Papaloloa was raided in turn by both factions then at war, and I have up to now been unable to procure a sufficient supply of laborers to put it in its former fine condition. Though the whole of the crops was carried off or consumed on the spot during three months when hostilities existed, it is safe to say that from the sale of the fine fruit crop now coming on, I will still this year be able to score at least as good a net profit as last; though this will not cover the great loss I met with in the destruction of my herd of cattle, and the loss of 750 cacao trees wantonly pulled up by the adherents of Tanu and Tamasese.

Part of my cacao has just commenced to bear, and I am forwarding its seed pods to my different trading stations as fast as they come on. At these points they are freely given to the natives, who are now commencing the cultivation of cacao in good earnest in several districts. At Pagopago, I have at present about 3,000 trees in all stages of growth, and on my property there I have still room for about 2,000 more plants, which will be set out this year.

After Papaloloa is cleared up I expect that eight men will be sufficient for the place while we are still raising fruit for export. Next year, I will have to abandon this on account of the rapid growth of my cacao. When this is done, I will increase the number of my cattle to fifty or sixty at least, and their natural increase will probably bring me nearly as much as I should have received from the fruit and this too with less labour and trouble.—*Fiji Times*, Feb. 17.

BRITISH TROUT IN KASHMIR.

The experiments in introducing British trout into Kashmir have come to an untimely end owing to the shipping agents at home having sent the ova in a slow steamer unprovided with a cool room. Captain Allan, who went to Karachi to meet the box, found that the Duke of Bedford's gift to the Kashmir Association had developed from ova into trout long before the steamer had passed Aden. The Association has however sufficient funds at its disposal to make a further trial, and another attempt will we hear be made in the coming autumn.—*Pioneer*, March 21.

THE TEA DUTY.

SOME FIGURES.—The announcement that the Budget speech would be made on Monday was only known at the close of last week, and occasioned considerable surprise owing to the early date. A rush was made to get dutiable articles out of bond, and some of the largo tea distributors have been working early and late. It is a philosophical way of looking at the matter to say that the extra duty will not affect the general consumption. Anyway, it will fall heavily on the poor, to whom tea is at once a necessary and a luxury. Although the Chancellor of the Exchequer does not appear to think so, tea contributes quite enough to the national exchequer. The additional burden of 2d per lb. is expected to produce in the course of twelve months a sum of £1,800,000. The duty from tea has produced, in the ten months ending January 31, £3,640,633 which is an increase on the corresponding ten months of last year of £344,833. The consumption per head for the period has therefore increased from 4.9 to 5.3 pounds. The receipts from coffee duty were £162,963, against £155,932; from cocoa £154,208, against £155,000. The decrease in the latter was caused by the increased import of raw cocoa (which is taxed at 1d per lb.) not quite compensating for the decreased import of foreign made chocolate and cocoa, which pays 2d. per lb. Brewers are not at all displeased with the Budget, for it is said they fully expected that the duty on beer would have been raised 2s. a barrel. Surprise is expressed that millionaires have been left untouched, and that coffee escapes. Certainly the Chancellor of the Exchequer believes in tea—as a source of revenue.

THE TAX ON BROKERS' CONTRACT NOTES.—Some uneasiness has been caused in commercial circles generally by the Chancellor of the Exchequer's proposal to tax contracts for goods sold by brokers. The precise wording of the resolution carried in the House of Commons on Tuesday was "that there shall be charged upon a note signed by any person carrying on the business of a broker to his principal advising him of the sale or purchase of any goods, wares, or merchandise the stamp duty following—namely: If the goods, wares, or merchandise are of the value of £5 and under the value of £100, 1d; of the value of £100 or upwards, 1s." This proposal is of a very wide character, and, whether intentionally or not, will be pretty sure to cause considerable friction in business circles. Meetings of merchants and brokers have been held hurriedly at the London Chamber of Commerce, and a deputation was appointed to present to the Chancellor of the Exchequer a very numerously signed memorial asking for information as to the scope of the next tax, and that the memorialists might be heard before any final decision was given. The Chancellor of the Exchequer has, we believe, agreed to receive a deputation next week, and ten representative brokers and merchants have been selected for this purpose. In the House of Commons last night Mr. C. McArthur asked whether the new stamp duty on produce contracts would apply to all descriptions of produce, including sugar, cotton, corn, provisions, and iron, and whether it would be levied on both spot and future transactions, and the Chancellor of the Exchequer replied in the affirmative. He also answered a question with regard to the payments at the Custom houses on Saturday and Monday in anticipation of the extra duties to be imposed by the Budget, stating that the amount paid was £2,500,000, and that he hoped shortly to make some proposal with a view to the prevention of such large anticipatory payments.—*Home and Colonial Mail*, March 9.

APPLYING MANURE TO FRUIT-TREES.—A mistake that is very often made in the application of manure to fruit trees is in heaping it right round the trunk and forking in within a radius of a foot or two. It is not difficult to discover how far a tree's roots extend, and to distribute the fertiliser accordingly.—*Queensland Journal*.

THE RUBBER-YIELDING FIGUSES IN NORTH AFRICA.

[FROM THE REVUE DES CULTURES COLONIALES
NOV. 5TH, 1899.]

(Specially translated for the "Tropical Agriculturist.")

It would be a mistake to suppose that Algeria and Tunis had climates which would permit of a profitable cultivation of rubber-bearing plants. It would be wrong to imagine that if the northern slopes of the Atlas Mts. were unsuited, the southern and Sahara slopes would be less so. The greater part of the Algerian territory is an elevated plateau with a severe winter, and desert region, generally elevated, which refuses all cultivation save that of the date palm. More than 25 years ago attempts at growing rubber-bearing plants of all kinds in the open air were made. Repeated experiments have shown that these plants cannot stand exposure to the winter chills and that even in sheltered positions they do not yield rubber in any satisfactory quantity.

The following kinds cannot stand the winter. *Bassia latifolia* and *longifolia* of India; *Mimusops Balata* (Guiana); *Chrysophyllum diversum*; *Hevea guyanensis* and *brasiliensis* and *Landolphia diversa*; Nor can the various *artocarpi*. The *Castilleja elastica* of Mexico the *Hancornia speciosa*, of South America and the *Manihot Glaziovii* though less delicate, can only rarely stand two or three winters out of doors. On the other hand the *Sapotilla*, *Ackras sapota* of the Antilles, succeeds well on the Algerian coast as to fructifying, but its vegetation is sluggish. The *Alstonia Scholaris* of the East Indies alone develops finely in the Hamma. This arborescent *Apocynce* there attains to more than 45 feet in height, but it does not yield any quantity of latex.

Various *Plumeria*, in rich soils in which water does not remain through the winter, have a fine growth, but they suffer from frost. Among the *Artocarpe*, the genus *Ficus* alone offers some fine specimens among the latex-bearers, but these are strictly limited to the neighbourhood of the sea.

At the Experimental Gardens of Algiers scientists have again and again experimented on the *Ficus* trees growing there, many 40 years of age. Those richest in latex are the *macrophylla*, *elastica*, *glumacea* the latter having a great resemblance to the *macrophylla* and then the *rubiginosa*. Then among the kinds with small leaves, *Ficus levigata*, *nitida*, etc.

(Then follow lists and descriptions of three groups of *Ficus*).

The value of the latex of the Algerian *Ficus* has long been questioned. Repeated experiments under various conditions showed that incision of the branch or aerial root let flow abundant milk, especially in the summer season; that this latex, of a pure white colour, was glutinous, coagulating rapidly, and sticking to the fingers in long filaments when they were fresh; but, as it got older, it lost all traces of elasticity and became a dry and powdery resin.

The question had reached this point in 1890. The *Ficus* had grown much, and their development was attributed largely to the frequent incisions that had been made. The late Aimé Girard of the Institute, whom I still remember with affection, determined to intervene and define the flow in the quality of the rubbers obtained. Later in 1896 Aimé Girard resumed the same work more methodically; he examined all the various rubber-like latex, I could collect

—which according to his directions underwent various preparations before they were sent to Paris. Death surprised this learned man in the midst of his labours, but M. Lindst has recently published a useful *resumé* of them.

I possess, however, the conclusions arrived at in private letters from M. Aimé Girard who kept me informed of his experiments.

He found the rubbers procured interesting from the anomalies they presented.

According to the different experiments of this learned man, it is at between 0.980 and 0.990, that we must place the density of ordinary rubber milk.

CEYLON TEA IN AMERICA.

That the importance of the Colombo market is likely to be steadily developed in the near future goes without saying. As an illustration of this truth we may instance the opinion of Mr. V. L. Tissera who accompanied "Mr." John Grinton to the Chicago Exhibition, remained in the States, started and has run the tea-importing firm of V. L. Tissera & Co. for the last eight years, and returned recently to Ceylon by the German steamer "Prinz Heinrich." He is of opinion that Americans prefer to have their tea brought to America direct from Ceylon and not *via* the home market. And Mr. Tissera's present visit to the East is mainly with the object of establishing branch firms in Colombo and perhaps, in Calcutta, by means of which he could import direct, though not yet severing his connection with the London market. Mr. Tissera's chief associates in the tea business at Chicago are the firm of Walsh, Lang & Co., who act as distributors through no less than 32 agents in the States. He finds that the American public are slowly, and by careful manipulation of the blends supplied, being brought to favour Ceylon teas, though the taste for China's is difficult to convert. Our visitor also does a certain amount of business with Ceylon coffee which is much liked by our American cousins.

Passing through Paris on his way East Mr. Tissera had the good fortune to meet our Commissioner, Mr. W. E. Davidson, who showed him round some of the buildings of the coming "exposition." He is reported also to have met a number of gentlemen in Paris, with whom he has arranged to run an "Oriental Booth," outside the Exhibition limits, for which unique depot he is shortly to send supplies of tea.

Mr. Tissera received some help last October from the Planters' Association representative, Mr. W. Mackenzie, in the shape of 11 half-chests of tea (black and green) in recognition of his furtherance of the interests of Ceylon tea since 1893. Our visitor is at present residing with his brother at "Tis Ville," Gregory's Road, Colombo.

GERMAN CHEMICAL INDUSTRY.—The approximate number of chemical factories in Germany is 5,950, employing 120,000 working men and 4,000 chemists. Heavy chemicals, such as soda, acids, &c, find employment for 16,000 workmen; fine chemicals, 17,500; aniline colours, 14,000; and fatty products, 9,000. Of the chemical staffs, 220 are employed in heavy chemical work, 250 for fine inorganic chemicals, 90 for fatty products, 400 in the metallurgical industry, 300 in sugar refineries, and 1,300 in aniline dye and organic chemical works. There are about 75 to 80 works in Germany devoted to the extraction of tar products and the manufacture of aniline colours.—*Revue des Prod. Chim.*

PROPOSED NEW DOCK CHARGES IN LONDON.

A statement issued by the London Chamber of Commerce reads:—"When powers were originally given to the dock companies of London it was provided, in order to maintain the freedom of the port, that lighters and craft should have free entry into the docks to deliver or discharge ballast or goods to or from on board of vessels lying therein. At the beginning of last year, however, certain rates were imposed by the dock companies on coastwise craft engaged in this work. Under the auspices of the London Chamber of Commerce (Cement Trade Section) the action of Burham Brick, Lime and Cement Company, Limited, v. the London and India Docks Joint Committee was thereupon brought before Mr. Justice Mathew in the Queen's Bench Division, when it was decided that the new charges on sailing barges employed 'in carrying cement and other goods from the Upper Medway to be discharged into ships lying in the defendants' docks, and in receiving goods from ships lying in such docks' were 'wrongfully demanded, and 'must be repaid.' Parliamentary powers are now being sought by the Dock Companies to impose dues of this nature, and, if obtained, it is estimated that the trade of London may be burdened with an additional contribution to the companies of over £700,000 per annum. As the dock dues, rates, and charges already levied in London are alleged to be heavier than at any other port in the kingdom or on the Continent, any further addition to the present high charges would be disastrous to the trade of London. Already notices have been issued by foreign commission houses warning their clients of the intended increase of London charges, and recommending transshipping services at Antwerp, Hamburg, or Rotterdam. A similar course was adopted during the great dock strike of 1889-90, which, as is well-known led up to the holding of stocks abroad, and the merchant when selling goods to the London market ordered lots by wire, to the detriment of London warehouse-keepers. Should the dock bills become law this course would most probably again be adopted. Amongst other public and mercantile bodies opposed to these bills as now drawn are the following:—The Corporation of the City of London, the London County Council, Association of Master Lightermen and Barge Owners, General Produce Brokers' Association, Wharfingers' Warehouse Keepers' and Granary Keepers' Association, London Flour Trade Association, Home and Foreign Produce Exchange, Limited, Wholesale Spice and Rice Dealers' Association, Indian Tea Association, Tea Buyers' Association, Ceylon Association, London Corn Trade Association, Barge Owners' Protection Society, Colonial Wool Merchants' Association, Short Sea Traders' Association, Wine and Spirit Association. Every effort is consequently being made to oppose the bills now before Parliament, or to have them referred to a Parliamentary Committee, with power to consider the whole subject of port administration."—*Home & Colonial Mail*, Mar. 9.

GUANO IN SEYCHELLES.

Writing from London on March 9th, Mr. John Hughes says:—"Probably Ceylon planters are not aware that in certain of the out-lying islands of the Seychelles there are deposits of Phosphatic Guano which from its composition is specially suitable as an ingredient of a good Tea manure. Already a few cargoes have been delivered in this country and samples have been submitted to me for analysis, so that I can testify to the quality from per-

sonal knowledge. I understand that this guano has been used for sugar-cane in Mauritius in conjunction with sulphate of ammonia, the two materials making an excellent mixture; for the guano itself contains only about 1½ per cent of ammonia and requires more nitrogen in the form of sulphate of ammonia to be added in order to render the mixture suitable for sugar-cane. It is intended to develop the working of this deposit, and no doubt the guano will be brought to the notice of Ceylon planters, as the material is in my opinion admirably adapted for tea manures for, it is not too stimulating like Peruvian and other highly nitrogenous guanos, which are quite unsuitable for tea and coffee. It would be interesting to hear whether there is any local knowledge of this Seychelles Guano, and the object of these few lines is to direct attention to the matter for further inquiry."

THE IMPERIAL BUDGET AND TEA.

We give in our daily the full report of that portion of the budget speech and debate referring to our staple. From the point of view of the Imperial Government, it is impossible to find fault with the increase of the duty by 2d a lb. at this time, and no serious opposition, or criticism even, was offered on the proposal. The large clearances of tea in anticipation of the rise, are referred to in Messrs. Gow, Wilson & Stanton's Circular (given as a daily *Supplement*) and are also the occasion of the following pithy paragraph by Messrs. Geo. White & Co.:—

As indicating the anxiety of the Trade to forestall any advance in the tax, 5,542,241 lb. were released from Bond on the 3rd, and 17,183,638 lb. on the 5th inst., making the unprecedented total for two days of 22,725,879 lb., representing nearly £379,000 sterling.

The disorganisation of the trade following on the new arrangement, caused the postponement of the usual weekly sales.—The Rood Lane firm furnish us with some suggestive figures this time in respect of the home consumption of tea in Great Britain, showing how it has risen from 3.42 lb. per head of population in 1866 to 5.98 lb. in 1899. Ceylon tea only appears from 1885 when 3,217,000 lb. were taken off, while last year the quantity was no less than 85,137,945 lb.! China tea has fallen from 97½ millions lb. in 1866 to 23½ millions lb. in 1899; while Indian tea has risen from 4½ millions lb. to 134 millions lb. in the same period.

THE GRAPE FARM.—The following letter is from Mr. T. J. Harris, of the Jamaica Public Gardens, to the Jamaica Agricultural Society:—

"SIR,—I am desired by the Director of Public Gardens to inform you that he considers it necessary for me to again visit the grape farm at Newport, to note the progress of the vines, and to carry out any work that I might find to be necessary. He also suggests that if you thought of visiting the farm shortly, we may go together to save expense, if not I am to proceed alone."

"A Grape Farm" is what should be started at an early date in the Northern Province of Ceylon to test the country for viticulture,

RUBBER TRADE OF THE UNITED KINGDOM.

The following interesting table respecting the rubber trade of the United Kingdom for the past three years will be interesting to our readers, and although it may be misleading in some respects it is important to notice that in spite of the supposed great increase in the use of rubber, the consumption in this country was less in 1899 by nearly 5,000,000 lb. weight than in the previous year, and the value about £500,000 less. Comparing the imports there was a marked increase on the total amount imported in 1898 over 1897 of over 10,000,000 lb. of nearly £2,000,000 value, but there was a considerable falling off in 1899, the weight decreasing 4,500,000 lb., but the value was only about £300,000 less. Curiously enough the re-exports of raw rubber have steadily increased both in weight and value, but taking the average value per lb. in 1897, the imports and exports were the same, namely, 2s 0½d per lb. while that used in this country only averaged 1s 11½d per lb. In 1898, the imports averaged 2s 3½d per lb., while the re-exports averaged 2s 4d per lb., that for home consumption amounting to 2s 4¼d per lb. During 1899, although the prices all-round were considerably higher than in 1898, the imports averaged 2s 2¼d per lb., the re-exports 2s 5½d, while that consumed in the United Kingdom averaged 2s 0¾d per lb. Of course there are a number of points connected with a general statement such as this which detract from the value to be placed upon the result. For instance, in the imports we get a large quantity of the best quality rubber from the South American market. The average value of the Brazilian rubber imported in 1897 was 2s 10 1/8d., while for 1898 it amounted to 3s 0¾d. The figures for 1899 we have not yet complete. Of our re-exports, a large proportion is of the better quality rubber, the cheaper African kinds being largely shipped to Continental ports direct, so that our re-exports average a high rate, while our home consumption is consequently somewhat lower in comparison. We are preparing a full statement of the rubber trade for the past three years, which will doubtless prove very interesting to all engaged in the rubber trade, and we shall be glad to receive particulars from any of our readers which in any way bears upon this question:—

	1897		Avr.
	Total weight	Total value	value per lb.
Raw Rubber.	lb.	£	s d
Imports	44,456,048	4,553,416	2 0½
Re-Exports	26,619,152	2,795,878	2 0½
Consumption	17,836,896	1,757,538	1 11½
	1898		
	lb.	£	per lb
Imports	51,833,072	6,214,933	2 3¼
Re-Exports	33,023,536	4,020,850	2 4
Consumption	21,809,536	2,194,083	2 4¼
	1899		
	lb.	£	per lb
Imports	50,360,464	5,925,643	2 2¼
Re-Exports	34,284,880	4,271,711	2 5¼
Consumption	16,075,584	1,653,932	2 0¾

--India Rubber and Gutta-percha Journal, March 1.

SOUTHERN INDIA PRIZE TEA.

We learn that the Agri-Horticultural Society's Gold Medal for tea has been again awarded to the Glendale Tea Estates, now under the management of the Nilgiri Plantations Company, Limited. The prize tea, which is being sold at As. 8 per pound, was valued by the brokers at twelve pence. The sample case has been most kindly presented to one of the Friend-in-Need Society's Women's Workshops.—*Madras Mail*, March 28.

PLUMBAGO IN CEYLON:

THE MINING INDUSTRY AND THE COMMERCIAL "BOOM";

IS THE LATTER A BLESSING, OR CURSE, TO THE SINHALESE?

PADDY CULTIVATION DISTINCTLY FALLING OFF.

DURING a recent visit to the Southern Province, we were much struck with the evidences brought under our notice of social disorganisation, and indeed demoralisation, among the Sinhalese, in connection with the great "boom" in plumbago. The recent sudden rise in value, by fifty to a hundred per cent., had quite turned the heads of the people in districts where there is any probability of the mineral being found. Not only was agriculture neglected,—work in the paddy fields delayed or postponed until too late, attention to gardens and planting a thing of the past,—but the "craze" had affected the villagers accustomed to work for the tea planters; it had moreover greatly disturbed domestic service—so that Sinhalese house servants were at a premium,—and it has even in some quarters emptied the schools! In their haste to be rich, Sinhalese parents insist on their children working all day in cleaning and sorting the precious mineral and they call home house-boys and appus to take a part in plumbago digging or exploiting. Not only so; but we were assured that the industry with the new and greatly increased wealth which it has brought and is bringing in, is provoking an unprecedented spirit of gambling. A European resident, who knows the people and their language well in the Galle district, declared that instead of 10 and 50 cents—the accustomed stake from each in a gambling bout,—the villagers or idlers now gamble for five rupees each; and in one case, away out in the country, he had found each person staking fifty rupees! Then, again, just as gambling on horse-races in England has been brought within the reach of domestic servants, so in South Ceylon—and perhaps in other plumbago-yielding divisions—persons now wander about asking appus and ayahs, cooks and table-boys, to take a rupee, or five-rupee ticket, in a new plumbago mining company or village syndicate; and so, in all these ways, plumbago mining and preparation has provoked an extraordinary amount of gambling, with its inevitable concomitant of crime, among the people.

We were especially struck with the many paddy fields out of cultivation, no doubt a direct result of the plumbago-mining mania. But we were assured by some old residents that ever since the abolition of the paddy rent—that is eight years ago—the tendency has been to circumscribe, rather than to extend, the area under culture. This is in accordance with experience in the Central Province under the old system which permitted the purchase of the rent at a value covering a certain number of years. Where such purchase was made, it was found that the object was almost invariably to have so much less to cultivate—to secure so many more holidays—rather than to get more crops or money! Who will say that there was not

philosophy in this, although it is enough to scare a Western political economist. It is certainly time that there was a careful investigation by the several Government Agents and their Assistants as to the effect of the policy adopted from 1st January 1892, on the staple of our native agricultural enterprise in the country. It may be supposed that the plumbago diversion complicates the matter; but it should be easy to distinguish between ancestral fields neglected for the first time this year and those previously allowed to fall out of cultivation; while, of course, the reason given by the owner for non-cultivation in each case, should be specially recorded and can then be taken *quantum valeat* by the Government and the public. The practical value of such an Enquiry and Report in connection with the Administration of the rural districts and the welfare of the people, cannot be over-estimated. We actually find a London journalist of some weight, heading an extract from a local paper,—“Ceylon and a Possible Famine,” basing this on the declension of paddy culture; and any day there may be questions on the subject in the House of Commons. Governor Sir West Ridgeway must see, therefore, the wisdom of being in a position, as soon as possible, to afford reliable information if called on to do so by Mr. Chamberlain. Should it appear that the wild rush into plumbago is causing the ruin of “paddy,” then it may be necessary for the Government to devise some check on promiscuous “mining” (and gambling) by the Sinhalese people,—a check that may serve to choke them off from a comparatively new and precarious industry, while urging, or compelling, their attention to the one occupation to which they have been accustomed from time immemorial, and which has always been held in the highest esteem amongst them.

THE COCONUT PALM AND SCIENTIFIC CULTURE.

How delighted the late accomplished Mr. Davidson, coconut planter in the Jaffna Peninsula, would have been to have had to guide him, such a paper as Mr. Cochran furnishes today—see page 764—for the benefit of all intelligent cultivators of the palm. There is a happy combination of practical experience and scientific investigation in the results arrived at and the recommendations made; and we should like to hear what such veterans as Messrs W. B. Lamont and W. Jardine and the present experienced Managers of Franklands and Goluapokuna, have to say on the paper, before us and its several series of analyses. The great advantage obtained for the palms where the husks are allowed to be returned to the soil, is made very manifest. Manufacturers of coir fibre, etc., must necessarily compensate their gardens for the additional drain upon them. Mr. Cochran incidentally shows that the application of salt to coconut palms growing along the seaside is not required; but does that of itself not prove how much good salt should do to palms grown in the interior, away up the Mahaoya valley for instance?

PLANTING NOTES.

“AGRICULTURAL EDUCATION IN GREATER BRITAIN.”—Under this heading, Professor Hedger Wallace read a paper before the Society of Arts, on February 27th. We are reproducing it in our monthly periodical, but meantime we give the paragraph referring to Ceylon:—

In Ceylon the elements of agriculture are taught as a specific subject in the Government schools, and a primer of agriculture has been published by the Director of Public Instruction. There is also a school of agriculture at Colombo which was opened in 1884, and has ten branch institutions. From this school, to which a dairy is attached, agricultural instructors are sent into remote rural districts to illustrate improved methods. The school for a number of years has also issued a monthly magazine and this, along with the *Tropical Agriculturist*, furnishes the agricultural literature of the colony, a colony, I may add, which has the reputation of being itself the best training ground for the tropical planter.

THE 1900 TEA SEASON has now fairly commenced. A number of gardens in several districts commenced taking leaf in the middle of this month and prospects are reported fair all round. Red spider is stated to have made its appearance in some Sylhet gardens after a dry spell, but a heavy fall of rain washed it away. It is too early to prophesy, but the general aspect of tea affairs is propitious for the coming season. We note from Government returns that in 1898 the area settled by time expired coolies in the Province of Assam amounted to 72,697 acres. It is explained that this does not show the whole amount of land settled with coolies, as it excludes the considerable area rented from private owners, but the figures are sufficiently suggestive, especially when contrasted with preceding years. In 1880 the acreage settled in this manner was 4,584, in 1885—3,196, in 1890—32,360, in 1897—67,923.—*Indian Gardening*.

PARA RUBBER AT THE STRAITS.—We call attention to a letter (see page 748) by our old (or rather young) friend, Mr. E V Carey, Chairman of the United Straits P.A. and at one time a Ceylon planter, like his father, Mr. Arthur Carey, before him. So important is the Para Rubber Industry in the Straits becoming, that the Chairman proposes (with apparently the countenance of Sir F Swettenham) that a special agent or expert should be sent to Brazil to report on the different modes of harvesting, preparation, &c. Now, we have no hesitation in saying that until full use is made of the information already available, such an expedition would simply mean a waste of money. In fact we question if any knowledge worth having could be added to what is already available from experts, tourists, travellers, journalists, who have ere now visited the South American rubber-yielding divisions and reported fully upon them. Has, Mr. E V Carey, for instance, digested the information in our compilation, “All About Rubber”? If he has, we should like to know what he requires from an expert visiting Para beyond what is in that volume? We are not writing egotistically; because the information referred to is not from our pen—it is taken from a hundred sources and deals with all rubber-growing countries, more especially Brazil. It would be well, therefore, for Mr. Carey’s Committee to study this volume and then to draw up a series of questions as to the points on which they wanted further enlightenment at the hands of an expert visiting Brazil.

A NEW "RUBBER PLANT."—The *Semaine Horticole* of January 13th publishes an illustration and a figure of a new species of *Ficus* called *F. Ectveddiana*. It is a moderate-sized tree, growing in the Belgian Congo. The leaves are on long slender stalks, the blades cordate oblong. It will form a fine shade tree in the tropics, and grows rapidly under cultivation.—*Gardeners' Chronicle*.

"MAZAWATTE."—A Ceylon friend at home sends us a specimen of this Company's advertising, from which we quote as follows:—£85,862 8s 8d Represents 19½ miles of 100 lb. tea chests, 5,151,746 lb. of delicious Mazawattee, equals over 2,300 tons. 1,300,000 cups of Mazawattee would fill a huge tea-duct 1,670 miles long by 1 ft. square. Reaching from London to Siberia, right across Europe. A river of liquid Mazawattee as long as the river Thames, 2½ miles long, 8 ft. wide by 1 ft. deep.

The Sugar to sweeten this Mazawattee tea (one lump of a cubic inch to each cup) would make a road of sugar 14½ miles long, 10 ft. wide by 1 ft. thick; and the milk for the delicious tea would fill a milk duct of 1 ft. square, which would extend from London to Dublin, a distance of 289 miles in a straight line.

THE TEA DUTY.—A London wholesale firm have through a trade journal made to their customers the following offers:—

If you remit us (PLAN A,) as a deposit, a sum equal to the present Duty of 4d. per lb. on any quantity of tea, we will hold on your account that quantity. Thus for every £25 you send, we undertake to enter for you 1,500 lb. of tea at our present list prices, and at the 4d. Duty rate, and you gain should an advance in Duty take place. If however, the Duty be not advanced, all we ask from you is to send us orders (before 31st December next) equal in amount to the sum you have actually deposited with us, and the transaction ends.

If you remit us (PLAN B,) a deposit at the rate of 1d. per lb. i.e., one-fourth the present Duty, on any quantity of tea, we will hold on your account that quantity. Thus, for every single sovereign (£1) you deposit with us, we will enter for you 240 lb. of tea at our present list prices, and at the 4d. Duty rate, and you gain if the duty be raised. You advance 1d., whilst we advance 3d., per lb. for the present Duty. If, however, the Duty be not raised, you on your part undertake to complete the purchase (before 31st December next) of all the Tea thus entered for you.

AN OLD SUBJECT REVIVED.—Few are aware probably that the question raised by "Wanderer" (see elsewhere) has been before discussed in our columns and the matter went so far at one time as that estimates of the cost of erecting a Paper Mill on the side of the Kelaniganga were prepared; but nothing came of it and there can be no harm in now reconsidering the subject of the introduction of a paper-making industry into Ceylon. Why should the Government not take a hint and guarantee a bounty for the first ton of locally-made paper? The value of actual local industries must be insisted upon and we are glad to find our correspondent draws further attention to this subject. Possibly people in the past have been asleep; so our correspondent thinks: and it is within the region of the future that the fibre and grasses of Ceylon can be put to other uses than they now command. At any rate we live and learn and the man who shall introduce a paying Paper Mill into Ceylon, will deserve the cordial thanks of all of us.

DR. GEORGE WATT, C.I.E., who is retiring from the position of Reporter on Economic Products in the Department of Agriculture of the Indian Government, has been associated with this department since 1884. He will be recalled as having charge of the Imperial Indian Economic Court at the Colonial and Indian Exhibition of 1886.—*British and Colonial Druggist*, March 2.

"NATAL PLANTS."—It is highly satisfactory at this time to receive from Natal the second part of *Natal Plants*. This consists of a series of quarto lithographs, with accompanying descriptions, from Mr. Medley Wood and Mr. Maurice Evans. In the present number we find various plants of garden interest, such as *Cyrtanthus Maekenni*, t. 51; *Leonotis leonurus*, t. 53; *Hæmantis natalensis*, t. 58.—*Gardeners' Chronicle*.

TEA.—According to the *Indian Daily News* the tea season in South Sylhet has begun on most of the gardens. Shamsiarnagar started "tipping" on the 3rd, which is early for the district. After a spell of hot dry weather, South Sylhet gardens since the 17th, have been getting a plentiful supply of rain, so that the lots of leaf may be expected. Red spider was in evidence, but the heavy rain expereinced will wash a good deal of it away. Gardens, on the whole, are looking well.

APPOINTMENTS FROM KEW.—We learn that an extraordinary demand for trained gardeners for positions of importance has been experienced at Kew within the last year or so. In addition to changes of situation which have occurred in the ordinary way, nineteen appointments have been filled by the authorities. Amongst these are nursery-foremen, head gardeners, assistants in the Royal Botanic Gardens, Calcutta (N. Gill and W. F. Green); superintendent, Agri-Horticultural Society, Madras, (B Cavanagh); superintendent, Parks and Garden, Shanghai (A. Arthur); Curator, Botanic Station, Accra (W. Brown); Agricultural Instructors for the West Indies (A J Jordan and M McNeil); Curator, Botanic Gardens Antigua (W N Sands); Assistant Superintendent, Botanic Gardens, Trinidad (W Leslie). These appointments have all been filled from the improver-gardeners employed at Kew, i.e., young men who after five years training in good private gardens or nurseries enter Kew for a two years' course.—*Gardeners' Chronicle*.

DESTRUCTION BY PAROQUETS.—A letter was read at a recent meeting of the Board of Management of the Jamaica Agricultural Society, from Mr. Charles H. Nunes and two others from Falmouth, Trelawny, bringing to the attention of the Board of Management, "serious loss sustained annually to the orange and lime crops by destruction thereof by parrots and paroquets, which birds were protected under the law. Not only did these birds destroy the above citrus plants, but they attacked young breadfruits. They asked the Board to bring the matter to the notice of the Government, in order that legislation might be amended in this respect, and thus yielding privilege to destroy the birds all the year round. The destruction of these birds was beyond description and they were really of no value whatever. They were sure that it opinion from different parishes be taken, if would corroborate the statement they made. The matter was referred to the Standing Committee on Fruit to report on the matter."—How about paroquets in Ceylon?

COFFEE, COCONUTS, RUBBER &c. AND PROGRESS.

(From a Special Correspondent.)

It is perhaps not so glowing a tale that is furnished when I turn to the world of planting and agriculture. The labour problem naturally enters largely into the former sphere and this remains still unsatisfactory. The Government has been a large employer of labour on railway and other works, and this has somewhat handicapped the planter in the way of cheap labour. In time this will right itself. The main planting industry has been coffee, but its existence in the Native States has, unfortunately, never been very flourishing, and recently the very low price of coffee, has been the means of bringing some of the best known estates to the hammer. In time those who have the financial strength will doubtless benefit, but meanwhile the weaker are being frozen out. When you see some thirteen piculs per acre as I did in the Klang district, it looks as though there should be a future. This was a lowland estate, and such a crop has not, I believe, been gathered on any of the estates on higher land. So much has been hoped for from coffee and so much capital expended, I can only hope that it will yet be a profitable industry to both individuals and the State. In other directions coconuts seem to be doing well and to be a fairly constant source of revenue, and Para rubber cultivation has made a good deal of headway and should in time make a fair show in the list of exports. I am not altogether sure, however, that the indigenous Getah Rumbong would not prove more profitable in the long run. If the price of its produce is not up to rubber, it is much more prolific in its yield, and as it is a native there is not the same difficulty about seed. Padi cultivation by natives has increased and gives signs of extension. It might well be the dream of every officer of the Government to see these Native States not only supplying their own rice requirements, but that they should be the granary of the colony of the Straits Settlements. It is well to know that land revenue is increasing, and that the cultivation of padi is being extended, but much more yet remains to be done. Unless I am mistaken, the Malay will increasingly go in for this class of work, but the progress will be less rapid than one might reasonably hope for. Some schemes for its larger cultivation have been, and are, under the consideration of the Government, and irrigation is being resorted to in more than one district.

It does not exactly come under the heading, but I may note a new industry at Ipoh that bids fair to do well. The Perak Marble Company (Limited) has been started to work on some excellent marble. It has first, good marble suitable for many domestic and ornamental uses; it is close to the line of railway, which gives the company good transport; it has good machinery, which was almost in working order at the time of my visit; and lastly, there should be a good market all around Malaya, and possibly over a more extended area. With good and economical management the company ought to do well. The material at its disposal is more than ample, and the marble is said to be of good grain.—*London and China Express*, March 9th.

TEA IN THE PHILIPPINES.

Mr. C. Ffolliott Pears, to whose adventures we have already referred fully in previous issues, having been enabled to publish a full account of them through the courtesy of Mrs. Pears, has returned from the Philippines, where he went in connection with the wreck of his vessel. He has given our evening contemporary a rough idea of what he thinks of the future of the island recently acquired by the Americans:—

TEA CULTIVATION.

“The country,” said Mr. Pears, “is exceedingly fine, and I should think that some portions of it

would be very suitable for tea cultivation. The soil looks as if it had plenty of iron in it. They grow coffee there already, and I did not notice any disease amongst it. Cacao is also cultivated, but the trees are sickly, and the pods very small. There is any amount of gold there, but it is not mined to any very great extent; and there is, as well, plenty of steel, from which the Filipinos make their swords. The climate of the country is exceedingly fine. In the early mornings it is nice and cool, similar to the climate of Dikoya. Of course, there is a certain amount of fever. Imported food stuffs are very dear and heavily taxed, but the industries in which there is ample room for development are sugar cultivation, saw-mills, and rice-mills. The English firms in Manila, I may say, do nearly all the business.

“The Americans,” added Mr. Pears, “are just beginning to buy Ceylon tea. Dr. Stephens, a dentist who used to be in Ceylon, has imported it to Manila, and the Commissariat bought up all he had and wanted a lot more.” Mr. Pears thought it would be advantageous if someone in Ceylon could secure a contract with the American Commissariat to supply Ceylon tea to the 60,000 odd troops in the Philippines.

COLOMBO COMMERCIAL CO., LD.

ANNUAL REPORT.

The following is the Report, which was to be presented to the fifth ordinary general meeting of the Company held in London, on Thursday, the 15th day of March, at noon.

The Directors have pleasure in placing before Shareholders statements shewing favourable results for the past year, viz. :—

Profit and Loss Account for the year ended 30th September, 1899.	
Balance Sheet made up to 30th September, 1899.	
It will be seen from the Profit and Loss Account that after debiting all charges, interest on Debentures, &c., the profit for the year amounted to..	£9,184 4 6
A balance was brought forward from last year of	1,303 8 2
Making the total at credit of Profit and Loss	£10,487 12 8
From this the following sums have been transferred, viz. :—	
To Exchange Reserve against Capital Expenditure ..	£1,400 18 5
To Reserve Fund	1,000 0 0
	<hr/>
	2,400 18 5
Leaving available for Dividend, &c., a sum of	£8,086 14 3

CENSUS OF THE ANIMAL KINGDOM.—The editors of the *Zoological Record* have recently drawn up a table that indicates approximately the number of the living species of animals. The following are the figures given :—Mammals, 2,500; reptiles and batrachians, 4,400; tunicata, 900; brachiopods, 150; crustaceans, 20,000; myriapods, 3,000; echinoderms, 3,060; coelenterata, 2,000; protozoans, 6,100; birds, 12,500; fishes, 12,000; mollusks, 50,000; bryozoans, 1,800; arachnids, 10,000; insects, 230,000; vermes, 6,150; sponges, 1,500. General total, 366,000 distinct species.—*British and Colonial Druggist*.

COCONUTS AND CHEMISTRY :

A SHORT CONTRIBUTION TO THE CHEMISTRY OF COCONUT CULTIVATION.

(By M. Cochran.)

It cannot fail to be of some service towards the perfecting of the art of manuring the coconut tree, if we compare, in respect of the more important constituents (from an agricultural point of view,) what the crop removes from the soil with what is added in manures by experienced planters.

There are several considerations which lead one to expect considerable diversity in the recommendations of experienced planters for the manuring of coconut trees, one of these is the great capability for increased yield which may legitimately be inferred from the great differences in the amounts of crop obtained from average trees grown under average conditions, and from trees grown under the most favourable conditions, thus, while the average crop all over the island is set down by some writers as between 14 and 20 nuts per tree per annum, there are trees to be found growing under very favourable conditions of soil, &c. which are said to yield for years in succession at the rate of 400 nuts per tree per annum. One writer in 1896, dating from Dombawinne estate, Mirigama, stated the maximum yield of a coconut tree as 900 nuts in one year. Another reason for the diversity in manurial recommendations is the fact that, in some cases, only the oil and part of the poonac, in others only the copra, is sent from the estate, while in other cases the whole nuts and some of the leaves are removed.

One system of manuring has for its object to return to the soil an amount of fertilising material equivalent to that removed by the copra. Taking 170 lb. of poonac as the produce of 1,000 nuts, and reckoning the poonac to contain 3.3 per cent of nitrogen, 1.35 per cent of phosphoric acid, and two per cent of potash, there would be removed in the poonac from 1,000 nuts 5.61 lb. of nitrogen, 2.295 lb of phosphoric acid, and 3.4 lb. of potash. Planters who manure expect to get at least 40 nuts per tree per annum. One planter informs me that he gets 15 nuts per picking per tree, and there are six pickings per annum, so that he gets 90 nuts per tree per annum. I shall suppose that, while some planters who manure get 40 nuts per tree, others get as many as 80. Each tree will at these rates of production remove from the soil in copra (as estimated from the poonac) in two years respectively.

	Trees yielding 40 nuts per annum.	Trees yielding 80 nuts per annum.
Nitrogen ..	4483	8376
Potash ..	272	5440
Phosphoric Acid ..	1876	3672

It is necessary, however, to take into account the fertilising ingredients removed from the soil in the husk, the shell and the "milk" of the ripe nut. From analyses I have made I find that

1,000 husks each weighing	1739 lb.
1,000 shells each weighing	666 "
50 lb. "milk" or 1/2 lb. per nut remove from the soil.	
Nitrogen ..	26618 lb.
Potash ..	134706 "
Phosphoric acid..	6420 "

From these data, it is easy to calculate what is removed in two years by the husks shells and milk of 40 and 80 nuts respectively, and, adding the same to the quantities found in the poonac, we get :—

Amounts of nitrogen phosphoric acid and potash removed from the soil in two years by crops of 40 and 80 nuts per annum respectively.

Nitrogen	6607 lb.	13214 lb.
Potash	13497 "	26984 "
Phosphoric acid ..	2350 "	4700 "

I shall now compare with these amounts of important ingredients removed by crop the amounts added to the soil by the different systems of manuring coconut trees as practised by experienced planters. First, we may consider the system of using the manure of cattle fed on the grass only of the coconut estate. This system, of course, adds nothing to the mineral ingredients of plant food of the estate ; but it should increase the amount of nitrogen available for the tree, and even the mineral ingredients are rendered more available for plant food by being assimilated, first by the herbage, and afterwards by the cattle. It will be interesting, therefore, to calculate the amounts of the fertilising materials that are drawn from the soil by the grass, and converted into still more available forms of plant-food by the cattle grazing on the estate. For practical purposes, the amounts of fertilising material in the grass may be taken as the same as that supplied in the manure seeing the cattle are not being fed with a view to being fattened. I have no exact data as to the quantity of grass produced on an acre of coconut field ; but I am informed by the well-known coconut planter Mr. Francis Beven, of Franklands estate, that 100 acres of coconut land can grow grass for 60 to 70 head of cattle. I also understand that he considers 50 lb. weight of grass, per head per day, as good average grazing, when there is no drought, but drought must be taken into the calculation, so I shall allow in this calculation 40 lb. of grass per head of cattle per diem. At this rate of consumption 65 cattle (the average per hundred acres) would require 2,600 lb of grass per day ; and, to supply this, each acre would have to yield a little less than 4 1/4 tons of grass per annum.

A sample of the grass on which the cattle on Franklands estate graze was analysed. In the anhydrous state it contained nitrogen 1.740 per cent, potash 2.375 per cent, and phosphoric acid .487 per cent. If these results are calculated into fresh grass containing 75 per cent. of moisture we get :—

Fertilising ingredients in fodder grass.	per cent.
Nitrogen	435
Potash	594
Phosphoric Acid ..	122

An acre of the grass furnishing 4 1/4 tons per annum would supply in the form of cattle manure in one year :—

Nitrogen	41412 lb.
Potash	56550 "
Phosphoric Acid ..	11614 "

Taking 75 trees per acre each tree gets per annum, and during three years respectively :—

	per annum.	during 3 years
Nitrogen	552 lb.	1656 lb.
Potash	734 "	2262 "
Phosphoric Acid ..	155 "	464 "

Passing now to cattle shed manure, we find that Mr. W B Lamont recommended, as the

teaching of his experience, an application of 5 cwt. of cattle shed manure per tree once in three years. The composition of cattle shed manure varies considerably with the character of the food of the animals, of the litter, and of the management of the manure. If we reckon it as about equal in fertilising properties to the average of ordinary farm yard manure, *i.e.* as containing per ton about 8 lb. nitrogen, 9 lb. of potash, and 3.6 to 4½ lb. of phosphoric acid, then 5 cwt. per tree would furnish per tree—nitrogen 2 lb., Potash 2.25 lb., Phosphoric acid .9 to 1.125 lb.

Another experienced planter, Mr. W Jardine, who has frequently written to the local press on the subject of coconut cultivation, has recommended the following mixture as a suitable application once in two years per tree:—

Castor Cake ..	12 lb.
Bone Dust ..	4 "
Wood Ashes ..	12 "

This mixture to be supplemented by one bushel of cattle manure when available. With materials of good quality these ingredients should furnish per tree about

Nitrogen ..	1.1 lb.
Potash ..	1 "
Phosphoric Acid ..	1.36 "

An experienced planter in the Kurunegala district informed me that, with liming the soil once in five years, the following mixture applied every two years yields 90 nuts per tree, *viz.*:—

Castor cake	6 lb.
Bone dust	3 "

This would supply at least half a pound of nitrogen per tree, about .07 lb. potash and .82 lb. phosphoric acid. The soil, in a case like this, must be rich in potash compounds on which the lime acts, liberating the alkali for the use of the plant; thus dispensing with the necessity of applying potash salts. Lime, by assisting in the process of nitrification, will also render available the more inert forms of nitrogen. Thus, by the addition of lime to the soil not only are applications of potash salts rendered unnecessary; but the proportion of nitrogenous manures required are also, for a time at least, reduced. Of course, it must not be lost sight of that, in adding lime to the soil, the soil is not thereby enriched with any of the three important elements of plant, food, so that the success attendant upon liming the soil will be in proportion to the natural resources of the soil.

Gathering up the foregoing results, I shall draw out in tabular form, for easy comparison, the amounts of fertilising material drawn from the soil per tree per annum by crops of 40 and of 80 nuts per tree, and also the amounts of the same materials which the different systems of manuring referred to furnish per annum per tree, together with some other interesting data:—

	LB. PER ANNUM PER TREE.		
	Nitrogen.	Potash.	Phosphoric Acid.
In 40 nuts with husks ..	.330	.675	.118
In 80 nuts with husks660	1.350	.236
In 40 nuts without husks	.269	.242	.102
In 80 nuts without husks	.538	.484	.204
In copra of 40 nuts225	.136	.092
In copra of 80 nuts450	.272	.184
In food or manure of grazing cattle—about 40 lb. grass per head per diem ..	.552	.754	.153

In 5 cwt. cattle shed manure equal in quality to ordinary farm-yard manure applied once in three years

.666	.750	.340
		.375

In castor cake 12 lb., bone dust 4 lb., wood ashes 12 lb., cattle manure one bushel applied once in two years.

.550	.50	.680

--	------	--

In 80 do ..

	1.714	
--	-------	--

In a year's rainfall according to Mr. Bamber's analyses for Colombo ..

.102	6.549	
------	-------	--

On inspecting the foregoing table, it will be observed that the amounts of nitrogen the cattle manures supply, equal, or nearly equal, that required for good crops of whole nuts. It does not, however, follow that the trees require all this nitrogen to be supplied in the manure, as the amount of cattle manure required is determined more by the amount of phosphoric acid required, than by the nitrogen; phosphoric acid being the fertilising ingredient in which cattle manure is most deficient. Cattle shed manure, supposing it to be equal in quality to ordinary farm yard manure, has an advantage over the manure of grazing cattle in respect of phosphoric acid, which in five cwt. of the former, is more than is in three crops of 80 nuts per tree. The amounts of potash, in these two forms of cattle manuring are about the same, and are in excess of what is required for crops of 40 nuts, but for crops of 80 nuts a very considerable balance has to be drawn from the soil.

In the mixture of manure recommended by Mr. Jardine, the amount of nitrogen slightly exceeds that in 80 nuts without husks and with the nitrogen in the rainfall added nearly approximates to that in two crops of whole nuts of 80 per tree per annum. The mixture has nearly three times the amount of phosphoric acid that is in the crops of 80 whole nuts; but it is mostly in the slowly available form and so cannot be regarded as excessive. The amount of potash is much greater than in the copra of two crops of 80 nuts per tree. It slightly exceeds that in 80 nuts without husks; but falls short of that in 40 whole nut crops (unless the ashes used are much above the average of wood ashes in respect of content of potash) so that, for crops of 80 whole nuts, a considerable demand would be made on the potash of the soil.

In the mixture used by the Kurunegala planter, the amount of nitrogen plus that in the rainfall, falls short of the amount of copra from two crops of 80 nuts per tree; but this planter gets 90 nuts per tree, hence the balance must be obtained from nitrification of the soil—nitrogen or other bacterial action, most of the potash is supplied in this case by the soil.

According to a recent local analysis, a tree bearing 80 nuts of large size removes from the soil in crop 1.714 lb. of common salt, while Mr. Bamber's analysis of a year's rainfall for Colombo shews a supply of common salt from this source of—6.549 lb. per tree per annum. These two re-

sults seem to demonstrate that applications of common salt to coconut estates, on the sea board at least, are unnecessary. They also suggest that the rain-water near the sea may possibly supply a not inappreciable amount of potassium chloride and magnesium chloride. Sea-water, according to an analysis of the water of the Irish Channel, contains between a thirty-fifth and a thirty-sixth as much potassium chloride as sodium chloride; and if it were borne on the sea-breeze in this proportion, the rain would furnish about 184 lb. of potassium chloride per tree per annum.

It does not follow, however, supposing potassium chloride to be present in the sea-breeze, that it is present in the same relative proportion to sodium chloride as in sea water: the proportion would probably be less, the weight of the molecule of potassium chloride being greater.

M. COCHRAN.

COFFEE—COCONUTS—RUBBER: SELANGOR PLANTERS' ASSOCIATION.

The annual general meeting was held in the Selangor Club, Kuala Lumpur, on Saturday, 24th Feb.

The CHAIRMAN informed the meeting that Mr. Carey had intimated that he was not prepared to accept office in either of the Associations for 1900, and was sure the meeting would agree with him that this was a great loss. Mr. Gibson, who had been their Honorary Secretary for a number of years, had also decided not to accept office again; but he was glad to say that Mr. Hicks had allowed his name to be put forward in the event of no other being forthcoming. He thanked all the members for their indulgence during the past year and wished the Association continued success.

Mr. TOYNBEE proposed, and Mr. SKINNER seconded—that Mr. Carey take the chair *pro tem*, which was carried unanimously.

Mr. CAREY said that, before proceeding with the next item on the agenda, which was to elect office-bearers for the new year, he should like to make a few remarks in the annual report which had been handed to them today. This, though nominally the Committee's report, was in reality the work of the Chairman and Secretary, who were to be congratulated in handing them such a good one. He was sure they would all agree with him that it was most encouraging to note that while coffee was selling at \$18 in November and \$20.50 in December last, it was now quoted at \$25, and confidential reports from London and elsewhere were most encouraging. They had undergone a most hard and severe struggle during the last two years and it was most creditable to find that so few had gone under, and they had every reason to be proud that the acreage under coffee had not decreased. The low prices of coffee had induced many planters in Selangor and other States to plant up large areas with Para and other rubbers and this promised to be a most profitable investment, as he had reliable information that a Para rubber tree in a neighbouring State, which was tapped twice in 10 months, half the tree at each tapping had yielded the enormous quantity of 16 lb. of rubber and the tree in no way harmed. Now the most sanguine of men could not expect such a result all over, but even supposing they got one-tenth of the above amount it would mean a fortune. Another product, which was most deserving of consideration, was the

coconut, which gave in their coast districts marvellous results—he had seen a tree in the Klang district which has been in bearing for over a year is now only five years' old and has over 70 nuts on it at present, and this tree was not at all singular. Altogether, he thought they would agree with him that the planters' prospects looked considerably brighter. Mr. Darby then proposed and Mr. Kendle seconded, a vote of thanks to the retiring office bearers, which was carried unanimously. TOM GIBSON, Hon. Secy., S.P.A.

TEA DUTY.

On tea the extra duty is 2d per lb. It seems clear here that the consumer will have to bear the addition. The opinion of the Mazawattee Tea Company's chairman, which company, by the way, is advertising that it has paid the record duty cheque of £85,860, is that people will take a 2s tea where they have been accustomed to pay 1s 10d for the same quality, that the cheapest tea (1s per lb.) will drop out, and that a better tea will be sold at 1s 4d. All tea issued by this company is now advanced 2d per lb. in price. Lipton's have advanced their teas by the exact amount of the duty, their 1s quality being put up to 1s 2d. Some interesting remarks were made by the Chancellor of the Exchequer on the subject of the tea tax, which are here reproduced:—

At the time of the Crimean War the duty on tea was 1s 6d in the pound. It was promptly raised by 3d with practically, I think, no objection from anybody concerned. The duty on tea in 1889 was 6d per pound, and my right hon. friend Mr. Goschen raised it by 2d. At that time the average wholesale price per pound of tea was 10.79d, making, together with the 6d duty, 16.79d per pound. Now, I am informed that the average wholesale price of tea is 8.87d per pound. If I were to add 2d to the duty that would make, together with the duty, 14.87d per pound, or 21 per pound less than the price in 1889. I propose to add 2d per pound to the duty on tea. (Ministerial cheers.) That will produce £1,800,000 in the course of the 12 months.

Mr. Labouchere pointed out that the tea-drinker would now have to pay one-sixth more for his tea, while the beer-drinker would only have to pay one-thirty-sixth more, and the whisky-drinker one-fortieth more.

Traders on the whole, with the exception of the produce brokers, are hearing the new duties with equanimity. True they made an unparalleled rush to escape the increases on Saturday and Monday, on the latter day nearly £500,000 being paid in London into the Customs House, on dutiable goods. The Chancellor of the Exchequer made some allowance for this rush in his calculations on what the duty would realise, but he was afraid afterwards that he had not allowed sufficient. The payments over the normal amount in the time were estimated at £1,000,000 sterling, and probably some £250,000 remained in the pockets of disappointed merchants who besieged the Customs on Monday. Some surprise has been expressed that a duty was not placed on coffee and aerated waters, and Mr. Gibson Bowles suggested a 100 per cent tax on diamonds, furs, feathers, lace, musical instruments, and artificial flowers, but the Chancellor of the Exchequer has preferred to keep to orthodox methods.—*British and Colonial Druggist*, March 9.

CHRISTY AGENCIES.—Messrs. Thos. Christy and Co. must surely have nearly the best—if not absolutely the best—claim to be the firm with the greatest number and variety of agencies, all suited to the drug trade. This is the reason why one can never call inopportunistly at 25, Lime Street for notes on novelties.—*British and Colonial Druggist*, March 2.

AGRICULTURAL COURTSHIP.

A potato went out on a mash,
 And sought an onion bed;
 "That's pie for me!" observed the squash,
 And all the beets turned red;
 "Go 'way!" the onion, weeping cried,
 "Your lover I cannot be;
 The pumkiu be your lawful bride—
 You cantelope with me."

But onward still the tuber came
 And lay down at her feet;
 "You cauliflower by any name,
 And it will smell as wheat;
 And I, too, am an early rose;
 And you I have come to see;
 So don't turnip your lovely nese
 But spinachat with me."

"I do not carrot all to wed,
 So go, sir, if you please!"
 The modest onion meekly said,
 "And lettuce, pray, have peas!
 Go, think that you have never seen
 Myself, or smelled my sigh;
 Too long a maiden I have been
 For favours in your rye!"

"Ah, spare a cuss!" the tuber prayed,
 "My cherrysed bride you'll be:
 You are the only weeping maid
 That's currant now, with me!"
 And as the wily tuber spoke
 He caught her by surprise,
 And, giuing her an artichoke,
 Devoured her with his eyes.

—Exchange.]

PLANTING AND MINES ALONG THE ZAMBESI AND THE OPHIR OF SCRIPTURE.

Dr. Carl Peters read a paper on March 7th before the *Society of Arts*. We quote as follows:—

Macombe's country is situated in the Portuguese sphere of interest, but up to this time it is practically independent. He gave me the right of starting a store in his country, and I think that this is well worth having, as he is rich in gold, ivory, wax, and india-rubber, and a well-managed store is sure to pay. Altogether I think this part of Africa, from an industrial point of view, must have a future. The advantage of the navigable Zambesi leading to it cannot be valued highly enough. When the Mashonaland railway has been finished as far as Tete, you will soon perceive that as the Zambesi trade turns towards Mashonaland, the trade of Mashonaland will turn towards the Zambesi, and seek an outlet at the Indian ocean. The country of Macombe is well adapted for plantations along the Zambesi. The sugar-cane grows abundantly on the banks of the Zambesi, and I think that fine tobacco may be grown all over the country. At the western side of the country, we discovered a mountain range called Baraouro, which rises up to 4,000 feet, and is well watered. Here tea, cocoa, coffee, and other cultivations may be started, and in this part European settlers will find a healthy climate. The south of the country towards the Purgwe is again a big forest, full of game, an Eldorado for the hunter. I will not here enter on the question whether we have in the Fura district, the real spot of the ancient Ophir, as this question is only indirectly connected with the natural wealth of Macombe's country. I personally have reasons which I will bring forward, that King Solomon's gold expeditions were directed to this part of the world. On the Zambesi Solomon's people could find all the goods, which are mentioned in the Bible as freight of the Ophir ships—gold, ivory, gum-trees, and guinea-fowls, as well as apes. Up to the Fura district was a continual water connection for the Red Sea. Merchants could sail up the river as far as the Lupata Gorge, and it is quite likely that they heard from the natives

at the mouth of the Zambesi of the existence of this alluvial district. The likeness of the names, Fura and Afer, is perhaps not decisive, but still very remarkable. So also is the fact that Fura today has the same meaning in the Makalanga language as Ophir had in the ancient Semitic languages, "hole" or "mine." The existence of ancient Semitic ruins, as well as the survival of the old Semitic religious ideas in the population are also remarkable. What I am inclined to consider a strong evidence in favour of my Ophir theory, is the fact that when the Portuguese arrived in South Africa Arab traders told them that up the Zambesi river was the gold land of Afur, our Fura of today, and this was identical with King Solomon's Ophir. Now the Arabs were the natural dependants of the ancient Sabæan conquistadores, and a continuity of tradition from the ages of their ancestors on this point is not at all surprising. I think critical scholars will agree with me that this is, indeed, a very strong argument. The Chairman Sir Owen Burne said while public attention was entirely centred on South Africa, and the war going on there, Dr. Peters had taken them a trek up north to the Zambesi, and given them a most interesting and instructive paper. He had pointed out in a convincing manner that our modern name of Africa was practically the Latin adjective form of the ancient Semitic word "Ophir" or Afer as it was termed in South Arabia, and had shown that the links between Asia and parts of Equatorial Africa were numerous in ancient times. It seemed also to him (the Chairman) that the few specimens of the Macombe language, as given by Dr. Peters, had a certain resemblance both to Arabic and Hebrew, and this bore out a growing opinion rendered highly probable by the accurate researches of M. D'Anville and Mr. Bruce that the ancient fleets of King Solomon after passing the Straits of Bab-el-Mandeb did not sail on to Ceylon or India, as many had hitherto thought, but held their course along the south-east coast of Africa, as far as the Zambesi and the kingdom of Sofola, whence they drew their rich stores of gold and silver. It seemed to be probable also, as suggested by Dr. Peters, that from these same localities the Queen of Sheba collected those quantities of precious metals and stones which she presented in such abundance to King Solomon. [So the claim of Ceylon to include the Ophir and Tarshish of Scripture is strongly disputed.—Ed T. A.]

RUSSIAN FRUIT.—Mr. P. Stcherbina, horticulturist, of Simpheropol, Crimea, Russia, has sent us some elaborate and beautifully prepared tables, showing the qualities of the best sorts of Cherries, Plums, Apricots, and Peaches, as observed during eighteen years. The first column contains the name of the variety, then come eleven columns showing the degree of hardiness; 2, the vigour of the tree; 3, its fertility; 4, its size; 5, its quality; 6, its firmness; 7, its market value. To each of these an allotted number of points is assigned, and these numbers are added together in a column of totals. In addition the time or season in which the fruit is available its form and colour, are given in separate columns, but these are not numerically assessed. To give one example we may say that Grosse Mignonne Peach has for the column above mentioned 8 points, 8 for vigour, 8 for fertility, 10 for size, 9 for quality, 8 for firmness, 9 for market value (not otherwise determined), forming a total of 60 points; while Early Beatrice gets only 55. Madeleine rouge has the highest number of points, viz., 73. Eighty-three kinds of Cherries are thus tabulated; forty-five Plums, and twenty-five Apricots. Some of the sorts are not known in this country, and that circumstance added to the length of the tablet makes it undesirable for us to publish them as full length.—*Gardeners' Chronicle*.

SUGAR AND WEST INDIAN AGRICULTURE

THE waking up of the West Indian sugar planters is of special interest to us as advocates of further trials locally with the sugar cane, and because it should help to keep before planters in the East—in Ceylon, India, the Straits, &c.—the importance of adopting the most advanced methods of cultivation and manufacture for each of their products. An Indian contemporary writes:—

The reports of the recent Agricultural Conference at Barbados afford some grounds for hoping that the very conservative sugar planters of the British West India Islands are at last beginning to realize that, if they are to keep their heads above water, they must abandon their old-world methods of business, and adopt the advanced scientific principles of the present day. They now recognize that the Bourbon cane, to which they have so long pinned their faith, must give way to the new seedling varieties, which yield much better results. Barbados 147 and Demerara 145, both improved canes, raised from recently-discovered seeds, yield about 3½ tons of sugar per acre, and other seedlings, are nearly as good. Dr. Morris, the Imperial Commissioner, clearly anticipates that by following the example of the European beet-growers, it will be possible, by careful selection, cross fertilization, and so on, largely to increase the saccharine yield.

So great has been the change of feeling on the part of the planters as to central factories that, instead of scouting the idea, as they did formerly, they are now petitioning to have co-operative factories started on the most approved modern systems of perfection in every detail, and if this spirit is maintained and encouraged, we may look forward to the dispersal of the gloom which has so long hung over the islands.

While every endeavour is being made to encourage the staple industry, no opportunity is lost in inducing cultivators to have a second string to their bow, and increased prosperity is expected from the extension of such minor industries as cacao, coffee, fruit, and other things. The latest introduction is indiarubber, Mr. Esme Howard being now engaged in establishing a rubber plantation in Tobago, the first of its kind in the West Indies. Dr. Morris is evidently doing his best to justify the inauguration of the Imperial Agricultural Department less than eighteen months ago!

COFFEE, TEA AND NILGIRI PLANTERS' ASSOCIATION.

The following is taken from the proceedings of a general meeting of this Association held on the 8th instant:—

LADY BIRDS.—The Honorary Secretary gave details under this heading and on his intimating that a limited supply of the Cape Lady Bird was available from Ceylon, several Members present booked the available supply.

PROPOSED TEA CESS.—Read reply from Indian Tea Association to negative the proposition passed by the U. P. A. S. I. at its 1899 meeting at Bangalore, viz., that the Secretary be instructed to write to the Indian Tea Association and press upon that body the great importance of obtaining funds for the American and Continental funds and to request it to approach the Supreme Government with the object of securing an Act, on the same lines as the Ceylon Act IV of 1894.

SEPARATE TARING OF TEA.—Proposed by Mr. Edmiston that as the subject is an important one and as tea interests are so inadequately represented at this Meeting that relative papers be circulated among tea planting members with a request that they communicate their views on the subject to the Honorary Secretary. Seconded by Mr. Scovell and carried.

GOVERNMENT SCIENTISTS FOR TEA.—Says the London correspondent of the *Calcutta Planter*, on March 2nd:—Each day that passes those engaged in practical agriculture show a greater desire to call in the aid of science to help them in their difficulties. Mr. Bamber, who for some time gave counsel to Indian Planters on the chemistry of the tea plant, has now been received with open arms by the Planters in Ceylon. This week another gentleman, Mr. J. B. Carruthers, has also left for Ceylon to give his help as mycologist, against the ravages of Fungi. Not to be left behind, the Indian Tea Association has decided to engage the services of Mr. Mann, an experienced agricultural chemist, who will in the course of this month, proceed to India to take up his duties. He is instructed by the Calcutta Committee to provide himself at the expense of the Association with all the needful requirements of a chemical laboratory. It is arranged that Mr. Mann shall visit the Ceylon tea districts *en route*.

AN OLD PROPRIETARY COLONIST:

MR. W. S. BENNETT RE-VISITING CEYLON AND THE STRAITS:—TEA, LIBERIAN COFFEE, RUBBER AND COCONUTS.

It is encouraging to see a Ceylon colonist who can date back to 1858, looking so fresh and "up to work" (in travelling and inspecting) as does Mr. W. S. Bennett, who, although retired for a good many years to a delightful Buckinghamshire home, continues to retain a proprietary and directorial tea interest in Ceylon, and has added to it an interest in Liberian coffee, coconuts and rubber in the Straits. Mr. Bennett has just returned from a visit thither. He thinks Singapore cooler than Colombo, with more frequent though very partial rains. He was much pleased with planting prospects, though coffee had suffered from ravaging attacks of caterpillars, large gangs of coolies being employed to pick them off. ("If only some hundreds of Ceylon Tamil coolies were available on each plantation." is the cry—and why not, in this year of famine in India—even extending to Madras?) Mr. Bennett is right in considering the Straits a special home for rubber, considering all the indigenous gutta and rubber-yielding trees in that region; and no less true, we told him, is it that in the Straits, we are nearer the original habitat—the great Decandolle considers it to be in Sumatra and the Eastern Archipelago—of the coconut palm than in Ceylon. So, if only abundant labour could be got, the Straits plantations should surely go on and prosper (that is, ahem, if all the Managers read and profit by the *Tropical Agriculturist*!). While travelling on the Perak river, Mr. Bennett had a sharp experience of what a thunder and rain storm can mean in the Straits, reminding him of wild monsoon bursts in his early days in Ceylon.

Mr. Bennett went upcountry to continue the inspection of estates which he began before going to the Straits. Travelling at night some weeks ago in a bullock cart between Awissawella and Ratnapura, after inspecting plumbago lands, he had an experience of what a "chill" in the tropics means, which, no doubt, he would have laughed at, when we first saw him in rude vigorous health as a young Colonist and ever-cheerful Devonian. Mr. Bennett reminded us how the Railway should really have gone up the Kotmalie valley to Pundaluoya and Dimbula with a branch to Dikoya, and that was certainly Mr. Tottenham's route when, in 1872, he offered Government to construct a 3½ feet line from Nawalapitiya to Haputale Pass, and we most cordially backed him up. There is a new private road planned near Oolapane, with a bridge across the river, which we are glad to hear Government is to give—a good bargain for the latter to get a road made by a private Company if the bridge is supplied.—We hope Mr. Bennett's short visit has proved enjoyable, and that he carried home a good report of the old Colony in which he lived and laboured so many years.

SCIENCE AND AGRICULTURE IN CEYLON: THE ENTOMOLOGIST AND MYCOLOGIST ON CIRCUIT.

THE Director of the Royal Botanic Gardens makes, through the Planters' Association, a very important announcement and one that will be welcomed by the planting community as by intelligent agriculturists all over the island. It is to the effect that he intends the new scientific officers on his staff—more especially the Entomologist and Mycologist—should make periodical tours in connection with their work throughout the country, when they can not only observe and collect subjects for investigation, but also confer with planters and others on the spot about local pests of any kind. No better mode of operations for a portion of their time could possibly be devised, and we feel sure that the various District Planting Committees will co-operate to the utmost of their power in studying the convenience, and extending all possible aid to their visitors. The first tour announced is one for Mr. E. E. Green as Entomologist to Batticaloa, the great rice and palm growing district of the East coast, where he is due on April 15th. Such a journey should be fruitful in much interesting information and finally in practical results of value to both classes of cultivators. Travelling by land, Mr. Green will pass through the Badulla and Passara districts and he proposes to visit and deal with each, as far as he may be able, either on his outward or homeward journey. Perhaps as the notice is so short this time, the latter would be preferable, in enabling the District Committees to consider the "situation" and make all needful arrangements so as to reap the full benefit of the Entomologist's visit.

COFFEE AND THE CURRENCY.

To the Editor "Madras Mail."

SIR,—Two days ago I visited, with the proprietor, an estate near this which I went over with him in 1865, and found that it looks better now than it did then. The coffee, indeed, is so flourishing that, though an old property, I should say that it will last as long as the world chooses to drink coffee. Another estate that I went over is in an equally thriving condition. In Mysore I know on the best authority that well managed estates never looked better, or more promising for the future. And yet, with these facts which ought to attract capital to the industry, we find that advances are being refused, mortgages foreclosed, and the surest sign of all of decadence, that wages have been reduced from the North of Mysore down to the Shevaroy Hills, and on the Nilgiris also. All of this, of course, indicates that the saleable value of estates has declined, and in the opinion of capitalists may still further decline should, as seems very probable, the wants of the Government induce it still further to force up the exchange. I need hardly add that with a decline in saleable value, and the possibility of a still further decline, the capitalist buttons up his pockets as regards loans on the security of plantations, and hastens to try and recover the money he has already sunk in mortgages.* * *

R BERT H. ELLIOT,

Coonoor, 25th, March.

THE PANAWAL TEA COMPANY, LIMITED.

The following is from the report of the directors to be presented to the shareholders at the eighth annual ordinary general meeting, to be held on Tuesday, the 27th inst. :-

The directors beg to submit the general balance sheet and profit and loss account for the year ending December 31, 1899, duly audited. The net amount at credit of profit and loss account, including balance brought forward at December 31, 1898, after providing for general expenses, directors and auditors' fees £ 3,210 6s 8d: dividends on the seven per cent cumulative preference shares were paid for 1899 in full, amounting to £371; an interim dividend of 2 per cent on the ordinary shares was paid on Sept. 15, 1899, amounting to £340, it is proposed to pay a final dividend of eight per cent on the ordinary shares for the year ending December 31, 1899, making a distribution for the year of 10 per cent free of income tax, which will absorb £1,360, to increase the reserve funds to a total of £1,000 by the addition of a sum of £508 14s 6d, to write down the estates purchased account by the sum £487 10s 5d and to write the cost of coolie advances down by £133 6s 8d leaving a balance to be carried forward to next season of £9 15s 1d. The directors recommend the distribution of a final dividend at the rate of eight per cent on the ordinary shares of the company for the year ending Dec. 31, 1899, making with the interim dividend paid to June 30, a distribution at the rate of 10 per cent for the year. No alteration has taken place during the last twelve months in the acreage of the company's properties, which stands at: tea in full bearing on December 31 last, 590 acres; jungle, on December 31st last 341½ acres. The directors consider that the shareholders have every reason to be satisfied with the result of the year's working. The crop realised for 1899 was 334,922, as against an estimate of 315,000. The yield in 1898 was 293,933. The visiting agent reported the properties as being in every way in excellent order at the date of his last inspection.—*H and C Mail*, March 16.

CACAO SUPPLY AND CONSUMPTION.

"WANTED: MORE CACAO."

Such is the heading put to a review of the cacao market by Mr. H. Hamel Smith, whose weekly reports must of late have attracted the attention of our cacao planters. We give prominence to the remarks and statistics furnished to show that the demand for cacao exceeds the supply :-

"The striking proofs which meet the eye on every side, of the steadily increasing popularity of cocoa and chocolate, either as a beverage, a highly nourishing food, or a sweetmeat, ought to encourage everyone interested in the planting of the raw article to push on and increase the area under cultivation as much as possible in order to avoid any chance of the demand exceeding the supply; for should it do so the result would be serious to producers and manufacturers alike, as it would force the price above the "margin of profit" limit, causing the makers to have to choose between losing money on their output, which they will not do, even if the scarcity was only temporary; or the very undesirable alternative of raising their list prices, which would not only check the consumption immediately, but would disorganise the trade for a very long time, as it is most difficult to get the public to agree to pay a rise in the price of an article which they have been in the habit of buying at a fixed price ever since its introduction; they do not quarrel if the

price is reduced by a cutting shopkeeper, but rather than agree to a rise, the general public do without the article, and the ground gained after years of fighting our way into public favour, by means of expensive advertisements and costly machinery would be speedily lost. And yet, unless more energetic steps are taken to increase the supply than is now being done one can see by the figures given below, unmistakable signs of the demand outgrowing the supply in a few years.

"The continental manufacturers, we are told are realising the true state of affairs much quicker than their English confreres, whose one dread seems centred in the fear that the spot price may go higher than they wish. As the increase both in the deliveries and consumption has been maintained, the three years given below will be sufficient guide to go by, and so prevent the reader being bothered with unnecessary figures :

The increase in the supply is :-

	1894.	1898.	1899.
	lb.	lb.	lb.
Guayaquil	38,951,000	42,172,000	50,441,800
Trinidad	20,961,200	24,568,700	24,808,000
Ceylon	2,156,000	4,319,700	4,786,880
Grenada	9,463,200	9,062,500	8,915,200
St. Thomé (African)	12,865,700	10,564,600	30,455,040

Showing an increase in 1898 of 17 per cent, and in 1899 of 39 per cent. over 1894.

The increase in the consumption is as follows :-

	1894.	1898.	1899.
	lb.	lb.	lb.
United King dom	22,411,000	32,087,084	34,013,812
Germany	17,227,100	32,351,100	37,255,300
Holland	19,896,300	29,086,900	28,923,600
France	30,112,300	35,135,900	35,383,400
Spain	1,166,800	9,592,300	12,467,500
Italy	471,700	690,400	778,200
U. S. A.	15,940,500	21,095,700	35,260,000

107,255,700 160,049,384 184,081,812
Showing an increase in 1898 of 50 per cent, and in 1899 of 64 per cent. over 1894.

Although it is true the above are neither all the producing nor consuming countries, they are by far the most important ones, and can be taken as a sound basis on which to form calculations, and to show that even if the consumption does not increase during the next five or six years, it would take all that time for the supply to come up to the same proportion of increase. But the consumption is not going to stop growing; for instance, Russia, although I believe, its consumption is increasing rapidly is almost a non-cocoa country, but when she takes to cocoa for her army as England and Germany are doing, and which Russia with its cold climate will do also before long, that alone will increase the consumption some millions of pounds; but putting the world's increase on a moderate basis, say 10 per cent per annum, during the next six years; if the present supply and demand of the whole world is two-hundred-and-fifty million pounds per annum (there is no doubt they are almost equal now, and as the seven countries mentioned account for 184 millions, and we have Russia, Austria, Portugal, Belgium, and the rest of Europe, as well as

all the cocoa producing countries which consume their own growths, I do not think another 66 million pounds too high an estimate) in six years, the supply would be adding the same increase (40 per cent) that has taken place since 1894, amount to 350 million pounds a year; whilst the consumption at a yearly increase of 10 per cent for six years, making 60 per cent in all, would amount to 400 million pounds; and as far as can be judged at present it is the consumption rather than the supply, that is the most likely to keep on steadily increasing during this period, so that about 1,907 there will be a deficit of about 50 million pounds or 280,000 bags, which would take at least 100,000 acres of land to produce.

At present, thanks to the large stocks that had been accumulating since 1895-1896, the sudden spurt in the demand has been able to satisfy itself, but this will not be the case in the future, as at present we are not only reducing the stocks, but are eating up the new crops as fast as they arrive. When Guayaquil and St. Thomé poured their bumper crops last year into the European markets, a tremendous fall in prices was prophesied, instead of which they were bought up greedily, and at the beginning of the year prices were higher than ever, and will be so again as soon as the first pressure to sell is over. If this year, and 1901 are large crop years (to honour the old fable of three fat years and one lean one) after that there is every sign of a much larger supply being needed by the manufacturers if the present demand for chocolate by the million is to be maintained. Meanwhile here are the figures comparing the present stocks for the past five years, by which it will be seen that in spite of the 21 million pounds extra, which the five producing countries mentioned gave last year over 1898, the present stock shows we have reduced the recent accumulations by 110,000 bags = another 20 million pounds, so that I am not far wrong in estimating the shortage in the next six years at about 50 million pounds unless the present rate of increase in the supply is considerably enlarged:—

	1900.	1899.	1898.	1897.	1896.
Stock—	Bags.	Bags.	Bags.	Bags.	Bags.
London	77,820	91,038	121,044	140,995	151,323
Liverpool	2,445	3,384	954	3,631	6,469
Havre	80,031	77,657	60,326	123,135	112,553
	160,296	172,079	180,324	267,761	270,345

ROYAL BOTANIC GARDENS.

With this issue of the *Tropical Agriculturist* we include in a *Supplement* the greater portion of Mr. Willis's Administration Report for 1899. There is no special novelty about it, save the first appearance of a subsidiary Report from the Entomologist; but there is a great deal of useful information under a variety of heads and signs of progress in a variety of directions. The Curator furnishes a good deal of interest respecting the Peradeniya Gardens (telling us, among other things, that the Experimental Plots now represent thirty different tropical products) just as Mr. Nock does regarding the Hakgala

Gardens where, however, besides drought, such enemies as hares, moosedeer, rats and porcupine are troublesome: while a small herd of elephants put in an appearance within 50 yards of the Superintendent's bungalow in June last! The laying out of the ground near the new Picnic Arbour is one of the great improvements of the year; and the young camphor trees are reported to be growing vigorously. As usual Mr. Willis has a good deal to say on our staple products and the closing paragraph on tea is so significant that we must quote:—

The planting community is now well acquainted with their appearance and with the ways of treating them (the tea blights.) There is thus every ground for hope that the industry will never suffer from blight in the way that coffee did, as the danger is much more likely to be recognized and taken in time by preventive measures. A "scientific" era is now beginning for this industry, and success will be to those who most intelligently apply to practice the improved methods of cultivation, manufacture, prevention of disease, &c., just as is the case with other long-established cultivation industries.

This must be reassuring; but we do not suppose that Mr. Willis quite means that had "a scientific era" been inaugurated during the early "seventies", it would have saved "coffee"? We have the fact that Dr. Thwaites, F.R.S., the then highest living authority as regards fungi, declared that he knew of no remedy for *hemileia vastatrix* in its attacks on coffee from the first day he saw it and his judgment was borne out by all after-experience under Dr. Trimen, Dr. Morris and Professor Marshall Ward. The drawing is to be allowed. Already, those engaged in the latter calling are protesting against the rule which compels them to take out a license—nominally free, but which they cannot easily obtain without sundry Santosums to subordinate Government servants. They are not likely to be pleased with the further proposed curtailment of their rights in regard to the enjoyment of their own property, by the refusal to allow sweet toddy to be drawn at all, in areas in which trees are taxed for fermented toddy. In South Capara, Tinnevely and Madras City, the Abkari Commissioner, while separating the two industries, has given instructions that jaggery manufacturers be allowed to commence work before their trees are marked and registered, and also be given longer hours than hitherto for plying their calling. Even these concessions have failed to satisfy Tinnevely, where there is a great jaggery industry, and which has set on foot an agitation for the removal of all rules and restrictions which harass an untaxed trade through blackmailers. Bombay has solved the difficulty by holding all palm juice to be fermented liquor, and taxing every coconut tree that is tapped, in some places as high as R12! How would that work-out for Ceylon, with its 300,000 coconut trees tapped for toddy? It would yield R3,600,000, plus the income from licenses for taverns for the sale of arrack! But it is the illicit trade in toddy we are dealing with now, and which we should like to see checked by a system of taxation which will leave the jaggery industry free, and that can best

be done by ensuring the free licensing of sweet toddy trees under efficient and trustworthy Inspectors, whose remuneration can easily be found from the new and necessary tax, and whose employment will be amply compensated by the suppression of the illicit trade and all the evils which follow in its train. The relative value of the two industries in Madras is shown by the fact that the annual toddy revenue of the district is over two lakhs of rupees, and the annual value of the purchases of jaggery by a single Madras firm in the district is over 15 lakhs! Absolutely no information is available in Ceylon on these points. Verily they manage these things much better in India, notwithstanding its immense area!

CEYLON TEA IN 1889 AND PROSPECTS.

A recent mail has brought us the annual report of Messrs. Geo. White & Co. on "Indian, Ceylon and Java tea." Writing of Ceylon tea, this Firm says:—"On the whole, prospects seem favourable to expansion in the sale of good liquoring descriptions, while that for very common may be partially abandoned, and the prevailing lowest retail price be 1s 4d per lb. If the purveyors to the public can induce their customers to purchase a slightly better blend than they have lately perhaps been accustomed to, they would not only benefit themselves, but also help to raise the whole Trade to a higher level than it has been on for some time."

It is interesting to note how the annual averages for the different divisions of Ceylon—as always specified in Messrs. Geo. White & Co.'s Reports—vary. Thus for,—

- Udapussellawa, Nuwara Eliya, New Galway, Dimbula and Lindula, the average runs:—1897 = 9³/_d; 1898 = 9³/_d; 1899 = 9³/_d.
- Maskeliya, Dikoya and Bogawantalawa:—1897 = 8³/_d; 1898 = 8³/_d; 1899 = 8³/_d.
- Lower Dikoya, Ambagamuwa, Kotmale, Yakdessa, and Dolosbage, it runs:—7¹/₂; 7; 7³/₈.
- Pussellawa, Ramboda, &c.—7¹/₂; 7³/₈; 7³/₈.
- Hantane, Hewaheta, Maturata, Rangala, &c.—7¹/₂; 7¹/₂; 7³/₈.
- Kelebokka, Knuckles, Hunasgeriya.—6³/₈; 7; 7³/₈.
- Matale.—6³/₈; 6³/₈; 7³/₈.
- Kurunegala, &c.—5³/₈; 6³/₈; 6³/₈.
- Kelani Valley, &c.—6³/₈; 6³/₈; 7.
- Ratnapura, Rakwana, &c.—7; 6³/₈; 7³/₈.
- Kalutara.—6³/₈; 6³/₈; 7³/₈.
- Udagama and Morawak Korale.—7¹/₂; 7¹/₂; 7³/_d.
- Haputale and all Uva.—8³/_d; 8³/_d; 8³/_d.
- General Average for all = 8d; 7³/_d; and 8d.

MOSQUITOS AND MALARIA.

A SCHOOL OF TROPICAL MEDICINE.

In the absence of Lord Loch, Sir Henry J. Jourdain presided last night at a meeting of the Royal Colonial Institute, held at the Whitehall Rooms, Hotel Metropole, when a paper was read by Dr. Manson, medical adviser to the Colonial Office, on "A School of Tropical Medicine." Among those present were Lady Gort, Sir Cecil Clementi Smith, Sir Henry Norman, Sir William Robinson, Sir C G Walpole, Sir J Goldney, the President of the Royal College of Physicians, and Mr. J O'Halloran (Secretary).

TROPICAL DISEASES.

After some prefatory remarks on the specialisation and division of diseases, Dr. Manson proceeded

to draw attention to certain forms of tropical disease, indicating their importance, showing the necessity for a special system of study to be applied to them, and pointing out how such a system could be best carried out. Dividing tropical diseases into the two classes, endemic and epidemic, Dr. Manson placed malaria first in importance under the former. It was, he maintained, the great disease of the tropics, the principal cause of sickness and death and of social stagnation. Malaria was the true reason why Africa was called the Dark Continent; and five millions died annually of fever, mainly malaria, in British India; while one-third of our soldiers in that country, European and native, suffered annually from that disease. The unhealthy, that is to say malarious, character of West Africa more than doubled the cost of government, and the death-rate there was 85.2 per 1,000. In fact, what with death and invaliding and leave of absence, two men were required to do the work of one, and to induce them to accept the employment double pay had to be offered.

PROPAGATION OF MALARIA.

The question was how could the cloud of malaria ever floating over such districts be dispelled. It was a common and misleading fallacy that disease was caused by climate: it was really caused by beasts and plants which were subject to man's dominion. The first thing was to discover the disease germ, and Dr. Manson proceeded to consider the underlying principles which govern the distribution, the propagation, the acquisition and the suppression of the malarial germ, adding that those principles would equally apply to nearly all tropical diseases. The germ of malaria lived in the human blood, it could be easily discovered there when present, and transferred by the needle of a hypodermic syringe into the veins of a healthy subject, who in a few days would develop malarial fever. This could be done in any country or climate by such artificial means, but Nature's needle and syringe was the mosquito. This was the reason why malaria was only acquired under natural conditions where and when the mosquito was to be found. The geographical distribution of malaria was therefore determined by the geographical distribution of the mosquito. Fortunately there was only a limited number of the hundred species of mosquito that propagated the malarial germ and until an insect had partaken of the blood of a germ-laden subject its bite would not be dangerous.—*Morning Herald*.

TEA DISEASES.—We have already given Mr. Collett's paper on this subject and intimated that we thought he deserved well of his brother planters for the same. We learn that while Mr. Collett does not at all presume to pose as an authority on plant diseases—although he has paid attention to the subject for a number of years—yet he thought it as well to commence thus early in the 'season' to agitate upon this question: (1) because many planters are as yet unable to identify the principal tea-diseases when they see them; and (2) because it occurred to him that an exposition of what is known of grey and brown blights, etc., up to the present time, might prevent much of the anxiety likely to follow the outbreaks of disease in July-August, which, he fears, are inevitable.

THE COCONUT PALM AND FERTILIZERS.

Following on Mr. Cochran's valuable exposition of the chemistry of the coconut, (see page 764) we have the needful commentary and illustrations on the said scientific paper, which only a practical planter can supply. "W.J." is well-known as an authority on the culture of the palm, second to none in the length and variety of his experience. On the whole, he is not only cordially appreciative of the value of the analyses supplied by Mr. Cochran; but his recommendations are to a great extent in correspondence, though he shows good reasons for pursuing an original course in the application of his fertilizers. This plan of application is just what an experienced planter might be expected to devise after, probably, a long course of experimental cultivation. We commend Mr. Jardine's counsel to the careful consideration of young coconut planters, of whom there are a good many now-a-days in different parts of the island. It has long ago been accepted as an axiom that no plant is so greedy of manure, or so responsive in profitable crops, as the coconut palm. One old veteran cultivator has been accustomed to say that for every rupee sunk in manure in a coconut garden, a return of from five to ten rupees may fairly be anticipated; while in our Manual, figures will be found recorded, showing how a proprietor raised the nett annual return from his garden to R130 an acre through judicious manuring. But here comes in the heresy of our friend "W.J.": he doubts the value of applying salt to the coconut palm!—and bases his argument on the fact that trees 50 or 60 miles inland yield as good crops as do palms by the seashore, where, of course, salt is more freely available in the soil and atmosphere. All we can say is that if trees in the interior do so well, they ought to do even better, after a judicious application of salt! But, of course, "W.J." is speaking from ordinary observation and not as the result of a definite experiment, taking gardens of about the same age, soil and planting—the one near the sea and the other say in Kurunegala district? Of course, if the rainfall in the interior is as rich in "salt" as Mr. Kelway-Bamber shows the Colombo rainfall to be, there is no more to be said. But it should be remembered that "common salt" (sodium chloride) is most useful in other respects besides that of being a direct fertilizer. It increases, for instance, the power of certain soils to absorb moisture from the atmosphere. What could be a more useful property than this in some parts of the interior? Scientifically, the fertilizing properties of salt when applied to land are thus given:—

- 1st.—It promotes decomposition of animal and vegetable substances in all cultivated soils.
- 2nd.—It destroys vermin, kills weeds, &c., which are thus converted into manure.
- 3rd.—It is a direct constituent or food of some plants.
- 4th.—It acts on vegetable substances as a stimulant.—Dr. Priestly proved this by various interesting experiments shewing that while an overdose of salt killed plants, a limited application in water kept them alive longer than those treated with water alone, A solution of chlorine in

water will make certain seeds vegetate which would otherwise rot in the earth.

5th.—Salt preserves vegetables from injury by sudden transitions in the temperature of the atmosphere.

6th (and most important).—Salt renders earth more capable of absorbing the moisture of the atmosphere, a property of the first importance, since those soils which absorb the greatest proportion of moisture, are always the most valuable to the cultivator. "It affords" (said Davy, Agric. Chem. p. 184) "one method of judging of the productiveness of land." The absorbent powers of common salt applied to land, are shewn by a table of experiments to be greater than those of six other well known manures. And now we come to "W.J.'s" closing challenge as to any coconut estate in the island in good cultivation yielding crop at the rate of 90 nuts per tree per annum over any considerable extent? We are not prepared to point to any such plantation; but after all that has been said of the wonderful effect of manure on the palm, it is very strange that there are no such model plantations available. Here, for instance, is what Mr. W. B. Lamont wrote on this part of the subject in December 1897:—

WHAT MAY BE EXPECTED OF PROPER TREATMENT.—The whole system consists of the regular tillage of the soil, and the periodical application of a fixed amount of suitable manure. There is no increase of crop in the first year of applying manure; but there is a considerable increase in the second, and a still greater one in the third; but in the fourth there will be a falling-off from the crop of the third year. To renew the operation of digging and manuring every second year, will therefore not only maintain the highest yield reached, but increase it year by year without any practical limit. It is well-known that individual coconut trees of good jat, that have happened to grow on a spot of naturally rich soil, habitually yield from 300 to 400 nuts per annum without any cultivation. It is then an extravagant idea that a field yielding from two to three thousand nuts per acre, with little or no cultivation, may with scientific treatment be made to yield double those numbers in a few years. Surely it is time some practical man in our midst, with a young garden, gave a thorough test to the statement that there is no limit (in reason) to the crop of coconuts, which judicious cultivation and liberal manuring may be expected to produce.

RUBBER ESTATES OF PARA, LIMITED.

WHY CRUDE RUBBER REMAINS HIGH.

The reports submitted at the second ordinary general meeting of the Rubber Estates of Para, Ltd., held in London on December 22, were far from satisfactory to the shareholders. They contain some points however, which may be of general interest as helping to show why Para rubber is high in price. The company employ rubber collectors, each of whom works two *estradas* (roads) of about 100 trees each. The company charge each collector a yearly rental per *estrada* of 25 kilograms (equal to 55 pounds) of rubber, regarded as equivalent at this time to £7 6s. The remaining rubber collected is bought by the company at a price which on the average is 7d per pound below the price in the Para market. There are thus two sources of income to the company against which they must pay the expenses of sending the collectors from their homes to the rubber fields and supplying them with working equipment. There is a further source of profit to the company in selling to the collectors all the food and other supplies needed by them and their families, for which purpose stores are maintained on the estates. But the company are far from realizing as net profit, the total selling

value of the rubber which they have to dispose of in the Para market. The expenses at Para have been large, and the cost of management at the London end has also been so heavy that retrenchment in the latter respect has already been agreed upon.

The statement made to the shareholders in April last as to the number of collectors at work was by no means fulfilled. It was based upon estimates made by the manager on the estate, who said at that time there were at least 650 men working, but that figure was subsequently reduced to 450, afterwards to 323 and finally to 290. Then it was estimated that it would require £12,000 to equip these 650 workers, whereas £23,000 was actually spent in equipping the smaller number. This sum is partially offset by the stores on hand at the end of the season ending June 30. The report was adopted, subject to an investigation by a committee of shareholders.

The estate referred to, on the island of Marajo, consisting of 284 square miles, was purchased in 1893 from the Visconde Sao Domingos who was reported to have derived from it as much as 250 tons of rubber per year. On account of delays in making the transfer, the company were unable to collect any rubber during the first crop season. During the second season the company received 58 tons (equal to 255.390 pounds) as a result of using up £23,000 of their working capital. Naturally there have been no dividends on the company's £350,000 in shares.

The *India Rubber World* has obtained some points from Mr. Henry A. Cowles who for some time past has been in charge of a rubber estate in Peru, owned by New York capitalists. The company pay for rubber collected on their own lands about 35 *soles* per *arroba* of 33 pounds, or in the neighborhood of 50 cents per pound. The rubber is sold in the Iquitos market at a certain advance, after which it passes, as a rule through several hands before reaching the manufacturer. There is no such thing as paying wages to the collectors; they keep closely informed as to the prices ruling in Iquitos, and with every advance in the market they demand a higher price. On account of the great scarcity of laborers throughout the Amazonian rubber districts, they are able practically to make their own terms. The company make a certain profit on the supplies furnished to the collectors, but the prices which can be charged is limited by prices in the Iquitos market, with which the rubber workers also keep well acquainted. The laborers are always in debt to the company, and the death or desertion of one of their number means a clear loss to the company. In answer to a question as who has profited by the rise in rubber which has been steady since the middle of 1895, Mr. Cowles says that the greater part of the advance has gone to the rubber collectors. Moreover, there is no hope of a lower scale of payment for their work for the reason that, having become accustomed to high wages, it will be difficult in future to get the men to go into the forest for less money. Good profits have also been made by the traders who explore every part of the rubber country, buying rubber in small lots for all kinds of goods, and selling the rubber collected to the exporting houses along the Amazon. Mr. Cowles is of the opinion, however, that manufacturers might profit by buying rubber nearer the sources of supply than is now the rule. He mentioned the case of one New York manufacturer who, within a year, has arranged for the purchase of rubber for direct shipment from Manaos, with very satisfactory results. He is convinced that the greater part of the Amazonian rubber resources have not yet been touched, but as new districts are gone into the labor supply becomes worse rather than better, with the result of pointing to higher costs of collection.—*India Rubber World*, March 1.

A FARMER'S EVERYDAY LIFE.

No. III.

(By *Cosmopolite*.)

March came not in like the proverbial lion, but like Mary's little pet lamb, and it has continued to provide us with quiet, mild and

summer-like days, which materially help farmers to overtake the work that fell into arrears during the snowstorm of February. The ploughs are rapidly turning over the soil and the appearance of March dust—a peck of which is said to be worth a king's ransom—gives indication of an early sowing season.

The microbe of influenza has taken its departure from our midst, and the late sufferers from this dire disease have begun to prance around on their bicycles, thereby laying the seeds of *Kyphosis bicyclistarium*, which is, I understand, the scientific term of bicycle rider's stoop. In a late number of the *Tropical Agriculturist*, I read an article to the effect that *Eucalyptus Globulus* is a preventative against influenza, but, although I have a healthy plant of some 8 feet in height, in my own special study, it yet failed to keep me in a state of immunity from the plague; indeed, on the contrary, I think, I had a more severe attack this year than ever I had before, and so another of our cherished beliefs in the beneficial influence of the Blue Gum is thus ruthlessly destroyed.

It is not every couple who can expect to live to see the

SPIRITS AND BEER

has been announced by the Chancellor of the Exchequer, in his budget speech, has filled with consternation, the drinking men of our Parish—and I regret to say their name is legion. Strong efforts have been made during the past two years to convert the "druuks" of our village to the paths of sobriety, but with very indifferent results. Let us hope that the extra duty on spirits may prove more successful. I was told that one of the most capable drinkers of our community had declared his intention of giving up the habit rather than pay the extra duty, and this augurs well, for he was about the last man that I would have expected it of. He speaks with a Scotch accent, so broad that one could cut it with a spade, and drinks whisky and water strong enough to float a marlinespike; but when I asked a neighbour if it was true that this dissipated member of society had given up spirits entirely, he replied:—"Well, I would not exactly say that, although it is quite true that he does not drink whisky since he took the pledge: he only soaks his bread in it." After that I am inclined to think his conversion to teetotalism will take place—as the bumper coffee crop of Ceylon was always expected—next year—"naleki"!

I am surprised to find that so many of my neighbours are shareholders in wild-cat

AFRICAN MINING SCHEMES.

Hardly a day passes without my getting prospectuses of companies to be floated in Westralia, Africa, South America or some other outlandish place; but these prospectuses quickly find their way to the back of the fire. My astonishment therefore was great when I learned that the reason why so many residents in this parish are taking a lively interest in the war in Africa is because of the shares they own in the mines of Johannesburg, etc. Faith, after all, is the lever that moves the world. The German-Jewish miner of Africa in his lonely but knows this full well, and so he digs a hole and sends up specimens, and then, like

the sterling fellow he is, he lets the public into the good thing—"there's millions in it"—and the shares are snapped up by all and sundry, even to the farmers of this remote corner of Scotland and scrip is in every man's pocket. Then comes the calls, even to the hundred and tenth, and the shareholders file up to the bankruptcy court, and there is an end of it. Ah! how many promising affairs such as these have turned out like the baseless fabric of a dream and left but the scrip behind. In this age the terrible desire to get on has become general. Poverty is dreaded, riches are worshipped, so that farmers even have taken to dabbling in shares and other speculative transactions, because they know too well that fortunes are rarely made at their own legitimate profession. I do not know that large fortunes have ever been made in farming; if they have, the process must have been slow and gradual. Unfortunately, it only happens about once in seven years that a good season is accompanied by good prices for farming produce, but that year gives the farmer a good lift to tide over the two or three middling years and, at least, one pretty bad one which generally follows, so that the utmost benefit a farmer derives from a fat year is that he can hold his own against the lean years which follow. But the pleasure of a farmer's life weighs against these untoward circumstances, and it is comforting to know that money made by legitimate farming, must be made honestly and no one is deceived or loses by his neighbour's success: whereas in commercial dealings, one man's gain is another man's loss. There is an old saying:—"Shoemaker, stick to your last," and I would recommend my brother farmers to stick to the slow process of accumulating wealth by farming, and not attempt to gain a rapid fortune by dabbling in shares. I know the game well, and saw plenty of it in Australia; so the prospectuses which I receive daily, by the post, go to the back of the grate in my house.

CEYLON TEA PLANTATION COMPANIES:

WONDERFUL RESULTS FROM LIBERAL CULTIVATION IN THE BASE OF THE PITAKANDE COMPANY.

Elsewhere we give the Reports of three local Plantation Companies; but two of them, we may briefly dismiss, remarking that we trust there are better days very near at hand for the Agra Tea Company with its fine property when a much more satisfactory dividend will be declared. The case is very different with the Drayton Company, which pays a magnificent 15 per cent and holds a very strong position with its fine compact Dimbula estates,—estates too, that can scarcely be said to have lost much of their pristine vigour during the coffee era. But now we come to a very different group of properties, in those appertaining to the Pitakande Company, (which also pays

its shareholders 15 per cent); for, the Pitakande and Damboolagalla estates must have been first planted in coffee by Mr. R. B. Tytler not later than 1844-42; while Sylvakande and Kinrara are also among our very oldest coffee plantations. In 1878, for instance, when coffee had reached its maximum, this group of Matale estates is returned in our Directory for almost exactly the same acreage of coffee as is now under tea. Here is how the group stood in 1878:—

Pitakande	...	300	acres	coffee	up to 37	years	old.
Damboolagalla	...	300	"	"	"	"	"
Sylvakande	...	338	"	"	34	"	"
Kinrara	...	203	"	"	"	"	"

Total 1,141 acres coffee.

And the Pitakande report gives 1,144 acres of tea on land, which has nearly all been in continuous cultivation from 50 to 60 years! It is, of course, when we take the results in crop that surprise and satisfaction may be felt; for, Mr. Fraser has brought his average yield up to 728 lb. per acre, with a maximum of 1,025 lb. Surely no such result has ever been achieved before on land so long in cultivation and it is all due to judicious manuring, the effect of which Mr. Fraser demonstrates to be cumulative. When tea is turned out at a cost of less than 23 cents per lb., or without manuring at 18.40 cents, while the nett return is over 36 cents, we need not speak of success—it is self-evident; and verily the working of the Pitakande Company affords an object lesson of a very attractive character to all tea cultivators; for, apart from the age of the estates, it must be remembered that the elevation—1,500 to 3,000 feet above sea-level—of the properties does not justify any expectation of more than ordinary teas.

THE USES OF TEA SEED OIL.—Tea seed oil is regularly used in Hongkong and the Southern parts of China as an illuminating oil. It will not, however, burn in a cold climate. We have in former issues, says the *Indian Planters' Gazette*, pointed out the many uses to which tea seed oil may be put. When tea seed becomes a veritable drug in the market,—and the day does not appear so very far distant,—planters may turn their attention to expressing the oil, and find a profitable market by so doing. We are aware that one or two planters tried experiments with tea seed oil, but they were on such a small scale that for commercial purposes they were valueless, and afforded no criterion to go by. An old skipper who has had considerable experience in the China seas, informs us that in the China trade, tea seed oil was looked upon as the best vegetable oil for preserving wood, owing to its possessing great penetrating power on dry wood; and that if it is put on fairly thick on the underwater side of a ship's wooden deck exposed to the hot sun, it comes to the surface in a few hours and materially adds to the hardness of the deck and to its life. The penetrating properties of tea seed oil on wood are superior to the ordinary bright varnish or pine oil in common use for preserving wood in Europe, and, like coconut oil, it possesses the peculiar property of shrinkage.

PLANTING NOTES.

SWEET POTATOES.—Here is what a Jamaica planter has to say regarding his method of treating vines of sweet potatoes:—"Cut in pieces the right length to plant (about 15 inches long) and pile them in a house or some other shade where they are entirely concealed from the sun, and wet them with water and let them lie in a pile until little roots put out, which will take a day or two; then stick them out in well prepared moist ground or in dry ground and water them, and you will hardly lose a plant. Stick them down with a small stick and if you water them do not fill the hole."—*Journal of the Jamaica Agricultural Society.*

CURING OF LIBERIAN COFFEE.—One of the drawbacks to the use of Liberian Coffee has been a strong unpleasant taste, and various remedies have been suggested. According to the *North Borneo Herald* it has now been successfully overcome on the Borneo Coffee Co's estate in Marudu Bay by washing the coffee after pulping and before fermenting. The washed coffee is in this way cleaned from all the minute bits of pulp which doubtless imparted an unpleasant taste and before being placed in the fermenting cistern it is thrown into large baskets—"coal baskets"—for a few minutes to allow the surplus water to drain off and is then fermented in a comparatively dry state. To increase the heat sacks are placed on the top of the coffee and after some hours the top layer is turned in below so as to ferment the parcel equally. The "tip" may be worth something, but we are somewhat inclined to lower our estimate of its value after reading our contemporary's further remarks, viz.:—"Liberian coffee, properly cured, has a splendid flavour which is well known by the trade who value it highly owing to the amount of chicory it can assimilate. As an after dinner coffee nothing comes up to pure Liberian coffee if properly cured."—*Planting Opinion*, March 31.

THE SUPPLY OF RUBBER.—An American who, for some time, has had charge of a rubber estate in Peru, from which the profits are small because of the difficulty about labour, is convinced that a great part of the Amazonian rubber resources have not yet been touched; but as new districts are gone into, the labour supply becomes worse, increasing the cost of collection.—Mr. C. D. Scott, of Nicaragua, reports rubber culture a failure in Central America; but we see it stated that the American Government is planning a series of experiments in Cuba, Porto Rico and the Philippines to demonstrate whether rubber can be produced in these islands. As the United States imports of rubber have increased as follows:—

Year.	Pounds.	Import Value.	Average Price.
1897	42,159,129	\$21,670,019	51.4 cents.
1898	44,236,070	25,937,108	58.6 "
1899	54,408,495	34,219,019	62.9 "

It can be judged how important is the trade in the Far West.—Just as we are writing, there reaches us from a Colombo merchant, an order for several of our "rubber manuals" for use in Central Africa and the Manager of the Company concerned adds below his order:—

British Central Africa exports a very good quality of rubber at present, but in a year or so the supply will be exhausted, unless steps are taken to plant up; for at present it is only growing wild and the natives usually exterminate the vines in collecting the rubber."

COFFEE HULLING: DUTCH EAST INDIES.—A French Official Report from Java says:—"The coffee planter has always been very desirous of finding a huller which, whilst not deteriorating the bean, would at the same time be able to deal with different kinds of coffee. The problem has now been solved by M. Schaap, one of the planters, who has invented a machine which can hull all the kinds of coffee grown in the colony. At the last coffee-planters' congress held at Malany in Oct. 1898, a prize of 2,000 florins was voted for the improvement of Schaap's system which could be made lighter, more economical in motive power, and able to treat at least three piculs per hour. Coffee hullers come generally from England and Germany, but on many plantations this work is still done in a very rudimentary way. The U.S.A. are now introducing machines made by the "Engelberg Huller Co.," of Syracuse, New York. They are giving great satisfaction and will soon become very widely spread."—*Planting Opinion*, March 31.

DR. MORRIS'S SCHEME FOR AN AGRICULTURAL DEPARTMENT—is not to be accepted in Jamaica without criticism and opposition. A Mr. Robert Craig writes very pungently on the matter and we quote as follows:—

A Board of Agriculture of nominated persons giving voluntary services, will not, I feel assured, be the solution. The department ought to have a capable responsible head, and to aid him an advisory Board of practical men representing the different branches of agriculture, and also commerce might be at his service. These men should be paid a fee to ensure regular attendance at meetings. I say this because few men connected with agriculture can today afford the necessary outlay for travelling expenses. The head of the department should be a man really interested in agriculture, with some knowledge of it, and if possible, with a training such as the work of the English Board of Agriculture would furnish. His first duty would be to promote good agriculture in every way—to help on Agricultural education and training—to advise the Government as to measures likely to advance and benefit agriculture—to facilitate the transport and inspection of produce—to assist in the suppression of contagious diseases in animals, and the improvement of their breeds, to collate statistics and generally maintain a bureau of agricultural information open to any one in or out of the Colony. The Agricultural Chemist should belong to his department, and the Public Gardens might be utilized for experimental purposes—whether the head of the Botanical Department should be subordinate is I think very doubtful—my own opinion is that he should not.

Agricultural and Botanical researches are not closely allied, and it has always appeared to me unjust and even absurd to regard, as many persons do, the Island Botanist as a referee in agricultural matters. If the Island cannot afford to maintain a Botanical Department—although that is not my opinion—it would I think be better to abolish it than attempt, as our economy, to amalgamate it with an agricultural bureau. A high degree of science should not in my view be aimed at, while the practice of agriculture remains primitive and so defective.

I am strongly opposed to the domination of the Secretary of State in this matter, and to the inclusion of Jamaica in Dr. Morris's Department of Agriculture for the West Indies. If a grant of money involves either control, it should, in my opinion be refused. It is certain, it would be a mere pittance, and to abandon our freedom of action for a dole would be contemptible.

The result was a special meeting of the Jamaica Agricultural Society on 25th Jan., largely attended, when after a full discussion, a special Committee was appointed to consider the Report recommending an Agricultural Department. Dr. Morris was not present and is not, of course, on the Committee.

RAMIE FIBRE SPINNING SYNDICATE, LIMITED.
—Registered on March 23rd, by Holman, Birdwood and Co., 50, Lime-street, E.C., with a capital of £15,000 in £1 shares. Object, to adopt an agreement with J. F. Woods, and to grow, cultivate, manufacture, and deal in rhea and other fibre. The first directors (to number not less than two nor more than seven) are to be appointed by the subscribers. Qualification, £100. Remuneration, one guinea each per board meeting attended. Registered office: 71-72, King William-street, E.C.—*Financial News*, March 30.

INDIAN TEA: CLOSE OF THE SEASON AND PROSPECTS.—Here is the record from Messrs. Baines & Co. for the three past seasons:—

1897-98	...	147,070,755 lb.
1898-99	...	153,196,217 ,,
1899-1900	...	170,475,965 ,,

The detailed table below shews that, apart from the large increase of shipments to the United Kingdom, there are satisfactory increases in direct returns to America and Australia; but only a slight addition in the case of "foreign Europe." We direct attention to what is said in respect of prospects in the several districts for next crop. Hail-storms have done damage in Assam as well as, we may be sure from our special telegram, in Darjeeling; but there is no reason to suppose there will be an appreciative, if any, falling-off.

THE FUTURE OF COFFEE.—It may be of interest to coffee planters to consider to what extent prospects have improved since this question was first raised, and to try to ascertain what probability there is of the present level of prices being maintained or improved. The actual present price of coffee, says the *Madras Mail*, is a complete refutation of the gloomy forecasts of last year that planters must look forward to a long continuance of the prices then ruling. The following quotations from which exceptionally fine marks of both E India and Costa Rica coffee are excluded, show that the rise has been about 50 per cent for all classes of coffee:—

No. 7 Rio.	Aug. to Oct., 1899	Feb., 1900.
	4 30 to 4 50 cents per lb.	6 70 to 7 30 cents per lb.

Costa Rica } Ordinary to } 28s to 52s p.cwt. Middling } 48s to 71s 6d p.cwt. E India B ... 30s to 50s do. 50s to 74s 0d do.
--

As regards the effect of the recent rise in prices on the Brazil industry, it is to be remembered that nearly all Brazilian planters are heavily handicapped with mortgages incurred during the last four years of low prices. Many planters have been ruined, and it will probably take some time to restore confidence in the industry. After the crisis of 1882-86, which was not nearly so severe in Brazil as the late crisis, it took five years of good prices to restore confidence, so as to increase the planted area; for it was not until 1896-97 that production began to increase materially. As the *American Grocer* recently remarked, it takes four years for coffee to come into bearing, and however low prices may stimulate planting, there must be a period of high prices before production can overtake consumption. In 1899 to 1898, moreover, Brazilian exchange fell rapidly. Now it is rising, and the chances are that it will continue to rise.

THE TOMATO AS A TONIC.—The tomato has a high dietetic value and has been especially recommended for use in cases of blood impoverishment—a suggestion which, perhaps, rests upon the fact that it contains a considerable amount of iron. The presence of iron may easily be detected by applying to the cut surface of a tomato the ordinary re-agent. As a food for supplying iron, the tomato is far superior to any of the combinations of iron as commonly used as a means of enriching the blood. It has long been known that these inorganic compounds cannot enter into the composition of the blood. It is possible, however, that they may sometimes be useful, for, as has recently been suggested, while they do not enter into the composition of the blood, they serve to neutralize acid substances which form insoluble salts with the iron of food, and thus prevent its absorption and assimilation. In other words they act as protectives of the nutritive iron compounds of food. The tomato may serve a similar purpose, and not only by supplying the source of iron, but the introduction of a larger amount than is needed, providing for the conservation of the amount actually required—*Journal of the Jamaica Agricultural Society*.

UNIVERSITY EXTENSION IN AGRICULTURE.—Mr. A. C. True has a paper in the *Forum* dealing with the American University Extension Movement on agricultural lines, at the head of which are the United States Department of Agriculture and the Agricultural Experiment Stations, which are departments of universities and colleges, and largely endowed by national grants of land and money. The American Department of Agriculture distributes 7,000,000 copies of 500 different publications annually. There are now fifty-six agricultural department stations in the United States, all of which publish reports of their own investigations:—

Under the direction of the agricultural experiment stations thousands of simple co-operative experiments in which farmers take part are now annually carried on in different parts of the country. They consist principally in the growing of different kinds of crops, such as wheat, grasses, sugar beets, vegetables, and fruits, or in the testing of different kinds of fertilisers as applied to the soils and crops in different localities. These experiments are performed in accordance with plans furnished by the experiment stations; and when they are conducted in the most effective way the co-operating farmers are visited, from time to time, by the officers in immediate charge of the experiments. Usually the experiment stations furnish the seeds, fertilisers, or other materials to be used in the experiments, while the farmers supply the land and the labour.

Farmers' institutes are also regularly held in at least thirty States. In these States where they have reached their highest development their importance as educational institutions is very great. This is indicated by the number of institutes annually conducted. In New York, Pennsylvania, and Ohio hundreds of them are held each year; in Massachusetts there are now 125, with an attendance of about 13,000 persons; in Indiana about 100, with an attendance of over 25,000; in Minnesota 50, with an attendance ranging from 300 to 1,000; in Wisconsin 120, with an attendance of over 50,000. In Michigan institutes are held in nearly every county, and the total attendance is reported to reach 120,000. Sixty thousand copies of the annual bulletin of the Wisconsin institutes, in which the best addresses are grouped together to make a book of over 300 pages, are annually distributed. A copy of this book is put into every school library in the State.

Correspondence.

To the Editor.

THE CHEMISTRY OF COCONUT CULTIVATION.

SIR,—Mr. Cochran's contributions to the literature of agriculture are always of interest and profit. His last deliverance is no exception to the rule.

As regards Manuring, we are to a great extent groping in the dark. The fact and figures placed before us by Mr. Cochran are decided steps towards the goal of scientific manuring. More, and of importance, remains to be done. We want a complete analysis of all parts of the tree. Mr. Cochran gives us analyses of copra, husks, shells, milk and pasturage, but he has omitted the leaves, very important organs that play the part, both of lungs and stomach. A good head of leaves is of great importance to the tree, to assimilate the food taken up by the roots. What is of great importance and should be borne in mind, is that the mineral constituents of the leaves are richer in fertilizing matter than any other single product of the tree. According to the analysis of Lepine, the leaves have less chloride of sodium and potash than only the husks, and have over 5-6ths of phosphate of lime, of the total quantity in every other part of the tree. And they have more lime than every other part of the tree. This will demonstrate the importance of manuring, not only for crop but for leaves.

It will be interesting to compare the mineral matter removed by the soil by 80 nuts per tree per annum according to Messrs. Lepine and Cochran. It is necessary to bear in mind that the latter gentleman's analysis includes only every part of the nut, while those of Mons. Lepine are of every part of the tree. The figures are in round numbers without decimals:—

LEPINE.

	lb.
Chloride of Sodium	100
Potash	734
Phosphate of Lime	300
Salts of Lime	262

COCHRAN.

	lb.
Potash	101
Phosphoric Acid	18
Chloride of Sodium (previous analysis of) ..	1
Lime	97

According to Lepine all parts of the nut remove in mineral matter by 80 nuts:—

	lb.
Chloride of Sodium	48
Salt of Potash	530
Phosphate of Lime	27
Salts of Lime	116

This is a great deal higher than Mr. Cochran's analysis.

However if, as I maintain, we must, manure for the proper growth of the tree and for the production of nuts, the manure we apply must be on the basis of Lepine's analysis. But the question will naturally arise, can Lepine's analysis be accepted as absolutely trustworthy and correct? In July 1897, Mr. Cochran had occasion to analyse the husk of a coconut. The result proved so divergent from Lepine's analysis as tabulated by Davidson, that he felt com-

pelled to impugn its correctness, or attribute the difference to the difference in the soil on which the trees grew. Mr. Davidson himself is not inclined to place absolute reliance on Lepine's analysis.

Mr. Cochran will be adding greatly to the obligation under which coconut planters are to him, if he will add to his analysis of the whole coconut, Lepine's analysis of the other parts of the tree and suggest a mixture sufficient to meet the annual drain on the mineral constituents of the soil. The mixture suggested by Mr. Davidson, to replace the mineral matter removed by 75 trees yielding 80 nuts per tree per annum is:—

	lb.
Salt	25
Wood ashes	240
Bones	45
Lime	15

Mr. Jardine's mixture which provides for organic matter as well, per acre, is

	lb.
Castor cake	960
Bone dust	300
Wood ashes.. ..	900

or the half of that for one year. This mixture errs on the side of liberality. It will be interesting to now compare the mineral constituents removed by 75 trees yielding 80 nuts per annum as given by Lepine, with the mineral constituents returned to the soil by Mr. Jardine's mixture:—

LEPINE.

	lb.
Salt	100
Potash	734
Phosphate of lime	300
Salts of lime	262

JARDINE.

	lb.
Potash	374
Phosphoric acid	51

The number of cattle that 100 acres of coconut land can support in full health and feed depends on many circumstances—climate, soil, age of tree &c. A wet climate and a rich heavy soil will of necessity produce more pasturage than a light soil in a dry climate. Grass grows more luxuriantly, sometimes too luxuriantly, on a young plantation than on one whose leaves shade the soil and whose roots are in full occupation of it. On an old plantation on soil with body, there is an even sward; on a light, sandy soil the grass seems to grow in individual blades and in tufts. Under these circumstances, it is not safe to fix the number of cattle that 100 acres of coconut land can keep in food. I am inclined to think that on old plantations with average soil, 100 acres for each head of cattle is fair; and on light sandy soil, where pasturage is scant, four acres for each head of cattle. So with the weight of grass per head of cattle per day. It is dependent on circumstances. I think 50 lb. of grass per head per day a high average and exceptional.

Since the above was written I have read with much interest and profit Mr. Jardine's letter.

My experience is one with Mr. Jardine's of the value of the droppings of cattle tethered to trees at night. The cattle were only grazed on very poor pasturage and their droppings were dug up without the addition of the bones, castor-cake and ashes, Mr. Jardine rightly suggests, and the results were most encouraging—in fact better than the results of applying other manures. The trees had a head of dark green leaves and gave good crops for two years and the color of the leaves did not change to a yellow as is usual during a period of drought. I think the chief value of

cattle droppings is in the extreme solubility of their manurial constituents. A mixture approximating this will be of great value to coconut planters.

The system of carting husks and burning them with leaves, between every four trees, is a rational form of cultivation; but its cost is against it being carried out on a large scale. The more economical system would be to burn the husks where the coconut heaps are, and to apply to each tree, when manuring, ashes representing the husks of twice the annual average crop.

Mr. Jardine's experience of "hungry" soils must be the experience of all those who unfortunately have to do with them. A very large proportion of the manure applied goes to build up the tree and a very little to put on crop. If manure be not applied to trees growing on such soils every other year, the results of less frequent applications are positively *nil*.

Mr. Jardine's heresy as regards the use of salt in coconut cultivation is unfortunately not his only heresy. I always maintain that even if salt was not a manure, it was of great value agriculturally, owing to the chemical and mechanical changes it caused in the soil, more especially in heavy soils. Mr. Davidsou, than whom perhaps no more competent man ever engaged in the cultivation of coconuts, and who was the Gamaliel at whose feet Mr. Jardine as a young man learnt the lessons in coconut planting which entitle his opinions to respect, held very decided opinions of the value of salt in coconut cultivation. I am a great believer of the use of salt in coconut cultivation especially in inland districts having heavy clay or alluvium soils. Perhaps if Mr. Jardine gives salt a trial, say on ten acres, he may find the yield of nuts so increase that he will apply it on a large scale and will no more be able to say: "I have never known any estate in Ceylon where the trees have 90 nuts each, per annum, over any extent of land." He will then be under no necessity to "go a long distance to see it," as he will be residing on it. B.

PAPER MAKING FOR CEYLON.

SIR,—Will anybody tell me why ordinary printing papers are not manufactured in Ceylon. I am not unfortunately a chemist, or a paper expert, but I think I am right in saying that, within 20 miles of Colombo, there is an opening for this industry, not merely as regards its local sale, but in respect to the supply to the Far East and India.

Of course Ceylon mills would have to do what the Indian mills have to do: import (not necessarily from Great Britain) from other countries a great part of the chemicals used in the manufacture.

There is plenty of water power not far from Colombo, which would meet all the requirements of a mill working both day and night, and all through the year if sufficient demand arose.

If a paper mill could be established in the vicinity of Colombo I need hardly say how valuable it would be (1) to the local papers; and (2) to all other consumers of papers. Once start the industry and each of the several branches would rapidly develop.

By simple machinery, though I do not say it would not be costly, the light timber on our hills could be floated down to a convenient point, and then converted into wood-pulp, and could be used on the spot in the manufacture of paper or exported to Indian mills.

The light wood (easily re-grown) is what is wanted, and mixed with constituents Ceylon possesses would probably prove of great value in the making of good paper.

It would pay the Government to have a special report made by an expert on the subject; if the Government decline, why should not the Chamber of Commerce take the question up? Our fibres and grasses are not sufficiently valuable for export to other paper-making countries, but delivered to a paper-mill near at hand they would be a most remunerative help in producing the material required for good paper for writings and printings of various qualities.

The volume and quality of the water available at the spot where the mill is placed must also be taken into consideration.

Paper is now and has been rising in price in England, India and America: the paper market of England, if ever shut off by war with the Continent, will take a leap, the extent of which few can suspect; and I write this letter in view of the possibility (and may I hope the probability) of Ceylon stepping in the way and trying to establish a paper mill on the banks of one of the rivers or canals on this side of the island that would at any rate feed part of our local supply at once, and in due course become an industry of considerable benefit, not only to Ceylon, but to neighbouring countries.

It seems to me that the local Government would do well, as they cannot take the initiative, if they were to offer a prize through Ceylon, English, American or Australian papers of a fairly substantial amount which would result in an experiment being carried out on lines that I have ventured to refer to.

WANDERER.

Herewith a cutting which I met with after writing the above:—

The offer of the New Orleans *Times-Democrat* to give 500 dols. as its share of a prize to be offered by the newspapers of the United States to the inventor who may find a cheap and suitable substitute for wood pulp in the manufacture of paper has brought forth suggestions of cotton-wood or sweet gum, bagasse or the refuse from sugar-cane, cotton-seed hulls, rice straw, and pine straw as the substitute. Against these products of the South the objection has been made that they do not quite reach the market. But the *Times-Democrat* is urging chemists and inventors to do all in their power to overcome the suggested difficulties. W.

THE INDIAN MUSEUM, CALCUTTA.

Indian Museum, Calcutta, March 4th.

From GEO. WATT, Esq., M.B., C.M., C.I.E., etc., Reporter on Economic Products to the Government of India.

SIR,—I have the honour to acknowledge, with many thanks, the receipt of your letter dated the 3rd March 1900, together with the marginally noted publications.* These have been recorded as presented by you and placed in the Commercial Room of this Museum.—I have the honour to be, sir, your most obedient servant.

GEO. WATT, Reporter.

[Dr. Watt having applied for one or two of our publications for his Museum, we sent him several more. Hence this acknowledgment.—ED. T.A.]

TEA IN CHINA AND ITS CULTIVATION, &c.

March 30.

DEAR SIR,—It may be interesting to some of your readers to know what Samuel Ball in his book on Cultivation of Tea in China has to say incidentally on the effect of manure on the lasting qualities of the tea bush.

In the first place the Chinese did not manure the 'black tea,' because for one reason the demand would not make it profitable and also because as one of these authors says:—'That tea is the most fragrant which is not manured.'

They do not manure it, but Mr. Ball goes on to quote a Spanish missionary's account of its culture:—'Every year in February and August the ground is weeded, raking up even the grass. When the ground is hilly, and appears exhausted and sterile, after having weeded it in February, it is usual to go and dig soil from a neighbouring mountain and bring it and place it around the roots of the shrubs. If this soil be previously exposed to the sun or burnt, it improves it.' And of such tea he says '*it will last fifty years.*'

With regard to the 'green tea' culture we read:—'The shrubs are manured twice a year, in spring and autumn; the ground weeded and turned up about the roots four times a year. In about seven years they are cut down, nearly close to the ground, to produce an exuberance of succulent shoots and leaves; and in about thirty years they become useless, when they are rooted up.'

It is impossible scientifically that these tea bushes should differ in lasting power intrinsically, though of course, the 'green tea' is grown in the soil of the plains and the 'black tea' in the mountainous soil. Yet discarding that factor it is shown that the highly manured 'green tea' does not last so long as the *un-manured* 'black tea.'

In reality this is an argument for scientific manuring as against the injurious stimulating of the plant with constant applications of ordinary manure, for the virgin soil from a neighbouring mountain added to the black tea would contain all the good qualities which the soil of that district had been chosen for possessing.—
Yours, etc.,
Z.

[But the difference between "green" and "black" tea is all in the preparation, not in the bushes—though perhaps the Chinese make a distinction.
ED. T.A.]

PROPOSED PERIODICAL TOURS OF THE SCIENTIFIC OFFICERS OF THE R. B. GARDENS.

Planters' Association of Ceylon Kandy, March 30.

DEAR SIR,—I herein enclose, and would invite attention to, letter received from the Director of the Royal Botanic Gardens, Peradeniya, on the subject of proposed periodical tours by the new scientific officers of his department, which speaks for itself. Commending the scheme to cordial co-operation by those interested.—I am, dear sir, Yours faithfully,
A. PHILIP.

From the Director, Royal Botanic Gardens, Peradeniya, to the Secretary, Planters' Association, dated 28th, March, 1900, subject:—

TOURS OF ENTOMOLOGIST AND MYCOLOGIST.

SIR,—I have the honour to inform you that the periodical tours of the new scientific officers of this department will shortly be commenced, and to ask your assistance in making them of as

much value to planters and to the work of the officers themselves as possible. It is impossible for them to go over every estate looking for diseases, and they must depend upon the help of the planters for information. I propose that, if you agree, I should give notice to you some time in advance of the districts proposed for visitation and the approximate dates. If you would then be so kind as to inform the local Committee, perhaps a meeting could be arranged between the travelling officer and the Committee to discuss the diseases, etc., prevalent in the district (the Committee having previously collected information from the planters of their district). At this meeting arrangements could then be made for visiting particular estates, and notice given to planters as to the movements of the officer concerned in the district.

As a definite instance, I may mention that the Entomologist is going to Batticaloa to reach that place about April 15th and that he proposes to visit the Badulla and Passara districts either on the outward or homeward journey.—I am, sir, your obedient servant,

(Signed) JOHN C. WILLIS,
Director, Royal Botanic Gardens.

COCONUT PALM CULTIVATION IN CEYLON:
THE VALUE OF DIFFERENT MANURES;
THE VALUE OF SALT; DOES ANY ESTATE IN CEYLON GIVE 90 NUTS PER TREE PER ANNUM?

April 2.

DEAR SIR,—I have read with very great interest Mr. Cochran's most useful paper on "Coconuts and Chemistry," (see page 764). I am sure that all who are interested in the cultivation of the coconut palm will appreciate highly the care and trouble Mr. Cochran has taken to place before them, such full and valuable information on the subject of the proper manures to be used in securing the best results in the cropping of their trees. Mr. Cochran's analyses being authoritative, we cannot do better than to endeavour to follow his advice, and to restore to the soil the manurial ingredients removed from it in crops of nuts, in the proportions pointed out by him.

I have not much faith in the value of cattle-shed manure where the cattle are fed only on the grass of the estate, and a lot of weeds and grass are thrown in daily to swell the bulk; for, by the time the manure is sufficiently rotted to allow of its being applied, it will have lost its most valuable constituent, ammonia; and the chief value of what remains will, in my opinion, be its mechanical action in the better subdivision of the particles of the soil. I should not apply manure of this description alone, but it would be a useful addition to bones, castor-cake, &c. Even the droppings of cattle, fed largely on oil cakes—as in the case of animals used in chekko yards,—loses much of its value after a short exposure, and is greatly inferior in results to that obtained where cattle are tied direct to the trees and the manure dug in so soon as they are removed to other trees. The very best results are obtained by tying two head of cattle to each tree

at night, spread evenly the droppings in a 6 foot radius and scatter upon this 3 lb. finely grown bone dust and 4 lb. white castor-cake, then dig to a depth of six to eight inches, mixing the soil and manures in the process; upon this dug-surface sprinkle 8 to 12 lb. good wood ashes and rake lightly in. The object of applying the ashes on the surface is to allow of the soluble potash being absorbed by the soil, in its passage down with the rain water, before it can get below the reach of the feeding rootlets. Where cattle are not available for tying to the trees, good chekku yard manure or white castor-cake must be used.

I have seen good results follow the application of *lime* to reclaimed swamp and low-lying land, and on lands containing much marl and clay. Its cost, however, in some districts prevents its being used to any great extent. With reference to the insufficient amount of potash in the mixture I recommend, I would point out that the husks are never allowed to be removed from the land, but are carted out to the field, and the quantity of husks removed from the average field of nuts per tree per annum are burnt between every four trees; thus the potash removed from the soil by the husks is each year returned to it, and it is only necessary to add what has been removed in the kernels, water and shells, and the quantity I allow, Mr. Cochran says, slightly exceeds this. Where husks are removed, or where they are burnt in large heaps and the ashes applied to only a few hundred trees, as is too often the practice, the quantity of ashes or potash in some other form, equal to what is removed in the husks, should be added.

Mr. Cochran's analyses refer only to the manurial ingredients removed in the crops of nuts, but takes no account of what is taken up by the roots, stem and leaves of the tree for their maintenance in health and vigour. My experience has taught me that when an estate has been at all neglected, or where the soil is a hungry one, a very large proportion of the manures of the first and second application, goes to build up the trees and fit them to bear crops; and even after the trees are in full vigour, a certain proportion of the manures of subsequent applications, must go to keep them in that condition; so that when manuring is first begun upon an estate it would be well, in the first and second applications, to allow one-third more than would be necessary afterwards.

Never having applied salt to coconut trees I cannot speak as to its value. If it really is a necessary ingredient in the successful cultivation of the coconut tree then nature, in her chemical laboratory, is able to produce it from substances existing in the soil, else how is it that we find trees from 40 to 60 miles inland growing and cropping better than most of those within the influence of the sea breeze? Salt, like lime, I believe to be a solvent of animal and vegetable substances in the soil and a destroyer of vermin and weeds, but that it is a manure, in the true sense, I doubt.

I have never known any estate in Ceylon where the trees have 90 nuts each, per annum, over any extent of land, even with high cultivation; and I much doubt if there is any such estate in Ceylon. If there is, I would go a long distance to see it. I admit that under exceptionally favourable conditions there are fields, even up to 100 acres, which produce 90 nuts per tree and even more; but those are exceedingly rare. It is a very general practice with native owners of coconut property when asked as to the yield per acre to reply that they get so many nuts at a

picking, and they are sure to name the largest number gathered at any one picking. Now this is very misleading, as no two pickings are alike. If the two largest pickings of an estate for the year are, say, 100,000 nuts each, the next largest will be about 70,000, and the remaining three will be say, from about 30,000 to 40,000 each picking.

Messrs. Freudenberg and Baur have introduced several manures which have not been much in use until recently, but are now having a fair trial. It would be interesting and useful if either of these firms would supply us with the information as to the money value of the unit of nitrogen, potash and phosphoric acid in their manures as compared with its value in white castor-cake, bone dust and wood ashes.

W. J.

COCONUTS IN MATALE.

Awliscombe Estate, Matale, April 11.

SIR,—Coconut planters have been much interested in the articles appearing in your esteemed paper, on the subject of coconut cultivation. The district of Matale, though famed for cacao, has not yet drawn the attention it deserves in the matter of coconut cultivation. This estate, situated on the North Road six miles from Matale, was planted with coconuts and tea in the latter end of 1896. It was abandoned in the middle of last year and purchased by Mr. C. M. Fernando two months ago, since when I have been in charge. A palm, which the kanakkapulle, who was in charge tells me, was planted just three years and five months ago, is in bloom, and contains three separate bunches and two flowers. Other trees give promise of an early blossom. The plants came from Veyangoda and were from six to eight months old when laid down—the estate was never manured and the land was originally in chena. Does it not seem as if Matale North is deserving the attention of those interested in the staple product of the island?—I remain, sir, yours faithfully,

LEO. P. FERNANDO.

MINOR PRODUCTS REPORT.

CINNAMON.—In auction 26 packages Ceylon offered and part sold at 8d per pound for coarse and 6d for low. Of "wild" bark 621 packages offered, and 200 sold—thick bark 1½d to 1¾d, broken quill ¾d. and thin quill 1¾d to 2½d per lb. Chips and bark dull of sale.

CINTRONELLA OIL.—The market is easier inclined since the auction sale of last week. It is reported that 10½d per pound c. i. f., has been refused this week for drums. 11d being wanted. In cases 11½d is quoted on the spot.

LEMONGRASS OIL.—Dull of sale at 2½d to 3d per ounce spot.—*Chemist and Druggist* March 24.

THE AGRICULTURAL MAGAZINE, COLOMBO

Added as a Supplement Monthly to the "TROPICAL AGRICULTURIST,"

The following pages include the Contents of the *Agricultural Magazine* for May:—

Vol. XI.]

MAY, 1900.

[No. 11.

A LOCAL WORK ON CATTLE.

“CATTLE Notes” is the title of a booklet by W. A. De Silva, V.S. This is not the first little work published by the author who has already written more than one useful pamphlet on Agricultural subjects.

The contents are tabulated under the following heads: 1, Cattle and Buffaloes; 2, Description and Aging; 3, Cattle Food; 4, Cattle Sheds; 5, Handling of Cattle; 6, Signs of Ill-health; 7, Nursing and Attendance; 8, Medicinal Materials; 9, Prevention of Disease; 10, Disease and Treatment; 11, Milk Cows.

Chapter 10, dealing with diseases and their treatment, will, perhaps, be considered of most value by cattle owners, who should be glad to be furnished with directions and prescriptions in which common and easily-obtained drugs are recommended. A convenient list of these medicinal agents, together with their Sinhalese and Tamil names, is supplied on pages 39-42. We regret, however, to find that the author writes disparagingly of the value of protective inoculation against rinderpest, a means which we are confident is bound to play an important part in the stamping out of this scourge. We are quite at one with the writer when he says that “it is a great mistake to repose complete reliance in any one measure or remedy,” and as

a result neglect all ordinary recognised methods of prevention, but when modern science offers us an admittedly valuable means of controlling the spread of epizootic diseases, it would be hardly wise on our part not to take advantage of the offer and so make the most of every means at our disposal. However, that doctors disagree is proverbial, and considering the class for whom “cattle notes” is intended, we think that the author has succeeded admirably in explaining himself in simple and popular language so as to be easily understood by all classes of stock-owners.

Recorded by Mr. J. A. G. RODRIGO,

THE CULTIVATION OF YAMS.

It cannot be denied that the cultivation of yams is not sufficiently carried on in Ceylon, and that the product is not sufficiently made use of for food purposes. Indeed, such cultivation as we have is on the most limited scale, and only unsystematically carried on. In the West Indies on the other hand the yam is a regularly grown crop and duly appreciated as a food product.

In Ceylon we are accustomed to hear the word "yam" applied indiscriminately to the produce both of true yam plants, members of the natural order Dioscoraceæ and that of the Colocasias which belong the order Araceæ. But in the West Indies the name is confined to the former only, while the word "tauia" is used to distinguish the produce of the Colocasias.

The following account of yam cultivation in the West Indies by Dr. Alford Nicholls is worthy of reproduction, as containing many valuable hints which should prove useful to local cultivators.

Yams are the esculent tubers of several species of *Dioscorea* that have been cultivated in warm countries for ages. More nutritious than the common potato, they supply an abundance of wholesome food to the inhabitants of tropical and sub-tropical regions; and, in the West Indies they enter very largely into the diet of all classes of the population.

Most of the cultivated varieties of yams are probably natives of tropical Asia, that have been introduced into the West Indies at an early period of their colonisation by Europeans, and now become almost wild. The only yam of good flavour and food value, that naturally belongs to the flora of the West Indies, is the "Wawwaw" of Dominica, *Rajania pleioneura*, which grows abundantly in the forests of that island. It is dug up by the woodmen and sold in the markets of the chief town, for it is deservedly held in much estimation. After the hurricane of 1883, when most of the provision grounds in Dominica were laid waste, many of the country people subsisted for weeks almost entirely on wawwaws, dug up in the forests. All the yams are the produce of plants with slender twining stems measuring often as much as twenty feet in height, and bearing underground tubers which spring from the principal roots. The tubers vary in size and weight from the small cush-cush no larger than ordinary potato to the enormous yam weighing thirty or forty pounds, and measuring three feet in length. There is confusion in regard to the names and characters of the different yams, each country appearing to have its own nomenclature. There are four kinds of yams, however, commonly cultivated in the West Indies, and the most noticeable particulars concerning them are as follows:—

WHITE YAM (*Dioscorea Alata*).—This is sometimes called the Barbados yam, is a native of the Moluccas and Java. The stem is square and winged at each angle. The leaves are large, heart-shaped and opposite on the stem. A peculiarity of this plant is that bulbils or small yams are borne on the stem, and when they are ripe they fall to the ground and reproduce the species. The tubers are large weighing from eight to ten

pounds when grown in good soil. There are two principal kinds, the white and the red, the surface of the latter is of a deep purplish, and the interior of the tuber of a light purplish colour. A third kind called the water yam is characterised by the interior of the tuber being of a moist and clammy nature. These yams will keep well out of the ground, and they are much liked on account of their digestibility and their superior flavour.

NEGRO YAM (*Dioscorea Sativa*).—This is sometimes called the yellow, creole, or common yam, and it is a native of Java and the Philippine Islands. The stem, which grows to a length of fifteen or twenty feet, is round, prickly below and smooth above. The leaves are heart-shaped and alternate on the stem. The tubers grow to a large size weighing usually about ten pounds; they are palmated in shape and they are so brittle as to be easily broken. They are of a white or yellowish colour within, but the white kind is liked best. These yams do not keep in good condition for any length of time after their removal from the ground.

GUINEA YAM (*Dioscorea Aculeata*).—In Jamaica this is sometimes called the Afou yam. It is largely cultivated throughout the West Indies, but its native country is Cochin China, and it comes also from Malabar. The stem is round, prickly and much branched. The leaves are broadly heart-shaped, and either alternate or opposite on the stem. The tubers are very large, reaching a length of two or three feet, a diameter of six or eight inches, and a weight of from fifteen to twenty pounds. The interior is of a white or yellow colour, and when cooked the flavour is somewhat bitter.

CUSH-CUSH YAM (*Dioscorea Triphylla*).—In Jamaica this is sometimes called the Indian yam; and in Guiana it is known as the Buck yam. The stem is roundish, the leaves are opposite on the stem and divided into three leaflets. The tubers are roundish—indeed, something like a potato in shape. They rarely exceed nine inches in length and three inches in diameter, but they are usually much smaller. It is said to be the smallest and most delicate of all the yams. The plant is prolific, sometimes bearing a dozen tubers on the roots. There are two principal kinds, the white and red, the latter bearing tubers that are purplish within.

SOIL AND CLIMATE.—All the yams require a rich sandy loam, deep and friable, for the rich tubers will not be able to develop properly in stiff heavy soils. The white yam, however, will grow well on calcareous soils of moderate depth. Good drainage is necessary, and this applies to most plants bearing underground tubers. The climate must be warm but not necessarily hot, as the plant thrives in the mountains and in extra-tropical regions. One authority states that yams will grow within a wide zone extending thirty degrees north and south of the equator.

CULTIVATION.—Most of the yams are propagated in the following way:—When the tubers are ready to be dug up, the tops are cut off with the vines attached, and care is taken not to disturb the plant more than is really necessary. The top is then buried again in the ground, and it and the base of the vine is moulded up with good soil and left undisturbed for about three months, when another

yam called the *head* is produced. Plants are then made by cutting the head into pieces, care being taken that each cutting possesses an eye, or bud, from which the new plant develops.

The land is usually lined out at distances of two feet each way or in rows three feet apart, the plants being set at distances of eighteen feet in the rows. At the site of the pickets the land is dug up, all stones and roots being removed, and the surrounding soil is then raked up so as to form a support for the vine to climb on. Sometimes two plants are set in each hill. The land must be kept weeded and an occasional moulding up may be necessary, as the heavy rains tend to wash down the hills. Catch crops of maize and sweet potatoes are sometimes taken off the land between the rows, but this system is a bad one except in very rich soil. From January till April is the best planting season, and the yams require from nine to eleven months to mature. Planting may, however, be undertaken in every month of the year so as to ensure a constant supply of esculent tubers. It has been calculated that an acre of land will yield four or five tons of yams in the year, and it is said that the same quantity of sweet potatoes may be taken as a catch crop of the ground; this brings the return up to nine tons, that is, the yield of ordinary potatoes from an acre of good land in England. But as yams and sweet potatoes contain more nutrient matter than the common potato, the actual yield of food is greater in the case of the tropical vegetables.

THE VALUE OF SEA-WEED AS MANURE.

Chemists tell us that the composition of seaweed is very similar to that of farm-yard manure; if so, it is a matter for regret that so little use is made of it for manuring cultivated lands near the sea-borde. As is to be expected sea-weed contains a large percentage of moisture, and for that reason its carriage for long distances inland would not pay, but those whose lands lie near the sea should not neglect the opportunity thereby offered of a plentiful and cheap supply of manure, at certain seasons, that contains all the necessary elements of food for cultivated plants.

We are induced to take over from the *Australian* the following account of the successful use of sea-weed in fruit culture in England, in the hope that it will encourage those who have an opportunity of using this waste material as a fertilizer, of doing so:—

A writer in *The Garden* says that those who have not tried seaweed in their orchards and fruit-gardens would be surprised at the beneficial effect it has on the trees, especially apples and pears, when, of course, it is used with care and moderation. This is particularly the case during dry seasons. An illustration of the value of seaweed is given. At Bembridge, Isle of Wight, some land was recently reclaimed from the sea, and it was converted into a fruit, flower and vegetable garden. There is a great depth of sandy soil, composed to a great extent of thoroughly decayed seaweed and sand, and the way all vegetation thrives in it is marvellous. In other places during the last two summers crops were

collapsing from the want of moisture, in spite of the mulching of stable litter freely applied. For light soils and for use during a very dry season seaweed will undoubtedly prove more valuable as a mulch than any other material generally used for this purpose.

Apart from any manurial properties it contains, it is, like salt, moisture-holding as well as feeding, the value and importance of which should not be ignored by those whose fruit trees are growing in too porous soils and where the rainfall is light. No healthier trees or better samples of apples could be seen than those growing in the garden referred to. It is not recommended that fresh seaweed be buried near to the roots of established trees, or that it be incorporated with the soil in forming a new orchard or fruit-garden, but frequent mulchings of the surface ground, piecemeal, are a safe means of stimulating growth and sustaining the trees under the trying influence of a long drought. By this means it would gradually find its way into the lower ground and undoubtedly improve its staple.

Another instance of the value of seaweed is given. The gardens at Arundel Castle are justly celebrated for their extent and the fine order in which they are kept. For many years past heavy mulchings of stable litter were annually applied to the fruit-trees, but it was found that the manure formed fine harbours for woodlice, beetles, earwigs, and weevils, as well as for sparrows and other birds; the fruits suffered in consequence, and the finest specimens formed the feeding ground at night of the numerous insect depredators. It occurred to the head gardener to use for a mulch seaweed, this was done, and now the fruit is large, bright, without a speck, and uninjured by any of the above-named pests.

Occasional dressings of seaweed to vines are also recommended. Too frequent applications of stable manure cause the soil to become sour or uncongenial to proper root-action. Seaweed varies considerably, some being far too coarse and heavy for the purposes mentioned, unless it has first had sufficient time for partial decomposition. Preference is given to that of a finer and lighter character, which, when collected, generally contains a fair amount of sand, making it more suitable in every way for use in the garden, whether it be for asparagus, fruit-trees, or even as a plunging material for pot plants during the summer months.

AN ACCOUNT OF THE COCONUT PALM.

There is hardly a tropical country on the face of the globe where the cocoa palm does not flourish, and it is impossible to ascertain its native country, though it is thought to be indigenous to some parts of Asia, perhaps Southern India. In the Coromandel and Malabar districts, and in the adjacent islands, it grows in the greatest luxuriance, preferring the sandy and rocky sea shores to the higher country, though it is often found some distance inland. It is common in Africa, and abounds in America and the West Indian Islands. Dr. Parry found it plentiful on the Islands of Santo Domingo, where it forms groves

on the sandy beaches at the outlet of mountain streams and bears fruit abundantly. It is found in Southern Florida, 20,000 trees having been planted on Long, Lignum-vitae and Sands keys alone, while examples 80 feet high and 50 years old are found at the mouth of the Miami River. Grows to 100 feet.

Its extensive geographical distribution is accounted for by the fact that the tree growing in such close proximity to the sea, the fruits falling on the beach are washed away by the waves and afterwards cast upon some far distant shore, where they rapidly vegetate. It is in this way that the Coral Islands in the Indian Ocean have been covered with these palms.

Coir fibre appears in the form of large, stiff, and very elastic filaments, each individual of which is round, smooth, very clean, resembling horse-hair. It possesses a remarkable tenacity and curls easily. Its colour is a cinnamon brown. These filaments are bundles of fibres, which, when treated with the alkaline bath and ground in a mortar, are with difficulty separated by the needles for microscopic examination.

The individual fibres are short and stiff, their walls very thick, notwithstanding which this thickness does not equal the size of the interior canal. The surface does not appear smooth; it is often sinuous and the profile appears dentated. The diameter is not very regular. The points terminate suddenly and are not very sharp. The walls appear broken in places as if they were pierced with fibres, corresponding with the tissues of the broken sections.

The fibre of the coconut palm is contained in the husk of the nut, which is composed of a mass of coir, as the separated fibre is called. The husks are removed by forcing the nuts into sharp iron or wooden spikes fixed in the ground, one man being able to remove the husks from 1000 nuts daily. The proper time for cutting the fruit is in the tenth month, as the fruit must not be allowed to get thoroughly ripe, for the fibre becomes coarser and more difficult to twist, and must remain longer in the soaking pits, which is a disadvantage, as the fibre is rendered darker. These pits in some of the islands are merely holes in the sand, and the nuts lie under the influence of the salt water a year, kept from floating away by large stones placed over them. Sometimes the nuts are soaked in freshwater tanks, and as the water is not changed, it becomes in time very foul and dark-coloured, which affects the colour of the coir. After soaking the fibre is readily extracted by beating. Fresh water is said to weaken the fibre, and, in fact, too long soaking will produce this result in any event. The coir from the islands of Kadamat, Kelton and Chetlat in the Laccadives is said to be of the best description, and the manufacture into cordage is done entirely by women. After it is taken from the pit and sufficiently beaten, the extraneous matter is separated from the fibrous portion by rubbing between the hands. After it is thoroughly cleaned it is arranged into a loose rowing preparatory to being twisted, which is done in a very ingenious manner between the palms of the hands, so that it produces a yarn of two strands at once. According to the old native system of treatment, the nuts

sometimes remained in the pits eighteen months. The best commercial coir of today is obtained by better methods, and the soaking is accomplished in tanks of stone, brick, iron, or wood, the water being warmed by steam, which shortens the duration of the treatment very materially. Where machinery is used (in the after processes), the husks when sufficiently soaked are passed through a crushing mill, which flattens and crushes them ready for the extractor or breaking down machine.

In the latter the fibres are completely disintegrated, and are then passed through a "willowing" machine, to free them from dust and refuse. It is calculated that when treated in England 10,000 husks will produce 45 to 50 cwt. of spinning fibre and 9 to 16 cwt. of brush fibre. In the process of separating the fibre, the following commercial qualities are produced: The mat, or long fibres used for spinning purposes; the shorter, or more stubborn fibres (bristles) for brooms or brushes; the low or curled fibre for stuffing cushions, and the dust or refuse for gardening purposes. When dyed black, the tow has been used as a substitute for horse-hair. A singular use was proposed a short time ago for coconut dust or refuse. Taken before it is quite dry and subjected to great pressure, it is capable of forming plates of varying thickness, like mill board, only much more brittle. These boards, if used as backing for steel plates of ironclads, swell up on being punctured below the water line and soon close the orifice. If really effective, such plates could be produced at a trifling cost, for thousands of tons of coconut refuse float away annually down the rivers in India and elsewhere.

Three large coast coconuts will yield 1 lb. of coir, measuring about 130 feet, whereas ten small inland nuts are required for 1 lb., but it will give over 200 feet. Two lbs. of such yarn, averaging from 70 to 75 fathoms, are made up into sooties, of which there are fourteen in a bundle, averaging about a maund (28 lbs.). A Mangalore candy (560 lbs.) will thus be the produce of 5,600 nuts, and should contain 20,000 fathoms (20,000 feet) of yarn.

Coir fibre is used by the Spaniards of the South Seas instead of oakum for caulking their vessels, and it claimed that it will never rot. Coarse cloth is sometimes made from the fibre which is used for sails. The principal use of coir, however, in the commercial world is for cordage and matting. "The character of coir has long been established in the East, and is now in Europe, as one of the best materials for cables, on account of its lightness as well as elasticity." Ships furnished with coir cables have been known to ride out a storm in security, while the stronger made but less elastic ropes of the other vessels snapped like pack thread. Coir cables were used extensively in the Indian Seas until chain cables were introduced. It is rougher to handle and not so neat looking as hemp rigging, but it is well suited to running rigging where lightness and elasticity are desired, as for the more lofty sheets; it, however, is too elastic for standing rigging. In vessels of 600 tons it is generally used for lower rigging. Tests of coir cordage by Dr. Wright gave the following results: *Hibiscus cannabinus* broke with 190 lbs. strain, coir broke with 224 lbs., but

bowstring hemp (*Sansevieria zeylanica*) required a strain of 316 lbs. to break it. In another series of experiments made at the office of the Marine Board of Calcutta, palm coir stood a strain of 823 lbs., when a remarkably fine specimen of European hemp stood 1,967 lbs. In this test the coir stood No. 12 in strength and No. 1 in elasticity, stretching 32 inches against 9½ inches of the hemp. Unfortunately, the length of rope was not given, though its size was 1½ in circumference.

The cocoa palm has other uses than for fibre which are of sufficient interest in connection with its textile uses, to briefly mention: The Cocoa-nuts are sometimes used for illuminating purposes, to light roads, and an excellent charcoal is yielded by the burnt shells. These in the entire state are manufactured into a great variety of vessels for household use. The tree itself is used in the manufacture of small boats, frames for houses, rafters, spear-handles, furniture, and fancy articles of different kinds. It is exported under the name of porcupine wood. "The Ciugalese split the fronds in halves and plait the leaves so nicely as to make excellent baskets, and they form the usual covering of their huts, as well as the bungalows of the Europeans." These dried fronds also furnish fuel and are used for torches, or they are made into brooms by trying the midribs together. The leaves furnish mats, baskets and screens, and combs are made of the midribs of the leaflets in the Friendly Isles. Mats are also made of the coconut leaf cut out of the heart of the tree, which are described as of fine quality and used in the Laccadive Islands as sails for boats. A downy fibre is also taken from the plant which is used to stanch the blood in wounds after the manner of lint.

Coconut oil is one of the best-known products of the palm, especially as it is employed in the manufacture of stearine candles. In the East it is employed as lamp oil, and also for anointing the body. Fifteen coconuts produce about 2 quarts of oil. The drink known as toddy or palm wine is derived from the flower spathes before they have expanded. It is also distilled and produces an intoxicating liquor or arrack. It is also made into vinegar, or, if it is not allowed to ferment may be made to yield jaggery or sugar which is brown and coarse.

The palm grows well in Southern Florida, and while already producing nuts the coconut industry has assumed no importance, though a single company in Massachusetts extracts the fibre from imported nuts.—*Dr. Dodge, Washington.*

PRACTICAL HINTS TO HORSE OWNERS.

BY A. CHINNAH, G.B.V.C.

CHAPTER I.—(Continued.)

The eaves of the stable roof should be so constructed as to admit of the free passage of air.

Ridge or roof ventilation is an important condition in a stable. The absence of it induces the accumulation of impure air which would otherwise rise and pass out of the stable making way for a supply of pure air. Other systems of ventilation are adopted in continental cities, but it is

unnecessary to describe these as they will be hardly of any practical use to my readers.

CHAPTER II.—FOOD AND FEEDING.

There is a great variety of horse foods, and a description of the chief foods, together with analyses, will be given later.

By nature the horse is intended to serve as an animal of activity and speed, but in a state of nature, where speed and activity are exercised either for pleasure or as a means of security against assailants, natural herbage suffices for the nutrition of the animal, which, to a great extent, expends its energy according to its strength. In a state of captivity, however, and as a slave to man, expending energy not according to its own instincts or inclinations, but according to the will and fancy of his master, the same food does not suffice to supply the wear and tear of the tissues induced by regular and hard work. While grass alone does not supply sufficient nutriment to a hard-working animal, it is also to be objected to on the ground that if partaken of in large quantities, from its bulky nature it interferes with the free action of the lungs, and as a result incapacitates the animal from hard and fast work which it is expected to perform; while again energy is unnecessarily exhausted in the effort to digest and assimilate so bulky a food. It is for these reasons that working animals are fed on artificial concentrated food-stuffs. No single foodstuff, however, can be said to contain every element required for the proper nutrition of the animal economy, and it therefore becomes necessary to make up for the deficiency of certain elements of nutrition in one foodstuff by using with it another which supplies the want, and so two or more ingredients are mixed till the required standard of diet is attained. For instance, oleaginous seeds have to be mixed with cereals rich in starch and so on. For many reasons grains raised in the country are selected; they are of course to be preferred on the score of convenience and cheapness.

(To be continued.)

THE RATTAN INDUSTRY.

We are indebted to the *Kew Bulletin* of September-October, 1899, for the following account of the Rattan industry extracted from the Report of Henry P. du Bellet, United States Consul at Rheims for January, 1898:—

"Rattan is the name given to more than one hundred species of climbing palms of the genus *Calamus*, natives of inter-tropical Asia and Africa, most or all of which are perennial, simple or unbranched, cylindrical, jointed, very tough and strong, from the size of a goose quill to the size of the human wrist, and from 50 to 100 feet in length.

In the regions where it grows wild, rattan renders forests inaccessible by reason of its long, tough, and thorny stems, running from tree to tree and on the ground. These stems are used in the manufacture of numerous articles, the principal among which are walking sticks (very much in demand and often very high priced), riding sticks, cables, and very strong ropes, and when split into thin strips, are used for making seats of chairs,

baskets, withes and thongs, and all sorts of wicker ware.

One species of rattan—the *Calamus Draco*—from which is extracted a red, resinous substance, is employed for medicinal purposes.

From India is taken the rattan used in making walking sticks; its stem is very long, a little over 0.39 inch in thickness, with joints 19.63 to 39.37 inches apart.

From Cochín China and the Sunda Islands are annually exported large quantities of *Calamus rudentum*, one of the largest kinds of rattan used for cables and ropes. Its stem is very long and 0.78 inch thick near the middle, and from 1.37 to 1.96 inches in the lower part, its joints being often 78.74 inches distant from each other. These natural cables are so resistant and strong that, it is said, they are used for capturing wild elephants. Strong and handsome walking sticks are made from this species, and also from the *Calamus Draco*, the joints of the latter being from 59 to 62 inches part.

From the Sunda and Philippine Islands are taken: (1) the *Calamus equestris*, used in the manufacture of riding sticks, a species from 196 to 221 feet in length and no more than 0.39 inch in thickness, with its joints 7.87 inches apart; (2) the *Calamus viminalis*, a species slimmer than the latter, which is used for wicker ware.

The manufacturers of rattan in the consular district of Rheims buy their raw material in Germany and Holland, whither it is shipped from Dutch India after a first preparation.

First of all, the bark is taken off and is used for making seats of chairs. The core of the stem is then split into several thin pieces and rounded off, when it is ready for making baskets.

To whatever use the rattan is put, it must be first decorticated and scraped. If it is desired to bend or plait it, it is softened in hot water, to which is added muriatic acid. Thick rattan is bent with light saw cuts, as is done with ordinary mouldings.

The output of the factories of this region is mostly consumed in the neighbouring territory and sold to wicker workers residing therein; the balance is purchased by Paris and a few London firms.

There are only two important and well-known rattan factories in this consular district which do a very good business.

Raw rattan, taken on board vessels in French ports, sells as follows: First quality \$15.44, and second quality \$13.51, per 100 kilograms (220,46 pounds.)

[The following are the species of *Calamus* (which belongs to the Palm family) found in Ceylon: 1, *C. Thwaitisii*; 2, *C. Pseudo-tenuis*; 3, *C. Rotang*; 4, *C. Rivalis*; 5, *C. Delicatulus*; 6, *C. Radiatus*; 7, *C. Pachystemous*; 8, *C. Digitatus*; 9, *C. Zeylanicus*; 10, *C. Ovoidens*; all of which except the second (also found in India) are endemic.]

CLASSIFICATION OF USEFUL FIBRES.

(Continued.)

The surface fibres are still more varied in form. They may be the elongated hairs surrounding the individual pods which contain the single seeds of

the thistle, familiarly known as thistledown, or they may be the hairy growths covering the clusters of seeds contained within large pods, as the cotton boll, the pod of the milk weed, or the seed envelope of species of *Bombax* found in tropical countries. In this group also is placed the leaf-scales or tomentum found on the under surface of leaves, &c., or on the leaf buds of both endogenous and exogenous plants, which can only be used for upholstery or as tinder. Epidermal strips of palm leaves, raffia being an example, are also included with the surface fibres.

The pseudo fibres are not fibres but substances used as their substitutes. However, they are so clearly defined in the scheme of classification, it will not be necessary to describe them further or to give examples.

The highest use for which a fibre may be employed is in the manufacture of cloth or woven fabric. As these fabrics vary greatly in texture from the fineness of the delicate linen cambric to the coarseness of jute bagging, it would seem that a large number of fibres might be considered spinnable forms and capable of manufacture. In point of fact, however, a comparatively small number are actually spun and woven as commercial articles, these having proved their superior adaptability for special purposes for which they are employed, and the form and appearance of the different manufactures from them having become in a measure so fixed that change could not be made without serious result. And, besides, it should be recognised that such change might necessitate complete change in the entire system of textile machinery employed in a special industry. Examples of the fabric fibres of the first rank are China grass (bast fibre), pineapple (structural fibre), and cotton (surface fibre); of the second rank, jute (bast fibre) and coir or coconut (structural fibre). The fabric fibres are, therefore, easily disposed of, and we come to the next of the higher uses in which fibres are employed, the manufacture of threads, twines, cords, and ropes, or, reduced to a term, cordage. The fibres employed for this group of manufactures include all the spinning and weaving fibres, which for the most part are employed in the manufacture of thread and fine twines, and a large number of coarser fibres, which also have their substitutes, for the manufacture of which ordinary systems of cordage machinery are generally adapted. In this group must also be included a still larger number of "native" fibres, or those which are extracted, prepared, and rudely spun or wrought into ropes by hand by the natives of the countries where they are produced, the finer kinds being used for sewing thread, fish lines, nets, and hammocks. Even the group of native fibres used for cordage is capable of subdivision into prepared fibrous material for spinning and twisting, and unprepared bark, or the whole stems or leaves of plants or bundles of unprepared bast, simply twisted together to form a very rough rope or cable. Such cordage has been largely used in South America and in India in the construction of rope bridges. Examples of the cordage fibres are: Commercial—for threads, flax (bast fibre); for twines, common hemp (structural fibre); Native—for fine twines, fish lines, &c., Indian hemp (or *Apocynum*) (bast fibre); for ropes, the *Yucca*

(structural fibre); for binding and rough sewing material, spruce roots (woody fibre); and for fish lines, kelp or sea-weed, used in Alaska and other high norther latitudes (pseudo fibre).

The third use is the preparation of certain tree basts that are extracted from the bark in layers or sheets, and which, by pounding, are made into rough substitutes for cloth. Such cloth has long been used by the natives of the Pacific Islands, and is known as *Tappa* or *Kapa*. Other forms, such as the *Damajagua* of Ecuador, are used in South America as cloth, while similar fibrous bast is employed in India in its primary form for sacks, &c. In this group are also included the more delicate tree basts that are extracted in thin lace-like layers and known as lace-barks, as well as other forms of which the cigarette bast or Cuban bast is an example. Certain close-textured fibrous growths from palm trees, when they may be secured in thin sheets, likewise come into this category.

A fourth use is in the manufacture of brushes and brooms for which a different class of fibres are employed than either the fabric or cordage fibres. The first essentials of a brush fibre are toughness and stiffness, qualities found in many of the fibres from Endogens, and the brush fibres, therefore, especially the commercial species, are largely derived from palms. Grasses and grass roots are also used, while the best substitute for animal bristles is a species of Agave, the fibre-vascular bundles of which are large, smooth, rigid, and cylindrical. The most important commercial brush fibres derived from palms are noted as Piassaba or Bass, of which there are several forms from as many different species. An American example of palm brush fibre is found in the finished product from crushed and softened palmetto leaf stems. Coarser brush material consists of twigs or small stems of woody plants, or even of splints of wood, while the aborigines and "natives" use anything that has the requisite stiffness, from a bunch of grass to the small branches of bushes tied together. Examples of commercial brush fibres are Tampico from *Agave heteracantha*; Piassaba or Bass, from *Attalea funifera*, a palm; and broom root, from the roots of *Epicampes Macroura*, a Mexican grass.

The fifth group of uses comprises plaited or coarsely-woven manufactures of articles employed in the domestic economy, some of which are of commercial importance, while the greater number are "native" productions. The materials used are the whole stems of weeds, rushes, or grasses, palm leaves, coarse tree basts, &c., wrought or plaited together in the simplest manner possible. Some of these articles may be enumerated as follows:—Mats and mattings, screens, wallets, bags, saddle cloths, sandals, hats, toys, chair seats, and basketry in endless form.

Examples of the commercial manufactures are the Japanese mattings from the mat rush (*Juncus effusus*), the Russian mattings from the bast of the linden tree, the finely-subdivided leaves of *Carbudovica palmata* for panama hats, and the split stems or straw of wheat, rye, barley, and rice for braids or straw plait, all of which are structural fibres save the Russian bast. Examples of "native" or aboriginal manufacture are the

sleeping mats from various sedges or grasses, the East Indian *tattees* and screens from the fragrant roots of the khus-khus; the split leaves of Yucca used for making sandals, and the rain-coats of China and Japan.—*Useful Fibre Plants of the World.*

THE DIFFERENT FORMS IN WHICH NITROGEN IS UTILISED BY PLANTS.

If we follow the example of Boussingault and plant a sunflower seed in a sterile soil to which the necessary mineral matter and increasing amounts of nitrates are added, or if we repeat the experiment of Hellriegel and plant barley in well-washed sand to which sufficient mineral matter and increasing amounts of calcium nitrate are added, we shall find that the crop produced increases with the amount of nitrate added. In Hellriegel's experiments less than 1 gm. of dry matter was produced when nitrates were not added, the production of dry matter increasing to 25 gm. when sufficient nitrates were supplied.

These experiments, however, simply demonstrated in an exact manner facts which were already well known in practice. The consumption of nitrate of soda would never have reached its present enormous proportions if farmers had not learned to appreciate the efficacy of nitrates as a fertiliser. At the present time they enter into all fertiliser formulas. The application of this fertiliser is necessary, because we are not yet able to so control nitrification in the soil that it can be made to furnish sufficient nitrates for the demands of the crop at exactly the time in the spring when they are most needed. Nitrates are produced only in warm and moist soils, and they are found in the drainage water in larger proportion in autumn than in any other season. Fortunately the roots of living plants have great capacity for retaining the nitrates, and thus reduce the loss in drainage.

If wheat roots are drawn from the soil during the winter, dried and soaked in sulphate of diphenylamin, they will take on a deep blue colouration. The amount of nitrates contained in wheat roots is surprisingly large. The author has found as much as 1 per cent. in dried roots, but the proportion decreases as growth advances. They pass from the roots to the stems and then to the leaves, where they are used in the formation of albuminoid substances. It might be a matter of surprise that substances which are so easily soluble in water as the nitrates can nevertheless be taken up and retained by roots even when surrounded by moist soil. Demoussy has shown that nitrates can not be removed from the roots by washing in cold water, but are extracted when the roots are treated with warm water or when they are subjected for some time to an atmosphere of chloroform and then washed with cold water. It appears, therefore, that the nitrates penetrate by osmosis into the interior of the cells and form unstable combinations with the protoplasm, resuming their normal state only when the protoplasm is modified by elevation of temperature or the action of chloroform.

Experience has shown that whether nitrates are formed in the soil by the action of micro-organisms, or introduced in the form of fertilisers, they exert a decided influence upon the crop. Nitrates are not formed in soils like those of meadows or forests, which are highly charged with decaying organic matter, since these soils are acid and therefore do not furnish a suitable medium for the nitric ferment. Liming renders such soils more favourable to the activity of the nitric organisms.

In meadow and forest soils nitrogen appears to be taken up by plants in the form of ammonia. Bréal has shown that nitrogen is also taken up by plants in the form of humates of lime or potash.

Hellriegel has shown in experiments with barley fertilised with variable amounts of nitrates that the amount of water transpired by the plant per gram of dry matter increases as the amount of nitrates applied decreases. Barley, which received the most favourable amount of nitrates, evaporated 260 gm. of water per gram of dry matter produced. The plants which received no nitrates and which made a sickly growth evaporated from 700 to 800 gm. of water per gram of dry matter. Normal, vigorous plants obviously evaporate more water than sickly ones, but if we calculate the ratio of the quantity of water transpired to the weight of dry matter produced we find that the proportion is greater in the sickly than in the vigorous plants. This fact may be useful in determining the efficacy of a fertiliser.

By pursuing this method of investigation the author found that the Gramineæ and Leguminosæ do not take up and utilise plant food in the same manner. The Gramineæ are especially benefited by chemical fertilisers, particularly nitrates, while they do not utilise humus substances to very great advantage. On the other hand, Leguminosæ are more benefited by the humates than by nitrates or ammonia salts.

Rye grass and clover were planted in large pots, each of which contained 50 kg. of soil exhausted by continuous cropping. Equal amounts of phosphoric acid, potash, and nitrogen were applied. In one case the nitrogen was applied in the form of nitrates, in the other in the form of humate. A black extract from manure which contained a mixture of humate of potash and humate of ammonia was also used. At the end of the experiment it was found that the rye grass which had received no manure had transpired 682 gm. of water per gram of dry matter, that which had received humates 435 and 469 gm., and that which had received only chemical fertiliser 233 gm. The results were quite different with clover. In this case the transpiration was: without manure 454 gm., with chemical fertilisers 398 gm., and with humates 272 and 265 gm. These results confirm the conclusions of Bréal, Snyder, and Lawes and Gilbert. The latter have shown at Rothamsted that it was impossible to grow clover continuously on the same land unless the soil was abundantly supplied with organic manures.

To summarise, then, nitrogen is taken up by plants in the form of nitrates, ammonium salts, and alkaline humates. The Leguminosæ can utilise free nitrogen only when it has been brought into combination by the action of the organisms of the root tubercles. It has frequently been

claimed that other plants besides the Leguminosæ are capable of absorbing free nitrogen, but it has been shown that this absorption does not take place without the intervention of the organisms which fix nitrogen.

THE BANANA AS AN ARTICLE OF FOOD:

[SPECIALLY TRANSLATED FOR "INDIAN GARDENING" FROM THE *Belgique Coloniale*.]

In the Congo country, and in almost all tropical countries, the Banana constitutes an important resource of food for European and native alike. Hardly is a new station or village formed than a Banana plantation is started to ensure, after a brief period, food in abundance.

The Banana is very nutritious and forms almost a complete sustenance; it contains more than 25 per cent. of assimilable organic matters. According to Humboldt, it is 48 times more nutritious than potatoes; and according to Crighton Campbell, the apostle of the diffusion of the Banana in America, it is 28 times as nutritious as the best wheat bread.

The negroes occasionally consume Banana meal, which they prepare in an altogether primitive manner. They dry the fruits and pound them in a mortar. Placed in jars or sacks, away from damp, this meal remains good for a long time. It is also very nourishing and used especially on journeys. A very healthy and refreshing drink is made from it. In Central America, Columbia and Venezuela, Banana meal is made on a great scale.

For the preparation of Banana meal the fruit is stripped of its skin and cut in rounds, which are placed in a drying apparatus. After it is completely dry, it is ground and passed through a sieve. The production of meal is from 20 to 25 per cent. An amount of raw material 15 lbs. in weight gives 3 lbs. of meal.

In order to obtain more exact ideas of the nutritive value of Banana meal, Dr. Thoms, Director of the Laboratory of Pharmaceutical Chemistry at the University of Berlin, has analysed it. It contains 1.455 per cent. of nitrogen, corresponding to 9.01 per cent. of nitrogenous matter. In consequence, the nutritive value of Banana meal is very great and sensibly approaches that of the best wheat flours, which do not contain more than 9 to 11 per cent. of nitrogenous matter. For the manufacture of meal, it is preferable to use fruit which is not altogether ripe, as the starch which is contained changes to sugar in a measure as it arrives at maturity. For the rest, the following results of analysis show its value abundantly:—

	Unripe Bananas.	Ripe Bananas.
Water	... 70.92	67.78
Starch	... 12.06	Traces
Grape Sugar	... 0.08	20.47
Cane Sugar	... 1.34	4.50

In Venezuela Banana meal is specially given to children; it is recommended also to aged persons, convalescents, to wet nurses and to all who suffer from disorders of the stomach.

According to the *Tropenpflanzer*, Banana meal is put to the following uses in Central America and Venezuela, where it is sometimes sold under the name of *Musarina*.

1. *Atol comun.*—A spoonful of *Musarina*, a small cup of milk, a little sugar and salt. After dissolving the meal and sugar separately in a little water, the ingredients are mixed together, and after baking (*cuisson*) for a few minutes, the salt is added.

2. *Atol tonico.*—The same preparation, water being substituted for milk; a little cloves, cinnamon, aniseed, fine herbs, or orange may be added.

3. *Chocolate or cocoa.*—A small spoonful of *Musarina* is mixed with a cup of chocolate or cocoa to facilitate digestion of these beverages, and to render them more nutritious; in this fashion also feeble stomachs may be habituated to cocoa.

4. *Sopa salada.*—A spoonful of *Musarina* dissolved in cold water is added to a cup of broth and left for some minutes; a few spices may be added.

5. *Cordial.*—The yolk of an egg is beaten up and mixed with 30 grammes (about 1 oz.) of sugar and one spoonful of *Musarina* dissolved in a cup of milk. A little powdered cinnamon may be added.

6. *Postre.*—Three well beaten eggs, 250 grammes ($\frac{1}{2}$ lb.) of sugar, the rind of a citron, 125 grammes ($\frac{1}{4}$ lb.) of *Musarina* dissolved in a cup of milk; mix, adding 30 grammes (1 oz.) of butter and place in an oven in a buttered shape.

Torta à la sarten—Sixty grammes (2 oz.) of *Musarina*, a well beaten egg, a cup of milk, a little salt, and a small spoonful of butter; mix and cook.

Banana meal may be utilised also in the same manner as the "superior" flours, except for the making of bread, the Banana containing no gluten.

Banana meal is delivered at the London market at 27 livres per ton (ex warehouse at the London docks); but the sale is insignificant owing to the high price and the ignorance concerning the employment of the product.

The day may perhaps come when Europe will have, like America, its Crichton Campbell to devote himself to the diffusion of the Banana as an article of food.

GENERAL ITEMS.

Rinderpest has broken out in more than one part of the Island. In Colombo there have been but few cases so far, but the disease appears to have appeared with greater virulence upcountry, in the neighbourhood of Talawakele and Nanuoya, and both the Government Veterinary Officer (Mr. Hoole) and Veterinary Surgeon Chinniah have been in requisition in these districts, where the latter has been carrying on preventive inoculation. We trust that with the change in the weather the outbreak will soon disappear.

Professor Farmer, of the Royal College of Science, South Kensington, has been appointed assistant to Dr. Watt, Reporter on Economic Products to the Government of India, to which post it is expected he will succeed on the retirement of Dr. Watt.

It will astonish not a few to hear of buttons made of milk, but this is no hoax, as the following from the *Queensland Agricultural Journal* will prove:—Those creamy-looking white buttons which you see street hawkers in London offering you at twelve for a penny, one of which you may wear on your shirt collar, are made of milk. The milk is that which has become sour at the large dairies. It is sent to three large manufactories in the East End of London, and there churned very much after the manner of making cheese, into buttons. This cheese is then put under enormous pressure until every drop of moisture is wrung from it, when it is passed into a chemically heated room. It is then, while under great heat, bleached white and flattened out, ready to be punched into the required shapes. It is found that buttons can be made in this way at less than half the cost entailed in manufacturing bone ones, and, besides never rubbing away, do not turn their colour.

The watering of live stock is an important part of the farm work. But, while all animals on the farm require more or less attention in this particular, none need it more than the cow giving milk. Many farmers fail to realise the importance of giving their milch cows all the pure water they require both winter and summer. The amount of water a cow will drink depends upon the kind of feed she is getting. Where roots or ensilage is fed the amount of water is considerably lessened, because there is a considerable amount of water in these feeds. Cows, as a rule, require more water during the winter than during the summer when on fresh pasture, and a cow in a full flow of milk requires a great deal more than one not in milk. In fact, a cow cannot give the very best returns in the milk pail unless she is liberally supplied with drinking water. Several experiment stations in the United States have tested this question with somewhat varying results. At the Copenhagen station it was found that seventy-six cows required an average of 97.9 lb. of water per day, or about 12 gallons each. At the Pennsylvania station it was found that cows averaging 733 lb. in weight confined in stalls in the summer and living on fresh grass drank 61 lb. each per day, while confined in stalls at a temperature of 73 degrees and fed on dry grass they drank 107 lb. According to Professor Henry, cows, generally speaking, require about 4 lb., or half-a-gallon of water to each pound of dry matter in their food. A New York authority says that provision should be made for eight gallons a day per cow in order to be sure of a full supply. At the Geneva station it was found that cows in full milk required $4\frac{3}{4}$ lb. of water for every pound of milk. It follows, therefore, that the heavier the milk the larger the amount of water is necessary.—*Scottish Farmer*.

The *Queensland Agricultural Journal*, quoting the following from the *Danish Milk Times*, says:—The question has been asked: Ought milking to be done in quick or slow tempo? To answer this a series of trials have taken place in Germany, one of which we herewith publish. On the farm where the trials took place were the same lot of cows—five in number—alternately milked by an elderly woman, who milked very slowly, and by a very able young milkmaid, who finished her work in a very much shorter length of time. The following figures gives the milk-yield from the same

number of cows—milked at the same time of the day—in pounds:—

No.		Slow Milking.		Quick Milking.
1	...	32	...	38½
2	...	34½	...	51½
3	...	50	...	68½
4	...	40½	...	43
5	...	44½	...	50

As an explanation of this enormous difference it is said that, by the quick milking, the milk-glands were influenced so as to give a larger quantity of milk.

No. 12.

A SKETCH OF THE HISTORY OF INDIAN BOTANY.*

BY SIR. GEORGE KING, K.C.I.E., LL.D., M.B., F.R.S.

(Concluded from page 731.)

THE preservation in good condition of a type specimen is therefore, from the point of view of a Systematic Botanist, as important as is the preservation to the British merchant of the standard pound weight and the standard yard measure on which

the operations of British commerce depend. 'Types' also stand to the Systematic Botanist much in the same relation as the national records do to the national historian. The latter are guarded in the Record Office, I understand, with all the skill which the makers of fire-proof, damp-proof, and burglar-proof depositories can suggest. If, however, the type of a species happens to be deposited at Kew, what are the probabilities of its preservation? Such a type at Kew is incorporated in what is admitted to be in every sense the largest and, for its size, the most accurately named, the most easily consulted, and therefore the most valuable Herbarium in the world, the destruction of which would be a calamity commensurate in extent with that of the burning of the Library at Alexandria. One might therefore reasonably expect that a people who rather resent being called a 'nation of shopkeepers' would feel pride in providing for this priceless national collection a home which, although perhaps somewhat inferior to that provided for the National Historical Records, might at least be safe from fire. This expectation is not fulfilled. The infinitely valuable Kew Herbarium and library have no safer home

than an old dwelling-house on Kew Green, to which a cheap additional wing has been built. The floor, galleries, and open inner roof of this additional wing are constructed of pine coated with an inflammable varnish, and on the floor and galleries are arranged cabinets (also made of pine-wood), in which the specimens (which are mounted on paper) are lodged. The provision of a fire-proof building, capable of expansion as the collections extend, is surely not beyond the means of an exchequer which last year netted over one hundred and six millions sterling of revenue. On behalf of the Flora of India, I venture to express the hope that the provision of a proper home for its types may receive early and favourable consideration by the holders of the national purse strings. But India is by no means the only portion of the Empire interested in this matter, for the types of the Australasian Floras, those of a large part of the North American Flora, and those of many species inhabiting countries outside British rule or influence, find their resting-place at Kew. The safe custody of the Kew Herbarium is, therefore, not merely a national, but a cosmopolitan responsibility.

In this address I have hitherto made little reference to Cryptogamic and Economic Botany. As regards Cryptogamic Botany there is a little to relate. Except Griffith, no Indian Botanist of the earlier of the two periods into which I have divided my sketch ever did any serious work amongst non-vascular Cryptogams. During the second period two men have done gallant work under difficulties which no one who has not lived in a tropical country can thoroughly appreciate. I refer to Drs. Arthur Barclay and D. D. Cunningham. The former made some progress in the study of Uredinous fungi, which was cut short by his untimely death, while the latter, in addition to his bacterial and other researches connected with the causation of human disease, conducted protracted investigations into some diseases of plants of fungal

* From the Report of the Sixty-ninth Meeting of the British Association for the Advancement of Science held at Dover in September, 1899.

or algal origin. Some of the results of Dr. Cunningham's labours were published in the 'Transactions' of the Linnean Society, and in a series entitled the 'Scientific Memoirs, by Medical Officers of the Indian Army.' To the 'Annals of the Botanic Garden, Calcutta,' Dr. Cunningham also contributed elaborate memoirs on the phenomena of Nyctitropism, and on the mode of fertilisation in an Indian species of *Ficus* (*F. Roxburghii*). There is no doubt that in the past Cryptogamic Botany has not been studied in India as it ought to have been and might have been. This discredit will, I hope, be soon removed; and I trust that, by the time the twentieth century opens, a Cryptogamist may have been appointed to the staff of the Calcutta Botanic Garden. The collecting of Cryptogams was not, however, altogether neglected in India in time past. For, from materials sent to England, Mitten was able to elaborate a Moss Flora of India, while Berkeley and Browne were enabled to prepare their account of the *Fungi* of Ceylon. Dr. George Wallich, in whom the Botanical genius of his father burnt with a clear though flickering flame, did some excellent work amongst Desmids, and was among the earliest of deep-sea dredgers.

Economic Botany has, on the other hand, by no means been neglected. It was chiefly on economic grounds that the establishment of a Botanic Garden at Calcutta was pressed upon the Court of Directors of the East India Company. And almost every one of the workers whose labours I have alluded to, has incidentally devoted some attention to the economic aspect of Botany. Roxburgh's 'Flora Indica' contains all that was known up to his day of the uses of the plants described in it. Much of Wight's time was spent in improving the races of cotton grown in India. The Botanists of the Seharunpore Garden during the middle of the century were especially prominent in the branch of Botanical activity. Royle wrote largely on cotton and on other fibres, on drugs, and on various vegetable products used, or likely to be of use, in the arts. These Botanists introduced into the Himalayas more than fifty years ago the best European fruits. From gardens which owe their origin to Royle, Falconer, and Jameson, excellent apples grown in Gharwal and Kamaon are to-day purchasable in Calcutta. Peaches, nectarines, grapes, strawberries, of European origin, are plentiful and cheap all over the North-West Himalaya, and are obtainable also in the submontane districts. Potatoes, and all the best European vegetables, were introduced long ago; and at Seharunpore there is still kept up a large vegetable garden from which seeds of most European vegetables are issued for cultivation during the cold season in the gardens of the various regiments of the Queen's troops quartered in Upper India. More or less attention has been given in the past by Government Botanists in India generally to the improvement of the cultivation of flax, hemp, rhea, tobacco, henbane, dandelion, vanilla, sarsaparilla, coffee (Arabian and Liberian), cocoa, ipecacuanha, aloes, Jalap, indiarubber, Japanese paper-mulberry, cardamoms, tapioca, coca, tea, and cinchona. Only to three economic enterprises, however, have I time to allude in any detail. These are (1) the cultivation of tea, (2) the introduction of cinchona, and (3) the formation of the Forest Department. But before proceeding to the consideration of these I wish to give a short account of the inauguration of the office of Reporter on Economic Products. Up to the year 1883 there had been no special Government department in India for dealing with questions connected with the natural products of the Empire. Whatever has been done prior to that date (and the amount was by no means unimportant) was the result of isolated and uncoordinated effort. In 1883 the Government of India founded a department for dealing with the Economic Products of the Indian Empire, and under the title of Reporter on these products they were fortunate enough to secure Dr. George Watt, a member of the Bengal Educational Service. Dr. Watt is an accomplished and able Botanist. He has collected Indian plants largely, and has made

numerous notes both in the field and in the bazaar. The great work which, on the initiative of Sir Edward Buck, Secretary to the Department of Revenue and Agriculture, and of Sir W. Thiselton Dyer, of Kew, Dr. Watt began and carried to a successful termination was the compilation of his 'Dictionary of Economic Products,' in which valuable book is collected all that is known of almost every Indian product, whether vegetable, animal, or mineral. The study of Economic Botany is now pursued in India as part of a highly specialised system of inquiry and experiment. Dr. Watt has a competent staff under him in Calcutta, one of whom is Mr. D. Hooper, well known for his original researches into the properties of various Indian drugs. Dr. Watt has arranged in Calcutta a magnificent museum of economic products, and there is no doubt the economic resources of the empire are now being studied with as much energy as intelligence.

Tea cultivation is one of the enterprises in the introduction and development of which Botanists took a very leading part. The advisability of introducing the industry was first pressed on the attention of the East India Company by Dr. Govan (of Seharunpore), and in this he was seconded by Sir Joseph Banks as President of the Royal Society. Royle in 1827, and Falconer slightly later, again urged it as regards the North-West Himalaya. In 1826 David Scott demonstrated to rather unwilling eyes in Calcutta the fact that real tea grows wild in Assam. In 1835 Wallich, Griffith, and McClelland were deputed by Government to visit Assam, to report on the indigenous tea. In the year 1838 the first consignment of Indian-grown tea was offered for sale in London. The consignment consisted of twelve chests containing 20 lb. each. This first sample of 240 lb. was favourably reported upon. Last year the exports of tea from India to all countries reached 157 millions of pounds, besides 120 millions of pounds exported from Ceylon.

The introduction of cinchona into India originated purely with the Government Botanists. As everybody knows quinine, and to a less extent the other alkaloids present in cinchona bark, are practically the only remedies for the commonest, and in some if its forms one of the most fatal, of all Indian diseases, viz. *malarious fever*. The sources of supply of the cinchona barks in their native countries in South America were known to be gradually failing, and the price of quinine had for long been increasing. The advisability of growing cinchona in the mountains of British India was therefore passed upon Government by Dr. Royle in 1835, and he repeated his suggestion in 1847, 1853, and 1856. Dr. Falconer, in his capacity of Superintendent of the Botanic Garden, Calcutta, made a similar suggestion in 1852; and his successors at Calcutta, Dr. T. Thomson and Dr. T. Anderson, in turn advocated the proposal. In 1858 Government at last took action, and, as the result of the labours of Sir Clements Markham and Sir W. J. Hooker, of Kew, the medicinal cinchonas were finally, in the period between 1861 and 1865, successfully introduced into British India—on the Nilgiris under Mr. McIvor, and on the Sikkim Himalaya under Dr. T. Anderson. Various experiments on the best mode of utilising the alkaloids contained in red cinchona bark resulted in the production in 1870 by Mr. Broughton, Quinologist on the Nilgiri plantation, of an amorphous preparation containing all the alkaloids of that bark. This preparation was named *Amorphous Quinine*. Somewhat later (1875) a similar preparation, under the name of *Cinchona Febrifuge*, was produced at the Sikkim plantation by Mr. C. H. Wood, the Quinologist there; and of these drugs about fifty-one tons had been distributed from the Sikkim plantation up to the end of last year. The preparation of pure quinine from the yellow cinchona barks, so successfully grown in the Sikkim plantation, long remained a serious problem. The manufacture of quinine had hitherto been practically a trade secret. And when the Indian Government had succeeded in providing the raw material from which a cheap quinine might be made for dis-

tribution amongst its fever-stricken subjects, the knowledge of the means of extracting this quinine was wanting. Philanthropic platitudes were freely bandied about as to the intensity of the boon which cheap quinine would be to a fever-stricken population numbering so many millions. But there was a singular absence of any practical help in the shape of proposals, or even hints, as to how quinine was to be extracted from the rapidly increasing stock of crown and yellow bark. The officers in charge of the cinchona plantations in India had therefore to their best to solve the problem for themselves. And it was ultimately solved by Mr. C. H. Wood, at one time Government Quinologist in Sikkim, who suggested, and Mr. J. A. Gammie, Deputy-Superintendent of the plantation there, who carried into practice a method of extraction by the use, as solvents of the cinchona alkaloids, of a mixture of fusel-oil and petrolenn. The details of this process were published in the 'Calcutta Official Gazette,' for the benefit of all whom it might concern. Very soon after the introduction of this method of manufacture the Government factories in Sikkim and the Nilgiris were able to supply the whole of the Government hospitals and dispensaries in India with all the quinine required in them (some 5,000 or 6,000 pounds annually), besides providing an almost equal quantity for the supply of Government officers for charitable purposes. The latest development of the quinine enterprise in India has been the organisation of a scheme for the sale at all the post-offices, in the province of Bengal, and in some of those of Madras, of packets each containing five grains of pure quinine, that being a sufficient dose for an ordinary case of fever in a native of India. These packets (of which some are on the table for distribution) are sold at one pice each, the pice being a coin which is equal, at the current rate of exchange, to one farthing sterling!

In conclusion, I wish to make a few remarks on the third great economic enterprise connected with Botany in India, viz. the Forest Department. The necessity for taking some steps to preserve a continuity of supply of timber, bamboos, and other products from the jungles which had for generations been exploited in the most reckless fashion, was first recognised by the Government of Bombay, who in 1807 appointed commissioners to fix the boundaries of and to guard the forests in that Presidency. This scheme was abandoned in 1822, but was resumed in a modified form during 1839-40. Seven years later a regular forest service was established in Bombay, and Dr. Gibson was its first head. Dr. Gibson in turn was succeeded by Mr. Delzell—and both were Botanists. In the Madras Presidency the first man to recognise the necessity of perpetuating the supply of teak for ship-building was Mr. Connolly, collector of Malabar, who in 1843 established a teak plantation at Nelumbur, which has been carried on, and annually added to, down to the present time. In 1847 Dr. Cleghorn (a Botanist) was appointed to report on the conservation of the forests of Mysore (which contain the well-known sandal-wood), and the following year Lieutenant Michael (still with us as General Michael, a hale and hearty veteran) was appointed to organise and conserve the public forests in Coimbatore and Cochin. The crowning merit of General Michael's administration was the establishment, for the first time in India, of a system of protection against the fires which annually used to work such deadly havoc. In 1850 the British Association, at their Edinburgh Meeting, appointed a Committee to consider and report upon the probable effects, from an economic and physical point of view, of the destruction of tropical forests. This committee's Report was submitted to the Association at the Meeting at Ipswich in 1851. The weighty evidence collected in this Report so impressed the Court of Directors of the East India Company that, within a few years, regular forest establishments were sanctioned for Madras and British Burma, the two main sources of the supply of teak.

In 1856 Mr. (now Sir Dietrich) Brandis was appointed to the care of the forest of the latter province. These forests had been the object of spasmodic efforts in conservancy for many years previously. In 1827 Dr. Wallich reported on the teak forests, and five years later a small conservancy establishment was organised, officered by natives. This, however, was kept up for only three or four years. In 1837 and 1838 Dr. Halfer reported on these forests, and an English conservator was appointed. In 1842 and 1847 Codes of Forest Laws were drawn up, but do not appear to have been enforced to any extent. In 1853 Dr. McClelland was appointed superintendent, but he continued to hold the office for only a short time. A few years after Sir Dietrich Brandis's assumption of the charge of the Burmese Forests, he was appointed Inspector-General of all the Government Forests in British India; and it is to him that we owe for the most part the organisation of the Indian Forest Department as it now exists. That organisation includes two Schools of Forestry (in both of which Botany is taught), one in connection with Cooper's Hill and the other at Dehra Dun in Upper India. The latter has for many years been under the direction of a gentleman who is distinguished both as a Forester and as a Botanist. In the Cooper's Hill School, the higher grades of Forest officers received training; at Dehra Dun those of the lower grades receive theirs. The officers of the Department on the Imperial list, according to the latest official returns, now number 208, divided into the grades of conservator, deputy-and assistant-conservator, with a single inspector-general as chief. In the addition to these, there are 566 provincial officers, ranking from ranges upwards to extra deputy-conservators.

Botanists took a leading part in moulding the department in its earlier years; for, as already stated, its pioneers—Gibson, Balzell, Cleghorn, Anderson, Stewart, and Brandis—were all Botanists. And to most people, who give even casual attention to the matter, it appears fitting that the possession of a knowledge and liking for Botany should form a strong characteristic of officers, whose main duties are to be in the forest. And this belief did for some time exercise considerable influence in the selection of recruits for the department. But, except in the Dehra Dun School, it does not appear to guide the department any longer. For example, at the Entrance Examination to the Forest School at Cooper's Hill only three subjects are obligatory for a candidate viz. mathematics, to which 3,000 marks are allowed; German, to which, 2,000 are allowed; and English, for which 1,000 are given. Botany is one of the nine optional subjects of which a candidate may take up two, and in each of which 2,000 marks may be made.

Botany is taught at Cooper's Hill, and (according to the Calendar of the College) it forms one of the 'special auxiliary subjects' for the Forest student. I do not wish to say a single word in depreciation of the Botanical teaching at this College, which is probably excellent of its sort. I do not know what value, as part of their professional equipment, students are accustomed or encouraged to attach to the possession of the means of acquiring a knowledge of the trees and shrubs in the midst of which they are to pass their lives in India. But this I do know, that the ordinary Forest officer educated in England now arrives in India without sufficient knowledge to enable him to recognise from their Botanical characters the most well-marked Indian trees. To tell such an officer the name of the natural family to which a plant belongs conveys no information to him whatever, for he knows nothing of Botanical affinities. Moreover, the Forest officer after he has arrived in India is not encouraged to familiarise himself with the contents of the forests under his charge. This will be better appreciated by giving an example than by any number of remarks. Some three years ago, Mr. J. S. Gamble (a Forest officer) published a monograph of the Bamboos of British India. From bam-

boos, as you may possibly be aware, a very large amount of Forest revenue is annually derived. The sales of Bamboos for the year 1896-97 amounted to no less than 110 millions of stems. A great number of the species of bamboos have the curious habit of flowering gregariously at remote intervals of thirty or forty years, and the flowering is followed by death. The absence from the forests for years in succession of flowers of a number of the species, and the similarity of many of them in leaves, had hitherto made members of the group most difficult of identification. Mr. Gamble had devoted himself to their study for many years. He had carefully examined all the previously collected materials stored in the Herbaria at Kew, the British Museum, Calcutta, and elsewhere; and large special collections had been made for him by Mr. Gustav Mann and other officers of Government. Moreover, he had General Munro's great paper in the 'Linnean Transactions' as a basis. Mr. Gamble's work was undertaken with the full approval of Sir Joseph Hooker, who indeed accepted Mr. Gamble's account of the bamboos for his 'Flora of British India.' Mr. Gamble's monograph is illustrated by a life-sized drawing of each species, with analyses of the flowers on a large scale. When completed, the book was published as one of the volumes of the 'Annals of the Calcutta Botanic Garden.' In consideration of the supposed great importance of the book to the forester, and in the belief that the copies would be eagerly taken by the Forest Department, an extra hundred copies were printed, and these hundred copies were put into stout canvas binding suitable for camp use. These copies, or as many of them as he cared to take, were offered to the Head of the Forest Department in India at the reduced price of fifteen rupees per copy. The result was an official refusal to buy a single one, although the purchase of the whole hundred (which was not asked for) would have cost only fifteen hundred rupees—a sum which would have reduced the revenue of the year by about one twelve-thousandth part! An appeal against this ruling having been made to a still higher authority, a modified order was subsequently issued permitting such Forest officers as desired to possess the book to buy copies and charge the cost in their office expenditures. I may state that the book was not a private venture. It was produced at the expense of the Government of Bengal.

It is not because I like to play the censor that I have made these remarks about the Forest Department. Having myself served in it from 1869 to 1871, I can speak from my own experience as to the value, from the utilitarian point of view, of a knowledge of the names, affinities, and properties of the trees, shrubs, and herbs which compose an Indian jungle, and of a knowledge of these as individual members of the vegetable kingdom rather than as masses of tissue to be studied through a microscope. The appointment which I held in India for twenty-six years after leaving the Forest Department gave me full opportunity of getting into touch with all who interest themselves in a knowledge of plants, and of discovering how few of these at the present day are Forest officers. The majority of the latter, if they love their trees, are content to do so without knowing their names or relationships! There are, of course, splendid exceptions who know as well as love. The general decadence of the teaching of Systematic Botany in England during the past twenty years is, perhaps, to some extent, the cause of the low estimation in which the science is held by the authorities of the Indian Forest Department. Twenty-five years ago Systematic and Morphological Botany, no doubt had too great prominence given to them in the teaching at universities and colleges of this country, and the other branches of Botanical science were too much neglected, although I do not think they were despised. Now it appears to me that Systematic Botany is too much neglected. I hope it is not also despised! Few of the systematists who survive in England are now to be found attached to the universities. They are

mostly clustered round the two great Herbaria in London; and such of them as have to look to Systematic Botany for the means of livelihood are not in the receipt of salaries such as one might reasonably expect in one of the richest countries in the world!

NOTES OF A CAMP ON THE PERIAR DAM, TRAVANCORE.

SPORT WITH BISON & C.

6th April.—Count Teleki and self left Stazbrook Estate at 1:30 p.m.; arrived at Carradygoodie Estate at 3:30 p.m.; stayed the night with Mr Leany.

7th April.—Left at 6:30 a.m.; reached Thakady, the head of the Periar dam, at 6:30 a.m.; got on the steam launch at 11 a.m., and steamed down to the dam itself, which we reached at 1 p.m. The dam is still full of standing timber; it covers 16 square miles of water. We put up at a bungalow kept for use by the Engineers, and found our servants and stores all safely housed. The launch then returned, leaving a jolly boat and a canoe for our use. We started out at 3 p.m. and rowed some 2 miles, landed, and after some walking I saw a herd of 14 Bison with a very fine bull. I made the stalk ahead of the Count and got within 50 yards of them and waited for Count Teleki to come up; by the time he arrived they were about 200 yards away. He fired at the bull with his 577, hit him, but he got off into thick Eta jungle, and getting dark we had to give him up but expect to find him dead later on. Got back to camp at 7:15 p.m.

8th April.—The Count had a blistered foot, so I started alone at 5:30 a.m. below the dam down the river bed and went in the direction of Placard Estate. About 7 a.m. I came suddenly on a large solitary bull in long grass about 25 paces off. I fired with the 10 bore and hit the base of the horn; he then charged but I was slightly above him, and had no difficulty in bringing him down at close quarters. He proved a splendid beast, and having a measuring tape with me I took the following measurements:—Height from foot to wither in straight line 76 inches; spread of horns 41 inches; between tips 27 inches; girth of horn at base 22 inches; neck from 18 inches below ear 95 inches; length from nose to rump 11 foot 7 inches. After lunch I saw a herd of 5 Bison, and after a difficult stalk came up to them in long grass, but unfortunately came right on a young cow who gave the alarm, and I could not get a shot at the bull; so returned to Bungalow about 6 p.m. pretty well tired out.

9th April.—The Count and myself got up at 4 a.m. and left at 5 a.m. in the jolly boat and rowed up the right arm of the dam under the guidance of a "Mannam" villager called "Lord George." We then climbed and walked about 2 miles when I saw with my glasses a solitary bull. The Count got within about 200 yards and fired with his 577, wounding him; he then got into a small piece of Eta jungle; I ran to far end to stop him with my Estate Kanganv named Assnrwathen, and the bull came very close to us and snorted, but I could not see to fire. Mr. Assnrwathen threw away my small rifle and threw himself into the Eta tearing off the lobe of his year. He crawled out and swore the bull had put his horn through it. Meanwhile the bull had tried to get back at other end of the Eta jungle, where Count Teleki was waiting, and he finished him off at 100 yards. This bull measured 37 inch, spread, 21 inch between tips, and 17 inch girth of horn at base. We tried on until 4:30, when a heavy thunder-storm came on, so we returned to camp very wet at about 6:45 p.m.

10th.—The Count's foot was bad again, so I started by myself at 5 a.m., landed at 5:45 walked until 8, when I saw a herd of Bison, but they got our wind and went into jungle, did a good deal of walking, but saw nothing else. Returned at 7 p.m.

11th.—Left at 5 a.m., rowed about one and a half hour, and then walked for about half an hour. We got close to 6 small sambar at different places, then we came on fresh Bison tracks, which I proceeded to explore, leaving the Count sitting down. I tracked them into a small piece of jungle, perhaps 200 acres, and then wrote to the Count to join me. Just then I heard a shot and found the Count had shot a stag, but with a poor head. We waited all day for the Bison to come out, but the shot had disturbed them and they never appeared. I took a round about 4-30 p.m. in the hopes of seeing them, and the Count took the direct cut to the boat. I saw nothing, but the Count came on a single Bison which he thought was a bull and shot, when, much to his disgust, it proved to be a large cow. We had hardly got in the boat when a terrible thunder-storm came on—one of the worst I have ever been out in. We arrived back drenched to the skin and found letters with English mail.

12th April.—Got up late for first time at 6 a.m. and wrote letters till 9 a.m., when the steam launch came by arrangement and took us up to head of lake to a place called Malowpara, which we reached soon after noon, walking from river to camp about one mile. We found a small native hut made of Eta, which we bought from the owner for servants and stores and put up my tent. About 3 p.m. I went out alone and climbed a hill about 2 miles away, and while stalking a big stag with but a poor head I saw 3 bears on a rock in some long grass about 400 yards away. I tried to get near them, but though not frightened, they got in the grass and I could not see them, so gave them up and finished the stalk of my stag which I shot dead. Reached camp about 6 p.m.

13th April.—Left with the Count at 5-30 a.m. and walked till 7-15, when I saw a fine solitary bull below me. Waited for the Count and gave him the shot, which he took at quite 200 yards, and dropped him dead in his tracks. He measured: Spread 36 inch; between tips 25 inches, girth of horn 19 inch, height at wither 74 inch, nose to rump 10 feet 6 inch, neck 90 inch, girth of nose 26 inch. After this I went for a long climb after Ibex but found none, but came on eight hinds and one large stag, I could not get nearer than 250 yards. Fired and wounded him in foreleg, but he got away into Eta jungle.

14th April.—Count Teleki was so shaken by a fall he had yesterday he could not come out. I left at 5 a.m., and 5-30 saw a long way off a herd of Bison, 15 in all. After a very stiff climb at 7-10 a.m. I was under a ridge over which they were feeding. I had only about 50 yards to complete my stalk when I saw two cows' heads over the cliff looking at me, and they immediately gave the alarm and I could hear them running. I had to run up the ridge and managed to get a shot at the bull, but I was so out of breath. I shot and hit him in the back. He got away into a steep jungle, and though I followed for some time I had to give him up. I then walked till 11 in another direction, but saw nothing except a stag that got our wind, and returned at 4-30 p.m. very tired.

15th.—Went out at 5-30 a.m. in a heavy mist which did not clear until 7-15. The Count was unable to come. I climbed the big Ibex hill, having seen one buck Ibex, but after a long tiring climb came on two female Ibex who gave the alarm, and I never got a shot. On way home saw and shot a hind sambar as we wanted meat for the camp, the Man-nams not eating Bison flesh.

16th.—The launch came for us and we reached the dam again about 11 a.m. I went out alone below dam and heard two tigers move off the carcass of my first Bison, but could not see them. Saw fresh tracks but no Bison. Coming home saw 12 hind sambars. Returned to camp at 7-15 p.m.

17th.—We got up at 3-30 a.m. by moonlight, left at 4-30 a.m. and round up lake, landing at 5-30 a.m. After half an hour's walk came on Bison tracks, and shortly afterwards a herd of 11 with 2 bulls.

Gave Count Teleki the stalk, and he got one barrel at and wounded a fine bull, who went into thick Eta jungle. I followed him alone till 8-30 a.m., when I came up to him on my hands and knees and shot him dead with my 10 bore. He proved a big beast, 11 foot 6 inch nose to rump, tip to tip 21 inch, spread 36 inch girth of horn 19 inch. Got back to camp at 2 p.m.

18th.—Left at 4-35 a.m. and got to a place known as Upu Para at 6 a.m. After an hour's walk disturbed 3 bulls together, no cows with them; they went off over some hills about 1½ miles. I took the stalk, and about 7 a.m. came up with one on edge of an Eta shola in long grass. Had to fire at 200 yards with small 500 rifle and wounded beast in foreleg. He moved into the jungle; at same moment a big tiger came bounding down the long grass. I seized the 10 bore and had two shots, but missed him. In same time as it takes to write the other two bulls came running down the same ravine in the long grass, and I got one of them with my 500 rifle. On going up to him I heard the tiger growling, but could not see him. I then began to follow bull No. 1, who made off up the shola in the direction of where I had left Count Teleki, who saw him come out with a broken leg and fired at and hit him with his sight up at 300 yards, but he got away into thick Eta jungle almost impenetrable and of large dimensions, and we never got him, but hope to get his head later on as he is bound to die.

19th.—The Count was feeling unwell, so I went alone. Tramped till 10-20 from 5-30 a.m. and saw nothing; then again from 1 p.m. till 4 p.m., when I heard elephants in some jungle below me. Went round and came on them feeding in short grass about 4-45 p.m. I got within 100 yards and took a snap-shot with my kodak. Then they fed close up to me, but the tusker, a fine beast, kept behind, and as the herd was unpleasantly close I had to fire at 90 paces at him. Hit him twice in the head but missed the brain, and he got away; blood and water tracks, but I could not get him. Hope I may yet find him dead and get his tusks.

20th.—Returned to Carradygoode Estate—a 16 mile ride—and slept there; next day rode 14 miles and arrived home for breakfast.

H. DRUMMOND DEANE.

AGRICULTURAL EDUCATION IN GREATER BRITAIN.

PAPER READ BEFORE THE FOREIGN AND
COLONIAL SECTION OF THE SOCIETY OF ARTS, ON
TUESDAY FEBRUARY 27, 1900.

BY R. HEDGER WALLACE.

(Continued from page 136.)

"In the province of Quebec there are several smaller agricultural schools in different parts of the province, the most important of which is located at Compton, Quebec, in connection with an experimental farm.

"A School of Agriculture has been in operation at Truro, Nova Scotia, associated with an experimental station, for ten or twelve years past, and in the same province a School of Horticulture has been in operation for the past three or four years at Wolfville, N. S.

"2. *Other organisation.*—Other agencies which also render valuable help in this connection are Dairy Schools, Travelling Dairies, Farmers' Institutes, Live Stock and Dairy Associations, Fruit Growers' Associations, Poultry Associations, and Agricultural and Horticultural Societies. These are all maintained or assisted by the several provinces, by annual grants, and there are many of such organisations in every province. The members connected with these associations, &c., meet from time to time to discuss matters relating to the branches of agriculture they represent, and the more important papers read at such meetings are published by the provincial governments, and distributed, free of charge, to farmers who desire to receive them.

DOMINION AIDS TO AGRICULTURE.

"The progress of agriculture in Canada has been greatly stimulated by the organisation and maintenance of experimental farms by the Dominion Government. Five of these farms have been established in different parts of the Dominion. This work was begun in 1887, the institutes being so located as to tender efficient help to the farmers in the more thickly settled districts, and at the same time to cover the most varied climatic and other conditions which influence agriculture in this country. The Central experimental Farm is situated at Ottawa, near the boundary line between Ontario and Quebec, where it serves as an aid to agriculture in these two important provinces. A site for one of the four-branch experimental farms was chosen at Nappan, Nova Scotia, near the boundary between that province and New Brunswick, where it serves the purpose of the three maritime provinces. A second branch farm has been established at Brandon, in the central portion of Manitoba; a third at Indian Head, a town in Assiniboia, one of the North-West Territories; and a fourth at Agassiz in the Coast climate of British Columbia.

"At all these farms, experiments are conducted to gain information as to the best methods of preparing the land for crop, and of maintaining its fertility, the most useful and profitable crops, to grow, and how the various crops grown can be disposed of to the greatest advantage. To this end experiments are conducted in the feeding of cattle, sheep, and swine for flesh, the feeding of cows for the production of milk, butter, and cheese and of poultry both for flesh and eggs. Experiments are also conducted to test the merits of new or untried varieties, of cereals and other food crops, of grasses, forage plants, and trees and samples particularly of the most promising cereals, are distributed freely among farmers for trial, so that such as promise to be most profitable may be rapidly brought into general cultivation. New varieties of cereals and fruits are also produced by cross fertilising and selection.

"At the Central Experimental Farm there is a scientific staff engaged in solving such problems as may arise in connection with the chemistry of Agriculture, the diseases to which cultivated plants and trees are subject, the ravages of insect pests and the spread of noxious weeds. Experiments are also conducted in the planting of trees for timber and shelter and in the testing of ornamental trees, shrubs and plants.

"An annual report is published containing particulars of the work done at each farm, and the report is sent, free of charge, to every farmer in the Dominion who ask for it. The annual edition now required to meet the demand is 60,000. Occasional bulletins on special subjects of immediate importance are also issued from time to time as required. A large correspondence is conducted with farmers in all parts of the Dominion, who are encouraged to ask advice and information from the experimental farms in reference to all questions affecting their calling. Farmers are also invited to visit the various farms, and inspect the work in progress. The officers attend many of the more important gatherings of farmers in different parts of Canada, at which opportunities are afforded of giving fuller information regarding the work conducted and the results achieved from year to year."

As noted by Dr. Saunders, the province of Quebec has several small agricultural schools or colleges. For instance, the schools and farms, three in number, belonging to the Corporation of the College of St. Ann's, Richmond, and L'Assomption, have each but one regular professor—that on agriculture. There are many schools also at which the pupils receive lessons in agriculture and horticulture, such as, for example, that at Roberval, Lake St. John, and at the Monastery of the Good Shepherd, Montreal. In the province of Quebec more also has been done in the way of editing and publishing text-books in various

departments of agriculture than in any other province.

Turning now what might be termed the sister province Ontario—I find that though between 1870 and 1898 five text-book on agriculture for use in Ontario public schools have been published, yet the Deputy-Minister of Agriculture, speaking in 1898 before the Provincial Teachers' Association, is reported to have said that an interesting discussion might be made on the subject of why the trustees of rural, public schools in that province have not insisted upon having instruction given in agriculture. The five text-books in question referred to are one by Dr. Ryerson, one by Professor Henry Youle Hind, one by Sir Wm. Dawson, the "first Principles of Agriculture," by Dr. Mills and Professor Shaw of the Guelph College, and "Agriculture," by the Deputy-minister for Agriculture himself. The text-book coming from the Guelph College, I may add, seems to be regarded as the "most perfect and complete text-book of agriculture" published in Canada. In the technical schools also in this province instruction in agriculture may be given, and a special feature of the School of Mining and agriculture at Kingston—an institution affiliated to Queen's University is the dairy school under the control of the provincial government. As Dr. Saunders points out, the best known institution in Canada is the Ontario Agricultural College at Guelph, which is also affiliated with the provincial university. The course of study at this institution is one of two years for the diploma, which admits to the status of "Associate of the Ontario Agricultural College," with a further course, for associates only, of an additional year which qualifies for the degree of B. S. A. (Bachelor of the Science of Agriculture). The subjects embraced in the two years' course of study are the following:—English and political economy, drawing and book-keeping, mathematics, physics, and mensuration; agriculture, including stock-breeding and rearing, and dairying; horticulture, including fruit-growing, vegetable gardening, and forestry; chemistry, agricultural, and analytical; botany, geology and zoology; economic entomology and bacteriology. Those who remain for the third year have to take a general course in English, agriculture, chemistry, geology, and botany and one special course either in agriculture, dairying, horticulture, biology, bacteriology or chemistry, and physics. A feature of the training the college provides is that the students have to devote their afternoons to practical work outside; from one to five in the winter and one to six during the rest of the year, while during the summer term all students in attendance are required to work at least 10 hours per day and receive pay. Another feature is the scale of tuition fees. All residents of the Province of Ontario who are farmers' sons, or can produce evidence that they have served one year at least on a farm, are charged \$20 a year, and those of this class who cannot produce satisfactory evidence of this are charged \$30 a year. Outside students, that is, from the other provinces or from foreign countries who can show satisfactory evidence that they have served at least one year on a farm are charged \$50 a year; but if they cannot produce this and have had, therefore, simply an urban training, they are charged \$100 for the first year and \$50 for the second year. This scale recognises, in a practical form, that more care and labour has to be spent in teaching a youth entirely unacquainted with the practices and processes of agriculture, than in teaching one who has already gained only a slight familiarity with them. This college has also a dairying course which lasts for three months, and short special courses in various branches of practical work, which can be taken as convenient.

Before leaving the Dominion of Canada it might be as well to note that in the graded schools of Nova Scotia agricultural chemistry is taught in the rural schools in the summer in the second year. Of the two schools in this province mentioned by Mr. Saunders, it may be of further interest to add that

Mr. Mackay, the Superintendent of Education for the province, made the following report in 1897:—

"The Provincial School of Agriculture at Trinro, established in 1885, has now two instructors, in addition to the manager of the farm. The attendance in 1896 was 81 for full and special courses, besides the 141 students taking the Normal school special courses. The school has conveniences for the practical study of agriculture and horticulture and dairying. The school building proper is fitted up with qualitative and quantitative chemical laboratories, a dissecting room, biological laboratory and apparatus, reading-room, and technical library. Under the annual inspection of the School, there are five local agricultural schools in the charge of graduates, who also conduct, in affiliation with the agricultural work, the ordinary public schools of the section.

"The Provincial School of Horticulture at Wolfville was established in 1893, by the Fruitgrowers' Association, with the aid of an annual grant of \$2,000 from the Provincial Government. The attendance in 1896 was 67."

In the Province of Manitoba, a course of agricultural instruction has been laid down and a text-book prepared adapted to the conditions of that province. In British Columbia agriculture has been introduced and made a compulsory part of the curriculum in the schools. There seems also to be a movement in New Brunswick, to have there an Agricultural College affiliated to the Provincial University—and where students may take advantage of certain courses of lectures likely to be helpful to them. All the provinces also employ, from time to time, specialists to go round and lecture in different parts of the country, especially on noxious insects, or "bugs," as they are usually termed.

Leaving the Dominion of Canada, I pass on to what claims to be our oldest colony—Newfoundland. In reply to my inquiries, the Minister of Agriculture in this colony states that he regrets—

"That to all your queries I have to answer in the negative. Agriculture is not taught in any of our schools, we have neither farm schools nor agricultural colleges, neither have we any lecturers nor experiment stations. The Government of this colony appointed a Commission last year to inquire into Agriculture and Industries, and in their report they recommend the adoption of nearly the whole of the methods of agricultural education above mentioned, and I hope that in the near future many of them will be carried into effect".

The Government however, I find, issues reports dealing with agricultural subjects, and Mr. Moore states that there is an Orphanage at St. John's where the boys are instructed in agriculture as well as in various trades.

The Report of the Commission referred to by the Minister of Agriculture states, I find, that agriculture in Newfoundland is not as yet sufficiently advanced to warrant the Government in establishing special institutions, such as agricultural colleges, farming schools, model farms, and experimental stations, but it recommends instead, "that a modicum of agricultural instruction be imparted in our present schools, and under our present educational system." It is also recommended that the "high schools should undertake to teach an elementary course in agricultural chemistry," and that "in the colleges of the colony should be taught more fully than in the schools already enumerated the technic of agriculture, and a more advanced knowledge of agricultural chemistry." The Commissioners "further recommend that the theoretical knowledge imparted in the schools be supplemented by instruction given by travelling professors or teachers."

It must be borne in mind, with respect to Newfoundland, that though the agricultural resources of the colony are considerable, yet, in the past, they have been neglected, as the staple industry hitherto has been the fisheries.

Leaving in turn Newfoundland I now come to the West Indies. Here the economic conditions must be

first studied and understood. I have to acknowledge my own indebtedness to Sir William Thiselton Dyer, the Director of Kew Gardens, for having pointed out to me the scope of the work undertaken in the West Indies in regard to agricultural education, and for having placed at my disposal much of the information embodied in this paper. The aim and object of the agricultural instruction organised in the West Indies appears to be to change the system of cultivating crops on large estates or plantations by a coloured race directed by a few of a white race, to that of small areas owned, directed, and worked by the coloured race themselves, it being accepted as proved that under present economic conditions plantations and the planting system of agriculture is a failure. It is to bring about this change, as far as I can gather, that the present educational policy as regards agriculture in the West Indies is directed.

It must also be borne in mind that the agriculture to be taught here differs from that of other portions of the Empire—Canada for instance—in being tropical. If a reference, for example, be made to Dr. Alford Nicholls' "Text book of Tropical Agriculture," published by the Government of Jamaica in 1891, it will be found that the following crops are treated, *i. e.*, coffee, cacao, tea, sugar-cane, orange, lime, banana and plantain, coconut, pine-apple, nutmeg, clove, pimento, cinnamon, ginger, cardamom, pepper, vanilla, tobacco, cinchona, castor oil, coca, Jalap, sarsaparilla, anatto, turmeric, logwood, indigo, maize, rice, guinea-corn, cassava, arrowroot, yams, and sweet potatoes; and these are all new to the farmer of Britain or Canada. Some of the tools used are also new to one acquainted simply with temperate agriculture, for instance, the digger or earth chisel and the cutlass.

IS SUGARCANE A PROFITABLE CROP?

TO THE EDITOR, "INDIAN GARDENING."

SIR,—I have carefully perused your article on the above subject. Your conclusions seem to be based on the result of experiments carried on in the Government Farm in Cawnpore. In the absence of any detailed statement of expenses and returns, it is impossible to check the correctness of the figures *viz.*, ₹910, the total proceeds of the crop, and ₹3,004 representing the total cost of cultivation, which shows a loss of ₹2,094 on the working, which is in other words, a loss of 66 per cent., a very high percentage indeed! This is a result which can only be possible in a Government farm, and no where else. The farms under the Bengal Agricultural Department, however, show better results. If you read the reports of the Sibpur and Bardwan farms you will seldom find such a disastrous result as referred to by you. These farms generally pay the cost of their cultivation of all crops and sometimes show large profits on particular crops.

I have been engaging myself in the pursuit of agriculture for the last seven years, and although my cultivations, especially of certain crops, have been mostly of an experimental nature, I have during this period never suffered such a loss.

I experimented in sugarcane cultivation with very little loss, as will be seen from the appended copy of statement, which I submitted to the Director of Land Records and Agriculture, Bengal, for comparison with the results obtained in the farms under his Department. Of course, the result was far from encouraging but the loss was chiefly attributable to the free distribution of canes and juice, which is customary in the mofussil, and which in my case was greater, owing to there being no other cane growers in my place that year. My expenses also were rather heavy and above normal, and so susceptible of some reduction.

I am fully convinced, and my conviction has been established by long years of experiment, that the cultivation of Sugarcane is sufficiently remunerative, al-

though the margin of profit may not be large enough in comparison with crops like paddy, jute and potatoes.

Yours faithfully,
JOGENDRA NATH MITRA
Proprietor, Pioneer Agricultural Farm,
Ajhapur.

(Sd.) JOGENDRA NATH MITRA.

CALCUTTA, 25th February 1895.

[NOTE].—We have much pleasure in publishing the above, as it goes to show that agricultural experiments are conducted by the sons of the soil in an intelligent spirit of enquiry. Our figures were taken as a whole from the report on the Cawnpore Experimental Farm for 1898-99. The detailed figures will be found at page 12 of the report. Here are the figures for one plot, 968 square yards:—Rent, R12; ploughing, R6-4; manures, R13-5-3; wages of weighing, carting and spreading, R2-8; seed, R68-14; wages of sowing, R4-12; weeding, hoeing, etc., R18-14-6; irrigation; canal dues, R3 5-4; labour, R14-2; cutting, crushing and gur-making, R189-7-3; total, R338-8-10; estimated price of gur per acre, R151-9; loss, R181-15-10. It is added that "the actual price of gur sold in the market, including commission of the auctioneer at 5 per cent., has been distributed according to the outturn of gur from each plot."—ED. I.G.]

SUGAR CULTIVATION IN AUSTRALIA.

The cultivation of sugarcane is largely carried on in the northern coast districts of New South Wales, where soil and climate are admirably adapted for that purpose. In a recent issue of the *Agricultural Gazette*, published by the New South Wales Department of Agriculture, some details of the cutting and latter processes of the industry are given, and sugar-planters in the West Indies and India may thus compare these with their own methods. As regards cane-cutting, it is said a gang of good men can each cut, top, and load about six tons of cane a day. After the cane has been hauled to the nearest mill, of which there are several, the largest being owned by the Colonial Sugar Refining Company, which virtually has control of the Australian sugar supply, it is taken to the carrier—a great endless belt made

of wooden battens—about 5 feet wide, running from a sort of trough to the shredding and crushing machinery. On each side of the trough a cane laden dogger is moored, and men throw the canes evenly on the belt, which revolves slowly, and is at times stopped to prevent checking of the shredding appliances. As the cane is carried up it is toppled on to the shredder, and falls from there, commingled with water, on to a crusher. The juice flows away beneath, and the woody matter is elevated to a macerating tank, and again passed through powerful rollers, which crunch out the last possible vestige of juice. Then the megass is carried away by means of an elevator to a loft from which it is fed—down shutes—to the furnaces, which it assists in feeding. The juice from the rollers pours down channels—The stream from the first crushing being far more copious than from the second—and into a reservoir, whence it is raised to vats in the next storey. Here it is heated to boiling-point, and lime is added to precipitate organic matter mechanically suspended in the juice. A quantity of waste matter is also cast to the surface, and this is skimmed off by the men in charge of the vats. After a couple of skimmings, the hot juice runs into the subsider, a huge vat on the ground floor. It is left in the subsider a little while to enable any dirt to settle down to the bottom. Meanwhile, the refuse from the skimmings and precipitation, with a little more lime added, is passed through the filter presses, contrivances in which enormous pressure is effected by means of screw turned by wheels. The presses are not unlike concertinas in construction, and at each bugle or segment there is a tap—a regular regiment of taps—opening over a little gutter, from which any juice extracted runs into the subsider. The residue is a dark, slightly moist mass of material, called filter-press muck, which, on account of the lime it contains in the first place, and of the organic matter, is a comparatively useful fertiliser and source of soil humus. The juice is taken from the subsider to the evaporators (on the top floor). These are huge vats, in which the juice is raised to boiling-point again, with the object of driving off in the form of steam, the water that has been added in maceration and is contained in the juice itself. The juice (or solution as it is called) goes into the evaporator at a certain temperature to an appliance for determining the density or percentage of sugar, and passes through a series of four evaporators. In each evaporator there is a sort of window, in which the solution can be observed boiling furiously. On emerging from the fourth and last evaporator the solution has become a fairly thick syrup, and is passed up into the vacuum pans and afterwards to the centrifugals. When cooled the sugar is removed to a funnel, through which it passes in a brownish yellow stream into bags holding about two hundred-weight each. Each bag is sewn up with twine, each mill employing a distinctive colour, and shipped to the refineries in Sydney, from which it finds its way into every part of the Southern Hemisphere.

CHINA TEA: A HOPEFUL OUTLOOK.—In his report of the Foreign trade of China in 1899, Mr. Taylor, the Statistical Secretary at Hong-kong, states that the black tea export trade is reviving, in spite of the hold of Indian and Ceylon teas on the English market. Mr. Taylor derives comfort, not dissatisfaction, from comparison of Chinese and Indian exports. If, he says in effect, India with her excellent roads, her railway system, and her light taxation, can show a total export trade three times the size of China's, has he not reason to be optimistic about the future of China, larger in extent, naturally richer, inhabited by a more numerous and more industrious population, when she shakes off the burden of a lack of roads, absence of railways and a crushing taxation?—*Pioneer*, April 27.

PERAK SUGAR CULTIVATION CO., LD.

(From the address of the Chairman, Mr. W. V. DRUMMOND, March 14th.)

A new concession of 5,600 acres was in 1894 offered to this company and the directors agreed to take it over for the sum of \$1,000. The land was reported as being excellent for sugar cultivation. It adjoined the company's estate and was situated on the banks of the Gula-Kalumpang Canal, the rights over which the directors were anxious to acquire as being a means of supplying the estate with fresh water from the Kurau river. The acquisition of the property also secured the company against the formation of a rival estate situated on its borders, which might seriously complicate the estate labour question. Between 1894 and the present time a sum of slightly over Tls. 12,000 has been spent in quit rents, survey fees, clearing jungle and opening up the land, and against this outlay we have received. Tls. 7,300 (\$10,000) for about one-third of the property—an outlying block on which nothing had been spent and which the company would not have been able to utilise for several years, if at all. As you will see from the accounts the sum of Tls. 4,828-89 now stands as an asset in

THE BALANCE SHEET

representing a property of 3,500 acres, of which about 800 acres have been cleared of jungle, 28 acres have been planted with canes, 21,000 feet of drainage, navigation and boundary canals, and over 10,000 feet of drains have been dug. A small bungalow for a foreign overseer, and buildings sufficient for the accommodation of 250 coolies have been erected.

With regard to the development of this property, you will remember that the company is under certain obligations to the Perak Government. A *bona fide* commencement to cultivate had to be made within twelve months from the date of the lease (30th June 1896). This condition has been complied with—further, at least one-fourth of the whole area must be in cultivation at the end of ten years, that is by 30th June 1906: otherwise the whole of the uncultivated portion of the land will lapse to the Perak Government. The directors have had before them for some time a scheme for the cultivation of sugar cane on this property for the manufacture of basket sugar. Basket sugar, or as it is sometimes called Muscovado, is a coarse kind of sugar which is used largely by the natives in the East and is also exported to Europe, where it is sold to refiners and brewers. It has been

CULTIVATED IN THE MALAY PENINSULA

for the last fifty years with success, but the cultivation has hitherto been in the hands of natives. There is a large local market for it and considerable quantities are shipped to England. The market for it is, we learn, practically unlimited. The adoption of a scheme for such cultivation involved the raising of new capital, and the financial position of the company has hitherto hardly warranted the directors in placing it before the shareholders. The financial position of the company has now however, undergone a considerable change for the better; the profits of last season paid a handsome dividend, besides placing a substantial sum to reserve, and the prospects for the current season are fully as good as, if not better than the last. At the same time the directors feel that any extension of the company's operations must be provided for by new capital, one of the great difficulties which the company has had to contend with in the past having been insufficient capital. This difficulty, in the earlier days of the company, necessitated the expenditure on capital account of a considerable amount of money out of the earnings of the company, and the borrowing of money at a high rate of interest. At the present time, however, the company is in possession of a fine property of nearly 2,500 acres in cultivation, and an up-to-date plant capable of earning good dividends on the capital. The manufacture of basket sugar possesses these advantages over the higher grade sugars, in that it requires much simpler and there-

fore much less expensive plant, it finds a ready market, and the profits calculated on a most conservative estimate are considerable. Moreover, with a comparatively

SMALL OUTLAY OF CAPITAL

the company is able to fulfil its obligations under its lease to the Perak government. The erection of a second factory will provide the means, in the event of a serious breakdown in the principal factory, of taking off the estate canes which might otherwise be lost through over-ripeness, or have to be sold at a great sacrifice to neighbouring estates. It is proposed to erect the factory in a central position as regards the whole property and to arrange it in such a way that at some future time, should it be deemed advisable, the vacuum pan and centrifugal process can be introduced without difficulty. It may interest you to know that other foreign companies working in the neighbourhood of our estate have also recently entered into arrangements for the manufacturing of basket sugar, which has been hitherto confined to native planters. An article in a recent issue of the International Sugar Journal, the principal organ of the sugar industry describes a plant, the first of several to be erected in the Straits for the manufacture of this product. The names of the promoters who are also largely connected with our successful neighbours in Province Wellesley, the Penang Sugar Estates Company are a sufficient guarantee of the soundness of the undertaking. The amount of capital which it is estimated is required to provide a factory and plant capable of crushing canes from 2,000 to 2,500 acres, and to open up an area of about 1,600 acres is roughly Tls. 75,000.—*N. C. Herald*, March 21.

THE "CUNDALL" OIL ENGINES.

Messrs. Brown & Davidson, of Talawakelle, have just brought out a new catalogue, with testimonials, of the patent oil engines, for which they are sole agents in Ceylon and Southern India. We must in the first place congratulate Messrs. Jordan of "the Lindula press" for the very creditable work in turning out this catalogue with its gold lettering and border on brown and dark cloth cover—all extremely neat and effective. We gather that the Talawakelle Engineering Firm is quietly effecting a notable work upcountry in superseding steam engines with the "Cundall" oil engine, and if it be true that the saving (in fuel &c.) is equal to one cent and upwards per lb. of made tea in many cases, we can readily see the great inducement, more especially in districts where fuel is scarce. In the book before us we see such thoroughly practical managers as Messrs. A. Cantlay, W. H. Morrison, Bowie, Rolland, Hudson, Peile, J. R. Jenkins, &c., all testifying to their great satisfaction with the new oil engines, there can be no doubt of success. We understand that the demand is now so considerable that there is a steady flow of the engines for orders to the island. To ensure proper erection and a good start, an assistant thoroughly acquainted with the engines was got out from Messrs. Cundall & Co., a circumstance which adds to the confidence of all using this special motor.

THE INDIAN FOREST DEPARTMENT.—The number of officers recruited annually in England for the superior branch of the Indian Forest Service will be raised from six to nine for the next few years, to meet the heavy losses the Forest Department has been sustaining from invaliding.—*Madras Mail*.

SPORT IN CEYLON:

SNIPE SHOOTING ROUND KANTHALAI LAKE,
TRINCOMALEE.

Kanthalai Lake is on the coach road between Kandy and Trincomalee, twenty-five miles from the latter place. The eastern portion of Ceylon is infinitely superior to Colombo in point of climate; the atmosphere is much drier, and there is none of that damp hot-house sensation that one experiences on the Western Coast. Kanthalai is excellent as regards climate, being not far from the Eastern Coast. It has the same dryness as Trincomalee, while for some reason or other it always appears to be a good deal cooler. The rest house is in a condition of hopeless dirt and decay; the erection of a new one a little east of the ancient site has been approved, but goodness knows when the work will be done. At present those who stay at Kanthalai must be prepared for a good deal of discomfort; strange reptiles, many of which bite virulently, abound. There are also piles of old tiles close to the bungalow, in which some cobras live; these are said to roam from room to room in the night, but as I was always fast asleep then, I cannot vouch for the accuracy or otherwise of this report. The dining room of the next house is a curiosity in the way of architecture. Imagine a large square space with a ramshackle roof over it with a bit of wall in front, and closed in behind, but open completely to the air and the poochies of heaven at the two sides. Here and there are crooked trunks of trees serving as pillars to prevent the ancient roof falling upon one. The floor is of concrete seamed with great irregular fissures as if by an earthquake; from these great cracks battalions of ants and other things march forth, to devour and destroy squads of geckos, chase each other and catch flies up and down the decaying walls, or drop from the roof with a plob on the floor. Down below gleams the lovely lake,

A MYSTERIOUS FAIRYLAND

bathed in mystic moonbeams. Looking over the moonlit water one dreams of the armies of workmen who built the great bund sixteen hundred years ago. Wonders how many thousands of lives the huge work cost, and then almost expects to see a procession of dusky Sinhalese flitting along the huge dam which they spent their lives over in those ancient days, when stately cities stood on sites which have since become pathless jungle. So utterly forgotten are those once beautiful temples that the villagers even are utterly ignorant of the positions of the ruins, and they are only discovered by the survey parties when mapping out the country. The Government surveyors often find forgotten tanks and ruins within a few miles of a village, of which the villagers themselves are completely ignorant.

There are

NO PROPER SHIKARIS IN CEYLON,

there are nocastes who dare leave the beaten tracks in the jungle; the mysterious forests which clothes so great a portion of this beautiful island are practically a sealed book. Anyone who has the time might with great profit to himself explore these jungles, and discover patches of open country where he could shoot to his heart's content, among echeetal and sambhur, which have probably never even heard the crack of a rifle. But I intended to

WRITE ABOUT SNIPE SHOOTING,

and I have stayed away to talk of deer. The coach road passes the resthouse running along the great bund for a couple of miles. Two or three

hundreds yards east of the resthouse there is a sluice by which the paddy fields below are irrigated. One can see the paddy fields from the bungalow, and a path leads straight down to them, so that one can reach their edge in a few minutes walking. Here and there among the paddy are small patches of bush, and by beating these one can nearly always get a few snipe out. The snipe go into the shade during the heat of the day, and if there happens to be a handy bush in the middle of the paddy some of them sit under it, in preference to betaking themselves to the big jungle round the edges of the cultivation. One can get very sporting shots by sending a coolie just inside the big jungle at the edge of the paddy, and instructing him to walk along making a noise parallel to the edge and about twenty yards inside. If the trees are large the snipe get very high up before they come out, and one gets high overhead rocketters of the most superior description.

Although the paddy just below the resthouse always holds a few snipe it is not worth taking seriously. Supposing one wants a few birds for the larder an hour or an hour and a quarter will be enough time to go down and get back again with two or three couple.

To get to ground where the snipe are numerous one follows the little stream which comes from the sluice, across the near paddy and then turns away to the right by a jungle path which after a walk of three-quarters of a mile brings one out in some old cultivation which is known locally by the name of the "Director's Paddy-fields." Here the snipe, though usually wild,

ARE AT ANY RATE PLENTIFUL.

In two hours shooting a couple of guns can easily get twenty or twenty-five couple, and of course if one stuck at it the whole day working the ground backwards and forwards systematically it would be easy to make a large bag. There are, however, snakes, as I discovered one day to my cost, and I would strongly advise any one shooting there to wear putties or gaiters, not stockings alone. I was shooting one day in short knickerbockers and socks with my legs bare. I had two snipe down near some bushes in long grass, and was looking for them. All at once I felt what I thought was one of those jungle ropes round one leg and glancing down saw I had a snake in a large loose coil round my bare leg. I gave one instinctive and very high jump, and the snake fell off and vanished at once in the grass. I did not see its head, but I am almost certain from the hurried glance I got of part of its body that it was a cobra. I never found the snipe which I had marked down to just about the spot where I encountered the snake, and it struck me afterwards that perhaps the snipe fell near the snake, and the snake bagged it and had it in its mouth when it was round my leg, and so did not bite me. I don't know enough about snakes to venture an opinion as to whether a snake would take a dead or dying bird which fell near it. This adventure gave me a lesson, and I never intend to shoot among long grass without putties again in any snake-infested country. Some of the shooting in the "Doctor's Paddy-fields" was among big trees spaced well apart, and was about as pretty as anything one could desire. The trees were not too leafy, and the chances one got at snipe as they zigzagged through the openings were quite ideal. One bad deplorable habit the Kanthalai birds have: When they are shot at a bit they make off to the thick jungle where one cannot get at them again: so it is a case of

"gathering the rose buds while ye may." I do think, by the bye, that the snipe shooter in Ceylon wants a choked gun, for on some days all the shots seem to be long ones, and I never found it the custom of the snipe anywhere to rise close to one's feet as they sometimes do in India. I used an "Ubique" which is three-quarter choked, as regards pattern, in both barrels, and found the possession of such a gun quite an advantage. I also tried an ounce of No. 8, but soon went back to one and an eight ounce, as you want all the shot you can use comfortably. We will now leave the "Doctor's Paddy-fields" remembering that it is there the heavy bags are to be made if any where, and visit one or two other spots round Kanthalai where one can always bag a few couple without difficulty. Across the lake, i.e. about two miles by boat from the resthouse, the shore is edged with short turf with here and there patches of reeds. In a few places one will find small bushes near the water which are moist and shady underneath. All about this part of the lake there are quite a number of snipe; they rise from the reeds or bushes and usually fly straight out over the water so that sometimes they fall where it is too deep to get them out. A boat should therefore be handy to recover dead birds, for Kanthalai abounds with fish-eagles which are always on the look out; and if a bird of any kind falls on the water and is not gathered at once, one of these ever-watchful osprey swoop down and carries it off in triumph. I lost one or two teal and several snipe in this way.

EAST OF KANTHALAI

and about a mile from it there is another tank, along the edges of which one can shoot a good many snipe. The best way to reach the place is to walk about five hundred yards along the coach road from the rest-house in the direction of Trincomalee, and then turn off to the left along the eastern shore of Kanthalai. A branch path to the right takes one away for the Kanthalai shore through a gap in the "women's bund" to the smaller tank. The "women's bund" is so called because it was built entirely by female labour; it skirts the eastern shore of Kanthalai and evidently the lake once was of considerably larger dimensions, as this bund is now at its nearest point about a hundred yards from the shores of the lake, when it is at its fullest.

The smaller tank is very irregular in shape, and has long stretches of grass here and there between the water and the jungle. This grass is in some places very high, and consequently the place is beloved of pig and wild buffalo, while deer are also to be got round its shores, the snipe are all round the edges of the tank, but there is one place in particular where the shooting is very pretty. This is along the south bank where the hill side rises jungle-clad almost from the edge of the water. Big forest trees, open underneath, grow near the tank and beneath their shade are stretches of damp cool earth. During the hot part of the day the snipe sit under these trees, and on one's approach they dash out from beneath over the tank giving the most charming shots. The walking as in fact all about Kanthalai

(INCLUDING THE "DOCTOR'S PADDY-FIELDS,") is quite easy, and one can shoot snipe under the most perfect conditions. You can go out in the early morning, bag a pig or cheetah, and then walking back round the edges of this tank shoot five or six couple of snipe, and then stroll back to the bungalow via

the "women's bund" under shade the whole way, in time for breakfast. Both Kanthalai and the smaller tank abound with teal but it requires a certain amount of engineering to make a bag. The jungles too swarm with pigeons of three kinds; one is the small green pigeon, the second is about the same size, but is brightly coloured with an orange breast; then there is a great big pigeon with a green back, and the rest of the body, with the exception of a rufous patch at the vent, dove colour. By sitting under one of their favourite fruit trees one can bag any number of these pigeons. The difficulty is of course to find a tree they resort to. In some places they can be shot fighting to and from the trees; but undoubtedly the best way of getting sport with them would be to use a small bore rook rifle, and shoot them sitting.

I killed about a hundred of them at Kanthalai, but most of them were killed sitting with a shot gun. I used to go and sit under a pigeon tree, and wait for pigeons when I had had a hard morning's work after deer, and felt too slack to tackle the snipe.

"FLEUR-DE-LYS."

—Asian, April 3.

CEYLON PIGS BUILD HUTS.

Mr. Gordon Reeves writes to the *Field* of March 17 as follows:—

In your issue of January 27th last, your correspondent, "H.H.O." describes a colony of pigs and their dwellings ("huts"). These pig-huts are well-known to sportsmen in the hill country of Ceylon, though I have never seen them in the plains, or heard of them there. They are commonly found, and more usually single, on the forest and jungle edges, where rank "mana" (lemar grass) is found, and are composed of this grass. When built in the forest itself, which is a more unusual procedure, they are generally composed of "nilla," a species of acanthus which forms the greater proportion of the undergrowth at elevations between 3,000 to 5,000 ft. Having been a constant observer and hunter of pig for the last twenty five years, I have on more than one occasion witnessed the building of a hut, and on both occasions the work demanded the attention of two pigs. One pig simply laid down, while number two grabbed up the grass by the roots and heaped it over the recumbent one. I cannot account for the fact that pig-huts in this country are more frequently found single. I have on occasion found colonies of three and four, but the almost invariable rule is a single hut. They are not built for family purposes, for, although I have occasionally turned out a single sow, I have much oftener found the huts to be tenanted by boars. Their occupation does not appear to last more than a day or two, and then only during wet weather. I have on one occasion known a wounded pig to take refuge in a hut. I had noticed the hut in the morning, and had also noticed that it was untenanted, owing to its shape. On following up my pig, I at once recognised, by the dome shape of the hut, that he had gone home.

E. G. REEVES.

Ratnatenne, Madulkele, Ceylon, Feb. 21st.

CLOSE OF THE INDIAN TEA SEASON.

Total quantity of Tea passed through Calcutta from 1st April to end of Season:—

	1b. 1899-1900.	1898-1899.	1897-1898.
Great Britain	149,374,164	135,381,722	133,782,962
Foreign Europe	1,435,146	1,171,146	797,313
America	5,923,404	3,273,096	2,086,369
Asia	5,492,815	6,972,251	3,601,532
Australia	8,250,433	6,393,002	6,802,579

Total 1b. 170,475,965 153,196,217 147,070,753

AGRA TEA COMPANY, OF CEYLON, LTD.

ANNUAL REPORT.

The Directors have the pleasure of submitting their report on the transactions of the Company for the year ending 31st December, 1899.

The acreage of the Company's property is as under:—

Tea in full bearing ..	197 acres.	
Tea in partial do ..	5 do.	
Tea not in do ..	30 do.	
		332 acres.
Forest ..		26 do.
Grass, waste land, &c.		9 do.

Total area 367 acres.

The estimated crop for 1899 was 160,000 lb. and the out-turn 167,880 lb., or a surplus of 7,880 lb. This crop realized R70,159.8 equivalent to 41.79 cents per lb., as against 45 cents in 1898. The expenditure on Sackarawatte, as shown in the accompanying accounts, was R45,138.63, or 26.89 cents per lb. as against 27.4 cents in 1898. The estimated crop for 1900 is 180,000 lb. tea to be produced at 28 cents per lb., which includes a liberal allowance for manuring.

The net profits on the working of Sackarawatte Estate amounted to R25,020.45, which, after deduction of R2,177.88 written off for depreciation of machinery, represented about 5½ per cent on the value of that property as shown in the balance sheet.

In accordance with the resolution of the shareholders, passed at the last general meeting, the 1898 profits, amounting to R14,111.03, have been transferred to the General Reserve Fund.

The net profits for the year 1899 amount to R14,722.12, out of which the Directors propose to pay a dividend of 3 per cent on 559 shares (R8,385.) leaving R6,337.12 to be carried forward to next account.

With regard to Kalkudah Estate, the Directors have made arrangements with the vendors for the latter to take back the property for the price paid by the Company, viz:—R60,000, plus the amount expended on it with interest at 4 per cent. Payment is to be made by the surrender to the Company of 120 fully paid shares, and the sanction of the Court has recently been obtained to the capital of the Company being reduced by the cancellation of such shares.

The Standard Life Assurance Co.'s mortgage over the Company's property has been reduced by £1,000 sterling, and the mortgage over Kalkudah released, a loan of R15,000 having been obtained for that purpose.

The condition of the Sackarawatte Estate is satisfactory as regards general appearance, cultivation, and crop prospects.

In terms of the Articles of Association Mr. John Symonds retires from the Board of Directors, but is eligible for re-election.

PITAKANDE TEA CO., OF CEYLON, LTD.

ANNUAL MEETING.

REPORT FOR 1899.

ACREAGE.

Tea in full bearing ..	500 acres	
Tea in partial bearing ..	260 do	
Tea not in bearing ..	240 do	
		1,000 acres
Cardamoms in bearing ..	44 do	
Cacao and Crotons in bearing ..	100 do	
Fuel Trees ..	40 do	
Forest and Grass Land ..	227 do	
Waste Land and Buildings, &c. ..	80 do	

Total area.. 1,441 acres

The Directors submit their report and accounts for 1898. The crop secured amounted to 553,130 lb. tea, being 143,177 lb. more than the yield in 1898. The net average price realized was 36.14 cts. per lb., whilst the cost f.o.b. was 23.916 including the cost of manuring or 18.400 cts. exclusive of this item. The average yield per acre was 727.775 lb. including all tea planted up to March, 1896. The cocoa and croton crops were disappointing, but the cardamoms exceeded expectations.

The net profit for the year including a balance of R440.05 from 1898 amounted to R69,588.51. Interim dividends aggregating 12 per cent have been paid, and the Directors recommend a final dividend of three per cent making a total of 15 per cent for this year, and that a sum of R23,000 be transferred to reserve or extension fund account as a set-off against capital expenditure, and that the balance of R88.51 be carried forward to next year's accounts.

In terms of the Articles of Association Mr. Robert Morison retires from the Board of Directors, but being eligible offers himself for re-election. The appointment of an Auditor for the current year rests with the meeting.

DRAYTON ESTATES CO., LTD.

REPORT FOR 1899

The crop secured from the Company's estates was:

Drayton	460,708 lb	increase	57,938 lb
Yuillefield	89,270 "	do	12,246 "
Cwm	35,452 "	do	3,660 "

Total 585,430 as against 560,000 estimated.

The following figures may be of interest to the Shareholders:—

	Acreage.	Yield per acre.	Average pruned.	Manured Artificial.	Manured Bulb.	Prunings buried with	Basic Slag
Drayton ...	769	599	421	233	64	300	
Yuillefield	218	419	86	60	—	—	
Cwm ...	90	391	48	—	—	—	
	Cost f.o.b. exclusive of Manure	Cost f.o.b. inclusive of Manure	Price per lb.	Profit per lb.	Profit per acre.		
Drayton ...	20.97	24.77	46.26	21.78	R180.46		
Yuillefield	26.34	28.98	45.00	16.79	68.76		
Cwm ..	25.32	25.32	45.26	21.03	83.17		

The total cost of 585,430 lb., exclusive of depreciation and Cwm rent, was 25,833 cts., against an estimated cost of 27,500 cts., and 657 acres were manured as against an estimate of 440 acres only.

Allowing 45 cts. per lb. for tea unsold, the nett value of whole crop will average 46.35 cts. or practically the same as last season, leaving a profit of 20.52 cts. as against 18.07 cts. in 1898 and 16.87 cts. in 1897.

On Drayton a new factory has been built 88 feet long by 48 feet broad, framework all of iron, with two withering lofts 88 feet by 36 feet. Machinery consists of a 9½ Oil Engine, 2 Economic Rollers, two Desiccators, and a Roll Breaker, cost complete, except as regards some factory fittings, was R31,483.64.

It has been used for withering purposes since May last.

A further sum of R4,241.35 was spent on lines, 34 new rooms having been built, and 44 rooms re-roofed with iron.

The Company's properties consist of:—

Drayton—Tea in Bearing	... 769 acres.
Grass Land	... 26
Timber	... 10
Forest	... 9
Waste and Roads	... 69
Yuillefield—Tea in Bearing	... 218
Forest and Timber	... 7
Waste	... 8

Total .. 1,116 acres.

The Estimated Crop for 1900 is:—

Drayton	.. 500,000 lb.
Yuillefield	.. 100,000
Cwm	.. 35,000

Total 635,000 lb., estimated cost 26 cents f.o.b

In terms of the Articles of Association Mr. H. Whitham retires from the Board by rotation, and, being eligible, offers himself for re-election as a Director. The Shareholders will be requested to appoint an Auditor for the current year.

A dividend of 10 per cent was declared, making 15 per cent for the year.

Mr. H Whitham was re-elected director.

Mr. H P Church was appointed auditor for the current year.

KELANI VALLEY TEA ASSOCIATION, LTD.

ANNUAL REPORT.

The Directors have the pleasure to submit to the Shareholders the Report and Accounts of the Company for the year ending 31st December, 1899. Since last Report Debentures for £850, which matured on 1st July last, were renewed for five years at 5 per cent. per annum. The total Crop from the Company's four Estates amounted to 575,255 lb, against 578,169 lb in 1898. The average price realised for the who Crop was 7d, against 6½d in 1898, and the average rate of exchange is 4 25-64d in place of 1s 4 19-64d in the previous year. There has been no alteration in the Company's acreage, details of which were given in the last Report.

The new factory for Wreagalla and Parusella has now been in use for some months, and the directors are pleased to say that the cost of production has thereby been materially reduced, and the quality of the tea is being improved. The planting of coconuts through the tea on Degalessa and Dover estates has been proceeded with, and Mr. Porter, on his recent visit to the estates, reported that they were looking well.

The directors have written 10 per cent off the cost of buildings and machinery for depreciation, and the amount, £1,098 1s 3d, appears in the accounts. The net profit for the year, after deducting the above sum of £1,098 1s 3d, written off for depreciation, amounts to £2,167 3s 3d, which, with £341 2s 7d brought forward from last account, gives £2,508 5s 10d to be now dealt with, and this it is proposed to appropriate as follows:—

Amount as above	£2,508 5 10
Interim dividend of 3 per cent (free of income tax on £18,765 paid in September)	£562 19 0
It is now proposed to pay a final dividend of 7 per cent (free of income tax) on £18,765 (making 10 per cent for the year)	1,313 11 0
To write off amount expended on new clearings, etc. in 1899	212 13 5
	2,099 2 5

Leaving a balance to carry forward of £419 2 5

In accordance with the Articles of Association, the Hon. D A C Scott retires from the Board, and, being eligible, offers himself for re-election. Mr. J B Laurie, C.A., offers himself for re-election as Auditor.

By the Articles of Association the Annual Ordinary Meeting has to be held each year in the month of April. In consequence of this limitation the Directors have been unable to convene the meetings as early as they would otherwise have done, and they now propose that the Articles should be altered so that in future the meetings may be held at such time as the Board see fit. For this purpose an Extraordinary General Meeting will be

held at the conclusion of the Ordinary Meeting, and formal notice of the Extraordinary Meeting accompanies this Report. G. W. PAINE, Chairman
16, Philot Lane, London, E.C., 21st March.

THE VELLIKELLIE TEA COMPANY OF CEYLON, LTD.
ANNUAL REPORT.

Presented at the Third Ordinary General Meeting of the Vellikellie Tea Company, of Ceylon Limited, held at the offices of the Company, 12, Fenchurch Street, London, E.C., on Thursday, the 29th March, at two o'clock. Your Directors have the pleasure of submitting their Report and Balance sheet for the year ending 31st December, 1899.

The yield of the Estates has been 234,200 lb. of which 218,755 lb. have been shipped to London, and sold at a net average of 8d per lb. The total yield of the Estates netted 7-75d per lb.

The acreage and yields of the respective Estates were as follows:—

	Acreage.	Yield.	Average per		
				lb.	Acrc.
Ouvahkellie 279 ..	118,803	...	426	including 40 acres of young tea.	
Vellikellie 259 ...	115,398	...	446	No young tea.	

The average cost of the tea f.o.b. Colombo was 30.43 cents per lb.

The crop for 1900 is estimated at 242,950 lb. Exchange has averaged 1s 4 9-32d per rupee against 1s 4 13-64d in 1898.

The working Account discloses a surplus of receipts (£2,596 17s 1d), which after the addition of the balance brought forward (£119 16s 5d) and the deduction of dividend on Preference Shares (£285 0s 0d), of an interim dividend of 2 per cent. on Ordinary Shares (£705), and of Preliminary Expenses (£127 8s 0d), and Income Tax (£27 17s 0d), leaves sufficient for the payment of a final dividend of 4 per cent., free of income tax, on Ordinary Share (£1,410), and a balance to be carried forward of £161 8s 6d in respect of Superintendent's commission on net profits, income tax, etc.

Mr. G A DICK, at present in Ceylon, expresses himself as thoroughly pleased with the local management of the Company's property and affairs, and considers that the present season opens with prospects of increased financial success.

Mr. P L JOHNSON retires from the Board on this occasion, and, being eligible, offers himself for re-election.

Mr. J HAMILTON ALSTON, the Auditor, also offers himself for re-election.

TALAWAKELLE ESTATES COMPANY, LTD.

ANNUAL REPORT.

Presented at the second ordinary annual general meeting of the Company, held at the Office of the Company, on Tuesday, the 3rd April, at noon.

The Directors have the pleasure to submit the balance sheet and accounts of the Company for the year ending 31st December, 1899, duly audited.

The mortgages has been reduced to £18,500, by the payment of the second instalment of £1,500 on the 31st December last, which has been charged against the profit of the year.

The estates are reported to be in excellent condition and are being liberally cultivated. The Directors are well satisfied with the result of the season's working, for although the balance carried to profit and loss account is £344 11s 2d less than last year, the expenditure includes the sum of £200 4s 8d spent on felling and clearing 30 acres

of forest and on the purchase of tea seed; a larger acreage has been manured, and the average rate of exchange was 1/4 5 16ths against 1/4 3 16ths last year.

The total yield was 419,541 lb. Tea plucked off 802 acres, being at the rate of 523 lb. per acre costing about 27 cents, or say 4½d per lb free on board Colombo. The gross average price of the 419,110 lb. sold in London was 10 23d per lb. Last year the crop amounted to 421,231 lb. tea, and was sold at an average price of 10 57d per lb.

The Net Profit for the year amounted to ..	£7,291 7 2	
To which has to be added Interest ...	87 6 10	
And the balance from last year of ..	924 19 9	
		£8,303 13 9
Interest on the Mortgage less Income Tax, has been paid, amounting to ..	£966 13 4	
The second instalment of the Mortgage of £21,500 has been paid, viz. ..	1,500 0 0	
Dividend on the 6 per cent Preference Shares for the year less Income Tax, has been paid ..	319 0 0	
An Interim Dividend of 4 per cent, free of Income Tax, on the Ordinary Shares was paid on the 30th September ..	1,482 16 0	
Income Tax ..	320 9 4	
It is proposed—		
To pay a Final Dividend of 8½ per cent on the Ordinary Shares free of Income Tax, making 12½ per cent. for the year, which will require ..	3,150 19 0	
And to carry forward the balance of ..	563 16 1	
		£8,303 13 9

The Directors desire to place on record their appreciation of the efficient management of the estates by their Superintendent and his Staff.

The Director retiring on this occasion is Mr. Charles Murray Robertson, and he being eligible, offers himself for re-election.

Mr. John Smith, the Auditor, also retires and offers himself for re-election.—By order of the Board, ROBERTSON, BOIS & Co., Agents and Secretaries.

BANDARAPOLA CEYLON COMPANY, LTD. ANNUAL REPORT.

The following is from the report of the board of the directors presented to the shareholders at their seventh annual ordinary meeting, held at the

office of the company on Thursday, April 5th:—
The directors have now the pleasure to submit to the shareholders the accounts and balance sheet for the year ending 31st December 1899.

After payment of debenture interest and all other charges, the net profits, for the year amount to £3,924 3s 6d, to which has to be added £54 8s 8d brought forward from the previous year, giving a total sum to be now dealt with of £3,978 10s 2d. An interim dividend of 3½ per cent. (free of income tax) paid in September, 1899, absorbed £735. It is now proposed to pay final dividend of 6½ per cent. (also free of income-tax), making 10 per cent. for the year, and amounting to £1,865. To write off for depreciation on buildings and machinery, 10 per cent. on £5,850 12s 5d, £585 1s 3d; to write off the capital expenditure incurred during 1899, £103 10s 6d; and to place to reserve, bringing that account up to £2,000, £475, £3,766 11s 9d; leaving a balance to carry forward of £211 18s 5d. The crops secured during the past season amounted to 524,259 lb. tea, and 295 cwt. 3 qrs. 20 lb. cocoa, against 395,270 lb. tea, and 195 cwt. 0 qrs. 11b. cocoa in 1898, showing the very satisfactory increases of 123,989 lb. and 100 cwt. 3 qr. 19 lb. respectively. The average return over all the tea in full and partial bearing was 716 lb. per acre, which shows a considerable advance on previous years, while the average price realised was 6 63d against 6 15d for 1898. The systematic manuring of the company's property is being steadily proceeded with, 225 acres having been treated during 1899 at a cost of about £630, which, as usual, is included in the year's expenditure. During the course of the year a little lot of land, about two acres, has been bought and planted, and the acreage of the estate is now approximately as follows:—Tea in full bearing, 576 acres; Tea in partial bearing, 296 acres; Tea not in bearing, 2 acres; Cocoa in full and partial bearing, 226 acres; Grass, &c., 12 acres; Total cultivated areas, 1,022 acres; reserve, jungle, &c., 520 acre: total estate, 1,542 acres. The board again take the opportunity of recording their appreciation of the services of their Ceylon manager, Mr. James Anderson. The debenture issue remains unchanged at £14,900, of which £2,500 matured for payment on January 1st last, and were renewed for a further period of three years at five per cent interest. In accordance with the articles of Association Mr. G. W. Pain retires from the Board, and, being eligible, offers himself for re-election. Mr. John Dalgleish, C.A., also offers himself for re-election as Auditor.—
G. W. PAINE, Chairman.

—H. and C. Mail, March 23rd.

HIGHLAND TEA CO. OF CEYLON, LTD. ANNUAL REPORT.

Report of the Board of Directors. Presented to the Shareholders at their Fourth Annual Ordinary Meeting held at the Office of the Company, 16, Philpot Lane, London, E.C., on 3rd April, at noon.

The Directors have pleasure in submitting to the Shareholders the Report and Accounts of the Company for the year to 31st December, 1899.

The net profits for the year amount to £3,006 8s 4d, to which has to be added £702s 1d brought forward from previous accounts, giving a total to be dealt with of £3,708 9s 5d.

An Interim Dividend of 3 per cent (free of Income Tax) paid in September, 1899, amounted to £960 0 0.

It is now proposed to pay a Final Dividend of 4 per cent. (also free of Income Tax) (making 7 per cent for the year) absorbing 1,230 0 0
To place to Reserve Account 500 0 0
And to write off New Clearings, &c. 250 0 0

Leaving a balance to carry forward of £86 10 5

The total crop of Tea secured from the Company's Estates was 259,233 lb., against 212,415 lb. in 1898, and the average yield per bearing acre was 413 lb., against 352 lb. for the previous twelve months, shewing the satisfactory increase of 45,818 lb., in the total and 91 lb. in the average.

The Tea sold in London realized an average price of 8½ per lb., against 9d for the previous year, and the rate of exchange was 1/4 25/64ths, against 1/4 5/16ths.

During the past year about 135 acres have been manured at a cost of about £350, which has been debited to 1899 expenditure, although the full benefit will not be derived until current season. The estimates for the new year provide for the further treatment of 144 acres, and it is the Board's intention to go on with the systematic manuring of the Company's Properties, from which they anticipate good results to accrue.

PUNDALOYA TEA CO. OF CEYLON LTD.

ANNUAL REPORT.

The following is from the report presented at the third ordinary annual general meeting of the company, held at the office of the company on Thursday, the 29th March:—

1 The directors now submit their Report for the year ending 31st December 1899 together with the balance sheets and accounts of the company made up to that date and duly audited.

2 The tea crop amounted to 644,565 lb., of which 641,035 lb., shipped to London realised a gross average of 9'28d per lb. The crop exceeded that of the previous year by 16,679 lb. and as it was plucked from the same acreage the increase is satisfactory. But the most satisfactory feature is the decreased cost of production, and although this is chiefly due to fortuitous circumstances, still a saving has been effected in the principal items of expenditure, and the board have much pleasure in recording their appreciation of the successful efforts of the estate managers in this direction. During the year thirty-nine acres of forest land have been planted with tea. On surveying the clearings opened in this and previous years however it has been found that the acreage planted in 1897 and 1898 turns out to be less than was estimated, and the total planted since the formation of the company is therefore 192 acres. During 1900 it is proposed to plant a further clearing of about fifty acres, for which there is an ample supply of plants in the nurseries.

The following statement gives details which may be of interest:—

Season.	Acreage Plucked.	Total Tea Crop.	Yield per Acre.	Cost of crop per lb. I.o.b. Colombo.	Gross average price obtained per lb. Tea.	Average rate of Exchange per Rupee.	Dividend on Ordinary Shares free of Income Tax.
	acres.	lb.	lb.	d.	d.	s. d.	per cent.
1899...	1,640	644,565	399	4'31	9'28	1 49-32	6
1898...	1,640	627,886	383	5'29	9'27	1 43-16	6
1897...	1,640	623,699	380	5'22	9'52	1 33-8	6

The net profit for the year amounted to £8,902 9s 9d, to which has to be added interest, £129 10s 4d, and the balance from last year of £127 0s 11d, making a total of £9,159 1s 0d. The directors have already paid out of this interest for the year upon the mortgage, less income-tax, £411 17s 4d; dividend for the year upon the 6 per cent. preference shares, less income-tax, £1,914; income-tax, £216 14s 8d, and they propose to deal with the balance as follows:— To pay a dividend of six per cent. free of income tax, on the ordinary shares, requiring £3,960; to transfer

to reserve for depreciation and general purposes (increasing this account to £1,500), £2,000; and to carry forward the balance of £626 9s. It will be seen that the above balance, which it is proposed to carry forward, is considerably larger than usual. The directors deem it expedient to do this in order to provide for special expenditures on various works, which are necessary or desirable in 1900. The Director retiring on this occasion is Mr. Frederick H. Christian who being eligible offers himself for re-election. Mr. John Smith, the Auditor also retires, and offers himself for re-election.—By order of the Board,

ROBERTSON BOIS & CO,
Agents and Secretaries.

SCHEDULE OF THE COMPANY'S ESTATES, ON 31st DECEMBER, 1899.

—H. and C. Mail, March 23rd.

BATTALGALLA ESTATE CO., LTD.

ANNUAL REPORT.

The following is a copy of the tenth annual report submitted to the Shareholders at the annual meeting held in London on March 28th:—

In presenting their report on the working of the Company's business for the past year, the Directors are pleased to be able to give again a satisfactory account.

The quantity manufactured shows a slight increase on last year, being 224,803 lb., against 222,414 lb. in 1898. The average selling price in London has been 8'43d., against 9'13d. in the previous year, and in Colombo 37'04 cents, against 32 cents.

London sales amounted to 191,350 lb., realizing net £5,835 7s., and Colombo sales to 32,600 lb., realizing £12,075'20. This compares with 184,055 lb., realizing £6,153 15s. 1d., and 37,430 lb. realizing £12,016'10, sold in 1898 in London and Colombo respectively.

The average rate of exchange has been 1s. 4½d., against 1s. 4½d. in 1898. No further expenditure has been incurred on capital account.

An interim dividend of five per cent on the shares, free of income tax, was paid in September last, and, after writing off £221 15s. from machinery account, the Directors have a balance of £856 0s. 2d. at credit of profit and loss account left to deal with. They propose to pay a final dividend of five per cent. free of income tax, absorbing £750 and to carry forward £106 0s. 2d.

In accordance with the Articles of Association, Mr. Edward H Hancock retires from the Board by rotation, and, being eligible, offers himself for re-election.

The Directors wish again to express their best thanks to the superintendent on the estate, Mr. G C R Norman, and to their Colombo Agents, Messrs. E Benham & Co., for the attention shown to the Company's interests.

BALMORAL (CEYLON) ESTATES CO., LTD.

ANNUAL REPORT.

Report presented at the second annual general meeting of the Balmoral (Ceylon) Estates Company, Limited, held at the offices of the Company, 12, Fenchurch Street, E.C., on Tuesday, the 10th April, at noon.

Your Directors have the pleasure of submitting their report on the year's working for the season ending 31st December, 1899.

The estimated crop was 470,000 lb., and the yield has been 528,804 lb., or 58,804 lb. in excess of the estimate. Exchange has averaged throughout the year 1s. 4 $\frac{3}{4}$ d. per Rupee as against 1s. 4 $\frac{1}{4}$ d. in 1898.

Sales in London have averaged as follows:—

Sandringham, 9.44 per lb. gross } Combined average
Clydesdale, 9.51 per lb. gross } 9.47 per lb. gross.

The approximate acreages are as follows:—

	Full Bearing.	Partial Bearing.	Not in Bearing.	Grass, Pataas, etc.	Total.
Sandringham and Yarravale ..	413	114	4	12	543
Balmoral & Clydesdale	265	115	76	170	626
	678	229	80	182	1,169

The working account discloses a balance of profit £9,168 1s. 1d., which, with the addition of £726 18s. 2d. from last year, makes a total surplus of £9,894 19s. 3d., and such sum has been applied or is recommended for application as follows:—

PAYMENTS MADE:—

Dividend on Preference Shares, £30,000 at six per cent	£1,800	0
Interim Dividend on Ordinary Shares, £52,035 at four per cent	2,081	8
Income Tax	115	6
Preliminary Expenses have been written off	322	10
AND IT IS PROPOSED:		
To pay a Final Dividend of 8 $\frac{1}{2}$ per cent on Ordinary Shares (free of Income Tax) making 12 $\frac{1}{2}$ per cent for the year	4,422	19
To carry forward a balance of	1,152	14
(Out of which Income Tax has to be paid).		
	£9,894	19

AND IT IS PROPOSED:

Mr. J. Hamilton Alston offers himself for re-election as Auditor.

TYSpane TEA COMPANY, LIMITED.

ANNUAL REPORT.

Report presented at the fourth ordinary general meeting of the Tyspane Tea Company, Limited, held at the offices of the Company, 12, Fenchurch Street, London, E.C., on Tuesday, the 10th April, at 2.30 p.m.

The Directors beg to submit their report on the working of the Company's estates for 1899.

The crop was 258,370 lb. this year against only 226,410 lb. in 1898, when most unfavourable weather prevailed.

Shipments to London aggregated 181,250 lb., and realised net the amount of £4,865 2s. 11, or a net average of 6.44 per lb. against 183,270 lb. in 1898, bringing in net proceeds of £4,605 10s. 9d., and a net average of 6.03 per lb.

Exchange averaged 1/4 23-64th per rupee as against 1/4 7 32nds in 1898.

The result of the year's working and the application or proposed application of profits may be thus summarised:—

Profit on working during 1899 ..	£1,589	11	6
Add Balance undistributed in 1898 ..	315	3	10
	£1,904	15	4
Less Interim dividend of 3 per cent paid ..	£540	0	0
Proposed payment of Final Dividend of 5 per cent	900	0	0
Proposed transfer to Depreciation Reserve (making the total £500) ..	250	0	0
Balance to be carried forward ..	214	15	4
	£1,904	15	4

It will be noticed that the Directors again propose to transfer £250 to Depreciation Reserve Account, in view of the considerable further capital expenditure (about £700) to be incurred during the current season, on an increase of withering accommodation, and the purchase and erection of two new fans.

Consequent on the death of Brigade-Surgeon John Bennett, and the protracted residence abroad of Mr. E. Dumaresq Thomas, the Directors have appointed Mr. Walter Cross-Buchanan and Colonel E. D. Newnham-Smith to seats on the Board, and their names are now submitted for election to the shareholders.

The Auditor, Mr. J. Hamilton Alston, offers himself for re-election.

The acreage of the estates is as follows:—

	Acres.
Tea in bearing	665
Tea in partial bearing	12
Tea planted in 1895	16
do 1896	47
do 1897	10
do 1898	28
do 1899	4
Timber clearings	22
Jungle, Scrub, &c.	164
	968

YATIYANTOTA CEYLON TEA CO., LTD.

ANNUAL REPORT.

Report of the Directors submitted at the third annual general meeting of shareholders held at the London Commercial Sale-rooms, Mincing Lane, London, E.C., on Monday, the 9th April, at 2.30 p.m.

The Directors now beg to submit their report on the working of the Company for 1899, together with the duly audited accounts to 31st December of that year, and they are pleased to be able to present a statement which they trust the shareholders will join them in regarding as satisfactory.

The plucking area, in full and partial bearing, on all the estates was 2,376 acres, and from this area the crops amounted to 1,343,387 lb. In addition, 8,128 lb. tea were made from purchased leaf, giving a total crop, as shown in the estates' working account, of 1,351,515 lb.

Of this quantity, 766,575 lb. were sold in Colombo, and the balance of 584,940 lb. was shipped to London; the net average realized for the whole being 5.68d. per lb.

Including purchased leaf, the average cost f.o.b. (or delivered to buyers in Colombo) was 3.48d. per lb., at an average exchange of 4 of 1s-16d. per

rupee. The outlay includes Rs15,859, being the cost of cultivating 614 acres not in bearing; but on the other hand, the year's expenditure has benefited by a profit on rice issues, amounting to Rs8,037.

The following comparative statement will be of interest:—

Year.	Crop secured from Company's Estates. lb.	Yield per Acre. lb.	Cost of Crop. per lb.	Net av'ge Sale price per lb.
1897 ..	1,014,291	499	3'91d	4'98d
1898 ..	1,135,794	507	3'62d	5'35d
1899 ..	1,343,387	565	3'48d	5'68d

The net profit for the year amounts to £12,117 10s 6d; to which has to be added, balance from 1898 account, £779 0s 7d; together 12,896 11s 1d.

Dividends have been paid, as follows:—On the preference shares at 6 per cent per annum—on 1st July, 1899, and first January, 1900, viz:—£2,700; on the ordinary shares —on 3rd October, 1899, an interim dividend of 3 per cent was paid which absorbed £2,700=£5,400 leaving now to be dealt with £7,496 11s 1d.

This the Directors propose to appropriate a follows:—(1) In payment of a final dividend on the ordinary capital, of 4 per cent (free of income tax), making in all 7 per cent for the year £3,600; (2) in writing off cost of properties, including depreciation of machinery and buildings £1,000; (3) in carrying forward to 1900 the balance of £2,896 11s 1d=£7,496 11s 1d.

During the year there was expended on additions to buildings and machinery the sum of £1,244 3s 4d; while, on the other hand, under the Branch Roads Ordinance, a sum of £361 5s 7d was received, which has been deducted from capital expenditure. The net addition to capital outlay is therefore £882 17s 9d.

The following are details of the acreage of the different properties as on January 1st, 1900:—

Estate.	Acreage under Tea.			Total.	Forest Reserves, &c.	Total Acreage.
	Bearing.	Partial Bearing.	Not Bearing.			
Polatagama ..	665	72	54	791	251	1,042
Weoya & New Polatagama..	632	95	...	727	345	1,072
Walpola ..	671	200	...	871	145	1,016
Rondura ..	386	133	82	601	629	1,230
	2,354	500	136	2,990	1,370	4,360

The Directors are pleased to be able to state that the reports received from Ceylon, regarding the condition of the Company's properties, are of a very satisfactory character. With the maturing of the younger fields, steadily increasing crops may be expected, but, as regards the cost of production, the Directors wish to record their opinion that, compatible with efficient working, no further reduction can be reasonably looked for.

On leaving for a short visit to Ceylon, Mr. Alexander Thomson (in view of Mr. Harries' approaching return to the Island) resigned his seat on the Board, and Mr. W H Figg was appointed to the vacancy. Mr. Harries has since resigned his Directorship, and has again taken up the management of the Walpola group, and the Visiting Agency of the other properties of the Company. Mr. Thomson has been appointed to succeed to Mr. Harries on the Board, and the appointment will be submitted for confirmation by the Shareholders. The retiring Director is Mr. W H Figg, who does

not seek re-election. The Directors recommend that Mr. W J Smith, who is now on his way home from Ceylon, be elected to fill the vacancy.

Messrs. Cape and Dalgleish, C. A., offer themselves for re-election as Auditors of the Company.

SOUTH WANARAJAH TEA ESTATES, LTD.
ANNUAL REPORT.

Report of the Directors submitted to the shareholders at the Ordinary General Meeting, held at 30, Mincing Lane, E.C., on Monday, 9th April, at 12 o'clock.

The Directors have pleasure in submitting their report, also Statement of Accounts duly audited for the year 1899.

The profit for the season, after writing off the balance of £200 of Preliminary Expenses and £300 for Depreciation, is £2,978 17s. Out of which a dividend at the rate of 6 per cent. on £7,000 preference shares has been paid £420, leaving a balance of £2,558 17s. From this the Directors recommend the payment of a dividend at the rate of 7 per cent. on £20,000 Ordinary Shares, £1,400; and propose to carry the balance to the Reserve Fund £1,158 17s.

During the season the tea crop, including bought leaf, was 551,981 lb., and the gross average price 7d per lb. The increased out-turn is owing to the very satisfactory yield from the Company's estates, and to the amount of bought leaf being larger than last year. The average rate of exchange was 1s 4-27d per rupee.

The outlay on capital account, as stated in the balance sheet, was £1,079 18s 11d, the greater part of this being for a new machinery house below the present Dartry Factory. The building is now complete, and will allow of a much larger crop being dealt with in future. A new bungalow was also built on the Blackburn estate for the use of the Assistant.

The Managing Director reports that all the estates are in good order, with well-equipped factories sufficient for all requirements.

The acreages of the Company's estates are as follows:—

	Tea 3 years and over.	Young Tea.	Grass, etc.	Total.
South Wanarajah ..	230	—	25	255
Dartry ..	584	28	68	680
	814	28	93	935

Under Clause 97 of the Articles of Association, Mr. O C Magniac retires from the Board, but, being eligible, offers himself for re-election.

Messrs. Fuller, Wise and Fisher, the Auditors, also retire, but offer themselves for re-election.

THE GALAHA CEYLON TEA ESTATES AND AGENCY COMPANY, LTD.
ANNUAL REPORT.

The following is from the report of the directors, submitted to the shareholders at the third annual ordinary general meeting, held at 30, Mincing Lane, E.C., on April 10:—

The gross profit for the season, after providing for depreciation on machinery, &c., is £12,555 12s 4d; add balance of last account, £173 6s 5d; from this has to be deducted—Interest on £55,000 debentures at 5 per cent per annum, £2,750; dividends on £60,000 preference shares at 6 per cent per annum, £3,600. London charges; Fees to trustees, directors, and auditors, &c., £795 7s 10d; interest on loan, £740 17s 2d, leaving a balance of £4,842 13s 9d; which the directors propose to appropriate as follows: Transfer to

reserve fund, £1,300; dividend, 7 per cent, on £50,000 ordinary shares, £3,500; balance to carry forward, £42, 13s 9d.

Notwithstanding that the buildings, machinery, and tramway have been maintained in the highest state of efficiency during the year, the directors have written off £700 for depreciation on the machinery and tramway, and propose, in pursuance of the policy indicated in their last report, to transfer the sum of £1,300 to the reserve fund, bringing it up to £2,300. In regard to crops, the out-turn of tea has been most satisfactory, the quantity having exceeded the estimate by over 74,000 lb. The total yield, including 5,704 lb. of bought leaf, was 1,164,876 pounds, which realised a net average price of 6.10d per pound. The yield of cardamoms, owing to the season being too dry for that product, did not reach the estimate, the quantity secured being 15,990 lb, which sold at a net average of 2s 0.76d per lb. The rate of exchange for the company's drafts on London for the year was 1s 4.29d per rupee. The capital outlay during the season slightly exceeded the estimate, owing to the purchase of some adjoining land and the planting of more cardamoms. On December 31 last the company had under cultivation in tea 2,867 acres, of which 2,375 acres were three years old and over, and in cardamoms 230 acres. The crops of the current season are estimated at—tea, 1,163,650 pounds; and cardamoms, 24,400 pounds. In addition to the cultivated land there is a large area of forest, Patana, &c.

EDERAPOLLA TEA CO. OF CEYLON, LTD. ANNUAL REPORT.

The Directors beg to submit to the Shareholders the report and accounts of the Company for the year ending 31st December, 1899.

Inclusive of 12,767 lb. bought leaf, the total out-turn from the three factories amounted to 466,149 lb. tea, shewing an increase of 19,123 lb. over the output for last season.

The average price realised was 6.959d. per lb. as against 6.375d. per lb. last year, and the average rate of exchange 1/4 27/64ths against 1/4 1/4d. for 1898.

Owing to the difficulties experienced in coming to a satisfactory working arrangement with the native contractors for mining plumbago at Ardross, it was decided early last year to stop all work.

Consequent on Mr. Porter's visit to the estate in January last, work has been resumed on a basis favourable to the Company, pending the drawing out of a formal agreement, which your Directors hope shortly to complete on terms satisfactory to the contractors and the Company.

The net profit for the year amounts to £2,921 9s. 5d., which with £56 17s. 7d. brought forward from last year, gives £2,978 7s. 0d. to be now dealt with and this it is proposed to apportion as follows:—

Amount as above	£2,978	7	0
Interim Dividend of three per cent (free of Income Tax) paid in September, absorbed	£765	0	0
It is now proposed to pay, a Final Dividend of five per cent (free of Income Tax), making eight per cent for the year, absorbing	1,275	0	0
To write off Estates Account	500	0	0
To place to Reserve Account (making it £1,300)	300	0	0
	<u>2,840</u>	<u>0</u>	<u>0</u>

Leaving a balance to carry forward of .. £158 7 0

In accordance with the Articles of Association, Mr. Robert Porter retires from the Board, and, being eligible, offers himself for re-election.

Messrs. Cape and Dalgleish, C.A., also offer themselves for re-election as Auditors.

BURNSIDE TEA COMPANY OF CEYLON, LIMITED.

ANNUAL REPORT.

The Directors beg to submit the shareholders the Report and Accounts of the Company for the year ending 31st December, 1899.

The total crop secured from the four estates during the year was 378,608 lb. made tea, against an estimate of 370,000 lb., and 62 maunds of tea seed and 226 lb. of cardamoms were obtained as against 116½ maunds and 202 lb. respectively for last season.

The average yield per acre was 345 lb., the average price 7.3-16d per lb., and the average rate of exchange 1s 4 13-32 d per rupee.

During a recent visit to Ceylon, Mr. Porter inspected the Company's estates and his full and interesting reports on them have afforded satisfaction to the Board.

Mr. Charles M Henry has been appointed Manager of Midlothian estate and it is hoped that under his experienced management a larger yield, and better prices may be obtained for the tea from this estate.

On the recommendation of the Manger of the Burnside Group, your Directors have purchased for R500 the land at Udispattu, on which the Wattagalla Store stands, and for which a ground rent of R40 per annum has hitherto been paid. This is the only addition to the Company's property made during the past year.

The net profit for the year amounts to £1,276 6s 4d, which with £70 13s 8d brought forward from last account, gives 1,347 to be now dealt with, and this it is proposed to appropriate as follows:—

Amount as above	£1,347
Interim Dividend of 2½ per cent. (free of Income Tax) paid in September absorbed ..	£440
It is now proposed to pay a final Dividend of 2½ per cent. (free of Income Tax), making 5 per cent for the year absorbing ..	440
To write off Estates Account ..	300
	<u>1,180</u>
Leaving a balance to carry forward of ..	£167

In accordance with the Articles of Association, Mr. Robert Porter retires from the Board, and, being eligible, offers himself for re-election.

Messrs. Cape and Dalgleish, C.A., also offer themselves for re-election as Auditors.

POONAGALLA VALLEY CEYLON COMPANY, LIMITED.

ANNUAL REPORT.

The Directors beg to submit to the Shareholders the Report and Accounts of the Company for the year ending 31st December, 1899.

The net profit for the year after providing for Debenture interest and other charges, amounts to £902 2s 7d., which with £164 11s 3d. brought forward from last account, gives £1,066 13s 10d to be

now dealt with, and this it is proposed to appropriate as follows :—

Amount as above	£	s	d
Interim Dividend of 2½ per cent. (free of Income Tax) paid in September, absorbed	1,066	13	10
It is now proposed to pay a final Dividend of 2½ per cent. (free of Income Tax), making 5 per cent. for the year, absorbing	£437	10	0
	437	10	0
	875	20	0

Leaving a balance to carry forward of £191 13 10
 The total Tea Crop secured amounted to 302,614 lb. made Tea, against an estimate of 300,000 lb., showing an excess of 2,614 lb. over the estimate, and an increase of 41,450 lb. on the crop for previous year.

The following figures afford further comparison between the season now closed and the preceding year.

Total	1899.	1898.
Tea Crop secured	302,614 lb.	261,161 lb.
Coffee Crop secured	960 bushels	724 bushels
Average		
Price realised for Tea	7.509d per lb.	8.182d per lb.
Rate of Exchange	1s 4 29-64d per Rupee.	1s 4 9-32d per Rupee.

The new central Factory at Poonagalla is now practically complete, except for an important addition to the withering space, which is now being carried out, and when this is in good working order an improvement in the quality of the Tea made is confidently expected.

As intimated in the Circular issued to the Shareholders on 1st February, Catton Estate, adjoining the top Boundary of Luangalla, has been purchased for £3,250, and towards providing the necessary funds for this purchase and for extending and equipping Poonagalla Factory, a Call has been made of £2 per share on 2,500 shares.

Mr. Porter has recently visited the Company's Estates, with the condition and appearance of which he was greatly pleased, and was confirmed in the opinion held by the Board, that the new purchase will prove of considerable benefit to the Company.

In accordance with the Articles of Association, Sir George A. Pilkington, M.P., retires from the Board, and being eligible, offers himself for re-election.

Messrs. Cape and Dagleish, C.A., also offer themselves for re-election as Auditors for the current year.

AUGUSTA TEA ESTATES COMPANY, LTD.

ANNUAL REPORT.

The following is the report submitted at the third annual general meeting of the shareholders of this Company held at the offices of the Company, 51, Lime Street, E.C., on 4th April :—

The directors beg to submit the audited accounts for the year closing 31st December, 1899. The accounts show a profit of £349 8s, after paying fixed charges; out of this amount the preference dividend has been paid, and the directors propose to write off the remainder of the preliminary expenses account, viz., £130, and £50 off machinery account, and to carry forward the small balance.

The quantity of tea manufactured during the year has been 119,596 lb., of which 104,905 lb. have been sold in London at an average price of 6.94 per lb., and 14,691 lb. in Colombo at an average of 31 cents per lb. The average rate of exchange has been 1s 4 13-32d, and the average

cost of production 28 cents, or 4.60d per lb. f.o.b. Colombo.

The year has been a more favorable one, prices have been higher, and the garden has produced more tea, and it is hoped that the coming season will also prove satisfactory.

By the articles of Association, Mr. T.J. Lawrance retires by rotation from the Board, and, being eligible, offers himself for re-election.

VISIT OF MR. SMITHETT TO CEYLON.

Mr. Smithett, senior (of the well-known Mincing Lane Firm) who arrived in Ceylon some time ago, returned to Colombo after a very pleasant visit upcountry. He went as far as Bandarawela, and also travelled through Maskeliya, Matale and Dolosbage. He is very much pleased with his visit, which has been a most enjoyable one. He walked through a number of tea and cacao estates, among them being Waripola where he was shown over by Mr. Dickinson, and Pallekele and many others. As his trip was mainly on pleasure, he did not occupy his time in closely inspecting any of the estates or tea factories, although during his short stay upcountry, he travelled a great deal, covering 20 to 25 miles a day. Regarding the future of tea, Mr. Smithett is of opinion that Ceylon will hold her own for a long time to come, and he does not think too much tea is yet made in the island. Every pound of tea manufactured is put in the market and finds ready buyers, and the product is being pushed on in almost all parts of the world. Speaking of China tea, Mr. Smithett thinks that the Celestials as a body are not an exporting nation, hence the great fall in their teas. Ceylon is alright in his opinion as far as tea is concerned. It is most probable, Mr. Smithett added, that the price of fine teas may keep up and the average altogether for last year for Ceylon teas was a very good one. On the subject of cacao, Mr. Smithett says that the production and consumption of this product is extending in every direction. At the beginning of the current "cacao" year there was a shortage in crop and in stock; but it is very likely to be made good before the close of the year.

Mr. Smithett, who is accompanied by the Misses Smithett and Miss Wardell, left for London on 10th April by the P. & O. ss, "Malta." The plan previously made was to visit Calcutta and Darjeeling; but owing to the prevalence of the plague in Calcutta, the arrangement had to be altered.

We trust Mr. Smithett and his party will have had a safe and enjoyable return home and carried away pleasant recollections of their visit to this

"Eden of the Eastern wave."

ORANGES AND LEMONS in profusion (in the Riviera) hang on their parent trees, and bananas ripen, in their second year, in the open air; the ponderous bunches, however, have to be protected in wire cages from the depredations of rats, which live chiefly in the upper branches of the orange trees, and take heavy toll of the golden fruit.—*Travel.*

GAME IN THE MATALE DISTRICT.

INTERESTING ARTICLE IN "THE FIELD"

It is a common occurrence to hear, in connection with the advice given to a young man with planting intentions, words to the following effect:—"Don't you imagine, young man, that you are going to get hunting anywhere about the estates in Ceylon. Look at me! I have been a planter for twenty-five years. The only game I have seen was a hare; that was mobbed by my pluckers." I commence with this statement, because when, quite twenty-five years ago, I proposed to take up coffee-planting as a business, and big game hunting as a no less secondary pursuit. Words much to this effect troubled my mind during my outward voyage, which the old Messageries boat took twenty-six days to accomplish from Marseilles to Point de Galle. I still live to thank that honest old Channel Islander for his warning; it has served its purpose. Business is business, but none the less sport is sport; and, as my good friend has long since passed away, I can give no offence by saying that I have proved his statement to be incorrect—at least in part; for, of course, in Ceylon, as in other countries,

GAME MUST BE SOUGHT FOR

where it is likely to be found. The lover of society, with its concomitant joys, lawn tennis and croquet meets, &c., will naturally seek a billet or purchase a property, if he be a man of capital, in one of the so-called "favoured districts."

The general feature of these districts at the present time is one unbroken sheet of tea, tea, stretching for miles, interspersed only with lines of grevilleas, the silver oak of the southern colonies, and a few clumps of gums and wattles. In such a country *Lepus nigricollis* is probably the only game which exists; such a district was probably in my old friend's mind when he used that warning note. My own proclivities, though by no means adverse to the company of my fellow creatures, led me to avoid such a country, and to look for employment rather in such places as would be most likely either to hold game, or to be within easy reach of its haunts. When, therefore, on arrival at Kandy, I became attached as assistant to a well-known

ESTATE ONLY FIVE MILES OUT

of that town, my eyes began to wander around; finally, from wandering they commenced to settle, like the compass needle, and the direction of that settlement was, also like that of the needle, due north.

In less than eighteen months I received the offer of the choice of two berths; one in a favoured district, and the other in the old and, as it was then considered, worn-out coffee district of Matale, lying some twenty to thirty miles north of Kandy. Needless to say, in spite of its imaginary drawbacks, I at once decided on the latter. The old district has now passed through its trials, and we can show fine fields of tea, though perhaps not such great stretches of it as some of those highly favoured and highly flavoured places where the day's work winds up with social gatherings and even at-homes and dancing; but we can show besides, what these more civilised places certainly cannot

show, fine clearings of cardamoms, cacao, coconuts, rubber, and vanilla walks, and amongst minerals, no small store of plumbago. On the whole, therefore, we are very well satisfied. Here amongst these northern outposts of the great mountain system of the island has been my home since the middle "seventies"—an

IDEAL HOME FOR A NOT TOO AMBITIOUS SPORTSMAN.

I have spoken of these hills as the northern outpost hills, and such they are, culminating at an elevation of 6200 ft., but lower spurs stretch north and east into the level plains, the home of the herd elephant, buffalo, leopard, bear, besides, of course, deer, peafowl, and in the season many species of waterfowl. Here we are perched 4,000 odd feet up in the mountains, yet not fifteen miles distant as the crow flies, and not more than one day's march with a good horse, from all this wealth of game. But of that more perhaps hereafter. We have now only to deal with such as comes within our daily observation.

In a district with such a range of climate and elevation as this possesses, every man can suit his taste. The lover of warmth and constant sunshine will find a California in miniature amongst the cacao walks and coconut groves of the Matale valley. Here at the

LITTLE TOWN OF MATALE.

the headquarters of the Government Agent, is the railway terminus, distant hence some sixteen miles. From this point a "bike" journey of about three hours will land the sportsman in good game country. The majority of men will, however, prefer the cooler climate of the hills, and they have for choice any elevation from 700 ft. to 5,000 ft. My own modest home stands at an elevation of 4,200 ft., almost in the centre of a natural amphitheatre formed by a lofty ridge and its projecting cliff-browed spur rising to 6,000 ft.

This forest-clad range, its loftier ridges cantily clad with gnarled and knotted rhododendrons, gay osbeckia bushes, downy slopes of tassock grass, with great slabs of the mother rock glistening in the warm sunshine;—this is a never-ending source of interest and pleasure. From the bungalow to the highest point of the ridge may be some 2,500 yards, but the atmosphere is so clear that the movement of game, and even of such smaller animals as Wanderoo monkeys (Presbytes), which frequent the open grass and slabs at mid-day to bask and gambol, are clearly visible without the aid of field glasses. In the fine weather, after the N.E. monsoon, from January to May, when the ridge is usually free from clouds, sambur are rarely out of sight, except at mid-day; sometimes as many as eight or ten may be seen at one time. One herd of five, with a magnificent master and a very warrantable second in command, we have seen almost daily for several weeks, and only last week took toll in the life of No. 2. Neither is

MY LORD

the elephant absent we have occasionally seen as many as three, but one old fellow is always with us, generally on view and more or less under our protection. A troublesome old gentleman; not so much

perhaps, owing to his own temper, never good at the best of times, as to the particular devotion of our dogs to the sport of elephant baiting. Elephant once winded, though perhaps half a mile distant, there is no getting those dogs off. A wild elephant bayed by a pack of dogs is a sight well worth seeing, and perhaps worth the risk of seeing once, not oftener. The one occasion on which I actually witnessed such a scene is not likely to fade from my memory. The terrible turmoil and tumult caused by the baying hounds, and the wrathful screams and trumpeting of

THE INDIGNANT ELEPHANT,

the wrenching off and thrashing of branches, the rattle of pebbles, the final flight of self and dog boy down the narrow game track, elephant giving chase, dogs, full cry bringing up the rear and threatening flanks. Not again will I venture to view an elephant at bay in heavy jungle armed with a '40 Winchester rifle and a Canadian hand-axe. We escaped chiefly owing to an intimate knowledge of the forest, and the propinquity of some old sawpits, in which our pursuer got a check which enabled us to make the nearest tea clearing. The hounds thereafter enjoyed another good half hour's baiting, and came home beaming with pleasure at their morning's fun.

Sambur are, as I have inferred, very plentiful, being constantly supplied with reinforcements from the unbroken wilderness, extending from our ridge east and north; but, owing to a partial annual migration, more plentiful during the N. E. monsoon and its later fine weather season. During the dry season—February and March—these deer are found low down, and come into the tea and cardamoms at night, and may be heard roaring up to ten o'clock in the morning. I have heard a stag as late as ten o'clock roar a dozen times, apparently challenging the wailing cry of old watchmen set to frighten off monkeys in the cardamom clearing. At any rate, the stag replied roar for shout for fully a quarter of an hour.

Pig, which afford excellent sport hunted with the kind of dogs we keep—the only kind suitable to a very extensive and broken country, a mixed lot of half-breeds—are generally plentiful, and in some seasons extraordinarily numerous. The hill-country pig differs in one respect from his relative of the plains in being more massively built, of greater length, but comparatively lower at the withers. We can generally

"RAID PIG"

on the usual estate rounds without interfering with our day's work, more especially by making an earlier start than usual, and taking up a trail from one of the ravines and swamps interspersed in the tea fields where pig come down at night to grub. I have accounted for over thirty pig in a season by this plan. A very large, but not too old, boar will often supply sport and continue to inflict reverses and damages for weeks before he is finally brought home trotters up. This particular branch of hunting has a peculiar fascination of its own; the strained earnestness of one moment giving way, perhaps, at the next to some ludicrous

incident. On the whole, however, it may be said of the hill-born pig that familiarity with him does not breed contempt, but usually something very much the reverse.

Amongst other game which this district holds is the barking deer, common in almost any low jungle and scrubland below 3,500 ft.

THE SPOTTED AXIS,

though numerous in the plains, is of less frequent occurrence in the planting district of Matale, yet fairly common about the estates lying in the northern end of the valley. With the barking deer excellent sport, similar in all respects to roe deer hunting, may be had with dogs on the open downs interspersed with clumps of trees and bracken and fern brake, which are a feature—the most beautiful feature—of the eastern slopes of our Matale Hill, and many an enjoyable camp can I recall in the company of old sporting chums. Given fine weather, it has always been good sport. Perhaps one, perhaps even three deer bagged before 9 a.m., not to mention such stray items as hare, jungle fowl, pigeon, and perhaps a couple or so of snipe.

As I look up from my writing table the upper slopes of the great ridge are glowing with the last rays of sunset. Below all the heavy forest is almost black. Far away to the left, just below the ridge, three objects keep appearing and disappearing. There is a red flash and it is gone, then another and another. The

SAMBUR ARE COMING DOWN

to graze on the young nilloo shoots. They are more succulent than on the eastern slope. The flanks of these deer are very glossy, and reflect the light to an extraordinary degree. Now at sunset they flash glowing red; after ten in the morning you should look for something almost white; at and soon after dawn, looking east, they will show almost black. Get the glasses off the old boar's head in the porch, and let us have a look at this lot. What do you make them out to be? All three bucks, all three in the pink of condition, but only one with a good head. They will disperse later on when they have done a bit of swaggering on that conical knoll, and we will start tomorrow early with a bottle of cold tea and a couple of cabin biscuits in the cartridge bag, and see if we can strike the trail of this fine fellow.

—Field, March 31.

E.G.R.

THE ASSAM RUBBER PLANTATIONS.—The total quantity of home and foreign rubber turned out from the forests of Assam during 1898-99 was 3,599 maunds, which, compared with the total of the previous year showed an increase of 753 maunds. The increased outturn was most marked in the Cachar, Darrang and Lakhimpur Forest Divisions and was due to more active operations having been carried out in the Manipur, Dalfa, Naga, and other hills in response to an increased demand accompanied by a high rise in prices. The outturn, though considerably above that of the previous year, was below that of 1896-97, which was over 4,000 maunds, and is due to the constant but steady destruction of the trees by the excessive tapping of the previous years, induced by the great demand for rubber, which fetches about four shillings a pound on the London market.—*Pioneer*.

AN ELEPHANT HUNT:

IN THE SAHARANPUR SIWALIKS.

The junior classes of Imperial Forest School were encamped at Dolkhand on January 25th. They were to march on to Beribara early next morning. But the sun of the 26th, which was somewhat late in shewing itself, having to pierce through a heavy cloak of mist, saw them mustered strong at Chillawala, 5 miles in the opposite direction. Never was an order more welcome or more heartily appreciated than the one that was circulated late in the evening of the 25th postponing the march and permitting the students to witness the Khedda that was going to be held in the Siwaliks the next day, and the majority of them sat up the greater part of the night through sheer excitement. The Khedda party in question belonged to the Bahampur State. They had

ALREADY CAPTURED ONE ELEPHANT

in the Eastern Dnn, and a large number in the hill forests of the Garhwal district, across the Ganges, and had, the previous day, moved from Beribara to Chillawala in hopes of capturing those that had been reported to have been sighted a day or two back in the hills behind that place.

The left bank of Chillawali Rau presented to-day a scene very different from its wont. There stood, tied to the strong-rooted Zizyphus and other sturdy trees close upon a hundred elephants of all sizes—from the gigantic Negandar Gaj to the newly caught liliputian baby, with whom Nageshwar Parsad, another gigantic tusker is fond of playing. In low sheds, hastily put up the previous day, lay the caretakers and their families and the beaters of the Khedda, while shouldaries were pitched on one side to accommodate a small detachment of the State Cavalry together with the captain and his assistants, altogether a motley band quite 500 strong. Then there were a hundred camels and an adequate number of camel-men, no novelties to the Forest School. Add to all this the village folk, whom curiosity had brought there in large numbers.

After we had seen all the elephants, played with the youngest baby, and teased and vexed others until long after the appointed time, 8 o'clock, we ourselves began to show signs of impatience tinged with vague forebodings of disappointment, when a very powerful voice was heard above all the tumult. This was the order for

WATERING THE NEWLY-CAUGHT ELEPHANTS which the Mahawats proceeded to obey at once. Two tamed elephants were detailed to each new captive, one on either side, with a strong hawser from neck to neck. The majority had been caught only two weeks ago, yet they did not seem to require much tugging or goading from their warders, and went to, and came back from the water very much of their own accord. While this was going on, the same voice shouted out an order for the *Dharwalas* or beaters to receive blank cartridges and percussion caps, and forthwith Jamadar Sultan Khan was seen dealing them out at the rate of six per gun. It was past 9 o'clock now, and our impatience was pitched a tone higher. We were told that scouts had been posted who were expected every moment to transmit *khobar* by signal as to the exact position of the wild elephants. At 10 a.m., a bugle call announced that the much wished for *khobar* had come at last, and thereupon the elephants were made ready for the sport.

Another, and yet another bugle sound, and the beaters filed out and let the van at a fast pace up the Chillawali Rau. They were about a hundred strong, draped in no particular uniform, and armed with fire-arms of all imaginable sizes and shapes, with the exception of a few stalwart Purbias who clung affectionately to the ancestral male-bamboo *lathis*, which, by the way, were by no means less effective than the guns for offensive or defensive purposes. They were closely followed by a long line of trained elephants, not less than sixty in number, headed by the formidable-looking Janna Parsad whom Nanneh Khan the captain chose for his mount, all marching on in profound silence. Only

FOUR ELEPHANTS CARRIED PADS

all the rest were to participate in the Khedda, although it seemed rather incredible, for they were armed with nothing more formidable than a strong rope. The students of the Forest School were given a ride on these latter as far as the first halt, which was made where the Gadawali Sot joins the main Rau, about four miles from the Forest Chanki at Chillawala. The *khobar* was to the effect that there were seven wild elephants near the head of the Gadawali Sot. The beaters therefore parted company here to take up positions along the water-parting of the Sot, and shortly afterwards the captain proceeded up the Sot, very slowly and cautiously followed by the students, now on foot, with strict injunctions from him not make any noise.

We proceeded with the rest of the elephants up the Gadawali Sot, which became narrower and narrower as the mouths of successive tributaries were passed. Presently we sighted the captain coming towards us with a very long face, and we whispered to one another "what's the matter?" The matter appeared to be very serious indeed, and for a while the 'long face' malady was infectious. Before the beaters were well in possession of the vantage points

THE WILY HERD

had scented our designs had crossed clean over to the next *Khol*, and there was nothing for it but to beat a retreat with the forlorn hope of once more getting near them in time for a drive that day, for it was past 1 o'clock already.

The students, who had taken up positions high up on the hills, were then signalled to come down, and were told to be particularly careful not to make any noise until the game was over or finally given up, and it must be said to their credit that they obeyed this order very loyally.

Slowly then and not in an enviable frame of mind we came down the Gadawali Sot, and were once again in the main Rau, which we followed up for about a mile, and then entered a tributary to the left called the Patdwari Sot. This Sot splits into two about a mile from its mouth, leaving a triangular peninsula between the arms, the third side being formed by a precipitous cliff the crest of which is the main water-parting of the Siwalik range. At the point of junction of the two streams there is a

VERY STEEP KNIFE-EDGE SPUR

on the east or left bank, and a hill with a moderate declivity—over which, in fact, the elephants had entered this *Khol*—on the opposite side. We took up our positions on the former, from which we could command a full view of the forest clad peninsula where the elephants were hiding. Meanwhile, the Khedda elephants spread them-

selves along the streams across which alone was escape possible for their besieged brethren.

No sooner had this manoeuvre been completed than the guns which were so long invisible, began firing from the heights overlooking the peninsula. Presently there was a movement in the forest, boulders rolled crashing down, bamboos and forest trees cracked and in a small glade we became aware of

SEVEN WILD ELEPHANTS

mad with fear and rushing helter-skelter through the jungle. For aught we knew, they might have been in that very glade ever since we had perched ourselves on our hill, but the unwashed brutes had a grey earthy hue, very different from the glossy slaty black of their domesticated friends and looked for all the world like huge ant-hills or exposed hill sides, both of which are common in the locality. With incredible agility the well-trained Khedda elephants hemmed them in from all sides, and very soon succeeded in dividing the herd. The main tactics of the captain seemed to be to avoid frontal attack, and to cut out individuals from the herd as opportunity offered. Each individual so cut out was pursued by several noosing elephants while the remainder kept guard.

The first capture was a female infant about a year old, which was noosed with great ease by Mahawat Allan Khan from Gaiidkali. Besides being young the baby was tamed, facts which discounted the value of the capture. Little as she was she seemed to be of a vicious temper, for besides giving desperate tugs at her hawser offener than any other captive, it was she that did nearly all the trumpeting, and was most troublesome in sundry other ways. The next capture was the largest female in the herd, presumably the baby's mother who, however, never missed an opportunity to disavow the relationship. She was lassoed by Saiti from the neck of Vinayak Parsad, a moderate size young elephant, of rather a slim build, who rejoices in only one tuck, but has, nevertheless, helped to capture more elephants than any of his stronger comrades. Next followed in quick succession four others, ranging from 8 to 18 years in age, two of which were males and two females.

But the most exciting event of the day had yet to take place. Of the herd of seven, six were already accounted for, but

THE HUGE TUSKER

who was seen towering over the rest, was not forthcoming. He had gone up the peninsula, and no amount of firing had for a time any effect towards dislodging him. Batches of Khedda elephants were then despatched to hunt him out. As soon as he sighted them the gigantic beast rushed down the hill with tremendous speed, smashing everything before him with a terrific crash. In a moment he was down in the Rau, crossed it, and made straight for the hill on the opposite side, and it seemed for a while as if he would cross over again to the Gadawali Valley. The Khedda elephants, however, foresaw this, and after a hard struggle succeeded in heading him back to the Rau. Once in the open, he ran straight down the Rau with a speed which must be witnessed to be fully realized. The mugrimen hammered harder than ever, the Mahawats caused streams of gore to flow down the heads, ears, and trunks of their charges, and the race was furious and prolonged. But the odds were very much against the poor wild brute who at last Mahawat Bandu lassoed from Deo Parsad itself a splendid animal. He was promptly assisted by Nagendar Gaj, the pride-

of the Khedda. Then followed a brief period of trumpeting trugging and rampage, which however, ceased when about a score of tame elephants closed round him on all sides with their heads and all their might brought to bear on him. Thus reveted he was powerless to move. The

FEARLESS MUGRIMEN

then crept underneath his huge barrel and hobbled his hind legs with a very tight bandage of hawsers. Examined at close quarters, he turned out to be a fine young animal, for he was not more than 35, with a most splendid head. Altogether he was a most valuable capture, although the tusks were not particularly big, owing, we were told, to his constantly rubbing them on sand or stone, and they had yet to grow.

Thus ended a most successful Khedda operation in which neither a single elephant, wild or tame, was killed or wounded, nor did anything happen to the brave men who participated in it, beyond a few trifling cuts and bruises such as they are fairly well used to.

The *modus operandi* is most charmingly simple and judging from results, attended with a minimum of danger. Each elephant carries two men, the mahawat and an attendant called mugri-walla. It also carries on a small pad a strong cotton rope, 20 to 25 feet long, and about 2 inches in diameter, one end of which is securely tied to the elephant's neck, the other end being formed into a running noose. The attendant is armed with a spiked wooden club about a foot-and-half long, with which he beats the elephant near the root of its tail. Attached to the sides of the pad are the ends of a short rope somewhat resembling a pair of reins. The mugri-walla stands near the root of the elephant's tail. With his left hand he keeps hold of the rope to maintain his position. With his right he vigorously plies the club. The manner in which he deftly avoids branches of trees and other obstructions in his way, now by leaning back or swinging round, and now by leaping over them when he is in danger of being brushed off, is simply marvellous. As soon

AS A WILD ELEPHANT

is approached near enough, the mahawat lifts the noose end of the rope, his attendant promptly lifts the rest of it, and then they together throw it over the head of the desired captive, who is kept running on ahead all the time and never given a chance to turn round and charge. If he has the trunk uplifted, which however he seldom has, the captors try to throw the noose round it, in which case it readily slides on to the neck. But more generally the terrified beast carries his trunk closely coiled, in which case the noose is made wide enough to go both round the head and the trunk. As soon as he feels the rope on the trunk, he lifts it, and naturally shoots ahead with great fury, both actions helping to bring the noose well round the neck. The capturing elephant keeps running after him as fast as it can to prevent strangulation. Almost simultaneously a second trained elephant hastens to the rescue, and throws another rope round the neck of the captive. Between the two the refractory brute is now steered pretty straight, and presently he finds himself surrounded by as many Khedda elephants as are available, and completely nonplussed. From this moment, his stubbornness gradually wears out, and in about two months' time, the whilom monarch of the forests becomes a willing slave of man, perchance a captor of his kin.—*Indian Forester*, March. U.K.

PLANTING NOTES.

MINING LEASES AND ROYALTIES IN INDIA.

—We direct attention to the letter of the Secretary of the Chamber of Mines on the above subject, in which he shows that 2½ per cent. *ad valorem* is the levy made by the Indian Government on plumbago. Taking so high an average value as £80 per ton, that would only mean £2 per ton; but of course this is for plumbago dug on private lands—if Government lands are entered on there will require to be a lease and annual besides.

RUBBER.—The Burma Government contemplate starting a Government rubber plantation of 10,000 acres, which will probably be in the Mergui district. This Sir Frederick Fryer thinks should bring some benefit in the shape of a demand for labour, and will increase the trade of Mergui. It has been decided to set aside areas for unrestricted taungya cultivation in the Maliwun township. In these areas people will be allowed to cut down reserved trees, and it is reported that 191 families are prepared to take advantage of this concession. Arrangements have also been made to facilitate the supply of opium to Malays in Maliwun, who were said to be leaving the township because they could not procure opium there as cheaply as they could in Siam.—*Indian Agriculturist*, April 2.

CURING OF LIBERIAN COFFEE.—One of the drawbacks to the use of Liberian Coffee has been a strong unpleasant taste, and various remedies have been suggested. It has now been successfully overcome on the Borneo Coffee Co.'s estate in Marudu Bay by washing the coffee after pulping and before fermenting. The washed coffee is in this way cleaned from all the minute bits of pulp which doubtless imparted an unpleasant taste and before being placed in the fermenting cistern it is thrown into large baskets "coal baskets" for a few minutes to allow the surplus water to drain off and is then fermented in a comparatively dry state. To increase the heat sacks are placed on the top of the coffee and after some hours the top layer is turned in below so as to ferment the parcel equally. Liberian Coffee, properly cured, has a splendid flavour which is well-known by the trade, who value it highly owing to the amount of chicory it can assimilate. As an after dinner coffee nothing comes up to pure Liberian Coffee if properly cured.—*British North Borneo Herald*, March 1.

THE INDIAN TEA TRADE.—Messrs. Thomas and Company—says the *Pioneer*,—publish in connection with their annual review of the Calcutta tea market an extremely interesting chart of the distribution of the Indian tea crop throughout the world. The most remarkable feature of the past season has been the growth of the North American trade, which increased by nearly 100 per cent. The figures for the last decade are an astonishing record of successful business enterprise. In 1890-1. North America took 133,290 lb. of Indian tea. There was a substantial increase the next year and then a drop of a hundred thousand pounds. But since that date the trade has grown by leaps and bounds, until in 1898-99 it had reached 3,032,027 lb., while in the present year no less than 6,191,685 lb. have been disposed of. In Australia and New Zealand too, the sale of Indian teas has largely increased, the figures for the last two years being 6,293,950 lb. and 8,229,190 lb., respectively. It is satisfactory to learn that the prospects of the coming season, so far as the Calcutta trade is concerned, are also considered good.

"THE TROPICAL AGRICULTURIST."—A busy planter writes:—"I always find it very convenient to note all the Tea Companies' Reports embodied in the *T.A.* from year to year—it is so easy to refer to them by the index. I trust, therefore, you are keeping up the practice of reprinting such reports."—We can assure our friend that careful attention is paid to giving a full reproduction in our monthly of all such Reports bearing on Ceylon.

TEA AND COCONUTS.—With reference to a paragraph from our evening contemporary, which we recently reproduced, a Veyangoda proprietor writes:—"There is evidence in the orders I continue to receive for seed coconuts and plants, that the planter has not lost faith in the combination of tea and coconuts. I have an order now for four thousand seed nuts from Yatiyantota. Ultimately, the shade created by spreading fronds and the net work of vigorous roots must prevent the profitable cropping of tea under coconuts; but for six or seven years the tea leaf should be a valuable catch-crop, while the cultivation of the tea should hasten the bearing of the coconuts.

TEA PLANTERS IN JAVA—says the *Straits Times*—rejoice at the progress in the cultivation of the shrub there last year. The advance was slow but none the less sure. The prices for the leaf were not high. But countervailing advantages lie in the fact that they are less liable to fluctuations than quotations for other produce articles exported from the island. The fluctuations in the price of cinchona, sugar, coffee, and indigo are so widely divergent that tea-growing in Java is the most stable line of cultivation open to investors. Tea planters had little to complain of as to insect-ravages last year. In the planting districts of West Java, the produce crops now suffer heavily from the unusual wetness of the season. The tea crop, this year, is expected to be of inferior quality. Coffee refuses to ripen well. The barries in many cases rot on the trees. Cinchona trees show signs of canker on branches and roots. The roads are in an almost impassable condition. It is well nigh impracticable for planters to convey produce to market.

"IS TEA INJURIOUS?"—We are surprised, and rather disgusted to find our contemporary of the *American Grocer* republishing under the above heading, wellnigh a couple of columns of opinions—medical and otherwise—adverse to the use of tea, without a word on the other side! Is the *Grocer* tied up in the coffee or cacao interest? Surely the Editor is aware that the people most freely consuming tea—the Australians to wit—are among the healthiest and most athletic. And we fancy there are more dyspeptics per thousand of population to be picked up in the United States than in the United Kingdom. We know that both the *Grocer* and *Christian Advocate* are widely circulated in America, and to get the Editors to recognise the other side, we are sending them copies of our tri-lingual letter and of Mr. Kelway Bamber's "Dietetics of Tea." Our Commissioner should go and interview the Editors in question and get them to make amends,

WYNAAD NOTES.

(From an ex-Ceylon Planter.)

April 19.

While you appear to be having, or to have had, a somewhat longish spell of dry weather, through much of Ceylon, the Wynaad has been favoured with a great deal of

HEAVY RAIN,

and more especially since the 1st instant. On Jan. 10th, a thunderstorm gave us from '50 to 1'40 over some 250 square miles of the country. On the 26th of the following month, we registered from '25 to '87 upon about the same extent, but south of the first downpour, while between the 18th ultimo, and the 31st idem, the rainfall varied between '20 and 1'50 and several inches have been recorded this month. Good Friday, being one of the wettest days the writer has ever known during pluvius April,—the rain scarcely ceasing between 2 and 10 p.m.

This seasonable weather, has proved most beneficial to all growing vegetation,

THE COFFEE BUSHES

having been covered with several splendid blossoms, all of which appear to have set extremely well, while TEA, old and young, has had a famous start—more particularly during the past fortnight.

Though the Wynaad has been so highly favoured in the matter of these spring storms, other South Indian planting districts, such as Coorg and Mysore, are reported to have experienced an uninterrupted drought from the first week in November to the end of March; but as coffee seems to be exceptionally well-cared for in those regions, both in the matter of shade, and high cultivation, fine crops are likely to be the rule, provided a heavy plump of rain *inaugurates* the insetting of the blossoming showers in these localities and no *hail* descends on the *open flower*.

The Wynaad has been entirely depleted of lowcountry

WEST COAST LABOUR,

the whole of which left the plateau two weeks ago, to foregather at the first of the two great annual Malabar Feasts, known as the "Vishoo," the ceremonies in connection with which drew to a close on Easter Monday, so that we shall have our Chermers, Kanacas, Tyens, Nairs and Moplahs trooping back in full force, in a few days, and in greater numbers than usual, as the failure of the wet crops, all over Malabar towards the close of 1899, has compelled, and will compel, a much larger proportion of these people to visit the district in search of employment, than under ordinary circumstances.

For a similar reason, the Mysore Canarese are likely to return to estates this spring, many weeks earlier than is their usual practice, for the distress now prevalent in the adjoining province—as the immediate consequence of failure of the Raggi harvest which forms the chief food staple of the whole of the labouring classes in Mysore—is likely to drive in the Canarese at an early date.

With two successive indifferent Raggi crops, the stocks of such grain held by all the poorer classes of ryots, have been almost entirely exhausted, and from advices just

received, from unimpeachable sources, I gather that in addition to losing their cattle wholesale, from a deficiency in pasture and water, these unlucky Mysoreans are compelled to eke out their scanty food supply, with jungle produce, such as edible roots and berries. With such a

DEPLORABLE CRISIS

widely prevalent—it seems extraordinary that the Mysore Durbar are unable to allot funds for relief works—though a sum of a lakhs of rupees has just been assigned to defray the outlay incidental to the erection of a building, to be specially provided, on the occasion of the wedding ceremonials of the youthful Maharaja and of his younger sister on the 6th June next.

The area already planted with

TEA,

in South and South-East Wynaad, is to be largely increased during the ensuing South-West Monsoon; and work on such extensions, is in a very advanced condition already, so that the whole of such tracts ought to be planted up by the end of June, if the monsoon reaches the west coast on a normal date; and as for the reasons already detailed, we are likely to suffer from a plethora of labour, there should be no difficulty in keeping every coffee and tea property in the acme of good order this year.

The improved tone of the home coffee markets, consequent (it is assumed in well informed quarters) on *consumption* having overtaken *supply*, is also likely to stimulate farther extensions under coffee, especially in North Wynaad, where some really splendid Arabica has been developed, within the past quinquennium, under the auspices of prominent Coorg planters—in proximity to the Coorg and Mysore boundary lines.

Another product, which is likely to be planted over a great deal of suitable land this year is

PEPPER

the market for which continues to be very firm. Where the best bearing variety of the pepper vine is cultivated, or rather grown—for no special cultivation is necessary—in conjunction with coffee, a nett profit on the sale of the spice of fully R250* per acre can be reasonably expected; while pepper grown alone—where the vines have once been thoroughly well started—can be well cared for on an outlay of ten rupees per acre annually, and upon such tracts the nett profit should not fall below R500.†

HYBRID COFFEE

continues to promise extremely well, as all the best original trees are undoubtedly immune from leaf-disease,—though some are prone to occasional attacks of white bug—and by judiciously selecting the best strain, from the third generation, we are gradually covering our hybrid coffee lands, with very fine trees of a highly productive bearing capa-

* "The poor Old Women"—a cryptic name for Ireland. Pronounced Shan Van Vo.

† We should say these figures are far too high or apply only to small patches highly cared for, —ED, T.A.

city and entirely free from leaf blights, the produce from which is valued by London brokers at an all round average of over £100 per ton.

Just now we are having a good deal of sickness in the district, for, in addition to the ordinary maladies prevalent at this time of year, such as malarial fever and dysentery amongst the native population, smallpox is rife and is claiming its victims from the local or indigenous tribes.

RUBBER INDUSTRY IN MEXICO.

The United States Consul at Mexico in a recent report on the rubber industry of that country, says that land suited to the growth of rubber can be had anywhere from 4s to 5s per acre. The titles will be found vested in private ownership: none are in the hands of the Government. The land will in all cases be a dense jungle. Cacao, pineapples and bananas can be grown as well as rubber. Prairie grass land is not adapted to this product. Rubber may be planted from branch cuttings, root cuttings, and from trees grown in the nursery from seeds. From 150 to 300 trees are set to the acre, and they are tapped anywhere from five to fifteen years after planting, according to the locality. Under the most favourable conditions a tree will yield an average of one to two pounds of rubber. The present market price at Frontera is about 2s 9d per lb. The tree is long lived and the production increases with age. No machinery is required for handling the gum. The rubber districts of Mexico, as a rule, are remote from centres of population; they are always thinly inhabited. Oriental labour must be imported. The approximate wage is four shillings per day. Knowledge of the language of the country is desirable for a person about to engage in the cultivation of rubber. As to the comparative cost of living in the United States and Mexico, the Consul is of opinion that if a man is content to live in Mexico as the natives live, he can exist very cheaply; but if he desires to live in the manner to which he is accustomed in the United States—eat the same food, prepared in the same way—it will cost him a great deal more than at home.

The rubber tree of Mexico is found growing from the Guatemalan boundary as far north as Tuxpan on the Gulf coast, and as far north as Colina on the Pacific coast. The maturity of the tree and its production are measured by the quantity and uniform distribution of the rainfall, together with high temperature throughout the year. In low altitudes, localities of 150 and 200 inches of rainfall distributed over eight or ten months in the year enjoy the best conditions, although rubber does grow where they have six months of rain and six months of dry weather; but in these localities it requires from twelve to fifteen years for the tree to mature, while in districts with an ample rainfall it will flower within five or six years.—*India-Rubber Journal*, April 2.

GROWTH AND MANUFACTURE OF SUGAR.

AN EXPERT OPINION FROM JAMAICA.

To the Editor of the *Times*.

Sir,—At the meeting of the Association of Chambers of Commerce, reported upon in your issue of yesterday, Sir Nevile Lubbock said:—

"It was true that *The Times* Special Commissioner to the West Indies estimated that, by the use of seedling canes and improved methods of manufacture the cost of producing sugar in the West Indies might be reduced 50 per cent. But, with all due respect to the Commissioner of *The Times*, he was evidently not a gentleman of large experience in the use of seedling canes or sugar manufacture, and he did not think his evidence was worthy anything at all."

Perhaps Sir Nevile Lubbock might be interested in the following communication which I contributed to last week's *Gardeners' Chronicle*. The conclusion at any rate coincides with that of your special commissioner.—I have, &c.,

ROBERT THOMSON, Late Supt. Botanical Dept., Jamaica.
March 16.

At pp. 127-128 in your issue of February 24, 1900 you reproduced from *American Gardening* a remarkable article on the above subject. Thus:—"The average yield of sugar to the acre of cane is greater in the Hawaiian Islands than in any other cane-growing country in the world; and its position in this respect demands our attention. The average yield of Maui, for instance, is about 3½ tons of sugar to the acre; Hawaii's average is lowered by the smaller producing qualities of her leeward or dry side, but would not go lower than four tons; Kauai, from four to five tons; and Oahu, six to seven tons. There are of course, pieces of ground, even entire plantations, on each of these islands, where the yield would greatly exceed the average of the island; one plantation of Oahu, for instance, yields 10 tons of sugar to the acre (it takes seven to eight tons of cane to produce a ton of sugar), and special yields of even 16 tons per acre have been obtained from given sections of the same Oahu plantation." When we compare with the foregoing statement of results the average yield of sugar per acre from our West Indian colonies, including British Guiana, the latter are thrown completely into the shade. Thus the average yield per acre for a long period of years in Jamaica stands at less than one ton. British Guiana, Trinidad, and Barbados yield an average of about one-and-a-half ton. Under peculiarly favourable conditions of soil, coupled with most propitious seasons, as much as five tons of sugar are produced per acre from time to time in our West Indian colonies, but this only on very limited areas—i.e., from five to some ten acres. Three tons per acre are not, however, uncommon over somewhat larger areas. By way of further comparison, reference may be made to your leading article, dated February 10, 1900, p. 88, in which you advert to the special efforts of Dr. Morris, Imperial commissioner of Agriculture for the West Indies, relative to the improvement of sugar productions by means of new varieties of cane—a new feature of cane cultivation. Thus, you say, "Several new canes, notably that known as 'B. 147,' had maintained their position, and were regarded by the planters as most valuable varieties. The amount of available sugar was at the rate of 3½ tons per acre." Of course, this does not mean the realization of a general average of 3½ tons; but if the average yield from the new varieties amounts to two or 2½ tons per acre, great benefit must eventually accrue to the welfare of the West Indies.—Robert Thomson, late Supt. Botanical Department, Jamaica.—*London Times* March 19.

ESTATE OF THE LATE MR. A. C. WHITE.

CEYLON PROPERTY VALUED AT R821,850.

At the Appeal Court today before the Hon. Mr. Justice Lawrie, Mr. Advocate Keppel Browne, instructed by Messrs. F J and R F de Saram, made application for an order confirming sole testamentary jurisdiction on the District Court of Colombo, with regard to the estate of the late Mr. Alexander Campbell White, of Weybourne, Cheltenham, in the County of Gloucester. He submitted that Mr. White died on the 1st January last, leaving a will dated the 30th Nov. 1899. By this will he appointed his five nephews—Messrs. William J Chrystal, John Chrystal, John Melville Stephens, Robert Francis Barclay and Fredrick Tichhurst—as trustees and executors of this will. All of them proved the will in the High Court in

England on the 16th February last. The executors have sent out a Power of Attorney dated the 3rd February last in favor of Mr. Alexander Cantlay, of Mount Vernon Estate, Kotagalala, to administer the property in Ceylon belonging to the estate of the deceased. The deceased's property in Ceylon consists of:—

	R.
Mount Vernon Estate in Dimbulpa	600,000
Mortgage executed at Hatton ...	30,000
Do at Gumpola ...	15,000
Do „ Hatton ...	9,750
Do „ Nawalapitiya ...	75,000
Do „ Colombo ...	63,750
Do „ Kandy ...	15,000
Debts due to the Estate ...	13,350

Total R\$21,850

He also stated that according to the will, the estates had to be sold, and debts recovered, and after payment of the legacies out of the proceeds, the balance had to be divided amongst the five nephews. He also submitted that though the estate was situated, and many of the mortgages were executed upcountry, it would be very convenient for the applicant as well as for his proctors, to have the testamentary proceedings in the Colombo District Court, and he cited some precedents, under similar circumstances where jurisdiction was conferred on the Colombo Court. He submitted an exemplification of the will, and an affidavit and petition from the applicant. Order was reserved by his lordship.

THE DRIEST SPOT ON EARTH.

The reputation of being the driest spot on earth is claimed by many spots in many climes. The latest claimant says "Siencia Siftings," is Payta, in Peru, a place about five degrees south of the equator on the coast that has risen 40 ft. in historic times. Professor David G. Fairchild, a recent visitor, reports having reached there in February just after a rain of more than 24 hours, the first for eight years. The average interval between two showers is seven years. Sea fogs are common. Of about nine species of plants noted seven were annuals, and their seeds must have remained dormant in the ground for eight years. In spite of the lack of rain, the long-rooted Peruvian cotton is grown in the dried-up river bed, furnishing crops that yield subsistence to the natives.—*Globe*, March 23.

RUBBER: CONSULAR NOTES,

HINTS TO MERCHANTS AND TRADERS FROM INFORMANTS ABROAD.

The importance of the rubber industry to the State of Para, in Brazil, and the extent to which it is taxed will be realised when it is remembered that out of a total income of £476,000 from the taxation of exports, no less than £437,000 is derived from the imposts on the exports of india-rubber. The crop of 1898-99 amounted to 25,374 tons, of which 9,839 tons were produced in Para, as against 8,919 tons in the previous year; while the total shipments of Amazonian rubber during 1899 amounted to 25,491 tons, of which 8,954 tons were sent to the United Kingdom. According to Mr. Churchill, the British Consul for the district of Para, Belgian capitalists have lately been very active in the State. Syndicates have purchased not only an india-rubber estate, but also the goodwill and plant of an electric light company, and are in addition negotiating for the transfer to them of the tramway system and the

electric lighting of the city of Para. There are now in the State three European companies engaged in the extraction and export of rubber, one only of which is British. It is interesting to note that the Belgian Rubber Company was the first to introduce labour into the State from the British West Indies.—*Financial Times*, April 5.

EXPLORING AND PROSPECTING FOR MINERALS.

A recent *Gazette* contains rules regulating the grant of licenses to explore and prospect for minerals and the grant of leases of minerals. An exploring license granted by the Government Agent allows the holder to search the surface of Crown and unoccupied land and also occupied land with the consent of the owner for minerals of every description and to remove samples or specimens, but it does not authorise him to mine or quarry. The license is only for a year, but it may be renewed on a fee not exceeding R10, and a royalty, not exceeding 15 per cent on the value of all precious stones found and removed by a licensee will have to be paid to the Government. A prospecting license which will apply to Crown land only will enable the holder to mine, quarry, and remove any mineral found. No such license, however, shall be granted, except to a person approved by the Governor and security must be given to the extent of at least R1,000, which shall be carried to his credit, should the depositor afterwards become the lessee of the mining lease or be returned to him, should he decline or fail to obtain the lease. The license shall be granted for one year or such shorter term as the applicant may desire, and may be renewed for a further term not exceeding two years. A moderate rent, not exceeding one rupee per acre will be charged for the land covered by the license, and a royalty at a rate not exceeding 15 per cent be payable on the value of all precious stones at the rate of 10 per cent. on the value of all plumbago, and at the rate of 20 per cent. on the value of all other minerals won and carried away over and above the quantity the Government Agent may allow to be taken free for the purposes of experiment. No private property shall be cut or injured in any way without the consent of the owner and at the determination of the license holder must restore the land and buildings that he may have damaged in the course of prospecting. As to mining leases, these may be granted for one or more blocks, each exceeding ten acres in extent and not exceeding one hundred acres in extent, provided that the total area does not exceed five hundred acres. The length of a block shall not be allowed to exceed four times its breadth, and the lessee must pay a royalty at the rate of 10 per cent on plumbago of R300 a ton and upwards in value, of 5 per cent on all plumbago below that price, and in the case of other minerals not exceeding 20 per cent of the value. The rent will be R100 per acre but no lessee shall pay both royalty and rent in respect of the same lease, but only such one of them as may be of the greater amount. For other land not used for mining purposes the yearly rent shall not exceed R10 per acre.

NOTES OF OBSERVATIONS OF SOME TEA DISEASES.

At a late meeting of the Ambagamuwa Planter's Association (Ceylon), under the presidency of Mr. HUTCHINSON, the following paper was read by Mr. OLIVER COLLETT :—

In a paper on the

PREVENTION OF TEA PESTS,

which I had the honour of reading before this Association last year*, one or two suggestions were made which attracted some attention at the time, and have since, in the case of a number of estates, been put into general practice. These related to the importance of removing moss from the stems of the bushes, of resting, poor and weakly plants and of generally paying more attention to the condition of individual trees, with a view to increasing their power of resistance against disease.

I now offer some further notes of what I have been able to observe of the nature and characteristics of some of our more prominent tea diseases and of their modes of attack, in the hope that they may serve as a contribution towards a more general knowledge of the subject.

It is, I think, now generally acknowledged that the

MOST DESTRUCTIVE DISEASES

by which tea is likely to be affected, are those which belong to the order of fungoid or cryptogamic parasites. Insect pests are of course, always with us, but as the harm they do is of a more or less transient nature and can, as a rule, be met by comparatively simple remedies, they are of less serious moment than those diseases which are due to the agency of parasitic fungi—especially as these latter, are very largely controlled as I am about to show, by the operations of climate and atmospheric conditions.

The two principal fungoid pests at present affecting tea are those commonly known as

THE GREY AND THE BROWN BLIGHT.

Grey Blight (*Pestalozzia Guenipi*) is, according to Dr. Watt, "one of the most destructive and dangerous of parasitic fungi to which the tea plant is liable." It appears to be more or less prevalent in every district of the Island, and is particularly noticeable upon wind-blown ridges, and upon tea in exposed fields, where the soil is worn and poor. Its worst effects are, however, always seen upon bushes that have been too heavily plucked, and whose constitution has thereby become impaired.

The spores of this fungus are widely disseminated by winds in the dry season, and germination usually follows as soon as wet weather and sufficiently moist conditions prevail. A preliminary outbreak of the disease may be expected to appear, soon after the first April rains, but as a rule growth upon a large scale, does not take place until June, when wet and windy weather is continuous and the light is dull. Under these favouring conditions, a state of rapid infection and re-infection of the bushes is set up, and is prolonged throughout the months of July and August,—the last-named month being as a rule that in which the climax is reached.

Practically then, Grey Blight appears to be a

MONSOON DISEASE,

and it seems only too probable that it will (if measures be not taken to withstand its progress) increase in virulence with every season. It would

therefore seem that it is of the first importance for us so to treat our bushes that they may be prevented from falling into that condition of health which invites disease. For we may safely assume that the power of each outbreak to cause permanent injury to tea, will, in every instance, be in exact proportion to the degree of vigour of the bushes at the time of the invasion.

There seems good reason to believe that all plants—particularly those under cultivation—have much to contend with during the monsoon; and that in an abnormal season (such as that which we experienced last year) their natural resources are severely taxed. At this time, not only is there wind to carry the spores of disease, and continuous moisture to secure their rapid germination, but the dull light prevailing diminishes the transpiration of the leaves (the tissues of which are now nuduly filled with water) and by reducing their normal vitality predisposes them to ready infection.

Moreover, it has been observed that at this season the

GROWTH OF THE FEEDING ROOTLETS

of tea is suspended. This important fact which was first noticed in Ceylon by Mr. William Cameron of Ythanside Estate, is without doubt, one which will have to be taken into careful consideration in connection with the operations of pruning, manuring, etc. in different districts. It will probably be discovered (as Mr. Bamber has already suggested) that the seasons of root growth and decay vary to some extent in every part of the Island; and carefully recorded data from different localities would prove of the utmost value. In Ambagamuwa, I find that the rootlets die back in May, and commence to grow again in September; but my experiments in this direction are as yet far from being conclusive. It is curious that very little is known of this phenomenon up to the present time. Mr. Willis of the Peradeniya Gardens tells me that no observations have been hitherto recorded in Ceylon regarding it; though he points out its great significance in connection with the question of manuring. It is, for example, obviously inadvisable to manure tea at a time when its feeding rootlets are not in a proper condition to assimilate it.

The actual effects of an attack of Grey Blight upon tea have been as yet very imperfectly observed in Ceylon. In some instances, an attack of the disease which has almost denuded the trees of their foliage, has been followed, after the monsoon, by healthy flushes, which might lead one to suppose that the blight had acted in the form of nothing more than

A SUBSIDIARY PRUNING.

In other cases—especially where the trees have run too long from pruning—they have shewn little power to withstand the effects of the attack; and here it seems likely that the result has been permanently harmful. It is at least very noticeable that Grey Blight does not attack young and succulent leaves; and the inference appears to be that more frequent pruning may tend to keep this disease in check.

In the case of

BROWN BLIGHT

(*Colletotrichum camellicæ*) the situation is somewhat different, and at present, I am inclined to regard this as the more serious disease of the two. For while grey blight is practically confined (as just stated), to the older leaves of tea, brown blight is frequently found upon the younger growth (though not upon the flush itself), and it often

* *Tropical Agriculturist*, Oct. 1899.

does much damage in recently pruned fields. Further, this disease, although it is most troublesome in the monsoon season, is more or less prevalent throughout the year.

The effect of this disease upon the leaves is very similar, apparently, to that of grey blight, which at first glance it closely resembles; but the fungus is much more common, and, so far as my observations go, is able to reproduce itself with far greater rapidity. It is said to be generically distinct from grey blight, but little is as yet known of its complete life history.

There is another growth which is fast becoming noticeable upon tea in the Central Provice—more especially in the vicinity of jungle—and which I will refer to as the

“ORANGE DISC BLIGHT.”

Though it is not a fungus, but belongs to the family of Algae, its nature is undoubtedly parasitic. I think (though for reasons which need not be stated at present, I am not quite sure) that it is identical with the species observed by Dr. Cunningham in the tea districts of Assam, and named by him, *Mycoides parasitica*. I have so far noticed it upon tea in Dikoya, Dimbula and Ambaganuwa, and also upon several species of plants in the jungles of those districts, hence it is probably widely distributed. According to Dr. Cunningham the growth in Assam appears to be harmless so long as it is confined to the leaves only, but when it attacks branches and stems it becomes a serious disease, and usually kills the parts affected. So far as I have seen in Ceylon, only the older and lower leaves of tea have been attacked and up to the present time the stems have remained untouched. The appearance of this blight upon tea has, I think, hitherto escaped the notice of planters, owing to its strong resemblance to blotches of “betel juice” upon the leaves. These markings are found, upon closer examination, to consist of groups of minute flattened orange coloured discs, closely adhering to the surface of the leaves. I have counted as many as three hundred discs upon a single leaf. The life history of this parasite has not been observed in Ceylon, but it is probably very similar to that of its Indian representative; concerning which latter Dr. Watt has said that “its presence is in any case and under any circumstances to be regarded with suspicion.”

There are several other

FUNGOID DISEASES

affecting tea which is it not possible to refer to today. Those here mentioned are probably the most destructive in Ceylon up to the present time. It has been suggested that tea diseases have been imported into the Ireland with seed from the Indian districts; but I am inclined to think that the view is erroneous, and that it is far more likely that they have emanated from our own jungles.

Fungi, it must be remembered, are the

SCAVENGERS OF THE FOREST.

It is their office to remove dead and decomposing organic matter, and assist in reducing it to its simple elements, in order that it may be re-converted into mould,—and so again enter into the life of plants and trees.

Now, recent science has brought to light the interesting fact that certain kinds of fungi which are by nature saprophytic (i.e. dependent for their nutrition upon dead matter only) may, where weakened powers of resistance form an inducement, become

PARASITIC,

and invade the tissues of living plants. This discovery (which is due to the researches of the Japanese botanist Myoshi) suggests a possible explanation for the apparently sudden appearance of fungoid parasites in localities where they have previously been unnoticed. Thus, it is conceivable that all the fungous diseases to which coffee and tea have been subjected in Ceylon are to be found in a more or less undeveloped condition in our jungles.

However this may be, experience has taught us that the long-continued cultivation of any one product in a given locality is very apt, sooner or later, to

ENGINEER CONDITIONS OF DISEASE.

On this account it behoves us to be constantly on the look-out, and to lose no time in learning to identify the different forms of fungi which are likely to prove harmful; so that we may know how to act for ourselves in an emergency. In this way much of the loss and trouble occasioned by outbreaks of disease may be circumvented.

The following specimens were exhibited in illustration of this paper:—

1. Typical examples of Grey, Brown and ‘Orange Disc’ Blights.

2. Under the microscope: a portion of a diseased tea-leaf, rendered transparent by the action of glycerine, in order to show the effects of the fungus upon its internal tissues.

SUGAR IN HAWAIIAN ISLANDS.

The average yield of sugar to the acre of cane is greater in the Hawaiian Islands than in any other cane-growing country in the world, and its position in this respect demands our attention. The average yield of Maui, for instance, is about 3½ tons of sugar to the acre; Hawaii’s average is lowered by the small producing qualities of her leeward or dry side, but would not go lower than 4 tons; Kauai, from 4 to 5 tons; and Oahu, 6 to 7 tons. There are, of course, pieces of ground, even entire plantations, on each of these islands, where the yield would greatly exceed the average of the island; one plantation of Oahu, for instance, yields 10 tons of sugar to the acre (it takes 7 to 8 tons of cane to produce a ton of sugar), and special yields of even 16 tons per acre have been obtained from given sections of the same Oahu plantation. The quality of these figures is the better appreciated by comparison with the yield of Louisiana. The average yield of Louisiana—according to the figures of Professor W C Stubbs, director of the State Experiment Station, varies from 1 ton to 2½ tons of sugar per acre, the average being, perhaps, not over 1½ tons.—*American Gardening*.

ESTATE SALE IN THE WYNAAD.

The “Woodlands Estate,” a property comprising over 800 acres of land, and containing some fine pepper and coffee, which is situated in close proximity to the Choondale-Sultan’s Battery High Road, 46 miles from Calicut, has just changed hands, at an excellent price to the vendor, the purchaser being a well-known Tellicherry merchant. Under capable management, “Woodlands” could probably be developed into a fine tea garden. An experimental tea clearing, planted by the late Captain Alfred Griffin, of Ootacamund, about 14 years back, grew some very promising tea; moreover, this holding is remarkably well situated for local labour and market supplies, and enjoys a well distributed infall.—*Madras Mail*, May 1st.

MINERAL PRODUCTION OF INDIA.

(From the *Indian Agriculturist*, April 2.)

The Mineral Production of India during the four years between 1894 and 1898 has just been reported upon by the Director-General of Statistics. Foremost among the minerals, it may be well to place coal, especially as greater attention is now being paid to it, and one eminent specialist arrived in India a few weeks ago for the purpose of reporting upon the various coal fields of India. The industry is shown to be expanding so rapidly that the output almost doubled itself in four years. The total yield of the mines rose from 2,820,000 tons in 1894 to 4,605,000 in 1898. Indian coal is now exclusively used on some of the railways of this country and extensively for coasting and river-steamers, mills, and factories. We have enough for all steam purposes, but some of the coal-fields are so remote from railways and rivers that at present it would be impossible, profitably to work them. Until difficulties of transport are overcome, we shall still have to import from England and Japan 360,000 tons annually. But our coal will never make coke, and we shall forever have to import the foreign product if we wish to utilise our own iron deposits: as for smelting purposes Indian coal has been authoritatively pronounced useless. It is not cokeable. Of course the production of iron is quite in its infancy in India, the ore being worked only in the Raneeungee district of Bengal. Only fifty thousand tons of iron were produced in 1898, and whether it will be possible to utilise the iron deposits of the Central Provinces, Madras, and elsewhere, is a question which Mr. Morgans, the expert, of whom we have made mention, may be able to answer. The section of the report, which refers to gold, shows that the metal which used to be shipped from Bombay to London to be refined and coined is now minted in Bombay from Mysore, the only district in which it is found in any quantity. In 1898 the output of the Mysore mines amounted to 404,625 ounces, the product of Madras and the Nizam's territory being little over six thousand ounces. This metal realised four pounds an ounce, and thus the value of the gold obtained in India in 1898 was £1,642,000. The production of last year is known to have been materially larger, but the figures are not yet obtainable. The quantity of salt produced annually in this country averages a million tons. There are salt wells and lakes in Rajputana, rock salt in the Punjab hills, and brine wells in Upper Burma, which contribute to the supply. But in Bombay, Sind, Madras, Lower Burma, and Aden salt is obtained from the sea. But what we obtain is not sufficient for our wants, and Bengal and Burma find it necessary to import from Liverpool, Hamburg, Aden, and Egyptian ports of the Red Sea. Saltpetre is plentiful. Indeed, the supply is now greater than the demand. It was formerly wanted in large quantities for the manufacture of gunpowder and for the preservation of food. But it has been superseded for both purposes, and now we only need produce about a quarter of a million tons per annum, which is refined in Calcutta, and then exported. The remaining minerals of the country are summed up in a few words. Rubies and jade are found in Burma, diamonds in Central India and garnets in Rajputana, and manganese, mica, and tin are produced in some quantities, but are of comparatively little commercial importance. No rubies have been obtained since 1896 when 144,011 carats were taken.

TEA IN INDIA: REVIEW FOR SEASON 1899-1900.

(From Baines & Co.'s Tea Review, 1899.)

CALCUTTA, 12th April, 1900.

The close of another season gives us the opportunity to review the market for the past year, and the prospects for the coming one.

No estimate of the crop was published at the commencement of the season, as the Committee of the Indian Tea Association decided that, with the climatic uncertainties, it would be better to work on a basis of results, and therefore waited until September, to give the actual outturn of manufacture to end of August, estimating the balance of the season upon the previous year's figures for the remaining period. From this it was assumed that the crop would be about 163½ million lb., of which 135 was apportioned to the United Kingdom. Owing, partly, to an exceptionally favourable year in *Cachar* and *Sylhet*, the crop proved to be 11 millions in excess of this estimate, of which the United Kingdom absorbed 149½ million lb. There is not much doubt that the high prices ruling for lower grades during the first five months of last year led to coarser plucking on many gardens, which may account, in some way, for the great increase in the crop.

CALCUTTA ACTUAL FIGURES OF CROP.

	1899-1900	1898-1899
Exports to United Kingdom ...	149,374,164*	135,381,722*
Australia ...	8,250,436	6,398,002
America ...	5,923,404	3,273,096
Asia ...	5,492,815	6,972,251
Foreign Europe ...	1,435,146	1,171,146
Local Consumption (estimated) ...	4,380,438	not given.
Total ...	174,856,463	153,196,217

* Re-exported to other countries to end of February 1900 ... 6,014,000
Do. 1899 ... 6,006,000

At the start of last season the statistical position was undoubtedly strong. The stock on 1st of May 1899 was 40½ millions, being nearly 9 millions under that of the previous year, and the very small available supply of Pekoe Souchongs "for price," resulted in values for this description, being enhanced to 8d per lb. for commonest. By the 1st of June exports were 3 million lb. ahead, and during July and August continued to increase. The new season's crop proved unattractive in quality, and the result of these heavy arrivals, caused a quick decline in prices of common leaf, and medium descriptions, common leaf being 5½d in August, which had been 8d in May.

Those who sold in Calcutta during the early part of the season have every reason to be satisfied, as these Teas could not be sold to cover cost on arrival in London, and most of them showed smart losses on the falling market.

Throughout the year, the abundance of medium teas, and the demand for common grades for the cheap canisters, resulted in a very low market for Pekoes and Broken Pekoes, which very often showed only a fractional difference in the prices ruling for Pekoe Souchong leaf. The average for the year being 8½d against 8½d and 8½d for the two previous seasons.

At the present time, the end of March, visible stocks are under 40 millions, which, we have shewn, cannot be taken to represent the true statistical position, as all retail dealers must be more than usually well supplied owing to the heavy clearances before the duty was imposed, but at the same time, it would indicate that the Trade is capable of working off the surplus before new season's teas arrive in any quantity.

FOREIGN EUROPE.

The deliveries for the ten months, from 1st June end of March, were 138,829,000 lb. against 119,886,000 lb. and 106,573,000 lb. during the two previous seasons.

Since May 1890 the duty on tea, which is now raised to 5d. per lb., had been 4d. per lb., and it remains to be seen what effect the additional 2d. will have upon the Trade. The tax represents about 80 per cent of the average value of tea, and the lowest retail price will therefore be about 1s. 2d. per lb. The opinion is held by some, that this should lead to greater use of medium and fine teas, the former of which have been unduly depressed for months past, while commonest kinds will be in less request.

The total crop from Ceylon was 129 millions against 120½ of the previous season, and was distributed as follows:—

	OTHER
U.K.	103½
AUSTRALIA.	15
AMERICA.	3
RUSSIA.	4
PORTS.	3½

The estimate for 1900 is 137 millions, of which 106 are expected to go to London.

As will be seen our trade with outside markets continues to improve, and increase excepting in the case of the Bombay market, which was crippled, somewhat, by the scarcity which has prevailed on the Western Coast. In spite of this, the quantity sold in Calcutta, is less than it was in 1895, notwithstanding the crop has increased from 135 to 175 million lb. With the fact before us that the consumption of tea in England has nearly reached its limit, it becomes the duty of all concerned in the welfare of the industry, to contribute to the supply of new markets, and to open out fresh ones. In South Africa, and South America, we have markets which hitherto have not been exploited, while Australia and North America are capable of much expansion. We trust growers will now begin to recognize the importance to their own interests of fostering these markets, by supplying the Calcutta centre, thereby encouraging trade, checking oversupplies to the London market, and ultimately benefiting the producer by expanding the sale of the article.

AUSTRALIA.

Our trade with this country continues to develop, exports for the year being 8,250,436 lb., against 6,398,002 lb. and 6,802,579 lb. for the two previous seasons. The principal proportion of this export is common to medium leafy kinds, but a growing demand for the better class of teas is apparent, which, we regret to say, has been somewhat ignored, especially by Darjeeling gardens. A decided preference for Indian Teas against Ceylon has been shown by this market, notwithstanding this, our exports are only about half of those of Ceylon.

As we pointed out last year, Ceylon has better facilities in freight, with the many liners calling at Colombo, but this does not account for the large difference in exports in its favour.

AMERICA.

The Export figures are 5,923,404 lb., against 3,273,096 lb. and 2,086,369 lb. for the two previous seasons. In addition to this 2½ millions were re-exported from London. These results speak for themselves, and show that our trade with this country is increasing. A direct line of steamers running every month has been a boon to the Trade.

ASIA.

Exports are 5,492,815 lb., against 6,972,251 lb. and 3,601,532 lb. for the two previous seasons. The falling off in this trade has been due to the scarcity which has prevailed on the Western Coast, nevertheless the prices paid for suitable Pekoes by this market compare most favourably with the values ruling in London for similar teas. *Cachar* and *Sylhet* especially have reasons to be grateful for this outlet.

Export figures 1,435,146 lb., against 1,171,146 lb. and 797,313 lb. for the two previous seasons.

The growing demand increases steadily from Germany, Constantinople and other European markets, the preference shown for direct supplies from the country of growth continues. A regular line of German steamers now carries this country's produce direct.

THE CROP.

The Crop on the whole has been a useful medium one, the proportion of fine teas has been less than usual. The large increase of good medium teas from Cachar and Sylhet has naturally told against Assam, whose teas owing to cold wet weather in June-August have not been, on the whole, as good as usual, and cannot compete in cost of manufacture with the above named districts. The Dooars, in many instances, were hardly up to the usual standards, and Darjeelings, with few exceptions, have been disappointing.

MANUFACTURE.

We must again impress upon our friends, the Planters, to pay the closest attention to improvement of quality, every effort should be made to secure good appearance, and liquor by care in the manufacture. With the large increase in consumption of British grown teas both at Home and in Colonial and Foreign markets, the consumer has become more critical, and is no longer content to take poor liquoring, badly made, teas, such as were marketable in the days when China controlled the market. We would deprecate very coarse plucking, or the manufacture of common undesirable teas, as tending to lower the standard of excellence to be aimed at. With the extensions of 1896-1898 now coming into full bearing, we may look for an increase in the crop, but we do not anticipate this will be very much more than the past season, which was unusually favorable from some districts.

FACTORY BULKING.—During the past season greater care has been given, on the Factory, to bulking, which has been fully appreciated in London, where the saving of bulking charges has been made. But more especially has satisfaction been given in Australia and Foreign markets, and we would urge upon the grower, the great importance that attaches to level quality in invoice breaks. Equality in tares, well made boxes, and careful weighing, should have the individual attention of every manager. In recent years great improvements have been made in all these matters, which is proved by the great diminution in the number of claims for loss in weight. Care must be exercised, where boxes are homemade, that the wood is thoroughly dried and seasoned, as most of the claims for cheesy taint arise from neglect in these matters. Size of Breaks should not be less than 20 chests, 30 half-chests, 50 boxes, as lots of lesser size than these are sold separately at the end of the auctions; only, when a full sized break of 20 chests cannot be obtained, it might be packed into 30 half-chests; but we do not advocate many half-chests on account of increased charges.

ASSORTMENT.—There is no occasion for a garden of medium size to make more than four qualities; a Broken Pekoe, a good Pekoe, a Pekoe Souchong, and a leafy Broken Pekoe Souchong. In addition to this, a tippy Broken Orange Pekoe or Orange Pekoe can be sometimes made. Dusty teas should be avoided. The weight of chests should not exceed 100 to 110 lb. broken leaf and 90 to 100 lb. whole leaf. Dusts should be packed in half-chests or small chests, weighing not over 90 lb. nett, as above this, loss in weight frequently ensues.

PROGRESS IN THE PHILIPPINES.

(By an ex-Ceylon Resident.)

Manila, March 15.

I am trying to get the Government to go in for tea, and to give me a salary to superintend operations. They wrote to ask what salary I want to make Botanic Gardens on Negros Island, and I said R800 a month, and I have not had a reply yet. They only give colonels R800 a month and may not give me so much.

I know a rich man who has rice mills and sugarcane crushing mills and distillery, who might get desiccating machinery, and coconuts are plentiful at R30 per 1,000. What is the price of nuts in Colombo? A lot of desiccated coconut is sent from Colombo to Australia, and freight from this to Australia is less than from Colombo to Australia. No arrack is made here. I saw salt being made by natives at Dagupan and Lingayen: it is very impure, sandy and dirty, and it would pay to make it as the Government does at Hambantota. Sea-water is used here, after it has drained over miles of slimy swamps, poisoned by drainage; the natives all have skin diseases, very probably from eating impure salt. Very little is being done in gold mining, as a party of prospectors were murdered and the Government stop parties from going, but there are about 50 men prospecting, and I have seen some of them bring in good samples of quartz. There are still some armed bands in the hills in this island, and over 100 natives were killed in a fight last week. The railway is very unsafe and since I came up, natives have removed rails twice and trains went off the line, but no one was hurt, as they do not go fast. Soldiers are not allowed to go out of these towns, and when I told them I walked eight miles alone from Dupagan to Lingayen, they thought I was a hero. I go bathing in the sea with them, only half a mile from Lingayen town and they all carry revolvers. Any natives caught with arms, will be hung in future, so that will put a stop to their nonsense.

PLANTING NOTES.

SUGAR AND SCIENCE.—A good many complaints have lately appeared in the Indian press about disease in their sugar-cane. We referred one report to a correspondent who is among the oldest and most successful of sugar planters. His reply coming at this time rather startles us:—

"About the Cane disease in Madras, it is not a thing to be feared, unless those so-called 'scientific experts' are allowed to go fooling with it. We have had both the forms of disease here which they mention, along with others; but they have never been allowed to do any harm, although our scientific men prophesied dire results and recommended impracticable remedies." Now we have two things to remark on this:—(1) that the information we quoted from the London *Times* yesterday, seemed to show that science had done a good deal for sugar planters in the West Indies at least; and (2) that in Ceylon we had in our coffee days full experience of scientific warnings which all planters at first scoffed at, but which nevertheless came true. So sending away the Scientist (any more than the Doctor) don't always succeed!

PLANT DOCTORS.—A writer in a contemporary urges the need of a new class of educated physicians, whose business shall be the cure and cure of disease-threatened and disease-stricken plants. "The time will come," he says, "when every agricultural district will have its plant doctor." He even foresees the development of specialties by many doctors just as by other physicians, so that in many difficult and obscure cases of disease affecting valuable plants the services of such specialists will be employed.—*Indian Gardening and Planting*,

REPORTED BOLIVIAN RUBBER ENTERPRISE.—Newspaper despatches from New Orleans dated February 26th reported that Captain Frank Moritz, of Pennsylvania, and Robert J Skeffington had arrived in that city from Bolivia, in the interests of the Chicago and Bolivia Rubber Co., and had chartered a steamer from the United Fruit Co. to convey a force of negroes and supplies for them to the rubber fields. The general manager of the United Fruit Co. informs *The India Rubber World* that no steamer has been chartered from them, as reported. Inquiries made in other directions in regard to the Chicago and Bolivia Rubber Co. have not as yet elicited any information.

RUBBER.—The United States Consul at Para has lately called attention to the recent extensive purchases of rubber estates in the Amazon Valley, which is evidence that considerable interest is being taken in the collection of the raw rubber, but warns India Rubber Manufacturers that they are in danger of finding themselves at the mercy of great syndicates. So far as the supply of Para rubber is concerned, I do not see there is much reason for fear, as it would be impossible for any syndicate to control the rubber market, this having already been attempted several times, but has met with the failure it deserves.—*India-Rubber Trade Journal*, April 2.

GREEN TEAS.—Encouraged by the success they have made with black teas in America, the planters of Ceylon have been experimenting in order to produce a green tea—pure, uncoloured and unfermented—to compete with the so-called pure Japan teas. Samples have been coming over for several months for examination by our experts, says the *New York Mail and Express*, and in nearly every case the reports of the experts have been highly favourable, and to the effect that the teas are clean and free from adulteration and colouring matter (which Japans are not), and in body and strength are far superior to Japan teas. This greater strength (notwithstanding it makes the teas more economical) is an obstacle, according to some of the experts, as consumers in drawing the tea will use as much as they do of Japans, and therefore find the cup much too strong. But common sense in the end must prevail and show them that to obviate this objection they have only to put less tea in the pot. Several small lots of Ceylon greens, made after the manner of the most approved samples, have arrived and have been eagerly purchased, and at present the demand is in excess of the supply. Some distributors in New York raise the objection that grocers, finding these teas clean and uncoloured, will not take them, as their customers, having been accustomed to Japans, judge by the appearance of the leaf. A cup test, however, will convince the most sceptical of the superiority of the cleanly, uncoloured green teas of Ceylon.

TO ALL PARTS OF ASIA, AFRICA, AMERICA AND OCEANIA.

Seeds & Plants of Commercial Products.

Castilloa Elastica Cervantes.—Orders being booked for the coming crop of seeds available in March and April, selected seed from very old trees. R. N. Lyne, Esq., Director of Agriculture, Zanzibar, writes under date 24th August, 1899:—"Please send me 200 seeds of *Castilloa Elastica* for further trial; the seeds of *Castilloa* you sent me last August germinated very well." Price and particulars in our Circular No. 32; special quotations for large orders according to quantity; immediate booking necessary to avoid disappointment.

Hybridised Maragogipe Coffee.—A large-beaned superior variety of Coffee in demand; orders booked for the coming crop of seeds, February and March delivery. Price according to quantity on application.

Hevea Brasiliensis (Para-Rubber).—Orders being booked for the coming crop available in August and September, 1900. This is the only crop of seeds in the year. All orders should reach us before the end of July to avoid disappointment, as we have to make arrangements in time; guaranteed to arrive in good order at destination. We have already booked a large number of orders. A Sumatra Planter writes, dating 9th March, 1899:—"I consent to the price of £———per thousand. I herewith order 50,000 upon condition that you guarantee at least 83% seeds germinating." Plants can be forwarded all the year round in Wardian cases. Price and particulars as per our Circular No. 30. A Borneo planter writes dating, Sandakan, 17th August, 1899:—"The last lot of Para seeds turned out very well."

Ficus Elastica (Assam and Java Rubber).—Seeds supplied by the pound with instructions; price according to quantity. This tree grows equally well in high and low land, in forest and grass land, its cultivation being extended largely by the Indian Government. For price of seeds with particulars as per our Circular No. 33.

Manihot Glaziovii (Ceara or Manicoba Rubber).—Fresh seeds available all the year round; price as per our Circular No. 31. It is superior to Mangabeira rubber and second to Para rubber.

Urceola Esculeuta (Burma Rubber) and Landolphia Kirkii (Mozambique Rubber).—Seeds and plants, both are creepers.

Clachoua Seeds.—Different varieties.

Sterculia Acuminata (Kolanut). Superior quality, seeds and plants; price on application, packed to stand the transit well for several months, a hardy tree, cultivation easy.

Erythrina Lithosperma.—Thornless variety, new crops of seeds ready in December, May and June. Price according to quantity on application.

Seeds and Plants of Cinnamon, Nutmeg, Clove, Sandalwood, Pepper, Cardamom, Vanilla, Arabian, Liberian and Maragogipe Coffee, Cacao, Tea, Coca, Fibre, Medicinal and Fruit Trees, Shade and Timber Trees, Eucalyptus various varieties, also Palms, Bulbs, Orchids, &c.

Our enlarged Descriptive Price List of Tropical Seeds and Plants of Commercial Products for Foreign Countries for 1899-1900 are now being forwarded to applicants in different parts of the world. Also Descriptive Price Lists of Seeds and Plants of Fruit Trees, Bulbs, Tubers and Yams, and Orchids.

"SOUTH AFRICA."—The great authority on South African affairs of 25th March, 1899, says:—"An interesting Catalogue reaches us from the East. It is issued by William Brothers, Tropical Seed Merchants, of Henaratgoda, Ceylon, and schedules all the useful and beautiful plants which will thrive in tropical and semi-tropical regions. We fancy Messrs. Williams should do good business, for now that the great Powers have grabbed all the waste places of the earth, they must turn to and prove that they were worth the grabbing. We recommend the great Powers and Concessionaries under them to go to William Brothers."

A leading Planter writes from *New Hebrides* under date 17th January, 1899:—"I shall like a few more of your Catalogues to distribute through these Islands, as I feel sure many would place themselves in communication with you, did they know where to write for Seeds and Plants."

Our New Descriptive Price Lists of Seeds of Shade Trees for Coffee, Cacao, Tea, Cardamoms, &c., Timber Trees, Trees for Avenues, Hedges Wind and Shelter Belts, Ornamental Trees, Shrubs and Climbing Plants; and Seeds and Plants of Palms, Calamus, Pandanus, Cycads, Tree and other Ferns, Crotons and Dracinas, now being prepared and will be ready shortly.

Agents in London:—MESSRS. P. W. WOOLLEY & Co., 33, Basinghall Street.

Agent in Colombo, Ceylon:—E. B. CREASY, Esq.

Telegraphic Address:

WILLIAM, VEYANGODA, CEYLON.

J. P. WILLIAM & BROTHERS,

Tropical Seed Merchants,

HENARATGODA, CEYLON.

IMPERIAL CEYLON TEA ESTATES, LTD.

The total acreage of the Estates as on 1st January, 1900, was as follows:—

ANNUAL REPORT.

The Directors now beg to submit the balance sheet and profit and loss account for the year ending 31st December, 1899.

The Nett Profit, after payment of Debenture and other interest for the year, amounts to	£4,716 0 11
To which has to be added the balance brought forward from 1898	42 4 6
	£4,758 5 5

This the Directors propose to deal with as follows:—

(1) In writing off from cost of Properties, as Depreciation of Machinery, &c. ...	£500 0 0
(2) In payment of a Dividend of 4 per cent (free of Income Tax) on the paid up share capital of the Company	3,600 0 0
(3) In carrying forward to next year the balance of	658 5 5
	£4,758 5 5

The item of £430 11s 8d for manuring brought forward from 1898, and the whole expenditure under this heading during 1899, have been charged in the Profit and Loss Account now presented.

The following table gives the acreage and results for the year:—

Estate.	Acreage in full and partial bearing.	Tea Crop, lb.	Yield per acre.	Cost of Crop per lb. in cents.	Nett Price realised per lb. in pence.	Working Profit.
						£ s d
Binoya ..	441	193,134	438	27.75	6.12	1,421 14 4

The working profit of Nonpareil arises principally from the Coffee Crop of Bus. 2,548½ which realised £1,912 3s 5d, as shown in the accounts. The Tea fields on this Estate have made very good growth during the year, and in this respect they have exceeded expectations. A larger acreage is therefore being retained in Tea than was stated in last year's report. Some land is being planted with Cardamoms, there being about 40 acres suitable for this product.

The returns from St. Vigeans were adversely affected by drought in the earlier months of the year, from which the bushes did not recover in time to benefit by the more favourable weather latterly experienced,

The acreage given of Edinburgh includes 11 acres in full bearing and 2 acres in partial bearing of Tea, planted in reservation land rented from Government.

The Capital Expenditure during the year on Tea clearings was for the upkeep of 390 acres not in bearing, and for opening and planting with Tea 23 acres on Edinburgh.

NUWARA ELIYA TEA ESTATES CO., LD.

REPORT OF THE DIRECTORS FOR 1900.

The Directors have pleasure in submitting the duly audited accounts of the Company to 31st December, 1899, and they trust the Shareholders will join them in regarding as satisfactory the results of the working for the past year.

The Crop Account, after deducting £1,734 15s 6d, the cost of necessary additions to Buildings and Machinery during 1899, shows a profit on the year's working of £20,271 16s 1d.

The Profit and Loss Account includes £1,609 17s 10d brought forward from 1898. The Directors have written off the sum of £2,000 against the Estates Cost Account, and have added £300, as before, to the Sinking Fund against Cost of Leases. After providing for these items, as also for Debenture Interest and the usual General Expenses, there remains for distribution a balance of

£16,599 0 10

An Interim Dividend of 3 per cent, free of Income Tax, was paid on 12th Oct., 1899, absorbing ..

£6,000 0 0

It is now proposed to pay a Final Dividend of 4 per cent, free of Income Tax, making 7 per cent for the year, which will absorb a further ..

8,000 0 0

14,000 0 0

And to carry forward to next year the balance of

£2,599 0 10

The Crop of Tea from the Company's Estates amounted to 1,326,875 lb., which realised an average nett price of 8.62d per lb. shewing a decline of 0.59d. per lb. from the average price of 1898, and caused mainly by the markets during the year being more in favor of the lower kinds than of high grown Teas.

The average rate of Exchange for the year works out 1s 4.9-32d rupee. The cost of the placing the crop free on board Steamer, or delivering to buyers in Colombo, was 4.77d per lb., which cost includes the rent of Leased lands, as also the

upkeep of 264 acres Tea not in bearing, and the planting of a new clearing of eight acres.

The following table shows the results of the working of the different Estates for the past year:—

Estate.	Acreage in bearing in 1899.		Tea Crop. lb.	Av. yield per bearing acre. lb.	Nett price realized per lb. Tea d.	Profit per bearing acre.

1,961 383 1,326,875 566 8.62 9 8 5

The yield from Tea in full bearing was 605 lb. per acre, and that from Tea in partial bearing was 362 lb. per acre, as compared with 545 lb and 292 lb. respectively in the previous year. The improvement, as compared with 1898, was due, in part, to more favourable weather.

The acreage of the Company's properties as on 1st January, 1900, was as follows:—

	Acres.	Acres.
Tea in full bearing ..	1,922	
" " leased lands ..	30	
" " partial bearing ..	373	
" " " leased lands ..	8	
" " " not yet in bearing ..	222

	3,047	

Mr. W Megginson, who has been in Ceylon since December last, has reported specially upon all the Properties of the Company, and the Directors are pleased to be able to state that the Estates are in excellent condition and responding in a satisfactory manner to careful and systematic work.

The Directors desire to express their satisfaction with the work of the entire Planting Staff during the season.

The whole of the Shares of the Company are now officially quoted on the London Stock Exchange.

CEYLON TEA PLANTATIONS COMPANY, LD.

ANNUAL REPORT.

Report of the Directors submitted at the thirteenth annual ordinary general meeting of shareholders, to be held at the Office of the Company, on Wednesday, 25th April.

The Directors have the pleasure to submit the general balance sheet and profit and loss account for the year ending 30th December, 1899, duly audited.

	£	s.	d.
The net amount at credit of Profit and loss account, including balance brought forward at 31st December, 1898, and after providing for General Expenses, Directors' Fees, Income Tax, &c., is ..	51,971	16	2

Dividends on the 7 per cent. Preference Shares were paid for 1899 (less Income Tax) amounting to ..	5,486	16	0
---	-------	----	---

	£	s.	d.
An Interim Dividend of 7 per cent. on the Ordinary Shares was paid 28th October, 1899, amounting to ..	11,716	12	0
It is proposed to pay a final Dividend of 8 per cent. on the Ordinary Shares (making 15 per cent. in all, free of Income Tax) which will absorb ..	13,390	8	0
To pay a Bonus of 3 per cent. on the Ordinary Share Capital (free of Income Tax) which will absorb ..	5,021	8	0
To add to Reserve Fund ..	5,000	0	0
To write off for Depreciation ..	5,000	0	0
And to carry forward to next year a balance of ..	6,356	12	2
	£51,971	16	2

Since the incorporation of the Company the production of Ceylon tea has risen from 13½ millions to 130 million lb. per annum. Notwithstanding this great increase, and the continued fall in the price of tea, the Directors are again in a position, for the thirteenth consecutive year, to recommend to the ordinary shareholders the usual dividend of 15 per cent., and in addition a bonus of 3 per cent.

It is proposed to write off for depreciation the sum of £5,000, and to add £5,000 to the Reserve Fund, which will then amount to £100,000, and to carry forward £6,356 12s 2d.

The yield of tea was 485 lb. per acre as against 460 lb. the previous year.

The crop for 1899 was as under:—

Estate Tea..	Bought Leaf Tea..	Leaf Tea manufactured for others:	Total.
lb.	lb.	lb.	lb.
3,973,820	566,664	517,663	5,058,147

The gross price realized for the Company's tea sold in London was 8.10d as against 8.24d in 1898, and the average rate of exchange is 4.19-64d compared with 1s 4.3-16d the previous year.

The coconut crop gave an increase of 236,323 nmts over previous year, and the crops for the last four years have been as under:—

Years.	Coconuts. No.
1896	875,570
1897	1,209,980
1898	1,180,520
1899	1,416,843

Enclosed with this report will be found a Statement showing the results of working for the last thirteen years, together with a schedule of acreages of the Company's properties.

The Directors would again desire to express their satisfaction with the services of the staff both in London and Ceylon.

ALLIANCE TEA CO. OF CEYLON, LTD.

REPORT OF THE DIRECTORS

Report submitted at the annual general meeting of shareholders, to be held at the Company's Offices, 9, Fenchurch Avenue, London, E.C., on Wednesday, 25th April, at 11.30 a.m.

The Directors have pleasure in submitting the balance sheet and profit and loss account for the year ending 31st December, 1899.

	£	s.	d.
The Nett Profit, after payment of Debenture and other interest for the year, amounts to ..	7,901	4	9

	£	s.	d.
To which has to be added the balance brought forward from 1898 ..	500	9	5
	£8,401 14 2		
An Interim Dividend of 3 per cent was paid on 30th September, 1899 absorbing ..	£1,957	16	0
And the Directors now propose to deal with the balance as follows—			
(1) In writing off from cost of properties as Depreciation of Machinery, &c. ...	1,000	0	0
(2) In payment of a final Dividend (free of Income Tax) of 5 per cent (making 8 per cent for the year)	3,263	0	0
(3) In carrying forward to next year the balance of ..	2,180	18	2
	£8,401 14 2		

These figures compare very favourably with the results for the season 1898, when the total dividend paid was 7 per cent, £300 was written off for Depreciation, and £500 9s 5d carried forward. The profit now available would admit of the payment of a larger dividend than is proposed, but the Directors consider it prudent and desirable to utilise the present favourable opportunity for strengthening the financial position of the Company by making a substantial deduction from the cost of properties and by retaining a large balance in hand.

The following table gives the acreages and results for the year :—

Estate.	Acreage in full and partial bearing.	Tea crop, lb.	Yield per Acre.	Cost of crop per lb., in cents.	Net price realised per lb. in pence.	Working Profit.
Aberdeen	347	139,361	402	24.61	5.68	968. 3 3
Calsay	352	171,577	498	27.16	7.23	2,009 1 10
Dunkeld	517	207,296	401	29.18	6.59	1,589 1 4
Luccombe	550	219,184	399	29.33	6.03	1,181 12 0
Thornfield and Glencagles	457	247,912	542	28.20	8.14	3,691 13 3
Radella	405	202,452	500	26.87	7.19	2,670 4 2
	2,623	1,187,732	452	27.80	6.96	12,109 15 10

From the above particulars it will be seen that all the estates have done well, Aberdeen and Luccombe exhibiting a considerable improvement on the previous year's working, owing to the higher range of values established this season for low-grade teas.

The total acreage of the estates as on 1st January, 1900, was as follows :—

Estate.	Acreage under Tea.			Total.	Forest Re. serves, &c.	Total Acreage.
	In full bearing.	In partial bearing.	Not in bearing.			
Aberdeen	347	—	14	361	119	480
Calsay	342	10	13	365	92	387
Dunkeld	481	36	—	517	79	596
Luccombe	550	—	—	550	200	750
Thornfield and Glencagles	457	—	7	464	48	512
Uda Radella	367	38	57	462	93	555
Kehelgama	—	—	—	—	322	322
	2,514	84	91	2,719	683	3,602

The prospects in Ceylon for the current year are favourable, and the Directors look forward with confidence to satisfactory results from this season's operations.

In accordance with the articles of Association, Mr. J Bell-Irving retires from the Board at this meeting, and, being eligible, offers himself for re-election.

Messrs. W B Peat & Co. also offer themselves for re-appointment as Auditors to the Company—By order of the Board,

April 11th. W. H. BARTLETT, Secretary.

STANDARD TEA COMPANY (CEYLON) LTD.

REPORT FOR 1899.

The Profit and Loss Account shows a profit on the working of the Estates in Ceylon of £12,524 10s. 6d, which with amount brought forward from last year, less interest and home charges, shows a sum of £11,425 0s. 1d. available for division.

In August, 1899, the Directors, under the powers entrusted to them, distributed an interim dividend for the six months ending 30th June, 1899, of 5 per cent. (10 per cent. per annum), absorbing £2,975.

They now recommended a Dividend at the rate of 10 per cent. (making 15 per cent. for the year) absorbing £5,950; the placing £1,000 against reserve, and £700 against depreciation; and the carrying forward to the next year £800 0s. 1d.

The Coffee crop was 399 cwt.; it realised about £1,100.

The average Exchange for the Company as drawers in Colombo was 1/4 9-32, against 1/4 5-32 in 1898, and 1/3 15-32 in 1897.

Fine teas were again lower in price this last season. Uda Pussellawa Teas sold in Mincing Lane in 1899 averaged 1d per lb. lower than the preceding year.

The new Factory on Gordon, to deal with the produce of that Estate and Tulloes, was in working order on 28th March, 1899.

The Directors have not issued any of the Preference Shares authorised; as money became dearer last year, and in consequence there was little to be gained by disturbing existing arrangements and substituting Preference Shares for the loans.

The Company's Properties at the close of 1899 were 3,465 acres, with 1,919 acres of Tea considered in full bearing, viz :—

In Uda Pussellawa—St. Leonard's, Coneygar, 901 acres 399 acres Tea bearing.
Liddesdale 814 acres 145 acres Tea bearing.
Eskdale 240 " 220 "
Gordon 386 " 304 "
Tulloes 419 " 237 "
In Up. Maskeliya—Gouravilla and Up. Cruden 705 acres, 614 acres Tea bearing.

There are also 405 acres Tea in partial bearing, and some 160 acres in addition planted with Tea.

On St. Leonards, Liddesdale and Gordon Estates there is still some Coffee interspersed through the Tea.

Mr. Alexander Brooke, the Director who retires by rotation, being eligible, offers himself for re-election. By Order, A. TRAFFORD BROOKE, Secretary.

25, Fenchurch Street, London, 11th April, 1900.

EASTERN PRODUCE AND ESTATES COMPANY, LIMITED.

REPORT FOR 1899.

The Directors submit Report and Balance Sheet for the year ending 31st December, 1899.

The profit for the year is £32,892 0s 10d, which, added to £9,930 9s 10d, balance from last account, amounts to £42,872 10s 8

From this has to be deducted:—	
Interest in Debentures ...£4,275 0 0	
Debentures for £7,500 drawn and paid off, with bonus of 5 per cent, on 31st Dec., 1899	7,575 0 0
Interim Dividend 2½ per cent, on Preferred and Ordinary Share Capital, paid 4th November, 1899..	7,475 1 6
	19,625 1 6

leaving a balance of 23,247 9 2

which it is proposed to appreciate as follows:—	
Final Dividend on the Preferred Shares of 2½ per cent., making 5 per cent. for the year, and on the Ordinary Shares of 4½ per cent., making 7 per cent. for the year	13,440 1 6
Balance to be carried forward as provision for retirement of Debentures in the current year	9,807 7 8
	£23,247 9 2

It will be observed that the Debenture Debt, which originally stood at £195,200, will, after the appropriation of £7,500 provided for in this account, stand at £80,000.

As shown in the Schedule below, the Company on 31st December last, had 10,926 acres under Tea cultivation, of which 10,039 were over four years old.

The yield of tea in 1899 was 3,959,870 lb., the average gross sale price being 7.29d.

The average rate of exchange for the year was is 4½d, as compared with is 4 13-64d in 1898.

J. U. L. NICHOLSON, Chairman.

41, Eastcheap, E.C., 11th April, 1900.

Schedule of the Eastern Produce and Estates Company's estates at 31st December:—

Arapolakande, Asgeria and Bulatwatta, Colonna, Condegalla, Doombagastalawa, Dromoland, Hope, Ingarugalla and Berrevella, Kirimettia, Kumaradole, Kambukkan, Labukellie, Meddecoombra, Norwood, Rothschild, Sogamma, Vellai-oya and Dandukelawa, Wevekellie.

	Total ... 16,499

RANGALA TEA COMPANY (CEYLON), LTD.

REPORT OF THE DIRECTORS.

The Directors beg to submit the Balance Sheet and Profit and Loss Account to 31st December 1899, duly audited.

The balance brought forward from last year amounted to	£ s d
518 1 3	
Less—Amount written off from cost of Properties as Depreciation of Machinery, etc	300 0 0
	218 1 3

To which has to be added the Profit for 1899	£ s d
1,715 18 5	

1,933 19 8

An Interim Dividend for the year 1899 was paid on Sept. 21, '99 amounting to 660 0 0

Leaving a sum of	£1,273 19 8
Which it is proposed to deal with as follows:—	
1 In payment of a Final Dividend of 2 per cent for 1899, free Income Tax (making 5 per cent for the year)	£440 0 0
2 In writing off from cost of Properties as depreciation of Machinery, etc.	500 0 0
3 In carrying forward the Balance of	333 19 8
	£1,273 19 8

The Tea crop amounted to 2,113,361 lb., and the Cardamoms to 4,211 lb. (or 3,743 lb. net) as against the original estimates of 2,000 lb. and 3,000 lb. respectively. The bought leaf was 13,867 lb. ing a total to the year of 225,228 lb. of Tea. The sales of Tea show a net average price per lb. of 7.03 pence, being equal to, say, 42 cents per lb. Exchange for the Company's drafts during the year has averaged 1s. 4 9-16d, as against the exchange for 1898 of 1s. 4 7-16d.

The following Table gives the acreage of the Estates for the last five years:—

	1895	1896	1897	1898	1899
Tea in bearing	591½	591½	591½	591½	591½
do partial bearing	—	63	63	70	90½
Tea not in bearing	112½	61	61	34½	34
Cardamoms	65½	56	56	56	56
do not in bearing	—	—	—	10	14
Grass and Fuel Timber	25	25	25	25	25
Forest and Waste Land	446½	444	444	434	430

Total 1,241 1,241 1,241 1,241 1,241

The following is a Statement of the Tea and Cardamom crops with the yield of Tea per acre for the same period:—

	Tea.	Cardamoms.	Yield of tea per
	lb.	lb.	acre. lb.
1895	201,631	2,172	340
1896	228,360	4,842	380
1897	212,535	8,291	360
1898	206,620	4,026	349
1899	211,361	4,211	357

During the year an additional expenditure of £398 18s. has been incurred on Capital Account, but from this must be deducted £22 13s. 5d. realised by the sale of Tea Plants.

The prospects for the current year are so far satisfactory, the estimated yield being 220,000 lb. of made Tea, and 4,000 lb. dry Cardamoms, and according to recent advices received from Ceylon the yield for the first two months of the present year was 4,175 lb. made Tea in excess of the corresponding period last season.

LINDOOLA TEA COMPANY, LIMITED.

REPORT FOR 1899.

Report presented at the third annual general meeting of the Lindoola Tea Company, Limited, held at 12, Fenchurch Street, London, on 10th April:—

The Directors have the pleasure to submit the balance sheet and accounts of the Company for the year ending 31st December, 1899, duly audited. The season proved a favourable one, and the total yield was 189,020 lb. tea plucked off 320 acres, being at the rate of 590 lb. per acre, costing free on board Colombo 24.78 cents per lb. The gross average price of the 180,729 lb. sold in London was 8½ per lb. Last year the crop amounted to

186,776 lb. tea, and the average sale price in London was 8³/_d per lb. gross. The current season's crop is estimated at 185,000 lb. tea. The rate at which drafts were negotiated was 1s 4 19-64d against 1s 4 7-32d last year. The Directors desire to place on record their appreciation of the services of Mr. W. Sandy Thomas, the Manager in Ceylon. The net profit for the year amounts to £2,398 15s 11d; to which has to be added the balance from last year of £223 6s 6d; making together £2,622 2s 5d. Out of this the Directors have written off the balance of preliminary expenses account £223 15s 10d; the premium paid for consols £105 14s; the dividends on the 6 per cent preference shares for the year ending 31st December, 1899, have been paid £780; income tax £58 12s 8d; it is proposed:—To pay a dividend of 6 per cent free of income tax on ordinary shares, requiring £1,300; and to carry forward to next year the balance of £153 19s 11d. Total £2,622 2s 5d. The investment in consols has been written down to par; but in view of the expenditure on buildings and machinery charged to revenue account, the Directors do not consider it necessary to write off a specific sum for depreciation. The Directors have been deprived, through death, of the services of their late colleague, Brigade-Surgeon John Bennett. The Director who retires on this occasion is Mr. Charles Murray Robertson, who, being eligible, offers himself for re-election. The Auditor, Mr. J Hamilton Alston, also offers himself for re-election.

ROBERTSON, BOIS & Co., Agents and Secretaries. London, March 30th, 1900.

CRAIGHEAD TEA COMPANY, LIMITED.

REPORT FOR 1899.

Reports presented at the second ordinary annual general meeting held at Fenchurch Street, London, on 12th April, 1900.

The Directors have the pleasure to submit the balance sheet and accounts of the Company for the year ending 31st December, 1899 duly audited. The mortgage has been reduced to £4,050 by the payment of the first instalment of £450 on the 31st December last, which has been charged against the profit of the year. The estates are reported to be in good condition and are being liberally cultivated. The total yield, excluding 5,025 lb. tea from purchased leaf, was 342,250 lb. tea and the gross average price obtained in London was 7-82d per lb. The expenditure included the sum of £350 spent on buildings and machinery and the up-keep of young tea not yet in bearing which has this year been charged against revenue. In the coming year a new roller and drying machine will be necessary, and the withering shed will be completed.

The net profit for the year amounted to £3,145 17s 10d; to which has to be added the balance last year of £457 0s 8d. Total £3,604 18s 6d. Interest on the mortgage has been paid £225; the first instalment of the mortgage (£4,500) has been paid £450; dividend on the six per cent. preference shares for the year has been paid £421 16s; an interim dividend of 2¹/₂ per cent on the ordinary shares, free of income tax has been paid £572 15s; preliminary expenses have been written off £153 8s 3d. It is proposed to pay a final dividend of five per cent free of income tax on the ordinary shares which will require £1,145 10s; and to carry forward the balance of £636 9s 3d. Total £3,604 18s 6d. Mr. George Alston, the

Director who retires on his occasion, being eligible, offers himself for re-election. Mr. J Hamilton Alston, the Auditor, also retires and offers himself for re-election.

ROBERTSON BOIS & Co., Agents and Secretaries, London, April 3rd, 1900.

CEYLON PROPRIETARY TEA ESTATES CO., LTD.

REPORT FOR 1899.

Report of the Directors submitted at the Third Annual Ordinary General Meeting of Shareholders held at the Office of the Company, on Wednesday, 9th May, 1900.

The Directors herewith submit the General Balance Sheet and Profit and Loss Account for the year ending 30th December, 1899, duly audited. The net amount at Credit of Profit and Loss Account after providing for General Expenses, Income Tax, &c., is

Debiture Interest paid paid to 30th September, 1899 (less Income Tax), amounts to	£6,911 12 9
to	£725 0 0
less from last Account	181 5 0
	£543 15 0
Three months' Debentures Interest to 30th Dec., 1899, (less Income Tax) amounts to	181 5 0
Preference Dividends paid for 1899 (less Income Tax) amounts to	1,262 16 0
Interim Dividend of two per cent on the Ordinary Shares paid 31st October, 1899, amounts to	1,567 12 0
It is proposed to pay a final Dividend of three per cent on the Ordinary Shares (making five per cent in all, free of Income Tax), which will absorb	2,351 8 0
And to carry forward to next year a balance of	1,004 16 9
	£6,911 12 9

For the past year the Company's Estates have given an increased crop of tea of 70,000 lb, and a yield of 439 lb per acre as against 407 lb, the previous year.

The gross price realised for the teas sold in London and Ceylon averaged 7-11d as against 6-94d last year, and the average rate of Exchange 1/4 26-64 against 1/4 15-64.

The following statement shows the results of the working of the Company for the last three years:—

Year.	Acreage Tea in Bearing.	Yield per Acre.	Rate of Exchange per R.	Sale Price of Tea.
1897 ..	2100	413	1/3 15-32	6-90
1898 ..	2105	407	1/4 15-64	6-94
1899 ..	2111	439	1/4 13-32	7-11

Year.	Estate Bought		Tea manu- fact'd for		Profits	
	Tea.	Leaf Tea.	lb.	lb.	£	s. d.
1897 ..	868,710	32,799	89,307	990,816	6,277	6 9
1898 ..	857,351	38,530	94,370	990,251	4,834	3 11
1899 ..	927,395	61,772	1,681	990,848	6,790	2 5

There are 2,356 acres planted with tea and the total area of the Estates comprises 3,058 acres.

The Radella factory was totally destroyed by fire on 26th October last. The loss was covered by Insurance, and it is expected that tea manufacture will be resumed in the new building in June next.

Under clause 69 of the Articles of Association, Mr. G. A. Talbot retires from the Board on this occasion, but, being eligible, offers himself for re-election.

The Auditors, Messrs. Harper Brothers, Chartered Accountants, retire from office and offer themselves for re-election.

RAGALLA TEA ESTATES, LTD.

REPORT FOR 1899.

Report of the Directors to be submitted to the shareholders at the fifth annual ordinary general meeting, to be held at 30, Mincing Lane, E.C., on Wednesday, May 2nd, 1900, at 12 o'clock noon.

The Directors beg to submit their report, and also statement of accounts duly audited, for the period of 18 months ending 31st December last—

	£	s.	d.
Showing a net profit for that period of	3178	13	10
Add the balance of last account	64	14	9
	£3243	8	7

Out of which the following dividends have been paid :—

1899, 1st January—Preference shares	£1050	0	0
1899, 1st July—Preference shares	1050	0	0
1900, 1st Jan.—Preference shares	1050	0	0
	3150	0	0

Leaving a balance to carry forward of	£93	8	7
---	-----	---	---

The Directors much regret that they have to present accounts, the results of which do not allow of a dividend on the ordinary shares, but owing to the shortage of crop on Kelburne, the higher exchange and the low prices obtained for the high grown Ragalla teas last season, the profits have not reached the amount anticipated.

During the season, which covers 18th months as arranged at the last meeting, the crops realized were :—

Tea, 700,398 lb., at a gross average of 8-92d per lb.
Coffee, 147 cwt. 0 qr. 24 lb., at a gross average of 78s 11d per cwt.

The following are the acreages of the Company's estates :—

Name.	Tea.	Coffee.	Timber.	Patna, &c.	Total.
Ragalla and Haigran Oya	907	—	180	303	1390
Kelburne	742	10	165	64	981
	1649	10	345	367	2371

The estimates for the current season, from 1st January to 31st December, are :—

Ragalla Tea, 425,000 lb.
Kelburne D 240,000 lb. Coffee, 20 cwt.

Under Clause 97 of the articles of Association Mr. M. P. Evans retires from the Board, and being eligible offers himself for re-election.

The appointment of Auditors rests with the shareholders, and Messrs. Fuller, Wise and Fisher offer themselves for re-election. C. E. STRACHAN and M. P. EVANS, Directors, and M. P. EVANS & Co., Secretaries.

London, 24th April, 1900.

SALE OF MADULKELLY ESTATE.

Madulkelly estate in the Kelebokka Valley, which has just been sold by Mr. M. H. Thomas for £7,500 to Mr. J. G. Mutter, covers no less than 785 acres, of which 258 or thereabouts are in tea. It was at one time a very fine coffee estate, being one of the earliest opened in "the Valley," and always a favorite. We believe it has also been doing very well in tea. Mr. M. H. Thomas still retains Galheria (427 cultivated acres) and Ooonoagalla with 487 acres in cultivation.

THE LONDON COCOA MARKET.

(By HAROLD HAMEL SMITH.)

FANCY PRICES FOR GRENADA COCOA.

April 12, 1900.

The Grenada cacao planters have shewn a novel but practical way of proving the interest they take in the South African War Fund. Twelve of them sent over 14 bags of cocoa for sale with instructions that the net proceeds were to go to the credit of the fund. In consideration of this, the cocoa was carried freight free, and no dock or landing charges commission, &c., were charged by those buying or selling the cocoa, in order that the fund might get the benefit of the full amount realised, and to show their appreciation of this generosity fancy prices were offered by the trade for the 12 lots offered. Seven bags sold at 90s, 5½ bags at 105s and one half bag at 106s or about 25s to 35s above their normal value.

The sales went off this week with good competition, and at higher prices all round, especially for Grenadas. The market is still bare of Guayaquil, and there are no signs of the large receipts at Guayaquil to rival last year, which were prophesied at the beginning of the crop, the total receipts at that Port to 31st March being 72,300 quintals, against 83,500 qts. in 1899, 70,000 in 1898, and 91,500 in 1897; and the present stock in London is under 19,000 bags, while there are 25,000 at Havre. On Monday (9th) 500 bags Summer Arriba sold at 78s to 80s. All the Grenadas, and nearly all the Trinidads and Ceylons offered sold this week. Next week, owing to the holidays there will be no sales, but those to take place on 31st April will be fairly well supplied with Grenadas and Trinidad, now being landed or "en route" but the present rise in price is expected; to be maintained, if not augmented, as the Government, who have not been buyers for some times, are expected to come in, and the way the demand, without the Government competing, is taking up all available supplies as they land, gives increasing strength to this idea.

The reports from Trinidad this mail complain of the shortness of supplies, and that the quantity of cocoa coming to market grows sensibly less. The total shipments to 29th March were 7,600 bags behind last year's (67,564 bags against 75,117 bags) and large orders were in hand for Europe and America when the mail left, which owing to the short supplies coming forward could not be filled. The future prospects depend entirely on the weather, but no improvement is looked forward to till July or August, and only then, provided the weather continues favorable.

In answer to my enquiries as to the cause of "worminess" in Trinidad cocoa, Mr. Eugene Smith, a Trinidad planter of great experience and who is now looking after a cacao estate belonging to a well-known English manufacturer, writes that "it is caused sometimes by putting the cocoa into bags whilst still warm; or keeping it after being bagged in a damp place. The 'worm' is in the seed itself, that is the cocoa seeds produce it. If you examine the insect carefully you will see it is very much like a weevil, but of a rounder build and with bigger wings. Whether the insect first starts as a worm

and then develops into a weevil, I am not in a position to say, but I believe it does so as it is in the shape of a worm that it 'rots' the cocoas as it is called, though that is hardly the proper term. I think if you take note you will find that it happens in the better fermented cocoa oftener than in the commoner class."

Of the 7,204 bags offered this week 6,506 bags sold at, and after, the sales. Of the 4,367 bags of Trinidad offered 4,120 bags sold, middling to good red 71s to 73s, fine marks 75s to 79s. One lot of "San Antonia" mark 83s 6d. Of 1,512 bags Grenadas offered all sold, common to good 67s to 69s 6s, fine 70s and 71s.

Of 829 bags of Ceylon offered 686 bags sold, smalls 64s 6d to 70s; dark red 70s to 72s, fair 76s 6d to 80s, good to fine 82s 6d to 89s 6d. One lot of 2 bags picked beans, fine bright red 92s. There is still a good demand for fine bright red. The sales included Maria 70s and 71s, Rosebury and Benveula 76s 6d, Lower Haloya 77s, Kepitigalla 78s 6d, Wiharagama and Marakona 80s, Gangarooka 82s. (4 bags 83s bid refused), Palli 102 bags 85s. 180 bags 88s to 89s 6d, CTC 2 bags 92s.

	1899	1900
Stock of all growth in London	108,197	92,547
" " at Havre	82,897	80,872
Ceylon & Java stock in London	12,000	8,813

(BY HAROLD HAMEL SMITH.)

London, E.C., April 20.

Owing to the Easter holidays there were no cocoa sales this week, and except a sale of some reddish grey Caraquez (Guayaquil) at 73s. I have not heard of any cocoa having changed hands. Meanwhile there is still a good demand for all descriptions, but especially for fine Ceylons, which are evidently much wanted, and the first lots to arrive should command high prices. In Trinidads low middling and middling red are at a value out of proportion to the good red, some of the two grades I expect will realise the same price this week, about 72s, same as last week. Some of the Dominicas which sold at 67s was out of approporition to the quality, but the demand for these cheaper qualities is very good. At present 4,500 bags are advertised for sale next week, but no particulars are given, though I believe about 1,400 are Grenadas, and the rest mostly Trinidads, all of which have only recently arrived.

The present stock of Ceylon is 8 010 bags against 13,420 bags last year, prices are unchanged say, dull and dark red 70s to 72s, fair 76s to 80s, good to fine 82s 6d to 89s 6d, there is no saying what price would be paid for a really first class lot fine cinnamon break of creollo Ceylon

I see Cadbury's have only advertised 25 tons of butter next month, but at present prices have not advanced much: today it is quoted 1s 5½d. The Dutch are expected to have up about 70 tons.

PLANTING NOTES.

MINING.—Negri Sembilan Government notifies that no new application for mining land, or for water rights for hydraulic mining will be entertained at the Seremban Land Office until further notice.—*Straits Times*, May 1.

SUGAR PLANTERS in Java are doing well, despite hindrances from the land laws which discourage the leasing of ground by Government for long terms. Figures speak eloquently of the headway made by planters under these difficulties. Ten years ago the sugar crop in that island reached 3½ millions of piculs. The yield in 1899 rose to 11 millions of piculs.—*Straits Times*, May 1.

RUBBER.—A parcel of Para rubber (341 lb.) and samples of Rambong, *Ficus elastica*, and Singre, *Willoughbia firma*, prepared at Kuala Kangsar were sent to London by Mr. Derry for sale. All the best rubber sold at the rate of 3s 10d per lb. the highest price ever heard of for Para—excepting Brazilian produced—and 6d per lb. more than realised for that sent from Kuala Kangsar two years ago.—*Perak Pioneer*, May 2.

PERFUME FARMING.—There is about to be started in Monrovia, California, the first perfume-farm and perfume-manufacturing plant operating on an extensive scale that has ever been established in the United States, some thousands of acres having been bought for the purpose in Southern California. Expert German and French chemists have already been engaged, and this spring the plant, it is said, will be in operation. Several New York and Chicago capitalists have the matter in hand, and it is intended to organise a stock-company, incorporated under the laws of Illinois. The wonder is that there is nothing of the kind in India!—*Planting Opinion*, May 5.

GOOD SHOOTING IN NEPAUL.—Sir George Luck's party has just returned from the Nepaul jungles, having had a most successful shoot. The other guns were Sir Bindon Blood, Colonel Ellis, R. E. and Captain Cook, A. D. C., while Major Pennell, A. D. C., and Captain Bald, 15th Hussars, were with the camp at different times. The spoil consisted of 14 tigers and three leopards, besides deer and good bags of quail were made at off times. Of the 14 tigers, eight were males, and the smallest measured nine feet two inches; all the tigresses too were good specimens. The arrangements were in the hands of Colonel Ellis, who was assisted by that good sportsman Khan Bahadur Bala Khan of Sherpur, Philibhit, and everything went without a hitch.—*Pioneer*.

THE GENERAL CEYLON TEA ESTATES COMPANY.—It is no doubt disappointing that the directors have been unable to recommend a dividend for the past year, but in the circumstances explained by the Chairman (Mr. Jas. Sinclair) to the meeting of shareholders which is reported in another column—there being only £4,000 of working capital left and the debenture interest amounting to £7,000—we think the most prudent course was adopted, having in view the best interests of the Company and the strengthening of the financial position of the concern. If a considerable improvement has not taken place by July, the shareholders will then be called together to consider a proposal to reduce the Company's capital, both preference and ordinary, to such an extent that an annual profit of £23,000 would cover the debenture interest, pay the preference dividend and something on the ordinary shares, and also allow of an appreciable amount being set aside annually for the redemption of debentures.

Correspondence.

To the Editor.

RUBBER YIELD IN NICARAGUA.

TO THE EDITOR OF THE "INDIA RUBBER WORLD,"
Bluefields, February 9, 1900.

SIR,—I have returned to my plantation on the Bluefields river, in Nicaragua. You may be interested in the result of my experiment in bleeding one of my cultivated rubber trees (*Castilloa elastica*), at the age of five years and two months from the seed. I extracted from this tree 12 ounces of pure marketable rubber, without apparently injuring the growth of the tree. At the present price here of 60 cents per pound, the 12 ounces would be valued at 45 cents, gold, on the plantation. The yield will increase, of course, as the tree grows older.

WILLIAM S. ARMSTRONG.

COCONUT CULTIVATION.

Franklands, Veyangoda, April 11.

DEAR SIR,—Mr. Cochran's farewell gift to the Island—not final, I trust—is not the least with which his powers of observation and patient investigation, have endowed it. His researches into the constituents of the various parts of the coconut tree, of the nut and its different components, from the husk to the water, have helped to correct information previously available, and to bring within reach of the intelligent planter scientific facts of the highest value. His last letter published in your issue of the 29th ultimo has brought together a mass of information of the greatest interest, which ought to help planters to revise pre-conceived notions, and to stimulate inquiry and experiments.

In responding to your request for information from this estate, I wish it to be distinctly understood that I am myself a learner, and that what I note down, as having come under my observation and experience, are matters which may be further elucidated, and in respect of which I am open to correction. There are, however,

TWO ARTICLES OF THE AGRICULTURAL FAITH to which I am irrevocably committed—that coconuts respond appreciably to liberal treatment, and that the proprietor who neglects to keep his plantation clean and to manure his trees in all but exceptionally rich soil, denies himself a safe and legitimate source of income. It may seem superfluous to record statements which are regarded as axiomatic by the scientific agriculturist; but I have often marvelled at the conservatism of intelligent men on the subject of manures. I mean, not as regards its uselessness or wastefulness on rich soil—of which, by the way, the Island cannot boast much—or as regards its inefficacy on stiff, hard, irresponsive soil. In dealing with average soil, they admit that manure will increase the yield; but they object that there is danger in accustoming the tree to manure, and that the effect of the stoppage of manure will be to throw the trees back dangerously. They are not clear why one should stop manuring one's trees, when an average expenditure of, say R10 an acre a year, will ensure an average increase of income of R20 per acre per annum—or, say R10 per acre net. Nor do they insist that unmanured trees will never deteriorate, or that they bear as well as manured trees

on similar soil. This distrust, or suspicion, of manure is a curious fact; but it must not be supposed that it is confined to Coconut Planters, or to Ceylonese. Similar conservatism and scepticism have found expression in the Press from Tea Planters; and although more enlightened views are gaining ground, there seems to be much confusion yet, as in matters affecting the animal kingdom, so in matters relating to the vegetable kingdom, between stimulants and food; and objection is raised to substances which are intended to build up a plant, or to restore to it what is taken from it in crops, which would be applicable only to stimulating substances which may force unnatural crops and leave the tree exhausted.

I do not pretend to be a scientist; nor can I claim the wide and prolonged experience which finds expression in Mr. Jardine's interesting letter in your issue of the 6th instant, but such experience as I have had, encourages me

TO CONTINUE THE USE OF MANURE,

and to counsel its use by friends. The special manures to be used and the system of application, must depend on the varying conditions of soil and climate to be dealt with; and Mr. Cochran's letter indicates generally the direction in which information may be sought and applied. Those who have no faith in the scientist, or who distrust artificial manures, may yet be guided by observation and the experience of their neighbours, and find abundant materials on and about their estates wherewith to maintain their trees in heart and increase their crops.

Mr. Cochran's reference to some information he obtained from me on application, calls for a slight correction. He is probably under the impression that I dig in the droppings of the grazing cattle—which are tied, two and two, over night, under each tree, for a week or ten days according to circumstances—without any further application. Such is not the case. Three lbs. of bone dust are sprinkled round the stem of each tree and dug in with the droppings, and the clods are covered up with fallen branches,—ashes, if available, being previously sprinkled. Generally, the ashes are applied to the trees whenever the fallen branches, &c. are burnt under each tree. Mr. Cochran's calculations show that the droppings—one advantage of which is that but little of their ammonia is dissipated—possess sufficient manurial substance for the needs of the tree; but as the grass under coconut trees steadily grows less under the influence of the overhanging shade, it is impossible to maintain on a cultivated estate grazing cattle enough for all its manurial wants. At least one half of this estate is manured with cattle-manure from road-side sheds and chekoo yards; and although this stuff ought to be richer, from the poonac, &c. on which working cattle are fed, much of its value is lost by exposure of the heaps to sun and rain. About a cwt of this road-side manure I apply to each tree, with bones and ashes in similar quantities as before mentioned; and the results seem about equal. In a young plantation in which new trees are constantly coming into bearing, it is difficult to compare field by field with absolute accuracy; but both in the appearance of the trees and in the crops gathered from them, the results are practically the same.

About the end of 1897, Messrs. Freudenberg & Co., kindly placed at my disposal certain artifi-

cial manures—Thomas' phosphate, sulphate of ammonia, sulphate of potash, kainit—which I applied to trees, alongside others which were treated with cattle-manure and bone-dust in the manner above described, and

A SEPARATE RECORD

was kept of the crops plucked off the trees thus treated at twelve pluckings, extending over two years. My Superintendent duly sent in his Report on the experiments; but here, too, no marked difference was observable, either in the appearance of the trees or the crops gathered. Probably, more continuous experiments are necessary.

It must not be forgotten that, just as the coconut tree is much longer coming into bearing than tea or coffee, so the effects of manure must be watched for during a longer period. Speaking roughly, improved crops cannot be expected during the first year, as it takes a year for all the nuts on the tree to ripen; and it is during the second year that the benefit which a tree has derived from the application of manure will show itself in fruit. If the quantity applied is sufficiently large, the third year, too, may show results; but I prefer not to put down too much manure at a time, and think the disturbance of the roots in alternate years is not too frequent. I share Mr. Jardine's scepticism regarding the harvesting of

90 NUTS A TREE

over any considerable undivided acreage. Not that such a return is inconceivable, or outside reasonable expectations in a good district, on estates intelligently opened up, and planted with carefully selected seed; but it is only recently that attention has been paid to good seed nuts for nurseries; and the inequality of the trees—whether through bad seed, early neglect, or a tracherous subsoil—in vigour and as crop-bearers, even on the best estates, is one of the most disturbing experiences in coconut cultivation. Then, it is one thing to put an average of 90 nuts on the trees over extensive fields, and quite another thing to keep them there during the trying droughts which denude the trees of tender nuts, twice or thrice a year in the best districts. An average of 40 nuts to the tree is not to be despised; and most people will be content if they can attain to 50 a tree, or 3,500 per acre, which systematic cultivation can secure in an average district, and which should represent a very satisfactory return on a safe investment. As to trees, of which Mr. Cochran has been informed, bearing 400 nuts for years together, they should be worth going a long way to see. I have some trees here which carry 200 to 300 nuts; and it is difficult to see where the extra nuts are to be packed and maintained. As for 900 nuts on a tree—well, they may be arecanuts!

I have not lost the faith in

SALT,

as a manure for coconuts, which I first felt, reasoning from analogy, and looking to the splendid growth of trees along the sea-borde. True, that there are trees in inland districts which look as vigorous and bear as heavily as those on the coast line; but look at the difference in soil, and it will be clear that salt plays an important part in building up and maintaining the productiveness of the tree on poor soil. As against Mr. Jardine's doubts, I may set the confidence of a Proprietor in Henaratgoda, who has used salt with the best results, which he may be induced to make public. His example would be very readily fol-

lowed by many, if only the Government pursued an enlightened policy by issuing salt at cost price for agricultural purposes. And there is hope now, after Sir West Ridgeway's recognition of the need of scientific experts to help on agricultural industries. Meanwhile, in hush, the Planter has a waste product, rich in potash, which he can utilize, either by packing trenches with it, or reducing it to ashes.—Yours truly,

F. B.

WHAREHOUSE CHARGES ON TEA LONDON

London, April 12th.

SIR,—I venture to trouble you with the enclosed copy of correspondence, and if you can find room to publish it, you will, I think, confer a favour on the tea planting community, as it throws a flood of light on the reasons why the charges on tea warehoused in London are maintained at so high a level.

I must explain that when the wretched draft dispute was forced upon the trade, by the ill-advised action of the Ceylon Association in London, I, with others associated with me in adjoining offices, wrote a letter to the Association protesting against their bringing on the dispute (unfortunately without avail). We then strongly urged the Association to take up the dock charges question, as being a much more important matter.

The Secretary replied that the Committee had tried in 1893 without success, and then made the statement referred to in the enclosed correspondence, which, from the sequel, he is likely to regret.

You will now see that the dock company, who warehouse about a fourth part of the entire import of tea into London, have always been in favour of reducing charges; but they are outvoted by the other members of the "Ring," who among them, take charge of the other three-fourths.

The manager of Cutler Street tells me that one great obstacle to a reduction in rates arises from the fact that Syndicates are formed for importing tea, in which some Wharfingers take an interest, and that some of those interested in such Syndicates do not object to the very profitable nature of the business of warehousing tea, because it fosters such operations and gives commissions all round.

How the planters, who must inevitably pay these exorbitant charges, benefit by such business, I fail to see. The tea required for consumption in the United Kingdom must come here, whether on Growers' or Buyers' account. What the planter has to do is to endeavour to reduce the cost of putting his tea on the London market. The existence of this "Tea Clearing House," or "Tea Warehousing Ring," as I prefer to call it, is a deliberate tax on the grower of tea. That ring ought to be broken up, and the sooner it is done the better.—Yours faithfully

DUNCAN W. H. SKRINE.

From Ceylon Tea Association in London, to A. Thomson, Esq.

9th April.

DEAR SIR,—In reference to correspondence with yourself and others in May last, I have the pleasure to enclose for the information of yourself and the other gentlemen associated with you, copies of letters that have passed between myself

and the Docks Joint Committee.—Yours faithfully,
(Signed) WM. MARTIN LEAKE.

Tea Clearing House Committee, 21 Mincing Lane, 10th April.

W. Martin Leake, Esq., Secretary, Ceylon Association in London.

DEAR SIR,—The attention of this Committee having been drawn to recent correspondence between yourself and the representative of the London and India Docks Joint Committee, respecting the question of rates and charges on Tea, I am desired on behalf of the Tea Clearing House Committee to state that there is absolutely no foundation for the statement that the Tea Clearing House Committee are ruled by the London and India Docks Joint Committee, and that the latter have been in favour of increasing rather than of reducing the charges in connection with the warehousing of tea. At no time have they made any such suggestion, but, on the contrary, they have always advocated a reduction of rates with a view to meeting the applications made on behalf of the Importers.—I am, dear sir, yours faithfully,

(Signed) GEO. T. POOCK, Secretary.

London and India Docks Joint Committee, 109, Leadenhall Street, April 5.

Martin Leake, Esq., Secretary, Ceylon Association.

DEAR SIR,—I am informed that the following is an extract from a letter dated the 16th May 1899, and signed by you as Secretary of the Ceylon Association, and I have to ask you to be good enough to give me the authority upon which you made such unfounded statements, and which are calculated to do the Joint Committee considerable harm, when addressed, as they were in this instance, to Importers of Tea.

“In regard to the Dock and Warehouse rates, the Tea Committee did its very utmost in 1893 to move the Tea Clearing House to make a change, but that Institution has a monopoly ruled by the Joint Dock Committee, who would rather increase the rates if they possibly could.”—Yours faithfully,

(Signed) J. GREENWAY, Assistant to Manager.

From W. Martin Leake to J. Greenway, Esq.
April 9.

DEAR SIR,—I have your letter of the 5th inst. I must point out that my letter, from which you send me an extract, was written in reply to certain representations made by several members of my Association and is clearly of the nature of a privileged communication.

Setting that aside, I am willing to admit that the word “ruled” is somewhat too strong to be applied to the great influence undoubtedly exercised by your Committee over the proceedings of the Tea Clearing House. With that exception I merely stated facts that seem to me unquestionable.

(1) That in 1893 my Committee attempted (without success) “to move the Tea Clearing House to make a change” in its rates. (2) That the Joint Dock Committee at the date of my letter had, consistently shown a wish to increase Dock rates if they possibly could.

On the latter point it is not necessary to go beyond my own personal experience. In February 1896, I was instructed, as Secretary of my Association, to forward to your Committee a protest

against their attempt “to secure a monopoly of warehousing of products by imposing a direct and unwarrantable charge upon all goods intended for delivery to craft” (see my letter to your Manager 24th February, 1896).

In 1899, at the very time when my letter, of which you make complaint, was written I was acting in my capacity as Deputy Chairman of Cement Section of the London Chamber of Commerce on a Committee appointed to resist new charges imposed by the Joint Committee, charges which being subsequently shown to be illegal were ordered to be refunded.

Recent writings and speeches of your Directors can, of course, not be quoted in support of a letter written last May, but having read the memo issued by Mr. Sydney Holland and the recent speeches of the Dock Chairman, I have difficulty in understanding in what sense your Committee considers a statement that it would gladly increase rates if possible, to be “unfounded.”—Yours faithfully,

(Signed) WILLIAM MARTIN LEAKE, Secretary,

WAREHOUSE RATES ON TEA.

27, Mincing Lane, London, 10th April.

W. Martin Leake, Esq.

DEAR SIR,—With reference to your letter to Mr. A Thomson, dated 9th April, and its enclosures, I am at a loss to understand your remarks to Mr. Greenway that your letter of 16th May last was “clearly of the nature of a privileged communication.”

That letter was written in reply to one signed by several large tea importers, headed by myself, making a strong representation in favour of your Association taking up the subject of the excessive rates for working teas.

In reply you made a positive statement to the effect that the “Tea Clearing House is a monopoly ruled by the Joint Dock Committee who would rather increase rates if they possibly could.”

I and the other firms sent a rejoinder on the subject, of which we did not even receive an acknowledgment.

Finding that your Association was either unwilling or unable to do anything in the matter, I and my Manager, Mr. T A Williams, have never relaxed our efforts to bring the facts home to the growers of tea (on whom more particularly the incidence of the present heavy rates mainly fall) and to do what we could here to bring pressure on the Dock Company, who we thought should have a preponderating influence in the settlement of rates to be levied.

To my surprise, I found that your statement above quoted, was contradicted point blank, by the Joint Dock Committee, and as a matter of fact it seems, that in voting at the Meetings of the Tea Clearing House, the hand held up by the Dock Representative has no more weight than the hand held up by any of the smaller members of the body.

When challenged by Mr. Greenway on the subject of your statement to me, and my co-signatories, you make what I must venture to call a very inadequate reply, and endeavour to obscure the issue by reference to the charges for the use of Dock water by barges, and to charges on cement. What there is germane to the subject of charges for warehousing tea in these questions, I fail to see.

From enquiries that I have made, I now learn that there are many of those now connected with the Ceylon Association who have made arrangements, by which they and, (or) the Firms or Companies with which they are connected, get, either directly, or indirectly advantages out of the charges levied by the members of the Tea Clearing House, which are denied to importers generally.

This being so, it is not surprising that there is not the same energy displayed in carrying on the agitation for the reduction in rates, which would otherwise be the case.

I learn that even the wholly inadequate reduction of 5 per cent. has not yet been agreed to, although strongly supported by the Joint Dock Committee.

This disposes of your reference to the "great influence undoubtedly exercised over the proceedings of the Tea Clearing House" by the Joint Dock Committee.

It would seem that the collective votes of a number of comparatively small wharves, is quite capable of rendering nugatory the efforts of the Joint Dock Committee to do, what I am assured they are wishful to do, viz: make a substantial reduction in the charges on Tea.

The Tea Clearing House is, no doubt, a very powerful body, and may consider that the Importers are at their mercy, but in the end, I believe, that they will find it politic to agree to a thorough revision of the rates; if they do not do so, I and those associated with me, who I feel sure will be supported by the Planters generally, will not rest until a strong effort is made to break up the "ring" for good and all.—Yours faithfully, (Signed) p.p. DUNCAN W. H. SKRINE, THORNTON A. WILLIAMS.

London and India Docks Joint Committee, Cutler Street Warehouses, 10th April.

DEAR MR. WILLIAMS,—In my letter of the 5th instant, I omitted to mention that some months since the Docks Joint Committee brought the question of Tea Warehousing Charges before the Tea Clearing House Committee, and proposed a reduction therein, which they continued steadily to press, until their efforts have now been attended with partial success.—Your faithfully,

(Signed) J. GREENWAY.

Thornton A. Williams, Esq., 27 Mincing Lane.

COCONUTS, OR COPRA?

Hanwella, April 29.

SIR,—The following figures taken from last year's records of the estate I am on, (20 miles from Colombo), may be of some use to your correspondent "Goiya."

Excepting a few thousand nuts, the whole crop was sold in copra. The average price obtained for the year was R41.13 per candy, 1,133 nuts having been required to the weight. The cost of curing the crop, including husking and burning of husks, was R1.62 per 1,000, which added to the cost of transport, gave a net proceed of R32.40 per 1,000 nuts on the estate. I may add that I have begun this year under better auspices, having obtained so far R35.28 net.

Estates where nuts are easily disposed of, enjoying competition amongst buyers, need not make copra, but others less favourably situated, will find considerable advantage in selling their produce cured.

It is time the growers should co-operate and endeavour to improve on the system, so far followed, in offering their copra to the buyers, which if organized will secure a full market value for their produce and their labour thereon. Z.

COCONUT CULTIVATION.

Hanwella, April 20.

SIR,—Coconut planters must be grateful to Mr. Cochran for his scientific observations—and having supplied these with important information, showing what their produce removes from the soil, and what some of them, (unfortunately not all) return to it in different forms and proportion of fertilizers.

Mr. Jardine contributes most useful and practical advice—which derived as it is from experience, and known success, nobody should hesitate to follow.

In the *Observer's* editorial of the 6th instant, comments have been made upon the considerable diversity in returns from manuring—and the desirability of experiments being made to see to what extent the bearing could be increased by manuring. This could be done with a small patch or particular field, but not over a large area—unless it is on an estate—properly treated from its infancy—and otherwise a model one—besides manuring.

It is beyond doubt that the coconut like almost every other product cannot be successfully cultivated without the use of fertilizers—but this is no reason why it should be considered imperative that it must be arithmetically and scientifically proportioned, to entitle us to a sure and abundant crop. The results of manuring must certainly vary with different growers—though they might follow the same prescriptions in form and quantity and this difference will be due to the composition of different soils—irrespective of fertility and moisture available. A great deal will also be due to *jat* and the *modus operandi* at the start, and not a little to the system followed in the application of the fertilizer.

In the case of a modern plantation—the cautious planter will have been in the first instance careful in the selection of the land, and with the nuts for planting—so that the results of his labors to follow—cannot be disappointing. It is not so with old plantations more or less neglected. Here the cultivator is supposed to vastly increase his average crop, even to the extent of making a certainty of it—by manuring. Undoubtedly this must tend to an improvement, but time must be allowed and a more liberal system of manuring followed for satisfactory results.

Mr. Jardine properly points out we must not only manure for fruit, but leaves, stem, and roots as well, and what a quantity some neglected trees will require, before they can spare any for fruit!

Very frequently on old plantations we come across some very bad patches of soil, where little or no cultivation is possible, as the growth and spreading of roots are obstructed by stone, cabook, or laterite. The trees in such soil—others of bad *jat*,—those with their trunks damaged, and barren ones:—on such little improvement can be effected by manuring, consequently this must tell on the average crop of the estate.

I agree with Mr. Jardine and doubt the existence of estates on which the trees yield an average of 90 nuts per tree. Should there be any, I do not believe that the owners of such estates are better off than those getting only 50 to 60, when the size of their respective nuts are considered in the out-turn of the number of nuts to the candy of copra. This is another point Mr. Cochran should consider in the making of his tables.

Now that we are supposed to know the manurial ingredients required for the coconut, it will be useful to learn the different opinions respecting the system of application to be followed. This in my point of view being the most important.

My humble opinion is that the drier the climate, the deeper into the soil should the manure be applied and the farther from the tree to encourage the growth of roots deeper from the surface, where more moisture will be available; and farther from the trees they are drawn, the larger will be the area over which the moisture is absorbed. Of course, I would not manure where there are no signs of roots, but it should be the effort of the cultivator to bring them gradually where they have not been before and encourage them to go farther if possible.

In conformity with my views and the little experience I have gained, the following is the system I would adopt and on which I should very much like to hear the opinions of Veteran Planters.

In the first year I would spread the manure, one foot clear of the trunk in a radius of 4 ft. and the soil turned if possible in lumps to a depth of about 10" this operation in a field planted say 22' apart will leave between lines—both ways,—a strip of 12' uncultivated soil. The third year one of these strips is manured uninterruptedly between each line, and the cross strip is taken in hand and dealt with similarly in the fifth year—having thus in three applications manured and tilled all the soil over the whole field and encouraged the growth of roots everywhere—and avoided disturbing them too frequently—as it would if regularly manured every third year at the foot of the tree.

Further manuring when due would take place between lines, each application made between trees every other year crossing one another.

Considering that a good tillage of the soil cannot be given without severing a large number of roots of the coconut it must follow that the farther from the tree this injury is inflicted the less it will be felt.

As with every other products, so with the coconut, cultivation must be carefully and thoroughly done and the old saying "that what is worth doing at all, is worth doing well," is as true of this as any other cultivation.

C. Z.

TOMATOES AND THEIR CULTURE.

April 22.

DEAR SIR,—With reference to your remarks regarding tomatoes from Dehiwala, it is no surprise to have tomatoes produced during dry weather; in fact, I find they cannot well be grown under any other conditions, as unless sheltered from rain in wet weather they become affected by a disease. I should like to know the experience of some of your readers in growing this very useful esculent.

X.

PINEAPPLE CANNING.

Kandy, April 23rd.

DEAR SIR,—In one of your issues. I note that you wondered why Ceylon did not can and export pineapple like Singapore. For the best of all reasons, I fear, because the trade is overdone. The pineapple canners in Singapore have been losing money on the business and a good deal of the land formerly in pineapples, has been let slide; so I was told when at Singapore last year.—Yours truly,

PLANTER.

ARTIFICIAL MANURING.

A NEW AGRICULTURAL ANALYST.

Colombo Commercial Company, Limited,
Colombo, April 26.

DEAR SIR,—The greatly extended use of valuable concentrated fertilizers calls for exact scientific information on all points connected with the selection and preparation of

manures, in order that there may be no waste and that the best economic results may be obtained. We have, therefore, deemed it advisable, as well in our own interests as estate agents and proprietors, as in the interests of our constituents, to engage a trained Agricultural Analyst. We have pleasure in informing you that we have secured the services of Mr. Robert Eadie, who has worked under Professor Aikman, of Glasgow, for twelve years, and for the last seven has acted as his Chief Assistant. Mr. Eadie, who is well acquainted with the methods adopted in modern manuring, will analyse any sample of soil submitted; and, if desired, make a manurial recommendation. Having regard, however, to Mr. Bamber's investigations and his continued residence in the planting districts, we do not anticipate that Mr. Eadie's assistance will be required so much in this direction as in preparing and analysing manures. In future we shall be able to verify all analyses furnished to us, and thus from our own knowledge guarantee the purity of each manure we sell.—I am,

Dear Sir, yours faithfully,

JOHN G. WARDROP, Manager.

IMPERIAL TEA COMPANY (CEYLON).

CORRESPONDENCE RESPECTING AGENCY CHARGES, &C.

SIR,—Now that the Imperial Tea Company of Ceylon has issued its report for 1899, and now that the lucky shareholders are aware that the perennial and princely dividend (perennial it would seem) of four per cent is to accrue to them, it may interest some of them, if I give an extract from some correspondence I had with the local agents during 1898. As there has been no difference made, to my knowledge, in the charges, shareholders can draw their own inferences as to how much profit is absorbed. (Vide local Agent's letter.)—Yours, &c.,

ARTHUR R. WIGGIN.

Oddington, Lindula, May 1.

Extract from a letter to Messrs. Whittall & Co., Agents for the Imperial Tea Estates Company of Ceylon dated August 5th, 1898:—

I notice that Agency Charges in Colombo are 1 per cent on disbursements. I presume this applies to all monies paid into estate accounts. Is there no commission on drafts? I also note 1 cent per lb. is paid on all tea shipped or sold locally; is charge for shipping included in this one cent, or is this a separate charge? (Answer gives it as included.) I notice in balance-sheet for 1897, 2 per cent. is paid to the London Agents for all produce sold in Colombo. Assuming that all produce of the Company's estates was sold in Colombo, am I right in supposing the Agency Charges would be as follows:—

Allowing the crop to be this year the same as last 565,170 lbs. and supposing it all to be sold in Colombo at, say, 40 cents; and taking all Estates expenditure to be 30 cents, including brokerage etc., profits would be, so far as ordinary charges went, R56,517-00—less Colombo charges at 1 cent per lb. R5,651-17; less London agent's commission at 2 per cent.—commission R4,531-36, or 18 per cent. of the Ceylon profit. Please correct me if I am wrong. Add to this the Directors, and 27 per cent. is accounted for. (£350 at 1/4=R5,250) (Signed) ARTHUR R. WIGGIN.

P. S.—The answer to this I cannot be at the trouble of copying out, but it was so effect that my figures were in the main correct but misleading.

Shareholders appear to have no redress, as the Directors apparently entered into these harmless

arrangements on their behalf, and they will be in effect until the Directors renew them. It is justifiable to assume that the London Agents have an equivalent commission on tea sold in London to that sold locally. (Copy forwarded to local agents—reply affixed)—A. R. W.

A. R. Wiggin, Esq., Oddington, Lindula,

Dear Sir,—We return herewith the press copy enclosed in your letter without date. The following clause appears in the Directors' Report, dated April 17th 1899, of which you doubtless have a copy:—

* "The Directors are pleased to report that the Colombo Agents have voluntarily made a modification in their scale of charges, as from the commencement of the 1898 season, to the advantage of the shareholders."

It is therefore, unnecessary for us to go into the question of corrections of inaccuracies in your letter to the Press. For any further information we would refer you to the Head Office of the Company.—Yours faithfully,
(Sgd.) WHITTALL & Co., Agents.

The Imperial Ceylon Tea Estates, Limited, Colombo,
May 3rd, 1900.

MR. SUTTON'S SAFETY STEAM DRIER.

Talawakelle, May 3.

DEAR SIR,—I am sending you a sample of cocoa dried in my Patent "Safety" steam heated dryer and shall be glad if you will kindly give me your opinion about it.

In the first place I must tell you I know nothing about cocoa, nor had I any one to assist me during the drying process, bar coolies. I carried out the instructions given me by a few kind friends to the best of my ability. Had I had some experienced person to help me the result would have been better.

The beans were fermented at Katngastota, washed and put in a bag and sent to Drayton factory to be dried, where I have been experimenting with one of my "Safety" dryers. The beans were 24 hours on the road from Katugastota to Drayton before they were put in the "Safety;" they were washed in cold water.

The boiler which supplied steam to the "Safety" was also supplying steam to an 8 HP engine driving three tea-rolling machines. The pressure of steam in the boiler was 60 lb per square inch, by means of a reducing valve, the pressure of steam in the coils of the dryer was only five lb per square inch, which gave a very even temperature of 140 degrees F during the whole time the beans were being dried, from start to finish. The beans were spread over two trays, one deep, but I think they could with ease be spread two or three deep and thus give a far larger outturn. The trays have galvanised iron wire mesh, a piece of hessian cloth was spread over the wire mesh and the beans spread on it.

The following are particulars and results of the experiment.

MONDAY.—Weight of cocoa after washing 54 lb. Spread on two trays 3' 6" by 3' 6". Time in the dryer three hours, turned over about 15 minutes. Weight of beans after three hours drying 35 lb. They were then spread out on a wooden floor and covered over with Hessian cloth and left so till next day.

* No mention of amount or any details given.—A. R. W.

TUESDAY.—Weight of beans before being put in dryer 34 lb. Kept in dryer four hours and turned over as before. Weight when taken out 27 lb. They were then spread on the floor as before and allowed to ferment till next day.

WEDNESDAY.—Weight of beans before being dried 26½ lb. Duration of time in dryer third day six hours (these could have been spread on one tray only). Weight of beans after six hours drying 23 lb. They were then spread out on the floor as before.

THURSDAY.—Weight of the beans as per sample 22 lb.

Result 54 lb. green beans, 22 lb. dry.

One 16 Tray "Safety" will dry at 12 lb. of beans per tray placed one dryer on the tray, 192 lb. in 3½ hours, 3 by 192, 576 lb. per day of 10½ hours, or 1,152 lb. per day of 10½ if placed two deep, or 1,728 lb. per day of 10½ if placed three deep. It can only be found out by experience what is the correct thickness to place them in on the trays, also what is the correct temperature they ought to be subjected to during the different periods of drying.

The temperature can be regulated and evenly maintained to a degree, from that of the outside air, to anything up to 260 degrees F with fifty lb. steam pressure. The consumption of fuel was very hard to ascertain correctly, as the boiler was supplying steam to the engine as well during the first two days, but on the third day when the boiler, an eight horse power loco, was used for the dryer alone, it used one yard of moderately dry firewood to raise steam from cold water and kept up steam during the whole of the six hours. The result would have been the same had all the trays been in use as has been proved when drying green tea leaf. A greater economy in fuel would be effected if a boiler of three to four horse power were employed, which is ample to supply steam for two or three sixteen Tray "Safetys."

The "Safety" in which the experiment was made has sixteen trays 3' 6" by 3' 6", but these machines are made in larger sizes of 32 by 48 trays.

I should be very glad to receive advice on the subject, of artificial drying of cacao from cacao planters, also their opinion of my experiment.—Yours faithfully,

G. W. SUTTON.

P. S.—The dryer has been doing very fair work, drying tea, considering the low pressure of fifty-five pounds per square inch, at which it has been worked. I will send you full details as soon as I get the reports on the samples.—G. W. S.

A NEW COCOA-DRIER.—We draw attention to Mr. Sutton's interesting letter on another page, describing the working of a new cocoa drier which appears to have turned out very successful results. The tin of dried beans forwarded to us commend the merits of the drier; for the finished article is as clean and evenly fired as the most fastidious chocolate manufacturer could desire; and further, having tasted several of the beans, we can pronounce judgment that their flavour has been excellently preserved.

FUNGOID PESTS AND THEIR TREATMENT.

Trio Lodge, Jail Road, Borella, May 5th.

DEAR SIR,—I have read in different Ceylon papers something about a pest which is attacking tea. By the descriptions given I believe it is to be a fungoid pest. The methods recommended for coping with this enemy are cultivation, and manuring; they no doubt are very good as an adjunct, but by themselves are inadequate.

As I have had to cope with both fungoid, and insect pests in Australia, my experience might be of some little use to the tea planters.

The advantage and profit of spraying for fungus diseases is now placed beyond doubt in Anstralia and America. In order to obtain the best results, good cultivation, including drainage, and judicious manuring ought to be attended to, and if this is followed up by the constant and careful use of the *spray-pump*, the end will be found to fully justify the means.

Amid the multiplicity of remedies and treatments there are three, which may safely be selected on account of their inherent value and of having stood the test of experience:—

1. The Bordeaux mixture,
2. Ammoniacal Solution of Copper Carbonate.
3. Modified Eau Celeste.

The following is the mode of preparation I adopted and which I found the easiest and best, and the formula:—

Quicklime (to be freshly slaked)	4 lb.
Molasses	4 lb.
Bluestone (sulphate of copper)	4 lb.
Water	20 gal.

Take a wooden vessel, holding at least about 18 gal. of water, and place in it 4 lb. of quicklime which has been freshly slacked, cooled, and passed through a sieve. Next pour over it the four pounds (4 lb.) of treacle, and run on a few pints of water from a tap to stir up and mix the ingredients well. Then make up to 16 or 18 gal. with water, and leave standing for a few hours, giving a good stir once in the interval. A clear treacle-coloured liquid is the result, with the unused lime at the bottom of the vessel. Next take a wooden pail, holding from two to four gallons of water, put the powdered bluestone in a coarse canvas bag and suspend it in the water until the sulphate is completely dissolved. Pour the solution of blue stone into the spraying machine, and decant or pour of the clear, treacle-coloured liquid into the same vessel without allowing the sediment to pass. This will give 20 gal of beautiful greenish liquid, ready for spraying. If the soaking of the lime, and treacle and the solution of the bluestone is allowed to go on over night, the liquid will be ready for mixing in the morning, and while it is desirable to use the material as fresh as possible, yet if rain should intervene or any interruption, the treacle and lime mixture will keep without injury for a few days.

To get the best results use fresh lime, and lime of good quality, see that the bluestone of a deep blue colour does not contain an admixture of copperas or sulphate of iron and let the water used be cold. Only 56 parts of lime are required to neutralise or destroy the acidity of 250 parts of bluestone, so that between three and four times as much lime is over to render the mixture alkaline. When sprayed upon the trees and exposed to the air, the lime present will become converted into carbonate of lime, which will form an insoluble crust, and help to retain the copper salt on the foliage, while the sulphate of lime which is also a component of the spray will be gradually be dissolved away.

Spraying should be done thoroughly to be effectual and a fine mist is what is wanted, not a drenching downpour. If too coarse the fungicide is wasted, and the collecting in quantity on the leaves is more likely to do damage. A cool calm day is best for the purpose; when wind is blowing there is a waste of material, and the spray is not uniformly distributed. The strength

I should recommend for use among tea is 40 to 80 gallons of water to the same quantity of material. a dilute solution being particularly necessary for the delicate foliage of the tea. In cases where the spores of the fungus are on the under surface of the leaf, it is desirable that such portions receive the most thorough spraying.

(2) AMMONIACAL SOLUTION OF COPPER CARBONATE.

Copper Carbonate	3 oz.
Ammonia (26 per cent.)	1 qt.
Water	22 gal.

In a wooden pail mix the Copper Carbonate with sufficient water to make a thick paste, and see that it is thoroughly wet; next add the ammonia water, having a strength of 26 per cent., to dissolve the paste. When all is dissolved, pour the solution into a barrel and dilute the 22 gallons of water. This is the strength we use in winter in Anstralia, half the strength, or twice the amount of water to the same quantity of material, is what I should recommend for the tea bushes.

(3) MODIFIED EAU CELESTE.

Eau Celeste, or azure-blue water, is a solution of bluestone and strong ammonia, while the modified form has the addition of washing soda.

Bluestone (Sulphate of Copper) ..	2 lb.
Washing soda (Carbonate of soda) ..	2½ lb.
Ammonia (26 per cent.)	1½ pt.
Water	32 gal.

Dissolve the bluestone in a wooden pail, in say two gallons of water; treat the washing soda in the same way and pour it into the first solution, stirring them well together.

Before spraying transfer the solution to the spraying machine, add the ammonia and dilute to 32 gallons of water. This being the strength I would recommend for local use.

It is very desirable that experimental committees should be formed in the infected districts to test the efficacy of various compounds and find out the cheapest and best for combating fungus diseases. The experiments should also consist of (1) Manurial treatment alone; (2) Chemical treatment alone; (3) Manurial and chemical treatment combined.

The strength of the preparations, the best time and mode of application, the cost and the result can best be ganged by carefully conducted tests in the infected districts.

While these points are being settled for local benefit and guidance, it is not to be imagined that the application of these mixtures has not been sufficiently tested elsewhere, for in Anstralia we have used them successfully for years. Ceylon is just beginning to become alive to the fact that fungus diseases and insect pests threaten the tea estates. They must not be allowed to become the master, but the planters must master them, mainly on the lines of the good old principle that "prevention is than better cure."—Yours faithfully,

P. GEO. SCHRADER.

TEA : OPTIMISM AND PESSIMISM.

Upcountry, May 5.

DEAR SIR,—Who is "W.E.J." that he takes so one-sided a view of the contents of your columns? He says "notes and letters" cry down tea "every day" and he cites just one miserable timorous letter as his illustration. Now for my part, I have been more struck with the *optimism* than the *pessimism* of your columns on tea. What about the series of articles on "Prosperous Tea Companies," W.E.J.? Why if a steady series of 15, culminating in an 18 per cent dividend—a second series of 15's—then 10, 8 and 7 per cent dividends all prominently dilated on editorially, don't cheer up tea men and prompt them to do likewise, what can? Then there was "Manuring" and such opti-

mistic writing that one planting authority, I think, asked you not to publish such facts and figures, lest there should be a rush to do likewise. After all this, I think we can do well with a little of the pessimistic.—Yours truly,
REGULAR READER.

["Fiat Justitia," in whatever subject is handled in our columns, will always mean that we shall endeavour to show both sides of the shield. We overlooked the exaggerated tone of W.E.G.'s (not W.E.J.—as incorrectly printed) remarks; but the above rejoinder is well deserved. Pessimism attracts attention, though it be expressed but seldom; but sunny optimism is borne along on the smiling wave of public recognition (and sometimes illusion) and, by some, more speedily forgotten.—Ed. T.A.]

PLANTING NOTES.

COCONUT FERTILISER.—Mr. Arthur Keyser, the British Consul for Borneo, writes to the *Malay Mail* that coconut trees at Sandakan in British North Borneo thrive luxuriantly from being manured with the refuse of the mangrove bark after extraction of its dyeing materials.

AUSTRALIAN PRODUCE FOR DELAGOA BAY.—The latest consular report of Lourenço Marques and district (Delagoa) states that the erection of large cold stores for frozen meat, &c., gives hope that the development of the Australian frozen meat and fish trade, begun in 1893, will assume large dimensions. The principal agricultural products of the Portuguese possession are :—Sugarcane, ground-nuts, manioc, sweet potatoes, millet, mealies, wheat, barley, oats, and potatoes.—*Sydney Mail*, April 14.

SNAKE POISON INVESTIGATIONS.—Captain Elliot, I.M.S., in the "General Deductions" with which he concludes his last paper on snake poison investigations, remarks :—"It seems clear that the serum obtained from the blood of venomous snakes is, when obtained pure, antidotal in its properties. The antidotal power possessed does not, however, appear to be of a sufficiently high order to warrant the hope that (the blood of these dangerous reptiles will yield a fluid of commercial value as an antidote to snake-bite, unless means are found of separating the antidotal constituent from the serum. More than this I am not at present prepared to say."—*Madras Mail*.

CINCHONA SEED FROM JAVA.—Now that cinchona planting has recommenced in several districts in Ceylon, it is of great importance to know where good seed can be got. Java has now, undoubtedly, the richest cinchona trees in the world, and Java seed ought to do well in Ceylon. We used to consider bark analysing up to five or seven per cent as valuable; but the advertisement from Java which we publish in our daily indicates trees with bark up to 17 per cent! The seed from such trees, if carefully plucked and transported, must be very valuable. The prices fixed are from two to five guilders (each about 2s in value, we believe,) per gram, of which about 200 go to the ounce. The seed is, therefore, priced very high, undoubtedly; but we suppose an appreciable quantity is found even in each gram, or the 200th part of an ounce. Can there be any mistake in our calculation?

SERICULTURE AT BANGALORE.—It is interesting to learn that the mulberry bushes (*Morus alba*) which were grown at the Lal Bagh, Bangalore, for the experiments in sericulture, are now more advanced and will soon assume a commercial aspect. The two Japanese experts employed by Mr. Tata are hopeful of good results from the introduction of eggs from Japan, and have been partially successful in obtaining a cross between the indigenous and foreign varieties.—*Pioneer*, May 2.

MR. SUTTON'S TEA-DRIER.—Says the *Indian Planters' Gazette* (April 28th) on Mr. Sutton's tea drier, the good results of which with cocoa beans we recorded yesterday :—"Tea men in India would no doubt be better able to judge of the capabilities of the new drier if they could see it working. Mr. Sutton, we understand, intends to exploit India, but he will find it uphill work campaigning against the excellent machinery which is already so well-known and so widely popular with Indian planters. Messrs. Davidson and Messrs. Marshall Sons, Ltd., at present hold the fort, and it is not likely that they will surrender the field without a great contest. Mr. Sutton, however, is certain of a fair field and no favour."—We doubt that a machine of such excellence, as Mr. Sutton's, will find the work so very uphill as our Indian friends anticipate; but before being able to form to a precise judgment on its excellences in dealing with tea (although, theoretically, is ease and range of regulation is just what has so long been wanted) we await further figures from Mr. Sutton, after he has analysed his first experiments with our staple.

LIFE IN FIJI appears to be popular with the Indian coolie, since, out of a total Indian population of over twelve thousand, nearly eight thousand, according to the last official Report to hand, are coolies who have stayed on after completing the five years for which they were originally shipped. Their prosperity is testified to by the fact that, during the twelve months, they were enabled to deposit £16,000 in the local bank, besides buying a good deal of property in land and houses and sending nearly £2,000 to relatives in India; while in one district alone 13,000 tons of sugarcane were grown, on their own account, by the time-expired coolies. These figures are the more striking as the Report states that the majority of the time-expired coolies prefer starting a homestead for themselves to continuing plantation work. The health of the community appears, on the whole, to have been good, and the birth-rate high. The principal drawback at present is a social one, and lies in the fact that the number of women imported into the Colony is disproportionately small as compared with that of the men. The last returns show just three men to every woman in the population. The result has naturally been a state of disorganisation which has upset the family life of the coolies and led to a good deal of crime, no fewer than six murders, from motives of jealousy, having taken place during the year under review. The question of remedial measures, we are told, is under consideration, and attention is drawn to the case of Trinidad, where it has been found necessary to materially increase the proportion of coolie women sent out. Some such measure will, no doubt, have to be taken in the case of Fiji.—*Indian Witness*, April 27.

ANALYSES OF CEYLON TEA..

Mr. John Hughes—the well-known veteran Analytical Chemist of Mark Lane,—deserves the thanks of all interested in the Tea Industry of Ceylon for the trouble he has taken to arrive at definite results as to the requirements of the tea plant. We append his very interesting paper and analyses, the whole being so clearly put that the youngest planter can make no mistake in following the investigation and understanding the results arrived at. These may be summed up briefly as shewing the overwhelming importance of “potash salts” in any manure for tea under ordinary circumstances. (Of course, a soil naturally rich in potash would require less and so as to the other constituents mentioned). Next to potash in importance is phosphoric acid in order to enable high-priced teas to be produced and manufactured, and just as potash and phosphoric acid come first in the mineral or inorganic portion of tea, so does nitrogen stand first in respect of the organic needs of our staple. In fact to supply nitrogen in a slowly available form, Mr. Hughes thinks, is probably the first form of manuring required by tea. But we must leave this admirably clear and concise paper to speak for itself:—

Now that the necessity of manuring tea upon certain Ceylon soils is fully recognised and careful inquiry is being directed to the selection of the most suitable, and at the same time the most economical, materials for the purpose, it is very essential to ascertain what are the special requirements of tea. Indeed, in any attempt to carry out economical manuring the requirements of the crop should receive as much attention as the ability of the soil to supply the same. It occurred to the writer that comparative analyses of similar kinds of tea grown at similar periods of the year and presumably under similar conditions of climate, but which yielded very opposite market prices, would afford some interesting, and possibly useful information. At the writer's request, Mr. H. K. Rutherford, of the Ceylon Tea Plantations Co., Ltd., very kindly supplied six samples of broken orange pekoe, the sale room prices of which varied from 1s 4½d for No. 1 to 6½d for No. 6. The analyses occupied some time as it was desirable to determine the proportions of the four most important plant food constituents, namely nitrogen, potash, phosphoric acid and lime, the figures for which, together with other details, are contained in the following tabulated form. A careful examination of these results suggests the following remarks:—

1. The high priced samples Nos. 1, 2, and 3 yielded the most soluble hot water extract upon five minutes' infusion: this is only what would be naturally expected.
2. This extract contained, it will be seen, most of the mineral constituents and nearly the whole of the potash, but rather less than half the quantity of the total nitrogen, though the proportions soluble in hot water are, it will be noticed, much higher in the high-priced tea than in the low-priced samples.

3. A glance at the figures for total nitrogen shows the difference in a very marked manner. It is curious, however, that No. 3, which only fetched 1s 2½d per lb., at public sale, contained 4·93 nitrogen, while No. 1, which was sold at 1s 4½d, only contained 4·45 nitrogen, and the same amount was found in No. 2 sold at 1s 2½d. It is possible that No. 3 represents an illustration of defective manufacture, because the figures are similar for extract in Nos. 3 and 1, namely 45·30 against 45·15; also the figures for soluble mineral matter and soluble potash are in each case higher than in No. 1. Possibly, therefore, the determination of the percentage of nitrogen may be useful in ascertaining whether a low market price is due to leaf naturally poor in nitrogen or to imperfect manufacture.

4. The figures for soluble mineral matter are generally higher in the high-priced tea; but as regards the total ash constituents, the figures are higher in the low-priced tea.

5. Potash stands out very prominently as the dominant element of the mineral or ash constituents of tea, and plainly indicates how important it is that potash salts should be included in any complete manure for tea grown on soils that may be naturally deficient in this respect.

6. Phosphoric acid, though existing in the ash in much smaller proportion than potash, is evidently more abundant in the high-priced tea, the figures being ·87, ·92 and ·87 against ·66, ·71 and ·58 in the low-priced tea. As Ceylon hill soils are known to be generally poor in phosphoric acid and the better quality of tea is shown by these analyses to be much richer in phosphoric acid, it follows that every complete tea manure should contain phosphoric acid in a readily available form, and that it should only be omitted when the particular soil has been found by careful analysis to be naturally well-supplied with this constituent, which is evidently so essential to perfect production and early maturity. If the figures for soluble potash and phosphoric acid be added together the total results furnish an interesting correspondence with the market prices, if the figures for No. 1 be excepted.

	Nos. 1	2	3	4	5	6
Soluble Potash	1·87	2·13	1·92	2·07	1·98	1·98
Phosphoric Acid	·87	·92	·87	·66	·71	·58
	2·74	3·05	2·79	2·73	2·69	2·56

7. Lime appears to exist in smaller proportion in the high-priced tea and in larger proportion in the low-priced samples.

8. The figures for sand suggest that the specimens of tea containing the most quartz crystals were grown on soils containing much quartz or at least were more exposed to wind.

9. Manganese was present in very marked quantity in the hot water extract, and the determination of the variation in amount of this interesting constituent suggests a subject for future investigation.

10. Finally these analyses plainly show that nitrogen is the dominant element of the organic portion of tea, just as potash is the dominant element of the inorganic or mineral portion of tea.

Further that the supply of nitrogen in a slowly available form is probably the first

kind of manuring required by tea and that the necessity for such manure can be detected either by analysing the made tea or the soil producing such tea.

"UNDEVELOPED RESOURCES."

No man in the island by this time knows more probably of our different wild and unoccupied districts than the Conservator of Forests. This we have long seen from his valuable annual Reports and we gave a sample of out-of-the-way information received from the same source in our London Lecture. Mr. Broun has lately returned from the Hambantota district—a scene, for a great extent, of desolate chenas and hopeless scrub; but we are interested to learn that he came across cotton growing wild over considerable areas between Kirinda and Palutupane, and yet not at all on a kindly looking soil. The enterprising Parsee lessees of the Colombo Cotton Mills should send an agent to inspect these "wild" cotton fields. The Conservator has, of course, had experience of cotton in India, and he pointed out long ago a large stretch of cotton soil between Giant's Tank and Tunakkai in the Northern Province, which after proper working up, ought to grow cotton well. Unfortunately, this is by no means a very paying product at present, even under favourable circumstances; and we cannot count ourselves of those who think that the railway is to bring a rush of

capitalists or settlers all at once into the country. It will be a case of *festina lente*. It was amusing to read a would-be local authority the other day saying that the Northern railway would at once lead to English investments; while on the other hand he denounced all money spent on irrigation as worse than wasted. This was the converse of the memorable scene in Mr. Chamberlain's private room when a worthy knight descanted on the grand resources to be developed by the new railway and the leader of the Deputation who had, as Governor, travelled in that region a good deal, asked if he could name one single product that could be profitably grown without water and "Goompane could make no reply." There lay the secret, we believe, of the sudden determination to include "Irrigation" so largely in the Public loan. Of course, there are extensive forest and timber resources capable of being dealt with and we still hope to see a big sugar experiment begun on the banks of the Mahaweliganga. But time and patience will be required. As to the coupling of a railway and investments, it must be remembered that our very remotest planting districts were invested in before ever there was a mile of rail in the island, and when even the nearest road was 50 to 80 miles off—so sure is a really remunerative investment to be found out!

Returning to our original topic, and the Hambantota district, it is of further interest to learn that there was discovered there a fair sprinkling of *acacia sundra*, believed to be synonymous with *A. catechu*, which, in Burma, yields a large revenue over Dutch manufacture. It has been found before in small quantities in the Puttalam district.

CEYLON TEA CROPS AND INCREASED YIELD OF TEA PER ACRE.

The question was asked some time ago as to whether the export of tea of recent years had kept up with the extension of planted and in Ceylon. One of the best answers was that afforded by Mr. G. Thornton Pett, of Pussellawa, who, taking our "Directory" as his guide, produced the following set of figures—(all but the total planted area for 1899 which we have ventured to fill in):—

Year.	Total Tea Planted acres.	Tea in bearing acres.	Yield per acre lb.	Total Ex- ported lb.
1883	32,000	6,500	256	1,641,810
1888	183,000	77,000	309	24,381,296
1893	273,000	205,000	401	84,406,064
1898	364,000	289,000	414	119,769,071
1899	380,000	305,000	425	129,894,156

It will be seen that the yield per acre from land in bearing has steadily advanced. Of course, as Mr. Pett said, "an important factor to be taken into consideration with the increase of yield, is when the bulk of the tea in the lowcountry came into bearing, this would give the yield per acre for the whole island a perceptible rise. There is no doubt as yet that the lowcountry tea has not gone back, in spite of sporadic attacks of grey blight."

A FARMER'S EVERY DAY LIFE.

(By "Cosmopolite.")

The end of the month of March finds all agriculturists busily engaged with

SOWING OPERATIONS

and this is the time when the manure merchants use their most persuasive eloquence to induce farmers to purchase artificial manures, declaring that, without these, good crops cannot be obtained and high farming will become a lost art. Great Britain is spoken of as a country of intense agriculture, where farming is always done at high pressure, and where the greatest amount of produce is taken from the land, and this productiveness of the soil is accounted for by the skilful and thorough cultivation thereof, together with the liberal application of manures. We find a great deal of nonsense in the columns of the Agricultural Press, about the good that has been done by science in discovering various artificial manures, which have aided our farmers in attaining their present position in the fore rank of agriculture. It is not for me to set myself up as an opponent to the theories of those scientists; but having tried, I believe, every kind of artificial manure, I consider that I have some small right to say a word on the subject. My present farm had been badly *konnached* (to use a good Scotch word) for about 20 years, so, when I signed my lease, I knew that I had a considerable up-hill work before me; but, by an ample dressing of cattle manure, I so surprised the soil which had, for years, been accustomed to a scanty application of artificials, that it forthwith proceeded to produce excellent crops. Not only do I manufacture a large quantity of bulky manure, on the farm, but I buy much more from any of my neighbours who are willing to sell, and who prefer the cheaper style of manuring by artificials. In course of time people began to remark my fine crops and supposed that my bills for artificials was a very heavy one, to which my reply invariably was "not a penny." And now, when I see an extra good crop in any field, and am inquisitive enough to ask what it had been manured with, the answer is "cattle manure." When I see a field of turnips badly attacked by finger and toe disease and I ask what is the reason of this, I find that superphosphate has been applied. One year I spent some time at Swanley, in Kent; it had been a very dry summer, and the crops were simply ruined. I paid a visit to a gentleman who, as an agriculturist, was highly spoken of in his district, and was shewn round the farm by him. Coming to a field of potatoes, I found about

50 DRILLS A MAGNIFICENT CROP;

the remainder of the field being almost barren soil. I asked for an explanation when he told me that he had manured these fifty drills with cattle manures, and the others with artificial. He also showed me a small field of wheat—a magnificent crop—which had been similarly treated, whilst his other fields were as bare as those of his neighbours who worshipped at the shrine of artificials. He added that they never, in that district, used cattle manure, as it was too expensive and laborious a task carting it to the fields, but purchased artificials in preference, which meant a great saving in labour. Undoubtedly the master's eye and foot are the best manures for the field, for he can see what acts best on his class of soil; but, so far as my experience goes, in various parts of the world,

artificials *sometimes* give a good result, if the weather is suitable, but cattle manure *never fails*. I have often heard proprietors speak grudgingly of some of their tenants, declaring that they were growing extra heavy crops and taking too much out of the ground. Could anything be more ridiculous?

HEAVY CROPS

cannot be grown systematically without raising the condition of the land; the more produce we take off a field—not spasmodically, but year after year—the better is the condition of the soil, because such a thing could not be done without a liberal and judicious manuring being kept up, and if landlords would only have the sense to know what is good for them, they would stick to the tenants who can grow big crops and get rid of those who, by haggling the land, are thereby stopping its productiveness.

ACME TEA CHESTS.

The Company is turning out 13,000 chests a week, the factory can do no more—immediately they are in a position to supply them to Ceylon you will hear. The veneer chest is a great success, nevertheless there are still many people sticking to the original steel chest which proves that your belief in is from the beginning was quite correct. So they go manufacturing both kinds, and orders come pouring in without even being asked for.—*Glasgow Cor.*

RETURN OF A FRENCH SCIENTIST.

M. Prudhomme, director of the Department of Agriculture in Madagascar, who was in Ceylon in January last with two collaborators, M. Guyon and Lucaze, returned to Ceylon per M.M. "Australien" from a three-months' trip in Sumatra and Java. His assistants in this mission of scientific and administrative enquiry left for Japan, and M. Prudhomme returned alone to spend the last available month in the East, of his year's leave from his official position, in Ceylon and India. M. Prudhomme stayed in the island for a week; proceeding to Negombo and afterwards visiting Kandy.

DESTRUCTION OF RATS.

Mr. P. R. Gordon, Chief Inspector of Stock, gives the following simple method which, according to American papers, has been most successful in clearing rats off premises where previously they had defied the presence of from twenty to thirty cats:—Get a few small pieces of shingles or thin boards. On each of these put a teaspoonful of molasses, and over this scrape a small amount of condensed lye, and lay the boards or shingles around the rat holes, or wherever their runs are. The molasses will draw them, and the lye will eat out the coating of their stomachs. Four days are given as the time when the rats will have been cleared out. From the fact that this mode of destruction has appeared, at intervals, in many well-conducted journals in the States, for months past, Mr. Gordon is induced to think it is well worth a trial here. The recipe is simple, cheap, and easy to carry into effect.—*Queensland Agricultural Journal*, April 1.

THE GAME LAWS OF CEYLON.

(By Mr. Alfred Clark.)

Previous to the year 1872 there were no game laws and all persons without distinction were at liberty to kill deer and buffaloes in the Crown forests at any time, in any quantity, whether for food or trade.

In the year named

AN ORDINANCE (NO. 6)

was passed to prevent "the wasteful destruction of buffaloes and game, whereby the food-supply of the people is diminished." Game was defined to mean "deer and elk." Government Agents were empowered to declare close seasons for their provinces, not to exceed five months in each year, and to prohibit killing of game in any reserved forest. Battues or driving of game were prohibited. No restriction was placed on the killing of game by persons, whether Europeans or natives, within the Korales, Vidana Arachchies or Udaiyars' divisions in which they resided and they were empowered under the Village Communities Ordinance to make rules for the killing of game within their divisions. Buffaloes could not be killed anywhere without a license. Any person wishing to kill game outside his division was required to get a license from the Government Agent, which was in force to the end of the year in which it was taken out and cost R10. A license to shoot buffaloes cost R5 per month. Any person who shot game without a license or transferred it, or killed in the close season or in a reserve forest, or by battue, or driving, or was unable to account satisfactorily for meat in his possession in the close season, was liable to a fine not exceeding R50 for each offence. No imprisonment could be inflicted. An informer could be paid a moiety of any fine recovered.

This Ordinance was in force nineteen years and was then repealed, Government apparently being satisfied that it had failed in its object of preserving "the food-supply of the people."

A NEW AND VERY STRINGENT ORDINANCE.

No. 10 of 1891, was then passed—"to prevent the wanton destruction of elephants, buffaloes, and other game."

Under this Ordinance, a license which costs R100 is required to shoot an elephant. It may be obtained from the Colonial Secretary or any Government Agent, or Assistant Government Agent, who, however, may refuse to issue it or may revoke it after issue. If a license is refused or revoked, appeal may be made to the Governor, but it must be sent in within seven days of date of letter refusing or revoking the license. The shooting of tuskers is expressly prohibited and license is given only to "shoot at or kill" one elephant and the holder of the license is not at liberty to fire at and wound an unlimited number of elephants till he kills one. The officer issuing the license may insert any conditions he pleases, such as that no cow-elephants, or any bulls under a certain height are to be killed, and may restrict the district or forest and the time within which the animal may be shot at. No license can be in force more than three months. Free licenses may be issued to shoot any "troublesome or dangerous tusker or elephant, or buffalo." Elephants (also buffaloes, deer and peafowl) trespassing on cultivated land may be shot without license, but information must be given at once to the nearest headman or police-officer. Any person shooting a tusker without a license is liable

to a fine of R1,000 and confiscation of the tusks, and shooting a tusker without license involves a fine of R250, with perhaps six months' rigorous imprisonment added.

To capture a tusker or other elephant, a license costing R10 is required, which will cease to be in force after three months. If the elephant caught is taken out of the Island, an export duty of R250 must be paid.

To shoot a wild buffalo, a license which costs R20 and which will only be in force three months must be obtained from the Government Agent or Assistant Government Agent. A license to capture one only costs R2. Any person shooting or capturing a buffalo without a license may be fined R100 and given three months' imprisonment in addition. These rates and penalties are evidently designed to preserve these creatures in the interests of native agriculture. There is no close reason for buffaloes.

As the Game Ordinances were passed ostensibly to preserve "the food-supply of the people," it is as well to consider here how the Ord. No. 10 of 1891

AFFECTS THE NATIVES.

By it the right previously enjoyed by all persons of killing game within their headman's divisions is taken away. Game is defined to mean sam bur, spotted deer, red deer, barking deer and peafowl and the penalties for breaches of the law are increased, imprisonment being added. Though the wet months of the year constitute practically a "close season" for natives as they cannot or do not stalk game in the open in European fashion, the Ordinance adds an additional close season of the five dry months, which is the native shooting season,—by moonlight at drinking places.

Any jungle villager wishing to shoot or trap game must pay R3-50 for a license from the Government Agent or Assistant Government Agent, which will be in force from date of issue till 30th day of June next following. This seems a small sum, but is really a heavy charge on a villager whose income is probably not more than R5 per month. If a European, drawing R500 a month, was charged proportionately he would have to pay R350 for his game license.

Should a villager get a license, he is prohibited from shooting during the close season which is the five dry months of the year, the only season in which he can or is accustomed to shoot; he may not shoot at night, which is practically his only method of shooting; and though his license permits him to "capture" game, he may not "spread any net or snare." If he shoots without a license he is liable to a fine of R30 for each animal killed, plus three months' imprisonment. If he shoots at night or spreads any net, or snare at any time, or transfers his license, he may be fined R100 and given three months' imprisonment. If he shoots during the close season or cannot satisfactorily account for meat in his possession during that time, he is liable to a fine of R50, plus three months' imprisonment. An informer may be paid half the fine recovered.

In addition to this stringent Ordinance, Government passed another (No. 11) in the same year, imposing

A PROHIBITIVE EXPORT DUTY

on the hides and horns of sam bur and spotted deer, making it no longer worth the while of traders to employ native shikkaris to shoot for them. These two Ordinances practically put an entire stop to the shooting of game by natives, as it is evident that a license with such conditions

is of little use to a native, if an honest man, even if he can afford to pay for one.

It seems strange, under these circumstances, that Government should be so often charged by European sportsmen with not taking proper steps to protect the game of the country. It is very generally believed that in spite of these severe laws the game is being killed out. That forest districts contiguous to large centres of population are being depopulated of game and that illicit shooting to a considerable extent is going on everywhere does not admit of any doubt, nevertheless there is danger of exaggerated views being formed and statements made on the subject. When the difficulty of watching the actions of many thousands of jungle villagers scattered through some twelve thousand square miles of wild forest, is considered, it seems remarkable, that the destruction of game is not even greater than it is.

It is commonly supposed that

A VAST TRADE

in dried deer's meat is being carried on. No doubt a considerable quantity of venison, fresh and dried, is sold in towns like Puttalam, Trincomalee, Batticaloa and Hambantota, and in bazaars in planting districts which are within marketable distance of large forests; but that there is any regular or large trade throughout the country, is doubtful. The natives in the interior are well aware of the game laws and the meat of animals illicitly shot by them is mostly consumed locally.

The fact that large quantities of "cut" horns are from time to time shipped from the Island is conclusive proof that many deer are annually killed; but some of the conclusions which have been drawn by sportsmen, from the Customs House figures, as to the total annual slaughter are probably beyond the mark.

It has been asserted that many of the horns brought to market as "shed" horns are really taken from shot animals and "faked" to look like shed ones. It is, however, difficult to understand why any village hunter, or anybody else, should trouble himself to laboriously carve the hard bone base of a "cut" antler which he has a perfect right to possess and sell at any time (not being "meat") and which is of trifling value, only about 10 cents per lb. if from a sambur and 75 cents per lb. if from a spotted deer. To "fake" a horn, so as to deceive anyone of any experience, would require considerable time and skill. A native, if asked how he came to have "cut" horns in his possession during the close season, would be sure to say that he had picked them up in the forest, they having belonged to a buck which had been killed by a leopard. The falsity of such a statement cannot easily be proved. Some allowance should in fact be made for horns picked up by natives in this way. When it is considered that scores of leopards roam the forests, killing deer all the year round, it will be seen that the number of bucks pulled down by them is not likely to be altogether inconsiderable.

It will, of course, be said that it is not so much that the law is in fault as that its provisions are not enforced with sufficient energy. Sportsmen writing to the papers usually call upon Government to

"STIR UP THE HEADMEN,"

a class of persons about whose duties and capabilities they as a rule know little. Head-

men in the lowcountry are nearly always ignorant villagers who are expected to perform multifarious and onerous duties without pay or hope of promotion. They are responsible for the good behaviour of the people in their districts, for the sanitary condition of the villages, for collection of road tax and arrest of defaulters, and for registration of cattle; have to report on applications, enquire into all complaints and disputes and to attend to many other minor matters. They have their own livelihood to make. They know that if they take proceedings against game-killers, they will have to trudge to Court, perhaps 40 or 50 miles, and, it may be, three or four times owing to postponements of the case—bearing all expenses themselves. They are certain to make deadly enemies of the men prosecuted for an offence which, in their eyes, is scarcely any offence at all. Government officers, who are aware of these facts, only exercise ordinary common sense in not expecting much from headmen. An educated European, who would zealously perform a distasteful duty, practically at his own expense, under such circumstances, would be considered by most of his countrymen as almost too good for this world and would be regarded by many as a quixotic fool.

The most effective way of preserving game in the interests, both of the natives and European Sportsmen, would probably be for Government to appoint for each Province

A GAME BOARD,

consisting of the Government Agent, the Assistaat Conservator of Forests, and two unofficial members, one a European who would, of course, be nearly always a local European sportsman, and the other a leading native to look after native interests. The board would confer on all matters relating to the game laws, registration of guns, &c. The Government Agent would issue licenses, proclaim sanctuaries, sanction prosecutions, fix rates and give orders generally with the approval of the Board. Licenses on payment would be issued only to *bonafide* sportsmen, shooting for amusement.

In order that

"THE FOOD SUPPLY OF THE PEOPLE"

should be provided for, a number of free licenses would be issued annually to native hunters, say one for every five hundred inhabitants of any forest district on the following conditions:—(a) that the man is a permanent resident in the district in which he is allowed to shoot; (b) that he does not allow any other person to use his licensed gun; (c) that he does not shoot more than a specified limited quantity of game during the year; (d) that he brings to the Kachcheri the horns and hides of all deer shot, which will be sold by auction quarterly and half the proceeds paid over to him; (e) that he sells the meat, either fresh or dried, only to villagers for local consumption, at prices fixed by the chief headman with the approval of the Game Board; (f) that he does not use any irregular methods of killing game, such as pitfalls, traps, spring-guns, driving with dogs or poison and that he does not kill fawns; (g) that he does not shoot in "sanctuaries"; (h) that he furnishes within three months after issue of license, a list of all guns in his district; (i) that

he does his utmost to prevent killing of game by unlicensed persons; (j) and that his license may be cancelled at any time if not availed of or abused.

These free licenses would only be given for purely forest districts and none would ever be issued to Government officials or headmen of any rank. The licensed hunters would be allowed to shoot at any time all the year round and be entitled to a moiety of all fines recovered for offences against the game laws reported by them. If in the opinion of the Game Board game is scarce in any particular district, no free license would be issued for that district or only a very few head allowed to be killed in it.

Some of

THE ADVANTAGES OF THIS SYSTEM

would be that—(a) it can be adopted at once by mere order of Government without any change of the existing law; (b) it would relieve Government of responsibility for the preservation of game and throw it on the people themselves; (c) a body of unpaid game-keepers would be formed whose interest it would be to prevent illicit destruction of game; (d) the jungle people would be able to get meat for food of which they are practically deprived by the present Ordinance; (e) the useless destruction of game through wounded animals dying in the jungle would be reduced as licenses would only be issued to men known to be good shots and to possess good guns; (f) reliable information would be obtained as to quantity of game killed annually; (g) the killing in each district could be regulated to some extent, according to the head of game it carried; and (h) the nuisance of a close season would be abolished.

It is not claimed, of course, that this system will put a entire stop to illicit destruction of game, but it is believed that it would work a great deal better than the present one under which it is not anybody's interest to prevent unlicensed persons from shooting. The principal danger under the new system proposed will be that the licensed hunters will be tempted by greed to allow other men to shoot for them, also to exceed the limit allowed; but there would always be plenty of persons, jealous of their privileges, who would be ready to inform against them. The penalties threatened by the ordinance of R100 fine and three months' imprisonment with loss of a lucrative occupation, would probably induce to act fairly honestly.

The only absolutely certain way of preserving game is the establishment of

"SANCTUARIES,"

In a few years the Forest Department will have large "reserved forests," scores of square miles in extent, every river, tank, rock-pool and other drinking place in which will be known and shewn on maps and will be constantly visited by the patrolling forest watchers. Any person trespassing within the defined limits for any purposes whatever, without a pass, will be liable to arrest and punishment. When these "reserved forests" have been proclaimed, the game laws may safely be relaxed, as there will be no fear of deer being killed out when they have such extensive cover to breed in unmolested.

The preservation of game in the low country is, in fact, mainly a question of water. If plenty of drinking places are provided to which the deer can resort without fear of being fired at by native hunters, they will increase rapidly.

SPORT IN INDIA.

MR. DRUMMOND DEANE AND COUNT TELIKI'S EXPEDITION.

Mr. H Drummond Deane, formerly of Maskeliya, and Count Teliki, who was recently on a visit to Ceylon, have been (says the local "Times") having some excellent sport in Travancore. They were under canvas from the 7th to the 20th instant, camping out on the Periar dam, and spent most of the time in the jungle. They left Stagbrook estate on the 6th instant and reached Thakady, at the head of the Periar dam the following day, and steamed down to the dam itself in a launch. The dam is full of standing timber, and covers sixteen square miles of water. This quarter is

TEEMING WITH BISON,

and on the first day both sportsmen stalked a herd of fourteen, and the Count wounded a bull which escaped in thick eta jungle, it getting dark. The following day Mr. Deane started alone below the dam, down the river bed, and came suddenly on a large, solitary bull in long grass about twenty-five paces off. He shot and hit the base of the horn when the brute charged, but he was dropped at close quarters. It was a magnificent animal, measuring in height 76 inches from foot to wither in a straight line; having a spread of horn of 41 inches; between; tips 27 inches; girth of horn at base 22 inches; neck from eighteen inches below ear 95 inches; and length from nose to rump 11 feet 7 inches. Later in the day he went after a herd of bison, but could not get in a shot. On the 9th both rowed up the right arm of the dam under the guidance of villager called "Lord George," and landing the Count wounded a bull. Mr. Deane, running some distance with his estate kangany, tried to intercept the brute, but the kangany, throwing away the rifle he carried, threw himself into the jungle to escape the bull, tearing off the lobe of his ear in so doing. The wounded animal turned back, and the Count finished him at 100 yards.

PLANTING NOTES.

CHEAP MANGOES PROMISED TO ENGLAND.—A few mangoes from the East Indies have been lately bought up readily on the London markets. There will be a good supply of these delicious fruits this year, as they are to be shipped in larger quantities than in any previous year. The mango is a high-priced fruit, but it is expected that big supplies from the East Indies will materially cheapen them in the future.—*Daily Mail*, April 24.

TEA AND GREEN FLY.—"How is it," writes a planter, "that seldom or never heavily-pruned tea escapes green fly?" Our correspondent states that he has noticed that almost invariably heavily-pruned tea in his district is covered with green fly about May. It may last a month or it may last longer, but it is generally about the month of May (or if the weather is dry a little earlier) that it makes its appearance. Pure Assam jât, he states, does not seem to attract the green fly, as hybrid does. Our friend has noticed caterpillars coming out, they seem to have just emerged from the egg, and are all together on a branch. As they get older they separate into two or three bunches, but keep to the same bush, till they have finished with it and then go off to pastures new.—*Indian Planters' Gazette*, April 21.

THE IMPERIAL TEA ESTATES CO.—A home shareholder writes in severe criticism of the management of this Company as being far from economical. He wants to know why shareholders should not have, half-yearly, an interim memorandum stating "conditions and prospects" and this ought to be the rule in all backward Companies. The idea is not a bad one and we submit it to the consideration of Directors.

THE WETTEST PLACE ON EARTH.—Cherrapunji, in Assam, north-east of Calcutta, has the reputation, says the Scientific American Supplement, of being the wettest place on the earth, the average annual rain-fall being 498.15 inches, while it has the record of one month in which 147.17 inches fell. The first half of the past year beat all previous records, 267.84 inches of rain having fallen between January and the middle of June, five months and a-half, while 73.79 inches, over 6ft of water, fell in a single week.—*Auckland paper*, April 6.

THE NEW DUMBULA CO., LIMITED.—We owe a special apology to the Directors and shareholders of this Company for a slip made some weeks ago in stating that the total dividend for 1898-99 was 16 per cent—whereas an *ad interim* dividend of 5 per cent issued March 29th, 1899 and one of 15 per cent issued October 18th, 1899 make a total of 20 per cent, about the highest dividend paid in connection with Ceylon plantation Companies, there being only one other Company, we believe, giving so good a return.

LIMES AS A GERMICIDE.—It may not be generally known that fruit acids are germicidal, but the information is of special value to planters on tea gardens. The juice of lime and lemon is as deadly to cholera germs as corrosive sublimate, or sulphur fumes, or for maldehyde, or any other disinfectant. It is so powerful a germicide that if the juice of one lime or lemon be squeezed into a glass of water, that if then left standing ten or fifteen minutes, the water will be disinfected. It makes little difference where the water has been obtained, or whether it has been boiled or filtered. This is a fact worth knowing, for anyone may at any time find himself under circumstances in which it is impossible to get either boiled or filtered water. In such a case the juice of a lime or lemon will purify the water perfectly.—*Indian Planters' Gazette*.

RUBBER CONCESSIONS IN MATTO GROSSO.—Favorable reports are made relative to the Compagnie Produits Civils, a Belgian enterprise organized in 1895, with a capital of 5,000,000 francs, to operate in the Brazilian state of Matto Grosso. Benefits have resulted from a recent reorganization of the company's staff in Matto Grosso. The extensive concession of *Hevea Brasiliensis* rubber, granted to the company during the revolutionary period in Brazil, which at one time appeared somewhat doubtful, has now been definitely confirmed. The company have asked of the government another and very important rubber concession, situated between their properties in Descalvados and the first concession, near the Bolivian border. It is stated that this claim is now on the point of settlement. The new concession will in one sense establish a unity among the different centres of operation of the company, resulting in a complete change, which, it is hoped, will increase the profits of the shareholders.—*The India Rubber World*.

ADVANCED CULTURE.—The following paragraph from the latest Nyassaland paper shews great enterprise on the part of a local proprietor. It will be interesting to know how the experiment turns out:—

We are glad to hear from Mr. Partridge of Sharrer's Estate, that Mr. Shiarrer is doing something in the way of improving his estates by the importation of large quantities of Lucerne seed, beans, lentils, and other nitrogenous plants. Most of the estates are being gradually shaded. Albizzia, Silky Oaks, and native trees are being used.

Has any one in Ceylon tried an experiment in the same direction?

SHAREHOLDERS AND AGENTS.—Discussing the affairs of the "Imperial Tea Estates Company, Ceylon" in reference to Mr. A. R. Wiggin's letter, our evening contemporary has the following remarks:—

We think with him that the shareholders of the Imperial Company have some cause for grievance. They have nothing to complain of in the now reduced shipping rate, which at half a cent per lb. admits of no margin. But the 2 per cent charged on the proceeds of the crop, which by agreement is payable to the London Agents is one-thirteenth of the whole of the profit carried to the balance sheet, and Directors' fees bring the ratio down to between one-sixth and one-seventh. Considering that there is also at this end to be paid 1 per cent on Disbursements, and 1 per cent on Receipts, with doubtless a few other items, we think the remission of half a cent shipping charge yielded in 1899 might have been supplemented by some consideration for the shareholders from London. Of course, the shareholders have themselves to thank for being saddled with this hard and fast commission by neglecting to examine the Articles of the Company, which provided for this rate of commission, before investing in it. But our experience is that intending shareholders do not examine Articles as a rule; they only rely, in the case of tea shares, on the price paid per acre, and on those who are connected with the Company as Agents and Directors. Messrs. Whittall & Co.'s name has always been associated with some of the most prosperous Companies in Ceylon, everything was known to be straight and above board, and the public willingly went in with regard to this charge of 2 per cent, we think, in comparison with the London Office work done in other cases, that it is high, and we should like to see the shareholders of the Imperial met by the Directors until, at any rate, better times would make such a change less felt. But we have no sympathy with any attempt to reduce Directors' fees. If times are bad and results are poor, all the more anxiety for the Directors and the less should their remuneration be attacked. As a rule, the Directors' fees in Ceylon Companies are anything but excessive, and the typical "guinea pig" is few and far between. A brilliant instance of how good Directors can steer a Company with judgment and care, and gradually get it off the shoals and safely sailing in deep water is the Eastern Produce and Estates Company. And yet there was a time, doubtless, when shareholders were much inclined to begrudge the men at the helm a satisfactory remuneration for the work that was absolutely necessary, to achieve the present good position of the Company. It is not given to all to be able to take a balance-sheet to pieces, nor to criticise it, and we think Colombo or London Agents might give many more details with much advantage, laying themselves out to depart from the old set rules which provide a few, bald scanty particulars, and instead to place results before shareholders in such a fashion that all, or nearly all, could grasp fully the contents of the balance-sheet of their investment. The Indian Tea Companies do this very fully; and Ceylon, which is never behind India, might "go one better."

HELP FOR DEPRESSED INDIGO.—On the representation of the Committee of the Bengal Chamber of Commerce, the East Indian Railway authorities have made arrangements with the Bengal and North-Western Railway that freight charges on indigo shall be reduced from third-class to second class, viz., from two-thirds of a pie to half a pie per maund per mile. The intimation of this reduction in freight—which is to come into force from the 1st July next—has been received with much satisfaction by the representatives of the indigo industry in Calcutta, and also by the Behar Indigo Planters Association.—*Friend of India*, May 3.

PROGRESS IN THE WYNAAD:—TEA, COFFEE AND PEPPER.—A Wynaad correspondent sends us a letter which does not convey good news to Ceylon in one respect; for it speaks of a considerable extension of tea-planting as probable during the current year, the land being available and labour superabundant. But we should think proprietors, who regard "the signs of the times," would be chary of spending capital on a product which is already in danger of over-production. Very interesting is the information given of coffee and especially of the hybrid varieties which are said to resist leaf disease. But still more important to Ceylon planters is the information about pepper. It is monstrous after all these years of urging on planting attention, that more is not made of this product in some of our Ceylon districts. There is no reason why it should not do as well in Dolosbage, Yakdessa, Kelani Valley and perhaps in the Matale's, as in the Wynaad, where we are told, from R250 to R500 per acre of nett profit is made. We do not accept such estimates as practical or reasonable. But even if these figures be divided by four, the encouragement is great in these days when it is difficult to fix on any secondary product at all likely to be profitable on ordinary plantations.

THE WEST AFRICAN ROOT RUBBER.—Herr Baum, a botanist who accompanied the Kunene-Zambesi expedition in behalf of the Colonial Agricultural Committee [of Berlin] made some inquiries in regard to root rubber. The district in which this plant (from its description probably *Carpodinus lanceolatus*) grows, is situated on the other side of the Cubango, and is so devoid of water that the natives going to the rubber root district have to carry water with them, and return when the supply is exhausted. The rubber is obtained by beating the root sticks, and it is said to be so toilsome that a negro will consume three days' time to produce a piece as large as a banana, and even then it is mixed with stand and splinters of wood. Herr von der Keller, to whom Herr Baum is indebted for this information, asserts that the root sticks, which seldom have a thickness of more than two fingers, contain at least 60 per cent. rubber; also that they cannot be broken, but can be stretched until torn asunder. In the gathering places the plants are exterminated by the negroes to such an extent, that for many years this plant is not to be seen again. The botanist Schlechter, the leader of the rubber expedition to West Africa, also reports on the root rubber at Stanley Pool [in the Congo Free State], and states that the plant grows on such sandy soil as exists nowhere in the Kameruns, and its cultivation therefore is more adapted to South-western Africa than to the Kameruns.—*Der Tropenpflanzer*.

AGRICULTURAL CHEMIST FOR BEHAR.—Professor Rawson, the able Chemist of the Behar Planters' Association, is now due in India, and will take up his quarters at Muserie Factory, where a bungalow and offices are being built for him; many concerns are going to use the learned Professor's patent oxidizing process this year.—*Indian Planters' Gazette*.

JAPANESE TEA.—The quantity of tea exported from Japan during 1899 exceeded that shipped abroad during 1898; but all the same the tea business in Japan is becoming more and more unsatisfactory each year, and for the foreign merchant at any rate, there is a little or nothing to be made out of it. In quality the tea of 1899 compared unfavourably with the crop of 1898. The practice of picking the young leaves in the early spring before they are properly matured, for the sake of obtaining exorbitant prices for small quantities is undoubtedly having a very injurious effect on the plants, and it is surprising that Japanese tea-growers do not realise this fact. Of the teas shipped from Yokohama during 1899, 31 per cent. went to New York, 26 per cent. to Chicago, 14 per cent. to San Francisco, 26 per cent. to Canada and 3 per cent. to Europe.—*Consular Report*.

"MARAM GRASS."—An old friend sends a copy of a Jersey paper with a glowing paragraph from the *Melbourne Leader*, as to the value of this grass in Australia for its "sand-binding properties" and also that it is "a splendid fodder both for fattening and milk production." This grass (botanically *Ammophila arundinacea*) is a native of North America, and therefore, though acclimatized at Port Fairy in Victoria, it is a question if it would succeed in so warm or tropical an expanse as the sand dunes of Hambantota, for which our friend thought it adapted. It would be more likely to succeed at a high elevation in Ceylon if there were a sandy waste to cover; but we cannot understand the *Leader's* praise of this grass for fodder; because Law, Somner & Co., the well-known Melbourne seedsmen—who should have every reason to praise where they can—while admitting its usefulness near the shore, says, "It is of no agricultural value!" We shall send the *Leader* and the seedsmen (both in Melbourne) a copy of this note to learn which is right. The seedsmen sell Maram grass seed at 1s 6d per lb., and it would be interesting and useful to make at least a trial of some of it in Ceylon. This is what the "Treasury of Botany" says regarding it:—

A genus of Grasses of the tribe *Arundineæ*, inhabiting the sandy sea-shores of the coasts of Europe and North America, and extensively cultivated in many places, as in the eastern counties of England and in Holland, for preserving the sand-bank which prevent the inroads of the sea. In the northern parts of England, it is used for making table mats and basket work. It is the widely-creeping and matted rhizomes which serve to bind together the sand-banks on which it grows. The stems grow to or three feet high, and bear long, narrow rigid involute leaves and a spiked cylindrical panicle, with laterally compressed spikelets. The glumes are nearly equal, and lance-shaped, stiff and chaffy. The flowering glumes, or outer pales, are the shorter, with a tuft of hairs outside, but the inner pales nearly equal them in length. The genus is nearly related to *Calamagrostis*, from which the inflorescence, the stiff glumes, and the absence of an awn to the flowering glume, serve to distinguish it. The only species, *A. arundinacea*, or *Psamma arenaria*, is variously called *Maram*, *Marrum*, *Sea-reed*, or *Sea Matweed*.

“CASTILLOA ELASTICA :”
TRANSPORTATION OF SEEDS.

BY FRANCIS CHILD NICHOLAS.

Of the many rubber-producing species, the *Castilloa elastica* appeals most strongly to the interest of the intending planter, especially in the United States, on account of its rapid growth in regions comparatively accessible, and under conditions favorable for the settlement of white men. The tree is a prolific producer of seeds, but on account of their perishable nature planters have found difficulty in getting them to germinate except in the vicinity of their origin.

During the spring of 1899 the writer undertook to establish a plantation of rubber on one of the properties belonging to The South American Land and Exploration Co., Limited, on the northern coast of Colombia, within easy reach of the island of Trinidad, whence it was proposed to obtain the seeds required. Before seeding time, however, the British government decided that no further sale of rubber seeds for export should be made from the gardens in Trinidad, and it became necessary to obtain our supplies elsewhere. The next nearest point was in Costa Rica, which involved a trip of three weeks, whereas these seeds, under the most careful management, rarely have been preserved for this length of time.

My experiments with various kinds of seeds had convinced me that fermentation, mold, drying out, and germination before planting were one or all of them the cause of loss in shipping rubber seeds. Of these various causes, fermentation seemed likely to prove most disastrous, though I found later that germination before planting caused the greatest percentage of loss. As a result of my experiments I have become convinced that the seeds of *Castilloa elastica* can be transported for long distances, making it possible to plant this species successfully wherever natural conditions are favourable for its growth.

The *Castilloa elastica* is dioecious, and on the seed bearing trees a collection of compound fruits is developed rapidly in May and June. These fruits are compact together on disks formed by leaf scales, set one over another. The disks appear at the leaf joints, face downward, setting close to the under side of the small branches, many of which fall to the ground after the seeds have ripened fully. The fruits, which are of a bright orange vermilion, in sharp contrast to the velvety green of the leaves, adhere to the disk, and the group, when secured, with the ripened center of bright vermilion fruits, surrounded by a margin of lighter colored leaf scales, is suggestive of a delicate confectioner's tart. The better formed fruits contain the seeds, and a disk will bear from one to thirty or more, about the size of an orange seed with the outer skin peeled off. The veins of the cotyledons contain a small quantity of bitter fluid resembling in appearance the milk from which caoutchouc is obtained. The cotyledons are well developed and are folded together to protect the embryo and radicle, the whole being covered with a fine membranous skin. Germination is so rapid that I have often found seeds developed through their first stages, with rootlets and a pair of tiny green leaves, before the first disk had fallen to the ground.

The fruit disk falls when fully ripened, sometimes bursting and scattering the fleshy fruits for a foot or two around, but oftener the fruits do not scatter, but form a sodden little mass among the fallen leaves and mosses, where the seeds ferment and soon decay. Where the ground is favorable, and if the fruits be properly broken apart, the seeds begin to grow immediately, but more frequently, before the soil is reached through the carpet of leaves, moss, etc., the roots lose vigor, dry up, and die. This is one reason why *Castilloa elastica* trees are found in groups, occupying the more favorable spots, instead of being distributed evenly throughout the

forests in which they exist. Once started, the growth of the *Castilloa* is most vigorous, but under ordinary conditions propagation is not very free, and unassisted, it is probable that rubber forests, once devastated, would never reproduce themselves.

In operating in Costa Rica, I soon decided that it was useless to try to take any but fresh seeds, secured from the trees or such as had not lain on the ground for more than a day. All the various plans for packing the seeds suggested by persons having any experience were tried. The seeds packed pulp and all in bags proved a total loss, the pulp fermenting freely and turning acid, and involving the decay of the seeds. Such seeds as were separated from the pulp and allowed to dry slowly in the shade gave somewhat better results, but mold developed in the particles of pulp that remained and spread vigorously, causing a heavy percentage of loss. Some of the seeds were packed separately in pieces of paper and then placed in boxes, but they were a total loss.

The plan that did prove a success was this: I first selected fine specimens of fresh seed—for all are not of the same size and do not produce equally vigorous plants—being careful to separate from them any that had sprouted or showed signs of decay. They were then cleaned carefully by washing away the particles of pulp in cold water. The cleaned seeds, looking like little nuggets of ivory, were spread on cloths and allowed to dry in a cool room for six hours. They were then packed in sand, just damp, but nothing more, with which had been mixed wet charcoal in the proportion of 10 or 15 parts to 100 parts of sand. The object of the latter was to check fermentation and mold. The sand, by the way, was carefully washed before use. About 1,000 seeds were packed in a tin box 4×3×2½ inches in size, but they were rather crowded; 500 seeds to the box would have been better. In packing the seeds, I first laid a piece of flannel at the bottom of the box, then spread a layer of sand and charcoal, then a layer of seeds, covering them with more sand and charcoal, being careful that none of the seeds should touch the sides of the box. I found while transporting the seeds that in boxes where the sand was over-damp heating had set in, but this was checked by making holes in the lids of the boxes to admit the air. In these cases there was some loss ultimately. My experiments in Costa Rica have proved successful on the whole, since I have tens of thousands of young rubber trees as a result of bringing seeds from Costa Rica. This brief record is offered here for the reason that the same methods may prove valuable in other cases. The principle upon which the whole is based is that the packing of the seeds for a long journey must be designed to assist nature in protecting the seeds, or perhaps to provide them with surroundings for their protection which, because of their superabundance, nature has left unprovided.

The unfavourable conditions to be overcome in handling the seeds of the rubber tree may be briefly summarized under the following heads:

I. The tendency of the fruit to ferment, involving the seeds in the decomposition.

II. The fermentation and decay of the seeds themselves, if piled together, even if freed from the pulp.

III. Premature growth. If the seed does not grow it dries up, and the planter must retard the growth while yet providing moisture enough to preserve the vitality of the seed until it can be planted.

IV. The tendency of the seed to mold. The appearance of a dead white speck at the apex of the seed, in sharp contrast with the ivory like appearance of the outer skin, is a sure sign that it is lost, though otherwise it may appear in perfect condition. One bad seed will ruin a thousand good ones brought into contact with it.

V. The liability of the seeds to dry up, the outer skin becoming separated from the cotyledons, after which the value of the seed is doubtful—*The India Rubber World*.

PEANUT OIL.

In reference to the question as to whether the manufacture of peanut oil is possible in the United States, Consul Skinner, of Marseilles, writes: "The belief here is that the American nut is richer in oil than the African, and this quality can be increased by careful cultivation. Little change either in method of cultivation or price average is looked for in Africa. It is true that a large part of Africa is believed to be available only for a crop of peanuts, but the native labor, though cheap, is lazy and thriftless and hard to obtain when required. The soil is readily exhausted, and nothing is done to restore its virtue. There are no means of interior transportation, and the crop must be handled laboriously several times before it is loaded for the port of destination. It will be years before notable improvement can be expected. I am disposed to believe that the trade in Marseilles will not so much speculate on the prospects of success of American enterprise in this field as it will wonder why the effort has been so long delayed." Touching the process employed in France, the Consul writes:

"Peanuts are scarcely ever ground whole. Such a process produces an inferior quality of oil and a cake of little value. In fact, many of the nuts arrive in a decorticated state, after which the inner or red skin is removed as much as possible by a system of scrapers and winnowers. Particles of the inner skin will cling to the kernel under all circumstances and can be plainly seen in the cake. The greatest pains are taken with edible oil. For this the nuts are commonly received unshelled at the mill, and there decorticated by a special apparatus in conjunction with vibrating and ventilating machinery, the process somewhat resembling the wheat-cleaning operations in flour mills.

"The husking of the peanuts is performed by a pair of grooved rollers, adjustable in order that the space between them may be increased or diminished according to the approximate average size of the nuts to be husked. The rotation of these rollers is quite rapid, and the ridges of one of the rollers fit into the center of the grooves of the other roller. In the first process the husks are completely crushed, and a good many of the kernels are also split. This broken mass of husks and kernels is then separated by means of air currents, similar to the winnowing process applied to wheat in flour mills.

"Now, if the peanuts used are of old crop the kernel is likely to be dry, and the light, inner red skin of the nut becomes detached in the first husking process. A large proportion of it is removed in the first ventilator, and nearly all of that which still adheres to the kernel is removed by the following process:

"The kernels are passed over a rapidly oscillating sieve, the coarse-wired meshes cracking this red skin, which latter is then drawn off by another ventilating machine. I cannot give the full details of the cleaning process of the mass which emerges from the grooved rollers; but my informant assures me that no specially constructed machinery is employed for this purpose, the whole work being executed by a combination of oscillating sieves and strong air currents.

"If the peanuts are of new crop it is most difficult to remove the red skin entirely, as in this case it adheres quite firmly to the kernel, and thus the kernels of new-crop nuts generally go under the presses with the greater part of the red skin still adhering to them. In order to more thoroughly cleanse the kernels before they are prepared for the presses, the new-crop nuts undergo the same process as the old crop nuts.

"When the kernels have been separated and cleaned, they are ground, preparatory to being pressed. The pressing takes place in the same manner in which other oleaginous seeds are pressed, the meal being enveloped in strong, fibrous mats and subjected to hydraulic pressure. The resulting cake is then re-

ground the oil remaining in the meal secured as in the first instance. The oil is graded according to first, second or third extraction.

"The clarifying is done by means of filters, and the bleaching, if it may be termed thus, is done by the admixture of so-called 'terre a foulon' (fuller's earth), a highly porous mineral substance. The oil which is to be treated is poured into large vats and a certain quantity of 'terre a foulon' is added. The whole is mechanically stirred for some time, and then allowed to rest for a certain period, during which the coloring particles contained in the oil are absorbed by the pores of the mineral.

"The husks are of little or no value. When ground and mixed with cake (also ground) they form an inferior grade of cattle feed. About the only animals to which they can be fed without admixture are goats. When coal prices are very high, a number of crushers employ the husks as fuel. Crushers prefer to use new-crop nuts (despite the fact that the product is often inferior to old-crop oil), as they extract more oil from them. Decorticated nuts should average 37 per cent. of their weight in oil."—Brad-streets.

SISAL GRASS IN MEXICO.

Henequen; "jeniquen," Spanish; *ci*, Maya; "sisal grass," commercial term; *Agave sisalensis*, scientific term.

This plant has been in use among the ancient inhabitants of Yucatan from the earliest times. The writer has found it imbedded in the form of cord in the stucco figures that ornamented the facades of the mysterious ruined cities of Yucatan. There are two wild varieties of henequen, called by the natives "cahum" and "chelem." The fiber of these wild plants is used to some extent by the natives in the making of cordage for domestic use, and some claim that hammocks made from the fiber of the cahum are the best.

It is, however, the cultivated plant that furnishes commerce with the fiber known as sisal grass, Sisal being the old port from which the fiber was first exported.

Like the wild plant, the cultivated one is divided into two varieties—the "zacci," or white hemp, and the "yaxci," or green hemp. The zacci is considered the finest and best, but the yaxci is a good fiber, and by the time the henequen fiber reaches New York or Boston, it is simply as sisal grass, of a good or medium quality, as the case may be.

It has been generally supposed that sisal grass as an article of commerce has been known only within the last fifty years. This is a mistake.

Between the years 1750-1780, quite a furor was created in commercial countries of the Old World by the discovery that the fiber of a plant found in Yucatan was good for ship cordage. Spain sent over a royal commission to report upon the discovery, and in a few years many of Spain's commercial and war vessels were using cordage made from henequen. For some reason, probably because of the primitive method of preparing it, the use of the fiber gradually declined, until at the commencement of this century, the former trade had been forgotten.

In 1847, Yucatan, until then a cattle-producing cotton-growing and logwood-exporting country, was in the throes of an Indian war. The Maya Indians had risen in rebellion and had succeeded in driving the white race out of the most fertile portions of the peninsula, forcing them to rely for means of subsistence upon the products of a sterile rocky belt, too poor to sustain cattle in any numbers. Henequen was the only useful plant that would grow on such a soil. The first plantation, so far as I can learn, was planted in 1848, and the 50 acres planted were cleared by the use of the tonka, the primitive cleaner used by the native Maya. There was a good demand for the new fiber in ship rigging, and it gradually came into general use, until sisal was a well-known article of commerce. The Tonka was a piece of hard wood, shaped something like a handsaw, having the end curved in,

The leaf of the henequen was drawn through the sharp curve and the fiber was stripped of the thick, pulpy covering. The leaf was subjected to this operation two or three times, until the fiber was left clean and free. This tedious process was not long tolerated. A machine was found to increase the output, but the demand again outgrew the means of supply. Then the machine known as the "raspador," or the "solis," from its inventor, came into use and has held its own almost up to the present day. It consists of a large-toothed wheel that scrapes the pulp and leaves the fiber. Its simplicity made it peculiarly fitted for use by the native servants. Plantations came to be known as plantations of one, two, or a dozen wheels.

The constantly increasing trade necessitated still more rapid means of fiber cleaning. Many new machines were produced, each of which was said by its inventor to be far better than any of the others. To-day, the following machines are in actual use in Yucatan:

Hemp cleaning machines now in use upon the plantations of Yucatan.

Machine	Number of leaves cleaned in 10 hours	Actual horsepower	Number of men needed	Cost of Machine		No. in use
				Mexican*	United States	
Lanauz	130,000	35	3	\$6,000 00	\$2,856 00	6

NOTE.—Compiled from data given me by the inventors themselves or their authorized agents.

I give below a table showing the exportation of sisal grass from Yucatan during the ten years ended December 31st, 1898:

Year	Quantity		
	Bales	Kilograms	Pounds
1889	243,968	40,641,521	89,598,297
1890	260,106	45,079,423	99,382,096
1891	310,090	52,065,024	114,782,552
1892	353,525	58,584,813	129,156,078
1893	355,123	58,097,925	128,082,685
1894	373,883	61,635,695	135,815,915
1895	381,504	61,729,584	136,089,041
1896	397,163	65,762,910	144,980,911
1897	419,975	70,545,153	155,523,844
1898	418,972	68,834,268	151,752,027

Total for 10 years 3,514,309 582,946,316 1,285,163,448

The Mexican Government requires all weights to be stated in the metric system.

In 1888 and 1889, the price of hemp reached 15 centavos per pound. The cost of production was then about 4 centavos per pound.

Exports of sisal grass from Yucatan during ten months of 1899.

Month	Quantity		
	Bales	Kilograms	Pounds
January	52,128	8,735,545	19,258,383
February	21,360	3,506,832	7,731,162
March	58,069	9,621,763	21,212,006
April	43,580	7,075,447	15,598,580
May	30,869	5,015,166	11,056,435
June	31,629	1,133,882	11,318,156
July	26,937	4,296,939	9,473,032
August	26,204	4,202,208	9,264,188
September	44,973	7,456,101	16,427,725
October	35,595	5,695,200	12,555,638
Total for 10 months	371,294	63,739,323	140,519,711

* The United States Director of the Mint estimates the average value of the Mexican dollar in 899 as 47.6 cents,

Prices during these months have ranged from 15 to 18 centavos (7.1 to 8.7 cents).

It is said that the best fiber-producing plant grows on the poorest and rockiest soil; but this does not accord with experiments made by me, and to my mind is open to contradiction.

One method of planting and cultivating is as follows: The field is first cut and burned off. The burning produces a certain amount of ashes, and many planters set out seed corn at the same time they plant the henequen. The one does not interfere with the other in the least, and the corn crop helps to pay the cost of the henequen.

The henequen plant is propagated, not by seeds, but by scions, or suckers. The plant produces seeds, and in a natural state propagates itself by both seeds and scions; but the planter uses only suckers from 18 to 20 inches high. By this method, he can produce a field of henequen ready to cut within five years, whereas by seed-planting he would have to wait from eight to nine years.

Once planted and properly tended—that is, cleared of weeds twice a year and not under or over cut—a field will last twenty years, and instances are not wanting of fields that have lasted longer.

A leaf is ready to cut when it extends at right angles to the trunk of the plant. A healthy, vigorous plant in the maturity of its growth should yield from eighteen to twenty-four leaves. One thousand leaves should produce from 50 to 60 pounds of good, clean fiber. This amount is a fair average.

When the plants in an old field send up a flower stalk, it is nature's signal that the crop is finished. The old plants must then be clipped of all useful leaves and cut down, to allow the young scions (which should have been already planted between the old plants) ventilation for growth.

Bad cleaning, allowing rot to be produced by the acids nascent in the plant pulp, and dampness produce red and moldstained fiber, of less than one-half the value of the good, clean, white, fiber. This is rarely exported, but is sold at home for domestic use.

In March of last year, the preliminary trials of the machinery in the new cordage factory La Industrial gave satisfactory results. This factory was the first of its class established in Mexico, and its progress has been closely watched.

It is, in the opinion of experts, as completely equipped as any similar enterprise in the United States, and its total cost has reached nearly \$700,000. The machinery is nearly all from the United States, and is of the best and latest pattern. The factory is now working double time in order to fill several very large contracts for binder twine from United States houses.

There are in Yucatan nearly twelve hundred henequen-producing plantations of various sizes. The largest plantation, or perhaps I should say the plantation producing the largest output, is, I think, on the line of the broad-gauge railway between Merida and Progreso. It is called Ticilche, and produces at the time of this report about 1,000 bales, or 375,000 pounds of cleaned fiber per month.

Prophecies are dangerous, and I venture to make one with diffidence; but I have recently been over the henequen-producing belt and have perhaps as much data as most persons. My belief is that if the maximum production of henequen in Yucatan for the next three years has not already been reached, it will not exceed this year's output by over 10 per cent. Many factors unknown in the United States are of importance here, and parties interested will do well to bear this in mind. I have no henequen interests, and my judgment may be the clearer for that fact.

EDWARD H. THOMPSON,

Progreso, October 29, 1899,

Consul

FOOD PRODUCTS OF ZANZIBAR.

SWEET POTATOES.

We propose to review, shortly, the food products grown in these islands by the natives in a series of articles which will naturally extend over some time because of the difficulty of collecting reliable information and also because we are, as far as possible, endeavouring to supplement the information by experience which can only be obtained by actually growing the crops themselves. Experience should extend over many years in order that the effects of seasons and different modes of planting may be studied. Natives are remarkably ignorant about their crops. Even the more intelligent of the overseers who have been planting sweet potatoes for 40 years are unable to inform you upon all points concerning the cultivation of the plant and sometimes cannot even identify all the varieties. Consequently many witnesses have to be examined and each and has a slightly different tale to tell. We do not, therefore, claim that these articles are by any means exhaustive.

SWEET POTATOES, *Viazi* sing. *Kiazi*, *Batata* (Arabic), *Ipomea batatas*, belong to the natural order *Convolvulaceae*. The "potato" is the tuberous root or tuber, sometimes also called tuber, but a tuber is, strictly speaking, a swollen rootstock or underground stem usually beset with eyes or buds. The ordinary European potato is a tuber. The distinction is observed in the different modes of planting. The European potato is propagated by planting a whole or a portion of the tuber, sometimes called a "set" but this method would be slow and uncertain in the case of the sweet potato because the "tuber" being a root contains, no normal buds. Hence slips or cuttings of the stem are planted.

Natives plant sweet potatoes at all times of the year when rain serves though the principal season is the *masika* or big rains in April and May. The earth is moulded up into long tortuous beds, two to three feet high and three to four feet wide and the cuttings crowded indiscriminately all over the surface. They rapidly strike and creep all over the beds, completely hiding the soil. In two to five months, according to the variety and season, the crop is ready to dig. Free sandy soils are preferred and showery weather. If very dry weather follows planting little or no crop will be produced. When digging the potatoes the natives may frequently be observed sticking in the tops again behind them for a second crop and in well made beds this process might be repeated several times. No manure is ever applied for this or any other crop as natives do not seem to understand its use, and often the same ground is planted year after year. Hence large crops of potatoes are seldom obtained, probably not more than two or three tons to the acre.

Varieties of Sweet Potatoes		
Small	1. <i>Viazi Kirihani</i>	red
	2. <i>Kindolo bungala</i>	white
Large	3. <i>Kindolo</i>	white
	4. <i>Kwata</i>	white
	5. <i>Kwata</i>	red.

1. **VIAZI KIRIHANI.** This seems to be the commonest variety. It grows in about 3 months, or less. The potatoes are 4 to 8 inches long 1-3 inches thick. They are not held in much culinary esteem as they cook watery but are planted because they are rapid growers and can get along with comparatively little rain. The stem is green and branching leaf; $3\frac{1}{2}$ inches by $3\frac{1}{2}$ inches, lobed, sinuate on the margin, base reinform as in all the varieties, apex acuminate; petiole of leaf 6-7 inches long. *Viazi Kirihani* bears many flowers which are white at the top and pink at the base.

2. **VIAZI KINDOLA BUNGALA.** A stouter plant than the last; leaf about the same size but 5-7 in. lobed; nodes of the stem, upper part of petiole and ribs at the back of the leaf purple; petiole 7-8 inches

long. This variety also cooks watery, but is a rapid grower with plenty of rain. The potato is white and truncate.

3. **VIAZI KINDOLO.** This is the slenderest plant of them all; leaf small, deeply cleft, 5 lobed, apex acute; purple coloured about the nodes, petiole and ribs, Potato grows to the size of a man's arm and cooks dry and flowery. Both this and the two following varieties take five months to mature and require more rain than *Kirihani*.

4. **VIAZI KWATA LA PUNDA.** White, plant in appearance, and size resembling *Bungala*. Leaf entire, not lobed, margin slightly sinuate apex acuminate; prominences coloured as before but to a slightly greater extent, as for instance the whole instead of extremities of the petiole. Potato white, larger than that of any other variety, growing to the size of a man's leg. It also cooks well.

5. **VIAZI KWATA LA PUNDA.** Red, the largest of the plants; stems as thick as a man's little finger; petiole 8 inches long, stout; leaf 5 in. by 5 in. entire, slightly sinuate, apex acuminate; none of the parts coloured. This is the best cooking variety and the potatoes grow to a considerable size.

Neither the varieties of *Kwata* bear many flowers while each of the other three have a good show. The *Kwata* are sometimes planted on the flat as they require a lot of moisture. Natives of Zanzibar trace their origin to the Mtoni district.

Little forethought seems to be bestowed upon the choice of varieties though a preference seems to prevail for the smaller quick growing. Sweet potatoes are displayed for sale in the markets all the year round in little heaps of one to two pounds weight, each heap selling for one or two pice, according to the supply. They occupy only a secondary place in the economy of the household ranking in this respect with the pulses and grams. Cassava and rice are much more important food staples. Sweet potatoes are boiled with salt and sometimes mixed with coconut, sugar or syrup.—*The Shamba*.

CEYLON COCONUT OIL.—The only important sale has been one hundred tons for May-July shipment at 5'45c. There is only a limited demand for spot good 5'70c to 5'75c, as to quantity and seller.—*Oil, Paint and Drug Reporter*.

THE NEW "CODE" FOR RURAL EDUCATION.—We have so many times urged the importance of differentiating between town and country in matters educational, that we have every reason to be pleased at the changes that the "Code" just brought out by the Education Department renders possible. Henceforth the course of instruction to be given in all elementary schools is to be suitable to the circumstances of the children and the neighbourhood. This means, of course, that in rural districts a knowledge of Nature bearing upon the culture of plants and the raising of stock will be imparted. Except in particular cases, the teacher will not be tempted to teach those special subjects which will bring him in extra grants in the easiest way. The grant will be one technically called "a block grant," made upon the efficiency of the school generally, whatever the subjects taught. Lessons on "common things" which in the country obviously will largely be "object-lessons from Nature," are to be given in the higher and lower standards alike, and a new course of household management has been devised for girls. Among the subjects on which special grants may still be obtained are manual instruction and gardening, and the school-garden may even yet become universal, in spite of the *Schoolmaster's* sneers at the Agricultural Education Committee, and the latter, knowing full well that all its wishes cannot be fulfilled at once, "hails with the greatest satisfaction the provisions of the new day-school Code," which we might add are due in a great measure to the energy displayed in the formation and work of that still youthful body.—*Gardeners' Chronicle*,

RUBBER CULTIVATION IN INDIA.

A GOVERNMENT PLANTATION SANCTIONED.

The Government of India, on the recommendation of Mr Ribbentrop, Inspector-General of Forests, have just taken an important step in connection with the cultivation of rubber trees. It has been fully proved by experiment that the Brazilian tree will thrive, reproduce itself, and yield rubber of the best quality when cultivated on the Tenasserim Coast. The Government have therefore sanctioned the establishment of a plantation of 10,000 acres of these trees at a cost of R2,10,000. It is expected that at the end of twelve years the plantation will have paid its cost, and will thereafter pay one lakh net annually. As the trees will be self-producing this income will be a permanent one. The calculation is based upon proved facts, the only uncertainty being the maintenance of the present high price of rubber, the demand for which is very great.—*Pioneer*, May 20.

CEYLON TEA: MONTHLY SHIPMENTS TO UNITED KINGDOM AND ESTIMATE.

Total Estimate for May 1900—10½ to 11 million lb.
 Total Shipments for May, 1900 — 10,500,000
 Do Do Do 1899 — 8,662,028
 Do Do Do 1898 — 9,943,674
 [Estimate for June, 1900:—11½ to 12 million lb.]

COCHIN MARKET REPORT.

COCHIN, May 26.

C. N. OIL.—With but a very moderate demand from the natives in the Bazaar for immediate requirements, prices are easier, and we quote today good white oil R34 net, and ordinary bazaar white R85 per candy.

COIR YARN.—No change to report and the common qualities of weaving yarn are easier. Shipments in completion of previous engagements are being pushed forward as fast as possible.

ROPE YARN.—The bulk of supplies now arriving as usual in this late part of the season is both coarse and poor in colour. Prices are easy.

COPRA.—Rassi R50/51 per candy.—*Cochin Argus*, May 26.

THE AGRICULTURAL MAGAZINE, COLOMBO

Added as a Supplement Monthly to the "TROPICAL AGRICULTURIST."

The following pages include the Contents of the *Agricultural Magazine* for June:—

Vol. XI.]

JUNE, 1900.

[No. 12.]

THE NEW SCIENCE OF HORTICULTURE.

HE article on Seedless Plants, taken over from the *Louisiana Planter*, is an interesting contribution in many ways, but there is more than one point in it which are apt to give rise to discussion.

We note that the means by which the horticulturist creates seedless varieties of fruits are by selection, starting with *lusi nature* as in the case of the naval orange. This particular instance, however, presents special abnormality, which it would be a mistake to suppose is always associated with the seedless conditions as the following extract from the above article would lead one to imagine: "In the effort to produce a monstrosity the seeds were apparently neglected." Against the acceptance of this as a general condition we would submit the fact that fruit monstrosities containing an abundance of good seed are by no means uncommon, while seedless fruits occur which present no abnormal structure. The plantain and papaw are instances of the latter. Again, there is the theory advanced with regard to the first-mentioned that "the use of suckers for purposes of propagation gradually made the seeds of less and less value, and that following out the law of nature the seeds, becoming useless organs, degenerated." But what is the explanation of the seedless condition in papaws? The freak of nature which produces seedless fruit sometimes as an exception (bringal) and again as a rule (plantain) is apparently not to be so easily theorised about. One

thing, however, seems to be pretty clear, and that is, that cultivation tends towards the elimination of seeds as regards their size and number, while the "wild state" tends to produce the opposite effect of seed development. The wild mango (appropriately called "eta-amba"—seed mango) is nearly all seed, while the wild orange is pretty full of seeds; on the other hand the so-called seedless papaw, which preserves this character when grown in good soil or when liberally cultivated, produces abundance of seed when allowed to run wild or grown on poor soil. It would thus seem that a special effort is put forward by plants growing under unfavourable conditions to propagate their species, and that in a wild state, in the general struggle for existence among plant life, special provision is made by nature for reproduction of the species.

We would now consider for a moment the following passage in the above-mentioned article: "That the seeds are really immaterial to the welfare of the plant is evidenced by the fact that perfect fruits are often developed whether the blossoms are fertilised or not." We take it that by fertilization is here meant the actual result of fertilization, the conversion of an ovule into a seed, *i.e.*, the formation of an embryo capable of development into a new plant. If so, we take no exception to the sense of the passage; if not, we cannot see our way to accept the dictum.

The transformation of an ovary either alone or in conjunction with such other parts of the flower as go to form edible succulent fruits, is always associated with the development of seed as the result of fertilization. We do not of course mean

to say that the former is a direct result of fertilization, but that the two processes are contemporaneous, and that possibly the *ante-decants* to the consummation of the fertilizing act (pollination and the subsequent growth of the pollen grains) induce the development of the ovary or other floral structures to serve as protection for the seed or to attract the fruit-eating animal. If on the other hand we are to infer from the expression "whether the blossoms are fertilised or not," that it is possible for fruit to form without any contact of pollen and stigma then it would appear that pollen is a useless element in fruit production and, in fact, if the best types of fruits, viz., seedless fruits, are to be produced, we must endeavour to eliminate the male organ of flowers. But the absence of fruit (seedless or otherwise) on pistillate dioecious trees which are beyond the influence of their staminate, congeners goes to contradict the conclusion that pollen is immaterial to the development of fruit. We are here reminded of the advice of an authority on poultry who recommends that if poultry-farmers wish to produce the best eggs for the market they should eliminate the male from the poultry yard. The authority referred to argues that the influence of the male is not necessary for the production of eggs (no more than, according to the above article pollen is necessary for the production of fruit), but that it is necessary for the development of the embryo (in the same way that the pollen is essential for the development of an embryo in the seed). Eggs without the embryo are said to keep much better and taste better, just as fruit without seed are to be preferred to fruit with seed! So that it looks as though the male must be eliminated both in poultry farming for egg production, and also in fruit growing. We will not speculate further on the developments that these theories may lend to.

As to the explanation of the fact why pollination and possibly pollen growth (assuming they are concomitants of fruit development) do not result in the fertilization of a single ovule, as in the seedless fruits, we must confess our ignorance, and leave the matter in the hands of experts. We do know, however, that many pollen tubes never reach the ovary, and that some ovules are left unfertilized while others develop into seed.

OCCASIONAL NOTES.

The School of Agriculture has had a number of foreign visitors of late. First came M. Em. Prud'homme, the chief of the Agricultural Department of Madagascar, with a party of fellow-travellers, then Dr. K. Giesenhagen, lecturer on Botany at the University of Munich, after him M. Alexis Teysloff, a Russian gentleman interested in Ceylon bees, and the last visitor was M. Leon Pynaert, a Belgium botanist. M. Prud'homme and his friends called with a view to gain an insight into the working of the School of Agriculture. Dr. Giesenhagen, whose duties include the examination of products in order to ascertain to what extent they are adulterated, was interested in the manufacture of our edible agricultural products, tea, coffee, cocoa, and desiccated coco-

nuts. M. Teysloff, who called with the Director of the Colombo Museum, examined the hives kept at the School, and secured some specimens of the Ceylon honey bee (*Apis indica*). M. Leon Pynaert, who is travelling in the East before settling down in the Congo with a view to establishing a Botanical Garden there, has, in addition to his continental training, been working some time at Kew Gardens, London.

The Government Dairy is fortunate in being free from rinderpest, while the plague has been prevailing in various parts of Colombo during the past few months. It is to be hoped that the valuable herd of cattle will continue to keep in good health till the disappearance of the disease.

The distribution of Dairy stock among the Government Agencies continues, and up to date the following animals have been sent out for breeding purposes in the provinces:—One stud bull to the Assistant Government Agent Matara; one stud bull, four bull calves and three cow calves to the Government Agent, Jaffna; two bull calves to the Government Agent, Kurunegala; one bull calf to the Government Agent, Anuradhapura; three bull calves to the Government Agent, Ratnapura, and three bull calves to the Assistant Government Agent, Kegalle.

We are indebted to Mr. J. P. Williams, the well-known firm of seedmen of Henaratgoda, for seeds of *Kickxia Africana* and *Hancornia speciosa*, both rubber-yielding plants, but the latter also said to produce a delicious fruit.

It is intended to establish a gymnasium on the grounds of the School of Agriculture, where it will be available to the students of all the schools located on the premises. We welcome this innovation (for this will be the first gymnasium established in connection with a Colombo College or school) as an institution which should be the means of "hardening" our students for the outdoor life which every agriculturist must be equipped for.

Bananas are again well to the front. Here is an advertisement of preserved Bananas:—"Mafuta" brand, described as a splendid substitute for figs and raisins, and unequalled for dessert. Small box (16 to 20 bananas) 6d, large box (30 to 40) 1/. In presenting these bananas to the public the manufacturers enumerate the following advantages:—

1. The fruit is picked when absolutely ripe, thus ensuring the real flavour, at present unobtainable owing to the immature condition in which it is necessary to export the fresh fruit.

2. There is no musty flavour as with a sundried banana, neither is the fruit parched or shrivelled.

3. The price brings the fruit within the reach of all; 1 lb. of bananas averaging 16 to 20 whole fruits.

4. There is no skin or stalk to waste; this can be eaten not only as bought, but cooked in a great variety of ways; especially during the winter months.

5. For cycling or picnic parties, tourists, travellers and others, this will be found a great convenience, a few bananas being sufficient stay and nourishment for some hours. The boxes are compact and easily cured.

Then follows a number of recipes, which we shall give for the benefit of our readers, in a future issue.

A correspondent sending us this advertisement writes: Why not in Ceylon at the Agricultural School? Why not indeed! We suppose because the Agricultural School is not given the opportunity of doing this and many other things which it might do. It has not had, as one of the speakers at the recent prize-giving ceremony put it, a "fair chance," and that explains everything.

KIÜL LANDS.

DEAR SIR,—What is the correct meaning and signification of *Kiül* (කිඹුල්)? It is used in reference to unproductive lands, on which nothing will grow. Clough gives the meaning as "absence of salt; insipidity." But the word *Kiül* is used with regard to water, which is brackish.

There are several patches of land in this district (Kurunegala) known as *Kiül*, which are useless and worthless. To give you a typical case. There is a patch of about 8 or 10 acres situate under and about two miles from Ma-Uswewa. The surrounding lands are under cultivation. The plot in question has been abandoned since three years ago. The whole tract, including the *Kiül* land, was asweddumised about ten years ago and gave good crops—12 fold. The portion in question began gradually to fail since then, till three years ago, when only grass (a peculiar and uncommon kind) will grow. When paddy is sown, a sickly plant comes up and withers away.

Please let me know what ails the soil. Can it be remedied, and what will you propose?

Yours truly,
FRANK MODDER.

Kurunegala, 21st July, 1899.

[We regret to find that this letter has been mislaid for some months, and apologise to our correspondent for the delay in dealing with the points raised. Our regret is all the keener from the fact that the author of the neglected letter should be so esteemed a correspondent as Mr. Modder, whom we know to be a close observer and an ardent student of Nature, as his work in the Royal Asiatic Society amply testifies

Without a personal acquaintance with the locality in which the unproductive tract referred to by Mr. Modder occurs, or indeed any definite notion of the character of the tract itself, we can but speculate as to the cause of the barren nature of the soil from our knowledge of the infertility of soils under conditions which are suggested by the general description given us in the above communication.

At first sight it would appear that there is some confusion in the use of the word "*Kiül*," but we think this could be explained away. The general meanings given by Clough are not far from the technical signification of the expression in its agricultural sense, for "absence of salt" or "insipidity" clearly enough describes the impotent condition of soils which, as our correspondent states, can grow nothing. The term "brackish," given as another synonym of the word in question is, it should be noted, not always correctly used in its application to water, which is so described whether it is tainted with common salt or whether it presents the stale odour and taste derived from organic acids. It is in the latter sense, we fancy, that the word "*Kiül*" is used to denote brackishness. Indeed, we are informed on good authority that there is another and distinct expression which conveys the meaning "brackish" where the condition is due to the presence of common salt, viz., "*Karijja*" (කරිජ්ජ).

To our mind the word "*Kiül*" expresses as nearly as possible the condition indicated by the expression "sour" as applied to land. This condition, as Dr. Fream puts it, is generally found in soils containing too much organic matter, as a result of the excess of organic acids which develop in the land as the vegetable matter decomposes. Land of this description is, as a rule, characterized by the presence of coarse inferior grasses such as are referred to by our correspondent.

The chief agent to be recommended in the treatment of such land is lime, which by combining with the free organic acids renders them harmless to plant life. But the adoption of this and any further treatment cannot be safely advised until after a careful inspection of the land.

PRACTICAL HINTS TO HORSE-OWNERS:

By A. CHINNIAM, G.B.V.C.

CHAPTER II. (contd.)—FOOD AND FEEDING.

Oats.—Oats stand pre-eminent amongst the concentrated or artificial foods for horses. Looking at the following analysis you will notice that the nitrogenous matter and the fat stand in the pro-

portion of about two to one, and the percentage of carbo-hydrate and fibre should also be noted, for it is found by physiologists that the latter (woody fibre) plays an important part in stimulating the assimilating functions of the digestive organs. This food given alone has been found to be very well suited to horses in the western countries, but in the tropics an unbroken course of feeding on this food is not always without ill-effects. When the horse is allowed to consume too much of oats it generally suffers from chronic-congestion of the liver. In the hilly regions of the island it may be used with less harm to the horse, but in the lowlying districts if an animal is to be fed purely on oats great care ought to be exercised in regulating the food. Occasional bran mashes at least twice a week should be substituted for the oat diet. Care should also be exercised that the oats are properly crushed. Oats are generally mixed with chaff in order to prevent the animal from swallowing without proper mastication. It is advisable, as a rule, that an addition of chaff should be made to any food to ensure proper mastication. The following is an analysis of oats:—

Water.	Nitrogenous Substances.	Fat.	Soluble Carbo-Hydrates.	Fibre.	Ash.	Albuminous.
13.0	12.9	6.0	55.4	10.0	2.7	11.0

Bran.—Bran by itself does not rank high as a food for horses. It is used by horse owners as an occasional laxative food. Its action as a laxative is more or less of a mechanical nature, and if it has got any stimulating effect on the liver it is an indirect one. The use of it lessens the tendency to sluggish action of the organ,—a condition generally noticeable in the hot weather. This want of proper action and the consequent diminution of the bile secretion may easily be detected by the disagreeable smell of the dung; and successive bran mashes instead of ordinary diet will correct this evil. Indian bran is more nutritious, owing to its containing a considerable quantity of flour. Bran mash forms an excellent low diet for sick horses. To make a good bran mash, put the quantity of bran into a bucket, throw into it a handful of salt, pour in boiling water just enough to wet it, taking care not to make it too sloppy, stir with a rod and then cover it with brown paper or a piece of gunny bag, and leave it for a couple of minutes. The following is an analysis of bran:—

Water.	Nitrogenous Substances.	Fat.	Soluble Carbo-Hydrates.	Fibre.	Ash.	Albuminous.
14.0	14.5	4.0	51.3	10.1	6.1	11.7

Bran mashes should be given when slightly warm. When bran is treated like this it becomes very palatable and most horses really relish it.

Gram.—Gram is a very commonly used food in India and Ceylon, and is undoubtedly a very rich food, for it belongs to that important natural order of plants, the Leguminosae, and most of the edible

varieties that belongs to this group are so very rich in nitrogen, that they have been used for centuries by the non-meat-eating people of India as a proper substitute for animal food. Good gram weighs from 45 to 55 pounds per bushel.

When a handful of good gram is thrown into water it will fall to the bottom quickly. Immature gram is of a greenish colour, with a bitter taste and does not readily swell like good gram. Gram is very subject to the attack of insects, and such damaged gram is very injurious to the digestive organs. Very fresh gram is on the other hand not considered wholesome, and a few months should be allowed to elapse after the harvest and before it is used as food, but of course the gram must not be allowed to become damaged in any way by mould or insects.

The following is Prof. Church's analysis of the common gram fed to horses: (*Cicer arietinum*) also called chick pea, which should be distinguished from what is known in India as horse gram or kollu (*Dolichos biflorus*):—Water 11.2, albuminoids 19.5, starch 53.8, oil 4.6, fibre 7.8, ash 3.1.

(To be continued.)

BEE-KEEPING IN CEYLON.

The experiment in bee-keeping at the School of Agriculture is still in progress, in spite of the many difficulties that have been encountered. A Colombo resident who has had considerable experience in apiculture in England was good enough to volunteer his help, and paid a number of visits to the school with the object of suggesting improvements; but we regret to say that he was not sufficiently encouraged (by the bees) in his endeavours to make them adapt themselves to modern civilized methods of treatment. The original swarm introduced into the school was one brought from Kurunegala by Mr. Chas. Andree, whose name is always associated with bees, and who, it will be remembered, gave most interesting demonstrations in bee-keeping at the Fruit and Flower Show of 1893, and the Agri-Horticultural Exhibition in 1899. We are unfortunate in not having easy access to Mr. Andree, who, had he been at hand, would, we doubt not, have been able to help us to overcome all our difficulties, from his intimate experience of Ceylon bees and their habits, of which he has made so special and successful a study.

Two other swarms were subsequently brought over from Cotta through the kindness of Mr. H. D. Wijesinghe, a student of the School of Agriculture, and installed in box-hives in the school apiary. These are of the same species as those which Mr. Andree had brought, viz., *Apis indica*, the common honey bee of the Island; but it is notable that the bees of these latter swarms are slightly larger in size than the Kurunegala bees, while they are of a characteristic rugose hue. There is also the important circumstance that they are decidedly savage compared with Mr. Andree's educated swarm. With such a wealth of floriferous vegetation as the school grounds possess, it is but to be expected that the honey produced in these hives is of exceptionally good flavour, and we were pleased to find that H.E. the Lieut.-Governor and the acting Director of Public Instruction at the time

were particularly pleased with the quality of the honey in the samples of comb we sent for their inspection.

Mr. Alexis Teysloff, a Russian gentleman, who lately called here with the Director of the Colombo Museum, was particularly interested in our experiment, and carried away specimens of the typical inhabitants of the hive which were asphixiated of means of the "Cyanide bottle." We have forwarded to Mr. Teysloff the papers on bee-culture, together with descriptions of the different types of Ceylon bees, which have appeared in this Magazine.

Our latest venture in apiculture is of a novel character, viz., an attempt to domesticate *Apis florea* (the native *Danduvcl*). This bee is described by the late Mudaliyar Jayatilleke (who may be considered the pioneer in Ceylon apiculture) in a paper read before the Royal Asiatic Society as an unprofitable bee, producing very little honey, though the honey is much esteemed by the natives as being cooling and delicious in flavour. Mr. Jayatilleke thus did not consider the bee adopted for rearing purposes.

Another authority, however (Mr. Benton, an American apiarist, who visited Ceylon and studied our native bees in 1881), gave it as his opinion that it should be possible under favourable circumstances to induce *Apis florea* to build parallel combs.

Observing a swarm of these little bees on the branch of a cacao tree near our office, and reminded of Mr. Benton's authoritative opinion as regards the possibility of domesticating them, we lost no time in securing the lot with the help of Mr. J. A. Rodrigo, Manager of the Government Dairy (who, by the way, is getting quite *au fait* in the handling of bees) and inserting them in a box hive. At present the little bees are still under imprisonment, being artificially fed, and we shall look forward with interest to the result of our attempt to domesticate them. So far as we are aware this is the first attempt to rear *Apis florea* under modern conditions. Mr. Benton, himself, is said to have carried some of these bees as far as Cyprus, but as he reports "an accident happened soon after to the queen of my little bees, and now they are no more." Let us hope our experiment will be attended with less disappointing results.

SEEDLESS PLANTS.

Much interest has always attached to the fact that sugar cane is practically a seedless plant. Notwithstanding the fact that it arrows in the tropics, throwing up a long tassel or panicle, bearing seeds, these as a rule are imperfect and will not reproduce the cane plant. The rare exceptions that are now engaging scientific attention in some quarters of the tropical world are matters of great interest, but do not materially affect our main proposition. We are led to these remarks from the fact that the U.S. Department of Agriculture has been making some experiments with seedless plants, and below we give the following remarks thereon of the *New York Sun*, which bring out very clearly these singular qualities in some of our well-known plants. A careful reading of the same will be of value to those interested in

the sugar industry, giving them a better comprehension of the whole subject matter:—

"Under modern methods of cultivation the seeds of our best varieties of fruits can easily be dispensed with, as they are of little practical value. Seedling stock, raised from the wild or common varieties, answer the purpose as well as the rare or choice trees, and their usual combinations of hardness and virility influences the budded scions for good. Nature has already anticipated horticulturists in dispensing with the seeds and depending upon other methods of propagation. The banana, for instance, is a seedless fruit which Nature has apparently changed through some peculiar process. Rudimentary seeds are to be found in the fruit to-day. By slitting the banana down lengthwise rows of the rudimentary seeds will be exposed to view. Undoubtedly at one time, in its primitive wild state, the banana propagated itself by means of seeds, but the use of suckers for this purpose gradually made the seeds of less and less value. Following out the law of Nature, the seeds, becoming useless organs, degenerated. Occasionally a banana is found that does propagate itself by means of its seeds, or at least perfect seeds are produced in the fruit which can germinate. If for any reason the suckers of this plant should fail to do the work intrusted to them, it is not unlikely that Nature would reinstate the seed organs and develop them gradually to their really responsible position.

"The pineapple and cauliflower are two other common illustrations of how Nature occasionally dispenses with seeds. The pineapple is almost seedless, and, like the banana, its propagation is entirely by suckers. The seeds are in a low, rudimentary condition, but at one time they must have had their function to perform in life, and they are capable, under stress of circumstances, to renew their vitality. The type would not be exterminated if the suckers should fail to perpetuate the plants. All the resources of the plants would go to the assistance of the seeds to develop and vitalize them once more. This has been found possible by experiment. By selecting the pineapple with the most promising seeds, and propagating them by the usual process the seed organs have gradually been developed until they are able to reproduce their kind.

"The egg-plant is more interesting than either the banana or pineapple. There we have a fruit which is only occasionally seedless. That the seeds are really immaterial to the welfare of the plant is evidenced by the fact that perfect fruits are often developed whether the blossoms are fertilized or not. In the hands of the horticulturists it would be an easy matter to produce egg-plants that would have only the slightest trace of rudimentary seed organs, or *vice versa*, it would be impossible to develop a class of fruits that would be supplied with an abundance of large full-grown seeds.

"Nature's hints, thus supplied in a few isolated cases, have been the opportunities of man to raise a class of seedless fruits. Sometimes it is merely a freak of nature that happens only once or twice in a generation, and if the opportunity is missed the loss is great. To this origin we owe our fine California navel orange (*Bahia*) which is generally

a seedless fruit, although occasionally a few small seeds are to be found in it. The navel orange was an effort of nature to produce twins, but one of the twins aborted, merely surviving as a protuberance in the blossom end of the orange, a little kernel enveloped in the skin, which closely resembles the human navel in appearance. In the effort to produce a monstrosity the seeds were apparently neglected. By taking the scions of this fruit tree and grafting them on seedling stock we have practically established a seedless orange. It is, furthermore, remarkable because of its excellent quality and size. Usually the freaks of nature produce fruits that are not very good. Thus quite a number of apple trees have been produced, the fruit which is nearly or quite seedless. Their origin has been largely the same as that of the navel orange. They are generally abnormalities, and they are often called 'bloomless,' because the blossoms have no petals and sometimes lack stamens. Their appearance and quality are not such as to recommend them to the general consumer. The core is small and insignificant, but the shape is peculiar and the flavour poor.

"But seedless apples and pears of good quality may yet be propagated, and gardeners are working toward this end. Recent new varieties show great improvements over those first produced, and in the course of time careful culture and selection may bring about the desired results. How much the culture, selection and environment have to do with the proper development of the fruits is apparent in the case of seedless currants of Corinth or the Sultana grapes of southern Europe. These were supposed to have been as full of seeds as any other fruits far back in history, but successive years of culture and selection eliminated the seeds and improved the quality of the fruits. How the culturists first got their hint of seedless fruits is not known, but it is reasonable to believe that they took advantage of a freak of nature which produced a vine with fruits that had very few or no seeds.

"Experiments are now being made in California with the famous Muscat grape of Alexandria (Hanepoot). This famous raisin grape would be greatly enhanced in value if the seeds could all be eliminated. Considerable progress has been made in this direction by selecting cuttings from vines which produce grapes with less than the normal number of seeds. Several smaller varieties of seedless grapes have been in existence for many years, but most of them are inferior in some way to the best raisin grapes raised for market. Seedless fruits will be a success only when, in addition to maturing without seeds, the size and quality of the fruits will be equal or superior to the best varieties in the country. That is the essential reason why the navel orange is the greatest success of modern horticulture."—*Louisiana Planter*.

SOME BIBLE PLANTS OF CEYLON.

I.—CAMPHIRE.

The Hebrew word *copher* or *kopher* occurs in the Song of Solomon, and has been translated Camphire. Thus the King says: "My beloved is unto me as a cluster of camphire in the vine-

yards of En-gedi;" and again, "Thy plants are an orchard of pomegranates, with pleasant fruits; camphire, with spikenard. The Hebrew word, (says Balfour) resembles the Greek *Kapros* or *Cypros*, which is applied by Dioscorides and Pliny to a plant known to botanists by the name of *Lawsonia inermis*, and belonging to the order Lythraceae or loosestrife family. The common names by which it is known are *Henna* and *Marathondi*. Its fragrant flowers grow in clusters and are used to dye the hair, the nails, the palms of the hands and the soles of the feet, of an iron-rust colour. Henna powder is procured from the leaves and stem of the plant. This is put into hot water, stirred and boiled well, and then left on the fire for two hours until the mass becomes a paste. It is then applied to the hair and the skin which it tinges an orange colour. The plant is also used for dyeing Morocco leather. The custom of dyeing the nails was an ancient one in Egypt, and it is said that the nails of mummies (particularly females) sometimes show traces of it. Some think that there is an allusion made to the practice in Deut. xxi. 12, where, in place of "pare her nails," the phrase might be rendered "adorn her nails."

Henna is also known as the Cyprus shrub or the Egyptian privet. Dr. Watt mentions that the selling price of the leaves in the Punjab averages Rs 12 seers, which makes the value of the crop per acre about Rs 66.

A decoction of the leaves is used for dyeing cloth, the colour produced being a shade of yellowish or reddish brown known as *Malagiri*. It is also used in combination with other dyes for dyeing handkerchiefs an almond colour. The plant is also much used medicinally for numerous complaints, while the sweet odour of the flowers makes it a great favourite in tropical gardens where it has earned the name of "tree mignonette." The perfume has always been in great repute, and both an otto and fragrant water was (and in some places still is) in use among the Jews, Egyptians and Mohammedans.

CLASSIFICATION OF FIBRES.

The uses of fibres or fibrous substances in the coarse weaving or plaiting of basketry is an industry that belongs to all civilized countries and that is practised by the native tribes of the world, but a catalogue of the varied forms would be too long for enumeration in these pages. By reason of the similarity of construction and materials used, we must also include in this class a considerable number of articles that resemble baskets, known as willow ware, such as hampers and infants' carriages, and even chairs that are produced from willow withes, and chair bottoms are also included. While the commercial basket material is confined chiefly to osiers, or willows, to certain forms of wood splints, and to a few species of rushes and grain straws, the native and Indian basket fibres are legion, for they include a range of vegetable substances from the stipes of delicate ferns and the smaller grasses, through the sedges, reeds, the bamboos, the palms and liliaceous plants, to the stems and

twigs of shrubs, and even the splints from the wood of trees, or their subdivided woody roots. A few examples of this class of manufactures are the sweet-scented grass baskets made by the New England Indians from the holly grass; the delicate fern baskets of the Sandwich Islanders, the Yucca oil baskets, and others by the Hopi Indians of Arizona, the sumac and yellow trays, and the spruce root baskets of northern fibres, palm leaf baskets, and those from bamboos, sedges and reeds. Among commercial forms are the Italian straw-plait baskets, the Buscola baskets from certain sedges, the osier manufactures from Italy, and the ash and white-oak splint baskets made in our own country, together with chair bottoms plaited in rattan or rushes.

A sixth form of utility is the employment of fibres or fibrous substances as filling material for stuffing pillows, cushions, mattresses, furniture, &c., or as packing substances. The surface fibres for the most part compose this class, as the bast fibres are too valuable, while the structural fibres are too stiff for such purposes, exceptions being the shredded leaves of palms, the commercially prepared Spanish moss (*Tillandsia usneoides*) known as vegetable hair, and the familiar corn "shucks." The pseudo-fibres embraced in group 5 are also largely used as packing material, though a notable exception should be made of certain leaves, as well as species of fungi and Alaskan sea-weed, the last being twisted into fish lines, the fungus used for making caps, table mats, &c. or employed as tinder. Mycelium has also been employed as a substitute for fabric.

A seventh and most important use is the manufacture of paper.

With this brief enumeration of some of the ways in which fibres are employed by man, the following economic classification, relating to the utility of fibre and fibrous substances is presented:—

A. SPINNING FIBRES.

1. *Fabric Fibres.*

a. Fibres of the first rank for spinning and weaving into fine and coarse textures for wearing apparel, domestic use, or house furnishing and decoration, and for awnings, sails, &c. (The commercial forms are cotton, flax, ramie, hemp, pineapple, and New Zealand flax.)

b. Fibres of the second rank, used for burlap or gunny, cotton bagging, woven mattings and floor coverings and other coarse uses. (Commercial samples are jute and coir.)

2. *Netting Fibres.*

a. Lace fibres, which are cotton, flax, ramie, agave, &c.

b. Coarse netting fibres, for all sorts of nets and for hammocks. (Commercial forms: Cotton, flax, ramie, New Zealand flax, agave, &c.) The native netting fibres are legion, and include the fibres derived from tree basts, palms, &c.

3. *Cordage Fibres.*

a. Fine spun thread and yarns other than for weaving; cords, lines and twines (all of the commercial fabric fibres sunn, Mauritius, and bowstring hems, New Zealand flax, and the so-called commercial hard fibres, coir, manilla, and sisal hems and other forms); the fish lines made from seaweed,

b. Ropes and cables (chiefly common hemp, sisal and manilla hems, when produced commercially. In native manufactures made from palm fibre, yuccas, and many other plants).

B. TIE MATERIALS (ROUGH TWISTED).

Very coarse materials, such as stripped palm leaves, the peeled bark of trees and other coarse growths used without preparation, and employed in the construction of huts, fences, as emergency cordage, and sometimes as cables for "rope bridges" with other native uses too numerous to mention.

C. NATURAL TEXTURES.

1. *Tree basts, with tough interlacing Fibres.*

a. Substitutes for cloth prepared by simple stripping and pounding. (Examples: The Tappa or Kapa cloth of the Pacific Islands; the *Damajuhato* of South American tribes.)

b. *Lace Barks.* (The best example is the bast from *Lagetta Lintearia* of Jamaica, which has been used for cravats, frills, ruffles, &c., and likewise as thongs and whips.)

2. The Ribbon or larger basts extracted in thin, smooth-surfaced, flexible strips or sheets. (Examples: The Cuba bast that is employed commercially as a millinery material, plain and dyed in colours; cigarette basts for wrappers.)

3. *Interlacing Structural Fibre or Sheaths.*

a. Pertaining to leaves and leaf stems of palms, such as the fibrous sheaths found at the base of the leave stalks of the coconut.

b. Pertaining to flower-buds. The natural caps or hats derived from several species of palms.

Note.—The separated filaments of these cloth substitutes, sheet or ribbon basts, &c., are also employed, by twisting, as cordage.

(To be concluded.)

SELECTION AND ITS EFFECTS ON CULTIVATED PLANTS.

From a paper by the late Monsieur Henry L. de Vilmoria in the *Experiment Station Record*, vol. xi. No. 1. U.S. Department of Agriculture

The word *selection*, taken in its general sense, means *choice*. In natural history, when applied to plants or animals which man raises under domestication, it assumes a more restricted meaning, and is applied only to the choice of individuals considered as agents of reproduction. It is in this sense alone that the word *selection* is used in this article.

The purpose of this paper is to indicate the reasons for making a certain choice, the results it may produce, the precautions that should accompany it, the practical methods of applying it, and the difficulties that may be met and may defeat the purposes in view.

Evidently the process is quite different from natural selection. The latter proceeds independently of man by the simple interplay of natural forces, while artificial selection is an act performed by man for the purpose of satisfying his needs and tastes. Nature modifies plants in *their* interest; man modifies them in *his*; but in the one case, as in the other, there is an acquirement of characters and a transmission of the characters acquired.

This article is not the proper place to discuss selection and its relation to evolution, of which the creation of varieties by selection is only one phase; nor is it the place to discuss the relative permanence of existing species. The task of the improver of cultivated plants is not to create new species, but to establish and fix in known species well-defined and constant races possessing distinct characters which may render them useful or agreeable to man.

The practice of selection is almost or quite as old as the practice of cultivation itself. It is certain that from the most remote beginnings of pastoral life primitive man has preferred the finest and best-shaped animals for breeding purposes. In the same way, when the culture of certain useful plants had succeeded to a more primitive form of pastoral agriculture, or had become associated with it, the domesticated races of plants were gradually ameliorated by the diligence of some men who were more observant and interested than others; and the improved races were disseminated from place to place.

THE EFFECTS OF CULTIVATION ON PLANTS.

Much has been said of cultivation as a means of improving plants. The writer believes, however, that the selection of the individual intended to reproduce a sort has done infinitely more in this direction than cultivation properly so called. Without doubt, the larger amounts of plant food, air, and room that are provided for the plant under careful cultivation, as compared with wild conditions are the means by which some given plants attain to a greater individual development; but cultivation in general advances improvement principally because it gives to man an opportunity to observe the plant closely, to notice even the slightest variation in the characters of the different individuals, to note at the time of their occurrence all the variations which appear useful to him, and to fix them by sowing the seed from all the individuals that have shown these variations. Superabundance of food supply undoubtedly favours the appearance, in cultivated plants, of variations which consist of multiplications of parts of a plant or the excessive development of certain parts among them; but heredity interferes to fix these characters, so that they are seen to persist in individuals escaped from cultivation and are perpetuated for a long time even after the causes that brought them into existence have ceased to act. We possess few records bearing on the history of the improvement by selection of the various useful or ornamental plants in ancient times; yet the figures which have been left to us in paintings, mosaics, and sculptures indicate a notable improvement of the species cultivated by the Egyptians, the ancient Greeks, and the Romans over the wild types of the same plants found in those regions at the present day. The leeks of Egypt, to the fame of which the sacred writings bear witness, are represented on the bas-reliefs and paintings of Egyptian tombs as of a size far superior to that of the wild leeks of the mountains of Central Asia, which, without doubt, represent the primitive type of the species. The Romans cultivated several varieties of *Brassica oleracea* that represented an immense advance over the

wild type found on the coast regions of Europe. The flowers and fruits, figures of which are found frequently in Roman works of art, resemble more the varieties of the present day than the primitive types from which they were developed.

In passing it may be remarked, in reference to those fruits and flowers that are propagated by grafts and not by seed, that selection is not entirely unconcerned in their culture, but even in such cases is found to exert its influence in various ways. A new variety generally originates from a seed which may have been accidentally planted, the resulting plant being reproduced and multiplied by grafting, or from seed planted by man, the various young plants being carefully observed from day to day and compared with each other, and meritorious novelties, if such appear, selected and propagated. In grafting, few things must be taken into consideration. In the first place, only those stocks should be used that are healthy, vigorous, as far as possible free from defects and diseases, and well provided with roots; and in the second place, the grafts should be taken from the youngest and healthiest shoots of the plant that is to be propagated, and always from those that represent most faithfully the characters it is desired to reproduce. Sometimes variations are produced in plants by dimorphism, as by variation in the form or colour of the foliage or in the shape or hue of the flowers, as often occurs in the chrysanthemum. There is then opportunity for the selection of the modified branch, which is propagated by cuttings or any other method. The question of the permanence or running out of varieties of fruit trees, which is so often and so contradictorily discussed in the horticultural press of all countries, is intimately connected with this question of selection. There is no reason why a given type should run out if only proper stocks and healthy grafts are used in propagation, but the variety will certainly disappear if it is attacked by parasites to the extent that it is no longer possible to find a graft that does not carry with it its enemy.

To return to the history of selection of cultivated vegetables and flowers propagated by seeds. Italy, Provence, Flanders, and the neighbourhood of Paris were, at about the beginning of modern times, the principal centres of the improvement of common plants. Seeds grown in these places bore a high reputation throughout Europe, and the popularity that they enjoyed shows that the characteristics developed in the different varieties of plants by these skilful and careful gardeners were well fixed, else they could not have reproduced themselves faithfully when cultivated under very different conditions of soil and climate. Vegetable gardeners have been for the most part the creators of European varieties of vegetables (and at the same time of many varieties of flowers, for the two occupations of vegetable gardener and florist were very often followed by the same individual, as is frequently the case at the present day), and the uniformity, the constancy, and the cooking qualities of the varieties of vegetables originating in Naples, Milan, Lyons, Paris, and the Low Countries bore witness to the skill, fine observation, and judgment in the application of selection which our predecessors possessed.

It is only since the latter half of the seventeenth century that the seed business has begun to be separated, little by little, from that of general gardening, and, as division of labour always results in an improved product, the establishments that have devoted themselves exclusively to the growing of seed have come to do it better and more economically than the common gardeners, whose time and effort were divided among various lines of production. In one respect, however, the competition of the market gardeners, as well as that of the florists properly so called, is still very useful to the careful seedsman in that it helps to keep him always in the front line of progress. To a less extent than the market gardener and florist the seedsman is brought in immediate contact with the consumer, whose needs are the source of progress and new acquisitions. The former sometimes supply these needs, but often they turn to the seedsman and point out to him the prospect of increased profits as the reward for the creation of new and desirable varieties.

At the present day species that have been cultivated for many years have become, so to say, like wax in the hands of special growers, who mould them and fashion them to their taste, obtaining the various modifications of shape, size, flower, &c. demanded by the preferences of their patrons and the caprices of fashion.

(To be continued.)

GENERAL ITEMS.

We cull the following from an article on Indian agricultural affairs, appearing in the *Indian Agriculturist*:—We all know that in private and semi-public life the helping hand is a great saviour to vast numbers. And that self-same helping hand embodied in an energetic, practical and scientific, and really working Agricultural Department, would assuredly do great things for India. It must create more wealth and therefore more revenue, more stability for the country, more ability to bear a famine among the people themselves, when it comes. It is gratifying to note from the Hon. Mr. Ibbetson's reply to the Maharaja of Darbhanga that the Secretary of State has sanctioned a Director-General of Indian Agriculture, but the right man for that post has not yet turned up. It may be safely observed that very much indeed depends on the right man for this post; he should, I venture to think, have full authority to pull down and build up: much wants absolutely destroying root and branch. Hand in hand with a great advance in railways there should surely go a great advance in agriculture, to say nothing of the great amplification Indian agriculture is open to. If a tropical country suffers from many disadvantages, it at the same time has many advantages too, and can grow many valuable products not possible in temperate climes. Undeniably able and brilliant as is the record of the Indian Civil Service, since neither practical or scientific agriculture forms a part of their training, it is most unfair they should be called upon to conduct an Agricultural Department at all, and it is still more unfair to agriculture, with its multifarious details and routine, that it should be saddled with a body of distinguished men who know nothing of its technique. It is no wonder, seeing this is so, the Department resolves itself into a mere statistical recording body, and that so much of its practical

agriculture as does exist is perfunctory, and utterly inadequate to the needs of the country.

We find that through an oversight the rainfall for November 1899 and January 1900 were not given in the pages of the Magazine. In order to maintain the record of the rainfall as taken at the School of Agriculture and for purposes of comparison with the Fort readings we give them now. In November 1 99 rain fell on the following dates:—3rd, .77; 4th, .02; 14th, .60; 16th, 2.25; 24th, .11; 26th 2.2; 28th, .20; 30th, .74. The total for the month was thus 6.89 in. with a mean daily rainfall of .22 in. In the month of January rain fell on the following dates:—10th, .16; 13th, 1.31; 19th, 1.43; 25th, .41; 26th, .02; 27th, .69; 29th, .02; 31st, .19. The total rainfall for the month was thus 4.38 in. with a mean daily rainfall of .14 in.

The following is a complete chemical analysis of an average sample of cow's milk, as made by Prof. Brunnich, Agricultural Chemist of the Queensland Agricultural College:—

Specific Gravity	1.0311
Water [86.75—86.79—86.70]	86.752
Casein	3.174
Albumin322
Butter fat [4.23—4.26]	4.245
Milk sugar (lactose)	4.850
Ash724
Total solids [13.29—13.21]	13.25
(Total solids calculated from fat and specific gravity)	13.13

Analysis of $\frac{1}{2}$ milk ash:—		
Sulphuric acid	SO ₃ ..	.285 per cent. = .002
Carbonic acid	CO ₂ ..	.390 per cent. = .003
Phosphoric acid	P ₂ O ₅ ..	29.430 per cent. = .213
Chlorine	Cl ..	13.343 per cent. = .097
Lime	CaO ..	22.520 per cent. = .163
Potash	K ₂ O ..	22.310 per cent. = .161
Soda	Na ₂ O ..	9.940 per cent. = .072
Magnesia	MgO ..	1.440 per cent. = .010
Iron	Fe ₂ O ₃ ..	.040 per cent. = trace
Undetermined, Loss, &c..		.302 per cent. = .003
	100.000	= .724

The following references to two well-known Ceylon trees occurs in the report of the Queensland Agricultural Department:—

PAWPAW.—The continued heavy rains in March had disastrous effects on our Pawpaw trees, killing many off by rotting the roots. Some would have recovered had not the wind blown them down before new roots could be made. Several good trees were lost, including the branching variety. There are several varieties not in the nursery, however. Three distinct varieties are known in Southern India, besides a Chinese variety, apart from the branching variety here. The Singapore Pawpaw is not especially large, but turns a golden yellow when ripe, and has a fine flavour. The Chinese is a long pointed fruit, and is a dark-green colour when ripe. This would probably travel better than most. The male tree is not a necessity in a garden, though there is nothing lost by retaining one should a number come up from the seed. The *Pawpaw carica* may be dioecious, monoecious, and even hermaphrodite. I hope to be able to deal with this interesting fruit tree later on by itself.

JACK FRUIT (*Artocarpus integrifolia*).—The only tree of this useful fruit in the Nursery shows signs of a past crop, but none of a further crop this year. The tree is rather slow-growing, but the

timber is hard and good. It is of a dark yellow, and is useful in making furniture. The tree is prolific. I have had over seventy fruit on one tree, averaging 35 to 40 lb. each, some fruit being 65 to 70 lb. each. The fruit has a strong but not unpleasant smell, though many object to it. Once the taste is acquired, the fruit becomes very popular. The seeds make an excellent vegetable, and are a good substitute for potatoes when boiled. When dried and ground the seeds or nuts give a wholesome meal. The nuts roasted are not unlike English chestnuts. The fruit, seeds, pulp, skin, and all except the rough outer covering are readily eaten by cattle, and pigs are specially fond of them and fatten on them.

The *Farm and Dairy* in referring to the proposal made by the Principal of Hawkesbury College N.S.W. to grow macaroni wheat along the coastal districts of the Colony and the subsequent establishment of macaroni works, quotes the following Despatch received from Her Majesty's Consul at Naples, giving an account of macaroni manufacture in that part of Italy:—Macaroni is made of hard red wheat from the Black Sea, mixed with Italian wheat, grown mainly in the plains around Foggia. This is ground into semolina (not flour), the bran and husks are removed, and the semolina kneaded in hot water till it has the appearance and consistency of dough. The dough is then placed in a vertical brass cylinder, about eight or nine inches in diameter, the bottom of which is a plate like the rose of a watering pot, which is fine or thick, according to the macaroni required. Thus for making vermicelli and all kinds of solid macaroni the holes are very small, while for making tube macaroni the holes are much larger. In the latter case also a conical blade is fixed in the middle of the hole to form a tube. The dough being placed at the top of the cylinder, it is driven down by hydraulic pressure through the perforated plate and cut off by hand in lengths of about three feet. It is then hung on canes in the sun to dry. In the case of the solid macaroni there is no difficulty in grasping the process. In the case of the tubular macaroni the conical blade and its attachment cut through the dough and the macaroni issues with a slit all along it. This, however, shrinks together at once and forms a perfect tube,

the join being practically invisible. No macaroni is now made by the laborious hand process. There was for a long time a prejudice against machinery, but this has been overcome. The best macaroni is made at Gragnano and Torredell' Annunziata. A little also of the best quality is made at Amalfi, Alfonso Grolalo, of Gragnano, being the most important manufacturers. About a million boxes are sent annually to the United States, and about 10,000 to London. The remainder is sold in Italy.

The following represents the amount of money that the New South Wales Government spent during the last financial year, ended 30th June 1899, on agriculture:—

	£
Department of Agriculture	29,218
Live Stock—	
Registration of Brands	563
Imported and Introduced Stock	11,008
Pastures and Stock Protection Act	3,790
Management of Pounds and Commons	440
Control, Marking, Fencing, and Improving Travelling Stock and Camping Reserves &c.	464
Special Prizes to be devoted to the Improvement of Agriculture	824
Distribution of Seed Wheat to Distressed Farmers	97
Vine Diseases Act—Expenses in connection with the Eradication of Phylloxera, and the Administration of the Act	2,499
Agricultural, Horticultural, and Pastoral Societies—	
Subsidy not exceeding 10s. on every £ awarded in Prizes for Agricultural, &c., objects	9,598
Special Grant to Agricultural Societies	3,975
Subsidy to Horticultural Societies	250
Cooma Pastoral and Agricultural Association, revote of 1895	100
Broken Hill Pastoral and Agricultural Association, Special Grant	300
Clarence Pastoral and Agricultural Society, Special Grant	200
Board of Export	2,095
Total	£65,421

LITERARY REGISTER SUPPLEMENT:

AND CEYLON

"NOTES AND QUERIES."

[Under this heading, in future, we mean to give a four or eight page "Supplement" with our *Tropical Agriculturist*, from quarter to quarter, according as there is matter of sufficient value, so to be preserved.]

NOVEMBER, 1899.

GEOLOGICAL SURVEY FOR CEYLON.

MEMORANDUM ON THE SCOPE, ORGANIZATION, AND FUNCTIONS OF A GEOLOGICAL SURVEY FOR CEYLON: BY MR. R. D. OLDHAM, OF THE GEOLOGICAL SURVEY OF INDIA.

Accepting as a fundamental principle that a geological examination of Ceylon is desirable, the first point to be considered is whether this can be carried out in a sufficiently satisfactory manner by the temporary employment of persons possessing the requisite knowledge, or whether it is desirable to establish a Geological Survey as a permanent Department of Government.

TEMPORARY EMPLOYMENT OF EXPERTS NOT DESIRABLE.

The temporary employment of individuals to make special examinations of selected tracts would be the cheapest as regards actual expenditure of money, as no liability would be incurred beyond the stipulated remuneration, and there would be neither permanent office expenditure nor any non-effective pay to be provided for. This, however, is all that can be said in favour of such a mode of procuring a geological examination, even if it were confined to part only of the Island; judged by the standard of results the economy is more than doubtful. Being employed only for a limited period the expert would be exposed to a temptation, greater than human nature can be expected wholly to resist, to take an optimistic view of the facts, and especially such a view as would lead to renewed employment. His conclusions would consequently be lacking in the judicial quality, which may more reasonably be expected in those of an individual of equal attainments who had no pecuniary interest to influence his conclusions, while it would be almost certain that his attention would be devoted mainly or solely to the points likely to make the best show of results in the shortest time, to the neglect of those which, if apparently less striking at the time, or requiring greater patience to work out, may ultimately be the most important.

An even greater evil would be the want of continuity in the work; each man coming fresh

to the Colony would have to start afresh; he would find no laboratory, library, or other requisites for thorough and systematic work, and would have either to neglect the proper working out of his field observations or to take his collections to Europe, where they would be lost to the Colony and inaccessible to his successors.

ADVANTAGES OF A PERMANENT SURVEY.

A permanent Geological Survey, properly equipped, would not only make a complete examination of the whole of the Island, both of those parts which appear to be of immediate economic importance and of those whose importance is yet to come, or in which there are no minerals of economic value; the results would be worked out and the records be preserved locally, and in course of time the headquarters office of the Department would become an Intelligence Bureau for the Island, so far as its geology is concerned. In this way the information accumulated will, in many cases, prevent the useless expenditure of money consequent on mistaken identifications, or, on the other hand, it will be possible to reply, immediately and without the undertaking of special investigations, to inquiries regarding the presence, distribution, and abundance of minerals in the island.

TIME REQUIRED FOR COMPLETION OF FIRST SURVEY.

The only doubt that might be entertained as to the desirability of maintaining a permanent Geological Survey is whether there would be sufficient work to keep it permanently employed; this I do not think need be seriously questioned. The Island has an area of over 25,000 square miles; of this about 10,000 probably consists of alluvium and recent deposits which can be fairly rapidly surveyed; the other 15,000 square miles is more rocky and cannot be surveyed so rapidly. I do not think that, allowing for leave, sickness, and casualties, an average of more than 1,000 square miles per annum in the one case and 500 in the other can be reckoned on. There are consequently about 40 years' work to complete a thorough survey of the whole Island, or if three men are employed a period of 13 years

should see the first complete survey of the Island, a period which may be shortened or lengthened according to the staff employed. This period would be further lengthened if, as I think would be desirable, part of the energies of the Department were, for the first few years, devoted to a general and purely preliminary examination of the Island as a whole, apart from the more detailed survey contemplated in the estimate above. The time required for the completion of the first survey would therefore be about 15 years if a staff of three men, the minimum number with which continuous work could be maintained, were employed.

MAINTENANCE NECESSARY AFTER COMPLETION OF FIRST SURVEY.

The work would not be finished at the end of this period, as the most thorough survey can never be perfect, and it is certain that during the progress of the survey many new facts will crop up, consequent on the extension of mining operations and of discoveries which must always be made by persons independent of the professional survey. The local resident has many opportunities which the geological surveyor, in his passage through the country, has not, and in this way new discoveries will be made which will necessitate revision or re-survey. Consequently, it will be desirable, even after the first survey is complete, to maintain a staff, which need not necessarily be of the full strength maintained during the survey, for purposes of revision.

NECESSITY OF CONTINUITY IN THE SURVEY.

From this it will be seen that the amount of work to be done is quite sufficient to justify the establishment of a permanent Geological Survey, but all the advantages will be lost unless it is conducted as a systematic survey and not as a Department for reporting on real or imaginary mineral deposits. Unless it is understood that the work of the survey is to be systematic and its object a complete examination of the island, it would be better not to establish a Geological Survey at all. This principle being accepted, all diversions of members of the survey to visit or examine isolated mines or sites of proposed mines is most strongly to be deprecated, as the interruption to the progress of the survey is serious and the advantage to be gained as a rule but small. Such diversions are especially to be deprecated in the case of lands in the position of, or proposed to be leased to mining syndicates or companies; whatever disclaimers may be made by the Government, the fact of such special examination is sure to be represented, formally or informally, as an implied Government guarantee, and in the case of failure of the venture the Government, though not liable, will be exposed to unnecessary obloquy.

SURVEY SHOULD BE BY AREAS, NOT MINERALS.

Equally to be deprecated are special investigations of particular minerals, *e.g.*, plumbago or mica. Such limitation of the scope of the survey is most apt to result in bad or imperfect work. By this I must not be understood to imply that no regard is to be paid to the economic applications or probable economic result of the survey. In arranging the programme of work from year to year the known or suspected economic resources of the district whose examination is decided on will naturally be taken into consideration and, among the tracts whose investigation will be taken up, precedence will naturally be given to those in which plumbago is known to be abundant and which are

most accessible to the outlets of trade. These investigations should, however, be by areas and not by minerals; that is to say, the instructions should be to survey a certain definite area, in which minerals of economic value are or are not known to exist, but not to examine or search for occurrences of a specified mineral, such as plumbago, in that area. Attention would, of course, be paid to the economic resources, and the instructions might inculcate a special attention to plumbago; but there should be nothing which could be interpreted as an order or justification for neglect of other parts of the area than those in which it was found.

This procedure is advisable even on purely pecuniary grounds, for not only might the neglected portions of the area contain other unnoticed minerals of value, but it may well be that in them the key to the mode of occurrence of the plumbago may be found, which will lead to an extension of the area over which the mineral is worked. From the point of view of the general progress of the survey this procedure is even more desirable, as a partial examination of an area only means that, when the survey comes to be completed, much work will have to be done again, and, when made in instalments in this manner, imperfections and discrepancies in the final survey are almost inevitable.

NECESSITY OF TOPOGRAPHICAL SURVEY.

It must also be borne in mind that a Geological Survey is very much hampered by the absence of a trustworthy topographical map. For this reason the geological survey should, as a rule, and in the absence of any special reasons to the contrary, be confined to those regions of which good maps are available; in making a departure from this rule it must be remembered that any examinations of areas of which there is no proper map can only be regarded as preliminary, and that they will certainly have to be re-surveyed as soon as proper maps are available. Precedence should consequently be given, in conducting the topographical survey, to those areas of which geological surveys are most urgently required, and it would be desirable that the Geological Survey should be consulted when the programme or work for the Topographical Survey is annually arranged.

ADVISABILITY OF COMBINING OTHER FUNCTIONS WITH THE GEOLOGICAL SURVEY:

(i.) MINERAL STATISTICS.

Though there is, as I have indicated, sufficient justification for the establishment of a Geological Survey on the customary lines in Ceylon, the Department would be a small one, and it might with advantage be required to take up duties which in larger and more specialised Administrations are usually separated from it. Foremost among these are those connected with the collection and publication of mineral statistics, a work which can only be carried out by the assistance of the officers in charge of the revenue and administration of the Colony, as far as the collection of the facts of production, and inception or abandonment of individual undertakings, are concerned. The collation of these statistics and the publication of an annual Review of the mineral production of the Colony might with advantage be allotted to the Geological Survey.

(ii.) MUSEUM.

Closely connected with this is the establishment of a Geological Museum more especially of th

economic geology of Ceylon, which should serve as an index to the known geology of the Island, and a place where visitors and inquirers could see at a glance what was known of the geology, and what were the mineral productions, of the Island. Such a Museum would not only serve for the instruction and information of the general public, but would be the greatest service to the Geological Survey itself, as an index to the work done up to date in the Island. In some form or other a collection would have to be established, and at a very slight increase of labour this might be made available to the public.

This Museum need not be a large one; 2,000 ft. of floor space would be ample, and for a while less would be sufficient, but the museum should be directly under the charge of the Geological Survey, and not made a department of the existing Museum in Colombo.

(iii.) PUBLIC LABORATORY.

If doubts may be entertained regarding the necessity of a public museum, none can be felt as to the desirability of a public laboratory. A laboratory of some sort, properly equipped for analysis of rocks and minerals, will be required in any case and, by a small extra cost for accommodation and establishment, its services could be made available to the general public, as a place where specimens collected by them could be identified and, if desired, analysed. This would not only be desirable on public grounds, but would be an advantage to the Survey, as among the samples sent in a certain number would be of interest and would afford information, which the Survey unaided would be unable to acquire. The services of the laboratory should be free of charge so far as the determination of specimens goes, but to prevent the time of the laboratory being uselessly taken up in compliance with frivolous demands a moderate charge should be made for analyses or assays.

AGRONOMIC SURVEY.

A somewhat distinct branch, which I consider would with advantage be combined with the geological survey, is an agronomic survey of the Island. In view of the great importance of the planting and agricultural interests of the Island, this ought not to be neglected, and as a laboratory will in any case have to be provided a slight extension of this and a small increase of the staff will enable an agronomic to be carried on in conjunction with the geological survey.

The work of the agronomist is, I may explain, somewhat akin to, though distinct from, that of an agricultural chemist. The latter is principally concerned with soils as altered by culture, with their chemical composition, and with advising on the particular manures that the chemical composition indicates as desirable for specified crops. The agronomist is, on the other hand, more concerned with the original characters of the soil and subsoil, with their relations to the underlying rocks, and with the physical constitution of soils, on which their adaptability to cultivation depends to a larger extent than on their chemical composition. The work of the two is consequently distinct, though overlapping, and the fact of an agronomic survey being in progress, or completed would not preclude the employment of an agricultural chemist proper, should that ever seem desirable, while the existence of an equipped laboratory would lessen the expense.

INDEPENDENCE OF THE DEPARTMENT

RECOMMENDED.

These additional branches of the Survey are not essential, but it is essential that the Geological Survey should be treated as a distinct Department of Government. The officer in charge of it should have the power of communicating directly with the Government, and not be put under the Public Works or any other of the existing Departments of Government, and this being so, the administration of the Department under him would make calls on his time which would prevent him from taking a large part in the actual execution of the survey. These interruptions would be practically the same if the additional branches of work were transferred to or taken up in addition to the geological survey proper. Consequently it is desirable to group the functions enumerated and to form a Department of Geology, Mines and Agronomy under the charge of a single head, who should be directly responsible to the Government, and who would find, in the administration of the Department, a task commensurate with the interruption to the actual execution of survey work in the field, which is inevitable if he is burdened with the administration of even the smallest Department.

LOCATION OF HEADQUARTERS.

An important point to be considered is the location of the headquarters of the Department. Practically there are only three places to be considered, as it is undesirable that its headquarters should be established at a place where they would not come annually under the ken of heads of the Administration. These places are Colombo, Kandy, or Nuwara Eliya. Of these, Colombo has the advantage of being the site of the headquarters of the Administration and the principal commercial town of the Island. On the other hand, its climate is relaxing to a degree, and seeing that the officers of the Survey will be exposed for six months in each year to hard work and exposure in a trying climate, often in malarious districts, it is eminently desirable that they should be placed, during the recess and when engaged in working up the results of their field season—that is, for from five to six months in each year—in a climate which would enable them to recruit their health and acquire fresh energy for the next season's work.

COLOMBO INADMISSIBLE.

This argument alone should be sufficient to prevent Colombo being selected as the headquarters of a new Department, though it may not be considered sufficient to necessitate the transfer of offices already established in Colombo. Apart from it, however, there are certain laboratory processes which cannot be carried on at the high temperature which prevails at Colombo; this is so much felt in the case of the Indian Geological Survey, where headquarters were established in Calcutta at a time when no other place was accessible, that the question of transferring the headquarters to a better climate is being considered, and I would most strongly deprecate the Ceylon Government committing itself to a mistake for which there is no reasonable justification.

KANDY ADMISSIBLE BUT UNDESIRABLE.

Kandy, centrally situated, is practically as accessible as Colombo, the distance between the two is no bar to personal communication between the officer in charge of the Geological Survey and the heads of

the Administration whenever desirable. If a Geological Museum is established, it would not be beyond the reach of any one who really wished to derive any information from it, while it would gain by being attached to the officers of the Geological Survey, both in the greater attention which could be paid to it and in the greater facility with which visitors, desiring more information than was obtainable from the show cases, could consult the unexhibited collections of the survey.

On the other hand, the climate of Kandy though preferable to Colombo is still far from perfect; the temperature is somewhat high for the work of the laboratory, which is best carried on at a temperature of about 60 degrees F., and for this reason I cannot recommend the adoption of Kandy as a site for the headquarters, though it would be preferable to Colombo. Its selection can only be justified if considered imperative on the score of its central position.

As a minor objection to Kandy I may, urge the lack of facilities for social intercourse, exercise, and relaxation. When men have been out in the districts for months, and for the greater part of that time leading a solitary life without companionship, it is undesirable to bring them into a place where, after their day's office work is over, there are practically no means of throwing off for a while all thought of the subjects they have been dealing with during the day, and finding in some active form of relaxation that change and rest to the brain which is to be desired, if only on the purely mercenary grounds of enabling them to turn out a larger and better daily task of work. This consideration is not, of course, to be given a foremost rank, but where there are no stronger grounds for giving preference, to one place over another, it should be allowed to turn the scale.

NUWARA ELIYA RECOMMENDED.

Nuwara Eliya has not only the advantages referred to in the last paragraph, but is in every other way preferable to Kandy or Colombo, so far as considerations confined to the place itself are concerned. Not only is the climate the best adapted, of the three possible places, to recruit the health of the officers after their field season and to give them vigour for the next, but the temperature is just that at which the work of the laboratory can be best carried on. Against this is only to be placed the greater distance from Colombo, in consequence of which it would obviously be useless to attach a museum to the offices of the Geological Survey. It would, however, be possible to have the museum in Colombo, where it might be attached to the existing Museum, the staff of cleaners and caretakers being placed under the Director of that institution, and the exhibited specimens periodically arranged and new ones added by an officer of the Geological Survey.

So far as the Survey itself is concerned, the disadvantages of this separation of the museum from its offices would be outweighed by the advantages of having the headquarters in Nuwara Eliya; for it is not the specimens exhibited to the public that will be most used by the Survey for reference, but the much more numerous, though less showy, specimens which are kept stored away in drawers. So far as the general public are concerned, the place where the headquarters of the Survey are situated is of little importance, as nearly all references made to it will be by letter; and so far as personal references are concerned, it is open to question

whether Kandy would be more convenient than Nuwara Eliya. I fancy that a larger proportion, of those who would wish to consult the Department personally, come to Nuwara Eliya than to Kandy, when they find it desirable to escape from the climate of the lowlands of Ceylon.

To sum up, the permanent headquarters of the Department should be established either at Nuwara Eliya or Kandy and not at Colombo; of these two I would recommend the former rather than the latter, if there are not good administrative reasons against it. If it is decided to form a local Museum of Mineralogy and Geology under the charge of the Geological Survey, this should be attached to, and in the same building as, the headquarters office and laboratory, if these are established at Kandy; but if they are established in Nuwara Eliya, then the museum should be in Colombo and in the same grounds as, if not built on to, the existing Museum.

SPECIAL LEGISLATION.

There remains but the question of special legislation to be considered. This, I understand, will not be necessary, but as the matter is one which should be referred to a legal expert I may indicate the powers which it will be necessary to give to the officers of the Geological Survey, if they are not provided for in existing Laws and Ordinances. They are, power to enter on private lands for the purpose of survey and examination, to clear paths where necessary through jungle, to enter and examine every part of any mine, to call for information regarding the extent and produce and inspect the plans and records—not the accounts—of any mine or quarry. If special legislation is required to confer these powers, it would be well to include in the Ordinance clauses covering the provisions of headings 1, 2, and 3 of the annexed draft abstract of Regulations for the Geological Survey, of which the clause relating to official secrecy is most important. The lines of the Act of Parliament establishing the Geological Survey of Great Britain might with advantage be followed, with such modifications as may be necessary to fit it to local conditions.

II.—ORGANIZATION.

• STAFF REQUIRED

For the working of such a Department a minimum of three officers would be required, who would have to be engaged in England; except for clerical and menial positions it will be impossible to employ either native or locally trained assistance at first, though when the Survey is established it may be possible to employ locally recruited assistants in subordinate positions, as collectors or for prospecting. If an agronomic survey is combined with the geological, four men would be required, but it is undesirable to go beyond this strength, both because a stronger establishment will be unnecessary and because it would be difficult to recruit even that number of competent men at once. At the same time it would be undesirable to contemplate the employment of a smaller number, as with less than three it would be impossible to maintain continuity of the work.

DIRECTOR.

Of the men engaged, one should be placed in charge of the administration of the Department, who should be responsible for its conduct, and through whom all orders from or communications to the Government should pass. On the choice of this man, who might be called the

Director, will depend largely the subsequent success of the survey. He will necessarily be a geologist of standing and acknowledged reputation, as without this it would be impossible for him to retain the respect or to command the obedience of his assistants, but it is equally important that he should not be a merely academic geologist. Besides his scientific attainments, he should be acquainted, and in sympathy with the economic applications of his science, and must, moreover, have some experience of, and known capacity for, administration. He must, in fact, be a man possessing business capacity; by which I do not mean that he must be acquainted with the art of buying and selling, but that he must be capable of organising the Department, of arranging the programme of work so that time will not be wasted, of prescribing a system of office routine at once adapted to the requirements of his Department and in conformity with the methods of the Ceylon Administration, and more especially of sufficient strength of character to enforce a strict adherence to the routine adopted, while at the same time of sufficient adaptability to readily adopt any modifications or improvements which prove desirable, without forgetting the paramount importance of continuity.

These qualifications, combined with the experience which will render them available and direct them in the right channels, are not to be looked for in a man whose experience has been purely academic or initial. They may be looked for in an officer of an established Geological Survey, though I would deprecate the employment of one who had acquired no experience outside the Geological Survey of Great Britain, as the methods of that Survey are not such as would lead to the development of the characteristics necessary for the conduct of a Geological Survey in Ceylon.

ASSISTANTS.

The appointment of the Director should be the first step taken, and his evidence should be considered, if not taken, in the selection of the other officers appointed. These will necessarily have to be appointed by selection, as there is no known method of competitive examination which will ensure the selection of suitable candidates. Besides their academic qualifications, of which their diplomas will be sufficient guarantee, they must be sound in body, hardy, of an active disposition, and, as they will have to carry on their work alone in the districts where they will be brought into personal contact with natives and residents, it is important that they should be gentlemen in habits and character. If three of these are appointed, one should be graded as a senior and the other two as junior assistants, whatever the actual titles selected may be, and it is desirable that the senior should have had some practical experience of administration and office routine, so that he may be able to take the place of the Director in case of casualty or absence.

MODE OF APPOINTMENT.

Candidates for these posts should be advertised for in the "Times," "Nature," and "Geological Magazine." The advertisements should state briefly the terms of service offered, and specify that candidates must be specially qualified in mineralogy, petrology, and inorganic chemistry, and in making the final selection from among the candidates one at least should be selected specially on account of his mineralogical and chemical attainments. The appointment of a man who has devoted his attention purely

to stratigraphical geology would be practically useless. Should the addition of an agronomic survey be decided on, the advertisement should state that one at least of the candidates must be qualified to undertake agronomic research, and in this case the advertisement should be inserted in two or three of the leading American Journals, as greater attention has been paid to the study of soils in that country than in England.

REMUNERATION.

As regards remuneration the salary offered to the Director should not be less than R12,000 to 15,000 per annum, and as he will necessarily be a man of some age, a certain number of years' service towards pension, depending on the age of the selected candidate, should be given to him. The senior assistant should have from R8,000 to 10,000 salary and the juniors from R5,000 to 7,000. In the first instance it may be desirable to appoint candidates to a salary above the minimum of their grade, and the succession to the post of Director, though it would ordinarily go in the Department, should not be exclusively restricted to it.

TERMS OF SERVICE.

At the commencement of the survey, and in my opinion in the case of subsequent appointments also, it would not be desirable to make permanent appointments and, as appointments on probation are but a delusive protection since, except in the case of most flagrant misbehaviour, it is practically impossible to discharge a man once appointed, I would recommend that appointments be made on a five-year agreement, at the end of which the officer would be allowed to go with a bonus of, say, five months' pay, or if both parties desired it should be re-engaged for permanent service, forfeiting the bonus, but counting his previous service towards leave and pension. I am convinced that terms such as these will prove more attractive than an offer of permanent service and lifelong expatriation; at the same time it is improbable that any candidate possessing the zeal and knowledge which would render him an useful officer will desire to take the bonus at the end of five years and terminate his service. On the other hand, the Government will be in a better position five years hence to know exactly what staff it will require and if necessary to reduce it, and will be able to get rid, without even the semblance of hardship, of members whose services are not satisfactory.

HORSE ALLOWANCE.

In addition to his salary each member of the Survey should be given an allowance for the keep of one horse at least. In most part of the Island it will be necessary for him to keep at least one horse, and in some it would doubtless be to the benefit of the public service for him to keep two.

TRAVELLING ALLOWANCE.

As regards travelling allowances the rules applied to the Survey Department might be adopted, the Director counting, like the Surveyor-General, as an inspecting officer, and the other members as Superintendents of Survey. The rule under which halting allowance is reduced after a three days' halt should however be cancelled as tending to bad work. In many cases, transport being permanently retained, halting is as expensive as marching, and the object of the rule can only be to prevent waste of time by unnecessarily long halts at places where there is no real reason for them. In the conduct of the

Geological Survey it will not infrequently be necessary to stay more than three days at a place to work it out thoroughly, and in such case a hard and fast rule would be a strong inducement to leave work unfinished. The rule might, however, be allowed to stand, provided that power be given to the Director to certify for the whole or a portion of the halting allowance where he is satisfied that the extended halt was in the interests of the public service and that, on account of the maintenance of permanent transport or other reason, the officer was put to such special expense as would justify the certificate. The limit of time beyond which such certificate is necessary, would with advantage be extended to seven days.

CONTROL OF EXPENDITURE.

In this connection I may urge that the control of the expenditure on travelling as also on contingencies should be vested solely in the Director of the Survey. The accounts will of course be submitted to the usual audit, but this should be confined to matters of account, and the Director having, by his countersignature to the bill, certified that it was for the benefit of the public service that the journey should be performed in the manner and by the route employed no question of time occupied or route followed should be raised by the Accounts Department. So, too, the Director should be the judge of whether contingent expenditure on coolies for jungle clearing or excavation, or other charges incurred by officers in the field, was necessary and incurred in the public service or not. An officer fit to be entrusted with the charge of the Survey may be trusted to attend to the interests of Government in these matters, and the power of control advocated will save him from much unnecessary correspondence of a petty and particularly irritating nature, and will prevent the waste of time which he could otherwise employ in a manner which would give scope to his special qualifications.

A Department a superior staff organised as suggested above would however be useless, if not properly equipped and provided with a subordinate and menial establishment. The equipment required consists of a laboratory, a library, and a suitable building for their accommodation and that of the officers, office staff and records of the Department.

LABORATORY.

For the laboratory with a floor space of some 1,200 square feet should be provided, if solely devoted to geological work, and about half as much again if agronomic work be added. This space would be divided into five rooms; the laboratory proper, or principal room, attached to which there should be a room for the assistant in charge of the laboratory, a balance room, a rough preparation and rock-slicing room, and a dark room for photographic work. The laboratory would have to be fitted with sinks, draught cupboard, workbenches, etc., and a Mansfield gas installation with a producer of (say) 500 cubic feet capacity should be provided for. It should be equipped with the necessary microscopes, balances, and other instruments and reagents, which would have to be procured from home, and a sufficient grant for its maintenance.

LIBRARY.

Besides a laboratory a working library would have to be provided and an annual grant provided for its maintenance as it would be of very small utility unless kept up to date.

ACCOMMODATION REQUIRED.

Sooner or later a special and properly designed building should be built for the accommodation of the Department, and, though at first it would doubtless be housed in a hired building adapted to the purpose, the sooner a special building is constructed the better. It is consequently desirable to indicate approximately the floor space necessary:—

Laboratory:	Square feet.	Square feet.
Principal room	750	
Assistant's room	250	
Balance room	200	
Rough preparation room ..	300	
Photo dark room	200	
		1,700
Library	—	700
Director's	—	400
Working rooms, preferably separate, say 3 at 300... ..	—	900
Clerical and record office ..	—	300
Godown.. ..	—	400
Total	—	4,400

This estimate allows for the permanent needs of the Department. In the early days, while in hired premises, less will be necessary, and a material reduction can be made if agronomic work is not combined with geological. If the headquarters are placed at Niwara Eliya, as I recommend, instead of Kandy, the floor space could be reduced by about one-third, and if it is decided to place them at Kandy and add a Museum, an additional 2,000 square ft. of floor space should be provided for.

CLERICAL AND MENIAL STAFF.

The clerical and menial staff required would not be large. A head clerk, who would also act as librarian would be required, he should be acquainted with official routine and, as with so small a superior staff, it may not be possible to arrange that one of them shall always be at headquarters, he should be fit to be trusted with the routine of the office, the drafting of routine letters, and the forwarding of such as require the personal attention of the Director. I understand that such a man could be got for a salary of from R1,000 to R1,500. An additional clerk on say R400, a bookbinder, office servants, and a couple of peons would complete the office establishment required.

For the laboratory it would be well to engage an assistant with some knowledge of chemistry, who would act as storekeeper and could be placed in charge of some of the simpler operations and analyses in the laboratory. I do not know whether it would be possible to obtain this assistant locally, but if not, one could be engaged in Madras or Calcutta. He should be paid about R600 to begin with, rising to not less than 2,000 as he becomes more proficient in the work. Two laboratory servants would be required for cleaning apparatus and preparing rock sections.

For the officers in the field a certain establishment of peons would be required. They might be provided for by an allowance paid to the officers but would preferably be entertained and paid for by the Survey. Four men permanently employed would, I think, be sufficient, the additional assistance required being entertained temporarily as, and to the extent, required.

IV.—COST.

I come now to the consideration of the cost, which may be considered under the heads of initial and recurrent expenditure. In the initial expendi-

ture may be included the cost of a suitable building, though this expenditure would probably be postponed. I have indicated the requirements; but leave the estimate of cost to those who are better qualified to give an opinion on this matter. The buildings should be substantial, airy, and well-lighted, with north or south lights, and in such a position that no light is reflected from any building into the principal working rooms, as this interferes with the proper use of the microscope.

LABORATORY.

Apart from the buildings the principal expense incurred will be on the fitting up and equipment of the laboratory. For the provision of proper sinks, draught cupboards, working tables, cases for reagents, and instruments, &c., a sum of about R2,000 will be required. If a Mansfield gas installation is added, which is so desirable as to be almost essential, a further sum of about R5,000 will be required, while the instruments (microscopes, balances, &c.) apparatus, and reagents may be estimated to cost from £300 to £400.

LIBRARY AND OFFICE.

In the office and library, bookcases will have to be provided, and as they should be well made and dust-tight a sum of R2,500 should be allowed for eight cases to commence with, further additions being made out of the grant for maintenance. A further sum of say R1,500 would be required for office furniture and fittings. The initial cost, "exclusive of the cost of building or of alterations to the building temporarily hired," would be approximately:—

III. EQUIPMENT.

Laboratory fittings	2,000
Gas Installation	5,000
Instruments, etc., £100	6,000
Library, say, £500	7,500
Bookcases and office furniture, etc.	4,000
	24,500

It is however improbable, in view of delays which will be inevitable in the inception of the survey, that all this will be spent during the first financial year. It should be treated as a lump sum, of which say R15,000 might be put on the estimates of the first year of the Survey, the unexpended balance being re-granted in the following year.

It must be understood that these estimates are necessarily only approximate, and it is not suggested that expenditure should be sanctioned on them and before the submission of detailed estimates, which will have to be prepared by the officer actually appointed to the direction of the Survey. The sums mentioned are liberal, and should provide for a well-equipped service, but are not excessive. I do not think that without unduly cramping the Survey they can be materially reduced.

ANNUAL COST.

The annual cost of a Department organized as described, would be, for salaries and wages, approximately as follows:—

	Minimum. R	Maximum. R
1 Director	12,000	15,000
1 Senior Assistant..	8,000	10,000
2 Junior Assistants..	10,000	14,000
1 Head Clerk	1,000	1,500
1 Assistant Clerk	400	500
Bookbinder at R30, Label Writer at R30, 2 Peons at R15 each, per month	1,080	1,080

	Minimum. R	Maximum. R
Servants, say R25 per month	300	300
1 Laboratory Assistant	600	2,000
2 Laboratory servants at R15	360	360
4 Permanent Peons at R15	720	720
	34,460	45,460

Beside this there would be required for contingencies and allowances approximately—

	R	R
Library	1,500	
Laboratory	1,500	
Office contingencies	2,000	
	5,000	
Horse allowance	1,440	
Travelling allowance, say	8,000	
Field contingencies	4,000	
	13,440	
	18,440	

Of these, the allowance for maintenance of library and laboratory would be fully required for some years, after which they might doubtless be reduced. The sum allowed for "field contingencies" is supposed to cover the cost of additional peons, of guides, jungle clearers where necessary, of carriage and purchase of specimens, and other kindred expenses contingent on the carrying out of Survey in the field. It is necessarily a guess, as the actual amount of expenses so incurred can only be learnt by experience. I have put it at a liberal figure, which is not likely to be materially exceeded, but the actual expenses incurred may well vary considerably from the sum stated in one way or the other.

From this it will be seen that a fully-equipped Department on the lines laid down could be provided for at a cost which may be put down, in round figures, at R60,000 per annum. For this a complete and careful Survey of the whole of the island should be made in fifteen years at the outside, after which expenses might be reduced by maintaining only a revising staff, the headquarters office as a bureau of information, and the laboratory for the determination and analysis of specimens. A staff of two superior officers would be sufficient for this, while there would be a considerable reduction of the charges for travelling and field contingencies. The subordinate staff would have to be maintained, if not increased and the permanent expenditure on the reduced scale would be about R30,000 per annum.

ALTERNATIVE PROPOSAL OF LIMITED SCOPE.

I have sketched out a scheme and given an estimate of cost of a Survey which would be of permanent value to the Colony. If the cost should be considered too great, I have no doubt some benefit would be attained by the employment of a competent geologist at a salary of say £800 (R12,000) a year. He would have to be provided with a laboratory and library at a cost of not less than R6,000, and for the purchase of books and instruments, of travelling allowance, and for contingencies at least R5,000 would be required, making with his salary R17,000 per annum, exclusive of the rent of the building, which would have to be provided for the accommodation of the laboratory and working rooms at his permanent headquarters.

I do not consider it desirable to attempt anything on a scale intermediate between this and the fully-equipped Geological and Agronomical

Department, for which a scheme has been sketched out, and the advantages of the fully equipped Department are so much the greater that they more than justify the additional cost.

30th August, 1889.

R. D. OLDHAM.

DRAFT ABSTRACT OF REGULATIONS
FOR THE CONDUCT OF THE GEOLOGICAL SURVEY
OF CEYLON.

[This draft is not intended to be issued verbally as it stands, but to indicate the scope of a Code of Regulations which should be drawn up and issued. They will require to be completed in accordance with the routine of work and record finally adopted, and will require, in addition to the subjects referred to in this draft, a definition of the procedure to be adopted in entering on private lands. They need not be embodied in legislation nor be issued as orders of Government; it will be sufficient for them to be issued on the authority and as the orders of the Director. If special legislation is necessary to establish the Survey and give powers to enter on private lands for the purpose of examination, the subjects dealt with 1, 2 and 3, might be embodied in such legislation.]

The whole time of officers of the Geological Survey being retained for Government work, they should be prohibited from taking up other employment, from examining and reporting on lands or mines for private persons, and from giving any opinion or report, verbal or written, to private persons or commercial companies, except through and by the express permission of the Director of the Survey.

All information gained in the course of examination of any mine must be treated as strictly confidential; it should be communicated directly to the Director and put on record when of sufficient importance, but must not be divulged to other persons nor published without the permission of the owners of the mine.

All observations and collections made in the course of the survey should be treated as the property of Government and handed in to the

Director. No publication of results or observations made in the course of the survey nor the retention of field note-books or specimens should be permitted without sanction.

Officers should keep a diary, an abstract of which should be submitted monthly on a form prescribed for the purpose. At the end of each field season a full report of the work done should be drawn up. Where possible this should be in the form of a final report for publication or submission to Government, but where, owing to the work being unfinished, this is impossible, a full progress report should be prepared and submitted, for record and incorporation in the final report. On account of the risks of interruption, owing to sickness, casualties, or the exigencies of the public service, which may necessitate an officer being temporarily or permanently diverted from the particular task on which he is engaged, every member of the Survey should strive to leave the work done by him on record in such form as shall allow of its being taken up by another person with the least possible waste of time.

Specimens of rocks met with in the course of the survey should be freely collected. So far as possible rock specimens should be trimmed to a rectangular shape, about 5 in. by 4 in. and as thin as possible, and with each specimen there should be one or more chips from which microscope slides can be prepared without injuring the principal specimen. At the end of each field season the rock specimens collected should be opened out; and, after rejection of those specimens which it is not necessary to preserve, should be numbered, entered in the register, and stored away for future reference.

Officers of the Geological Survey should be made directly responsible to the Director, and should not correspond with other Departments or officers of Government, or private individuals or firms, on matters connected with the work of the Survey, unless and only so far as they are put in communication with such Departments, officers, or other persons by the Director.

R. D. OLDHAM.

LITERARY REGISTER SUPPLEMENT:

AND CEYLON

"NOTES AND QUERIES."

[Under this heading, in future, we mean to give a four or eight page "Supplement" with our *Tropical Agriculturist*, from quarter to quarter, according as there is matter of sufficient value, so to be preserved.]

APRIL, 1900.

ROYAL ASIATIC SOCIETY: CEYLON BRANCH.

ANNUAL GENERAL MEETING.

The annual general meeting of the Ceylon Branch, Royal Asiatic Society, was held in the Museum, Cinnamon Gardens, on Feb. 13. The Bishop of Colombo presided, the others present being the Rev. F H de Winton and Messrs. Philip Freudenberg, J Ferguson, Milligan (New Zealand), Miss Ferguson, P Morgappah and J Harvard and G A Joseph (Hon. Secretaries.)

THE REPORT.

Mr. HARWARD read the minutes of the last general meeting held on the 29th July, 1899, which were confirmed. The Report was taken as read, save a portion in manuscript from Mr. Bell on his archæological work, which was read Mr. Harward:—

ANNUAL REPORT FOR 1899.

The Council of the Ceylon Branch of the Royal Asiatic Society have the honour to submit the following Report for the year 1899:—

MEETINGS.—Three general meetings of the Society were held during the year, of which the following papers were read and discussed, viz:—

- (1) "Correspondence relating to the Antiquarian Discovery under the site of the old Breakwater Office, Colombo," by Mr. G. A. Joseph.
- (2) "A Letter from the King of Portugal to Raja Sinha II., 1652," by Mr. D. W. Ferguson.
- (3) "Expedition in 1765 against the Prince of Kandy, Lubbert Jan Baron van Eck, Governor of Ceylon (1763-65)," by Mr. A. E. Buntjeus, B.A. Cantab.
- (4) "The Portuguese Inscribed Mural Stone in the Maha Saman Dewale at Ratnapura," by Mr. D. W. Ferguson.
- (5) "Alagiayanna Mohottala, the Author of Kusajataka Kavyaya," by Mr. D. W. Ferguson.

Interesting discussions followed the reading of the papers (1) and (3).

The following papers, which were not read at a meeting, have been printed, and will form part of the Journal for 1899, viz:—

- (a) "Christianity in Ceylon in 1630," by Mr. D. W. Ferguson.
- (b) "Contribution to Ceylon Malacology: (3) The Terrestrial Mollusca of Ambaganuwa (Part II.)," by Mr. O. Collett, F.R.M.S.
- (c) "João Rodriguez de Sa e Menezes," by Mr. D. W. Ferguson.
- (d) "Polyandry in Ceylon," by Mr. R. W. Levers, C.C.S.

The original manuscript of the capitulation of Trincomalee, 1795 (presented by Mr. G. A. Joseph to the Colombo Museum Library), has been lithographed and will appear in the journal for 1899.

MEMBERS.—During the past year six new members were elected, viz:—Messrs. K S Bath, B.A.; R H Ferguson, B.A. (Life Member); H T Gardiner, F.R.H.S.; D B Jayatilaka, B.A.; A G Tambi-Nayagam Pillai, Pleader-at-Criminal-Law, &c.; P E Pieris, C.C.S.

Five members resigned, viz:—Dr. P S Brito, Messrs. F Macindoe, Alfred A Clark, W C Macready. Two other members, Mr. H Wace (resident), Sir John J Grinlinton (non-resident), qualified as Life Members.

The Society now has on its roll 191 members, including 20 Life members and 10 Honorary members.

The Council record with regret the death of Mr. G C Trask and the Hon. Mr. L F Lee, C.C.S. Mr. Lee was for many years a member of the Society. He contributed to the Society's journal the following papers:—

- (1) "A Prose Translation of the Introductory Stanzas of the *Kusajataka*,"
- (2) "Notes on Sannas."
- (3) "The Romanized Text of the First Five Chapters of the *Balavatara*." (Journal No. 16, Vol. V., 1870).

LIBRARY.—The additions to the Library during the year numbered 329 volumes. The acquisitions are chiefly exchanges from Societies. The Library is indebted for donations to the following:—The Trustees of the Indian Museum; the Government of Bengal; the Government of India; the Government of Mysore; the Government of Madras; Cape of Good Hope Geological Commission; Australian Association for the Advancement of Science; Australian Anthropological Society; the Director of Public Instruction of Ceylon; H Sastri; J Harward, M.A.; T B P Kehelpennalla; H

C P Bell, c.c.s.; P Arunachalam, c.c.s.; O Collett; W H Furness, M.D.; and the Colombo Museum Library.

Besides those already on the exchange list, Council have decided to exchange with the Director, Mission Archeologique d'Indo-China, Saigon.

The Council still constantly receives applications from Societies and Institutions for exchanges of our Journal. The Council regrets having had to refuse some exchanges during the year owing to the large number of Societies already on the exchange list.

The Council regrets that the amount inserted in the draft estimates for 1900 for the Museum extension was not passed. Confident hope was entertained that the Museum extension would have been started in 1900, and that the congested state of the Library of the Society would shortly have been relieved.

The affording of relief for the overcrowded collections of books has been a crying want for a lengthy period. The Council have repeatedly in their reports and letters called the attention of Government to the difficulty of finding room for current accessions and for the books already in the Library. The Library of the Society and that of the Museum have outgrown the space available in the existing rooms, and it is necessary that there should be more accommodation for both. The Libraries need rooms large enough to allow for expansion, and at the same time to permit of a rational classification of the books on the shelves. Temporary measures have been adopted for some years to enable the Society to house the books in the room allowed to the Society. But the only real remedy for the present overflowing state of the Library is an extension of the building.

JOURNALS.—Vol. XV., No. 49, 1898, was issued during the year. It contains, in addition to the Proceedings of the Council and General Meetings, the following Papers:—

- (i.) "Contributions to Ceylon Malacology: (2) Description of a new Helicoid Land Shell from the Southern Province," by Mr. O Collett, F.R.M.S.
 - (ii.) "Aids to the Identification of Ceylon Birds: Part I.—Introduction and Key to the *Passeres*," by Mr. A Haly.
 - (iii.) "A Pertinent Account and Detailed Description of the Character, Nature, Coitus, and Production of Elephants in the Great Island of Ceylon," translated from the Dutch by F H de Vos.
 - (iv.) "Don Jeronimo de Azevedo, Governor of Ceylon from 1594 to 1611 A.D.," by Mr. A E Bultjens, B.A. Cantab.
 - (v.) "Monumental Remains of the Dutch East India Company of Ceylon," by Mr. F H de Vos.
- The printing of the Journal for 1899, No. 50, is in hand and will be issued to Members shortly.

ARCHAEOLOGY.—The Council regret that in 1899 the Archæological Commissioner was not able to furnish any report on his operations at Sigiriya, which have formed so interesting a feature in the recent numbers of the Journal. A concluding report on this subject will probably be submitted to a General Meeting early in the present year. The Archæological Commissioner has favoured the Council with the following synopsis of work done by the Archæological Survey during 1899:—

REORGANISATION OF THE ARCHÆOLOGICAL SURVEY.

As the result of the recommendations of the Commission appointed by H.E. the Governor to report on the more efficient prosecution of the Survey, the Archæological Commissioner's hands were strengthened from January 1899, by the:—

- (a) increase of the vote for Archæological purposes to R40,000.
- (b) appointment of a Labour Assistant to the Archæological Commissioner.
- (c) attaching to the Department two native Epigraphists (Messrs. D M de Zwickramasinghe and B Gunasekara, Mudaliyar.)

With this aid, proportionate progress has been made. For the first time excavations have been carried on simultaneously at two centres (Anuradhapura and Sigiriya); whilst preliminary work has been started in connection with the systematic and scientific publication of ancient inscription of the island (*Epigraphia Zeylanica*).

EXCAVATIONS, &c.

ANURADHAPURA.—At Anuradhapura half the labour force was continuously employed under Mr. Dashwood, Labour Assistant. Most of the year was spent in pushing excavations southwards from Thuparama Dagoba towards Ruwanveli Dagoba. In this long stretch of picturesque park little of the ancient ruins remains untampered with, ill-considered later day reconstruction from older buildings has transformed the site generally into a irregular congeries of insignificant and uninteresting monk's dwellings, with attendant out-houses innumerable. Amidst the mediocre medley of ruins, one or two stand out markedly e.g. the beautiful pair of shrines, miscalled "Pavilions," square columned with spreading dwarf-band capitals.

In the dry weather work was temporarily resumed at "*Elala Sohona*." Here the summit of the flat-topped mound has been thoroughly dug revealing walls, cross walls, tee of the superstructure of a dagoba, traditionally fixed as the tomb of the Tamil King, Elāla.

Towards the close of the year the whole force of coolies was concentrated at *Buliyankulam*, 2½ miles from the town with the object of finally completing the excavation of this extensive Buddhist monastery; between 30 and 40 pirivenas and lying regularly round and outside the main temenos, containing the dagoba and three Viharas, have been laid bare; and at the magnificent pilimagé the re-setting of the fallen slabs of the stylobate revetment was nearly completed.

SIGIRIYA.—The A C spent a final season at Sigiriya in rounding off the field-work of the Archæological Survey at *Sigiri-nuwara*. The excavation of the summit and terraces at the base of the Rock was finished in 1898. The past year was devoted to the digging out of the numerous caves beneath boulders dotted below the rock to the west besides sporadic excavations at other promising sites (e.g. three or four moated islands) within the *vil bemma*, or outermost ramp of the ancient city. In restoration steady progress was made in the heavy task of re-building on the old lines the southern approach to the gallery, as well as the wrecked portion of the gallery itself at the north end. The laying of a concrete bed for the foundations of the wall involved constant risk to life and great labour, but was safely accomplished by the end of the season. The preservation of the frescoes, as far as practicable, was commenced.

POLONNARUWA.—The lines for the occupation of the A. S. force are under construction at Topavewa. In 1900, after two months given to the necessary annual clearing of the ruins at Sigiriya, the A. C. will move on to Polonnaruwa, and break ground at that ancient capital.

AWARD OF A GOLD MEDAL AS AN ENCOURAGEMENT TO ORIENTAL LEARNING.—In 1897 the Council of the Royal Asiatic Society established a Gold Medal to be awarded every third year as an encouragement to Oriental learning amongst English-speaking people. To meet the expenses incurred in preparing a design, engraving dies, and finding an amount to produce an income sufficient to defray the requisite charges, a

sum of about £400 will be necessary. Subscriptions, with interest, of £300 have already been received, and a balance of about £100 is therefore still needed. Donations should be sent to the Chairman of the Medal Committee, Royal Asiatic Society, 22, Albermarle street, London.

INTERNATIONAL CATALOGUE OF SCIENTIFIC LITERATURE.—The Royal Society have undertaken to prepare and conduct a catalogue of all scientific literature published throughout the world. In pursuance of the scheme the Asiatic Society of Bengal has, at the request of the Royal Society, undertaken the formation and conduct of a Regional Bureau for India and Ceylon. This Society has been invited to co-operate in the work, and the Council take this opportunity of directing the attention of the authors of Scientific Papers to the Circular on this subject, which is published as an appendix to this report. The slips there applied for may be forwarded to the Honorary Secretary of this Society.

COUNCIL.—F M Mackwood was elected a Vice-President in place of Mr. Stanforth Green. The Council regret Mr. Green's departure from the Island. He was connected for many years with the Society, being a Member from 1866, and afterwards a Member of Council and Vice-President. Mr. Green always took an active interest in the Society's affairs, and his scientific attainments and general knowledge made him a most valuable Member of the Council. Two Members of the Council of 1898, viz., Messrs. O Collett, F.R.M.S., and P Ramanathan, C.M.G., having been, by virtue of Rule 16, deemed to have retired by least attendance, the vacancies caused by their retirement were filled by the appointment of Messrs. J P Lewis and H White.

FINANCES.—The total income for the year, exclusive of the balance in hand of R1,418'14, was R2,024'17, and the expenditure amounted to R1,839'29, the sum in hand at the close of the year being R1,603'02. Considerable difficulty is still experienced in getting in outstanding subscriptions.

ADOPTION OF THE REPORT.

The CHAIRMAN observed that the next business was the adoption of the Report.

Mr. J FERGUSON said that he had pleasure in proposing that the Report be adopted.

Mr. FREUDENBERG seconded.—Carried.

His Lordship the BISHOP then vacated the chair and on the proposition of Mr. Harward, the Rev. F H de Winton was elected Chairman *pro tem*.

ELECTION OF OFFICE-BEARERS.

The Rev. F H DE WINTON proposed the election of the following office-bearers for the ensuing year, observing that as at present there was no name available as Treasurer, the election of that officer be deferred.

President:—The Bishop of Colombo.

Vice-Presidents:—The Hon. Mr. Justice Lawrie, Mr. F M Mackwood.

Council:—Messrs. C M Fernando, A Halv, P Freudenberg, J Ferguson, P Coomaraswamy, F H Modder, Dr. W G VanDort, Messrs. W P Ranasinhe, H White, S M Burrows, E E Green, and E Booth.

Hony. Treasurer (vacant).

Hony. Secretaries:—Messrs. H C P Bell, J Harward, and Gerard A Joseph.

Mr. P MORGAPPAN seconded.—Carried.

The BISHOP then resumed the chair. In doing so he said he had much pleasure in returning thanks on behalf of himself and of the office-bearers for the expression of confidence reposed in them. The business before them was of a formal character, and he would not, therefore, trouble them with any remarks, beyond saying that he could assure them that the office-bearers would do their best towards one another and for the members of the Society. (Laughter and Applause).

Mr. FREUDENBERG proposed a vote of thanks to His Lordship for presiding.—Carried by acclamation.

His LORDSHIP said he returned thanks on behalf of himself and the Rev. F H de Winton, who had taken an important part in that laborious function. (Laughter).

BUDDHIST RELICS.

(From the Ceylon Secretariat.)

The following communication has been received from the Secretary to the Government of India with regard to the distribution by His Majesty the King of Siam of certain Buddhist Relics discovered in India to Buddhist Deputations from Burma and Ceylon:—

From J. P. Hewett, Esq., C.S.L., C.I.E., Secretary to the Government of India.

To the Hon. the Colonial Secretary, Ceylon, Colombo.

Calcutta, the 24th Feb., 1900.

Sir,—Adverting to the correspondence ending with the telegram from this Office, No. 2967, dated the 20th December 1899, upon the subject of the distribution of the sacred Buddhist relics by His Majesty the King of Siam, I am directed to forward, for the information of His Excellency the Governor, a copy of a communication from Her Britannic Majesty's Minister Resident and Consul-General in Siam dated Bangkok, the 16th January, 1900, and enclosure, showing that the relics were distributed to the deputations sent from Burma and Ceylon on the 9th Idem. A copy of the acknowledgment of the appreciation of the Government of India in reply is also enclosed. I have, &c., (Signed) J. P. HEWETT, Secretary to the Government of India.

Dated, the 16th January, 1900.

From C E W Stringer, Esq., Her Britannic Majesty's Charged d'Affaires and Acting Consul-General, Bangkok.

To the Secretary of the Government of India, Home Department.

With reference to your telegram of the 20th ultimo, stating that the deputations to receive the Buddhist relics from the King of Siam had left Colombo and Rangoon, I have the honour to forward herewith, for the information of the Government of India, copy of a letter from the Siamese Foreign Minister stating that the relics were handed over on the 9th instant, and expressing a hope that what the King has done in the matter of their distribution will meet with the approval of the Indian Government. The deputations are now leaving Bangkok on their return journey.

Dated the 14th January, 1900.

From Devwongse, Siamese Minister for Foreign Affairs, Bangkok.

To C E W Stringer, Esq., Her Britannic Majesty's Charged Affairs and Acting Consul-General.

With reference to my note of October in regard to the distribution of the Buddhist relics to the deputations from Burma and Ceylon, I have by His Majesty's command, the honour to state for the information of the Government of India, that the ceremony of delivering over the relics has taken place on the 9th instant, and that the object of His Majesty in the distribution was that as the Buddhist relics are the most sacred to, and most sought after by, all Buddhist public, His Majesty therefore desires that some portion of them should be kept at some important city or towns frequented by Buddhist pilgrims so that all of them may have equal benefits of worshipping it. Besides His Majesty thinks that the apportioning to any individual sect or community would create disaffection, because by doing so it would be making only certain sect or community of the owner of the relics.

2. For this reason, therefore, His Majesty has assigned one portion to Mandalay and another to Rangoon in Upper and Lower Burma respectively.

As to the three towns in Ceylon to which His Majesty has assigned one portion to each are:—

1. Anuradhapura, the ancient capital, which contains an important Pagoda.

2. Kandy, the present capital possessing the sacred tooth.

3. Colombo, on account of its being a large town of the present day.

3. Among the members of the deputations who have come to receive the relics, Burma has sent one to receive the two portions, one for Rangoon and one for Mandalay according to arrangements, but those sent by Ceylon representing various communities far more exceed the three portions which His Majesty has assigned to that Island, viz., Anuradhapura sent one, Kandy sent two and Colombo sent three. As there was only one deputation from Anuradhapura, therefore there was no difficulty with regard to that town, but there were two from Kandy, one of Malwatta and another of Asgiriya-wihares, each desired that the portion of the relics allotted to that town should be handed over to them.

Without recognizing into whose care it should be entrusted it was therefore, by His Majesty's command, handed over to both of them conjointly to be determined by common agreement as to the place in which it should be kept. But in case of disagreement and should they seek His Majesty's advice, the decision would be in favour of the Malwatta, for the reason of its possessing the sacred tooth.

4. Again there were three different sects from Colombo, one of Upaliwongse or Siamese sect, one of Maramawongse or Burmese sect, and one of Ramanawongse or Pegan sect, and each likewise desired to receive the relics, but His Majesty commanded that the one portion allotted to that town be formally handed over to the three sects in the same manner as the one for Kandy with the condition of mutual agreement as to the place of deposit. But if such agreement cannot be arrived at and should they likewise seek advice, His Majesty would give his decision for the one that possesses the largest temple in Colombo viz: the Syama Nikaya or the Siamese sect.

But in both cases His Majesty expresses the hope of, however, seeing the matter settled amicably between the different sects themselves.

5. Such as the handing over of the sacred relics is so far accomplished, His Majesty trusts that the Indian Government will consider the task of the King, my August Master, as ended and that it will meet with their approbation.

6. I avail myself of this occasion to express to you, Monsieur le Charge d'Affaires, the assurance of my high consideration.

From J P Hewett, Esq., c.s.i., c.i.e., Secretary to the Government of India.

To Her Britannic Majesty's Minister Resident and Consul-General in Siam, Bangkok.

Calcutta, February 24th, 1900.

SIR,—I am directed to acknowledge the receipt of your letter dated the 16th January, 1900, with which you forward a letter dated the 14th idem from the Siamese Minister for Foreign Affairs, stating that the Buddhist relics were handed over on the 9th idem to the deputations sent from Burma and Ceylon to receive them.

2. I am to say that the Government of India have learnt with much satisfaction that the sacred relics have been distributed by His Majesty the King of Siam in the manner stated in Prince Devawongse's letter. I am to request that it may be made known to His Majesty that the Government of India approve of the manner in which distribution was made and are obliged to His Majesty for the care and trouble undertaken in effecting it.—I have, &c.,

(Signed) J. P. HEWETT,

Secretary to the Government of India.

THE "TIMES" ENCYCLOPÆDIA; BRITANNICA IN CEYLON AND INDIA.

The mission of Mr. K W Johnson, the Agent for the sale in India and Ceylon of the now celebrated reprint of the "Encyclopædia Britannica," is practically ended and he left by the ss. "Rewa" on March 24th, for Madras and Calcutta. It is interesting to note that he has been the means of introducing to the island of Ceylon very many copies of a work in twenty volumes, which is aptly described as the most complete and perfect work of reference in the world. Previous to Mr. Johnson's visit there were only a very few sets (perhaps two) of the work (purchased at the original price, £37) in Ceylon and amongst these was the one included in the *Observer* library.

During the last year over 2,000 sets have been sold in India, and of these nearly one-half were taken by native residents, distributed over a very wide area and including several libraries and colleges, where they will be accessible to students and others.

The offer of the London *Times* was extended to residents in Ceylon on Feb. 3rd last and closed on March 15th. The number of the last order registered in the Colombo office is 168. Of these about 15 per cent are Sinhalese, about 10 per cent Burghers, and the remainder are Europeans. A few of the more prominent names are appended:—

Planters' Association of Ceylon.

Colombo Club.

Chamber of Commerce, Colombo.

Hill Club, Nuwara Eliya.

Post and Telegraph Library.

The Hon. W. T. Taylor.

The Hon. J N Campbell.

Mr. Chas. B Brodie.

Messrs. H. Don Carolis & Son.

Mr. H S Perera.

The Rev. W F P Waltham.

The Rev. Fr. D E Requis, o.s.B.

Mr. E W Glanville.

Mr. S F Tokmakoff.

Mr. J. Schrader.

Although the first offer to residents in Ceylon has been withdrawn it is still possible to obtain the work, at slightly increased prices, upon application to the head office of *The Times* Reprint of the Encyclopædia Britannica at 5a, Dalhousie Square, Calcutta.

FUEL FOR TEA MANUFACTURE, &c.

PRACTICAL INFORMATION FROM PRACTICAL MEN.

THERE has been a good deal of discussion of late in reference to the cost of oil, or rather of the working of oil engines, and some exceedingly satisfactory results have been reported respecting more than one well-known engine, while a new favourite is now coming to the front. But our purpose is not to discuss oil engines, but "fuel" at this time; for, some months ago, before we had heard much about oil, we issued—at the instance of a planting friend—the following "Circular" with questions to be answered:—

FUEL FOR TEA MANUFACTURE.

Questions.

1. Which fuel do you consider to be best for Tea Manufacture:—Wood, Coal or Coke?
2. What is the relative cost, and is it capable of being reduced?
3. With regard to Wood fuel, is the supply equal to the demand?
4. Is the supply dependent on Government, or is it in private hands?
5. Is the planting up of Fuel trees receiving attention?
6. Do you consider that it would be any economy to have Fuel plantations?
7. If so what kind or kinds would you recommend?
8. Apart from Fuel, would you plant Timber trees, *i.e.*, for Building and Tea Chests?

In response we got some fifty replies from responsible Managers in different districts of the country, and these we will now proceed to lay before our readers, according to the several divisions from which they are dated. But before doing so, we have two more elaborate replies to our enquiries, which deserve precedence. One is from a well-known Visiting Agent of wide experience and runs as follows:—

"I have not had very much experience of coal in connection with tea factories, but even on estates close to the railway, with cheap freights and other transport facilities, wood fuel will require to be *very* scarce and expensive before coal can with advantage

be substituted. The latter must always be costly, and if one had to pay as much as R2 per yard for *good* wood fuel, it would probably pay better to do this than to get up coal from Colombo. The *best* fuel is that which is obtained from well-grown forest. Grevilleas, even when fully matured, burn quickly, and it is, therefore, better to use them in conjunction with forest fuel if it can be so arranged. Gums burn well, and grow again freely after being coppiced; but the odour they emit is considered an objection by some.

"Speaking in a *general* way, the supply of fuel in private hands is, I should say, sufficient for present needs, and should continue so for many years to come if the planting of trees is kept up as it should be. Personally I know of very few estates which get their supplies regularly from the Government depôts.

"To shew what can be accomplished on a carefully-managed concern, I may mention that on an estate of about 280 acres in one of the young districts, where there is absolutely *no fuel whatever* beyond what is provided by gums and grevilleas, &c., growing in the ravines and amongst the tea, the Superintendent manages to keep his factory going, there being two driers to feed besides an engine. This estate, which is situated at an elevation of about 4,000 feet, gives an average of 600 lb. of made tea per acre, shewing that well-regulated shade need not necessarily affect the productiveness of the bushes, and there is, moreover, nothing much to complain of in the quality of the teas. Besides the coppices most of which survive, there is always a succession of young trees coming on, so there really is no reason why the supply of fuel should fail.

"Where there is a reserve of forest, planters will find it better, instead of felling trees indiscriminately, to make a clean sweep of a few acres at a time, stack the firewood, and replant the land with useful trees.

"Perhaps I cannot see far enough ahead, but I am no believer in planting trees for tea-boxes. I think we may safely look to the outside world to supply us with all we want under this head.—X.Y.Z."

The useful information and practical hints here imparted will, we feel sure, be valued by many proprietors and superintendents.

The next communication has been kindly sent us by a gentleman connected with the Forest Department to whom we sent a Circular and who responded as follows:—

"I will take your own headings in accordance with the numbers:—

1. This would depend on the drying machinery. For example, if you used Davidson's, Jackson's or Brown's, the fuel would vary. For the two first, small branch wood will get up a sufficient heat, while the latter is all the better for larger timber. Coal is, I think, likely to develop too great a heat, and is not necessary for the purpose. I would certainly advocate coke or wood.

2. I have not sufficient data to go on; as the price of imported fuel would be certain to fluctuate, and in a measure be affected by the state of exchange. The price of firewood is directly proportional—in the case of estates—to the length of transport and its means. The difference in the quality, or hardness of the wood does not, to any great extent, affect its cost of cutting, but it acts directly on its cost of removal. I would not lay down a hard and fast line therefore, and say the price per lb. of firewood should be so much, when, perhaps, certain local circumstances would completely alter the factors of calculation.

3. This is very difficult to answer. In districts where the white ant does not eat up the wood as fast as it is felled, a smaller quantity will last longer, but in lowcountry districts, especially where the rainfall is high, I feel sure many estates will be very seriously inconvenienced, if they are not in difficulties already.

4. For lowcountry places, both Government and private owners could help the planter. The former could supply most, but transport is the great difficulty.

5. In my humble opinion, I should say not sufficiently, generally speaking. The planter must not forget that it is not only his factory that wants firewood, but his coolies do too, to cook their food, and this should be provided for.

6. Yes, I certainly do, but if the plantation is to be on land that is too wretched and had to produce tea, it is not good enough for fuel, and it would be very false economy to plant such places with anything but grass.

7. This depends on altitude, soil, aspect and rainfall, and, if the land to be planted is fresh or worn out. I can lay down no very general rule with such combinations as the above conditions would bring about. I would advocate for low places, *Casuarina* "Wa" (*Cassia Siamea*) "Madatiya" (*Adervanthera pavonina*), "Gedumba" (*Trema orientalis*) and a few rubiaceous plants, such as "Rawana Idella" and "Unkunda," all of which are good fuel. Above 3,000 feet I don't think one can do better than to plant gums and grevillea, but they should be worked in a proper system, and upon a rotation that would be greatly indicated by the growth of the tree itself.

8. It will always be worthwhile for lowcountry places to plant jakwood for building wood, but I do not think it will pay to grow tea-box woods for individual estates. If the wood is very soft it is liable destruction by wind; if hard, the proprietor won't wait long enough, so long as a quicker substitute can be found.

At a time when planters are anxious to know how they can supplement tea, or economise in their outlay, the hints thus given should be welcome. It may be considered very slow work to plant jak trees in lowcountry reserves, not suited for rubber or coconuts—but it should be remembered that if selling at any time, the full value of the jak clearing would be taken into account.

Here then is the comparatively full response from a planter in North-East Matale:—

1.—No experience of coal or coke in tea manufacture. 2.—Don't know. 3.—Yes, here, from forest

reserve; grevillea fields and grevilleas planted throughout the tea. 4 and 5—Depends on the estate proprietor. The Manager can easily keep up the supply by the judicious planting of grevilleas throughout the estate. So far as I know this is being done pretty well all over the Matale district. 6—Yes, if not too far from the estate, or favourably situated for the fuel being transported by wireshoot. 7—For this district *Grevillea*, Pehimbiya, Dawata, Rose-apple. These all do well, planted amongst the tea, without doing damage to the tea, unless when planted too close. 8—Timber for building purposes take so many years to get to maturity that it would be hardly worth my while to spend money on growing such trees. For boxes the ucy Acme chests will, I trust, in time take the place of the wooden chests.

While on the subject of tree planting, I certainly advocate the planting of fruit trees of all kinds. If more of this had been done by the pioneer planters, most, instead of the few, of the old estate Superintendents would have had a plentiful supply of fruit for their own use and to spare for their Colombo and other friends who were less fortunate. Even the present generation of planters, I believe, are doing more in that way than our pioneers did. Yet more might be done, and if every planter, *P.D.* and *S.D.* were to do a little, a few years hence Ceylon might become as famous for its fruit as it is for its tea. I think more might be done for Ceylon residents by the Government Gardens, by advertising in the local papers monthly the fruit tree plants and seeds they have for sale, and stating the elevation or districts the various plants are known to do well. I know that plums, which are grown in Haputale without any trouble, grow, but do not yield any crop here, Pear trees the same, Peaches, I have not seen a ripe one in Matale. I have no doubt that the Government Gardens could supply fruit trees suitable to the planting districts were they to act on the suggestion. The railway ought to carry all plants from the Government Gardens free to encourage fruit culture.

This was written before Mr. Macmillan's useful "Circular" on fruit trees suitable for the lowcountry appeared. It should now be supplemented by similar advice regarding the country from Peradeniya upwards. Two other Matale residents favour us with their opinions, and first we have a well-known proprietary Visiting Agent who goes into figures to some purpose:—

1 Wood for driers—oil where an engine is necessary and where ample water power is not available.

2 The cost of wood fuel for driers is about '35 per lb. of tea and oil about '55 per lb. Where water is not available there is little or no scope for reduction.

3 Quite equal to the demand from trees planted from 10 to 13 years ago in many instances.

4 In private hands entirely.

5 All estates in this neighbourhood have planted largely, with the result that there will never likely be a fuel difficulty.

6 The planting of fuel trees on most old estates where there is no reserve jungle is necessary and economical.

7 *Grevillea*, *Cedrella Toona* and *Albizia stipulata* amongst the tea and thornless dadap, not for fuel but for light shade and to aid in improving poor patches of tea.

8 No, though in due course *Grevilleas* and *Cedrella Toonas* grown amongst the tea will supply all that is necessary for estates in the way of ordinary rafters, reapers, &c., for lines.

Next a resident Manager on a well-known Matale property tells us:—

1 I have only had experience of wood.

2 I have no experience.

3 I think so at present. Oil engines appear to coming more into favour.

4 Private hands.

5 Not much I think at present, although a good deal has been planted in the past.

6 I do. Firewood will be wanted in future, but trees for timber purposes and fuel should be combined.

7 Trees suitable for fuel as well as building purposes, such as Satin, Jak as well as Grevilleas.

8 Certainly. Timber for building purposes is very scarce indeed. For tea chests I hardly know what to suggest. Lunumidella grows very well in this district, and is a useful timber. Would it do for tea chests? Imbul are used by some.

We are inclined to think that there is no need to plant trees for tea boxes, considering not simply the large foreign supply, but the several substitutes in Acmes, Colindas, Venestas, &c., &c., which are pushing their way and which are bound to be improved and cheapened as time rolls on.

One of the oldest residents tells us:—

1 I only use wood, and have no experience of coal or coke.

2 I pay 25 cents per cubic yard, when cut and piled on estate.

3 In Rangala, Medamahanuwara and the Nitre Cave districts, the supply is plentiful: only a few estates buy firewood. Mr. Spence of Duckwari is the only one who uses coal or coke.

4 All in private hands. No Government wood sold here. Not required.

5 Any number of grevilleas all over the estates, more for shelter and shade than fuel; but they will come in handy for fuel if required.

6 Not about here: the supply is plentiful. If necessary grow grevilleas.

7 Nothing grows so well as grevilleas. Indigenous kinds take too long to grow.

8 No, life is not long enough. Would anything be worth using for timber under 20 years? Some of the softer woods might make tea boxes in that time. As a speculation or for one's children all waste land (poor) might be planted with grevilleas, albizzias, jak, &c., &c.

The Scottish Laird's advice to his son should not be forgotten:—"Aye be stickin' in a tree Jock; it will be growing when you are sleeping." Besides the intrinsic value of property is increased by all judicious planting of useful trees. A well-known Manager comes next, and here again it will be seen that "grevilleas" are the favourite tree to plant, as both fast growing and suiting the tea:—

1 Wood—being the cheapest, English coal costing about R60 per ton on estate.

2 From 1 to 1½ cent per lb. cured tea. Yes, it may be considerably reduced when the timber trees now planted on many estates come to maturity.

3 Yes, to most places in this district.

4 In private hands for the most part.

5 Yes, on large places such as this.

6 Great economy would be effected by early planting up of fuel trees.

7 Grevilleas for this district. They are fast growing and can be planted with advantage throughout the tea.

8 Yes, timber is always in requisition on tea gardens for buildings and factory requirements.

Very interesting information respecting grevilleas do we get from our next Rangala correspondent, and his experience is sure to be of use to planters in other districts who have not thought of grevillea shingles:—

1 I have only had experience with wood which is good if you have enough of it.

2 As time goes on the last will increase. At present we are under half cent per lb. of tea made.

3 Quite equal to the demand. Grevillea trees have been planted regularly every moosoon for years.

4 I would not like to have to depend on Government for fuel, and I hope I never shall.

5 Yes, and I do not think I shall ever have to apply to Government for fuel or other timber.

6 Certainly, rather grow your own timber than buy it.

7 Grevillea and Sapu for buildings.

8 Yes, for both purposes. It might interest some of your readers to know that grevillea makes good shingles. I send you by this post a piece of a shingle that has been on a set of lines for six years, and you will see that the wood, although rather weather-beaten on the surface, is quite good and fresh inside. This shingle was from a tree not over eight inches in diameter. I put on a patch of grevillea shingles when building a new set of lines, and the result was so good (as you will see from the piece I send you) that I have roofed a building with the same wood, but sawn in place of being split. Grevillea is not good as posts put into the ground, but is good for rafters, wall plates or reapers.

The shingle sample sent us is all that our correspondent describes: from no other district do we learn of the tree being turned to this use.

Then we have from the Gampola-side of the district:—

1 I only use wood and charcoal here and have no experience in coal or coke.

3 In some cases it is not; and wood fuel has to be bought at high rates.

4 In this district it is in private hands.

5 Yes, most of the estates have planted grevilleas for fuel purposes.

6 Planting timber trees for fuel purposes is absolutely necessary on a good many plantations until a new and cheaper fuel is found out.

7 Grevilleas. They thrive well and grow rapidly.

8 To do so is advisable.

Next we cross over to the West, including Kelani Valley, and we have an old planter writing:—

1 As the heat is drawn through iron, the tea is not affected by the fuel material. Wood is best because cheapest.

2 Wood only is used in these parts (West of Kegalla and West Dolosbage) and is not likely to be reduced.

3 Yes, and will be for some time, but not for long unless trees are planted.

4 In private hands mostly.

5 Not sufficiently so, especially since most of the estates were transferred to Companies.

6 Certainly, every nook and corner should be planted with all kinds of suitable timber.

7 All the indigenous hard timber, also grevilleas.

8 Yes, damba, keena, del, lunumidella, sapu, suriya, teak, gums, &c.

Next we have a Visiting Agent as well as Manager who gives his opinion in a very straightforward, practical way:—

1 Have only used wood.

2 No experience.

3 On most estates where an engine is the motor, supply of wood is inadequate and cost serious. Where water is obtainable, oil engines will be the future motor.

4 In the higher districts supply is generally dependent on Government; in the medium and lower districts it is more in private hands.

5 Yes, wherever fuel trees will grow they are being planted.

6 Too costly for private individuals to be successful: the work has to be done just as carefully and is as costly as the planting of tea.

7 Lunumidella, grevillea, gums.

8 No, would only plant a few lunumidella where elevation is suitable and gums higher up on the edges of ravines and on waste patches near swamps at wide distances apart. This would give shade in the present and timber for odd jobs in the future.

A Manager bordering on Yakdessa tells us:—

1 I have never used coal or coke for tea manufacture: most estates on this side of the district have large reserves of forest and chena. Firewood costing from 60 to 70 cents a yard delivered at factory.

2 The timber is not very good, mostly from quick-growing trees (a yard of well-seasoned Doon would be equal to about three yards). Cost per lb. made tea one cent where an engine is the motive power.

3 On some estates the supply of fuel is ample; towards the Gampola end of the district fuel is scarce.

4 Mostly in private hands.

5 Yes, very largely.

6 Yes.

7 Grevillea and iron bark gum grow best.

8 It takes too long for any suitable (building timber) tree to grow. Momi chests are so much better than the native-made ones, and in the end cheaper, that I don't think it is worth while paying any attention to growing timber for chests.

And then here is what a Manager in Allagalla or Kadugannawa North has to say:—

1 Wood is the cheapest if you have it good. Steam is more easily kept up with coal. I have not tried coke.

2 Coal costs about 1½ to 2 cents per lb. tea, wood about 1½ cent, wood and coal together about 1½ cent per lb. made tea. I have worked a Crossley's "Otto" oil engine and found the cost of made tea was under one cent per lb. and have been told the "Campbell"'s is about 1½ cent. This is cheaper than coal or wood.

3 At present there is plenty of firewood to be had from private hands.

4 In this district I think it is dependent on private hands.

5 Very little is being done in this line, and I think it should receive more attention.

6 It is very doubtful as long as firewood is available from private sources at a reasonable rate, there would be no economy in planting fuel trees, but we should look to the future.

7 Grevillea is a fast growing and useful tree and makes splendid firewood.

8 Certainly, plant timber trees for building: a small clearing of say jak, sapu, grevillea and lunumidella will be found most useful in the future.

From Lower Hantane a well-known Manager reports:—

1 Wood for driers, wood and coal for engine.

2 About one cent per lb. made tea. No; more likely to increase

3 Demand rapidly overtaking supply in this district.

4 No, Government forest in this district—most of the fuel bought from villages.

5 Yes.

6 When the cost of planting, upkeep, &c., is taken into consideration the saving is very little or nothing.

7 If timber is planted I prefer grevillea, jak, sapu and A. decurrens.

8 Yes, for building, no island timber equal to momi or deal for tea chests; would recommend jak and sapu for building.

From Hewaheta Upper we have a series of thoughtful, suggestive replies:—

1 Whichever fuel is cheapest. In this district wood. Personally I think charcoal in chulas, the very best way of drying tea, but too long and too expensive a process in the present day. We never heard complaints against the quality and keeping properties of Ceylon tea in the old chula days.

2 Never had occasion here to try coal. Wood is cut and delivered at factory for about 50 cents per cubic yard. Weight from 500 to 800 lb. per yard. I am using old "doon" trees which have been dead 40 years according to local tradition, some standing, some lying down. Most of it sound, but too worm-eaten for timber.

3 Yes.

4 In private hands.

5 Yes, nearly all the estates have grevilleas or "Eucalyptus robusta" planted along the roads and across the tea, more, possibly, as wind belts than fuel.

6 No need at present, but doubtless very useful in certain districts.

7 In this district grevillea and eucalyptus robusta: grevilleas up to 4,800 or 5,000 feet, eucalyptus robusta and melanoxylon from 5,000 feet up.

8 I fear the idea of planting timber for building and tea chests is utopian and apparently grevillea and gums not very suitable unless thoroughly seasoned. All the estates in Upper Hewaheta are fairly well off for fuel though "building" trees are getting very scarce. Rutland estate is using fuel from fuel plantations planted some ten years ago.

Crossing over to Pussellawa we have the following report from a Manager:—

1 Wood alone I consider the best fuel, but in this district I use coal and coke, the latter in conjunction with the wood or coal.

2 Coal is '95 cents per lb. tea. Wood is '79 cents per lb. tea. I am of opinion that the cost is not capable of being reduced.

3 No. In this district, taking it as a whole, in a few years wood will be very scarce.

4 In private hands.

5 On many estates fuel reserves are largely being planted.

6 Having no Government reserves, this is resorted to.

7 Grevillea seems to be a fairly quick growing tree and is hard; being, as far as I have seen at this elevation, the best for fuel.

8 I am not in favour of planting timber trees in this district under this heading as I consider the soil is not good enough to make it a success.

From Lower Pussellawa, towards Gampola, we have this return:—

1 Never having used, coal or coke, I cannot express an opinion.

2 With regard to wood-fuel I consider that the minimum cost per lb. made tea has practically been reached and that an increase in price is more than probable.

3 The supply is not equal to the demand, except in a few favoured cases, where the adjoining villages owning small pieces of forest, find it impossible to sell their fuel (owing to transport) except to the adjoining estate.

4 Exclusively in private hands.

5 Not the attention it should receive considering the importance of the matter.

6 Most certainly about 5 per cent of the acreage of estate should be exclusively for fuel.

7 If not in immediate want of fuel, grevillea robusta, but if a quick-growing fuel tree is required, I recommend albizzia molluccana to be planted. I have found albizzia molluccana planted through the tea at this elevation (? 2,500 ft.) not only useful and quick-growing, but beneficial to tea.

8 No. As regards building timber, although the first outlay is slightly heavier, my experience is that imported timber is the more economical in the end. The same with tea chests.

A Pundaluoya Manager suggests grevillea and toona as the trees to plant and that they should also be useful for building purposes.

The Manager of a large Tea Factory writes:—

- 1 Wood fuel is the best, cleanest and safest.
- 2 Quarter to one cent per lb. of tea.
- 3 Quite equal.
- 4 Some estates are dependent on Government.
- 5 Yes, any estate can supply its own fuel by opening fuel clearings.
- 6 Yes, one estate I visit is entirely dependent upon its fuel plantations which we have planted up.
- 7 Gum, grevilleas and acacias.
- 8 No; iron buildings will suit: what little timber is required could be imported.

A resident Manager tells us:—

- 1 Have no experience of any, except wood which is very efficient.
- 2 The cost varies on every estate in Ceylon from 25 cents to R2 per cubic yard. All depends upon situation and forest available.
- 3 The supply is barely equal to the demand at present, especially in Dikoya and Dimbula.
- 4 Almost entirely in private hands.
- 5 Yes, very extensive areas of tea are now being shaded with fuel trees.
- 6 Probably it is more profitable to grow fuel as shade on land already under other products.
- 7 Grevillea appears to be the best tree for tea; its leaves also make good cattle bedding.
- 8 Not in Ambagamuwa, where the railway renders it unnecessary.

Next we have a Dikoya Manager with varied experience:—

- 1 Forest wood preferable to quick-grown, planted timber. No experience in the use or cost of coal or coke.
- 2 Reliable figures will be highly interesting.
- 3 Supply available is being reckoned in mouths on some estates. It would be difficult to ascertain the proportionate acreage of such estates. Growing, planted, timber is being reserved as long as wood can be purchased from neighbouring estates. Supply in private hands is being limited.
- 4 A large supply of *dead wood only* is available from Government, by out-lying estates next Crown jungle. Transport cost on wood, either private or Government, to long distances would be prohibitive.
- 5 Most certainly. The amount of timber planted on many estates is very considerable. With careful coppicing it may be ample for such estates' future requirements.
- 6 The relative cost per lb. made tea, of even expensive fuel, is comparatively small and should be easily covered by the profit obtained from good tea land. It would not be economy to convert such land into plantations for fuel or for timber for buildings. Given waste land, unsuitable for tea, but suitable to timber, the economy of fuel for timber plantations is apparent.
- 7 Iron bark gum and various species of eucalyptus; acacia, various; red toona; grevillea; albizzia, various; sau, ficus, various; casuarinas and others according to soil and elevation.
- 8 No. 6 answers this as to "buildings." For tea chests, certainly not.

We now cross over to Maskeliya, and first we have a Visiting Agent as well as Manager reporting:—

- 1 Old dun timber of which there is still a large supply in this neighbourhood.
- 2 For the above 1-8th to 1 5th (12 to 20) of a cent lb. made tea.
- 3 In this neighbourhood it is and always will be. In the centre of the district, on estates where all forest has been cleared, fuel is scarce; but requirements are being met in most cases by the fuel trees planted in the last ten and 12 years.
- 4 None supplied by Government that I know of.
- 5 Yes, very largely; grevilleas chiefly.
- 6 No, unless on individual estates.
- 8 Yes, but for building purposes only.

A resident Manager:—

- 1 Wood; have no experience of others.
- 2 Wood costs from 1-10th to one cent per lb. made tea according to driving power and machinery used. Cost will increase.
- 3 Yes, at present; but in a year or two there will be a scarcity until fuel trees grow up a bit.
- 4 Government.
- 5 Yes.
- 6 Yes, for those with steam power. Most people have planted up poor patches which, with the trees throughout the tea, ought to be sufficient for the others.
- 7 Gums and grevilleas as being quickest growers.
- 8 No.

And finally we have a proprietary Manager reporting:—

- 1 Have only used wood, but coal or coke should be equally as good.
- 2 Have unlimited quantities on my estates.
- 3 I believe it is getting scarce and the price rising.
- 4 Government, so far in Maskeliya, have sold very little, but they have large reserves of forest available near cart road, not yet touched.
- 5 Yes.
- 6 As the jungle is cleared by Government it should be re-planted.
- 7 Blue gum and grevilleas.
- 8 Yes, grevilleas.

A well-known Manager of prolonged experience in this division—almost enough to make him the senior of the district—reports:—

- 1 Having abundance of wood myself, I have no experience of coal or coke.
- 2 The cost of wood fuel varies very considerably owing to facilities of transport or otherwise.
- 3 Yes, in Bogawantalawa.
- 4 In private hands.
- 5 Yes, considerable attention.
- 6 No, belts can be made and ravines planted, besides Government forests are all round us, and it would pay better to plant tea and buy fuel of Government.
- 7 Eucalyptus of all kinds and grevilleas, also red toona.
- 8 No, for reasons given above (No. 6) I would not.

Next, two proprietary planters give rather contradictory advice,—thus one:

- 1 Wood is the best at present in this district.
- 2 By far, the cheapest is wood, as most estates have a good supply.
- 3 Yes, and we are close to Government forests.
- 4 Most estates have some jungle and timber trees in belts and ravines.
- 5 To some extent, yes.
- 6 Not in this district.
- 8 No, it is better to purchase from Government forest.

And the other:—

- 1 Timber fuel alone is used in Balangoda district and I have no experience of any other.
- 3 Yes, on most estates.
- 4 On land in private hands entirely.
- 5 None that I have heard of.
- 6 I should hardly think so in this district at present.
- 7 Grevilleas appear to grow best.
- 8 Timber for tea chests might be grown to advantage in the lower portion of the district.

But from another proprietary Manager, we have, a very interesting experience recorded:—

- 1 No experience except wood.
- 2 Do.

8 I consider supply quite equal to demand now, timber trees have so generally been planted.

4 No. 3 answers this.

5 On most estates in this neighbourhood fuel and timber trees have been planted in large numbers.

6 I have just taken in over 1,000 yards of firewood from iron-bark trees, planted in a few ravines some six years ago, which speaks for itself.

7 Grevillea and iron-bark.

8 For timber, yes.

Iron-bark trees yielding so much firewood in six years shows what can be done, and we are told that the ravines so utilised were quite small, while the immediate cause of coppicing was that the shade was interfering with the flush on the neighbouring tea. But the iron-bark trees so coppiced have thrown up much healthy shoots, that it is quite expected four years more will give another similar crop of firewood!

And first we take the full report of a Manager in the Agras, who, it will be observed, expresses a decided objection to the use of coal in tea factories; and who also regards iron-bark as inferior as a fuel:—

1 Wood is preferable to coal, as the latter is too dirty for tea-making, the dust penetrating everywhere; and it also wastes very much. Coke is cleaner than both, and gives out great heat; but looking at the question from every point, wood is the most suitable fuel.

2 The facilities for getting firewood vary so much for different estates, according to their situation, that it is difficult to make comparison of cost. In my case, coal or coke would add over two cents per lb. to the cost of the tea.

3 The supply is equal to the demand at present; and with the large Crown forest acreage in and near the district, I think there is little chance of any other fuel taking the place of wood.

4 At present, the supply is mostly in private hands, and comparatively little is required from Government.

5 Most estates are planting fuel trees, and have been doing so for some years.

6 Fuel plantations have not been found a great success, though I think this is a good deal owing to the way they are worked, and, with a better knowledge of forestry, considerable improvements on the present system might be made.

7 For rapid growth there is nothing to equal gums; but I think it is a great mistake to plant iron-bark alone, which, though quick-growing, gives a much poorer fuel than blue gum and some other kinds. Grevilleas do not grow very quickly here, and would be a long time in giving any fuel, and then it would be of poor quality.

8 I do not think it would pay to plant trees for building and tea chest timber, as for both purposes it will always be got more cheaply, in sufficient quantities, and of better quality from the lowcountry and from abroad.

From Lindula comes a brief reply as follows:—

Coal or coke—as far as I can judge in going about as I do a good deal. Everyone is planting fuel trees and grevilleas are the best, for they do not injure the tea and they make excellent firewood and there seems plenty of it everywhere. The Government fuel or forest planting is a failure: they do not attend to the young plants same as a planter does.

From Kotagala, we have two answers from experienced Managers:—

1 Well-seasoned wood is preferable to coal for driers. I have not tried coke.

2 Wood is cheapest and best, when grown on estate. Where it has to be bought, the difference in cost between wood and coal is very little, for using in engine.

3 The supply is quite equal to the demand, taking the district as a whole.

4 In private hands.

5 Yes, to a certain extent, but not as much as it might.

6 Very little, excepting on land that will not grow tea; most of the land hereabouts can grow both, and usually better than it grows one.

8 I would plant for building purposes, but not for chests.

And, again, we have a specially good word for grevilleas for building purposes:—

1 Wood for drying purposes: it is clean and free from smell. Oil is most convenient for engines.

3 Grevilleas and gums grow very readily, and everyone on country can grow their own firewood.

4 A certain amount is dependent on Government; the greater portion is in private hands.

5 Has received and is receiving attention.

6 In waste land, gums and grevilleas can be grown very well together.

7 A mixture of iron-bark gums and grevilleas: they seem to live on different food, and about as many of each kind can be grown together as of one kind singly.

8 For building purposes, old grevilleas make a very good timber.

But our most interesting reply is from a Talawakele Manager who supplements his answers with a letter on the general subject of fuel supply:—

1 I have had no experience of coal or coke.

2 I understand that coal costs double as much as firewood per lb. of tea. Firewood costs from $\frac{1}{2}$ to 1 cent per lb. of tea. Everything depends on whether a steam engine is used or not. If a steam engine is always used, fuel costs about 1 to 1½ ct. when available on that particular estate.

3 Apparently so on most estates. There are, however, about fifteen estates to my knowledge that have no fuel.

4 Partly in Government, but in most cases in private hands. There is a fuel dépôt at Talawakele.

5 Yes: most estates are planted up with grevilleas round road edges, and on poor or steep patches, *e.g.*, those not capable of growing tea.

6 Yes: when poor land is available, but not on land capable of growing tea to yield over 150 lb. per acre.

7 Grevillea and iron-bark gum and acacia decurrens.

8 No: cost of sawing, transport, upkeep, etc., would only show a small profit as native low-grown timber, *e.g.*, sapu, jak, dawatas, etc., can be purchased at from R12 to R14 per 10 feet, delivered at the railway stations. Excellent Japan chests, etc., can now be purchased. No economy in planting timber suitable for chests.

On the question, as a whole, our correspondent makes the following interesting deliverance:—

With regard to the whole question of fuel, it has many times occurred to me that in those districts and on those estates which have facilities for transport, such as the Dimbula and Dikoya districts, the fuel question is not one of very grave importance as allowing that there is only a limited supply of firewood available, the extra cost of coal or coke over firewood would probably mean about $\frac{1}{2}$ to 1 cent per lb. of tea; and although even this saving is important, an estate that cannot afford this small extra cost must necessarily be in a precarious condition.

Outlying districts, as a rule, have facilities for getting firewood from jungle reserves, villagers and waste land, with the exception of the Pussellawa district, which, I believe, has for a long time found the fuel question, one of great importance.

Again, those estates that are now experiencing difficulties, e.g., the Kelani Valley, are erecting oil engines, and the improved dryers that are now on the market only use a small quantity of fuel per lb. of tea.

The cost of fuel per pound of tea on all those estates that I am interested in, is not more than 1 ct. per lb. of tea, and some of these estates purchase half of their supplies from villagers.

One of the great difficulties is not the cost so much as to transport, which unsettles labour, as coolies hate the constant hard work inseparable, where long transport is experienced, and especially in hot climates.

There is a great deal of truth in this: any extra work for coolies should be made as easy as possible.

Our first answer is from a proprietary resident planter:—

- 1 Hard wood is the best I know. Have no experience of coal or coke.
- 2 Good hard wood costs here 95 cents per cubic yard, and will go higher in price.
- 3 At present yes, in the future no.
- 4 Both.
- 5 Not that I heard of.
- 6 Yes, if we could at a quick-growing hard wood.
- 7 Don't know a quick-growing hard wood.
- 8 Lunuimidella for tea-chests; don't know any quick-growing building timber. Tried Hal ten years ago: some are now six feet high.

Next follows that by a Manager in the middle of the district:—

- 1 Wood, unless coal or coke can be procured cheap.
- 2 From half-cent to one cent per lb. in the low-country.
- 3 Yes, although of course some estates have to buy firewood.
- 4 Mostly in private hands. I know of no estate buyi g from Government
- 5 Not so much as might be done in the Kelani Valley. Albizzia moluccana is a fast-growing tree and makes a fine firewood.
- 6 Yes; I think all estates should plant up more trees than they do.
- 7 Albizzia and Ingasaman grow the quickest.
- 8 They might be planted, I believe, in planting trees about the estate in the low country; but any tree for building purposes would be too long growing.

This is a mistake: the property is improved in value by useful trees being put out in judicious utilisation of reserve or waste land.

The Morawak Korale is well off for timber to judge by the following reply thence:—

- 1 Wood; coal is unsuited for many of the firing machines. The smoke and fumes from it and coke make their use objectionable, where steam is the motive power: 0.50 cents to 0.80 cents per lb. made tea; without steam 0.20 cents approximately.
- 3 Yes.
- 4 In private hands.
- 5 No.
- 6 Not here.
- 8 No; supply is ample for long to come.

Next, we give the views of the veteran coconut planter who watches the widespread cutting of fuel for railway purposes near the railway:—

- 1 I know nothing of tea, so cannot give my opinion.

3 I fear before long wood will be very scarce, as Government use all they can get for the railway.

4 All depends on Government: we pay for supports 3 feet long at R3 per 1,000, the cost to cut 1,000 supports is R5, and removing the same from jungle R1.50 per 1,000, and pay Government for a permit each time 25 cents.

5 Government has planted some acres with Domba.
6 I would certainly plant any land I have lying waste with trees for fuel had I it.

7 Keeni, Domba, Lunuimidella, Ketakela and any other fast-growing trees.

8 Certainly, Lunuimidella, Kattu Imbul, Hal, Keena, Sapu, wild mango, Bombu, Hulabhuk.

And he adds:—

My opinion is that in course of time, the natives will have nothing in the shape of timber to sell. Even now they are cutting their Jak, Kaju and other trees and selling them to Government in order to get a little money for the time being. My belief is that by and bye the natives will not be able to provide any timber for the railway; and unless Government used coal or other fuel, it will be the ruination of the country. Government have planted a little Domba, but it is not suited for fuel. If I had 150 acres I would plant them for fuel.

It is certainly a question whether land suitable for growing casuarinas in the low-country would not prove a good investment for fuel purposes, if at all near the railway line or the city of Colombo. For year by year, no doubt, the available supply will become less, and year by year the fuel clearing would become more valuable.

A Visiting Agent reports:—

- 1 Experience only with wood.
- 2 Where procured from Government, capable of reduction, if estates' requirements received more favourable consideration.
- 3 & 4 A rather heavy acreage dependent upon Government for the supply of fuel.
- 5 Receiving attention and being energetically proceeded with.
- 6 Under certain circumstances, an undoubted economy ultimately. Patana land in this district should grow timber.
- 7 Robusta gum, toona, acacia decurrens.
- 8 Not quite necessary, perhaps, as a speciality in either case, especially as the amount of uncultivated land other than Government or military is limited.

Mr. Nock favours us with the following:—

- 1 Wood, in this locality, as the transport of coal or coke would be a heavy item.
- 2 Cannot say.
- 3 Yes, and likely to be for many years.
- 4 Altogether in private hands.
- 5 Yes, but to nothing like the extent I think advisable.
- 6 Most decidedly.
- 7 Acacia decurrens, acacia melanoxylon, acacia dealbata, eucalyptus robusta, frenela rhomboidea, and grevillea robusta (the first five above 4,000 and the last up to 3,000 feet elevation.)
- 8 Yes, certainly; and eupressus macrocarpa and eupressus knightianu come first for elevation above 3,500 ft.; they yield excellent timber for tea chests, and for all general building purposes. Pinus chinensis and pinus massonia are also well worth planting for this purpose; and for general timber acacia melanoxylon, eucalyptus robusta, grevillea robusta eupressus toulosa and sapu.

The following return shows the growth of some of the trees recommended, at the Hakgalla Gardens :—

	GIRTH.			
	(From ground.)			
	at 1ft.	at 5ft.	at 12ft.	at 20ft.
	ft. in.	ft. in.	ft. in.	ft. in.
Cupressus macrocarpa (age about 35 years—height 89 ft.)..	11 0	9 0	7 8	6 7
Cupressus, species, Knightiana? (age about 35 years—height 63 feet) ..	12 0	9 8	7 5	5 10
Acacia dealbata (age 17 years, for seed—height 77 feet) ..	10 9	8 0	8 0	6 6
Cryptomeria japonica (age about 30 years—height 54 feet) ..	7 8	5 8	4 9	3 8
Pinus montezumae (age about 30 years—height 55 feet) ..	9 0	7 0	6 8	6 0
Cupressus torulosa (age about 30 years—height 56 feet) ..	9 10	6 0	5 0	4 0

[Two trees of *C. torulosa* on Naseby, about 14 years of age, are between 40 and 50 feet high, and are 5 feet in girth at stoutest, tapering equally to summit.] There is surely encouragement here to go in for timber-tree growing to some extent in most high estates.

Finally, we have a very useful report from a well-known New Galway planter, who has always taken an interest in arboriculture :—

- 1 No experience except with wood-fuel.
- 2 At present, the cost of wood-fuel is 75 cents per lb. of made tea, and is not capable of being reduced.
- 3 At present, yes; and there are several thousand acres of Government forest-land in the vicinity.
- 4 No fuel is at present procured from Government, as estates, without a forest reserve, have their own private plantations coming on.
- 5 On most estates here, tree plants have been put on; but more for shelter than timber and fuel.
- 6 Most decidedly, as the day must come when private indigenous supplies will become exhausted; all inferior land should be reforested with quick-growing trees.
- 7 For medium to high elevation, say 4,000 feet and upwards, there is nothing so far to beat acacia decurrens, either for rapidity of growth or quality of fuel; but a good ravine should separate any plantation of acacias from one of another product as, though unlike many of the same family, it does not throw up suckers: it has very searching roots.
- 8 Building timber is always likely to be in demand and should receive general attention for high elevation. *Acacia melanoxylon* and some of the best *encalyptus* should be planted for timber, each species by itself. *Cupressus macrocarpa* grows to a fine tree and might be useful for tea chests, also *albizzia moluccana*.

Our next instalment, from Haputale, Badulla and Madulsima, will close the series.

Our first is from an Estate Manager in higher Haputale :—

- 1 Have only had experience of wood.
- 2 Cannot answer this, for above reason.
- 3 I have sufficient for many years to come.
- 4 Private.
- 5 A few acres planted up every year. Also *grevillea* planted along roads.
- 6 An absolute necessity, unless you have large reserves of forest.

7 *Encalyptus robusta* grows in any soil; but roots, if allowed to spread into tea, are injurious. *Grevillea robusta* is of slow growth at this elevation and in patana soil suffers.

8 Timber trees always useful for repairs of buildings. Would not pay at this elevation to grow trees yielding timber for chests.

From Badulla division we have two very practical reports from well-known Managers. First :—

- 1 I have had no experience of coal or coke, and can, therefore, express no opinion as to their relative merits.
- 2 Do. do. do.
- 3 In this district the supply of wood fuel is on most estates fairly good. In this town of Badulla, however, the supply is barely equal to the demand and the price tends to increase.
- 4 Government has discontinued the sale of firewood in Badulla and supplies are now obtained from private sources. The area of forest land, belonging to the Crown, is very small.
- 5 Yes; a very considerable area (376 acres) has been planted up on the Company's estates besides numerous wind belts and roadside trees.
- 6 Certainly. I consider much more should have been done by most estates in this direction.
- 7 *Grevillea*, iron-bark, etc.
- 8 *Cedrella toona* is a most suitable tree for ceiling work and grows freely. I do think we could grow timber suitable for chests on hills in Ceylon. Besides there is now an endless variety of tea chests on the market.

The second is not so full :—

- 1 I have experience of wood fuel only, and do not think any other kind has been used in this district.
- 3 Most estates have sufficient firewood. I know of only two factories that buy firewood.
- 4 Firewood is purchased from Government and from private people too.
- 5 Yes.
- 6 Yes; fuel must be planted for the future.
- 7 Iron-barks, I consider the most suitable for this district.
- 8 Not in this district.

Namunukula division sends us a full and suggestive statement as follows :—

- 1 I have only had experience of wood as fuel for tea manufacture.
- 2 Cannot tell, having had no experience of coal and coke.
- 3 On estates, where fuel has been freely planted, there is an ample supply.
- 4 Government supplies very little fuel to estates in this district.
- 5 On most estates it is; but on some estates where it has not been planted freely, the supply is short.
- 6 Certainly. Where the tea is all good on an estate I would plant fuel clearings, but on most estates there are hard exposed ridges, which should be planted up with fuel through the tea at sufficient distances apart.
- 7 *Grevillea* in tea, iron-bark and wattles in clearings, and also *toonas*; the growth of *grevillea* in this district is marvellous, and it makes excellent fuel.

8 Where there is no forest reserve, this should be done. *Cedrella toona* has been planted in this district with excellent results. The growth is good and so is the timber. I do not know of anyone who has planted timber for tea chests.

And next we have from Passara :—

- 1 I have had only experience of wood fuel.
- 3 Yes, there is a large supply generally and fully equal to the demand.
- 4 There is a good supply both in private and Government hands.

5 Yes, most estates in this district have fair acreages of fuel and shade trees planted.

6 Speaking generally of the strictly Passara estates, there is not much present necessity for fuel plantations, there being large supplies available.

8 It would be wise in my opinion were estates to plant suitable timber for building purposes, but not for tea chests.

Finally, we have the views of a Madulsima proprietary planter, who writes as follows :—

1 I have no experience of any fuel, but wood.

3 I think most estates in this neighbourhood have a fair supply of fuel, but one or two may have to start oil-engines before long.

4 The available fuel is almost entirely in private hands, but estates along the Lunugala cart road can easily obtain supplies from Government reserves.

5 Grevilleas have been freely planted everywhere and in a few years time, if not too soon, will add, very largely to the available fuel supplies.

6 I would not go to the expense of clearing up fresh land for fuel plantations, but parts of our old coffee land, which are too precipitous or of too poor soil for tea, might well be put into fuel.

7 Grevilleas and iron-bark gums seem to do best in this climate.

8 No! it would take far too many years for the trees to attain a sufficient size for sawing.

Believing that many planters will like to have the whole series of replies, suggestions and experiences—from Matale in the North to Morawak Korale and from Kelani Valley to Madulsima in the Far East—in a collected form, we shall put the whole together in a pamphlet form, uniform with the issue in respect of Manuring; Plucking, Pruning and Preparation; and Labour Supply—so as to be convenient for reference.

ROYAL BOTANIC GARDENS.

EXTRACTS FROM THE REPORT OF THE DIRECTOR FOR 1899.

1.—CHANGES AND MOVEMENTS IN THE STAFF.

THE Director was on leave from June 11 to November 10, inclusive ; the bulk of this time was spent in England, especially at Kew, in botanical work of different kinds. A careful study was made of the Ceylon and Indian *Podostemaceæ* in the herbaria and museums of Kew, Paris, &c. numbers of specimens of economic products were taken home for report and comparison ; and every opportunity of obtaining information of value in the conduct of the work done at Peradeniya was taken. Mr. Nock, Superintendent of Hakgala, acted as Director during the five months, and carried on the work of the Department with efficiency, his work at Hakgala being performed during the last two months by Mr. Macmillan, Curator of Peradeniya Garden. Mr. E. E. Green, hitherto Honorary Entomologist, was appointed to a permanent post as Entomologist during the year, and assumed duty on October 6. Mr. Parkin left for England in April, after the completion of his investigations into Indian rubber.

The conductor of the Badulla Garden, Mr. D. A. Gunaratna, retired at the end of January, and his post was filled by the promotion of Mr. D. D. Fernando, first upper gardener. Mr. M. G. Perera, clerk and foreman of Hakgala, retired in July ; and Mr. A. Perera, foreman of the Experimental Grounds, Peradeniya, was appointed in his stead. The latter foremanship was filled by the appointment on probation of Mr. J. M. Alwis, second upper gardener. The vacancies in the upper gardenership were filled by the appointment of Messrs. T. Young and W. de Alwis.

2.—GENERAL.

The general condition of the two principal gardens has been much improved during the year and there has also been an improvement in the branch garden at Badulla. The extension of the scientific side of the Department has also progressed steadily during the year. A new laboratory, in which there will be room for the proper carrying out of researches into the physiology and pathology of plants and the investigation of their properties and uses on a small scale, has been constructed by the Department of Public Works, and should be ready for occupation early in 1900. In it there is also sufficient room for a few workers from abroad, whom it is hoped to attract to Ceylon in increasing numbers. The scientific staff has been strengthened by the appointment of an Entomologist. Mr. Parkin left after carrying out some very useful investigations into the chemistry, &c., of rubber which are described elsewhere.

Much attention has been given to the thorough reorganization and equipment of the Department, and in a couple of years more this will, it is hoped, be fairly complete. The Library, the most essential part of such an establishment, has been overhauled, catalogued, and re-arranged, and some of the most serious gaps in the literature filled ; a large number of periodicals dealing with agriculture and botany are now received, and the Library will in a few years become a very good one. It may be well in this place to call the attention of the general public to the fact that this Library exists, and that reading permits may be obtained on application. The publication of circulars has been continued, and seems to be appreciated by those for whose use they are designed. With the increase of the staff these publications will be more frequently issued. A considerable number of experiments with economic plants have been carried on, but we are much handicapped by want of space for larger experiments, which would be better carried on in a special experimental garden.

3.—PERADENIYA GARDEN.

This has been much improved during the year. From the Curator's report I make the following extracts :—

General.—The process of rendering useful and attractive as far as possible every portion of the extensive grounds has been vigorously carried on. Special attention has been given to the old arboretum which was hitherto more or less beyond our means, and much useless and superfluous growth removed in favour of young and mor-

important trees and shrubs. The landscape effect of the river has been greatly enhanced by isolating into large clumps the hitherto continuous fringe of bamboos on the river bank which concealed from view a great part of the superb beauty of the river round the gardens. This was a very laborious task as the roots of the bamboos had formed huge masses very difficult to disintegrate, but which if left in the ground would quickly grow afresh and spread with renewed vigour.

Cultivation.—The propagation of all kinds of plants of economic value which are generally, or likely to be asked for by planters and others has been steadily carried on. Fruit trees especially have been considered, and of these there are at present in stock in moderate quantities about 68 kinds, most of which are included in a circular of fruit trees issued by us during the year. Ornamental aquatic plants are now becoming a feature of the gardens. The *Victoria regia* (giant water-lily) is now represented in the lake by several plants which at present (December) are flowering freely; and for the first time the supply of seed from our own plants has been more than sufficient for local and foreign demand. The effective Papyrus (*Cyperus Papyrus*) of the Nile has also become quite established and is much admired. The effect of the treatment we have lately been able to afford was to induce an unusually large number of trees to bear flowers and seeds for the first time here. Among these the following may be mentioned:—*Achmea mexicana*, *Acacia Hindsi*, *Albica Nelsonii*, *Amphicarpea Edgeworthii*, *Andira inermis*, *Cassipourea* sp., *Cyperus Papyrus*, *Dendrobium atrovioleaceum*, *Eleocharis grunites*, *Gasteria verrucosa*, *Gynura sarmentosa*, *Heteropteri purpurea*, *Pimenta* sp., *Randia mussaenda*, *Stereospermum glandulosum*, *Passiflora violacea*.

Experimental Plots.—The total of these now represent about thirty different tropical products. The situation formerly occupied by the different kinds of coffee close to the nursery having proved unsatisfactory owing to its rather swampy condition, the rarer kinds of coffee were transferred to a selected plot in the experimental grounds, where they are thriving; although some of these were 10 to 12 feet high at the time, and the weather proved deceptive as to rain, not a single death resulted from their removal. Five varieties of Arabia coffee, received last year from the Botanic Gardens, Java, as mentioned in last year's report, and 24 plants of the Liberian-Arabian hybrid coffee, were also planted here in well-prepared ground.

Tobacco seed of eighteen varieties was received towards the end of the year from the Jamaica Botanic Garden portions of which were distributed to all the Government Agents for trial in the different Provinces. The seedling from that which was kept and sown at Peradeniya are now being tended in the nursery, and separate plots have been prepared for their reception in different parts of the gardens.

Visitors.—The number of signatures in the book of visitors from abroad was 2,778, the largest number on record. Among these may be mentioned H. R. and I. H. Princess Henry of Prussia, who planted a Flamboyante tree (*Poinciana regia*) on the north-east side of the Circle; Lord and Lady Elgin; Director, Botanic Gardens, Calcutta; Director, Botanic Gardens, Trivandrum; Director, Botanic Gardens, Upper Congo, Africa.

4.—HAKGALA GARDEN.

This has been kept in excellent order. The following extracts from the Superintendent report show the chief work of the year:—

Perhaps the greatest improvement during the year has been in the laying out of the grounds near the new picnic arbour, and bringing it into a state more in keeping with the rest of the garden and the requirements of the increased number of visitors. A large quantity of rocks were blasted out, and a strong retaining wall 150 feet long with an average height of 8 feet, was built at a distance of 33 feet from and in a line with the front of the arbour. The space between the two has been filled in level and turfed, and now forms a nice green lawn, from which can be seen one of the finest views in Ceylon. The slope to the south has been planted with shrubs. The scrub at the back has been grubbed up, the ground made even and turfed, and the paths remade.

Hares and mousedeer were, if anything, more destructive than usual, and it was disheartening to see the damage they caused. Frequently, during a single night, many of the specimens of annuals and others, that had been carefully raised in pots and planted out, were totally destroyed. I am, therefore, very pleased to be able to report that 200 yards of one-inch mesh wire netting have been granted, and this was fitted up all round this garden in December. The posts to support this wire are of sawn timber, and it is hoped this will serve its purpose effectively, and will also be useful for training creeping plants on.

Rose Garden.—Nothing besides the usual pruning, manuring, and general upkeep was done in the rose garden. Although there was occasionally a very good show of blossoms, the plants generally have not done well. They have made but little growth and have an "unkind" look. The excessive rains followed by severe drought partially account for this.

Flower Garden.—Owing to the dull wet weather in December, 1898, and January this year, with hardly any sunlight, there being no less than 31.42 inches of rain on 43 days during the two months, and a bad attack of "black grub," bedding out plants had a very bad time of it. Large numbers of supplies had to be put out every day for some time. However, towards the end of February most things were established and flowered freely all through March, April, and May, and again in August and September, the pelargoniums and geraniums especially flowering well all through May. *Cypripedium* in pots also flowered well this month, and one plant that we have under the name *C. Stoneii* bore flowers that measured 8¾ inches from tip to tip of the tail-like sepals.

Camphor.—The growth of the young camphor trees has been very vigorous. The trees are 12 feet apart and although now only a little over four years old, some of them are touching. We now have ample material for making experiments of the extraction of camphor from the leaves and young shoots. The highest tree is now 18 feet with a spread of branches of 12 feet, and the stem is 20 inches in circumference at the base. Apart from the economic value of this tree, it is very ornamental and will grow in almost any climate.

Oxalis.—With an inadequate supply of labour, it is impossible to keep this obnoxious weed from spreading in all parts of the garden, but 35½ bushels have been carefully weeded out during the year from the borders and beds and from the herbaceous, flower, and rose gardens, &c.

Foot-and-mouth Disease.—This disease broke out among the cattle in the middle of July, and continued to be very bad for about a month. Nearly every one of the cattle was affected with it, some very badly, and one old cow died. The others soon recovered after treatment with Jeye's disinfectant.

Water Supply.—The want of a constant supply of water was again very much felt during February and March, also in July and August. At times during these droughty months nearly all the labour was engaged in carrying water and watering, and even then many plants were lost. I am glad to report that a trace has been surveyed by the Public Works Department, but, so far as I am aware, nothing else has been done. It is greatly desired that a vote for conveying a constant supply of water to the gardens should be sanctioned with as little delay as possible.

Survey.—I am very pleased to be able to report that a survey of the garden has been sanctioned, and I trust that this necessary work will receive early attention.

Porcupines.—These destructive animals made a raid on the gardens in June, and again in November and December. In the former month they destroyed a large quantity of arum and lily bulbs, and during the two latter months they pretty well cleared the garden of *Morea Robinsoniana* and terrestrial orchids and arum lilies in the fernery. I offered Rs. 2.50 for every one killed in and around the garden, but none have been caught so far.

Rats.—Large quantities of rats suddenly appeared in May and June, and committed great damage to the newly-sown seeds and young plants. In June no less than 145 were trapped. In 1887 we had a similar invasion, though not in such great numbers as this year.

Elephants.—A small herd of elephants passed through the upper part of the gardens, within 50 yards of the Superintendent's bungalow, in the early part of June, but I am glad to report they did no damage to cultivated parts.

Visitors.—The number of visitors recorded during the year was 1,805. This, however, does not include all, as during several months of the year only those who signed the book have been taken into account. The largest number in any one month was 424 in April, against 297 in the same month last year. The smallest was in October, when only 19 persons signed the book. The lowest number in any month last year was 74 in August.

5.—HENARATGODA GARDEN.

The garden has been kept in fair order during the year. Owing to my absence in England the general overhaul of its contents has been postponed to 1900.

Visitors.—The total number during the year was 517, against 222 last year.

6.—ANURADHAPURA GARDEN.

The available labour was largely taken up in watering the plants during the long and severe drought.

7.—BADULLA GARDEN.

The former conductor having retired on January 31, his place was filled by the appointment of Mr. D. D. Fernando, under whose charge the garden has been improved considerably during the year, and is more efficiently worked.

The general condition of the garden has been much improved this year, and the supplies of plants for sale have been increased. A considerably larger sum has been received during the year from sales of plants than in previous years.

10.—NOTES ON ECONOMIC AND ORNAMENTAL PLANTS.

Tea.—The total export is by far the largest on record, being 129,894,156 lb., against 119,769,071 lb. last year. Exchange has been practically steady at about 1s. 4d., and prices have been rather better than last year, especially for lower grade teas.

The export to Russia shows the very satisfactory result of a further increase to 3,949,740 lb. from 2,714,003 lb. in 1898; to America there is also an increase from 2,180,188 to 3,080,002 lb.; the export to the United Kingdom, however, has risen almost 8 million pounds.

The extension of cultivation has now practically ceased, and attention is being devoted more to improvement of methods of cultivation and manufacture, and to prevention and extermination of insect pests. Mr. M. Kelway Bamber has been in the Island the whole year engaged in investigations into the best methods of manufacture, &c. Insect diseases have given trouble in many places, as described in Mr. Green's report. The spread of certain fungus blights, more especially of the "grey blight" mentioned in last year's report, having given rise to some alarm, it was deemed advisable to lay the present state of affairs before the public by means of a circular on Tea Blights, which was issued in July, and in which the grey blight (*Pestalozzia Guepini*), the brown blight (new to science, and now

named *Cryptosporium Camellicæ*), and others were described, and the method of treatment and prevention indicated. The publication of this circular, and of many more or less alarmist letters in the newspapers, attracted universal attention to these blights, and the planting community is now well acquainted with their appearance and with the ways of treating them. There is thus every ground for hope that the industry will never suffer from blight in the way that coffee did, as the danger is much more likely to be recognized and taken in time by preventive measures. A "scientific" era is now beginning for this industry, and success will be to those who most intelligently apply to practice the improved methods of cultivation, manufacture, prevention of disease, &c., just as is the case with other long-established cultivation industries.

Coffee.—The export shows a large increase over 1898, being 18,542 cwt., against 13,313 cwt. The whole of this is plantation coffee, no native coffee having been exported.

Many varieties of coffee are on trial in the Peradeniya Gardens, but are still too young to bear. Experiments in grafting the various varieties on the hardiest stocks are in progress.

Cacao.—The absolute increase in the export is the largest since 1895, being 5,763 cwt. The total is 42,745 cwt., against 36,982 cwt. last year. The canker has given a good deal of trouble during the year, but on the whole planters seem now to be able to keep it in hand, and with a fungus pest this is, as a rule, the best that can be hoped for.

The new varieties of cacao that were introduced into Peradeniya some years ago are doing fairly well, but have not fruited yet. Experiments in grafting on hardy stocks are being tried here, but it is too early yet to publish any results.

Coca, Kola, &c.—There has been no demand for coca seeds or plants during the year. The kola trees in the south garden at Peradeniya bore fruit for the first time.

Cardamoms.—The export fell from 531,473 lb. last year to 499,959 lb. in 1899. A considerable area has been planted of late in the northern and some other districts.

Other Spices.—The export of cinnamon has again increased, that of chips from 1,414,165 lb. to 1,829,127 lb., though there is a slight fall in the export of bales, from 2,534,056 lb. last year to 2,515,033 lb. in 1899, and of oil from 183,312 to 118,778 oz. The export tables also show for the first time heading "Wild Cinnamon," of which 195,008 lb. bales and 628,418 lb. chips were exported. This consisted largely of the bark of *Litsea zeylanica*, *Aporosa Lindleyana*, and other trees mixed with real cinnamon. The fraud has now been exposed, and it may be hoped that this will also be the last time this heading will appear in the exports.

Vanilla continues to be planted, though not so much as in recent years. Experiments are being tried at Peradeniya on the suitability of various different trees and shrubs as supports. The young trees of scented allspice, received in 1890 from Dominica, flowered for the first time, but did not set fruit.

Cocoanuts.—The cultivation of this palm is still extending, and appears to be a profitable undertaking. Attention may be called to the fact that its cultivation is now being undertaken in Cuba and the other new American tropical colonies, and may in time become very important there. The nearness of Cuba to the United States gives it one great advantage over Ceylon for that market. The export of desiccated cocoanut has increased during the year, but that of all the other products has fallen off. The actual figures are for oil 400,979 cwt. against 435,933, for copra 325,401 cwt. against 506,277, for desiccated cocoanut 13,571,084 lb. against 13,040,534, for poonac 174,786 cwt. against 216,620, for nuts 11,723,392 against 12,027,714, for coir rope 12,090 cwt., yarn 75,525 cwt., fibre 91,533 cwt., against 12,333, 75,819, and 95,779 cwt., respectively.

Other Palms.—The export of palmyra fibre has fallen very much, and is barely larger than in 1897, being 16,838 cwt. against 41,522 last year and 16,793 in 1897. Kitul fibre has been exported to the extent of 2,030 cwt. against 3,794 last year. An interesting pamphlet on the Kitul and its Uses by Mr. T. B. Pohath-Kehelpannala was published early in the year by the Government Printing Office.

Indiarubber.—This product has attracted considerable attention during the year, and has been a good deal planted in the Colony, though not so much as in districts further East, where the soil seems more suitable. The auction sale of seeds was well attended, and the seed sold at a rate of about Rs. 15 per 1,000, a good price though little more than half of what was obtained last year.

A circular was published in April, dealing with Panama rubber (*Castilloa*), and pointing out the good qualities of this species, of which there is unfortunately but little in the Island. This was followed in June by a large circular, chiefly containing a paper by Mr. Parkin on Indiarubber in general, but with special reference to the species grown in Ceylon, and dealing with the new and improved methods of tapping and preparation for market. This is one of the most important papers on rubber which has been published in recent years. It will probably be supplemented during 1900 by a further circular dealing with the results of the analysis and valuation of the numerous samples that have been prepared by the various methods tried in the Colony.

The present position, with regard to rubber cultivation, may perhaps be summed up as follows. For those who have rubber plantations in bearing or of fair age the prospect is good, owing to the high price of rubber; this same factor of price, however, has induced a great deal of attention to the production of substitutes for indiarubber, and though at present none of these are so good as the natural rubber for most purposes, they are always being improved, and it is extremely probable that in a few years they may be largely used instead of rubber, and cause a drop of the price. It is therefore by no means so certain that rubber plantations now being laid out will prove so remunerative as is often supposed. It is essential to their future success that only good land be chosen, and that the best kind of rubber be planted, and the best methods of cultivation and preparation employed. It seems pretty certain, from Mr. Parkin's observations, that the young twigs or seedlings cannot be used as a source of rubber of good quality; they merely yield a glutinous substance, isomeric perhaps with caoutchouc, but without its elasticity and tenacity. It therefore appears almost certain that rubber planters will have to wait until the trees are six or more years old at any rate, and hence should give close attention to anything that is being done in the introduction of substitutes for rubber. The two species which appear on all counts to be the best suited for cultivation are the Para rubber and the Panama rubber (*Hevea* and *Castilloa*). Of these, the one which is better suited to the use of machine methods of preparation of rubber, and which also seems to give the larger yield, is the *Castilloa*, but there is every prospect that the *Hevea* will also prove successful, especially in swampy alluvial soil, the *Castilloa* needing better-drained, sloping ground. In view of the remarks made above, it would be unwise to recommend either species as an exclusive cultivation, but both may be recommended as adjuncts to tea or cacao, for which they appear to do pretty well as shade.

With regard to methods of preparation, it seems probable that it will be necessary, if good prices are to be obtained, to use the machines that are now being perfected, or the chemical methods as elaborated by Mr. Parkin; the latter are very suitable for *Hevea*, the former for *Castilloa*.*

Guttapercha.—There is nothing of special interest to record with regard to this. None has been planted, so far as known, in the Island during 1899.

Rhea and other Fibres.—There has been no demand for rhea this year, and unless some improvement in machinery, or some competition between the manufacturers, causes a better price to be offered for the ribbons, there seems but little likelihood of the cultivation being taken up here. A recent number of the *Indian Agricultural Ledger* calls attention to the excellent fibre afforded by the "wild or ban rhea" of Assam, *Villebrunea integrifolia*. The fibre has been reported upon very favourably in England; it resembles rhea (to which this plant is closely related), but is devoid of the gum, and is hence much more easy to prepare. This species grows wild in Ceylon (see Trimen's *Flora*, IV., p. 118), in Hantane, Alagalla, Nitre Cave, Haputale, and other places from 2,000 to 5,000 ft. elevation, and is worth the attention of tea planters as a possible source of revenue. Being a tree of 20 ft. high, it is perhaps scarcely to be recommended for actual planting without further demonstration of the good quality of the product, but those who have it wild upon their estates should preserve it, and if possible prepare specimens of the fibre and send them in for report.

Kitul and palmyra fibres have been dealt with above, also coir. There has been some inquiry during the year for *Agave sisalana*, *Furcraea*, and other similar plants.

Cinchona.—The export has again decreased, being 618,921 lb., against 975,784 last year. A very small quantity of this plant appears to have been planted during the year, and it is possible that the cultivation may still continue as an adjunct to tea, though not likely to be much extended. The demand for the alkaloids other than quinine (cinchonidine, &c.) may render the cultivation of *Cinchona succirubra*, *Ledgeriana*, and some of the hybrids again profitable.

Camphor.—The plants at Hakgala have done well this year. There has been but little inquiry for them. A fungus disease appeared on camphor in some districts during the year, and did some damage.

Tobacco.—Owing to the over-production of this product and the defective methods of curing in use locally, and other causes, the cultivation in the north of the Island has proved less remunerative, and with the view of extending, if possible, the demand from abroad for our product, experiments upon a comparatively large scale have been started during the year. Large quantities of the best kinds of seeds have been got from Cuba, the United States, Italy, and other countries, and have been distributed to those who have been willing to help in the trial by cultivating and curing these tobaccos in different parts of the Island. The tobaccos are as yet too young for curing, but seem to grow well in many parts of the Colony, and during the approaching curing season it is intended to try various methods of treatment, and to prepare a large number of good samples for further report

* Attention may be called here to an unfortunate misprint in Mr. Parkin's paper: On p. 148, last paragraph, the figures should be 0.9, 3.9, 0.25, and 8.0, respectively; and on p. 152, paragraph 2, line 11, for 8.3 per cent. mercuric chloride read 0.83 per cent.

and analysis in Europe. There seems no reason to suppose that Ceylon is incapable of growing a good quality of smoking tobacco, though it may not be able to compete with the best kinds grown in Cuba and other places. The cultivation is one which is likely to be of importance along the line of the new railway to the North.

Oils.—Cocconut and cinnamon oils have been mentioned above. The export of citronella oil has again increased, from 1,365,917 lb. in 1898 to 1,478,756 lb. in 1899. Olive plants are being tried in some of the up-country districts, but it is too early yet to see any result.

Tanning Plants.—The Crawford Cutch Co., established in 1895 (see report) to extract cutch from mangrove bark at Trincomalee, &c., has ceased operations this year. *Acacia decurrens* has proved a valuable tan bark for high levels and has been a good deal planted.

Fruit.—The supply of fruit plants has been increased so far as our resources will allow, and we have now a small supply of most tropical fruits available for sale at any time. The Curator of Peradeniya prepared a very useful guide to the cultivation and uses of the fruits suitable for moderate elevations, which was published as a circular.

Fodder Plants.—*Trifolium Johnsonii*, which has been recommended as probably suitable for up-country patanas, has been on trial at Hakgala. Six small beds were planted out in August on a piece of ordinary patana land. The ground was thoroughly broken up, made even, and the plants put out at distances of one foot apart; three beds were liberally supplied with manure, the others not. The plants in the manured beds grew well, and at the end of November had completely covered the beds with foliage and flowers 4 to 6 in. high. The unmanured plants hardly grew at all, and most of them died. It seems unlikely that this plant will grow on patana land without manure. The plants when in full flower were attacked by hares and eaten down; we have therefore no seed, but can supply a few dozen shoots to those who may care to give this plant a trial. Lucerne at Hakgala though the plants are now over eight years old, has continued to crop well during the year.

Trees.—The cork oak at Hakgala, which has been hanging back for some years, has at least made a start, and has grown well during the last six months. *Casuarina montana*, a Java species which seems likely to suit the barren Uva patanas, is on trial at Hakgala and other places. The drought told severely on the plantations of oaks and pines at Hakgala. Those, however, that have taken hold of the soil look very well.

Ornamental Plants.—The new varieties of Cannas at Peradeniya have been added to during the year, and have been a great success and in much demand for private gardens. The private nursery gardens in the Island have been improving considerably of late, and there is less need for the Government gardens to supply any ornamental plants other than the very newest sorts and rare species.

11.—REPORT OF THE ENTOMOLOGIST.

Mr. Green was absent in England from April 8 to October 6. He has done much work since his return.

Morowak Korale Tea Pest.—During my absence from Ceylon numerous letters appeared in the local press describing a caterpillar plague in the Morowak korale district. Alarming reports were published of the rapid spread of the pest, and the occurrence appears to have caused a considerable scare. No specimens of the insect seem to have been preserved, and its identity can therefore be conjectured only. From the somewhat vague descriptions received it is evident that the caterpillar belonged to the *Limacodid* family, and to the section bearing urticating spines. There may have been any of three species, *Thosea recta*, *Thosea cana*, or *Natada nararia*, three species that have on several occasions come into temporary prominence as tea pests. Several correspondents presumed the caterpillar to be the one described in my early work on "Insect Pests of the Tea Plant" under the name of the "blue-striped nettle-grub" (*Parasa lepida*). But that is a considerably larger insect, and one of which I have never experienced any serious outbreak.⁵

The caterpillar in question made its appearance in the latter half of July, and seems to have been extraordinarily abundant. It is reported to have completely defoliated ten acres of tea in as many days, and to have also stripped any cinchona trees that were growing in the affected area. The superintendent of the estate on which appeared made careful observations at the time, and has supplied me with the following particulars of the invasion.

The caterpillars were first noticed on the 15th July on a patch of about half an acre. Two days later 3 acres were affected, after which the pest extended its area at the rate of 5 acres a day, until 25 acres were attacked. Broad belts were cut round the affected area and all the included tea pruned. The prunings and sweepings were burnt. The pest disappeared completely for the time. Afterwards young caterpillars were observed on the new flush. The flush was therefore stripped for four successive rounds, resulting in the final extermination of the brood, and no further damage was incurred.

The point that attracted most attention, and was the chief cause of alarm, was the remarkable rapidity with which the plague is said to have spread. This must be accounted for, not by the caterpillars having actually travelled

* Since writing the above, Mr. F. M. Mackwood informs me that he raised moths from some of these caterpillars, and that they proved to be *Thosea recta*, Hmps.

at that rate—they are a slow moving species, belonging to the family *Limacodidae* (slug-like), and could not individually travel any great distance—but from the eggs of an earlier brood having been deposited on successive days, starting from the original centre and extending outwards as the moths became dispersed.

The second (or more properly the third) brood of very young caterpillars observed on the new flush no doubt resulted from eggs laid by moths from the survivors of the principal brood.

The superintendent reports that caterpillars were seen to emerge from some of the cocoons. I can only account for this by suggesting that some of the caterpillars may have temporarily sheltered themselves in empty cocoons; or possibly the cocoons may have been accidentally broken open, revealing the caterpillar reduced in size, as it always becomes just before pupating. The usual transformations must have been passed through: from egg to caterpillar, caterpillar to chrysalis (enclosed in its cocoon), chrysalis to moth; then another batch of eggs and a repetition of the cycle.

Caterpillar pests (of indigenous species), though temporarily very severe, are seldom of such serious importance as many less sensational pests. Their period of activity is usually short, and the attack is not often repeated on the same spot in the following season. Most of such outbreaks might be prevented if the earlier and smaller broods of the insects had been noticed and destroyed.

Tea Tortrix.—An exception to the usual rule (as regards repeated attacks) must be made in the case of the Tortrix caterpillar, which has recently been very destructive in the Dikoya and Hatton Districts. I have well-authenticated reports of successive attacks in October, November, and December. It is said to come on when the tea is in full flush, from four to six months after pruning, and results in a very serious loss of leaf. This pest is now being studied, and will form the subject for one of the Botanic Gardens Circulars.

Beneficial Insects.—The little colony of ladybirds (*Euxocheilus nigromaculatus*) from the Cape, the arrival of which was recorded in my report for 1898, at first thrived very well. During my absence in England it was well looked after by Mr. J. F. Jowitt, of Craig, Bandarawela, who, after liberating 70 beetles on bug-infested coffee in Haputale, returned to me 184 insects in various stages, making a total of 250 from the original 5 survivors of the consignment received just twelve months before. They continued to breed freely until about the middle of November, during which time 30 more beetles were liberated on an Araucaria tree infested with *Eriococcus araucarie*, and 32 were despatched to the Government Entomologist in Java for experimental work there. Since the middle of November no more eggs have been deposited. The adult insects have been gradually dying off, and there are no young ones to take their place. It is evident that this is the season at which the beetles naturally cease breeding. The same circumstances were noticed last year. I hope to be able to retain a sufficient stock till breeding recommences, about March, to further increase the colony, and to liberate larger numbers with a view to their becoming naturalized in the Island.

Though I am not very sanguine that these particular beetles will ever prove an efficient check to the ravages of "green-bug" (*Lecanium viride*), I am still of opinion that their introduction will be distinctly beneficial. They feed readily upon many different scale-insects, and may possibly prove more useful against other species than the coffee-bug. With regard to its work upon *Lec. viride*, it does not make a sufficiently clean sweep of the scale-bugs. It picks and chokes individuals, leaving others untouched. It is however more efficient than appears on the surface. It singles out gravid females and eats out the egg-containing parts. Many of the scales also, that at first sight appear to be untouched, have really been punctured and the fluid contents imbibed.

Disease of Annatto (*Bixa orellana*).—Early in October specimens of a common cattle fly (*Haematopota*, sp.) were sent into the office, with the report that they were causing serious injury to annatto plants in the Matale District. As the flies of this family are known to be blood-sucking insects, it was thought extremely improbable that they could be the real cause of the injury. An official-visit was made to the estate for the purpose of investigating the matter. It was found, as expected, that the flies, though present in large numbers, had no connection with the disease. It was a significant fact that the flies were thickest in the neighbourhood of a cattle-shed. The injury to the annatto shoots was referable to a canker disease, aggravated in some cases by *Helopeltis*, the eggs of which insect were occasionally found embedded in the diseased tissues.

Diseased cabbage plants were received from Nuwara Eliya in October. The roots were badly affected by the "finger and toe disease" (*Plasmidiophora brassicæ*), while the leaves were completely riddled by caterpillars of the almost cosmopolitan "diamond-back moth" (*Plutella cruciferarum*).

Tea-mites.—The annual loss inflicted by "red spider" and other tea-mites is engaging the attention of the office. Experiments are being started, designed to mark the effect of pruning in different months with regard to the prevalence or otherwise of tea-mites. A circular on the subject is being prepared, and it is hoped that ready assistance will be given in conducting the very simple experiments required and sending in the equally simple reports. It is only by the recording of abundant data, and its collation, that it will be possible to obtain reliable results.

Weevils on Tea.—In November a rather serious plague of weevils on young tea was reported from the Bogawantalawa District. The beetles appeared in young clearings at an elevation of about 5,000 feet, and caused serious injury by eating off all the new shoots springing from stumped plants. Specimens were sent to England for identification and proved to be *Brachyaspistes tibialis*, Jekel, MSS., a species hitherto represented in the British Museum collection by a single example only. Live beetles were kept under observation. They fed freely on young tea leaves and remained alive for more than two months. Small batches of eggs were laid by the beetles just below the surface of the ground, which hatched out as minute yellowish grubs, but did not thrive under the artificial conditions of a breeding cage, and soon died. It is probable that in nature the grubs feed upon the rootlets of plants, either of the tea itself or of some weed.

Quarantine experiments, in the form of fumigation of plants received in Wardian cases, have been attended with most satisfactory results. The hydrocyanic acid gas treatment has been employed. It has been ascertained that subjecting the plants to a high density of the gas for a comparatively short period is more effective than using a lower strength of gas for a longer period. For an ordinary Wardian case, with cubic contents (above soil level) of about 10 feet, gas was generated from $\frac{3}{4}$ oz. cyanide, $\frac{3}{4}$ oz. sulphuric acid, and $\frac{3}{4}$ oz. water, and the plants kept under

treatment for half an hour only, at the end of which time the case was thrown open. As a check on the experiments sprays of plants with living *Orthezia* insects (lantana-bug) were included. In each case the result was most satisfactory. Every insect was killed and not even the most delicate plant was appreciably injured. *It is important that the treatment should be conducted after sunset: 5.30 to 6 P.M. is the best time.* On subsequently examining the plants treated (which had just arrived from England) two notable scale-insects—not yet established in Ceylon—were found, viz., *Lecanium hesperidum* (the scale of the orange tree), and *Pulvinaria floccifera* (an enemy of Camellia plants). Both these insects would probably flourish in this country, the former on Citrus trees of all sorts, the latter on tea (a close ally of the Camellia). Fortunately the insects had been killed by the treatment. The plants have since been under observation, but no fresh attack has occurred.

Xyleborus fornicatus, the "shot-hole borer," still attracts attention and has been recorded from several fresh localities. Where attention is paid to the destruction (by burning) of prunings in affected fields, the pest can be kept within bounds, though it is practically impossible to exterminate it.

Orthezia insignis (lantana-bug) is still rampant. It has firmly established itself as a garden pest, where its presence causes the disfigurement of some of our most ornamental shrubs. Cases of its sudden appearance on small plots of tea have been reported; but prompt measures (pruning and burning) have been successful in eradicating it in such situations. No natural enemies have been observed. Nothing seems to relish the *Orthezia*.

The damage caused by *White Ants* (termites) in Ceylon and the cost of preventive measures to safeguard timber is recognized to be enormous. From its subterranean habit it is difficult to fight against this destructive pest. But this very habit would lend itself to the bisulphide of carbon treatment. The fumes from the bisulphide are heavier than air and sink to the bottom of any receptacle or hole. It is a well-known means of destroying wasps in their nests; it is the most effective way of reaching weevils and other insects in large masses of grains; and it is coming largely into use in parts of the United States to destroy rats and ground-squirrels in their holes. For white ants all that would be necessary would be to soak pieces of tow in the liquid and place them in the principal entrances of the ant-hills or burrows, block up all the holes, and leave the fumes to do their deadly work. Unfortunately carbon bisulphide is not obtainable in Ceylon. Owing to the inflammable nature of the fumes the Shipping Companies will not accept the risk for the sake of the small quantities required. I have been unable even to obtain a sample for experimental purposes. If it could be shown to be a certain means of exterminating white ants, large quantities of the chemical might be employed, and it might be possible to obtain supplies by some of the coasting steamers that now carry other explosives, paraffin oil, &c.

Many scale-insects in Ceylon are subject to various *Epidemic Fungal Diseases* which serve to keep them in check. With the assistance of Mr. John Parkin, of Cambridge, the different species of these entomophagous fungi are being studied, and cultures are being propagated with a view to their possible use against other scale pests.

Collections of *Coccidae* have been sent in for determination from India, Mauritius, Java, and Australia. Various other insect pests have been received from the planting districts of South India for examination and report.

In conclusion, I must earnestly ask for the assistance of planters and all agriculturists in the collection of specimens, observations, and all data connected with insect pests. Without such assistance it is impossible to efficiently carry on the work of the Department. I am frequently informed that such and such a product has been attacked by some insect; but that specimens were not sent in, as it was probably one that I knew all about, and that I must be overwhelmed with such letters and material. I would therefore impress upon planters that reports of each attack of even the commonest insect pest should be sent in to the Department, accompanied, whenever possible, by specimens. Such reports are filed and the specimens preserved and registered for future reference. This material will be of the greatest value in determining the times and seasons and the distribution of the various injurious insects.

12.—LABORATORY AND HERBARIUM.

The present laboratory has been occupied during the year by the following workers:—Mr. Parkin, from January 1 to April 14; Mr. A. K. Coomaraswamy, at intervals from January 1 to March 5; Professor K. Goebel, of the University of Munich, from January 22 to February 9; Mr. E. S. Goodrich, of Oxford University, from July 14 to July 18; Mr. E. M. Wilcox, of Harvard University, from September 19 to November 1; Mr. E. E. Green, from October 7 to December 31; Dr. A. Preyer of Berlin, from November 24 to December 31. Mr. Parkin was chiefly engaged in investigations in the methods of coagulation of indiarubber milks, the preliminary results of which have already been published in the circulars. Mr. Coomaraswamy was chiefly engaged in the collection of material for teaching purposes; Professor Goebel collected a considerable amount of material of various kinds for further study in Europe; Mr. Goodrich was occupied in zoological study, Mr. Wilcox and Dr. Preyer in investigations of various points in economic botany. The Director was engaged in marine economic studies, and in completing the monograph of the *Podostemaceae*; these studies were continued during the summer in Kew and Paris.

Peradeniya, January 30, 1900.

JOHN C. WILLIS,
Director.

REPORT FOR 1899.

WILSON SMITHETT & CO'S

CEYLON TEA IN 1899.

MEMORANDA. The two features which must stand out most prominently in a record of the tea market during 1899 are unquestionably the strong position maintained...

Throughout the autumn of 1898 tea prices, owing to the heavy supplies of India, had ruled on a quotation so low as to ensure its going rapidly into consumption. Consequently before the winter...

Between January 1st and December 31st, 1899, estimated quantity in lbs. and average prices realized.

Average Price for the year was 8d. per lb., against 7 7/8d in 1898, and 7 3/4d in 1897.

The initial letters following the estate names refer to the mean elevation as follows: L (low) sea level up to 1,000 feet; M (medium) 1,000 to 2,500 feet; HM (high medium) 2,500 to 3,500 feet; H (high) 3,500 to 5,000 feet; HH (highest) above 5,000 feet.

Table with columns: Week ending, Number of Pkgs. offered, Av. price per lb., Av. price per lb. for corresponding week 1898. Rows include months from July to December.

Home Consumption of Ceylon Tea during 1899 showed an increase of nearly 3,000,000 lbs. over that of the previous year.

Foreign Trade also showed a continued steady development. The re-exports of Ceylon tea during the year...

The effect of the sustained demand for low priced tea during 1899 is very apparent in comparing the returns obtained by the various Ceylon Tea Estates...

Last year we ventured to think the bed-rock of value had at length been struck, and when we consider that the increased supplies 1899 realized a fractionally higher average price...

The climatic originally made of the 1899 crop was 125,000,000 lb. of which only 95,000,000 lb. were expected to be available for export.

Small Beans.—The limits remain the same as during last year viz. 100 chests, 84 half chests, and 40 boxes.

WEEKLY PUBLIC AUCTIONS OF CEYLON TEA DURING 1899 WITH AVERAGE PRICES REALIZED.

Table with columns: Week ending, Number of Pkgs. offered, Av. price per lb., Av. price per lb. for corresponding week 1898. Rows include months from January to December.

Between January 1st and December 31st, 1899, estimated quantity in lbs. and average prices realized.

Average Price for the year was 8d. per lb., against 7 7/8d in 1898, and 7 3/4d in 1897.

The question of the preparation of the rubber from the milk is then taken up. The faults of the rough method hitherto in use in Ceylon are pointed out; putrefaction, mould, and want of thorough drying are the chief. Two methods of preparing Hevea milk are described, that by means of acetic acid and that by means of mercuric chloride. Both of these yield very good rubber indeed; the objection to the latter is that some of the mercuric salt is left in the rubber, which may interfere with its market value. Castilloa milk is then dealt with. At present the number of trees in Ceylon is too small to make it worth while to use the centrifugal machine, and creaming is recommended, this gives most excellent rubber at small cost. A modification of the ordinary cylinder glass churn, provided with a tap at the bottom, will probably serve the purpose excellently.

Mould and putrefaction are guarded against by the use of antiseptics, such as creosote and mercuric chloride, and by the rapid drying of the rubber on porous surfaces.

Many points still remain for investigation, and the experiments initiated by Mr. Parkin are being continued at the Peradeniya and Henaratgoda gardens. Their further results, and the reports of experts upon the samples of rubber now in hand, will form a subsequent Circular.

The introduction of these scientific methods of dealing with rubber milk has very much altered the whole question of what tree to plant, whether to plant as a chief or a minor product, and so on. This has been considered in the preceding Circular (No. 11).

LITERATURE.

The following books and papers, among others, may be consulted in the Library at Peradeniya; the initials and numbers indicate their position:—

Peradeniya, May 25, 1899.

GEO. WHITE & CO.'S TEA REPORT FOR 1899.

TEA IN CEYLON AND JAVA.
GEO. WHITE & CO.'S ANNUAL INDIA, CEYLON AND JAVA TEA REPORT.
LONDON, 31, FENCHURCH STREET, E.C.

At the date of our last report the chief feature of the Market was the high price ruling for the lower grades, and it is hardly surprising that the coarser plucking, which will realize a higher price than usual for all parts and consequently the average yield from common and medium Tea which have had to be dealt with during the current season, have been to the advantage of the grower.

In continuation to the first estimate given in 1898 by the Indian Tea Association of Ceylon, which was taken to full, that published in August, although not issued until the 12th September, was placed at 135 million lbs. available for Great Britain, whereas 134 million lbs. actually shipped to this country from Ceylon in 1898-1899. This addition is, no doubt, due to the more favourable season stated above and also to the more favourable conditions which prevailed in most districts, especially in Cachar and Sylhet, both of which in 1898 suffered severely from drought.

On the whole the crop has proved to be of a useful description, but the proportion of fine leaves has been less than usual. Darjeeling, with few exceptions, were disappointing, though choice standard consignments were rather scarce. Doars, for the major part were of a saleable style, yet in many instances lacked the rich colour infusions which are looked for from this quarter. Cachar and Sylhet showed improvement in quality, and benefited to a considerable extent by the comparatively advanced range established for common to fair kinds. A few of the Kangra were up to standard, while the bulk marked a falling off. Shipments from South India were liked on account of the fullness in cup often possessed by those from Travancore, and for the delicate flavour of the best from the Nellore and Mysore.

The demand for Pekoe Souchong and Pekoe "for prices" fostered by the low rates of 1898, was very noticeable, so that by April 1899, when there was some apprehension that supplies would be insufficient for the first-named was to be had under 8d per lb. During July and August, however, heavy arrivals of the finer grades were received, and the enquiry slackened, inferior leaf drooping to 5 1/2d per lb. Subsequently, with more attractive Tea to deal with, there was increased general buying, and the quotation rose to 6 1/2d per lb. in the middle of November, keeping fairly steady with some fluctuations until the end of January, when it stood at 6 1/2d per lb. afterwards receding to 6d per lb. While the relatively favourable situation of Common doars assisted many concerns it was to the detriment of others, as Medium Pekoes and Broken Pekoes were not so much wanted, and were often worth only fractionally more than the former. Fine and neat not being over plentiful nearly always commanded enhanced prices. Deliveries from the London Bonded Warehouses for these months ending 31st December 1899, were as follows:—

The following is a Comparative Table, showing QUINQUENNIAL IMPORTS of TEA into the Port of London from 1875 to 1895 and for each season subsequently:—

The produce of this island maintained its place both as regards leaf and liquor. Climatic influences were occasionally suitable to the production of fine flavoured, which was duly appreciated by Dealers. It would appear that so many estates it has been the practice to go in for quantity, encouraged thereby by the rates obtainable for common sorts in the spring, the market for which followed very closely that of India generally. The supply of medium at times was in excess of requirements, and there was frequently very little difference in the prices they brought as against those realized for the grades below them.

Although deliveries for the whole of 1899, viz., 94,226,000 lbs., were slightly above those of 1898, which reached to 93,489,000 lbs., they were nearly two million lbs. under the imports.

In January, 1899, the portion of the crop estimated for shipment to the United Kingdom was 93 million lbs., but the amount dispatched turned out to be over 103 million lbs. The entire output was 129 million lbs. as against 130 million lbs. in 1898, and 116 million lbs. in 1897.

For the twelve months the following passed through the London Auction Room:—
1899—1,138,100 pkgs. (Average 8d per lb.)
1898—1,108,800 pkgs. (Average 7 1/2d per lb.)
1897—1,138,000 pkgs. (Average nearly 8d per lb.)
The totals for the three years, therefore, were approximately, while the result did not differ very materially.

Since 1st January arrivals have been on an extended scale, being for the first two months of the year 19,673,000 lbs., while in 1899 they were 13,468,000 lbs.

The strong position of ordinary Leafy Teas here at the beginning of 1899 very likely attracted more than 280,000 cts. of the Public Sale, on 1st July to the 31st ult., included 38,300 packages, averaging 7d per lb., whereas in the two prior seasons they comprised 30,200 packages bringing 7d per lb., and 24,900 packages 6 1/2d per lb., respectively.

The introduction of India and Ceylon seed has caused the yield of the younger plantations to assume the characteristics of those Teas. They are freely taken up by the Blenders, who find them very suitable for their purposes, so that notwithstanding the shrinkage in the exports from this country the volume of trade has swollen.

N.B.—"Overseas" transshipments for the Continent, America, Canada, &c., via London, and direct shipments to other parts of the United Kingdom, are not included in the above. Prior to 1885-1889 lbs. are included in the above. From 1890-1898 lbs. Ceylon figures represent total exports from Colombo, that date being unimportant. Arrivals from Java are omitted, as they vary in different years, being regulated according to the state of the markets which take them.

Undermentioned are the Exports to other Countries than Great Britain, from Ceylon and Java, and the Development of which, although not so pronounced as in the year before, is having the salutary effect of checking over supplies to this centre, thus tending to support prices at a higher level than would otherwise be the case, to the benefit of the producer.

Table with columns: Shipments from Ceylon (1899, 1898, 1897), Shipments from Java (1899, 1898, 1897), and Shipments from Ceylon to other countries (1899, 1898, 1897).

The Board of Trade returns (which embrace all the Bonded Warehouses in the United Kingdom) for the past three calendar years were:—

Table with columns: Home Consumption, Exports, Total Deliveries, and Bonded Stock (Dec. 31st) for 1899, 1898, and 1897.

When writing at this time in 1899 we estimated supplies from all sources would reach 275 million lbs. Our actual requirements as shown above was 274,800,000 lbs., so that the total imports, owing to the favourable weather previously mentioned, will all probably be 287 million lbs., the statistical picture seems hardly likely to be so good on 30th June next as it was in 1899, although at this time it is somewhat unreliable owing to the recent duty increase.

From the several producing countries the following quantities should be ample to meet our wants during the coming season:—
India (including the Madras Presidency) . . . 153,000,000
Ceylon 108,000,000
Java 3,000,000
Leaving China to furnish 20,000,000
Total 284,000,000

Although receipts both from India and Ceylon during the past eight months have been considerably more than was anticipated, yet owing to the vitality of the industry both at home and abroad it is probable that the surplus will be to a great degree worked off before the new crop arrives from Ceylon in any quantity. Throughout the period under review business has at times suffered from many disturbing causes, among which were the 1 lb. draft dispute, dearness of money coupled with the unsettlement of affairs brought about by the war in South Africa, and by the disorganization existing prior to the declaration of the Budget. It is to be hoped that none of these untoward influences will be experienced in the near future to upset the calculations of all concerned. What effect the advance in the Duty from 4d. to 6d. per lb. may ultimately have it is difficult to foresee, but should it lead, as its anticipated by some people, to the extended use of medium and fine, the former of which have been unduly depressed for months past, it will be a boon to many, especially to those whose interests lie in Assam, Darjeeling and the higher parts of Ceylon, Russia and other countries have for several years past taken a fair proportion of fine Pekoes and Orange Pekoes, and thus supported these grades, while they have recently also bought appreciable quantities of Ordinary Leafy Kinds. On the whole therefore, prospects seem favourable to expansion in the sale of good liquoring descriptions, while that for very common may be partially abandoned, and the common may be sold at a lower price, say 1d. per lb. If prevailing retail prices be 1d. 6d. per lb. the purveyors to the public can induce their customers to purchase a slightly better blend than they have lately perhaps been accustomed to, they would not only benefit themselves but also help to raise the whole Trade to a higher level than it has been on for some time.

Under the circumstances already alluded to, and taking into consideration the larger area coming into bearing in some districts, it would seem policy to avoid very coarse plucking and the manufacture of undesirable sorts which foster a low quotation here and tend to glut the market.

Where briskness, pungency, or full-bodied liquor are attainable, every effort should be put forth to secure these characteristics. Plain featureless Teas are more or less neglected, especially in the very busy months, and good appearance without sterling cup no longer satisfies even the Continental buyers who use to take that style of China Congou. Comparatively fewer "cheesy" lots have come to

hand this season than in 1898-9, presumably attributable to the greater care used, during the process of firing in the "driers," so that little trouble has been experienced in regard to this. The weather appears to have been fairly propitious in most parts, although a smaller number of "autumn flavoured" lotes than usual have reached here. These, when not tea brown in leaf, found much favour with buyers, and if by any means, chemical or otherwise, more than they could be produced, they would meet a ready sale. It is reported that a scientific expert has been engaged to visit the different gardens throughout India, and such matters as well as fermentation and other stages through which the leaf is passed will no doubt, receive his attention.

No alteration has been made in the limits for large breaks since last year, which stand as under, viz.:—
India—20 Chests, 30 Half-Chests, 50 Boxes, Ceylon—18 Chests, 24 Half-Chests, 40 Boxes.
Lots of lesser size are sold separately at the close of the auctions.

It is not well to allow Tea to generally be the factory, as if kept for any length of time it is liable to lose its freshness, nor to send too many grades. Indeed, under present conditions when so small a difference often exists between the value of Ordinary Orange Pekoes, Pekoes and Ceylon Souchongs, it becomes a question as to the advisability of shipping them home in one line. This might at all events be followed in those small Estates where the crop is limited. The following continues to be a saleable assortment:—
A Broken Pekoe of 30 to 50 chests; a good Pekoe of 50 to 80 chests; a Pekoe Souchong of 70 to 100 chests, with an occasional break of Broken Tea or Ceylon Fannings. Parcels containing that are not readily marketable and therefore this should be sifted out of the patent packages now in vogue which are utilized so as to avoid leakage on the voyage resulting in loss of weight which often occurs with country made chests. The exception to the foregoing is when a tippy Broken Orange Pekoe or Orange Pekoe can be made, as when these really fine grades are made, as figures, which are from India or Ceylon. Should the quantity of leaf available for this not suffice for a full-sized break of 20 Chests it might be packed in 30 Half-Chests.

N.B.—In view of the necessity of economical handling of Tea we have compiled a few hints as to packages, bulking, &c., warehouse charges, and weighing, and these matters are dealt with in our "Notes for the Tea Factory," published separately, copies of which we shall be happy to furnish to those concerned in the cultivation of the tea.

MONTHLY AVERAGES OBTAINED IN LONDON FOR GARDEN INVOICES, FROM THE DIFFERENT DISTRICTS OF INDIA, ALSO FOR CEYLONS AND JAVAS, FROM 1ST JULY TO END OF FEBRUARY, FOR SEASONS 1899-00, 1898-99 AND 1897-98.

Large table with columns for months (July to February) and districts (Assam, Cachar and Sylhet, Darjeeling, Doars, Kangra Valley, Travancore & S. India, Total India, Total Ceylon, Total Java).

MONTHLY AVERAGES OBTAINED IN LONDON FOR TEAS FROM DIFFERENT DISTRICTS IN CEYLON DURING 1899.

Table with columns for months (January to December) and districts (1-13) and a general average.

COMPARATIVE TABLE SHEWING THE CALCUTTA, COLOMBO AND LONDON, MONTHLY PUBLIC SALES FOR 1899-1900 AND 1898-99.

Table with columns for months (May to April) and locations (Calcutta, Colombo, India, Ceylon, Java).

COMPARATIVE TABLE OF MOVEMENTS OF TEA FOR THE PAST THREE SEASONS.

Large comparative table with columns for India, China (including Japan), and Ceylon, showing imports, deliveries, and stock at end of each month for 1900, 1899, 1898, and 1897.

1899-1900.

The Planters' Association of Ceylon,

KANDY.

FORTY-SIXTH ANNUAL REPORT.

FOR THE YEAR ENDING 17TH FEBRUARY, 1900.

Your Committee, in discharge of its duty, herein begs to submit the forty-sixth Annual Report of the Planters' Association of Ceylon...

The Planters' Association of Ceylon was established at a Public Meeting held at Kandy on the 17th February, 1854...

It would scarcely be credited that the Railway—Kandy—Kandy, persistently agitated for nearly half-century ago—has been built, is a monument of engineering skill...

It may be incidentally noticed that the well-known bridge over the Mahaweli Ganga at Katugastota was successfully pressed for by the Planters' Association about 1855...

There have been occasions when the relations between the Planters' Association and the Government have been somewhat strained, but difficulties have been overcome...

Turning to the work of the past year, your Committee notes with satisfaction that the Register compiled well with previous years...

PLANTING PRODUCTS.

Last year may be said to have been a wet season as compared with the previous year, with the result that the tea harvested exceeded estimates generally...

Table showing tea production in India and Ceylon from 1897 to 1899.

Table showing duty payments for tea from 1897 to 1899.

Table showing exports of tea from 1897 to 1899.

Table showing analysis of above export of tea from U.K. during the last two years.

Table showing tea production in Ceylon from 1897 to 1899.

Table showing tea production in China from 1897 to 1899.

Table showing tea production in other countries from 1897 to 1899.

Stock of all tea in United Kingdom at the end of Nov. 1899, 103,348,000 lbs. 1898, 91,198,000 lbs. 1897, 91,095,000 lbs.

Production of Tea in India and Ceylon during 1899 barely equal to consumption, while although estimates of the 1899 crop point to a larger supply...

Table showing production of tea in India and Ceylon from 1897 to 1899.

The quantity per head of population in 1899 was 601, against 585 lbs. in 1898, and 581 lbs. in 1897. NEW MARKETS.—Considering the higher prices ruling for the lower grades...

TRADE DISPUTE.—The trade was considerably disturbed in July through a dispute between importers of Indian and Ceylon Tea and their buyers...

EXCHANGE averaged 14½ during 1899, against 14¼ in 1898.

Messrs. George White & Co., London, in their Ceylon Tea Memorandum of January, 1900, state that the quantities offered at Public Sale in the past three years were:—

Table showing London Tea Returns from 1897 to 1899.

Table showing stock of tea in London from 1897 to 1899.

From Messrs Wilson, Smithett & Co's London Tea circular for last month the subjoined figures of monthly shipments from Ceylon to the United Kingdom during the past five years are taken.

Table showing monthly shipments from Ceylon to the UK from 1897 to 1899.

Table showing tea distribution from 1897 to 1899.

Table showing tea production in various countries from 1897 to 1899.

As regards the quantity of tea sold in Colombo by the 'Ceylon Observer' quoted recently the annexed figures for a series of years.

Table showing tea sales in Colombo from 1897 to 1899.

During the first half of the year great attention was paid throughout the planting community to the then prevailing blights on tea.

With reference to this important matter, your Committee thinks that the time has come to discuss and consider it.

To apply to all parcels by ships reporting on and after July 1st, 1888.

For determining the class under which the break is chargeable, the average gross weight must be ascertained.

Although this sounds formidable, an examination will prove that the greater portion of it represents work which is quite superficial.

Tea is not infrequently bulked on the estate, and when this is done they are very rarely re-bulked.

We have been at pains to explain the actual charges complained of by producers, and will now proceed to point out why they are considered onerous.

Returning to the subject of the charges, it is clear, both from internal and external evidence, that they are excessively high as consideration for the services rendered.

The estimate for the year 1899 was about 40,000 cwts. The amount actually shipped was 42,327 cwts.

Table showing stock of tea in Liverpool from 1897 to 1899.

Table showing tea production in various countries from 1897 to 1899.

As regards the quantity of tea sold in Colombo by the 'Ceylon Observer' quoted recently the annexed figures for a series of years.

Table showing tea sales in Colombo from 1897 to 1899.

During the first half of the year great attention was paid throughout the planting community to the then prevailing blights on tea.

With reference to this important matter, your Committee thinks that the time has come to discuss and consider it.

To apply to all parcels by ships reporting on and after July 1st, 1888.

fact that on many of the older estates the crops this season have fallen off very considerably—some of them being as much as 50 to 60% short of estimates.

Your Committee has very little new information locally to report as regards this product, as it is difficult to obtain reliable data.

The India-rubber trade is of great importance to the United States, and has shown a rapid increase during the last few years.

A recent United States consular report shows that the importations of crude rubber amounted to 33,842,374 pounds valued at \$14,854,512.

Rubber is derived from the milky sap of a number of trees and shrubs, all native to the tropical regions of South America and the Old World.

The Ceara rubber tree, Mamoti glaziovii, is a native of one of the driest portions of Southern Brazil.

The Ceara rubber tree, Mamoti glaziovii, is a native of one of the driest portions of Southern Brazil.

Through the courtesy of the Hon'ble the Principal Collector of Customs your Committee places as an appendix hereto...

Your Committee estimates the Tea Crop for Export during the year 1900 at 158,000,000 lbs.

Table showing total export from Ceylon during the year 1899.

Members are aware that in General Meeting on the 17th February last year your Association endorsed its previous Resolutions on the question of Railway Extension.

The work has been begun at Rangama Road, Balakumbura, and Talawa.

There are four Assistant Engineers engaged in the work. A contract has been entered into with some Singapore contractors to build the combined upstair Passengers' Station and Station Master's dwellings.

As regards the Kolani Valley railway all the plans of the line have been prepared and sent to Government for transmission.

As regards the Kolani Valley railway all the plans of the line have been prepared and sent to Government for transmission.

TEA, COFFEE, CINCHONA, COCOA, AND CARDAMOM SALES.

NO. 23

COLOMBO, JUNE 19, 1899.

PRICE:—12½ cents each 3 copies
30 cents; 6 copies ½ rupee.

COLOMBO SALES OF TEA

LARGE LOTS.

Messrs. Forbes & Walker.
