The only drawbacks to the use of mushrooms are the cases of poisoning which occur nearly every year. According to Mr. de Zaczewsky, there are absolutely no empiric means of ascertaining the true nature of mushrooms. Neither the shape, nor the colour, nor the smell or flavour can be taken as a sure indication. Of course it is pure superstition to believe with some ignorant people that those mushrooms are poisonous which grow near a snake-hole, or close to a rusty nail, a mouldy piece of cloth, or a poisonous plant. Neither is it true that we can eat safely mushrooms which have been gnawed by insects. There are snails and insects capable of eating with impunity mushrooms which are highly poisonous to man. Even cows can eat varieties which it would not be safe for man to touch. But dogs, cats, and rats are affected similarly to human beings, and we can safely try on them suspicious varieties. Another groundless prejudice is to believe that if a silver coin or spoon or an onion become blackened by being put in the water in which mushrooms have been boiled, it is a sign of poison. It is not a poisonous substance which thus darkens those objects, but the presence of sulphur, which combines with other elements, forming thus sulphydric acid. Onions or silver boiled with eggs will become dark, too. Still, nobody would say that it is because eggs are poisonous.

As to the effects produced on our system by poisonous mushrooms, they are of two kinds,

Some varieties, as the *Russules*, act directly on the digestive organs, causing there an acute inflammation ordinarily from two to three hours after they have been eaten. These are very seldom fatal. An emetic such as ipecacuanha, or, still better, 15 grammes of emetic mixed with 30 grammes of sulphate of soda in a glass of water, to be taken in two draughts at intervals of five minutes, will be sufficient to free the stomach and save the patient.

Other varieties, such as some of the *Amanitæ*, are far more dangerous. Their poisonous principle is a narcotic, acting, not on the digestive organs, but directly on the nervous system. The effect takes place from six to forty-eight hours after eating the mushrooms, when the poison has all passed into the blood. It first causes headache, confusion of ideas, dejection, and stupor. Then follow nausea, vomiting, palpitations, acute abdominal pains, oppression, and intense thirst. The face is pale and panged; convulsions, delirium, and fantastic visions bring the patient into a comatous state. That condition, which is accompanied by intense pains all over the body, may continue for many days. But the result is nearly always fatal. Large draughts of strong tea or coffee are used to counteract the prostration. When the stomach is entirely free from the poisonous substance, then use ether and ammonia to prevent nervous accidents. Should the patient recover, he remains for a long time very weak, and the greatest care and precautions are to be used during his convalescence.

Such a terrible possibility as the above described should, it seems, be sufficient to deter anyone from eating mushrooms. Fortunately there is, according to Mr. de Zaczewsky, a perfectly safe means of eating with impunity even the most poisonous of mushrooms. It was discovered many years ago by Mr. Gerard, assistant botanist of the Jardin des Plantes in Paris. In the presence of a commission appointed for the purpose by the Academie des Sciences, he ate, and every member of his family did the same, some of the most poisonous varieties. The experiment was so conclusive that the members of the commission joined in the feast, and enjoyed with impunity some of the deadliest varieties of the *Amanita*.

The recipe is simplicity itself. Copy it, and paste it in a conspicuous place.

For every pound of mushrooms cut into pieces, take 1 quart of water, add to it 2 or 3 spoonfuls of vinegar or of salt. Soak the mushrooms in this for two hours. Then strain off the water and throw it away, as it contains all the poisonous principle of the mushrooms. Rinse the mushrooms well and boil in water for a quarter of an hour. Wash them in hot water and prepare in the usual way.

GENERAL ITEMS.

Mr. D. H. Maury, engineer and superintendent of the Peoria Waterworks Company, Illinois (U.S.A.), writes as follows to *Engineering News*:—In your issue of 11th May, I note an abstract from a paper read by Mr. Ernest R. Woakes, before the American Institute of Mining Engineers, the

item quoted relating to the necessity in the tropics of felling timber during the waning moon. I can entirely corroborate Mr. Woakes's statements in this connection, and I am all the more glad to do so because he is an old friend, as I happened to be for several years engaged in engineering work near him in Columbia, South America. It was an absolutely invariable rule there that all timber should be felled in *menguante*, or during the waning of the moon. The *creciente*, or the periods of the moon's increase, was employed in sawing the felled timber, all work having to be done by hand with a pitsaw. I have repeatedly tested the effect of the tropical moon on timber. On one occasion, in building a fence of the native bamboo, I had all the bamboo cut from the same thicket, and felled it all, except enough for one panel, during the waning moon. This one panel, which was cut while the moon was waxing, turned black in a few days, and had begun to rot in less than six weeks. The rest of the fence grew white and hard, and was in perfect condition when last I saw it, some three years after it was built. In making clearings for mining work, I have frequently noticed the rise and fall of the sap in the stumps of the felled trees, and have observed the sap to continue during each *creciente* to run out of the pores on the top of the stump down the sides of the stump for several months after the tree had been felled. During *menguante*, the same stump would be dry.

A writer in the *Australian Pastoralist's Review* says:—As I am a firm believer in the efficacy of the divining rod, your article on it in the *Review* of the 15th instant attracted my attention, as it should that of all who have to do with sinking for water in dry country. Sceptics may scoff, and unbelievers laugh as they like, but I assert there is a virtue in the divining rod; that it will indicate where underground streams are flowing, and that with certainty and accuracy when used by a person in whose system there is more than the average amount of electricity. The person holding the rod is, as it were, the battery, and, by holding the rod (I use a copper wire bent in a semicircle) at arm's length with one end of the rod towards him, will continue to attract it until he passes over something possessing a greater power of attraction than his body. If you hold the rod so tightly in your hand that it cannot twist round, it will rise up fully 45 per cent. if the subtle power arising from the earth be fairly strong. Upon one occasion, when experimenting with the rod in the south-west of South Australia, it rose to perpendicular, and then dipped slightly from me. When you have passed beyond the greater attraction than is possessed by the "diviner," the point of the rod will turn towards the holder. I have found the rod work better in summer than winter—sultry weather for choice.

Says an *Exchange*:—There are four items which every owner of cows should constantly remember. The first is to keep a record of the milk production of each cow for a year (if he can record the butter yield and cost of food for each, so much the better). The second point is to prevent the production of horns on his young cattle by

removing the hair around the "bosses" where the horns would be produced, then damp lightly with water, and rub only on the bosses with lunar caustic until the skin appears inflamed—about two or three minutes. The third point is to remember that a tablespoonful of carbonate of soda in a winebottle of water, if administered to an animal which has eaten grain, lucerne, clover, or other food causing it to be "blown" (otherwise called "tympantitis," or "hoven," or "blast") will at once remedy the evil. Lastly, when a cow is attacked with "milk fever" after calving, the best remedy is to give her at intervals of three hours two doses of brandy and water—about half-a-bottle at each time—and keep the bowels open.

A writer in an American sporting journal gives the following rule to estimate the height a colt will grow to:—Take a colt at any time between six weeks old and one year; stand him on a level surface, so that he will stand naturally, then measure the distance from the hair of the hoof to his knee-joint, and for every inch, or

fraction thereof, he will be hands high when matured. If he measures 15 inches he will grow to be 15 hands high; if 15½ inches he will be 15½ hands high; and so on.

The remedy for soft butter is as economical as simple. Purchase an 8 or 10 inch common, unglazed flowerpot. Wash thoroughly in clear water, then let it stand for an hour submerged in as cold well-water as can be procured. When saturated, drain a few minutes by turning the pot upside down. Prepare your butter on a plate a few hours before meal-time. Fit a cork into the hole in bottom of the pot to exclude all hot air.

Try this remedy for warts: Saturate the warts every few days with pure castor oil and they will disappear, leaving the surface as smooth as though they were never there. We have known of several cases where warts were removed from the nose of colts by simply rubbing them with lard occasionally.

REMEDIAL MEASURES AND INSECTICIDES.

By E. E. GREEN, GOVERNMENT ENTOMOLOGIST.

(Continued from page 231.)

BEFORE quitting the subject of general remedial measures and entering upon detailed descriptions of particular processes, something should be said upon the important question of the introduction of 'natural enemies' of the *Coccidee*. The same circumstances that make an imported pest so exceptionally dangerous act in our favour in the importation of beneficial insects. Just as the absence of its established natural enemies enables an insect pest to multiply without hindrance, so the introduction of a beneficial insect without its own natural checks will also permit of its rapid increase as long as an ample supply of congenial food is obtainable. When the food supply begins to fail, which means when the pest has been mastered by its imported enemies, then they will both decline together. There need be little fear that, when the food supply has been exhausted, the imported insect will itself become a pest. A predatory insect, by which is understood one that preys upon other insects or animals, will seldom, if ever, alter its diet and become a vegetarian.

It is noticeable that an insect seldom assumes any importance in its original home, unless through some accidental or artificial interference with the balance of nature in that part. (For instance, it has been asserted that the widespread destruction of moles in England has resulted in a marked increase of damage to pasture land from the grubs of the 'cockchafer' beetles and 'crane-flies,' upon which the moles fed.) Consequently, if we are to obtain any benefit from the use of natural agents, we must endeavour to reproduce the conditions prevailing in the country where the insect in question is known to occur, though without attracting notice as a pest. Or, if the original home of the injurious insect is unknown, we may reasonably hope for good results from the introduction of an insect that is found to prey upon some allied pest in another country.

The most important natural enemies of the scale insects, or, at least, those that have attracted most attention, belong to a family of small beetles popularly known as 'lady-birds.' The complete success attending the introduction of an Australian lady bird (*Redalia cardinalis*) into California, where it cleared the orange orchards of the destructive 'Fluted-scale' (*Icerya purchasi*) has led to numerous other experiments of a similar kind. These experiments have not always been successful. There must, of necessity, be many failures. We are still only in the experimental stage of the work. Even when the beneficial insects has been successfully established in a country, it is by no means certain that it will thrive. There may be climatic or other conditions against it. In that case, all we can do is to try another insect. Occasional, or even repeated, failures should not discourage the repetition of the attempt. The value of a single success will far outweigh the cost of many failures. In the course of such experiments the causes of failure will in time be ascertained, and improved methods be employed. The freezing method recommended by Mr. Kœbele seems to be rather an uncertain one, and has led to many disappointments. I am inclined to hope for more satisfactory results from the employment of 'Wardian cases,' as suggested to me by Mr. Lounsbury. In these the insects will remain active and be supplied with food. There are certain obvious dangers connected with this method, such as the possible introduction of the insect pest upon which the 'lady-birds' have been supported during the voyage. For this reason the business should be conducted under the supervision of trained entomologists only. In choosing the food supply, an insect that already occurs in the country to which the lady-birds are consigned should, if possible, be selected.* But, under any circumstances, the imported beetles should not be liberated immediately, but should be transferred to fresh breeding cages and supplied with local food, and the cage in which

* In a recent consignment of 'lady-birds' received from the Cape of Good Hope, the cochineal insect (*Coccus cacti*) was very judiciously chosen for the purpose. This insect is practically confined to the 'Prickly Pear' cactus, and is therefore not liable to become a pest.

they arrived should at once be thoroughly disinfected. In sending stocks by Wardian case, the larvæ of the beetles may with advantage be included. These will complete their transformations during transit, and are more likely to survive the voyage than the adult insects.

There are other natural enemies of the Coccidæ that may some day be advantageously employed in the same way. Amongst the two-winged flies (*Diptera*) we find the *Lestophonus iceryæ*, which attacks the 'Fluted-scale.' Nearly every species of scale insect is subject to minute internal parasites belonging to the wasp family (*Hymenoptera*). The family *Neuroptera* supplies the 'Lace-wing flies,' the larvæ of which are known as 'Aphis-lions,' from the voracious way in which they feed upon Aphides and scale insects. Even the butterflies and moths (*Lepidoptera*) provide a few coccid-eating species, such as the caterpillars of the butterfly *Spalgis epinus* end of several months of the genus *Eublemma*. The 'lady-birds' are included in the family *Coleoptera*.

Besides natural enemies belonging to the animal kingdom, scale insects are subject to diseases belonging to the vegetable world. There are several parasitic fungi that render great assistance in reducing the numbers of our Coccid-pests. In Ceylon, during the wetter months of the year, the 'green bug' (*Lecanium viride*) dies off to a large extent, attacked by a greyish mould which, after killing the insect, spreads outwards as a delicate fringe of interlacing whitish threads. A bright orange-coloured fungus (*Septoria* ? sp.) is useful in checking the increase of (*Fiorinia florinica* and *Chionaspis biclavata* on the tea plant, and *Aspidiotus aurantii* on orange trees. A very similar fungus (*Sphaerostilbe coccophila*) that attacks *Aspidiotus perniciosus* in Florida (U. S. A.) has been the subject of some very interesting experiments to test the possibility of communicating the disease to previously healthy colonies of the insect. Dr. L. O. Howard gives the following particulars of the experiments:—

'An interesting and important development of the past two seasons' work has been the identification and study of the parasitic fungus, *Sphaerostilbe coccophila*, Professor Rolfs, of the Florida Station, has devoted a bulletin largely to the consideration of this fungus, which, as previously stated, seems to be prevalent throughout the Southern States. He has shown experimentally that the fungus may be transferred to trees affected with San Jose scale, and the disease produced among the scales. His process was to inoculate acid bread with pure cultures of the fungus, and three weeks later the application was made in the following way:—A piece of the bread about an inch square was placed in cold water, and shaken until the bread was broken up and the spores distributed in the water. This water was then applied to the scaly tree by means of a sponge or cloth, or sprayed on. The applications were made in Midsummer of 1896, and observations were made as to the results late in February, 1897. Four of his experiments resulted successfully, and three unsuccessfully, while in the eighth experiment the result was doubtful on account of the tree having died between the times of treatment and inspection. Twigs from Florida containing San Jose scales, infested by the fungus, were sent to Mr. Horace Roberts, at Fellowship, N. J., about the middle of June. On September 25th Dr. Smith found the fungus upon almost, if not quite, all of the trees on which twigs had been tied. A number of instances have come to our observation of the death of the scale in a wholesale manner from the spontaneous work of this disease, or from some other cause. For example, we received scale-infested cuttings in January, 1897, from an orchard which was said to have been freed from scales by this fungus disease. Careful examination showed that upon one cutting, out of 183 scales, but four were living; on a second cutting, out of 723, but two were living; on a third

cutting, out of 579, but twenty-eight were living, thirty-four living scales out of 1485—a mortality rate of 97.7.'

I have, myself, repeatedly succeeded in disseminating the disease affecting *Lecanium viride* by tying branches with diseased insects on to trees on which the bug had hitherto remained quite healthy.

There are several methods by which spores of these parasitic fungi may be disseminated. As in the last-mentioned experiment, they may sometimes be communicated by merely transferring affected branches to the neighbourhood of the healthy insects. In such cases the spores are carried by the wind to their destination. But in some of these fungi the spores are gelatinous and agglutinated, in which case the wind would fail to disperse them. Fungi of this kind may be crushed up in water and used as a spray; or artificial cultures may be made and mixed with water, to be used in the same way. In the ordinary course of nature these gelatinous spores are probably carried from tree to tree on the feet of birds.

GENERAL LIST OF SUBSTANCES AND PROCESSES EMPLOYED IN THE TREATMENT OF SCALE INSECTS.

THE GAS TREATMENT.

Hydrocyanic acid gas is the material employed in this process. It is generated by the admixture of cyanide of potassium, sulphuric acid and water. For the details of treatment I cannot do better than quote in *extenso* from the admirable paper on 'Gas Treatment for Scale Insects,' compiled by Mr. C. P. Lounsbury from his personal experience as Government Entomologist at the Cape of Good Hope. The process described was principally employed against *Aspidiotus aurantii*—an insect that appears to be distinctly on the increase in Ceylon. I may add that I have followed Mr. Lounsbury's directions in my own experiments with most satisfactory results.

'Generation of the Gas.—Hydrocyanic acid gas is generated by the action of sulphuric acid on potassium cyanide in the presence of water. The required quantities of the cyanide and water are first placed in the generating vessel, the cyanide being broken into small pieces not above the size of lump sugar. The tree is then covered with the tent or sheet and vessel slipped under almost to the base of the tree; reaching in, the operator then adds the acid, pouring it slowly into the vessel so as to avoid its splashing on thus burning his hand or the cloth. He immediately withdraws and the men shovel a little soil on the edges of the cloth all around, to more thoroughly prevent the escape of the gas.

'The rapidity of the evolution of the gas depends largely upon the size of the pieces of cyanide. If these are like powder, the reaction is violent and immediate; but, if in lumps, the reaction takes place more slowly and continues for a minute or longer. The slow reaction is desired, partly because less injury results to the foliage immediately above the vessel. But the lumps must not be too large, for then the reaction is liable to be imperfect owing to a black coating (carbon?) forming over the lumps and preventing further decomposition by the acid. The water should not be added too soon or part of the cyanide becomes dissolved and gives a violent reaction. The residue which remains in the dishes is buried and; the dishes are washed in clean water before being again used.

'Time necessary for Treatment.—The cover is left over the tree for thirty minutes in the case of small trees, and forty-five in the case of those over twelve feet in height. At the expiration of this period the generating vessel is removed, and the residue buried in the soil.

'A number of trees are fumigated together, the endeavour being to treat as many at a time as can be covered and uncovered during the period of exposure. In this way the men are kept continuously busy, the time for the removal of the first tent arriving by the time that the last tree is covered.

* *Bulletin*, No. 12. (New Series.) U. S. Department of Agriculture (Division of Entomology).

'Absence of Sunlight necessary.—The origiuators of the fumigation process observed that the gas was most efficacious, and that less injury resulted to the foliage when the operations were performed at night than when they were carried on in sunlight. It is said that chemical changes are produced in the gas by the action of sunlight, and that the resulting gases are more injurious to the plant life and less to animal than hydrocyanic acid gas. Whether or not these theories are correct is of small practical importance, for the foliage of a tree will suffer serious injury if the tree is left covered with an air-tight oiled tent for half an hour in sunlight, without the gas being present. Having ascertained this fact by experience, the foreman in charge of the Board's outfit refrained from covering trees until the sun had sunk from sight on any but cool, dull days. The great majority of the trees treated have been fumigated after sunset. The ideal night for fumigating is quiet, cool, and moonlight, and without dew.'

It is evident, from the above that the period available for this process is somewhat limited. However, when only a few trees have to be treated, the hour immediately preceding nightfall will be ample for the purpose. I have personally found no ill effects following the operation when performed on dull, cloudy days, when the sun is entirely obscured.

Although hydrocyanic acid gas will certainly kill every insect—and even their eggs—if used in sufficient strength and for a sufficient length of time, both the necessary strength and time will be found to vary with different species of insects, and must be made the subject of careful experiment. I find that *Orthesia insignis* is a very difficult insect to kill, and requires a double strength of gas, continued for fully three-quarters of an hour.

Mr. D. W. Coquillet, one of the first to employ this process, gives the following directions for making an air-tight tent:—'The material commonly used in the construction of the tent is what is known as blue or brown drilling. A few persons have used ducking instead of drilling, but this is much inferior to the latter; in the ducking the threads extend only lengthwise and crosswise, whereas in the drilling they also extend diagonally—this belonging to the class of goods to which our merchants apply the term "twilled"—and for this reason the drilling is both stronger and closer in texture than the ducking.

'After the tent is sewed up it is given a coat of black paint, as it has been ascertained that tents treated in this manner last longer than those which have been simply oiled with linseed oil. Some persons mix a small quantity of soap-suds with the paint in order to render the latter more pliable when dry, and therefore less liable to crack. Instead of thus painting the tent some persons simply give it a coating of size. Sometimes a small quantity of whiting or chalk is added to this sizing, with or without the addition of lampblack. A few make use of the mucilaginous juice of the common cactus (*Opuntia Engelmanni*) for this purpose. To obtain this, the cactus leaves or stems are cut or broken up into pieces, thrown into a barrel, and covered with water after which they are allowed to soak for three or four days. The liquid portion is then drawn off, and is ready for use without further preparation. Tents which I saw that had been prepared with this substance were to all appearances as air-tight and pliable as when prepared in any other manner.'

For the oiling, Mr. Lounsbury recommends a mixture of four parts boiled linseed oil to one part turpentine. The cloth should be first well wetted with water, and the mixture spread lightly over the surface with a brush. A thin coating is found to be sufficient. Mr. Lounsbury has since informed me that he now uses, with completely satisfactory

results, tents made of cloth merely shrunk in water, without any subsequent oiling. Such tents are, of course, much lighter and more easy to manipulate. Mr. Coquillet gives the annexed table, showing the quantities of chemicals required for different-sized trees.

Height of tree.	Diameter of tree top.	Water.	Sulphuric acid.	Potassium cyanide.
Feet.	Feet.	Fluidoz	Fluidoz.	oz.
6	4	2 ³ / ₈	1 ¹ / ₈	1 ¹ / ₈
8	6	2	1	1
10	8	4 ¹ / ₂	2 ¹ / ₄	2 ¹ / ₄
12	10	8	4	4
12	14	16	8	8
14	10	10	5	5
14	14	19	9 ¹ / ₂	9 ¹ / ₂
16	12	16	8	8
16	16	29	14 ¹ / ₂	14 ¹ / ₂
18	14	26	13	13
20	16	36	18	18
22	18	52	26	26
24	20	66	33	33

Mr. Lounsbury, after practical experience at the Cape, publishes the following figures, from which it appears that he found smaller quantities sufficient. This is doubtless, due to difference in purity of the chemicals. Mr. Lounsbury was working with cyanide of 98 to 100 per cent. purity, while Mr. Coquillet was using cyanide of only 33 to 58 per cent. It is therefore important to know the exact amount of pure potassium cyanide in the particular brand employed.

Height.	Diameter.	Water.	Acid.	Cyanide.	Space enclosed.
Feet.	Feet.	Fluid oz.	Fluid oz.	oz.	Cubic feet.
4	3	1 ¹ / ₄	1 ¹ / ₄	1 ¹ / ₄	25
6	4	2 ¹ / ₄	2 ¹ / ₄	2 ¹ / ₄	65
8	5	1	1 ¹ / ₂	1 ¹ / ₂	140
8	6	1 ¹ / ₂	1 ¹ / ₂	1 ¹ / ₂	200
10	6	2	1	1	255
10	8	3	1 ¹ / ₂	1 ¹ / ₂	435
12	8	3 ¹ / ₂	1 ¹ / ₂	1 ¹ / ₂	535
12	10	5 ¹ / ₂	2 ¹ / ₂	2 ¹ / ₂	815
14	8	4 ¹ / ₂	2 ¹ / ₄	2 ¹ / ₄	635
14	10	6 ¹ / ₂	3 ¹ / ₄	3 ¹ / ₄	970
14	12	9	4 ¹ / ₂	4 ¹ / ₂	1355
16	10	7 ¹ / ₂	3 ¹ / ₂	3 ¹ / ₂	1130
16	12	10 ¹ / ₂	5 ¹ / ₂	5 ¹ / ₂	1585
16	14	14	7	7	2105
18	12	12	6	6	1810
18	14	16	8	8	2415
18	16	20	10	10	3085
20	14	18	9	9	2720
20	16	23	11 ¹ / ₂	11 ¹ / ₂	3485
20	18	29	14 ¹ / ₂	14 ¹ / ₂	4325
22	18	32	16	16	4835
22	20	39	19 ¹ / ₂	19 ¹ / ₂	5865
24	20	43	21 ¹ / ₂	21 ¹ / ₂	6500

The gas treatment has been largely used in combating scale insects (Particularly *Aspidiotus auranti*) on orange trees. It will be found the most effectual method for exterminating *Orthesia insignis*, or any other insect, upon individual trees.

SOAP AND SOAPY EMULSIONS.

Soap by itself has considerable insecticidal properties. In fact, in many popular mixtures, it is extremely probable that the soap is the most efficacious ingredient. It acts by asphyxiation, forming an impervious film over the breathing pores of the insects.

Whale-oil soaps are found to be the best for the purpose. In *Insect Life*, vol. vii, p. 369, the following conclusions are drawn from numerous experiments upon trees infested with the San Jose scale (*Aspidiotus perniciosus*) in America;—'Soap washes

* U.S. Department of Agriculture (Division of Entomology). *Bulletin*, No. 23.

particularly of whale-oil soap, have yielded the most satisfactory results; and at the rate of two pounds to the gallon, under the conditions of thorough drenching of the entire plant, with five or six days of subsequent fair weather, will destroy all the scales, whether applied in fall or in spring. The results with soap in less strength indicate that under the most favourable conditions the same result may be reached with mixtures containing only a pound and a half or more soap. The action of the soap at the rate of one pound or more to the gallon, applied in the fall, is generally to prevent blooming and fruiting the following spring, but the vigour and healthfulness of the tree are greatly increased. Applied in spring at the time of blooming, it does not injure the plant nor affect the setting of the fruit to any material extent in the case of the peach, and not at all in the case of the apple.

The experiments, as a whole, indicate the vastly superior merit of the soap wash and its fall application. The great vigour of the plant resulting from the fall treatment more than offsets the possible failing of bloom. Owing to the impossibility of controlling weather conditions, and the practical difficulty of wetting every part of the plant, one spraying cannot often be relied on to accomplish the death of all the scales, but two conscientious drenchings may be expected to accomplish this result. These may be (1) at the time of, or shortly after, the falling of the foliage in autumn, and (2) just before blooming in spring.*

Other soaps (hard laundry soap) are efficacious, but not to the same degree.

In another of the American reports* is an instructive paper on insecticide soaps, by Mr. C. L. Marlatt, from which I take the liberty of quoting largely:—The decided insecticide value of the so-called whale-oil (more properly fish oil) soaps, against scale insects particularly, has been fully demonstrated in the last few years in the work against the San Jose scale and has fully substantiated Professor Cornstock's early recommendation of this means of controlling scale-insect pests. The merit of these soaps is not only in their effectiveness as insect-destroyers, but from their being entirely without injurious effect on the treated plant. In this respect they are perfectly safe in the hands of any person, in contradistinction to all oily washes, which are very liable to be injurious in greater or less degree, although the injury may be insignificant or perhaps not apparent immediately, or during the first season. 'The use of soaps is attended with certain difficulties.' 'To be satisfactory for insecticide use it must, when dissolved at the desired rate, say two pounds to the gallon of water, remain a liquid capable of being sprayed with an ordinary nozzle at an ordinary temperature. This may be determined by a very simple test, and one which should be invariably given any soap before it is accepted for spraying operations. It consists in simply dissolving a small quantity of the soap at the desired rate, and allowing it to cool.'

Many soaps solidify or become gelatinous and fenacious on cooling. These are useless for spraying purposes. The common country soap of Ceylon has this defect. I have experimented in a small way with soap mixtures; but it is difficult to obtain here a brand that combines suitability with cheapness. Such a brand is a great desideratum. I find that one of the most useful properties of the soap mixtures is to prevent the escape of the young larvæ by blocking up the natural exists, and on this account the treatment is to be very strongly recommended.

(To be concluded)

GESTATION OF THE ELEPHANT.

Sir, Our Burma mahouts invariably maintain that the period of gestation in the elephant extends to

* *Bulletin*, No. 6 (New Series), U.S. Department of Agriculture (Division of Entomology).

three years. It may, therefore, be of interest to put on record an observation bearing on this statement.

Forest elephants in Burma are simply hobbled and turned loose in the nearest jungle to feed, and hence, unlike the Commissariat animals, are practically in a state of nature, and breed freely.

In June 1897, one of the mahouts reported that his elephant had been covered by the tusker attached to the division, whilst the animals were turned out to feed. The act was observed every evening for about a week, from about the 18th to the 25th May, 1897. Neither of the animals showed signs of sexual excitement previously, though the male paid assiduous court to the female for a few days before coition was permitted. They were both at work at this period—dragging logs—and gave no trouble to their attendants. The report was noted, but, I am sorry to say, forgotten, till the 3rd November 1898, when in the evening, the elephant gave birth to a female calf.

Fortunately, that day she had only carried a light load for a short march. The baby, though so weak that it had to keep itself upright by holding on to a bamboo with its mouth, was perfectly healthy and well formed, and after a day, could stand and suckle. The period of gestation, therefore, had been a little over seventeen calendar months, or almost exactly eighteen lunar months.—C. B. S.—*Indian Forester*.

JOB'S TEARS (*COIX-LACHRYMA-JOBI*)—A USEFUL FODDER.

By F. MANSON BAILEY, F. L. S., COLONIAL BOTANIST.

During Lord Lamington's tour round New Guinea in May last, at almost all the places visited was seen a luxuriant growth of the grass known as Job's Tears (*Coix Lachryma-Jobi* of the botanist). The growth of the plant and the beauty of its seeds made such an impression on Lord Lamington that he requested me to take seeds of each to Queensland for cultivation, which I did; and the accompanying plate illustrates the product of a single seed sown in my garden at Spring Hill, is by no means favourable soil or situation for foddergrowing. The plant represented comprised 26 stems from 2 to 4½ feet high, leafy throughout their whole length—in fact, it is a model fodder plant, suiting the climate both North and South of the colony and from this point of view is now brought to the notice of dairy men and farmers generally. The present form seems to be of a more succulent character than that generally found in garden culture. The two kinds met with in New Guinea differed considerably in the form of the seed—The one being tear-shaped, and the other linear or oblong; both are usually of a bluish-grey colour. The stems of each, from a single plant, are numerous and very leafy. So far as I have been able to judge, the long-seeded form is of smaller growth but my seeds of this were sown later than those of the other. I may remark that I have had specimens of this grass sent to me for determination from different parts of Queensland by persons who have met with it in a naturalised state, but whether these belonged to the New Guinea forms or not I cannot say. One advantage possessed by this plant over sorghum is that it does not make so strong a root, so that when necessary to plough out to renovate the plantation it will not form so strong a resistance to the work as the varieties of sorghum. The stems are also more slender and not so coarse. In sowing the seeds, place them about 1 foot apart in rows 2 or 3 feet asunder, during the months of September and October. The plants being perennial they will last for several years without renewing. The plant may also be increased by divisions of the stool, which allows of vacancies in the plantation being filled up.

The natives of New Guinea seem only to use "Job's Tears" for ornamentation purposes, the pretty bluish grey seeds being prized for making into necklaces and decorating their weapons, &c. I could not hear of the seeds being used for food by them, yet Sir J. D.

Hooker tells us that the plant is cultivated in India for this purpose; therefore in all probability the seed of the two New Guinea forms may be put to the same use in some parts of the island. Duthie states that in Oadh (India) the plant is largely eaten by cattle, and is said to be very fattening.

THE VANILLA BEAN.

This valuable product, which is highly prized for making extracts of perfumery and in cooking, has, within the past few months become very scarce, and the price, in consequence, has advanced to three times what it formerly sold for. Nothing has ever been found to take its place in cookery, or for perfumery, and consequently the price must remain high for some years to come, as it takes three years for the plant to come into bearing, after which it continues in fruit for several years, improving from year to year, if well cared for.

A recent published statement says that the shortage of 1894 was due to a frost, which destroyed whole plantations. Then in 1895 a clash between the Indians, who occupy and cultivate the large plantations around Papantla, Mexico, the centre of this industry, and the Mexican authorities, who own the lands, resulted in the former being driven out, but not before they had succeeded in almost entirely destroying the vanilla plants as revenge. These two causes account for the shortage, as it requires three or four years before a plant will yield fruit. This shortage is much greater than is generally known. The present price of beans is \$16.00 per pound, and it is not unlikely that it may advance to \$18 or \$20.

We have several times urged the planting of vanilla as a minor industry, as it will flourish here in almost any locality, where it has plenty of water, but is particularly adapted to the rainy sections of Hawaii. Although it requires three to four years for the vines to come into full bearing, it will then pay better than almost any other industry, that does not require much capital. Nor will it interfere with any other light work, and is particularly suited to females. In a future issue we will give some particulars regarding its cultivation and mode of curing the beans. — *Planters' Monthly*.

PARA RUBBER AND THE GOVERNMENT.

The following is the official report of a discussion on the supply of Para rubber seeds from Singapore at the U. P. A. at Selangor on Aug. 14th,—

The Chairman said that, in consequence of the attitude taken by the Singapore Government with regard to the supply of rubber seed to applicants from the Federated States, he had interviewed the Colonial Secretary in Singapore and had been told that, in booking orders for rubber seed from planters in the Native States, Mr. Ridley had acted without authority from Government, and it was the intention of the Singapore Government to repudiate his action, as all orders for seeds from the Colony must be first executed. In consequence of this it had been decided at a Committee Meeting, held on the 22nd May last, that a sub-Committee consisting of the Chairman, Secretary and Mr. Bailey should interview the Resident-General, laying all the facts of the matter before him for consideration and asking for his advice and support. (He the Chairman) and Mr. Bailey had seen the Resident-General, who said that those applicants who held no distinct promise in writing from Mr. Ridley had only a moral claim against the Government, and he doubted whether it could be enforced, but the case of Mr. Bailey was very different and he did not see how it could be disputed. That was how the matter stood so far, but Mr. Bailey would tell them what his case was and what action he was taking.

Mr. Bailey said that early in 1897 he ordered 500,000 Para Rubber seeds from the Botanic Gardens, Singapore, and on 1st April, 1897, Mr. Ridley wrote

saying he would supply him with that number as soon as he could at \$10 per 1,000. As he was forming a Company to plant rubber in Selangor, he wrote officially to Mr. Ridley on 12th August, 1898, asking him what number of seeds he could supply him with from 1st September, 1898, to 1st September, 1899, as it greatly depended on the number of seeds available as to whether the Company went through or not. In reply Mr. Ridley said he would be unable to supply the complete order from the present crop, but, as he was the pioneer of the cultivation, he would guarantee that he should have half each crop of seed till his orders were filled. The present crop of seed is expected to be 150,000 yet he is now offered only 15,000, which is a very different thing to above promise from Mr. Ridley.

The Resident General, at the interview mentioned by Mr. Carey, had stated that he had already put the matter into the hands of his lawyers.

The Chairman said he hoped the meeting would express their willingness to support Mr. Bailey in his action.

Mr. Lake asked if this expression was meant to imply that the Association should support the action in a momentary sense if necessary.

The Chairman said he certainly considered so, but there was not much likelihood that such help would be required.

The proposal met with the unanimous approval of the meeting.—*Singapore Free Press*.

POSSIBLE INDUSTRIES IN TRAVANCORE.

ANOTHER LAND OF PROMISE.

A correspondent writing to the *Madras Mail* urges the small capitalist to look to Travancore and take note of the possibilities that exist there for the successful cultivation of low-country products. As an inducement he leads off with a noteworthy example of what a small man at one time actually did.

THE FOUNDATION OF ONE FORTUNE.

The late Mr. Darragh, he says, started business in Travancore a little more than a quarter of a century ago with the very slenderest capital, and confining his operations chiefly to the products of the coconut tree died an extremely wealthy man. Not long before he died he turned his attention to cotton, and opened a mill in Quilon, which is still flourishing, although the cotton has to be conveyed to it all the way from Tinnevely. Labour, however, is so abundant and so cheap that the mill is said to be thriving concern.

ANOTHER FORTUNE GOING BEGGING.

A part from the mill industry in cotton, which is in the position of being some what overdone, it is puzzling why the enterprising European capitalist has not attempted to work coir and copra by machinery. In Travancore, with its vast output of capra and coir, the most primitive and unsatisfactory methods are still in vogue in extracting coccoot oil and in cleaning and weaving the coccoot fibre into rope, and it was by exporting these materials that Dr. Darragh scored such a brilliant success. The establishment of an oil mill or two with other machinery for dealing with the fibre, would make the fortune of the first person who supplied these wants. Both water-power and steam-power are available, and fuel is as cheap as it can practically be any where, where it is not to be had for the mere gathering.

WHAT A FEW SAW-MILLS COULD DO.

Again any European who turned his attention to the vast timber supplies of the State would find it paid him Timber for railway sleepers is now selected from a limited variety, viz., sal, teak, deodar, payngadu and pine. Another writer in the *Madras Mail* calculates that at least three million railway sleepers are wanted annually in India for renewal and extension work, and state that a saving of one rupee on a sleeper represented a sum of thirty lakhs of rupees saved! All this shows that only a little energy and plenty of

capital is necessary to make the timber trade—more or less stationary and languishing in the absence of enterprise—flourish and bring in to the State and to the speculator a large income.

THE HUMBLE PLANTAIN,

is also held out as a Travancore Bonanza. We quote:—It may interest some to learn that great possibilities exist in the cultivation and exportation of the plantain and its products. The fruit is now largely consumed in Europe, and it ought to be a matter of no great difficulty to establish on a firm footing a trade in this product from Travancore. Plantains in their raw condition plantains preserved, plantain flour, plantain fibre, etc., should bring in some profit. In fact, the value of Travancore as a great fruit-producing country is lost sight of.

THE POSSIBILITIES OF THE PINE.

Pineapples, for instance, grow with the greatest luxuriance, and are to be had in the season for the ridiculously low price of three pies per pine. The fibre is said to be particularly strong and silky, and is adapted for various kinds of manufactures. *Commerce* says it is a good substitute for flax and that a certain quantity of the fibre "prepared in Singapore tested against an equal quantity of flax sustained 350 lb., while the latter could not bear more than 260 lb." It is also said to be substituted for silk, and that an excellent linen is made from it.

OTHER PRODUCTS AWAITING THE CAPITALIST.

Waiving for the present all notice of pepper, ginger, and other garden produce attention may be drawn to the vast quantities of tapioca root available, which forms the staple food of the poorer classes, with rice. Very few people have any idea that the arrowroot plant grows wild in Travancore, and that enterprise only a needed to develop the trade in this root. There are various other substances in the shape of vegetable oils of sorts—laurel oil—gums and resins, indigo, etc., Lem n grass oil has been manufactured to some extent, but as it forms a good base for perfumes, essential oils and etc., greater opportunities in regard to its use might be seized. Travancore has now a European Government contractor in Mr. Mitchell, who appears to have his eyes open and when the long expected railway becomes an accomplished fact a greater number of enterprising men may give an impetus to local trade. The possibilities of paper manufacture in a land where material, fuel, water-power and a constant demand exist was long ago recognised by the formation of a Joint-stock Company and the construction of a mill on which lakhs of rupees were spent. After a time, the manufacture of paper was discontinued, for what reason is not quite apparent to the uninitiated. The plant lies idle, and the Company is moribund without any attempt being made to resuscitate the working, or wind up the affairs of the shareholders. If this letter, concludes the writer, will help to remind some energetic shareholder of his wasted money and his opportunities, it will not have been written in vain—*Madras Mail*.

DURBAN BOTANIC GARDENS.

A CURIOSITY, A BLACK BOY.

Mr. J. Medley Wood reports:—Since the date of my last report the weather has been exceedingly dry, only 0.91 in, having fallen at the Gardens since May 23, and during the August 0.22 in, only was registered. In consequence of this very unusual drought many of the plants in the Gardens are drooping, and flowers are exceedingly scarce. In addition to the usual routine work, which has been very heavy, some of the hands have been engaged in oiling the woodwork of the Palm-house and giving the class another coat of paint, as the coat first given has been found to be too thin; this work is now nearly completed,

The plant of *Xanthorrhoea hastilis*, the "Grass Gum Tree," or "Black Boy," a native of New South Wales has sent up a flowering spike from the centre of the rosette of leaves. This spike is now several feet high, and is thickly covered with hundreds of small white flowers, and is a curiosity not often seen in South Africa, a photo has been taken of it, and I suggest that it shall be reproduced in the annual report. It is to be hoped that we shall not lose the plant, which is the only one we have, and is much admired by visitors. It can hardly be less than 25 years old, and is probably more than that. [The name "Black Boy," says a correspondent to ourselves (*T.A.L.*) is only applicable as regards the appearance assumed by the plant in its native habitat, the Australian prairies, where its stout trunk becomes blackened both by bush fires and by a resinous excretion on the trunk, when seen thus in groups at a distance they have a weird appearance, which readily suggest the black aborigines. The gummy exudation from the trunk is made use of as a gum; hence the plant is also known by the name "Grass-gum tree." It belongs however, to the Lily tribe, and not to the grass-family, although its large crowns of thin, long, wiry leaves have much the appearance of grass.] One of the trees of *Aleurites triloba* has been felled for the purpose of testing the wood, the trunk to the lowest main branch measured 24 ft. with a girth at 10 ft. from the base of 6 ft.

Two cases of deaths of cattle from supposed poisoning have occurred lately on the Berea. The first I did not hear of until too late, but as the second case, when two valuable cows were lost, was brought to my notice in time, I visited the locality in which the cattle had been grazing, the herd boy being with me to point out the exact place. Unfortunately the whole, or almost the whole, of the underwood had been lately cut down. I think by the Corporation gang of labourers, but after some little search I found that many plants of *Moracairidioides* had been bitten off, and the herd-boy assured me that he had seen the cattle eating the plant, and that no other cattle had, to his knowledge, been grazing near. I am not aware that this plant has poisonous properties, but the species known here as "Tulip" or "Tulip" all belong to the genus *Moraea*. It would, I think, be advisable that this plant should be chemically examined. The native say that this plant is not usually eaten by cattle.

I have received from Mauritius two cases containing many valuable plants. The steamer which brought them was placed in quarantine, and the cases were taken on to East London, and returned to us from that port by another ship, but I was pleased to find that the plants had not suffered very much damage from the long detention. From Botanic Gardens of Cambridge I have received a valuable case of plants, chiefly ornamental, which arrived in excellent condition. I have also received packets of seeds as under:—Guina, 1; Kew, 1; Paris, 6; Mysore, 1; Sumatra, per Mr. Van Leenhoff, 19; Adelaide, 84; Bangalore, 1; Zomba, 1; St. Albans, 1; Mr. J. Benington, sweet lemon and mango; Mr. M. Matthews, bulbs.

For the Colonial Herbarium the second part, completing the first volume of "Natal Plants," is now ready and may be obtained from the booksellers, or on application at the Gardens. The first part of the second volume, which is confined to the grasses of the Colony, and will contain 25 plates and descriptions, is in the printer's hands, and will be ready in a few weeks' time; and the third volume, which will be similar to the first, is in progress. I have received parcels of dried specimens of foreign plants from South Australia, 81 specimens; Sydney, 200; Queenstown (chiefly Transvaal plants), 212; and from Mr. J. F. Quekett 16 specimens of foreign mosses; and I have sent away parcels of dried specimens of native plants as follows:—M. Eysn, O. E. Meuzel, J. H. Maiden, J. F. Duthie, Dr. J. B. Palacky, Biltmore Herbarium, Field Columbian Museum, and to the United States National Herbarium, two parcels.—*Natal Mercury*.

THE VELVET BEAN.

So much has been heard of late of the Velvet Bean as a green dressing, &c., that the following extract from *Louisiana Planter* of 4th March, 1899, will be of interest. The plant has been imported by the Botanical Department, and has produced a fair crop of seed, but not sufficient for general distribution. During the year a section will be set aside at the experiment grounds, St. Clair, for the local trial of this Legume.

VELVET BEANS.—This valuable plant has been grown extensively in this state during the past year. Our agricultural press has been filled with accounts of its superior excellence. The plant is still on trial, but promises to become a rival to our best varieties of cow-peas, wherever it can be grown. Unfortunately it is not yet well acclimated, so far as the production of seed is concerned, since an early frost last year destroyed many immature pods. By planting very early and using some tree, house bush, or arbor upon which the vines can climb, the seeds can be matured before frost. Gradually by acclimation and selection, it is believed its cultivation can be successfully extended even north of this state. As it requires comparatively few seeds per acre, planted as usually done, in rows about four feet wide and two feet apart in the drill, it is worthy of extensive cultivation even for its enormous vines, which can be easily cured into an excellent quality of hay. It is an enormous nitrogen gatherer, as analysis elsewhere shows. The tubercles on its roots are the largest of any plant so far experimented with. Coral-like clusters of tubercles, each as large as a hen's egg have been gathered from its roots, and analysis made of them by Mr. Clarke, station chemist, at State Experiment Station, Baton Rouge, La., showed six per cent. of nitrogen. The vines may be cured into hay or turned under easily with a disc plow. In summer old leaves are replaced by new ones and the ground, underneath the vines, becomes covered with dead leaves. The seed grow in velvety pods, which are collected into racemes, thus making them easy to gather. They are difficult to shell by hand. The seed are larger than a cow-pea, and a bushel will plant several acres.

The only work in the scientific investigation of this bean, that we have seen, is reported in Bulletin No. 35, of the Florida Experiment Station. Prof. A. A. Persons, chemist of that station, reports the following analysis of the bean, and then compares it with cow-pea.

"An analysis of the beans, not including the shells or pods, made by Professor A. A. Persons, gave the following results:—

ANALYSIS OF THE VELVET BEAN.

"Moisture at 100 degrees	11.93	per cent.
"Crude Ash	2.02	"
"Crude Protein	18.81	"
"Albuminoid Nitrogen	2.87	"
"Crude fat (either extract)	6.29	"
"Crude Fibre	7.45	"
"Nitrogen (free extract)	53.50	"

Calculated to a water-free basis, and compared with an analysis of the cow-pea under the same conditions, the following figures express the relative composition of the two:—

	<i>Velvet bean.</i>	<i>Cow-pea.</i>
"Ash	2.20	10.50 per cent.
"Protein	21.36	14.30 "
"Fat	7.14	2.60 "
"Fibre	8.46	29.00 "
"Nitrogen (free extract)	60.75	43.60 "

"The nutritive ratio of the cow-pea is about 1:3. It is impossible to assign a definite ratio to the velvet bean, for the reason that, so far as I am aware, its percentage of digestibility has never been determined. The only manner of accomplishing this is by means of practical feeding experiments with stock.

"Assuming the digestibility of this velvet bean to be equal to that of the cow-pea, it will be found

that it compares quite favourably with the letter and since it grows luxuriantly in different sections of the state, and since stock are known to feed upon it with great relish, it may, perhaps, play a prominent part as a forage crop in Florida in the future.

"It is to be classed among the feed stuffs which are especially rich in nitrogen [protein substances]. A feeding stuff so rich in nitrogen should not be fed alone but in conjunction with some coarse fodder containing a much larger proportion of carbohydrates [starch, etc.], such, for example, as corn fodder."

This analysis, supplemented by those given elsewhere in this bulletin, will furnish all the information necessary to form a correct estimate of the value of this plant as a nitrogen gatherer. There are rumours of a poisonous principle in the beans of this plant, but judging from the above remarks, and others made in the same bulletin by Dr. Clute and Mr. Green, on orange grower, of Orlando, Fla., these rumours are not founded in fact.

The velvet beans are largely used in Florida, and, to some extent, in this state, in the orange groves, both as a fertilizer for the trees and as a destroyer of weeds and grasses. It will completely destroy *Bernuda* and temporarily obscures *coco* or nut grass (*Cyperus rotundus*). It may, perhaps, successfully cope with *Jobson* grass.—*Trinidad Bulletin*.

MANURIAL PLANTS FOR TEA.

To say where seed can be obtained, and the cost it is a very simple matter, but to say what to grow is quite another and larger matter. The tea is already to a large extent in possession of the land on which it is proposed to grow legumes for its benefit; it has been systematically cultivated for more or less lengthened periods. On this class of soil it is proposed to grow legumes for the purpose of organising free nitrogen for the benefit of tea. Quite a number of practical considerations crop up at this stage of the enquiry, and in order to see what is really practical for tea we must look into them.

First comes the matter of convenience—getting freely about among the tea, facility for plucking, and pruning, and so forth. Any plant that materially interferes with these operations is manifestly out of the question, and that unfortunately places a number of eligibles without the pale, such as the Lupines; unless indeed they admit of systematically cutting down, which I think they do not. But we are so much in the region of the unknowable, or more correctly the theoretical, that I would beg the reader to take much that follows here as suggestive and matter for experiment; and likewise to fail not give us the result of any experimental knowledge he may possess, as a matter of first class importance to the tea industry at this stage.

Secondly there is the question of what will and what won't grow among tea plants, and when these plants will grow and when they won't grow to any advantage. These are points that cannot be answered off-hand. Again, it is highly improbable any one legume exists that will grow freely in all tea districts; and the different soils too; these are not going to grow legumes at random. I even question whether there are not thousands of acres that will not grow legumes to any advantage to the tea because it has been discovered certain plants organize free nitrogen.

I am strongly of opinion we have not, therefore, found a universal panacea for tea, and I would beg leave to caution planters against for a moment allowing themselves to imagine they have arrived on the verge of the millennium for debilitated tea, or that in this discovery there is found a sort of universal resuscitator. I nowhere gather that the most expert scientist is prepared to say or prove that the discovery has even caused a small revolution in agriculture where its advantages can be laid hold of to the fullest extent; let alone doing anything very great for tea. I am very far from wish-

ing to Jerry the discovery: it is interesting and important, but some scientific discoveries get too much magnified by some, and I think this is one of them. Agriculture, in particular rotations of crops, have all, unconscious of the scientific fact, been recognizing its practical utility for a very long period, but nothing at all out of the ordinary has happened. The way of this I think is because it is not a great discovery, but essentially a small thing. Those pre-eminently distinguished and now venerable Agricultural Chemists, Lawes and Gilbert, make it abundantly clear. In spite of all we know thus far, the *nerrick*, as it were, of nature below the surface is largely undiscovered.

However, in the matter of organizing free nitrogen from leguminous plants for tea, the time very speedily comes when it is necessary to destroy the organizers by digging them into the soil, in favour of a rotation crop, and it is not until some time after destruction, during the process of full decay that the full advantages of the free nitrogen is available and consequently in the ordinary course of things the succeeding crop gets the advantage, if indeed that is not nature's deliberate intention. In this case, however, it is for the tea plant; it will follow then that the rotation crop must also be dug in, and this crop to be of the best advantage all round must differ from the legume. The planter will do well to have always in mind that no soil, least of all much tea soil, will go on growing leguminous plants; and further that, although they organize free nitrogen by bacteria through the nodules of the roots, the plants themselves require a different nourishment, in part including abundance of lime, and no soil, and particularly tea soil, will go on successfully growing, of all plants legumes. There must be the indispensable and advantageous rotation and therefore in this case periodic destruction of both. Your correspondent will at once see this implies periodic renewal and re-sowing, and the pertinent question comes in here. Will the exigencies of tea operations admit of the planter saving his own seed? Because if it won't, then I fear it won't pay; unless indeed, and what certainly ought to happen by perseverance, the increase of tea is such as to admit of periodic purchase of new seeds. These are practical questions planters can solve for themselves. In any case it is well to have in mind that while nitrogen is locked up in the nodules of the roots of legumes it is not very likely to be of much service to deep-rooting tea; in order to be serviceable there must be a simple system of rotation, digging in, and renewals. But I believe the fact that some legumes organize free nitrogen is by no means the sum of advantage likely to accrue from planting them for the advantage of tea. I had here intended to have made a direct quotation from Mr. Cooke (Sirocco) but unfortunately have failed to find the particular sentence I wanted. However, this, if I remember rightly, is the gist of it:—"We do not sufficiently realize how much we gain or save by making less tea." This looks very like a paradox. Now I would advance a closely allied proposition, namely, that we do not sufficiently realize how much we should gain by doing less—in the way of cultivation—more especially if the cultivation is extended over lengthened periods, and I am fully convinced from a number of experiments of the great good of rest; total abandonment of cultivation, allowing nature to come in and do, as she undoubtedly does, some beneficent work. Very many planters should be sent on a tour round the world on foot or a bicycle for two years, and if the soil and tea could only speak I believe it would say Amen to the proposal very promptly.

Coming to practical suggestions for your correspondent, I would advise him to try a bushel of the ordinary field the pea-soup pea of commerce. I feel sure as a cold weather crop, and provided the soil is not deficient in lime, this would succeed in many cases well. Then it should be allowed to fully mature its crop, and here comes the question whether he should save his seed. I think from one

bushel two might be taken and all the remainder dug in. What would happen precisely, I cannot say; for Assam doubtless the hot weather would be too much for the dug in seed, but if that was not, the rains would be, I quite expect. However, if would not much matter what happened, because the seed as well as the plant would be a highly nitrogenous manure. There are very few legumes or food plants which contain so much nourishment as the pea—about 930 per cent. per 1,000 parts for the seed. This plant lays low and grows dwarf, and would not, I think interfere with the tea, and if the newly dug in seed grew, that would be an additional advantage. Again I have formed a very high opinion of some annual grasses which grow luxuriantly, but not tall, during the monsoon, are excellent fodder plants, seed freely, and die down in cold weather. There is a period when a valuable dressing of manure can be hoed in, and any amount of seed insuring a full crop another year. It is so far as is known true these grasses do not organize nitrogen in the way legumes do, but they contain a quantity, and I venture to think it may very well be that good annual grasses would prove of the greatest possible service for tea lands; any serious wash is impossible, soddened land is practically impossible. Once a year at the correct seed period the land could receive one through hoeing, no further cultivation being necessary. Of these grasses I will send your Dibrugurh correspondent a small packet of two kinds and ask him to be good enough to sow on the appearance of spring rains and watch their behaviour for Assam if he is satisfied he can himself increase the area a thousand fold by collecting his own seed. They have the great advantage of being non-creeping, no under ground stems—termed by Botanist Soboles—and there is no possibility of a permanent choked up soil. My very strong impression is, herein lies a good thing for tea:—A legume for the cold weather season and a good annual grass for monsoons, and only two very thorough hoeings per annum, one for the grass, one for the legume. The grass seed will abide the monsoon period without germinating to any extent, and would not be interfered with by the leguminous crop. Some other day I may make a communication to the *Planter* on sundry grasses, as I am getting seeds of a number from widely different parts of the world, but the time has not arrived to say anything further about them. The burden of it is, everyone should make some definite experiment in the direction of surface crop, which will protect the soil, and abolish in a very large measure cultivation, and yet forsooth it would be a kind of culture highly advantageous. When it is recognized that the tea plant is only a shrub above ground and that by artificial means and that below it has the roots of a tree; and that without manure you can neither add nor take from the soil over and above what nature allows; and that by annual crops due in you come as close as probably it will ever pay to an imitation of nature's methods,—then I believe planters will see their current methods in the long run are vanity and vexation of spirit; and based on heavy knows what dust perhaps, to solely and wholly for the tea plant and not as a general principle for anything.—"SECATUR INDICUS,"—*Planter*.

SOUTH SEA ISLAND PAPAYA.—The Curator of the Government Botanic Gardens and Parks, Nilgiris, reports the successful raising of a number of plants from seed of the South Sea Island Papaya (*Carica Papaya*) and observes:—"As soon as it becomes established, it is hoped that it will prove to be a desirable addition to the list of tropical fruits grown on the lower slopes of the Nilgiris to meet the demands in the local markets." The fruit of this tree at Bangalore is much larger than that usually seen on the ordinary Papaya.—*Planting Opinion*, Sept. 30.

THE CULTIVATION OF TEA :

MEASURES TO PREVENT DISEASE.

COMMON SENSE TREATMENTS, CALCULATED TO HOLD GREY AND OTHER BLIGHTS IN CHECK, COMBINED WITH PROFITS TO THE ESTATE.

I doubt not that such direct treatment as the picking-off of diseased leaves will (as calculated to defoliate bushes) soon be held as of minor importance, in the treatment of Plant Diseases, and it might, therefore, be as well to review some methods, which, though indirect, might be looked upon as far more effective, and the least that can be expected if such methods are carried out carefully, is that the increased returns from the tea treatment will cover the cost of such.

BURYING PRUNINGS.—As being the most important of such, let us first take the Burying of Prunings. Dr. Watt's remarks on this subject, are worth reading. He seems to have concluded from the result of his flying visit to Assam, etc., that prunings should not be buried for the reason that they would be likely to foster parasitic growth—(though in stating this I might add that he mainly refers to Thread Blight, a pest peculiar in that it spreads by long fibrous mycelium, has the power of living on the dead buried matter, and of afterwards resuming its parasitic life on adjacent plants)—and I do not think his remarks apply so much to grey and kindred blights. However, both he and Mr. Masseur, losing sight, I am afraid, of the object for which we grow tea, recommend the burning of prunings, condemning burying. Neither mentions the use of disinfectants in connection with such operations, and yet at the same time they have a lot to say about the great value of time, etc., as fungicides. So perhaps, we who are the most interested, might be permitted to view the matter in a more practical light and look upon burying as our cheapest and most feasible means of treatment—with two great advantages over burning: (1) a saving of almost all organic matter in the prunings, and (2) prunings would not have to be carried some distance—as in burning, in most cases—to suitable open spaces. It follows that doing so would give the wind every chance to scatter spores to great distances, whereas in burying a yard would represent the greatest distance to a place of burial. Prunings can be well buried—including careful sweeping of the ground, and the cutting of deeper holes than usual—with a dose of about 500 lb. of lime per acre, at a cost of about R20; the lime added quickly decomposes the mass buried, as well as acting as an indirect manure by freeing potash, nitrogen, etc., which may be locked up in the soil, in an insoluble form. As lime could hardly be used every time a field was pruned, some substitute might be formed, in solutions like the Bordeaux Mixture; such could easily be sprayed on the collected mass by the aid of an ordinary watering can or something of that kind, the only drawback at present being the prohibitive cost of sulphate of copper, as probably about 50 lb. would be used per acre. However, where this chemical is used in large quantities, it is extremely cheap; and, no doubt, when a demand was felt here, we should be able to purchase at a figure warranting our using such past experience on estates where prunings were buried solely in the way of

manuring, thus proving how valuable such operations are. Personally I have done such work on a small scale for some years with most gratifying results, and a well-known property on which this system has been carried out for some six years, stands probably today as the freest from pests and the healthiest estate in the island. Mr. Bamber, I know, is strong on prunings being buried, provided, of course, such work is done in a thorough manner, and I am sure that we shall find he will have a good deal to say on this subject in the Report he will shortly put before us.

BURNING.—Now for Burning, it is unfortunate that on almost every estate there are places too steep for burying or cultivation of this nature, and I believe there is also one district where the presence of something in the nature of thread blight, prohibits the burying of prunings; on such places burning must be resorted to as about the only method of treatment available. In this operation the value of the manure created plays but an unimportant part, the ash collected from the burning of prunings from an acre of healthy tea, would give about 20 lb. of potash, 6 lb. of phosphoric acid, and about 14 lb. of lime, losing about 40 lb. of nitrogen. This would be utilized were the prunings buried and, if these prunings were left undisturbed, most of the Potash, etc., in the ash would be available for the plants' use. And looking to the difficulty of properly re-distributing the ashes, it would be necessary, when applying artificially, to almost double the usual dose, where the ash has not been returned—in order to make up for the loss of same.

DESTRUCTION OF CHEDDIE.—Mr. Masseur says, remembering the very different kinds of plants on which this fungus is known to be parasitic (speaking of Grey Blight) it is probable that it also occurs on wild plants in the vicinity of tea. If such is the case,—and there is no doubt about it—all such should be removed if possible, as the *Conidia* is carried great distances by wind and other agencies, and no amount of attention to the tea would avail if the supply of *Conidia* necessary for inoculation, were grown in the neighbourhood. Now, there are two things which might be done with cheddies, etc., with a view to using such as manure. It might be buried in large pits (accompanied with a little Basic slag or Lime to assist rapid decomposition) to be afterwards applied as a bulk manure; or cheddies grass, etc., collected, might be burnt and the ashes collected under shelter till required. This would be of value, on account of the Potash and Lime contained; the amount of these would vary very much according to the class of vegetation, but we might take an average of 10 per cent as representing the quantity of Potash in the ash.

Another class of vegetation which would come under this head are the dense masses of belts and road trees we have in our fields, with the idea of either checking wind or acting as a fuel reserve. Such trees, it seems to me, do a great deal more harm than good, and excepting in districts like Udapussellawa are quite unnecessary. We will take gums; if we look at bushes adjacent to trees of this description, we find them in a most miserable condition. This is more due to the drip from

the leaves than anything else, as guns in most cases are deeper feeders than tea and therefore do not rob the latter, so much as other trees do. Grevilleas seem harmless, but if we examine them carefully, we shall find the branches covered with scaly bug, etc., the surrounding tea getting the benefit thereof; not to mention the shade created, which is so much to the liking of injurious growths. Another system to be condemned is growing trees for fuel amongst the tea. One need but look at the tea adjacent (a few months after these trees have been felled!) to wonder whether the fuel obtained were worth the damage done.

ARTIFICIAL.—Now, a few remarks on artificial manuring. It will be found that in many cases the results of application of artificial manures are unsatisfactory; this being due to our allowing our fields to go too far before manuring, the bushes being sluck; and if we examine the roots, we will find them in a like state. The result is, they are not in a condition to assimilate the manure applied, a part of which in consequence will be lost. One must allow for this in first application and give the bush a larger dose than would be required in succeeding ones. Surely the "Times," in claiming that Mr. Bamber has reduced the cost of manuring in the island by 50 per cent, makes an absurd statement and one very uncomplimentary to the Planting Community generally. I happen to know that Mr. Bamber is probably as surprised as we are at this statement, though I also know that the "Times" gathered this information from several different men. I can only say that Mr. Bamber's coming has indeed been a God-send—to such—but I most certainly think that the majority—including Mr. Bamber himself—would not for a moment dream of such extraordinary cheapening in the cost of manuring being possible. Mr. Bamber recommends cheap mixtures; so do others and such mixtures were used long before he came; and as he aims at permanent benefit to the soil, how we can attempt to place any value on his system till at least a trial of two years, I cannot see. At present the greatest tribute we can pay him, is that he came at the right moment, and played an important part in the upsetting of the Castor Cake and Bone Era of Conservatism.

HANKOW THE TEA MART OF CHINA.

THE TOWN AND ITS INDUSTRY.

(Specially written for the "Ceylon Observer.")

Hankow does not perhaps stand pre-eminent as a health resort, and indeed those who have faced a summer or two in that place, might look upon Colombo as a sanitarium; but as

A CENTRE OF BUSINESS ENERGY and activity it is, for three months—May, June and July—in a unique position.

Situated about 650 miles from Shanghai, up the Yangtze, on its right bank, it stands in the very centre of China as the mart of the China tea trade. Not that tea is the only article it trades in, but undoubtedly tea has made Hankow famous. Big businesses are done in hides, bristles, feathers and "all

sorts and conditions" of other articles; but tea has made Hankow what it is.

As the month of May approaches, the return of the tea-tasters, or "Chaaszees" as they are called, is noticed in Shanghai and ere long they take ship up to Hankow. There are three principal lines of steamers up to this port, known as Ewo, Taikoo and China Merchants; and if you ask a Chinaman which he prefers, he will answer thus:—Ewo is best for the Canton man who travels up, Taikoo best for the foreigner, and China Merchants best for Mandarins. This is borne out in fact and tea-tasters generally select Taikoo.

About three days are occupied in the journey and several interesting river treaty ports are touched at *en route*. Kiukiang is reached about a day before Hankow. All teas from Kiukiang districts arrive at this port first and several houses have representatives there in order to buy earlier than others. But the bulk of the teas are shipped up to Hankow and offered on that market.

QUIETNESS REIGNS SUPREME in Hankow when the "Chaaszee" arrives and the Bund wears a dreary and forsaken aspect; but in a day or two all is changed with the arrival of the first musters. The tea-taster buckles on his armour in the shape of his oldest clothes and the tea battle opens! A tea season is no child's play when once started and the musters arrive in a seemingly endless stream. The tea-taster in a "quick" season must be in his tea room by 5-30 a.m. and start operations forthwith, nor stay his hand (or rather tongue!) till five or six at night, barring short intervals for meals.

THE TEA-TASTER

is *not* a rigid abstainer during the season as stated in a recent "Century" article, but he perhaps takes his stimulants in rather smaller quantities and discards smoking altogether until after dinner and the day's work is over.

He proceeds on very similar lines to those in Colombo, the essential difference being the very great care necessary, and taken, compared with that in the case of Ceylon teas.

A very good-sized sample is sent round by the Broker—much larger he it noted than that allowed by the Colombo trade—and he then proceeds to become acquainted with the quality of the tea before him, using the same utensils for this purpose as in use in Ceylon. The "Century" article errs very much in its description of this phase of the subject.

If the tea suits him, he tells the Broker to forward a chest muster and thus has the useful opportunity of seeing a full half-chest of the tea before he has even made a bid for it. Should he still like it, he then makes a contract for the tea at the price agreed upon; but he has the option of returning the chest muster and making no purchase should he, on second tasting, dislike the tea. It will be realised that this is of great assistance to the tea taster in selecting suitable teas for his orders and if an error is made it is more often his own lack of judgment rather than inability to see what the tea really is from a very small sample.

If the tea taster is exacting in making his staff work, he also works very hard himself,

and requisitions Sunday as an extra twenty-four hours in which to work. His godown soon begins to wear a very animated appearance, and weighing, marking, matting and rattanning operations are constantly in process.

The "Century" article states that tea is brought to Hankow in sacks as well as half-chests and is frequently re-fired. This, however, is hardly consistent with facts. Little or no tea with any pretension to quality is so packed, only the common tea dust and siftings used in "brick"-making being brought in this fashion, and the merchant certainly does very little or no firing; as he prefers to open as few packages as possible. *Common* tea is frequently repacked from half-chests to chests, but the bulk of the tea is shipped in its original packages.

A great advantage the merchant gets in buying China tea is

A SUBSTANTIAL ALLOWANCE

in weight given by the tea-men and thus a loss in weight is impossible. This is a fact that might be seriously borne in mind by the planters of Ceylon if they wish to capture new markets, especially the Russian. As stated in a previous article, another great advantage is the large size of the break which a merchant is able to buy.

The arrival of the first Russian steamer is the sign of great activity on the Bund, hundreds and hundreds of coolies being employed in carrying tea to the cargo boats for transhipment to the big steamer. Each Chinaman will carry two half-chests slung one on each end of a bamboo pole across his shoulders and the rapidity with which he goes is a great contrast to the slow bullock cart of Ceylon. Six weeks of this feverish activity brings the "rush" to a close, but there is plenty of work for all for another two months, though carried on in a more leisurely way.

By the end of August Hankow residents settle down to wait for autumn and winter sport and their ordinary work; and the tea-tasters ship once more for happier and less busy climes.

HANKOW ITSELF

is flat and uninteresting, its Bund being the chief promenade for walking. In the month of July, the plains at the back are flooded and continue so for some time, and Hankow is thus practically shut in and riding operations are very much curtailed. As the new Concessions given to the French, Russians and Germans are developed, the place will grow in importance and some even go so far as to say, will rival Shanghai, if not in beauty, at least as a trading centre. Adjoining the English Concession is the densely populated city of Hankow, containing 800,000 Chinese, the majority living in indescribable hovels and filth. Its size may be judged by the fact that its principal street is over three miles in length.

The condition of life during the Great Heat must be appalling as the Chinaman knows absolutely nothing of sanitation and it is reported that thousands die during the summer from various diseases. The

principle of "survival of the fittest" is undoubtedly carried into actual practice to a very large extent in such a place as this. With all this, however, the average Chinaman seems to be a contented man and they seem to have solved the question of the "happiness of the greatest number."

Opposite to Hankow on the other side of the river is Wuchang, the capital of the Province of Hupeh, whose Viceroy is

THE CELEBRATED CHANG CHIH TENG, famed for his Western learning. Famed until he is known, when he is found to be, at bed-rock, of much the same build and character as the ordinary Mandarin. He has established arsenals, iron works, cotton mills and an agricultural department, but with only partial success. He has competent Europeans to guide things, but from lack of material given them, they are unable to get any very good results. His agricultural department is still without ground for the planting of seed,—a rather important item in agriculture, one would think. Also, while at the outset, he was willing to buy every agricultural implement existing, now it is hard to get those really necessary. Thus is China's most advanced man only surface-polished with Western ideas and at heart still the old-fashioned Oriental. What China needs most to-day are strong, honest and conscientious leaders and until she gets them she will continue in the rut of impotence she is now in.

ASSOCIATED TEA ESTATES OF CEYLON, LIMITED.

DIRECTORS' REPORT.

FOR THE 12 MONTHS ENDED 30TH JUNE, 1899.

The area of the Company's Estates planted with tea as per last report was ... 1,889 acres. to which falls to be added as completed during the year ... 16 do. and for certification of area at Doragalla ... 25 do.

Making a nett planted area in tea of 1,930 acres.

In addition to which there are 13 acres of fuel trees on Doragalla.

No further extensions are in progress.

The yield was as follows:—

	lb.
Silver Kandy	100,210
Chesterford	280,514
Horagoda	45,700
Doragalla	238,032
	<hr/>
	664,456

This shows a decrease of 43,513 lb. on the previous 12 months' yield, and of 119,294 lb. on the aggregate of the Superintendents' estimates. The two high-lying estates gave an increase of 34,371 lb., and the two low-country properties a falling off of 77,884 lb. The Superintendents and the Visiting Agent are unable to give any reason for the deficiency beyond natural causes, the weather in the low country having been unsatisfactory for producing a heavy yield of tea.

Of the crop, the entire produce of one estate was sold in London, and of the three others

partly in Colombo and partly in London. The portion sold in Ceylon, 288,215 lb., realised an average of 37·81 cents, and the 376,241 lb. sold in London, an average of 7·81d, making together, after allowance for freight and charges on the London portion, a total average of 7·28d per pound. This compares with 7·11d per pound for the previous year, and in view of the general level of prices is considered satisfactory.

The Superintendent of Chesterford Estate resigned his position in March, and the Superintendent of Silver Kandy was summarily dismissed on 25 May, under circumstances that may lead to legal proceedings. The item of £414 6s 9d appearing on the balance sheet as a doubtful debt, is money due by the latter to the Company. New Superintendents were appointed in each case, and so far as can be judged, the work under them is proceeding satisfactorily.

The estimates for the 12 months ending 30th June, 1900, are for a crop of 705,000 lb; which will, if realised, be an increase of 40,544 lb. over the yield for the previous year. The estimates are probably on the conservative side, and may with favourable weather conditions, be exceeded. The estate of cultivation, and the circumstances generally of the estates are in every way in satisfactory shape.

The revenue Account shows a nett profit of £3,622 0s 3d, to which falls to be added the balance of £9 4s 4d brought forward from last season, and £19 1s 6d on adjustment of previous year's accounts, making a total of £3,650 6s 1d. Out of this the Directors paid the Interim Dividend at the rate of 3 per cent on the preference share capital, and from the balance they propose to pay the final dividend on same at the same rate (making six per cent for the year) which will absorb £1,800, and to carry forward the balance to the next account.

The Directors regret that the anticipations expressed in the last annual report, and in the circular sent out on the 31st March, 1899, have been unfulfilled, and that consequently the revenue was insufficient to pay any dividend to the holders of the ordinary share capital. It looked during the spring as if a higher level of value was likely to prevail in the future for all tea, but circumstances led to a rapid and continuous fall in prices, and a very low level was current when a large proportion of the season's crops were being realised. In spite of this, prices show, with the exception of one estate, an increase. A profit is shown on rice supply, and exchange was effected at an advance of only three-eighths of 1d per rupee on the previous year. The adverse feature is obviously the deficiency in yield, which may be taken as explanatory of the bad result. The accounts show a material expenditure on manuring, which will be continued during the new season, as the Directors have satisfied themselves that a substantial increase in yield is likely to be obtained by liberal treatment of the cultivation in this manner. The continued failure of the properties to realise the profits expected from them when the Company was formed, has been a matter of grave concern to the Directors, who in a view of the financial results have again drawn only half their fees. The Secretaries have also again made a considerable rebate on the sum payable to them for the London management of the Company, and have waived the commission payable to them upon the amount of profits divided.

Only the small additional outlay referred to in last report has been made upon block account,

the Directors having decided to charge to revenue account, on an average spread over several years, any items relative to ordinary additions to buildings and machinery.

The Directors decided that it was contrary to the interests of the Company to take part in the attempt recently made by certain Tea importers to force upon the buyers in London a change in the conditions of sale by abolishing the pound-draft hitherto allowed on each package. While they would have been pleased to see this allowance abolished by mutual agreement, they considered it unwise to join in a quarrel with their customers, and consequently the teas of this Company were offered and sold on the old terms. The Directors have also declined to join in the proposed arrangement for regulating the quantities offered for sale, as they do not consider it would be in the interests of the Company to do so.

Mr. A Bethune, the former proprietor of one of the estates now owned by this Company, having retired from Ceylon after 20 years spent there in planting, has been invited to join the Board, and his name will be submitted to the shareholders at the general meeting for election as an additional Director. The members of the Board consider that his special knowledge of the estate in question, and his general practical experience, will prove of material advantage to the London-executive and to the Company's interests generally.

Under the articles of Association, Sir Alexander Wilson retires from the Directorate, and, being eligible, offers himself for re-election.

An Auditor falls to be appointed by the shareholders at the general meeting. Mr. J M Henderson, F.C.A., is eligible for re-election.

PRODUCE AND PLANTING.

AMERICAN TEA.—On the strength of a brief paragraph about the success of tea-growing experiments in the Southern States, some of the newspapers have endeavoured to construct a mountain out of a mole-hill. We can imagine that a few timid shareholders in tea companies have been made unhappy by the following paragraph, which has gone the usual round: "It is predicted that America will in time rival China and Ceylon in the production of tea. Experiments made in tea cultivation in the United States are said to have proved a complete success." The "prediction" comes from Fleet Street, we imagine, and we do not notice any serious decline in tea shares in consequence of it.

AN ATTEMPT TO SCARE TEA DRINKERS.—The latest news from the United States about tea is that certain people interested in coffee are endeavouring to create prejudice against tea by circulating exaggerated rumours about its injurious effect. That game has been tried here, but did not succeed. A New York telegram of Wednesday's date to the *Leader* has the following: The sensation today is the reported prostration through excessive tea-drinking of Mrs. Leslie Carter, America's greatest actress. The newspapers take the occasion to print violent articles on the baneful effects of tea, pointing the moral in the physical decline of the English race. The *World* editorially writes: 'Our cartoonists should inform up-to-date facts and depict John Bull as small and scrawny whereas Uncle Sam should be depicted as big and pot-bellied.' Several merchants whom I have consulted tell me that the tea-drinking scare is being fostered by the coffee trust, which fears that Sir Thomas Lipton's presence may induce Americans to take to tea."

INDIAN AND CEYLON TEAS IN THE STATES.—Whether it is due to a desire to push Ceylon tea or not, some

of the American newspapers are publishing information, says the *Pall Mall Gazette*, in respect to the increase in the popularity of the commodity which should gladden the hearts of the planters and cause Mincing Lane no little satisfaction. "The phenomenal increase in Ceylon and India tea has become very striking," is the somewhat tautological comment of one journal. The change of attitude on the part of the American public dates, it seems, from the time of the World's Fair, before which the Indian teas were practically unknown. Each year has shown a decided increase in consumption over the preceding period. No figures are given in support of the contentions, but we suppose that the statements themselves are deserving of some weight. The astute American mind is now considering whether or not tea can be produced in the United States. The conclusion arrived at is that there are several States where the climatic conditions are favourable, but that the cost of labour is too high. There is some hope, however, that the raising of tea in certain of the newly-acquired possessions of the United States will be attempted. Of course, the consumption of tea cannot be allowed to come under consideration without the inevitable reference to the Anglo-Saxon brotherhood. "What a contrast there is between that tea party," said one well-known merchant referring to the acceptance of a present of tea by Admiral Dewey at Colombo, "and the other one in Boston harbour! How indicative of the change of sentiment between two peoples!" Well, if the United States consumers will only buy enough, we can assure them that our Indian planters will be very grateful, and will show not a little enthusiasm on the subject of the Anglo-Saxon alliance.

THE TEA TRADE OF FORMOSA.—In the Consular report on the trade of Formosa the reference to tea is full, although it resembles official reports from other parts of the Far East in that it points to no improvement in the tea trade generally.

SOUTH INDIAN PLANTERS IN COUNCIL.—The planters of Southern India seem animated with a spirit of enterprise. Those of them who grow coffee desire to know all about the latest and best machinery for curing the product, and it is a pity that they cannot find the necessary machinery here without looking to the United States for it.

CINNAMON.—The supply at the periodical sales on Monday, the 28th ult., was extremely light, indeed far too scanty for the prevailing demand, and the 960 bales Ceylon put forward went off briskly at a further advance in value. The greatest improvement was seen in first and second sorts, which were 1d to 2d per lb dearer, and even the inferior qualities, that were less eagerly competed for, brought ½d to 1d better prices than were established at the auctions in May last, viz.: Firsts, fine and superior garden cinnamon at 1s 4d to 1s 7d, common to good at 10d to 1s 2½d; seconds, fine and finest plantation at 1s 4d to 1s 7d, ordinary to good at 7d to 1s; thirds, best at 1s 1d to 1s 5d, low woody to fair at 5½d to 11d; fourths, from 5d up to 1s 1d; and broken (in five boxes) at 7½d to 8d per lb.—*Home and Colonial Mail*, Sept. 8.

COCHIN MARKET.

C.N. OIL.—The market reopened this week with our last quotation, but with an increasing demand mainly from Bombay, prices advanced and a good business has been done at R89 to R89/8 per candy for prompt and R91 for one month forward delivery. The European firms have also brought a few parcels of good white oil at R88/12 net per candy. Market closes today firm at R90 per candy. The latest quotations from Bombay were R4/6 to R4/7 per maund of 28 lb., and Rangoon R58 per 100 visses equal to 365 lb.

COIR YARN.—A good business is passing with Europe on c.i.f. terms for forward shipment. Supplies arriving from the interior meet with a good demand both from shippers as well as dealers at prices ranging R30/55 per candy according to quality.

ROPE YARN.—This yarn is largely enquired for both from Europe and Indian ports. A good business is reported. We quote today, dry yarn fine color and make R34/42 and candy baled weight.

COIR FIBRE.—A few parcels of common fibre arrived during the week, and changed hands at R27/28 per candy. Good bright fibre is worth today R34 per candy.—*Cochin Argus*, Sept. 23.

RUBBER—ARTIFICIAL AND NATURAL.

ARTIFICIAL PRODUCTION OF INDIA-RUBBER.—The artificial production of india-rubber has long been a fascinating problem for chemists. Dr. Tilden has now succeeded in producing it in small quantities, although its commercial production does not at present seem very near realisation. A hydrocarbon known as isoprene was discovered years ago by Greville Williams amongst the products of the destructive distillation of india-rubber, and in 1884 Dr. Tilden obtained it by the action of moderate heat on turpentine. Some isoprene, which was made by Dr. Tilden in the course of his researches in terpenes, was preserved, and on examining these he was surprised to find the contents of the bottles completely changed, and in place of a limpid, colorless liquid the bottles contained a dense syrup, in which floated several large masses of a yellowish solid. This, on examination, turned out to be india-rubber, exhibiting all the characteristic reactions of that body with solvents and also its power of combining with sulphur to form a tough elastic body. The change from isoprene to india-rubber is extremely slow, taking several years to complete, and so far, Dr. Tilden says that although he has tried everything he can think of, all attempts to hasten the action have resulted in the production of a body known as colophene, a thick, sticky oil, quite useless for all purposes to which india-rubber is applied.

BARREN RUBBER TREES.—From a recent official report we learn that the cultivation of rubber in Madras has proved a practical failure, as, curiously enough, although the trees grow splendidly, they refuse to yield or even produce rubber. The Ceara rubber tree was experimentally planted in several localities in Southern India, and from the way in which the trees grew it was hoped that in due time large quantities of the juice would be secreted and an export trade spring up. Unfortunately these hopes have not been realised, since it has been found that the trees refuse to "bleed" at all when the bark is cut, or do so in such small quantity that it does not pay, expenses of cultivation. Mr. Hooper, who has made a microscopic examination of the inner bark, finds that while the laticiferous vessels or caoutchouc ducts are not absent they are undeveloped and scantily distributed in the bark. This unfortunate result is attributed by Mr. Hooper to the fact that the climatic conditions or soil are not suitable for encouraging the secretion of rubber in the trees.

RUBBER OF THE SOUDAN.—Whilst on the subject of rubber, it is of interest to learn from the recently-issued report of Sir William Garstin on the subject of the Soudan, that on the White

Nile, in the Bongo and Rohl districts, the india-rubber creeper (*Landolphia florida*) is found in great profusion, which, as is pointed out, should be an important asset in the future trade of the Soudan, although, of course, the rubber produced from this plant is not of such good quality as that from Para or Assam. We are accustomed to look upon the Soudan as anything but a source of wealth to its holders, but from this report of Sir William Garstin's to the Foreign Office it would appear that there are great potentialities of wealth in the district, and there is urgent need of a scientific examination of the country with a view to the development of its natural resources. The vast forests which line the banks of the Upper Blue Nile, and extend as far as the Abyssinian frontier, and those of the province of Bah-el-Ghazal, should prove sources of future wealth. In regard to the mineral wealth of the district, very little appears to be known. Iron ore is found in the Bah-el-Ghazal province and also at Darfur, and gold mines were at one time worked in the mountains south of Fazoql. At present coal does not seem to have been discovered.—*Daily Chronicle*, Sept. 8th.

NEW COMPANIES.

NOKHROY (ASSAM) TEA CO., LTD., (63479).—Registered Aug. 31st, with capital £10,000, in £1 shares, to acquire any tea estates, lands, warehouses, factories and machinery, to extend, improve, or add to such estates and generally to do all things appertaining to the business of tea planters and merchants. The number of directors is not to be more than 5; the subscribers are to appoint the first; qualification 150 shares. Registered by E. A. Jay 50 Bental Road, Stoke Newington, N.

STRAITS TIN, LTD., (63,455).—Registered Aug. 30th, with capital £10,000 in £1 shares, to acquire and turn to account any property in the Straits Settlements or elsewhere, and to carry on the business of miners, prospectors, farmers, merchants, financiers, etc.—*Investors' Guardian*, Sept. 9.

PALLEGAMA GRANT ASSOCIATION.

REPORT.

The Directors regret that it has been found necessary to stop further expenditure. This has been done with the exception of advances to the timber contractor to enable him to convey to the Matale Timber Depot the Ebony lying felled on the Estate.

Under the circumstances the Directors recommend that no further expenditure be incurred at present, and that the Agents and Secretaries be requested to settle so far as possible outstanding liabilities from proceeds of produce bearing in mind the loan specially contracted against the timber,

In the terms of the articles of Association Mr. E. Rosling retires, but is eligible for re-election.

The Balance Sheet made up to the 31st August shows on the one side:—Capital—2,000 shares fully paid up, R200,000; Debts due by the Company—To Timber Contractor, R500; to Auditor, R100; to Agents and Secretaries, R249'59; to Estate Account Balance Sheet, R686'05; to Loan Account, R1,107'26;—R2,642'90; total, R202,642'90. On the other side we have:—Property (Immovable)—Balance from last account, R201,893'59; Nett expenditure from date of last report to 31st August, 1899, R983'37; Less amount at credit of Profit and Loss, R307'07 = R676'30;—R202,569'89; Cash in Bank—R73'01; total R202,642'90. The Profit and Loss statement shows a balance carried to Landed Property account of R307'07.

AN AMERICAN SCIENTIST ON TOUR.

THE latest scientific visitor we have to welcome to our shores, is Dr. Edwin Mead Wilcox, Travelling Fellow in Economic Botany, of Harvard University, Cambridge, Mass, U.S.A., whose arrival and departure for the hills we chronicled a few days ago. Dr. Wilcox has since his arrival been staying at Kandy and studying the island's products at the Royal Botanic Gardens, Peradeniya, with the ever ready assistance of Mr. W. Nock, the Superintendent in charge. We had at first understood that Dr. Wilcox's visit was partly in connection with the experiments—or continued efforts rather—in tea-growing in the Southern States of America. But this, we learn, is not the case. Dr. Wilcox is making a tour, which is mainly confined to Ceylon, the Straits Settlement and Java, in connection with the project of starting a Sub-Tropical Department in Cuba in connection with Harvard University. The site of the proposed Department, corresponding in a sense—since it will be instituted with Government assistance—with Peradeniya here, will be in the mountains about seven miles from Cienfuegos, one of the two Southern termini of the railway that passes through Havana on the North. The interest of Dr. Wilcox lies chiefly, therefore, in sugar; and he proceeds by the "Bengal" (in about a fortnight's time) to Java, where Dutch methods of cultivation both in this product and in cinchona and tea will receive further study. Meanwhile Dr. Wilcox returns to the hills tomorrow, being specially desirous of visiting one or two cacao estates in full working, as well as of obtaining first-hand information upon tea. He will also, if time permits, make a visit to a citronella plantation in the Southern Province with a view to getting as complete a knowledge (as an eye-witness) of tropical products in full growth, that are likely to be of service in Cuba. Coconuts, we are told, are not expected to be taken up in this latest acquisition of the American nation. *En passant* we learn that the form of Government to be imposed upon Cuba is by no means decided yet; that a certain amount of lawlessness still prevails, reminding those in charge of American interests there of the former *regime* when Spaniards and Cubans by turn would come in bodies and fire a few shots upon the plantation dwellings, only ceasing when money had been given them to go away—then only to return at a convenient season, as did the Danes in Northumbria ere the power of a Saxon king was triumphant on English soil. Even now Cubans interfere much with the working of sugar properties, and the same one-sided guerilla warfare, periodically bought off, is often carried on. Not until more American soldiers can be spared for garrisoning Cuba—and the long drawn-out fighting in the Philippines now repels this prospect into the dim distance—can the exploiting of the fertile soil of Cuba be taken in hand with safety and success. We are gratified to learn that the *Observer* publications are recognised in the American Universities as giving the best book-knowledge to be had of Ceylon, and to hear that the *Tropical Agriculturist* is regularly consulted by

the numerous scientific students with a bent for colonisation and who are interested in the widely-collected information that is there brought together. We wish Dr. Wilcox a successful tour and hope that his impressions of this island may be among the pleasantest and most useful that he carries back with him to Harvard.

INDIAN TEA ASSOCIATION AND LONDON WAREHOUSE CHARGES.

The following is from the official minutes of the meeting of the General Committee of the above Association, held in Calcutta on the 5th instant:—

Considered letters, of dates varying from 7th to 29th August, from the twenty-six Calcutta Tea Companies, urging upon the Committee the necessity of taking action, in conjunction with the Committee of the Association in London, in order to obtain a reduction of the excessive charges at present levied by Bonded Warehouses in London. The letters had been previously circulated, and the General Committee in their letter of 17th August to the London Committee of the Association had pointed out that the question was being agitated in Calcutta, and had also enquired with reference to the fresh steps it was understood they had in contemplation, the nature of the action now proposed to be taken by the London Committee. Replies had been sent to the letters from the Companies stating that the whole question was under consideration and that the London Association had been addressed in regard to it. Further letters had subsequently been received from certain of the Companies in question, asking to be furnished with a copy of the letter addressed to the Committee of the Association in London.

The Committee also had before them a Memo., dated 29th August, drawn up by the Chairman of the Association on the subject. In this Memo. the letters received from the various Companies referred to were analyzed. It was also pointed out that judging from some of the letters there appeared to be an impression in the mind of the Directors of certain Companies that the question of the necessity for a reduction of the charges had not hitherto been considered by the Committee or at least had been dropped by them. This was of course incorrect, as the matter had been before the Association, both here and in London for some time past, and had been referred to in the Annual Reports, and also in speeches at the annual general meetings and the Committee had uniformly and at every opportunity followed the policy then indicated, and apparently unanimously approved of by members. The Memo. also dealt with other points in connection with the subject, especially with the question of the best course of action to be adopted in order to obtain a reduction of the charges with the least delay. The question was discussed generally by the Committee, and the following conclusions were arrived at:—

(a) That further simple agitation, without any counter-proposition in the event of a reduction not being conceded by the warehouse proprietors, would be ineffective.

(b) That the best method of procedure would be the establishment of a warehouse, or warehouses, to be worked on co-operative principles by tea concerns.

(c) That the agitation in favour of the abolition of the British import duty should be carried on concurrently with any action taken in the above direction.

The Secretary was instructed to draft a letter to the Committee of the Association in London, in continuation of the letter of the 17th August, stating these conclusions and giving the reasons on which they were based.

TROUT BREEDING AT NUWARA ELIYA.

The stewponds at Nuwara Eliya, containing the fry obtained from the last batches of trout ova, have not yet been dragged, owing, says a local "paper," to the present unfavourable weather at the Sanitarium. Having been used to quiet water all this time, it is feared that if the fry are put into the streams serious injury to them may result, and the authorities are therefore awaiting the cessation of the heavy rains. So far, the stewponds have proved a great success, and the experiment has also met with very satisfactory results at Calsay (Nanuoya), St. Leonards (Udapissella-va), and on the Horton Plains. At Nuwara Eliya there are three ponds situated behind the hatchery, and while two of them contain the ordinary fry, the third holds those of the rainbow species. Mr. Elhart who is in charge of the trout, thinks that of the ordinary fry there are about 1,500 and some 200 of the rainbow variety. All are healthy, and range in size from four to six inches. They are fed twice a day with shrimps caught in the local streams, and they take to this food very well. It may be remembered that the amount of rainbow ova got out was 10,000. Half of this amount was handed over to Mr. Wilson Wood, of Kotagala; but a large percentage is said to have died in transit. The consignment did not arrive in good condition, and the yield under the circumstances must be considered satisfactory, and the healthy appearance of those in the stewpond at Nuwara Eliya ought to be an inducement to the authorities to get out another consignment. When the next batch of ova is to be got out has not yet been settled; but the annual meeting of the Fishing Club at Nuwara Eliya is to be held next month, when the matter will be considered. We learn that the stewpond at Queen's Cottage has not been a success, and when last dragged there were a very few fry found in it. This is attributed to the spill not being a suitable one. The fry got washed away, and the pond besides is not fenced, with the result that otters have every chance of getting into it. Otters are said to be plentiful now at Nuwara Eliya, and seven or eight have been caught this year in traps. There are about twice the size of a cat, and R7-50 is being offered for each other killed, while traps for the purpose are also supplied. They have not been able to attack the stewponds, owing their being fenced in, but the streams are frequented and the traps are generally laid by the edge of the water.

The Fishing Club generally is receiving good support, and the number of license issued compares favourably with the past year. Mr. W. E. Davidson has spared no pains in attending to the stewponds, and takes the greatest interest in the welfare of the Club.

MINOR PRODUCTS REPORT.

CITRONELLA OIL.—For forward shipment business continues to be done on the basis of 10d per lb, c.i.f., in drums, in quantity. Spot is quiet at 1s to 1s 1d per lb.

CINCHONA.—The shipments from Ceylon for the week ending August 14 were nil, and the total exports from January 1 to August 14, 1899 show a decrease of 170,623 lb., as compared with the corresponding period of 1898. The cinchona-bark auction, to be held in Amsterdam on September 28, will consist of 5,459 bales Ledger and hybridin; 1,349 bales 702 cases Succirubra. The stock in first hands at Amsterdam consisted on September 5 of 2,165 packages Government bark; 8,855 packages private, including the quantity to be put up in the auction of September 28.—*Chemist and Druggist*, Sept. 9.

PREVENTION OF COFFEE-STEALING IN INDIA.

THE PROPOSED NEW LAW.

The publication in the *Gazette* of the draft Coffee stealing Act Amendment Bill marks, says the *Madras Mail*, another step forward in the adjustment of the planter's relations with his neighbours and his fellow men. It is now a quarter of a century since planters first brought to the notice of Government the need for legislation against coffee-stealing, a crime that was said to be "increasing terribly." In 1878 The Madras Coffee-Stealing Prevention Act, was passed. The Bill originally drafted provided that within certain localities, to be notified, it was to be declared unlawful for any person to deal in coffee without a license from a Magistrate, with whom the granting of such license was optional; every licensed dealer was to be bound to keep books and accounts showing details of every transaction in coffee made by him. Penalties were attached to breaches of these provisions, to the dealing in coffee by any person other than a licensed dealer, to the selling or bartering coffee to any person other than a dealer, to the buying of green coffee from any person other than a licensed dealer or owner of a coffee estate or some person authorised by him, to the possession of green coffee by a labourer employed on a coffee estate, who failed to account satisfactorily for such possession, to the removal of coffee from any premises without permission, and to the gathering, removal or loading and unloading of coffee on any estate between sunset and sunrise. In case of a second conviction for certain of the offences specified, flogging was to be awardable, and despite sundry saving clauses regarding purchases for domestic use, the draft Bill was seemingly a very formidable piece of legislation. The planters approved of the licensing system thus provided for, but objected to the limitation to green coffee indicated above, and desired certain protective regulations concerning coffee in transit. The Standing Committee agreed to alter "green" to "green gathered," but asserted that the "special protection which the coffee-planting industry might fairly demand could not properly extend beyond the crop on the ground and the harvested crop in transit through the coffee growing Districts." This is the principle that guided the farmers of Act VIII of 1878.

Complaints began as early as 1879, partly because the application of the Act was thought to be confined within too narrow limits. A host of receivers of stolen coffee were officially reported to be springing up. Not until 1893 was the question of amending the provisions of Section 9 of the Act raised, though this was from the beginning the weak spot of the Act. Since 1893 there has been a steady and persistent representation by the United Planters' Association, and the Nilgiri Planters' Association in particular, of the need for amendment of the Act. The matter eventually came before the South of India Planter's Enquiry Committee, and the result was certain recommendations which have now been embodied in the draft Bill. The words "parchment or cherry dried" are now added to Section 9, which will thus run as follows:—

"Any cooly, maistry or other labourer employed on a coffee estate found with green gathered, parchment, or cherry dried coffee in his possession, and failing to account satisfactorily for such possession, shall be liable, on conviction by a Magistrate, to pay a fine not exceeding five hundred rupees." Provision is also made for the rendering by coffee planters of certain returns, according to forms

to be laid down by Government. The object of this is clear. Sellers as well as purchasers of coffee are brought within the scope of the new Bill; and the provision just referred to will enable District officials not only to ascertain, for example, the amount said to have been obtained by a dealer from his own garden or by purchase, and its disposal, but to ascertain also the amount really produced in the dealer's garden. Properly applied, this Section should strike a severe blow at one of the commonest forms of roguery in connection with the theft of coffee and the receiving of stolen coffee.

THE SOUTH INDIAN COFFEE STEALING BILL.

The following is the full text of the Coffee-Stealing Bill published in *Madras Gazette*:—
No. 3 of 1899.

A BILL TO AMEND MADRAS ACT VIII OF 1878 (COFFEE-STEALING).

Whereas it is expedient to amend Act VIII of 1878 (coffee-stealing); it is hereby enacted as follows:—

1. This Act may be called the Coffee-stealing Act Amendment Act.

2. It shall come into force at once.

3. After Section 5 of the Act the following Section shall be inserted:—

5-A. Every person in occupation and enjoyment of a coffee estate who sells, barter or gives in exchange, any coffee shall at the time enter or cause to be entered in a book to be kept by him a true record of such transaction specifying.

(a) The name, residence and occupation of the person to whom such coffee was so sold, bartered or given in exchange.

(b) The date of the transaction, and

(c) The quantity and description of the coffee so sold, bartered or given in exchange.

4. In Section 6 of the Act for the words "Section 5" the words "Section 5 and 5-A" shall be substituted, and after the word "purchasing" the words "or selling" shall be added.

5. In Section 8 of the Act after the figure 5 the figure and letter 5-A shall be inserted.

6. In Section 9 of the Act after the words "green gathered" the words "parchment or cherry dried" shall be added.

TEA IN EAST AFRICA.

From an article in the *Zanzibar Gazette* of the 20th August we take the following:—

Tea.—We have decided to give this product a trial because of the healthy appearance of the tea bushes at Miss Thakeray's shamba, Mbweni, planted by Sir John Kirk. These were pruned down in October and flushed well, bearing enough new growth in two months to form a plucking surface and leave six inches of pruning wood. Half a maund of Horagalla, Ceylon, Assam Hybrid has been obtained and planted in the new nursery at Mpapa and is growing well. This should give us enough plants for six acres, planting five by five, and leave a margin for supplies and distribution.

I don't think that Zanzibar will ever enter the lists as a tea-producing country, even if low country varieties are found to flourish here, as the labour supply is too small and uncertain. The plentiful supply of organised labour in Ceylon is one of the chief reasons why that country has taken the lead in this industry, while Natal is an example where the comparatively adverse conditions of labour have operated unfavourably. In our present unstable condition of labour we could not do more than grow a few acres for local consumption and perhaps induce the Arabs and natives to cultivate a few trees for their own use. Another point to remember is that tea is a declining market and is probably already over-produced.

UNITED PLANTERS' ASSOCIATION OF THE FEDERATED MALAY STATES.

PARTS OF MINUTES of a General Meeting held in the Selangor Club, Kuala Lumpur, on Monday, 14th August.

PRESENT: Messrs. E. V. Carey (*Chairman*), W. W. Bailey, C. Meikle, L. Dougal, C. M. Cumming, W. Coates, H. d'E. Darby (*Members of Committee*), W. Meikle, G. Shepherd, E. B. Skinner, A. Cathcart, W. Irvine, J. H. Power, A. B. Lake, R. C. Tollemache, J. D. Toynbee, M. Stonor, L. Brooke, F. Callaway, A. Barnwell, W. Greig, H. M. Darby, F. B. Hicks and Tom Gibson (*Hon. Secretary*). Represented by proxy.—Messrs. L. Hawkins, V. R. Wickwar, James McClymont, Quintin McClymont and W. R. Rowlands.

Plantain Trade with West Australia.—The Hon. Secretary read a letter from the Resident-General forwarding copy of an inquiry from the Secretary to the Department of Agriculture, Western Australia, as to the possibility of exporting bananas from the Straits Settlements to Western Australia. The Chairman said he had replied to the Resident-General's letter giving him particulars as to the area under plantains cultivated by Europeans in Selangor and asking for information as to prices and demand in Australia. A day or two ago he had heard from the Resident-General in reply forwarding copy of a further letter from the Secretary to the Department of Agriculture, Western Australia, giving information as to best way of packing, quantity likely to be in demand and prevailing prices, and from this letter he had come to the conclusion that the suggested trade was such an extremely small business that it was scarcely worth while pursuing the subject any further, and had written to this effect to the Resident-General.

For the information of the meeting he would mention that in 1898 it appeared that 14,000 cases of plantains were imported into Western Australia, and that, roughly speaking, meant 42,000 bunches. 100 acres, planted 20' x 20', could safely be counted on giving 43,600 bunches per annum and, as there were about 325 acres under plantains on European-owned estates in the Klang district alone, it must be patent to all that there was nothing in it.

Supply of Para Rubber Seed from Singapore Gardens.—The Chairman said that in consequence of the attitude taken by the Singapore Government with regard to the supply of rubber seed to applicants from the Federated States, he had interviewed the Colonial Secretary in Singapore and had been told that, in booking orders for rubber seed from planters in the Native States, Mr. Ridley had acted without authority from Government, and it was the intention of the Singapore Government to repudiate his action, as all orders for seeds from the Colony must be first executed. In consequence of this it had been decided at a Committee Meeting, held on the 22nd May last, that a sub-Committee consisting of the Chairman, Secretary and Mr. Bailey should interview the Resident-General, laying all the facts of the matter before him for consideration and asking for his advice and support. He (the Chairman) and Mr. Bailey had seen the Resident-General, who said that those applicants who held no distinct promise in writing from Mr. Ridley had only a moral claim against the Government, and he doubted whether it could be enforced, but the case of Mr. Bailey was very different and he did not see how it could be disputed. That was how the matter stood so far, but Mr. Bailey would tell them what his case was and what action he was taking.

Mr. Bailey said that early in 1897 he ordered 500,000 Para Rubber seeds from the Botanic Gardens, Singapore, and on 1st April, 1897, Mr. Ridley wrote saying he would supply him with that number as soon as he could at \$10 per 1,000. As he was forming a company to plant rubber in Selangor, he wrote officially to Mr. Ridley on 12th August, 1898, asking him what number of seeds he could supply him with from 1st September, 1898, to 1st September, 1899, as it greatly depended on the number of seeds available as to whether the company

went through or not. In reply Mr. Ridley said he would be unable to supply the complete order from the present crop, but, as he was the pioneer of the cultivation, he would guarantee that he should have half each crop of seed till his orders were filled. The present crop of seed is expected to be 150,000, yet he is now offered only 15,000, which is a very different thing to above promise from Mr. Ridley.

The Resident-General, at the interview mentioned by Mr. Carey, had stated that he had a legal claim and he had already put the matter into the hands of his lawyers.

The Chairman said he hoped the meeting would express their willingness to support Mr. Bailey in his action.

Mr. Lake asked if this expression was meant to imply that the Association should support the action in a monetary sense if necessary.

The Chairman said he certainly considered so, but there was not much likelihood that such help would be required.

The proposal met with the unanimous approval of the meeting.

Proposed Agricultural Department.—The Honorary Secretary read a long letter from the Resident-General in reply to one from the Association urging on him the desirability of forming an Agricultural Department for the Federated Malay States. The Resident-General, while assuring the Association that the proposal is one which has his fullest sympathy, as the benefits to be derived from such a Department, if properly managed, are unquestionable, said the only point to be considered is whether the Federated Malay States can afford the funds required for such a purpose—he points out that the Association is mistaken in supposing that the present high price of tin is making such an increase in the revenue, that, after meeting the charges for railway construction, there are funds available for other purposes. On the contrary, the question is whether the funds can be found to complete the railway by the year 1902, a date which it was originally hoped would see the whole extension completed. The Government, however, has recently begun the organisation of a Forest Department to the prospective value of which they attach very great importance, and it might be possible for this Department to undertake some of the work the Association think should be entrusted to a new Department of Agriculture. The Resident-General further says that the question will receive his best consideration and asked the Association to favour him with an estimate of what the Committee, as experts, consider would be the annual cost of such a Department as they would recommend, for, say, a term of three or five years, showing the approximate area to be cultivated and the probable revenue that might be expected from the sale of seeds and plants.

The Chairman said that the above letter had been considered by the Committee on 22nd May, and the Honorary Secretary had been instructed to write thanking the Resident-General for his obvious sympathy with the request of the U.P.A., particularly with regard to the last paragraph, and informing him that the Committee hoped to submit certain suggestions on the subject at an early date. With a view to doing so, the Hon. Secretary was also instructed to send a circular to all members asking them what particular products they think should be experimented with and what information is wanted. This had been done and a number of replies had been received.

It was quite evident from the Resident-General's letter such a comprehensive scheme as that laid before him originally would not go through, so they had now to confine themselves to the Resident-General's suggestion in the last paragraph. The Committee had gone carefully into this matter and had come to the conclusion that if Government could be got to carry out certain experiments with those products at present of most importance to planters—viz., rubber, coconuts and coffee—great benefits might be derived by the planting community. It must not be thought that the

committee in mentioning these three products only had lost sight of many others which might be of importance, but what was wanted was a start, and he thought all present would admit that the three mentioned were the most important to planters at the present time.

After discussion the Chairman drafted the following resolution, which was proposed by Mr. Bailey, seconded by Mr. C. Meikle and carried unanimously—viz:—"That a letter embodying the views of the different members of the Association be drafted by the Hon. Secretary and circulated amongst the members of the Committee suggesting to the Resident-General that exhaustive experiments dealing with the products named should be undertaken in Perak under the guidance of Mr. Derry; and that a sum sufficient in that gentleman's opinion to put these experiments through in a thoroughly workmanlike manner be provided by the Federated Malay States Government, and that Mr. Derry's opinion be invited as to what the probable monthly cost of such experiments will be."

A Proposed Association for Stimulating the Consumption of Coffee.—The Chairman, in introducing the above subject to the meeting, said he hoped every member would give it his best attention as it was one of the most important that had ever come before the Association. Mr. Hicks had sent him a copy of the *South American Journal* containing the proposed scheme, and on reading it he had been struck with the excellence of the idea.

The suggested scheme of an universal self-imposed tax of five gold cents a bag—equal to about 10 of our cents—proceeds of which would amount to an annual revenue of £125,000, appeared to him so simple and so likely on account of its pressing so lightly upon the individual, to recommend itself to all producers that he thought some action should be taken in the matter and that was the main reason for calling this meeting. The great feature of the proposed scheme was its comprehensiveness, embracing, as it does, the interest of all growers, whether of the high-grade Arabica or the less valuable Rio and Santos and Liberian coffees, which are absolutely identified, and the suggested tax whilst if universally supported, it will provide such an enormous fund, still presses so lightly upon the individual as practically to amount to no tax at all, it was in fact the only workable proposal that had ever been laid before producers of coffee, and he sincerely hoped that the members present would give it their warm approval.

The following resolution was passed:—"That the Hon. Secretary be authorised to forward the *South American Journal* coupon to that paper, signed by the Chairman of the U. P. A., expressing their cordial approval and warm support of the proposed scheme, and further that the Government be asked, if in the event of the suggested proposal reaching a point where it is ready to be worked upon, they will cooperate by levying a 10 cents per pikul bag tax upon every bag of coffee exported from the Federated Malay States."

Mr. H. M. Darby seconded and it was practically carried unanimously, there being only one dissentient vote by proxy.

Mr. Brooke said he thought the scheme should be made as public as possible and would therefore propose the following resolution—viz.,

"That the Hon. Secretary send copies of the article to all other bodies and associations with whom we are in touch in this part of the world."

Mr. Lane seconded the resolution, which was carried unanimously,

TOM GIBSON, *Hon. Secretary, U.P.A., F.M.S.*

CACAO PESTS.

The "local fly"—I call it the paddy-field fly (writes a planting correspondent from Malacca)—is on again, I captured about two

dozen at 9 a.m. yesterday from my umbrella, while going through a cacao field. This, I believe, is about its tenth or eleventh appearance since April, 1897, the last being in February this year. Unlike the *helopeltis*, this fly seems to attack everything in vegetation, both cultivated as well as what is growing wild. No wonder this happens just after the paddy crops have been harvested, and lands for chena cultivation are being burnt and cleared all round. Much of the disease in the cacao, and paucity of flush in the tea, as it has been so destructive to my annatto, I am afraid, are all due to the attacks of this insect. To plant life its shadow is death! In April last I sent a specimen of this insect to the Director of the Royal Botanic Gardens, and he sent it on to the Director of the Museum; but neither could say what name it had in the world; and left its solution for Mr. Green after the latter had returned from Europe.

PRODUCE AND PLANTING.

IMPORT DUTIES ON TEA.—A despatch, dated July 12 last has been received at the Foreign Office from H.M. Ambassador at St. Petersburg, reporting that, according to a decision of the Council of the Empire, passed on June 4-16, 1899, and published in the Bulletin of Laws of June 25-July 7, 1899, the following alterations, under the Russian Customs Tariff in respect of the duty payable on tea are, according to the "Board of Trade Journal," decreed: 1, Brick tea, black and green imported into Russia across the European frontier to pay duty at the rate of R11:25 per pound (former duty, R31:50 per pound). 2, Black, flower, green, and yellow teas imported at the frontiers of the Steppe, Irkutsk and Cis-Amur Governor-Generalships to pay duty at the rate of R22:50 per pound (former duty R19:50 per pound). With the completion of the Russian lines of rail to the Pacific the rates of the duty on tea will be subject to further consideration.

TEA CULTIVATION IN THE UNITED STATES.—With reference to the exaggerated statements about tea cultivation in the United States, to which we referred last week, a writer in the "City Press," says: "I wonder what Mincing Lane thinks of the statement that experiments in tea cultivation in the United States have proved a complete success, and that America will in time rival China and Ceylon in its production. I do not know what is to prevent the successful cultivation of tea in the Southern States, but I could not think it likely to be profitable. There is about as much put upon the markets of the world as can be disposed of, and prices rule so low that there seems nothing to gain by further competition. There is, however, another side to the question. From the tea-drinker's point of view the revolution effected by the success of the Indian plantations has not been an unmodified advantage. I have never become reconciled to the flavour of the Indian tea, but have been sufficiently philosophical not to be very much troubled about it. If the American tea should prove to be superior in quality, and delicate in flavour, like the better teas of China and Japan, there may be some chance that its cultivation will pay." It will be seen that it is not from a tender regard for the feelings of India and Ceylon growers that this correspondent has been moved to write. While admitting that the experiments in America are unlikely to prove profitable, he is not averse to expressing a faint hope that there may be some chance for American tea if the growers can only produce that delicate flavour he loves so well. But even this does not demolish his contention that the cultivation of tea is not likely to pay.

PUSHING CHINA TEA.—The attempts made to revive the taste for China tea take various forms. The following, referred to by a correspondent of the "Liverpool Courier," refers to one of the latest of these. He writes: "It is the universal practice in London—and for anything I know to the contrary it may be the universal practice in the provinces—for hotel-keepers and publicans to designate the best liquors which they retail by the glass as 'special.' Hence the customer will call for 'a special Scotch' or 'a special Irish,' and even if he calls for a glass of port or sherry he will probably be asked if he wants 'special.' I mention this because it partly explains a significant little incident in my recent experience. I went into an unlicensed restaurant and called for a pot of tea. 'Special tea?' at once queried the dainty maiden in attendance. I was rather surprised and amused, for with a wide experience of such establishments I had never heard that question asked before. 'What do you mean by "special" tea?' I inquired. 'Why, good tea—China tea,' she answered, with a strong emphasis on the word China. Of course I ordered the special tea, and, served as it was with the accompaniment of cream, I found it very well worth the extra charge of twopence. The incident set me upon

making special inquiries, and as a result I find that the incident is simply the sign of a reaction against Indian and Ceylon teas and in favour of China tea. Having always used China tea in my household, and being familiar with its greater delicacy and superior hygienic qualities as compared with other teas, I rather wonder the reaction has not begun sooner. It has been hindered by the higher price of China teas which, taking them grade for grade, are about one-third dearer, whilst the very best qualities of China tea are more than double the price of the best Indian and Ceylon teas. Then, too the average housewife does not understand that China tea, especially if it is good, requires a minute or two longer to infuse. I now learn, however, that in the best hotels and the best houses in London it is China tea that is generally used, and that medical men are more and more advising their patients to give it the preference."

THE PROFITS OF TEA RETAILING.—The "Grocer" quotes from a handbill issued by a London tea retailing concern, in which is the following: "Remember—tea is sold at a price within the reach of all, viz., 2s per lb. Owing to its immense strength and fine quality it will go twice as far as many ordinary teas, and is therefore cheaper. The — Tea Company, Limited (incorporated under the Companies Acts, 1862 to 1898), will pay to every woman who becomes a widow the following sums of money: If, at the commencement of taking tea, the husband is under thirty years of age £30; forty, £25; fifty, £18; sixty, £12; seventy, £7; provided she has purchased a half-pound of tea for the five consecutive weeks prior to her becoming a widow. Customers who purchase a quarter-pound of tea weekly will receive half the above sums. In the interest of bona-fide customers the Company require that the husband shall be proved to be in good health at the commencement of the continuous taking of the tea. Quarter benefit in five weeks, half benefit in six months, full benefit in twelve months. List of moneys paid with the names and addresses of the widows who have received the benefit, can be seen at the registered offices of the company in London or at any of the company's branches."

JYREE TEA.—"By the kindness of Mr. G. S. Peterson, of Weston-super-mare," says the "Kew Bulletin," "we have received a sample of this so-called tea, and find that it is made of leaflets apparently belonging to some species of Acacia. Mixed with the leaflets are petals which may well be those of a Cassia, and a little ordinary tea had been added to one sample, but Mr. Peterson says that such is not always the case. Jyree tea is the name under which this mixture has been offered for sale in Britain. It is of Indian origin, probably from Madras, and cannot as yet be said to have any extensive use. 'Jyree,' we are informed, is a name derived from that of the native servant of an Anglo-Indian who claims to have discovered its virtues. 'Jyree' oil is said to be a cure for aches and sprains; 'Jyree' soap is said to soften the skin, and 'Jyree' may be used, too, for softening leather."

THE CHARGES ON TEA.

Elsewhere we refer to the question of Customs rates and Warehouse charges. Upon the subject of bulking in London, a correspondent, signing himself "Planter," in the course of a letter which is an indictment *inter alia* of the agency system, so far as charges, commission, &c., are concerned, which we do not think it necessary to print in its entirety, says: "Notwithstanding the most painstaking personal supervision of this operation, which I carried out at the factory for years, break after break of tea was reported from London as irregular in quality, necessitating rebulking there, and I ultimately gave up the practice and packed each day's manufacture separately. In the light of observation made during the past two years in London, it has become quite evident to me that my agents have not supported my efforts to the extent I, as manager

of the estate, or as a shareholder, am justified in expecting of them. It is obviously against the interests of companies selling in London to have their teas bulked there, as the charges are heavy, and besides the teas deteriorate in quality from the operation, and it is surely the duty of the home agents to see that those charges are avoided. They, however, say the broker is the responsible party, and if this connection be correct, then on what grounds do they—the agents—claim to earn the $2\frac{1}{2}$ per cent commission on gross sale proceeds of the teas. My agents charge $2\frac{1}{2}$ per cent at Calcutta and $2\frac{1}{2}$ per cent on this side."

"THE GEISHA" UP TO DATE.—An Anti-tannic Tea Infuser Syndicate has been formed to exploit the merits of a patent teapot, the invention of Miss Bain, and as one of the means to that end, arrangements have been entered into "to supply by cable notice sixty Geisha girls who would serve tea in full Japanese costume." Whether Japanese tea is to be served from the teapot or whether Indian and Ceylon teas will be considered good enough does not appear from the circular issued to the shareholders. This circular, which extols the merits of the "Geisha" teapot, mentions that it "should more or less cause a revolution in the liquid tea trade, and be placed in the heart of every household. Being a source of novelty as well as utility, it should also open up a splendid field for advertising. It is our intention," says the circular, "to take advantage of this means of profit by introducing so many thousand teapots to the public, as, for instance, the Lyons, the A.B.C., Slaters, Limited, or any other large company that will remunerate us for such advertisement without disfiguring the article. With regard to the dry tea trade, we intend to manufacture specially-designed pots, such as the Tower teapot, Mazawatte, &c., and to sell to all agents who deal in these particular brands of teas, so that their advertisement will always be under the immediate eye of the user. The Carpetto Syndicate have kindly consented to push our concern to the best of their ability, and as they are more or less working in every theatre, restaurant, hotel, music-hall, mansion, club, &c., their aid should prove invaluable—in fact, they are now putting the 'Geisha' before the Gordon Hotels, London and North-Western Railway and others with a view to supplying them throughout. It is reasonable to suppose that, if the A.B.C. could form such a gigantic concern on aerated bread, an article such as we possess must eventually prove to be nucleus of the liquid tea trade. We hope at no very distant date, if successful, to place before the shareholders a group of City shops, which we have well in hand, with a view of working them on the lines of a

'GEISHA' TEA-HOUSE.

Our chairman has also entered into negotiations with Japanese agents to supply by cable notice (if necessary) sixty Geisha girls, who would serve tea in full Japanese costume. The absolute novelty of this idea, combined with a better and healthier cup of tea, should prove very lucrative to the syndicate if they think it desirable to take the matter up. An attractive display of 'Geisha' teapots is on view at the Greater Britain Exhibition, Earl's Court, and inquiries are daily reaching the office from various parts of the country asking where these teapots can be bought in London and the provinces. It is gratifying to report that the 'Geisha' has been awarded the Exhibition gold medal. We have quite unexpectedly executed a trial order from Paris for teapots, and are now packing several teapots in completion of a repeat order from Messrs. Cooper, Cooper and Co., Limited, London, which firm has now had over 2,000 teapots within the past few months. Several china and earthenware manufacturers have applied to us for permission by license to manufacture

for sale to their own customers our patent teapots, for which they offer to pay royalty from 4d to 4½d per pot. For the present we have considered it prudent to grant only one license, and in that instance we have restricted the output to 100,000 teapots, which must be sold at prices and discounts uniform with our printed lists. We are at present considering offers from foreign manufacturers to make and sell in foreign markets; it is also our intention to have our teapots made in Japan at very low cost, and sample patterns are now on their way out."

THE TEAPOT AND THE TEA.—As regards the effect of the teapot on the tea, a report from Mr. George Combe Stewart, F.C.S., M.B.P.C., &c., public analyst and consulting chemist at the County of the City of Glasgow, says: "I hereby certify that I have carefully tested, in a practical manner, an ordinary teapot fitted with the tea infuser and separator (Bain's patent) which was submitted to me. I have also read the descriptive pamphlet which you have issued to the public, and I am of opinion that there is nothing stated in the pamphlet which the performance of the apparatus does not fully justify. The following points, which are not mentioned in your circular, were brought out by me in my experiments—namely: 1. It is a considerable saver of tea over the ordinary methods of tea making as now practised in this country. Given a teapot large enough for a family meal there would be no necessity for second infusions, the last cup served being as free from tannic acid as the first served off. 2. It thoroughly filters the infusion, allowing no sediment or powdered tea to be found in the beverage, and uniformly insures a beautifully clarified and refreshing cup of tea. 3. It allows the boiling water to be kept in contact with the tea leaves just the exact and proper time for extracting all the theine, allowing none of the bitter elements to go into solution."—*H. and C. Mail*, Sept. 22.

COFFEE CURING.

MR. JAMES WESTLAND'S LETTER.

Planting Opinion to hand contains a copy of a letter addressed by Mr. James Westland, of Gammaduwa, to the Secretary, United Planters Association, of South India, and forwarded through the Ceylon Planters' Association. The greater part of it is devoted to a description of coffee curing in Ceylon, which need not be reproduced; but the beginning and end of the letter is as follows:—

Sir,—In today's paper appears your resolution inviting information from members of your District Associations as to the result of any special system adopted in the Curing of Coffee on Estates. Although not a member of your Association, I have been a long time connected with coffee growing, and have had some experience as a Coffee Estate Manager during my nearly thirty years' residence in Ceylon. My system of curing coffee on the estate may be the system generally adopted by Indian planters; if so, you will know how to treat this, but should it be slightly different from that in general use, I think it will pay your coffee planters to closely follow my system, which I carried out on Golconda from 1872 to 1888. Old sale lists will prove, with what result.

Coffee dried slowly, and given a half-day's sun a day or two previous to despatch, will, when finally cured, be a far prettier bean than coffee cured by two or three successive days in the sun. It may help you to realize the importance of the system if I mention, at the risk of appearing egotistical, that the owner of an extensive property in Haputale gratefully acknowledged these hints, and gave me, through his son who was then the President Manager, a present of a cheque for Rs250, because of the result from his adopting my system of curing, and afterwards, on every occasion his son left for England, I had the

supervision of his large property in addition to my other charges. It may also interest you to know that in Ceylon there is a coffee sieve known as Westland's Sieve Plate, made by Walker & Sons, Kandy, which is recognised as a very useful style of sieve to have on one's Pulper. It has oblong instead of round holes, and allows almost no cherry to pass unpulped.

This letter is written solely with the object of aiding my brother-planters who are still trying to make the most they can out of coffee, and you are welcome to make any use of it you think fit.

LOCAL TEA REPORT.

(September 1899.)

MARKET.—Throughout the month has been very firm with an upward tendency, and closing prices for the month showed a distinct advance over closing rates in August.

QUALITY.—Shows improvement.

WEATHER.—Generally unfavourable for growth.

EXCHANGE.—Firm.

GENERAL.—Statistically the position of tea throughout the world is generally strong, and, judging from present prospects, the output of both Ceylon and India is likely to continue on a moderate scale. There is evidently every reason for presuming that prices, particularly for common kinds, will remain firm until the end of the year.

MINOR PRODUCTS REPORT.

(Chemist and Druggist, Sept. 16.)

QUININE.—Dull and easier. Quotations in second-hands, have dropped about ½d per oz. Today's quotation is 11½d per oz. spot (with buyers at 11¼d) and 11¼d for December delivery, which figure has been paid. Makers' prices are unaltered.

CINCHONA.—At auction on Tuesday supplies were again small, amounting to 1,907 packages (including 729 packages all more or less damaged by smoke in the late fire at Bull Wharf). The demand was quiet, although the bulk was disposed of at lower rates, or generally on a unit basis of 1½d against 1½d in August and 1½d at the last Amsterdam auctions.

CARDAMOMS.—Meagre supplies were catalogued today, consisting mostly of Ceylon-Malabars, for which there was no demand. The following rates were paid:—Ceylon-Mysore, dull bold long bleached 2s 8d to 2s 9d; medium ditto 2s to 2s 2d; small ditto 1s 10d; splits and pickings 1s 5d. Ceylon-Malabars, medium lean brown 1s 8d. No seeds were sold publicly. Some of the parcels offered were not on show in time.

The shipments from Ceylon for the week ending August 22 were 6,711 lb.

SALE OF A COFFEE ESTATE.

This afternoon at Messrs. Powell and Co's sale-room, the valuable property known as the Silian Coffee Estate, about ten miles from Port Dickson, was put up for auction. This freehold property which consists of about 2,000 acres, together with buildings thereon, was disposed of to Mr. Rahmin for \$8,500.—*Singapore Free Press*, Sept. 28.

THE INDIAN TEA TRADE, Mr. O'Connor in his review of the Trade of India in 1898, has a word of encouragement to say to those tea planters who are beginning to cry out about the decline in their industry. He points out that last year the outturn of Indian tea was the largest on record, giving a total of 157 million pounds, being more than double the quantity exported thirteen years ago. When a limited market is found in conjunction with an unlimited supply, the inevitable result is a heavy fall in prices. Yet Mr. O'Connor would not have the Indian planters give way to despondency. He recalls the fact that it took Indian tea twenty years to drive Chinese tea out of the market, and he reminds us that Indian tea is at present consumed in a comparatively limited area. A very large proportion of the white race of the world does not yet consume tea. In France, for example, the beverage is still used only for medicinal purposes. Mr. O'Connor warns the planters that in their efforts to force their way into these huge untapped markets they must be prepared for a struggle as strenuous as that undertaken by them when they entered the lists against China tea. But with courage and perseverance there is no reason why they should not forge ahead.—*Times of India*, Oct. 4.

CUSTOMS AND WAREHOUSE.

We append the Custom House rules as to teas bulked in London, and the warehouse charges on tea, which will be of special interest at the present time.

The difference between bulking, which costs 1s, and bulking and taring, which costs 1s 5d per chest of 129lb. gross, is 5d, a heavy item to pay for simply weighing an empty package. Ceylon bulks only 28 per cent of its import in London, while India bulks about 90 per cent here, thus increasing the cost of laying down its tea considerably, instead of following the example of its younger rival and completing the work on the factory. China and Java always put their tea on the market in a finished condition, while in India only a very small proportion of the planting community seem able to do this. The trade (including Lipton) all admit that they much prefer garden bulked tea (if it is properly done, of course), as it saves the tea from being exposed to much injury to its keeping qualities. Where the bulking is done here the tea suffers, while the lead lining of the box is almost destroyed. Before long it will be absolutely imperative that all the work be done in the factory, thus saving London charges. The example of the few Indian tea companies which bulk on the garden might with advantage be followed by all. They seem to have no difficulty in carrying out the process, or in securing even tares:—

GENERAL ORDER, CUSTOM HOUSE, LONDON, DECEMBER 22, 1894.

TARING OF BULKED TEAS.

Officers are informed that paragraph 62 of General Order 127, 1892, in regard to the taring of Indian, Ceylon and Java teas, has been cancelled, and that the following regulations are to be observed instead thereof:—

In the case of teas bulked in warehouse, for which average tare has been allowed prior to the operation of bulking, that tare may be retained, provided the packages which were selected for taring on taking the landing account did not vary to a greater extent than 2 lb; or the actual tare of each package may be taken at the time of bulking.

If the selected packages varied to a greater extent than 2 lb, each package must be tared at the time of bulking.

All copies of G. O. 127, 1892, are to be noted accordingly.

By order of Board
JOHN COURROUX.

GENERAL ORDER, CUSTOM HOUSE, LONDON, FEBRUARY 11, 1899.

REWEIGHING OF TEA AFTER BULKING ABOLISHED; AND AMENDMENT OF GENERAL ORDER 107, 1894; AND CODE PARAGRAPH 441.

The Board direct that the general practice of reweighing tea after the operation of bulking be relinquished, the usual request for permission to bulk parcels of tea being still required as hitherto. In order, however, to maintain the principle of a check on all operations in bonded warehouses, the surveyors at the tea stations will occasionally as a test-check in the ordinary course of their daily visits call for the production and reweighing in their presence of some of the packages of tea after bulking and re-filling. The board further direct that the regulations contained in General Order 102, 1894, as to the taring of bulked Indian, Ceylon, and Java teas be amended as follows:—

Delete the words—

If the selected packages varied to a greater extent than 2lb each package must be tared at the time of "bulking";

and substitute the words—

If the selected packages for an average tare vary to a greater extent than 2lb, and the surveyor be satisfied that the difference is only exceptional, an actual tare may be taken for the exceptional package or packages, and an average tare given for the remainder of the bed by selecting other packages in lieu of those rejected: provided that the warehouse keeper also agrees to the course adopted.

The Board further direct, in concurrence with the Board of Inland Revenue, that the provisions of Paragraph 441 of the Warehousing Code, which will be affected by the abolition be amended accordingly, by deleting the words—and payment to the collectors of a deposit sufficient to cover the expense of the officer re-weighing.

Copies of general orders, 127, 1892, and 104, 1894, and of the code, are to be noted accordingly.—By order of the Board, (Signed) R. T. PROWSE.

BONDED TEA WAREHOUSES.

CHARGES ON TEA.

To apply to all parcels by ships reporting on and after July 1st, 1888, and to New Season's China teas arriving prior to date.

Correspondence.

To the Editor.

THE LATEST ABOUT RUBBER.

London, Sept. 7.

SIR,—It may interest many of your readers, now that "India Rubber" is coming to the front, to know that we have received an important drawing and full particulars of the experience with this—*castilloa elastica* seed. In one case the seed had been planted in the shade, as was suggested and is adopted generally; the other was planted in the open. I had hoped to send you a photograph by this mail of a drawing which has been sent to us. I may tell you that the description at the foot of the drawing reads as follows:—

"Rubber plant raised from seed grown in open ground in full sunlight, 1st July 1898—measured and sketched 3rd July 1899, circumference of stem one inch above ground $5\frac{3}{8}$ inches, height of topmost branch 4ft. 2 in., spread lateral of branches 5ft." Alongside of this "large tree" are three others, "average sized plants of many thousands sown in forest shade 3rd July 1898—sketched and measured 5th July, 1879, height 1 ft. to 14 inches. Leaves larger than plants sun-grown, but stems very slender and will not bear transplanting into sunlight.

I send you a small drawing showing the difference in the size of the stems, but this will, I hope, be very clear when the photographs are printed.

There is another point that I would like to refer to: in your last number of the *Tropical Agriculturist* you state that you are not aware if one of the new rubber machines has been sent out to Ceylon. As far as we know, none have been sent to Ceylon. The work was first done in the West Indies, then in Brazil, and, as they have been found to answer, the demand is much larger than the supply and we have to beg of those who have had machines to be moderate and patient, because we think they cannot require such a quantity at once. We are endeavouring to send out machines to new countries when applied to, as they are very simple and inexpensive.

As your paper is so widely read, there is another event which has occurred this week which may be of interest to your readers. It has been known now for some time that there is on the East coast of Africa a plant, the root of which cures black-water fever, this quotation on the authority of an English surgeon who has well worked out the subject. He has sent home a hundred pounds of this root, which is evidently a plant of the acacia tribe, judging from the pod which arrived, in a rotten state, in the package. We have treated a certain quantity of this root in one or two ways, so as to bring it as near to the fluid extract as possible, because the surgeon stated that when he first found this bark it was to cure one of the native bearers on an expedition, and thinking that the man would be dead in the morning he spoke to the head man in charge of the coolies, when to his surprise he said: "Oh, the man will be perfectly well in the morning; I will give him a dose." He went with this man, dug up the roots, and watched the roots boiled down and the decoction given, and the result was as indicated, the man was well in the morning and able to carry his load. A supply of roots having been secured, they were tested on the East Coast and in every instance found to be efficacious upon Europeans.

We are sending out some of this fluid extract to be tested in cases of yellow fever in Brazil, and we are supplying different parties who have establishments on the East and West Coasts of Africa.—Yours truly,

THOS. CHRISTY.

RUBBER PREPARATION:

THE NEW MACHINE.

London, Sept. 15.

DEAR SIR,—Having seen the note in your issue of Aug. 1st, I have pleasure in sending you here-with a drawing of our "Beta" Rubber Machine, and at the same time directions for working. It will no doubt be of particular interest to you to hear that with this machine Para Rubber can be coagulated with ease. The enclosed piece of rubber is cut off from a sheet of *Castilloa Elastica* as turned out by the machine. You will see of what particularly good quality it is. The price of this apparatus is £6 10s 0d including five spare sieves.

Up to now there has been a great divergence of opinion as to the proper method of laying out plantations of *Castilloa Elastica*, and I have this week received some valuable information on the subject from several English gentlemen who have established large plantations in Southern Mexico. They tried the two ways of planting which are in vogue: first, planting out the young trees in places partly cleared in the forest, and secondly, planting direct in the open sunlight without any shade at all. The results are quite extraordinary. Those sown out in the open in full sunlight on July 1st, 1898, when measured on July 3rd, 1899, had a stem the circumference of which was, one inch above the ground, $5\frac{3}{8}$ inches, the height of the topmost branch being four feet two inches. These measurements were taken from an average plant.

An average plant of 11,000 sown in the forest shade on July 3rd, 1898, measured, on July 5th 1899, height between 12 and 14 inches, and the circumference of stem $1\frac{1}{4}$ inches.

What was particularly noticeable was that these plants, when transplanted into the open on account of their doing so badly in the forest, very soon died.

I trust by next mail to send you a photograph of the drawings, as a glance at this would show at once the extraordinary difference.—Yours truly,

GILBERT CHRISTY, F.L.S.

DIRECTIONS FOR USING THE "BETA" RUBBER MACHINE.

1.—The latex as brought in from the field must be mixed with 50 per cent. of clean water and then passed through a fine copper sieve to remove particles of bark, &c., &c.

2.—Pour the latex into the upper part of the machine or washer, turning the handle quickly. Have an assistant to pour in water continuously, so as to wash the latex through the wire gauze sieve which is fixed in the base, until the lower vessel is full. Then pass on to the next in turn, and fill up as many vessels as may be in use.

3.—The sieve must be removed and cleaned when required, by washing in clean water.

4.—Allow the vessels to stand until the rubber has risen like cream to the surface. When it is ascertained that the rubber has all come to the surface, draw off the

liquid from below, by opening the tap, until the liquor is seen to contain particles of rubber. Then stop and fill up again with clean water by pouring it into the aperture which carries it below the rubber at the base of the vessel. Perform this operation three or four times, or until the rubber rises white and clean. No loss of rubber occurs if the operator is careful to let the rubber all rise to the surface before drawing off the water.

5.—When the water is left off for the last time, some of the rubber will pass before the upper surface is sufficiently drained. This should be caught and returned to one of the vessels where washing is going on for the first time. The thickened cream or latex must now be poured into gauze sieves and set to strain over vessels holding water, so that no rubber may pass through and be lost, and this draining may also be returned to the washer.

6.—Allow the latex to stand in the sieves, occasionally filling up with washed latex until full. When fully drained the latex will coagulate of its own accord, and may be turned out in cakes or sheets. The drying of these sheets may be assisted by passing them through wooden rollers, and the sheets should be completely dried by passing through each a loop of twine, and suspending them in an airy place.

7. If it is required to hasten the process, a coagulator may be used, but better rubber is produced by simple evaporation.

8.—The parts of the machine must always be well cleaned immediately after use, as this operation becomes difficult if the rubber is left to harden on the sieve or the sides of the vessels.

9.—By keeping plenty of water with the latex during washing, any partial coagulation is prevented and a better class of product results. Latex mixed with water will stand without coagulating for 48 hours, without affecting the quality of the rubber produced.

10.—Rubber produced by this process will keep longer, and, is of far better quality than by any other process, as all the matters likely to deteriorate the quality are removed by the frequent washing.

T. CHRISTY & Co., 25, Lime Street,
London, England.

PLANTERS' ASSOCIATION OF CEYLON.

CEYLON TEA IN GERMANY:

MR. J. H. RENTON'S REPORT.

Kandy Sept. 20.

SIR,—I enclose for favor of publication copy of Report by Mr. J. H. Renton on the subjects of Ceylon Tea on the Continent of Europe and the Paris Exhibition,—Yours faithfully,

W. D. GIBBON.

Bukeburg, 15th Aug. 1899.

MY DEAR LANE,—I shall be in Ceylon, I dare say, as soon as this reaches you; but it is as well you and the "Thirty Committee" should have a report on Ceylon Tea in Germany, as I have made exhaustive enquiries during my stay in Bremen, Hamburg and Berlin.

CONSUMPTION OF TEA IN GERMANY.

I was quite under the impression that the consumption of tea was increasing. It seemed to me to be more drunk. I have seen many more advertisements of tea than formerly, and that in the largest towns there are shops that sell only tea and coffee, seemed to me indicate a greater consumption of the article. The importers in Hamburg and Bremen, as well as the largest retail dealer in Berlin, assure me this is not the case. The importation of tea has increased, but this is entirely due to the increase in the population,

and in fact that though the increase in imports has been an average one of from 10 to 15 per cent per annum for the past five years, the consumption per head, is not what it was 20 years ago. Though in Southern Germany the consumption may have grown a little, it has fallen off in some parts of Northern Germany, being displaced by beer and coffee. The reasons for the non-increase in the consumption of tea are various—first during the past two years is the great cheapness of coffee. You can get good coffee ready roasted for 1s per lb.: this is after paying duty. The large turnover in coffee and competition compel the retailer to sell it fairly cheap. But in tea, there is a small sale and the retailer will not trouble himself with sale of the same unless he makes a good profit. In tea, the retailer must have his 33 per cent. the dealer his 15 per cent. and the importer his three per cent.; they won't work for less: there is a duty of 6d per lb. on tea. If tea is to reach the masses it must be retailed at lowest at 2s per lb., but with a 6d duty, and charges varying from 60 to 65 per cent. There is, you will see, not much chance of a good tea being sold at this price, how then can the frugal housewife get a good tea for 1s 6d? Second, the non-staying power of tea: the average German takes only coffee, rolls and butter, to breakfast. At 1 o'clock he is ravenous on tea, but if he has had coffee he goes on much longer. Third, the difficulties in the way of the preparation: fresh boiling water, and a 2d tea pot. Tea is in 99 cases out of 100 not properly made, and the man who has tried it, once and liked it, when on the second and third occasions he gets a bad cup, gets disgusted and goes back to coffee. Fourth, the large increase in the production and consumption of beer. My lady friends in Hamburg tell me that in the days of their mothers and grandmothers it was considered very bad form for a lady to drink beer in the evening: now although tea is always prepared and there 70 per cent. of the ladies drink beer and wine. As regards the

CONSUMPTION OF CEYLON TEA,

it is used and used entirely for blending. Both the importer and retailer are of opinion that it will never be drunk by itself. Our medium and common teas are not in it, they say with other kinds; they are flat and dull. Our good teas are liked, but are much too bitter and harsh to be drunk by themselves. The German Customs, in their returns, make no distinction in the country of origin. The largest importer in Bremen, gave me it as his opinion that about two-thirds of the total tea imported, was from China, and the other one-third Indian, Java and Ceylon; and he considered that Ceylon had fallen off during the past two years, owing principally to the fact that Indians and Javas were relatively of much better value. Java teas had improved immensely. Their leaf was always good, but the liquor instead of as formerly being mere dirty water, now contained both strength and flavour. I myself was much surprised to see what very good teas indeed were being

SENT FROM JAVA.

This importer was emphatically of the opinion that Javas and Indians lent themselves much more easily for blending purposes than Ceylons. He dilated, and so did every one, I met on the non-keeping quality of Ceylon tea. This is an old and general complaint and I think it would be really worth our while to try, if Mr. Bamber can give us any help on this point,

Another importer placed the consumption of Chinas in Germany at three-fourths of the total import, and other kinds one quarter only. As regards a campaign for the pushing of Ceylon Tea in Germany, I found all the importers indifferant and some of them distinctly hostile. Some of them (personal friends of my own) seem to regard my mission as one meant to take the trade out of their hands and to transfer it to the retailer and wholesale dealer. My assurance to the contrary seemed at first to have little effect. I assured all these men that I wanted to work with the trade, and through the trade entirely. After a deal of conversation, I believe, I have got

TWO HAMBURG IMPORTERS,

and one Bremen one, to work with me. The two former will think the matter over, while the Bremen man is to get a series of well-written illustrated articles put in the illustrated newspapers, and further short articles in the other papers. I am to send him a supply of photos for this purpose. I have made it clear that we are quite as willing to assist their clients to advertise Ceylon Tea, as we are to assist Hagenbeck & Co. Hagenbeck's advertisements have evidently made a great deal of impression, but most of the importers think it is money thrown away, and hold that the immense amount of money spent will not be compensated for by the amount of business done. However, the very fact that his advertising has drawn the attention of the whole of Germany to him and his tea is significant.

HAGENBECK AND CO., BERLIN, AND THEIR WORK,

This firm have taken up Ceylon Tea, and pushed it on through business lines and with a vast amount of energy. They have only an office in Berlin, their warehouse is in Bremen, as is also their packing establishment. Their mode of work has been as follows:—Their travellers have visited 67 big towns in Germany. Prior to his arrival the town is placarded with posters and the dealers in that town and district receive musters of his teas. In every district he has now an agent or rather dealer and the dealers and travellers in turn take his teas round to the grocers. He works in tea and Ceylon Tea only. In addition to the 67 large towns his travellers have visited 37 smaller towns in Germany. I have of course not been able to verify this statement about the travellers, but their books show the following expenditure from time they started till 31st July:—

		Marks.
(1) Placards in 67 towns. Advertisements in 31 papers. Cost of postage 165,000 for samples. 275,000 post cards with views. 100,000 circulars. Six particular posters. 3,000 transparencies. 40,000 post cards from Colombo	...	4,2700
(2) Two travellers	... 14,000	} 21,100
Three Warehousemen..	3,500	
Two clerks	3,600	
(3) Rent of Warehouses in Bremen. Offices in Berlin.	} 6,600	}
Furnishing of do. do.		
(4) Purchase of 92,000 lbs. tea	...	40,000
		110,400

or say £5,520 or in advertising alone £2,135, against which we have given them £750. (Since this was written payments have been given for £907 1s. 0d. being one-third of £1,154-7-5 and one-third of

£1,566-15-6, in addition to the £750 grant, 5,000 lb. of tea for free distribution and R2,875-24 for duty.	
Receipts:—	Marks.
£750 from Thirty Committee	.. 15,000
Sales of 30,000 lb. tea	.. 14,000
Profit on do	.. 1,400
	30,400
Deduct receipts from Expenditure	.. 80,000
leaves a balance of	.. 26,000
Less value of 15,000 lb. tea sold but not delivered, and 47,000 lb. tea bought, but not sold	..
	54,000

or £2,700. being balance of money imported by Hagenbeck & Co. in first nine months. In other words they have up to date put £4,000 into the business. They are strongly of opinion that they must go on with their advertising and think it would be unwise to stop. I have pointed out that all those other articles of consumption which are so extensively advertised give a large profit to the manufacturers probably over 100 per cent—and they can well afford to advertise, but that our funds are limited and that we do not profess to advertise to this extent. Herewith summary of their estimate for six months advertising to be undertaken now:—

Advertising in six illustrated papers with a weekly issue	..	Marks 6,336
Eight ladies' papers appearing every fortnight	..	4,272
24 daily papers once a day	..	7,322
For special advertisements for grocers in their own provincial papers	..	9,000
Placarding towns	..	12,448
25,000 large posters	..	1,125
19,000 small do	..	1,140
12,000 inside do	..	1,800
12,000 transparencies	..	840
49,000 samples and postage	..	10,000
300,000 post cards	..	2,700
200,000 pamphlets (Bamber's)	..	6,000
		M. 62,983

or say £3,149. I have pointed out that we are quite ready to give one-third of this sum. They affirm that this is not sufficient and that they cannot risk more of their own capital. I have replied we cannot possibly devote such a large sum as this to him alone next year. I see from the Report of the Committee that a sum of £2,000 has been voted this year for Germany and that out of this Hagenbeck & Co. are to receive £1,500. I do not know, if this is in anticipation of more advertising on their part or in payment of part of the money M. 42,700 (£2,135) already spent by them. If this be the case, I think, Hagenbeck should receive other £500 next year in 1900—making a grant of £2,000 to them on account of their expenditure for advertising in '98 and '99—which will amount to a total of £5,284. See my private letter which accompanies this for fuller information as to this firm. For we must reserve £500 at least next year, for the importing houses in Bremen and Hamburg if they want it. Hagenbeck & Co. are particularly anxious to have some sort of official appointment. They have tried to take advantage of the present of tea to the troops to obtain contracts with some regiments, but unless they can shew that they are special agents for the Planters' Association, or the Ceylon Government, they will be regarded as swindlers, they say—I know how much importance some official recognition gives in Germany, but we do not do

this sort of thing in England, or Ceylon, and I must confess I do not see how Hagenbeck's wishes are to be met.

CEYLON TEA AT THE PARIS EXHIBITION.

I have had a long interview with the manager of Messrs. Lipton, Limited, tea Department. He has agreed to sell and advertise a blend of pure Ceylon tea, to advertise *Ceylon* tea extensively at his tea house and all over Paris, and to appoint agents all over France for the sale of his teas and Ceylon teas. In addition to the Blends of Ceylon Tea, he is to sell a Blend of Ceylon and China, and he is to give a guarantee that this blend will contain 50 per cent of Ceylon tea. If he carries out these promises, I have agreed to give him a grant next year, for advertising purposes. We must never forget that Ceylon tea made its way at first in Great Britain by being mixed with China, and I think we must follow suit in France and Germany, but at the same time get men to advertise *pure* Ceylon tea and keep it asked for.—Yours very truly,

(Signed) J. H. RENTON.

F. G. A. LANE, Esq.

DUKWARI (CEYLON) TEA PLANTATION CEYLON.

The Directors have pleasure in submitting the accounts for the year ending June 30th:—

The balance of profit and loss account, after writing off ten per cent. Depreciation on value of machinery and buildings, is	£2,914 8 4	
which the Directors propose should be applied as follows:—		
(1) In payment of seven per cent. Dividend on preference shares..	£840 0 0	
(2) In payment of seven per cent. Dividend on ordinary shares ..	560 0 0	
		1,400 0 0
Leaving		£1,514 8 4

to be carried forward to next year.

The returns of crop have been 277,408 lb. tea and 10,012 lb. Cardamoms, against 229,670 lb. tea and 12,655 lb. cardamoms last season. The large increase in tea is to be attributed to the free use of artificial and bulk manures.

The estimates for the coming season are 300,000 lb. Tea and 12,000 lb. Cardamoms.

The only Capital Expenditure during the year has been the purchase of a Roll Breaker and Sifter, costing £5 15s. 20d.

Mr. Spence retires from the Direction by rotation and, being eligible, offers himself for re-election.

The Auditors, Messrs. Brown, Flensing and Murray, also retire, and offer themselves for re-appointment.

CEYLON TEA IN MELBOURNE.

ALFRED HARVEY & CO.'S REPORT.

CEYLON.—Shipments from Colombo are 6,980,000 lb., as against 6,410,000 lb. at same time last year. Locally, arrivals have not been heavy, but have been painfully lacking in flavour and character, and in combination with high lay-down costs have been difficult to move. The want of careful manufacture has again been decidedly in evidence. The latest shipments, however, have contained a few breaks with good point, which indicate improved production. The market in Colombo is reported to have made a strong advance in sympathy with London buying and the increased demand from all parts of the world. Stocks in bond on the 16th instant were 449,986 lb. In Sydney during the month imports consisted principally of low to medium broken pekoes, ruling from 7½d to 9d; the few lines showing quality realised full

rates from 11d to 1s 1d. Pekoe sonchongs and pekoes were not in full supply, and were neglected by buyers in favour of Indian leaf, which showed better value in comparison.—Sept. 27.

PRODUCE AND PLANTING.

PLANTING IN CENTRAL AFRICA.—There are worse places for planters in some respects than British Central Africa. Of course capital is wanted, but the labour market is the cheapest in the world, the rate being about three shillings a month—paid in calico. Land is cheap, and will grow anything, and give enormous crops. On the other hand, it cannot be said to be a healthy country. There is a heavy, continuous rainfall for six months, the climate is malarious, and as black-water fever is prevalent, the death-rate is high. Whites fare well; Indian cooks, veritable chefs, are employed. There is no variety in the food, the staple is "chicken," but the game is excellent. Order is kept by a stand army of 300 Sikhs with white officers. The Deputy Commissioner commands the British Central African Rifles, which consist of two battalions of natives, one of which is at the depot in Manritins. The best coffee in the world comes from Nayasaland; it fetches the highest prices, and so does the tobacco. The planters are mostly Scotch. A good deal of rubber is also finding its way through the Protectorate from the Chartered Company's territory north of the Protectorate.

TEA RETAILING DODGERS.—The competition in tea retailing must be acute indeed, judging by the dodges resorted to for the purpose of inducing sale. "The Grocer" refers to a circular issued by a gentleman who announces that he has just returned to the home of his parents. His relatives were generous to places of worship, one of their gifts being an organ." Having come to reside in his native town he trusts his fellow-townsmen—especially Christians—will buy his "fine teas." It is his intention not to call for orders unless requested. In another instance somebody's brand of tea is referred to, to push the sale of which the "somebody" is "giving away" £300 in money prizes. The tea ranges from 1s 4d to 2s 8d per lb. and senders of the first forty orders opened each morning will have the amount sent returned with the goods, and two or three shillings to boot.

PLANTING TROUBLES IN BRAZIL.—Financial trouble in Brazil is having a serious effect on the coffee industry. The rise in the value of the milreis and the uncertainty of the power of the Government to maintain it paralyses trading in every direction.—*Home and Colonial Mail*, Sept. 29.

"ALL ABOUT RUBBER."—The further title of this handbook mentions that it deals with "all varieties in all countries, with harvesting and preparation, and gutta-percha." Therefore, Mr. J. Ferguson has launched out upon a large and important subject, with which, as editor of the *Ceylon Observer* and the *Tropical Agriculturist* he has proved himself qualified to deal: The volume is destined to be the India-rubber Planters' Manual, and it "includes the latest statistics and information, more particularly in regard to cultivation and scientific experiments in Trinidad and Ceylon." Having mentioned the scope of the book, and the fact that Mr. Ferguson may be trusted both as regards original writing and the sources from which he draws his quotations, it is merely necessary to add that all directly or indirectly interested in the India-rubber industry must acknowledge the convenience of obtaining so much valuable information in a handy form. Publishers—London: J. Haddon & Co.; Luzac & Co.; Kegan Paul, Trench, Trubner & Co. Also issued from Colombo, Singapore, and Java.—*Gardeners' Chronicle*, Sept. 16.

INDIAN AND CEYLON TEAS.

The popularity of British-grown teas is ever increasing with almost phenomenal rapidity, ousting China teas from the position they have occupied for so many years. The planters of India and Ceylon are far-seeing men, and, recognising that unity is strength and dissension commercial suicide, they have coalesced to conquer the world, and seem in a fair way to success. They have imposed upon themselves an export tax which is devoted to fostering the trade in their teas in countries in which they have not yet established a firm footing, and where they are comparatively unknown. Thus, in North America, two Commissioners, representing India and Ceylon respectively, were appointed, and, working harmoniously together, they have done splendid service. The merits of British grown teas have been persistently kept before our American cousins and Canadian brethren by means of advertisements and subsidies to firms who have taken up the trade. Blends containing Indian tea mixed with the long-known China variety were found to sell well, and as the proportion of Indian increased, so did the demand. The result of this wisdom and push is that British teas (bounty-fed, by the way) have a firm hold upon the North American markets, from which they are steadily driving China. The following table of imports gives some idea of the strides made in the use of Indian and Ceylon teas in North America of recent years:—

	1898. lb.	1897. lb.	1896. lb.
Indian ...	5,972,000	5,663,000	5,259,000
Ceylon ...	7,637,000	6,099,000	4,365,000
Total ...	13,609,000	11,362,000	9,624,000
	1895. lb.	1894. lb.	1893. lb.
Indian ..	4,072,000	2,423,000	2,111,000
Ceylon ...	3,745,000	2,295,000	1,871,000
Total ...	7,817,000	4,723,000	3,982,000

From this table it will be noticed firstly that the total exports of tea from India and Ceylon to North America have more than trebled in six years, and secondly that the produce of Ceylon meets with more favour than that of India.

We have taken North America to illustrate the pushfulness of the Indian and Ceylon exporters, because for the past few years special attention has been devoted to the trade there. Efforts are being made to develop the business in other countries, but not on such broad and liberal lines. The following table, however, shows very clearly that the tea exported from these countries is making rapid strides in Foreign and Colonial markets, exclusive of North America:—

	1898. lb.	1897. lb.	1896. lb.
Indian ..	20,053,000	16,536,000	13,947,000
Ceylon ...	28,763,000	23,250,000	19,101,000
Total ..	48,821,000	39,786,000	33,048,000
	1895. lb.	1894. lb.	1893. lb.
Indian ...	12,743,000	11,722,000	11,910,000
Ceylon ...	16,167,000	12,268,000	11,268,000
Total ...	28,910,000	23,990,000	23,184,000

Here again it will be noticed that the consumption of Ceylon teas is greater than that of Indian.

[Reference is then made to Russia but the information is scarcely up to date.—Ed. C.O.]

In the rest of Europe, in Australia, in fact all over the world, the same constant increase in the consumption of the tea grown in our great dependency, and its friendly rival Ceylon is found. It is even the case in China itself,

At home again we find the demand ever increasing, at the expense, to some extent, of China, although the total consumption of teas of all kinds is also growing. We append a comparative statement of deliveries in the United Kingdom for home consumption only.

	1894-5. lb.	1895-6. lb.	1896-7. lb.
Indian	113,500,000	121,000,000	123,750,000
Ceylon	71,500,000	76,000,000	83,500,000
Total	185,000,000	197,000,000	207,250,000
	1897-8. lb.	1898-9. lb.	
Indian	127,500,000	128,605,197	
Ceylon	87,000,000	80,108,167	
Total	214,500,000	218,713,364	
	1897-8. lb.	1898-9. lb.	
Cbina and other teas	30,000,000	24,000,000	
Total	215,000,000	223,000,000	231,250,000
	1897-8. lb.	1898-9. lb.	
Indian	127,500,000	128,605,197	
Ceylon	87,000,000	80,108,167	
Total	214,500,000	218,713,364	
	1897-8. lb.	1898-9. lb.	
Cbina and other teas	20,500,000	21,569,953	
Total	235,000,000	240,283,317	

The totals given above do not, of course, represent the imports into the United Kingdom; a large quantity in addition, which in 1894-5 was about 31 million pounds, and in 1898-9 was 33,400,398lbs., is re-exported every year.

A source of annoyance is the import duty, both in England and America. In this country the duty amounts to 4d per lb., and the Chancellor of the Exchequer derives from this source the comfortable sum of something over four millions per annum. Coffee, on the other hand, pays only about 1d per lb. in import duty, and the spirit of the tea-importer rebels against this "partiality," but in view of the fact that fourpence a pound is in itself a moderate duty, and that the impost on tea and tobacco are the only means of obtaining any sensible contribution from the temperate working man towards the expenses of the Empire, it seems unlikely and undesirable that any further decrease should be made. In America, also, coffee is more kindly dealt with than tea, and this was particular the case during the war with Spain, when a war tax of ten cents was charged upon every pound of tea imported. With the great reduction of the duty in recent years, there has been an immense impetus given to the cup which cheers and the hearts of good Imperialists especially rejoice at the knowledge that British gardens supply the great bulk of the tea tables of the world with fragrant leaf.—*Investors' Guardian*, Sept. 23.

MR. ALEX. WHYTE AND UGANDA CLOVER.—The Uganda clover is an ally of the widely dispersed *trifolium repens*, which it closely resembles, and was originally discovered by Sir Harry Johnston of Kilima N'jaro at 10,000 ft. in 1885, and has been found to be common by Mr. Scott Elliott at Kikuya at 5,000 ft. to 6,000 ft. A supply of seed has now been sent to Kew by Mr. Alex. Whyte, F.L.S., curator of the botanical station, Uganda, [late of Ceylon.—Ed. T.A.] who writes that it is a splendid plant to introduce into the hill pastures of tropical countries, as the pastures of Kikuyr in which it flourishes are very rich. Seed has been distributed for trial in the colonies and elsewhere, and the results will be awaited with interest by all those interested in tropical pastures at high altitudes.—*Chronicle*, Sept. 15.

LONDON CHARGES OF TEA COMPANIES.

Under this head the "Investors' Review" is publishing a series of articles. We give the first of these, taken from the issue of September 16:—

There is little doubt that the tea-grower is feeling the pinch of hard times rather severely. Under ordinary circumstances such a development as the rise in the Indian exchange from 1s 0^d to 1s 4d per rupee, with its concurrent advance in the cost of production in India and Ceylon, would have been accompanied by some improvement in the European price for tea that would have served as a mild offset to the increased expenditure of the planter. The mania, however, for extensions some years back has quite put this natural remedy out of the question, for the knowledge of the enormous area of tea plants coming to maturity, combined with the larger quantity of tea sent to market, has the effect of preventing any recovery. Consequently the average price of 8³/₄d. per lb. for last season was no higher than the average price obtained when the rupee was at its lowest, although last season was favoured by a little "boom" in the spring as a result of the accidental circumstance that for two seasons in succession the Indian crop as a whole had been poor in quantity. Anyone acquainted with the real position of the industry feels that if only the average yield per acre returns to its normal figure, a further decline in the price of tea must be faced.

This may be taken as an axiom, admitted but not talked about, by tea growers, and profits having been seriously eaten into already by the course of events, there has been a great searching to find economies that would in some respects guard producers against a further decline in price. Expression of this quest was visible in the campaign against the "draft" which ended so disastrously to the producers, and, the wisecracks of that body having had their turn, some of the practical members amongst the tea-growing community are now beginning to raise their voices. As things stand, where the chief evil is over-production, economies must be looked for rather from within than from without, for the buyer knows he is in the stronger position, and he should therefore be cosseted and soothed rather than talked to with a club. But economies from within, in the shape of stopping leakages in profits, reducing extravagant charges, and rendering unnecessary too much manipulation of the article produced, are just those reforms that lie open to every tea grower, and the closer he studies the minutiae of his business the more he will fend off the reduction in his profits. Every decimal point per pound saved in cost of production and charges relating to tea is so much in his pocket, which he is more likely to save than if he attempted to put up market prices against the buyer.

Regarding the outlay on the estates, we cannot speak with knowledge, for that expenditure is of such a special character that experts alone can give an opinion worth having. As a matter of fact, however, we believe it is admitted that as, generally speaking, this expenditure has been steadily reduced, if allowance be made for change having risen, salaries have been cut down, more economical forms of working have been adopted and in other ways prime cost of production has been lowered. Whilst this has been done of late years, there has been a growing discontent with the burden of London charges, which range from a little over 1d to 1³/₄d per lb., and these charges upon an average price of 8³/₄d for Indian tea and 8d for Ceylon tea appear to constitute an excessive burden. They mean that the Indian planter has 7d per lb. left with which to pay all working charges close down to the arrival of the tea at Calcutta and evolve a profit for himself, which the Ceylon producer has even less of a margin. Before we

go further, we ought to say that in many cases the burden of the London charges is rendered unnecessarily heavy by the management at the estates. If the tea is not properly hulked before leaving the estate so that a break of chests of one grade differs materially in quality, "bulking" has to be conducted in the warehouses in London, and although this charge is said to be unreasonably high, the process necessarily must be costly, for all the chests have to be opened, their contents spread out, and mixed one with the other, in order to produce a tea of equal quality throughout the break. And the warehouse responsible for this work, if it does not do it properly, and it is often not done well, takes care than the samples taken shall not be from the best part of the tea, for in that case the buyer has a remedy against the warehouse, and this hulking in London, therefore, tends to hinder the tea-grower from getting quite full credit for the quality of the tea he sends. Then, again, tea loses in value by being handled, and the weight suffers from the same cause.

Another fruitful source of loss arises to the planter if he does not make the weight of his tares equal, the bare weight, that is, of the packages in which the tea is sent. If this precaution he neglected, the tea has to be "tared" in the warehouse, which means that the chests, or a certain proportion of them, are taken, the tea turned out, and the empty packages then weighed. The charge for doing this is also high, and, again, the loss in weight and damage to the tea is considerable. A saving can also be effected by so packing the tea that it takes less space in the ship, and thus reduces the cost of freight.

To give a concrete example of what attention to these details means, and also in elucidation of remarks to be yet offered about warehouse charges, we give the following examples of two shipments of tea by small Ceylon concerns, and the London charges upon them. The first example is one where the cost was low, amounting as it did to under 96d per lb. The names of the estate and of the ship are quite fictitious, although every other detail is copied with strict accuracy

ROYALE ESTATE CROP, 1899.

Report on Outturn of 113 Packages Tea ex Oceana.	
Averages:—	d.
10,524lb. sold, grossing £319 11s 1d = 7 ²⁹ / ₁₀₀ per lb. gross.	
10,640lb. shipped, netting £280 9s 9d = 6 ³³ / ₁₀₀ per lb. net.	
116 Loss in weight and charges =	⁹⁶ / ₁₀₀ per lb. Equal to per lb. on Shipping weight.
Loss in Weight—	
Draft at 1lb. per package accounts for 113lb. and the actual shortage is therefore 8lb. ...	d.
Draft and actual shortage equal 1 ⁰⁹ / ₁₀₀ per cent on shipping weight ...	07
Freight—	
Rate, 25s Meast, 565. Amount £14 2s. 6d. Equal to 94lb per 50 cubic ft. on shipping weight ...	32
Dock and scale charges—	
Amount, £15 7s 1d. ...	35
Brokerage 1 p.c., and commission 2 p.c. Amount, £9 11s 9d ...	22
Remarks—	
All grades passed on an average tare.	
Total charges and loss in weight per lb.	96

In the above example all grades were passed on an average "tare," so that the tea did not have to be handled before it was sold. The result was that, allowing the 1 lb. per package for draft, the loss shown upon 10,524 lb. in the shipment was only 3lb., a mere nothing.

Turning to another shipment which passed through the hands of the same agent, but from another estate, we find the result very different :—

BINGOLE ESTATE CROP, 1899.

Report on Outturn of Packages Tea ex Wakera.
 Aveages :—
 2,620 lb. sold, grossing £103 14s 2d =9'50 per lb. gross.
 2,728 lb. shipped, netting £91 13s 2d=8'06 per lb. net.

108 Loss in weight and charges =1'44 per lb.
 Equal to per lb. on shipping weight.

Loss in weight :—
 Draft at 1 lb. per package accounts for 44 lb., and the actual shortage is therefore 64 lb.
 Draft and actual shortage equal 3'96 per cent. on shipping weight 38
 Freight :—
 Rate, 25s. Meast., 124'8. Amount, £3 2s 4d.
 Equal to 1,091 lb. per 50 cubic ft. on shipping weight 27
 Dock and sale charges.—
 Amount, £6 6s. 7d. 56
 Brokerage and commission :—
 Amount, £2 12s 1d. 23
 Remarks :—
 Each package tared involving heavy dock charges (tares 14—18 lb). Loss in weight is probably due to the same causes.

Total charges and loss in weight per lb. 1'44

In this shipment there were only forty-four packages and so the loss in weight from the draft was only 44 lb., but, as a matter of fact, 108 lb. was lost out of the total amount of 2,728 lb. shipped. Some little proportion of this was due to general causes, such as drying on journey and weeping, but the main reason was the fact that every package had to be tared at the warehouse. The shortage of tea on the shipment thus came to '38d per lb., instead of '07d per lb., as in the first example. Taring also added to the warehouse charge materially, this representing '56 per lb., as against '35d per lb. in the first example. The only respect in which the Bingle estate shipment compared favourably with that from Rotale was in that it was so packed as to allow 1,091 lb. of tea to be got into 50 cubic ft. on board ship, as against only 941 lb. per cubic ft. of the Rotale tea, the difference representing '05d per lb. in the freight charge. The net result was that the London charges for the tea from the Bingle estate totalled 1'44d per lb., as compared with only '96d per lb. upon the tea from the Rotale estate. And probably the tea from Bingle was in such good condition for selling at the end as that from Rotale. Whilst, therefore, we are not blind to the faults on the side of the planter and his assistants which contribute to keep the London charges heavy, we must confess to a strong opinion that he is in some respects unjustly treated. Let us analyse those London expenses as set forth in the examples given above. The loss in weight, after deducting the "draft," is a matter, as we have shown, very much in the planter's own hands. Then comes ocean freight, which is a charge very much outside his control. Freight rates vary at times from about 20s to 40s per ton, and their rise and fall are governed by many conditions quite outside the tea trade and that trade cannot be expected to receive special consideration from the shipping firms. The examples we give show a freight rate of 25s per ton, and we believe the present charge is 30s per ton. Next comes dock and sale charges. These are the warehouse charges about which there is so much complaint just now, and finally we have brokerage and commission. These latter embrace the usual one per cent to the broker who sells the tea and two per cent to the agents, the latter covering office ex-

penses and secretary's salary, if the concern is a company. The warehouse charge of 35d per pound does not look heavy to an outsider, and in the example we have given it is rather low, the average being nearer 40d per pound, when no special services have to be rendered. When, however, millions of pounds of tea have to be handled in a year, this apparently infinitesimal charge amounts up to a considerable total, and we have good grounds for stating that it is unduly high. Space will not now permit us to enter upon our reasons for this opinion, but they shall be set forth in another article—*Home and Colonial Mail*, Sept. 29.

MR. CARRUTHERS' ARTICLE IN THE "CONTEMPORARY REVIEW."

In the October number of the "Contemporary Review," Mr. J. B. Carruthers makes a brief, and closely reasoned, appeal for more Plant Doctors. By this term he does not mean herbalists or dealers in "simples," but doctors for plants, competent to prescribe for their ailments, like the physician or surgeon for man, or the veterinary practitioner for animals. This, as a science, is now, belonging almost exclusively to the latter part of the century. In our own country it has little encouragement, and naturally but few followers, of whom not all have been trained in the right way. Yet botanical therapeutics is an important subject and one obviously difficult; in some ways more difficult than in the case of men or of animals. The former can tell the doctor what they feel, and the more careful among them often take note of early symptoms, and consult him before a disease has become formidable. In the latter case, shepherds and herdsmen, carters and farmers, note incipient ill-health in the animals under their charge, and are able to send for the doctor in good time. But the plant not only cannot say what is going wrong, but also is often more slow in showing the symptoms of disease. Greater, too, are the difficulties of treatment. Surgery, no doubt, is a simpler matter, and experiment has a free field in vegetable pathology. The most zealous antivivisectionist has not yet protected against operations on "poor dumb plants." But this is their doctor's only advantage. His subject cannot swallow medicines; in it there is nothing analogous to the blood system of animals which helps him to convey remedies to all parts of the patient's body. External applications alone are possible, like salves, poultices, and embrocations. Besides this, many diseases of plants are due to injurious organisms which have not very different life conditions, and the remedy which is fatal to the parasite may be equally so to the victim. To prove the accuracy of a diagnosis by means of a *post-mortem*—though a pupil once made this boast of his professor—would scarcely tend to increase a practice. Another drawback is that the doctor, as a rule, is not called in till the patient is dying or dead. Now, *post-mortems* are all very well in their way, but the subject is more often sent to the pathologist than he is called to the patient, and often arrives in such a state of decomposition as to be of little use. Doctors, as Mr. Carruthers remarks, would not find it easy to discover remedies for diseases if, when they were summoned, the patients were either *in extremis* or dead, and, perhaps, a good deal more than that. Even when the malady had been ascertained, and a remedy found, plants present many difficulties which living creatures do not. Thus,

for contagious or infectious disease the patient is isolated, but most cultivated plants are crowded together, often under unnatural conditions. Pot flowers in a hothouse may be sent to a hospital, but this is not easy in the case of those in a garden, and impossible with trees in a forest. Some progress has, undoubtedly, been made in vegetable therapeutics, but Great Britain, as is too often the case, is left behind in the race of investigation. Germany and America both spend money liberally on promoting the scientific study of plant diseases. In England the workers are few and their time often occupied by other duties. The officials at the Royal Gardens, as we learn from the "Kew Bulletin," do their best; and as much is true of the British Museum and some Universities, Colleges, and Societies. But much more is wanted, and as it seems hopeless to look to the State, the beneficent millionaire is needed to found a school of plant pathology. But, it may be asked, what is the good of it; *Cui bono*, except to the endowed investigator? Mr. Carruthers answers the question. The cure of phyloxera in vines, of canker in trees, of many diseases in field crops, all mean money. The Department of Agriculture in the United States estimates the annual loss by plant diseases at forty million pounds, and the gain to peach growers in California alone, due to the cure of a disease in that fruit tree, is worth one hundred thousand pounds a year.—*Standard*, Sept. 29.

THE PARIS EXHIBITION.

THE CEYLON SECTION.

A visit to the Agricultural School—and it is a very pleasant drive there in the early morning—will enable Colombo residents to gain an idea of what will be the character of the Ceylon Exhibits, although the specimens of tea are not yet sent in. We need not go into particulars of these, all the details will be published in due course, and the exhibits may (in advance) be described as thoroughly representing Ceylon tea, grown under all circumstances. No district has seriously refused to contribute, though some temporarily did in connection with the Dreyfus protest. Each box of tea will have on the outside the name of the estate, the grade and quantity, the name of the district, estate, exhibitor or agent, quantity and quality obtainable, and the price. The elevation of the estate is also to be given, and its rainfall. All exhibits are to be sent in by December 15th. Mr. Renton and Mr. Davidson are entrusted with the final duty of submitting tea samples to the Tea Jury.

At the

AGRICULTURAL SCHOOL.

there are now arranged, though mostly kept under lock and key, a series of exhibits which will well illustrate the industries, the attractions and the resources of Ceylon. The series of photographs by Mr. H C P Bell, C.C.S., our well-known Archeological Commissioner, of the Ruined Cities, the excavations and their surroundings are familiar, having been on view before. They have been prepared for exhibition by Messrs. W L H Skeen & Co., and with them is associated a well-arranged series of views from the studio of the Colombo Apothecaries' Co. In close proximity we find the loan collection of

MALDIVIAN CURIOSITIES,

placed at the disposal of the Committee by Mr. Haly, and, those who look into the articles ex-

hibited, will be pleased by the excellent lacquer work. The Conservator of Forests, Mr. Brown, gives specimens of trees (hora, del, mango, kina, calamauder, and others), cut from trunks in most cases, which show that the forests of Ceylon (when cheap transport facilities are devised) can vie with other countries in the production of timber suited for those in the branches of carpentry requiring high and careful polish, and the durability of a hard surface. In this connection specimens of carved work (all from the hands of Sinhalese men), exhibited by Messrs. Don Carolis & Sons, are especially interesting. A carved ebony flower stand, an ebony clock stand, a tamarind wood carved chair, porcupine quill chairs, &c. Here we also saw a collection of native woods (sixty-five in number) made at the request of the A.G.A. of Kegalla by Mr. Elapata, Ratamahatmaya. Mr. Kellow, of Nuwara Eliya, has kindly aided by sending specimens of the *Acacia decurrens*, and its bark, in several varieties, and close to, handed down from a date not given, are two Kandyan wood pillars, carved grotesquely, and skilfully. They are lent by the Museum authorities, and are amongst the most interesting features (from an archaeological point of view) of the exhibits. Mr. Kellow again helps in regard to a collection of coffee sticks, which have been worked up into various articles carefully carved, and beautifully polished. By the side of these is placed, temporarily of course, the trunk of a kital palm tree.

MINERALS.

This is no summary of what will be shown of the mineral wealth of the island and we enumerate only the specimens received at the present time. Mr. Kellow, of Nuwara Eliya, has contributed specimens of limestone and blue spinel. Other interesting blocks and fragments are sent from Kegalla, from which come specimens of crystalline rock stone, white stone and limestone.

With Ceylon the occupation of

FISHING

must always have a prominent place, and which it has retained up to the present day as a purely native industry. In this connection the collection of boats of the kind that float around our shores, and on our rivers, lakes and lagoons, is of great interest. Fourteen models are shown of boats, and specimens of nets and other fishing appliances are also given, which are well worthy of observation, though we fear that in the Ceylon Court at Paris they will escape observation, unless they are well-displayed. The fishing appliances sent by the gentlemen, who have had the 'Veddah' department in charge, are unique in their character. The nets, the spears, and other weapons used are very singular. The model of the pearl-fishery boat (built by the order of Capt. Donnan) has been already referred to, and in this connection we should note the specimen of pearl shells sent from the Eastern Coast. The large Tambalagani shells have been mounted so as to form the wings of a beetle.

OILS,

too, come in for a share of attention. Our readers will remember the specimens of oils exhibited at the Colombo Agricultural Show by Mr. Warr. These are to be sent, and with them are placed 'wild' oils sent by Mr. J. A. Nugawella, Ratamahatmaya of Kegalla, and beside these there are essential oils forwarded by Messrs. Coates & Co. of Galle, as well as Anatto seed oils, which

have been received from Mr. Van Starrex. In addition to these, oils have been forwarded by the G. A. of the North-Central Province. There are, too, cases of arcanuts illustrative of their uses, some of which probably come under this head, and show what can be done with this product. In connection with this and the other departments a case of oils (open to visitors) will be shown for testing purposes.

Resins are sent from Anuradhapura: para and ceara rubber from Heneratgoda gardens, though there is room for improvement in the latter, not so much in regard to quality, as to the form in which they are to be exhibited, for the specimens admit readily of attractive design and this is at absent present.

In drugs there is much to interest. The Government Agents and the Assistant Government Agents of the various provinces are still at work and are sending in collections illustrative of the medicinal resources of the island. To the uninitiated visitor these exhibits will be "mere rows of bottles," but to many, we hope, there will be light thrown on the resources of a colony like Ceylon. The Government Agent for the Western Province sends in four cabinets which will when complete contains 360 varieties of drugs, all prepared from native recipes, and for each of which in the native *pharmacopœia* (unpublished we believe) there is a distinct use stated.

A small case, sent in by Don Gregoris Kappura Bandara, contains specimens of 200 cases of medicinal oils, all the products of Ceylon plants, &c. Another feature, too, is Mr. Stonter's specimen of plaintain flour. The production of this flour in the West Indies is developing into an industry of some importance, and why should it not find permanent root in Ceylon, especially in connection with a food-consuming population like that Australia boasts of.

In regard to

AGRICULTURE

there is a very interesting collection, made in miniature at the instance of the Government Agent of the Western Province, of Sinhalese implements of agriculture, in reference to which a good deal might be written. There is here need again for effective arrangement, combined with judicious colouring, but in any case to the curious hunter the collection will prove of more than passing value. The model of Peradeniya Tea Factory has been before described in these columns. It was exhibited at Chicago and has been thoroughly renovated so that it will show to our French neighbours the manner in which tea is manipulated in Ceylon at the present date.

Nor must we forget in the enumeration of the specimens the results of hunting and the specimens of

GAME IN CEYLON.

It is too early yet to speak of the big elephant, which is being taxidermically treated at Kurunegala: and of the many other specimens that we could refer to, which are hereafter to be received. We can only just name the horns and skins sent by the Government Agent of the Eastern Province of spotted and barking deer, elk, and also cheetah skins. From the Central Province have been received, not only specimens of the Veddah costume (if it can be so described), but also of their implements and weapons of hunting, fishing and otherwise gaining a living. Amongst the curious things shown are the bags

of bark skilfully torn in their entirety from trees (*viti* generally), and gourd bottles.

Minor industries in Ceylon (though we do not make anything but a rough calculation as to what should be classed under such a heading) include: baskets and mats sent by Mr. J. A. Weerasinghe, of Kalutara: carved coconut shells of fantastic design and with very interesting results: edible bird's nests (sent by Mr. Kellow): carved ivory handles for fans (well finished but too heavy for actual use); cloths from the Eastern Provinces, the work of hand-loom weavers: brass work from Negombo district (an industry that needs developing): double coconut shell lent by Mr. Plâté: fan, made of wood work with paddy interwoven in a very interesting manner.

THE MODELS

of Mr. Rost we have already referred to, and they are not amongst the exhibits at the Agricultural School, as they will be packed and despatched from the studio at De Soysa Buildings. There are, however, comprised in the latter complete costumes of natives, including a Tamil Chetty, and we may add that Mr. Andriesz, sculptor, will make models, taken from life, of Veddahs. Under instructions from the Government he has gone to the Veddah Country to prepare them.

But among the more interesting specimens of Ceylon industries, should be included the specimens, representing what may be fairly claimed to be amongst the

ART INDUSTRIES OF CEYLON

The calamander, ebony and tortoiseshell boxes shown, inlaid as they are with ivory, all admirable specimens of island workmanship. In one there are miniature representations of the conquest of Ceylon by Wijayo. At the instance of Mr. Lane, the mountings of the album presented by the Planters' Association to the Emperor of Austria, will be placed in a frame of velvet. The specimens of Kegalla workmanship in silver, including as they do models of a dagoba, and a jubilee amblam, as well as a salver, are very striking. A carved egg-shell (set in ivory) is also noticeable, while Meedeniya Ratemahatmaya of Kegalla has shown (in miniature in some cases) the silver apparatus used by a wealthy betel chewer,—a case of instruments that will repay a half-hour's scrutiny. Then there are specimens in silver, artistically engraved, including penholders, pencils and hair ornaments, &c.

ST. BENEDICT'S INSTITUTION.

Although not received we may state the fact that St. Benedict's is sending drawings—thirty in number—all representative of local life, the handwork of pupils of the Institution. There are representations in oils, water colours, pen-and-ink etchings, drawings of Sinhalese architecture, maps, etc. A striking bit of work is a picture three feet by two feet—a map of the Island, surrounded with drawings (from photographs) of the busts of all the Governors of Ceylon from the earliest to Sir Arthur Havelock. On the top is the British Court of Arms. At the bottom appears a view of Colombo Harbour. Another drawing is a map of the Island surrounded with water-colour paintings. The paintings represent many subjects: A Sinhalese chief and his wife; the Moorish moonstone cutter; the other subjects are a Mudaliyar and his wife; An appuhami and his wife; a Ceylon chetty and his wife; a Bombay merchant; a Sinhalese Buddhist Priest; a Veddah;

a Parsee; a Malay; a Devil Dancer; a Jaffna Tamil; and a Parawa. The paintings in oils consist of a Tamil woman; a Sinhalese Mudaliyar; a Sinhalese blacksmith; a Veddah; a Sinhalese farmer; a Sinhalese mountaineer (an octogenarian). Included among the oil paintings are representations of estate scenery and mountain scenery. In water colours there are king-coconuts; Green coconuts; the Vanilla plant; a bunch of *lovi-lovi*; nutmegs; a Kandyan headman; and Ceylon frogs.

Many more things might be particularised, but we have, we trust, already shown the comprehensive character of the exhibits in the Ceylon Courts, of which only a small portion have been as yet received at the Agricultural School. The task the Committee has to face is to avoid sending duplicates. From almost every Kacheheri specimens of Ceylon industries have to be received and the work of selection will not be an easy one.

A NEW CEYLON COMPANY: UKUWELA (TEA) ESTATES.

This new Company, has for its directors, Messrs. F. G. Ambrose, of Ukuwela. H. L. Anley, of Mahatenne, W. B. Anley, and J. B. Anley. The solicitors are, in London, Messrs. Harward and Stephenson, of Lombard St., and Messrs. F. J. and R. F. de Saram, of Colombo; the National Bank of India being the bankers. Mr. T. W. Palmer, of 165, Fenchurch St., is the Secretary (*pro tem.*) The prospectus runs:—

Share Capital divided into 378 Six per cent. Preference Shares of £25 each	...	£9,450	
302 Ordinary Shares of £25 each	...	7,550	
			£17,000
Debenture Capital 270 Five per cent. First Mortgage Debentures of £50 each	...		13,500
			£30,500

PROSPECTUS.

This Company is formed to acquire, carry on, work, and develop the Ukuwela and Bowatte Tea Estates, in the District of Matale West, Ceylon, and to purchase other suitable properties as favourable opportunities may occur. Ukuwela is situate within 200 yards from the Ukuwela Railway Station, and Bowatte adjoins Ukuwela on the West. The Estate comprise about 558 acres, of which 313 acres are Tea in full bearing, 47 acres tea rising two years, 13 acres tea rising one year, 13 acres tea planted this year, 82 acres cocoa just coming into bearing, rising four years, six acres grass land, 84 acres reserve land, total 558 acres.

The yields for the seasons, 1st January, 1895, to 31st December, 1897, averaged 914 lb. manufactured tea per acre over all the 300 acres which were then in full bearing, and realised a net average of over 35½ cents. per lb., whilst the cost of production delivered at Ukuwela Station was under 16 cents. per lb. The yield of the 300 acres in 1896 was 1,037 lb. manufactured tea per acre. The estimate for the 313 acres now in full bearing for the year ending 30th June next, is 230,000 lb. of manufactured tea, and as 207,500 lb. were secured up to end of March last, the estimate may be considered quite safe. Future yields should be considerably increased by the crop on the 73 acres of young tea which is gradually coming into bearing. Cocoa and other credits should realize R2,500. Placing therefore the cost of production of the 280,000 lb. manufactured tea at 18½ cents. per lb. delivered f.o.b., and taking the net average price at

31 cents. per lb., the profit should be as follows:—

Tea, 280,000 lb. at 12½ cents.	...	R35,000-00
Cocoa and other credits	...	2,500-00

R37 500-00

This, at the exchange of 1/4 per rupee, equals £2,500, which should, after paying the Debenture interest and Preference Dividends as well as the London expenses, leave a surplus sufficient to pay about 10 per cent. on the ordinary shares.

The Estates are in a good state of cultivation and are well equipped with a modern factory and machinery, three substantial bungalows, other buildings, and permanent Coolie lines.

The price to be paid by the Company for the purchase of the Estates, free from incumbrances, is £30,200 payable as to £11,500 in cash, as to £7,450 by the allotment of the 298 six per cent. Preference Shares, as to £3,050 by the allotment of 122 Ordinary Shares, and as to £8,200 by the allotment of 164 Debentures.

The only contract entered into is one, dated 4th May, 1899, between Frederick George Ambrose and this Company, being the contract for the acquisition by the Company of the above-mentioned properties. Nothing has been or will be paid in respect of promotion or underwriting.

THE DOOMOO TEA COMPANY OF CEYLON, LTD.

ANNUAL MEETING.

THE REPORT

of the directors was submitted by the chairman as follows:—

The Directors have the pleasure to submit their Report and Accounts for the season ending 30th June, 1899.

The quantity of Tea received from the two Estates was 196,585 lb. out of an estimated crop of 220,000 lb., against 205,902 lb. last year, and the price realized was cents 42·83 per lb. against cents 43·13 last year.

The expenditure on Verellapatna includes the upkeep of 120 acres young Tea which only yielded 80 lb. an acre.

After writing off R2,500 to Depreciation Account and R2,500 to Reserve Account there remains available a sum of R24,787·52 which your Directors recommend being disposed of as follows:—

That a dividend of 6% for the year be paid on the Capital of the Company, absorbing R24,000, and that a balance of R787·52 be carried forward.

The estimate for the current season is 220,000 lb. Tea on an expenditure of R72,440, which includes a sum of R5,700 for the removal and re-erection of the Doomoo Factory for use as a withering shed on Verellapatna.

The acreage of the two Estates now stands as follows:—

Doomoo	...	210 acres Tea 5 years old and upwards.
	3	" "
	28	" Timber.
	58	" Grass land.
		299 acres.
Verellapatna	310	acres Tea 5 years old and upwards.
	35	" " 4 " "
	120	" " 3 " "
	35	" " 2 " "
	24	" Under 2 years.
	10	" Grass land.
	154	" Waste and Patana.

688 acres.

During the year Mr. H. G. Bois having left the Island Mr. E. W. Bois was elected to the vacant seat on the Board.

In accordance with the Articles of Association Mr. W. B. Kingsbury retires from the Board, but being eligible offers himself for re-election,

TO ALL PARTS OF ASIA, AFRICA, AMERICA AND OCEANIA.

Seeds & Plants of Commercial Products.

Castilloa Elastica Cervantes.—Orders being booked for the coming crop of seeds available in March and April, selected seed from very old trees. R. N. Lyne, Esq., Director of Agriculture, Zanzibar, writes under date 24th August, 1899:—"Please send me 200 seeds of *Castilloa Elastica* for further trial; the seeds of *Castilloa* you sent me last August germinated very well." Price and particulars in our Circular No. 32; special quotations for large orders according to quantity; immediate booking necessary to avoid disappointment.

Hybridised Maragogipe Coffee.—A large-beaned superior variety of Coffee in demand; orders booked for the coming crop of seeds, February and March delivery. Price according to quantity on application.

Hevea Brasiliensis (Para Rubber).—Orders being booked for the coming crop available in August and September, 1900. This is the only crop of seeds in the year. All orders should reach us before the end of July to avoid disappointment, as we have to make arrangements in time; guaranteed to arrive in good order at destination. We have already booked a large number of orders. A Sumatra Planter writes, dating 9th March, 1899:—"I consent to the price of £——per thousand. I herewith order 50,000 upon condition that you guarantee at least 33 % seeds germinating." Plants can be forwarded all the year round in Wardian cases. Price and particulars as per our Circular No. 30. A Borneo planter writes dating, Sandakan, 17th August, 1899:—"The last lot of Para seeds turned out very well."

Ficus Elastica (Assam and Java Rubber).—Seeds supplied by the pound with instructions; price according to quantity. This tree grows equally well in high and low land, in forest and grass land, its cultivation being extended largely by the Indian Government. For price of seeds with particulars as per our Circular No. 33.

Manihot Glaziovii (Ceara or Manicoba Rubber).—Fresh seeds available all the year round; price as per our Circular No. 31. It is superior to Mangabeira rubber and second to Para rubber.

Urceola Esculenta (Burma Rubber) and **Landolphia Kirkii** (Mozambique Rubber).—Seeds and plants, both are creepers.

Cinchona Seeds.—Different varieties.

Sterculia Acuminata.—(Kolanut). Superior quality, seeds and plants; price on application, packed to stand the transit well for several months, a hardy tree, cultivation easy.

Erythrina Lithosperma.—Thornless variety, new crops of seeds ready in December, May and June. Price according to quantity on application.

Seeds and Plants of Cinnamon, Nutmeg, Clove, Sandlewood, Pepper, Cardamom, Vanilla, Arabian, Liberian and Maragogipe Coffee, Cacao, Tea, Coca, Fibre, Medicinal and Fruit Trees, Shade and Timber Trees, Eucalyptus various varieties, also Palms, Bulbs, Orchids, &c.

Our enlarged Descriptive Price List of Tropical Seeds and Plants of Commercial Products for Foreign Countries for 1899-1900 are now being forwarded to applicants in different parts of the world. Also Descriptive Price Lists of Seeds and Plants of Fruit Trees, Bulbs, Tubers and Yams, and Orchids.

"SOUTH AFRICA."—The great authority on South African affairs of 25th March, 1899, says:—"An interesting Catalogue reaches us from the East. It is issued by William Brothers, Tropical Seed Merchants, of Henaratgoda, Ceylon, and schedules all the useful and beautiful plants which will thrive in tropical and semi-tropical regions. We fancy Messrs. Williams should do good business, for now that the great Powers have grabbed all the waste places of the earth, they must turn to and prove that they were worth the grabbing. We recommend the great Powers and Concessionaries under them to go to William Brothers."

A leading Planter writes from *New Hebrides* under date 17th January, 1899:—"I shall like a few more of your Catalogues to distribute through these Islands, as I feel sure many would place themselves in communication with you, did they know where to write for Seeds and Plants."

Our New Descriptive Price Lists of Seeds of Shade Trees for Coffee, Cacao, Tea, Cardamoms, &c., Timber Trees, Trees for Avenues, Hedges Wind and Shelter Belts, Ornamental Trees, Shrubs and Climbing Plants; and Seeds and Plants of Palms, Calamus, Pandanus, Cycads, Tree and other Ferns, Crotons and Dracinas, now being prepared and will be ready shortly.

Agents in London:—MESSRS. P. W. WOOLLEY & Co., 33, Basinghall Street.

THE DARJILING TEA CROP.

ALL ABOUT RUBBER.

RESULTS OF THE DISASTER.

BY J. FERGUSON.

There has been, we cannot but think, some misapprehension about the effects of the cyclone which recently swept over the Darjiling district, as regards the damage done to tea estates and the probable results on the Darjiling crop for the year. A tea garden in the hills is planted, as a rule, on a series of small spurs, that is, on the side of a hill which is divided up into separate sloping strips by a number of *ghoras* or ravines. Flats—even what are called flats in the hills—are rare and of small area, and are usually narrow strips along the banks of the main streams, flowing at a moderate gradient at the bottom of the big valleys; these narrow strips being cut up into small sections by the minor *ghoras* or ravines joining the main stream. In any very heavy rain there is always the danger of bits along the edges of the *ghoras* being cut away by a big rush of water, or of being undermined and falling in; but there is very little possibility of the main surface of the spurs being carried away. We may therefore take it for granted that no one slip of any really large area is at all probable.

That there may have been a great number of small slips is of course probable, but we do not think that the aggregate area of these is likely to be sufficient to seriously affect the outturn for the balance of the season. Of Messrs. Finlay Muir and Co. gardens, it is stated, Moondakoti lost three houses, the people lost their belongings, but no lives were lost, and evidently no tea. Dhajia was "scarred with landslips from end to end,"—evidently slips in the *ghoras*; but "the tea, however, had not suffered." Phuguri reports considerable damage to buildings and forests, stable and tea house unroofed, factory and bungalow badly shaken (by the way—which is the tea house and which is the factory? reporters on the dailies are not very well up in *technique*;) roads were blocked and "about an acre of tea was damaged, but was being repaired." This latter remark was a touch of genius. We have no doubt many of our readers would very much like to know how damaged tea is repaired, and that a good deal more than an acre would be found, on most gardens, sadly in need of the "repairers" skill, without the excuse of a cyclone. Who does the tea repairs on a damaged garden?

Darjiling gardens as a rule stop plucking early, and the bulk of the crop had been made before the storm. Estimating that perhaps 15 to 20 per cent of the total outturn for the year was still to come, the couple of hundred acres of tea lost or "damaged" (assuming the figures quoted above stand good), will not effect the amount still to come down to Calcutta to any really appreciable extent, and there will probably not be the boom in Darjiling prices, that some seemed to anticipate.—*The Planter*, Oct. 7.

COFFEE IN JAVA.

Mr. Frank Adam writing to us from "Glen Nevis" Estate, Banjoewangie, Java, under date, 22nd Sept. 1899. Says:—I enclose herewith the two tables of coffee statistics, which I have compiled from reliable Dutch sources. See page 331. Perhaps you may like to have them for the *Tropical Agriculturist*.

Prospects in Java for next year's coffee-crop, are exceedingly good. We are having excellent weather for the blossom, which, this year, has been very early. Already on the three estates, which are under my directorship ("Glen Nevis," "Glen Fallock" and "Glen Luss") a nice amount of blossom has opened and set, and there is still a lot of bud to open, I am hopefully looking forward to crop, over the three estates, of somewhere about 11 piculs per bouw equal to about eight cwts. per acre.

About twenty years ago, when King Coffee was in his last dying struggles, and the Ceylon planters were turning their attention to other economic plants, in the hope of staving off the ruin which was staring them in the face, I, like many others, began to make enquiries about the cultivation of the rubber tree, only to find that the sum total of the information to be gathered, from all sources, was absolutely nothing. If, at that time, such a book had existed as the one I have just laid down,—“All About Rubber, by J. Ferguson,”—I am sure that many a disconsolate coffee planter would have rushed into rubber, and by this time, I doubt not, would have been a prosperous grower of caoutchouc trees. Had I not this work, with all its facts and figures, before me, I would have been disinclined to believe that so much knowledge of this subject existed, when I recall the state of ignorance we all laboured under, only a short twenty years ago. From a book of 340 pages of closely printed matter one naturally expects to be able to extract a considerable amount of information, but I am surprised at the extraordinary results of Mr. Ferguson's research, and can only congratulate the rubber planters of the present day in having such a source of knowledge to turn to, as this book is. We are not only told of the planting experiences of rubber in Ceylon, but in many other countries, and, in addition, about experiments carried on in Trinidad and the exploiting of the industry in the French Soudan. Indeed, no country that has been blessed with an indigenous growth of caoutchouc, or has imported and acclimatized the tree, is omitted from the long list laid before the reader of this valuable work. I know of nothing, the demand for which is more likely to increase as time goes on, than Indian rubber. What with cycle and carriage tyres, horse shoes, diggers' boots and macintosh coats, the quantity required annually must be enormous, and there is every probability of many other uses, to which rubber can be applied, coming into existence. Therefore I am inclined to believe that no planting industry shadows forth a better prospect than that of rubber-growing, and no book can compare with "All About Rubber" in usefulness to the planter who intends, or has already commenced, to cultivate the caoutchouc tree.

COSMOPOLITE.

OPIUM-EATING IN ENGLAND.—A warning note, as to the extent to which the practice of opium-eating prevails in the provinces (as well as London), is sounded by one of our readers. He writes:—"I believe that in the Fen districts of Hunts and Cambridgeshire opium is consumed to a large extent by the working classes, and is purchased by them from the local chemists, as I am informed, in 'pieces as large as your two fingers,' and made into pills by themselves. I know an old washerwoman of eighty who constantly takes it, and not unfrequently is found falling asleep over her wash-tub of an afternoon as a result. I believe that if inquiries were made in villages bordering on the Fen district it would be found that quite a trade is done by chemists in the drug.—*Daily Chronicle*, Sept. 23.

BUYO, OR BETEL-NUT IN THE PHILIPPINES.

HOW IT IS CULTIVATED.

This plant is cultivated with much care in every province, as its leaf, when coated with lime made from oyster shells and folded up, is used to coil around the areca-nut, the whole forming the Buyo (betel), which the natives of these Islands as well as British India, are in the habit of chewing. A native can go a great number of hours without food if he has his betel; it is said to be stomachical. After many years of habit in chewing this nut and leaf it becomes almost a necessity, as is with the case with opium, and its use, cannot with safety, be suddenly abandoned. To the newly-arrived European, it is very displeasing to have to converse with a native betel-eater, whose teeth and lips appear to be smeared with blood. The "bnyo" plant is set out on raised beds and trained (like hops) straight up on sticks, on which it grows to the height of about six feet. The leaf is of bright green colour, and only slightly pointed. In all market places, including those of Manila, there is a great sale of this leaf, which is brought in fresh every day.

—*Manila Times*, Oct. 4.

COFFEE IN JAVA.

PRICES SINCE 1827.

Table shewing HIGHEST AND LOWEST PRICES, respectively in each year, from 1827 to 1899 (to date) for "good ordinary" Java Government Coffee, (ordinary "East India" or dry preparation) at the Government auctions, held at Amsterdam. Prices quoted are in guilder cents, per half Kilo.

Year.	Prices.		Year.	Prices.		Year.	Prices.	
	Highest.	Lowest.		Highest.	Lowest.		Highest.	Lowest.

22nd September, 1899

THE PARIS EXHIBITION.

THE INDIAN TEA ROOM.

Calcutta, Oct. 11.—The Lieutenant-Governor of Bengal has sanctioned a grant of £500 sterling, and the Chief Commissioner of Assam R10,000, towards the expenses to be incurred in connection with the exhibition of Indian tea at the Paris Exhibition. A grant equal to £4,000 sterling has also been made by the Government of India. The Committee of the Indian Tea Association in London was desirous of raising £10,000, but it is understood that it will be able to make a fairly adequate representation of Indian tea for £6,600. Of this sum the Imperial and Local Governments have given the largest share, leaving only a balance of £1,433 to be subscribed from the American Market Fund. This latter Fund has now reached R98,000, and it is hoped that the amount (namely R1,20,000) contributed last year will again be raised.—*Madras Mail*.

AGRICULTURAL EXPERIMENTS continue to be conducted at the Dumraon farms, under the supervision of the Department of Agriculture. The results obtained there show that ashes of cowdung make the best manure for paddy, and cowdung itself for wheat, although apparently only on irrigated land. The experimental cultivation of varieties of paddy, wheat, potatoes, cotton, maize, and bajra was tried in the Dumraon farm during 1888-89. The results obtained showed that the bansmati variety of paddy gave the best yield.—*Friend of India*, Sept. 21.

RUBBER PRODUCTION IN THE AMAZON.

The principal rubber-bearing areas in the State of Para are the islands of the River Amazon near the city, the principal, Marago, having an area of 2,500 square miles; the banks of the river Tocantins; the banks of the rivers Zingú, Jary, and Tapajós. The upper and lower districts of the Amazon produce the same kind of rubber, but that coming from the upper river obtains a slightly higher price, being drier by the time it reaches the port of shipment.

The collecting season for rubber in the Lower Amazon begins when the waters have subsided—about July—and ends in January or February. Collecting is not undertaken, as a rule, in the wet season, because the quantity of water that accumulates in the forest impedes the movements of the Collectors, and the rain water that runs on the trunks of trees prevents the clay cups from adhering to the bark. The sap is also weaker in this season. The United States Consul at Para, in a recent report, says that the collectors employed are principally Brazilians, immigrants from the States bordering on Para, such as Ceara, Maravham, and Piahy, also Portuguese and half-castes. The pure South American Indian is of very little use as a labourer. He has but few wants, lives by fishing and hunting, and is less dependent on labour than more civilised people. There are many thousands of collectors in the rubber field, yet the number does not supply the demand.

The last few years have shown a steady and rapid increase in the exports of rubber, and while labour has also gradually increased, it has failed to keep pace with the fast-growing demand. Among other articles used in the india-rubber industry is a clay funnel, in shape very much like an ordinary toilet water-jug without a bottom or handle. It is made of the clay that is found in most parts of the Amazon region. The fuel used in the funnel consists generally of the nuts of the following palms:—Native name—"Urucuri," "Tucuma," "Inaga;" botanical name—*Attalea*, *Astrocaryum*, and *Maximiliana regia*. It was at one time imagined that the excellence of Para rubber was greatly due to the kind of fuel used in curing it. The palms that furnish the fuel were accordingly transplanted to Africa, with a view to the production of Para rubber there. The experiment, however, has not met with success. The reason these nuts are selected in Brazil is because they emit a continuous dense smoke, and are more portable than other fuel obtainable. However, when none of the palms named are accessible, bark and twigs are used as fuel.

Every one engaged in the forest carries a knife. One of its uses is to cut down fuel for the preparation of rubber. The blade is about 26 inches long, and about 2 inches broad. Owing to the damp climate, the blades are electro-plated, thus preventing their becoming rusty before they are marked. The handles are made of wood, and are carved or inlaid with brass. The rubber collector's axe is a very small affair. It is required to chip a smooth surface on the bark preparatory to attaching a cup to the tree. The handling of the axe requires great skill, in order not to injure the bark. A smooth surface is made in order to prevent impurities from mixing with the sap. The cups are of clay or tin. The former are attached to the bark by means of a little clay. Their weight, however makes them inconvenient to carry when the trees to be tapped are separated by long intervals; the collector then prefers to carry tin cups, which are much lighter than the others. They easily penetrate into the bark by means of their sharp edges, and hold to the tree without the use of clay. The use of the tin cup, however, is to some extent injurious to the tree.

Part of the collector's outfit consists of a light gourd, large enough to carry the contents of from 500 to 700 cups. A clay bowl is next required in order to receive the contents of the gourd. It is of sufficient size to contain the product of several days'

work before it is cured. The calabash tree provided calabashes which are employed to ladle the milk from the clay bowl into the mould. A broad-bladed wooden paddle is used as a mould, and is made locally. This completes the outfit for the rubber collector. All these articles are made locally, with the exception of the knives. The axes and the tin cups are manufactured in the towns and villages of the Amazon region. The collector has to use his knife to cut his way through the undergrowth, and also to cut down a sapling occasionally to bridge a rivulet. At times he is knee-deep in ooze or up to his waist in water. On arrival at a rubber tree, he chips away the rough parts of the bark, makes a more or less smooth surface, attaches a cup and makes a small gash above for the sap to fall into the cup, and repeats this process in a line round the tree until he has attached six or seven cups. Then he proceeds to the next tree and does the same. He continues this process until he has tapped from 75 to 150 trees, which can be done in a day, if they are not too far apart. On the following days the gashes in the trees are made a trifle lower down than the first ones. Some collectors tap the trees in the morning, and return to collect the sap in the evening, whereas others tap in the evening, and collect in the morning. An expert gathers 7 pounds daily in the Lower Amazon; in the Upper Amazon three times this amount is collected. When the accumulated rubber is sufficient—usually in three or four days—a collector lights a fire in the hut he has erected, places the funnel over the fire, pours a thin coat of milk over the paddle, and holds it over the smoke to coagulate. The process is repeated until a large cake has been formed. To release the paddle from the cake it is necessary to make a slit on one side. The paddle mould makes a cake of uniform and even shape, and is in general use in the State of Para. In other parts, a spit is placed on two upright forked sticks, and given a rotary motion. By this means, the rubber is cured with greater ease. Paddle-smoked rubber is decidedly preferred, as it is dried and seemingly more carefully cured.

Many attempts have been made to improve the curing apparatus. Up to the present, however, the efforts have not been successful, because the common method, although very primitive, possesses the advantage of being simple and inexpensive. The process of curing rubber is found to be very injurious to the eyes. Many cases of total blindness result from it. There are three grades of Para rubber, viz., fine, medium, and coarse. If rubber is not uniform, and contains impurities, it is classified as medium. The coarse quality, or "Sernamby," consists of scraps that have not been cured. In sufficient labour is the most serious difficulty in the rubber industry. Consul Kenneday says that it would scarcely seem advisable to invest money in rubber estates unless the owner can first see his way clear to obtain sufficient labour with which to collect the rubber.—*Journal of the Society of Arts*, Sept. 22nd.

THE BURMA RUBY MINES, which have had such a bad time of it are now beginning to show signs of improvement. A dividend of five per cent is for the first time to be paid. Representations having been made to the Government the arrears—R4,00,000—have been wiped out, and, in addition; there has been a remission of R2,00,000 made in the rent for the two years ending October last. Since the account were closed, it is stated that there is for the five months a mining profit of £11,470, as compared with a loss of £360 for the corresponding period last year. The present dividend might have been greater, but for the fact that the richest mine possessed by the company was flooded for four months last year.—*Globe*, Sept. 16.

GUTTA AND RUBBER IN BRITISH NORTH BORNEO.

BY HENRY WALKER, COMMISSIONER OF LANDS.

Borneo Guttas and Rubbers are quoted in the price currents of the world and are well known to trade. They have been collected and are still being collected by Dyaks in the vast jungles of British North Borneo. There are many qualities of gutta, the price of which varies from \$30 to \$380 a picul, say 5d. to 5s. 9d. a lb. Of Rubbers there are several kinds but the price is more constant, say about \$60 to \$80 a picul or 10d. to 1s. 2d. a lb. The railway to the interior, now constructed as far as Beaufort on the Padas river, promises to increase the export of gutta from the West Coast of British North Borneo as parties of Dyaks are already making their way up to the interior by the route in larger numbers than hitherto. In 1895, one Dyake Chief, Nakoda Balli, came down the Penotal George road with some Murnts from the far interior of North Borneo and sold his collection of gutta for \$3,600 (that was the first time that any of the interior tribesmen had seen the sea), but the collections likely to be made by Dyaks in the near future will probably beat that record. The Dyak collector only fells gutta trees over six inches in diameter, because, as he says, trees of a smaller size have too thin a bark to yield any gutta. Consequently the gutta collector does not exterminate—he merely collects a ripe crop and leaves nature to furnish a further supply in years to come. In this respect he differs from the gutta leaf collector who fells every tree, small or great; and if leaf collecting is allowed, extermination must ensue—or so few trees will be overlooked that future collection will not pay. Another point against leaf collection is the weight of the leaf, if not dry—the trouble of drying it—and when dry the small percentage of gutta extracted.

Having felled a gutta tree, the collector rings the trunk at intervals of about seventeen inches—cutting through the bark to the wood—and, if available, places a piece of bamboo below each cut to receive the juice and keep it clean. A great deal of the variation in price is due to bad treatment and to adulteration with leaves, twigs and soil. There are many trees in British North Borneo yielding gutta, but I am not yet able to give any but native names. At Tenom at the junction of the Pagalan and Padas rivers, which is to be the terminus of the present railway, a fair is now held every fifty days and is attended by traders who carry up salt, cloth, matches and luxuries, such as Rimmel's scents in superior bottles, and bring down gutta, rubber, dammer, rattans, bees-wax, skins, &c. At Tenom there are seven kinds of gutta with the following native names:—

Ilang, two kinds, red and white, price \$100 a picul. At Kaningow thirty miles higher up the Pagalan; this is better prepared and fetches \$120.

Gutta Durlan, red, \$100. Gutta Tagal, \$80. Bajorye, \$80. Merrisa, \$60. Menown, \$30 to \$40.

Of rubber two kinds are brought to the fair:—Kubal at \$60 and Menungunor Gutta Lichakat \$80.

The Menungun rubber creeper is cultivated by the natives dwelling on the Telicossan river, a very large stream—so large indeed that at times it causes a flood on the Padas. There are several large villages with long houses well raised above the ground containing sixty doors, i.e., families. Some of the people have plots planted with the Menungun creeper which they tap after about the seventh year and only retap when the last wound has healed, which probably means once a year. I am told that this creeper attains a diameter of twenty inches. I have seen it fully six inches thick on the Segama River and it is known all through North Borneo by the same name. The fruit resembles a very large orange and is sweetly acid—a most delicious fruit to eat. So far as I know it ripens in October. It should be grown together with rotan, which assists the creeper in climbing upwards.

All the above guttas and rubbers grow in the Tenom district where the Government is now opening an experimental garden under the charge of Mr. Chas. Keasberry. That gentleman informs me that he can get all the labour he requires and frequently has to refuse work to parties of natives from the Upper Padas. A large block of Tobacco land was marked out on the upper Padas by the Borneo Tobacco Syndicate and since then the natives are constantly enquiring when the estate will be opened. From what I can gather I should say that several thousand coolies can be obtained from the Upper Padas when required for planting purposes. The women work as well as the men. Until the railway is opened to Teuom the bridge path on the right bank of the Padas must be availed of. When I used the road in July it was in good order and I could have ridden a pony along it except for one small landslip at Royoh and one fallen tree. Mr. Tower, the Railway Engineer, who was with me, remarked that it was as good a bridge path as the hill roads of Ceylon. The telegraph wire runs along this path which can be kept in order by the telegraph coolies at a small additional expenditure.

At present a party of Dyaks are seeking gutta on the lower Padas district which contains gutta trees in large quantities:—a very reassuring fact to the planter who may think of taking up land along the railway line. An application has just been made by the Eastern Extension Telegraph Co. for a huge block of land between Bukow and Beaufort, along the railway line, for rubber and gutta planting.

At Kaningow on the Pagalan the great southern tributary on the Padas, a better class of gutta is brought called Kayan, a red Gutta, which sells for \$200 at Kimanis. It is of a superior quality, unbreakable when bent and comes from Menown on the south-east of Kaningow in the Daht country. This wealth of natural, indigenous, gutta extends across the territory to Sandakan, but at Sandakan a more valuable class of gutta is obtainable. The local name is Klapeii, a large and a small leaf, red underneath, growing on low hills the gutta from which sells for \$140 to \$380 a picul, say (at exchange 2/-) equal to 2/1 to 5/9 per lb.

I met parties of Dyaks on the Segama in 1885, who had been about 250 miles up that river gutta collecting, but the Kinabatangan and its great tributaries, which extend beyond the centre of our territory up to the Eastern slopes of the West Coast hills, afford the largest gutta collecting ground. The amounts collected must vary considerably, but as far as I can learn the gutta collectors earn about nine or ten dollars a month after paying their expenses. Their expenses are not great; a little rice, a little (a very little) clothing, matches, salt and tobacco, all of which they obtain on credit from a trader, who, of course, expects to buy the gutta on their return. He has to pay the current price and the Dyaks are quite able to take care of themselves in that respect. When in the jungle the Dyaks maintain themselves by fishing, snaring and hunting, in which they are assisted by their dogs. On the whole the gutta collector's life is a hard one—small profit and much loss of life—but their traditions and customs lead them into the jungle where they can indulge their taste for a wild, savage, life to the fullest extent except as regards head hunting which has been put down with so stern a hand by the European and the venture some Dyak now only rarely takes head.

Large collections of gutta are made on the head waters of the Padas by the local natives but these chiefly go to the independent territories and into Dutch Borneo and are sold to traders who supply repeating rifles and guns of sorts, the importation of which is not allowed in British North Borneo.

The exports of Gutta and Rubber from British North Borneo for the years 1897 and 1898 were as follows:—

	1897	1898
Gutta	\$93,639	\$125,280
India Rubber	\$49,513	\$ 79,600

—British North Borneo Herald.

NOTES FROM BRITISH CENTRAL AFRICA.

Mlangi, B.C.A., 18th Aug., 1899.

What fortunes might be made in

RUBBER

at present prices; but, as a man remarked to me the other day, his fortune would have been secured had his grand-father planted 100 acres of *ficus elastica*. We have the tree here at least a tree which answers the description I have read of it some where, most likely in your *T.A.* I have two enormous trees in my shade clearing and have just been tapping one and a man has just brought in 1 lb. 2 oz. of rubber for one day's work and I am quite sure there is a week's work before the tapping is finished, the rubber is a beautifully white sample. We have

ANOTHER RUBBER TREE

here *Kickxia Africana* which yields rather a sticky rubber that does not coagulate well—*Landolphia Kirki* and *Landolphia Petersiana* are the common vines of the country, but they are few and far between. The only rubber exported from East Africa seems to be the produce of these two vines, the natives don't know how to tap the rubber producing trees besides the above named, we have a very common vine of enormous dimensions, about a foot in diameter is a medium-sized one, in which I find a large quantity of rubber. It simply runs from the vines when cut like blood from a wound, but the natives cannot manage it either; it is so sticky they can do nothing with it. I took a couple of men with buckets and made them tap a vine holding the bucket under the wounds made and in one day the result was 2½ lb. of liquid rubber which I coagulated with acid. I don't know that this rubber vine has been identified, but think it must be the vine that I have read about being tapped in Madagascar.

THE NATIVES HERE

are very destructive in their method of collecting rubber. They cut down the vines, then cut them in handy pieces and slice pieces out of the bark here and there—of course only getting half the rubber they ought to get—and destroying the vines, which take many years to grow up again. Traders don't instruct natives how to tap rubber trees or vines. All they want is to secure the rubber at as cheap a rate as possible, with the result that there will be

NO RUBBER IN AFRICA

in the course of a few years. Government should take action in the matter.

Only the other day I arrested a party of men sent out by a European trader to collect rubber, and thus had any number of vines destroyed on my land, they got fined £3 each or six months hard labour for it. Of course the men didn't know they were doing wrong, having been sent by a white man, who by the way paid the fine and returned the rubber collected to me, I shall make him pay for the destruction of the vines if possible.

This is a poor man's country.

LAND AND LABOUR ARE CHEAP,

and when we get a railway, perhaps the country will be opened up a bit, progress is

slow principally owing to the country having got a bad name for B. W. fever. I don't think it is worse, if so had, than your tropical typhoid. The Malaria Commissioners begin to think they have come to the wrong place as they cannot get cases.

Don't send any Ceylon men here like that gentleman Stephens, who turned in a funk from Chinde: they are not the stamp of men to pioneer in a country like this. I got a letter from that gentleman which I never answered. I am afraid the stamp of planters you have in Ceylon now-a-days, at least few of them are like the old pioneers of coffee planting who had to suffer many hardships as well as sickness R. B.

DEPARTURE OF AN AMERICAN SCIENTIST.

Dr. Edwin Mead Wilcox, of Harvard University, Cambridge Mass., U.S.A., who has been spending a month in Ceylon, in order to gather information with respect to the cultivation of our chief products, left with Mrs. Wilcox last month by the P. and O. "Bengal" for Singapore. There he spends a week before proceeding to Java. Dr. Wilcox writes to us as follows:—"Thanks to many Ceylon planters and the great fund of information they all seem to have. I have secured much of value to me in my work in Cuba." Dr. Wilcox, we may remind our readers, is eventually to take charge of the Sub-Tropical Department of Harvard University that will be opened near Cienfuegos, in the South of Cuba. He will be studying tropical products in Java until May next year.

PLANTING NOTES.

RUBBER TROUBLES IN S. AMERICA.—Complaints are now made in Sao Paulo of the depredations of the mangabeira rubber gatherers. They do not trouble themselves to tap the trees, or shrubs, but they cut them down and even cut the roots. Of course they are rapidly destroying the sources of what might be a permanent and profitable industry.—*Rio News*, Aug. 22.

A JAPANESE GREEN MANURE.—The U. S. A. Experiment station at San-in (Japan) has been cultivating a plant known locally as umakoyashi (*Medicago denticulata*). This has been selected for experiment because its cultivation and utilization, as a green manure, is considered a matter of special importance locally. Analyses show the plant to contain 0.78 per cent of nitrogen.—*Planting Opinion*, Oct. 14.

CINNAMON FOR INFLUENZA.—A correspondent writes:—"As this drug is being recommended as a remedy for the epidemic influenza, it may be well to caution the public against depending upon the culinary essence known by that name, and sold at low prices. This is made from cassia, a bark which, whilst it is quite destitute of the medical virtues of the genuine article, resembles it so nearly in taste and odour that those requiring the one may receive the other. Those desirous of trying the remedy should obtain it from their chemist, and ask for genuine tincture of cinnamon, or spirit of cinnamon 98, and in no case take essence of cinnamon. Cinnamon is much more expensive than cassia."—*South Australian Register*.

CACAO SOILS IN THE WEST INDIES.

Government Laboratory, Georgetown, Demerara,
British Guiana, Aug. 31.

DEAR SIR,—My attention has been directed to an article in your issue of July 18th, 1899, in which Mr. Cochran has ascribed work done in this laboratory by myself and staff to Professor Carmody, of Trinidad. I shall be obliged to you if you will give to Mr. Cochran the two pamphlets I have sent under cover to you, the first entitled "The rocksand soils of Grenada" and "The agricultural chemistry of cacao" and the second an extract from a report on the agricultural work in the Botanic Gardens of this colony relating to cacao. I may remark that the Grenada soils were personally selected by myself from the plantations.

I have also a series of analyses of the very fertile cacao and coffee soils of Surinam, which I made for the purposes of comparison with the soils of the interior of the Colony, which, if they are of any interest to you or to Mr. Cochran, I shall be happy to place at your disposal.

Professor Carmody's analyses are not comparable with ours, as he uses a different method of attacking the soil with acid solvents. We have for the last 15 years used invariably the process described in one of the pamphlets.

I may say that my experience in the West Indies points to the great importance of the amount of potash in an available state present in the soil and to the lesser importance of phosphoric acid and nitrogen and this consideration is based on the analyses of sixty or seventy different soils.

Thanking you in anticipation for giving the pamphlets to Mr. Cochran.—I remain yours faithfully,
J. B. HARRISON.

Government Analyst, British Guiana.

Having handed on the pamphlets, mentioned by Mr. J. B. Harrison, Government Analyst, British Guiana, in his interesting letter which appears above to Mr. Cochran, as requested, the latter has kindly favoured us with the following remarks:—

City Analyst's Office, Colombo, Oct. 21.

I have to thank you for a reading of the letter of Mr. J. B. Harrison, Government Analyst of British Guiana, on the subject of the cacao-soil analyses, with which I dealt in the article you published on 20th July of the present year. I am also much obliged for the two pamphlets he has sent to me, embodying the results of his analytical work of many years.

They represent an amount of original and careful analytical work, which only an analyst can fully appreciate. I should also very much wish to see his analyses of the very fertile cacao and coffee soils of Surinam, which Mr. Harrison offers to place at your disposal.

Of the two sets of cacao-soil-analyses which I compared last July, only the second set, viz., the analyses of soils, of average fertility, was conducted under the supervision of Professor Carmody, Government Analyst of Trinidad; while the first set, the analyses of fertile cacao soils, was the work of Mr. J. B. Harrison, and his staff at British Guiana. I am sorry I did not know that Mr. Harrison was the analyst till I received his letter which you have forwarded. The copy of the proceedings of the Agricultural Society, in

which I first saw the analyses (published in 1897) was incomplete, some pages being a-wanting, and amongst them the first page of Mr. Harrison's report; but, even in the complete form which he now sends me, entitled "Extract from the Report on agricultural work in the Botanic Gardens relating to cacao" and printed by authority of the Government, neither Mr. Harrison's name nor that of any other member of the staff of the Botanic Gardens occurs!

As the two sets of analyses were by different chemists, using different analytical methods, they are of course not so strictly comparable, as if the same analytical methods had been followed, but a comparison is still instructive.

As Mr. Harrison has had great experience in the Analyses of cacao soils, planters will be glad to have the latest word he has to say on the subject which is as follows:—"I may say that my experience in the West Indies points to the great importance of the amount of potash in an available state present in the soil, and to the lesser importance of phosphoric acid and nitrogen, and this consideration is based on the analyses of sixty or seventy different soils."

I find the same view as regards nitrogen more fully expressed in Mr. Harrison's work entitled: "The rocks and soils of Grenada and Carriacow and the agricultural chemistry of cacao", where he remarks:—"Upon all the soils of Granada, light dressings of nitrate of soda or sulphate of ammonia will prove beneficial to plants and upon the soils which appear in the list marked 'nitrogen' such dressings are in my opinion essential to successful cultivation." (These last are soils in which the amount of nitrogen ranges from .032 to .137 per cent.) "Where such crops as cacao, coffee, and nutmegs are the staples, it is necessary to use great care with regard to nitrogenous manures. Heavy dressings of active nitrogenous manures may easily cause excessive leaf formation, and result in the flowers produced dropping without the fruit setting, and the anticipations of full crops raised by the brilliancy of the heavy foliage, will not be fulfilled. In view of this, I recommend that nitrogenous manures should be supplied to these crops as a rule in light dressings of not more than one cwt. of Nitrate of soda per acre at the outside, and applied only at the time when the main crops of fruits have just been picked. If the trees show a full leaf development with no signs of flagging, nitrogenous manures should not be applied as their use may result in more harm than good. For cacao, nutmegs and similar crops, I consider that nitrate of soda will probably be found a preferable source of nitrogen to sulphate of ammonia, whilst the latter will be found better for sugarcane."

There are several other very interesting points on Mr. Harrison's able reports, to which I should like to draw attention, if I had the time at present to go into the different subjects discussed; but the object of my present letter is simply to give Mr. Harrison credit for the analysis of the set of fertile cacao soils referred to in my communication published by you in July of the present year.

INDIAN TEA ASSOCIATION.

MEETING OF THE GENERAL COMMITTEE.

The following is an abstract of proceedings of a meeting of the General Committee of the India Tea Association held on 3rd October, when there were present: Messrs. H. S. Ashton (Chairman), H. C. Begg (Vice-Chairman), W. Brown, R. Magor, G. A. Ormiston, M. R. Quin, A. Tocher, R. K. Toynbee, and T. Traill:—

1. Proceedings of the last meeting of the Committee, held on the 5th September, having been approved in circulation, were confirmed.

2. Proceedings of a meeting of the Darjiling and Duars Sub-Committee, held on the 19th September, were laid on the table.

3. Proceedings of the Assam Branch for the month of August were to be recorded.

4. Minutes of a meeting of the Cachar Branch, held on the 26th August, were to be recorded.

5. Letters of 25th August, and 8th and 15th September from Mr. Ernest Tye, Secretary, Indian Tea Association, London, came up for consideration and disposal after previous circulation. The principal subjects dealt with in these letters were:—

(a) Ocean Freights.—Mr. Tye stated in his letter of 15th September that this question had been considered by the London Committee, and that it had been decided to send a copy of the General Committee's letter of 19th July to the Secretary to the Calcutta Steam Conference, with an intimation that the views expressed therein were strongly supported by the Association. It was also stated that a special Sub-Committee had been formed to take charge of the question.

(b) Paris Exhibition.—In his letter of 15th September Mr. Tye stated that he had interviewed the Secretary of the Indian and Ceylon Committee of the Royal Commission with reference to the question of tea exhibits. It was suggested at this interview that the samples should be arranged as a trophy and placed in the centre of the Court, or that they might be arranged in cases and exhibited in the tea room. It was considered that about one hundred samples, representative of the various tea districts, would suffice to illustrate the different classes of tea grown. Mr. Tye also stated that he understood the Revenue and Agriculture Department of the Government of India were prepared to receive and forward all exhibits. Special labels numbered and marked for attaching to the exhibits in Calcutta would also be supplied by the Exhibition authorities through the India Office.

The Committee directed the Secretary to communicate with the Secretary to the Government of India in the Revenue and Agriculture Department asking for definite information in regard to the dates by which samples would be required: and also in reference to the special labels mentioned in the London Committee's letter.

The Secretary was also instructed to write to Mr. J. Buckingham, C.I.E., Chairman of the Assam Branch, asking his assistance in procuring a collection of dried leaves of the various classes of tea. A collection of this description had been previously asked for by the London Committee as being likely to prove an interesting exhibit.

(c) London Warehouse Charges.—Mr. Tye stated in his letter of 15th September that the Committee in London had under consideration

the General Committee's letter of 17th August upon this question. After a full discussion they had decided again to address the Tea Clearing House Committee urging a reconsideration of the request put forward for a reduction of the charges.

As the General Committee's letter No. 561-O of 13th September in which the question was fully dealt with was not before the London Committee at the time Mr. Tye's letter was written, it was now agreed to await their views upon that letter of 11th September from the Acting Secretary, Planters' Association of Ceylon, in reply to the General Committee's letter No. 463-O, of 17th August, on the question of the abolition of the English import duty; also letter of 14th Sept. from the Honorary Secretary, Dehra-Dun Planters' Association, and letter No. 1,793 of 2nd Sept. from the Secretary, Darjiling Planters' Association, on the same subject.

In the letter from the Ceylon Planters' Association it was stated that the Committee of that Association were not convinced that the time was ripe for a movement in favour of the abolition or reduction of the duty; or that abolition would be in the best interests of the producers. They were, however, continuing to collect information, and asked upon what figures the General Committee had based their statement: "that it is admitted that reduction of duty in the past has tended to increase consumption as a whole, and that further reduction would have a similar effect."

The Honorary Secretary of the Dehra-Dun Planters' Association stated that he would be unable to submit the views of the members of that Association until November, when the next General Meeting would be held. He considered, however, that abolition would enormously stimulate consumption, but it was, he thought, a question whether the effect on production would not mean a very large addition to the area under tea; an addition probably out of all proportion to the increased demand, and which might eventually place the industry in a worse position than would otherwise have existed.

It was stated in the letter from the Darjiling Planters' Association that that Association cordially supported the action taken by the General Committee.

The Committee regretted the attitude taken up by the Ceylon Planters' Association and directed the Secretary to give when replying the figures upon which the statement referred to was based. The following extract from a speech made by the Chairman of the Ceylon Planters' Association on the 17th February 1899 was also to be quoted viz., "They knew, and they felt undoubtedly, the reduction of duty in past years had tended to increase consumption. Figures that were before him were most encouraging. Going back to 1837, when the Queen came to the throne, only 30,000,000 lb. of tea were consumed in the United Kingdom, and the duty was 2s 1d; in 1897 the duty was 6d, and the consumption was 183,000,000; and in 1897, ten years later, the duty was 4d, and the consumption 232,000,000. He did not mean to say that was entirely due to the reduction of duty, because the increase in population had to be taken into account, but it was quite sufficient for his argument that the reduction of duty tended to increase consumption."

The letters from the Dehra-Dun Darjiling Planters' Associations were to be recorded and the further consideration of the question was to stand over pending the receipt of the views of the London Committee, and of the Assam Branch.—*Englishman*, Oct. 12.

THE IMPROVEMENT OF COFFEE.—I.

(By a Planter.)

It was recently shown that a comparison of the prices given in the Public Sales List of the bulk of Costa Rica, Mocha, Santos and East India coffees, sold in London in the first half of this year did not support the contention that East India coffee has deteriorated as compared with its rivals. It has, however, been urged that such a conclusion cannot be relied on, as, though East India may produce a few very fancy sorts, yet brokers are of opinion that the bulk has deteriorated, and is being ousted by Central America coffee of a cheaper and better quality. This reply is obvious. The comparison was made on the prices realised for every class of coffee and not for fancy sorts only. The value of an article is the price it will fetch at public sale, and its comparative value is determined by the ratio of that price to that of its rivals. No amount of private opinion can outweigh the judgment of the public as shown by the price. Further, it was shown that brokers had just the same opinions as to deterioration of East India coffee, and the competition of Central America, in 1885 as now, yet by 1887, when prices had risen, these complainants had ceased. It was allowed that now, as in 1885, the sample may have been poorer than usual; but the point insisted on was that this is no proof of permanent deterioration. In 1885, eight samples of Wynaad A. coffee, selected by a Committee of the Association as representative of the various kinds of coffee grown in the District, sold as follows:—50s.; four samples 56s. to 57-6 61s.; 64s. to 65s.; 69s. 6d. These prices are 10s. to 20s. below the prices ruling in the first half of this year, but are on about the level of present quotations. The sample which fetched 57s. 6d. sold in 1886 for 76s. to 79s. 6d. and in 1887 for 96s. to 106s. 6d. The improvement was mainly due to a better market, and possibly in some degree to more favourable seasons, or to greater care in cultivation and curing; but the fact remains that it took place, and there is no reason why a similar improvement should not take place in the course of another two years. As to Central American competition, only this year compilers of coffee statistics have shown that, while the total crops of all other countries have not increased in the last 25 years, Brazil crops have increased 30 per cent. in that time, and over 50 per cent. in the last three years. These compilers have drawn attention to what has been an axiom in the coffee trade for the last 40 years, that it is the size of the Brazil crops which determines the price of all kinds of coffee throughout the world. In view of the fact that steps are being taken to raise Brazilian exchange, while no very efficacious steps are being taken in Central America, it is most important that we should keep clearly before us, that it is the over-production of Brazil which is the dominant factor in depressing prices. And we may take comfort from the reports in local papers that coffee is unremunerative both in Brazil and Central America at present prices in spite of low exchange.

Still, as in 1885 East India planters spared no pains to improve their sample, so now it is no less incumbent on them to do all they can to that end and it is proposed to consider in the light of practical experience the numerous remedies which have been so freely offered. Most of these are suggestions for improving the appearance of the bean by the use of machinery adopted in Central America. This consists of improved pulpers, washing machines, drying machines and polishers. Some time ago letters appeared in the *Madras Mail* stating that planters in South India used out-of-date pulpers, and, when these got out of order, the only remedy applied was to set them closer and cut the beans. There may have been instances of such careless curing, but the remedy is patent. In every planting district there are men capable of pulping coffee with any pulper in vogue for the last 20 years, so that

it is not possible on a careful inspection of the wet parchment to find a cut bean. Such men are quite capable, and constantly in the habit, of repairing their pulpers when they get out of order. Hull and Sabonnia diere, in their books on coffee planting mention that Ceylon planters allowed only one-half per cent. for the cut beans. It is, to say the least doubtful, if Central American planters can beat this more especially as their pulpers were introduced by manufacturers who had gained their experience in making for Ceylon and Indian planters. The idea that wooden pegs bruise and cut less than copper or brass shows a very feeble conception of the principles of pulping. For one of the best pulpers has sharpened steel edges to catch and remove the pulp and yet will not show a cut or bruised bean. Once it is possible to bruise the bean, a wooden pen will do it as well as any other instrument. The washing machines require pulped parchment to be fermented, as in South India, before the mucilage can be removed, and it is difficult to see what advantage washing in a closed box with revolving paddles can have over washing in an open cistern. Still, any one who likes to try it can get a machine from Messrs. John Gordon and Co. for £18 f. o. b. in London. The peculiar advantage of the Central American system of curing is said, however, to lie in the method of drying parchment in revolving cylinders through which hot air is driven. It is argued on the analogy of tea, the delicate colour of which is destroyed by exposure to the sun, that the colour of coffee is spoilt by this same agency.

A Ceylon planter has recently recommended that coffee, spread very thinly, should only be exposed to the sun for six hours, and then be spread on a reapered floor in the store. If this plan is adopted, it would require enormous storage room, something on the principle of a tea withering house, but on a larger scale, as coffee would take longer to dry than tea to wither. But the principle seems to differ little from that of the experiment, tried in Wynaad and Coorg in 1885-86, of drying on tables over which a pandal of arrowroot leaves, or coir matting, was stretched, at a height of some 5 feet, to keep off the direct rays of the sun. At first, it was thought this drying under shade improved the colour very much; but the Wynaad Committee, after repeated experiments and reference to London experts, arrived at the conclusion that no improvement in colour could be relied on from shade drying, and it was apt to produce a mottled sample, *i.e.*, mixed with faded or fading berries, probably due to uneven drying. It was found that the coffee of several estates so treated which fetched higher prices one year fetched lower the next, and lots dried in the shade and in the sun on the same estate and sold simultaneously, showed no difference in price, or a difference in favour of the sun dried. In a couple of years shade-drying was abandoned in both Wynaad and Coorg. The Central American system would of course avoid all danger of uneven drying, and, in view of the extreme importance of improving the sample, it would be well worth trying the experiment. A machine which will dry 500 lb. wet parchment in 24 hours, and can be worked by hand or power, can be obtained from Messrs. John Gordon & Co. for £56 f. o. b. London. This might be used on the estate or the coffee dried as little in the sun on the estate as possible and despatched to the coast for complete drying in the machine. It would be better to have a couple of machines, one on an estate and one on the coast, which would not cost over £130. It should be easy to arrange for any District to defray this cost. But it would not be fair to call on Agents to go to any great expense in this matter, willing as they are to adopt new machines of approved efficacy, until it had been conclusively proved that the Central American system shows a very decided improvement in the appearance of the bean over sun-dried coffee. For we are met, at the outset, with the objection that all East India coffee, some of it fetching the highest price in the world, both this year and for the last 50 years, has been dried

in the sun. Polishers have been long in use on the coast, and are found to improve some coffees, but not others. The effect is said not to be very lasting.

The fact is, the best method of curing coffee, both on the coast and on the estate, is well known in South India. This consists in picking only ripe coffee and pulping it the day it is picked; carefully separating all inferior coffee from the best parchment; fermenting the parchment only as long as is sufficient to remove the mucilage, and washing out in one day all that is pulped in one day; spreading the coffee thinly on the tables, and turning it constantly to ensure even drying; putting it in store before the parchment cracks, and keeping it cool and dry in store by constant turning. The Wynaad Committee found coffee dried to 35 lb. a bushel in the sun gave the best results, but some planters prefer 40 lb., and good results have been obtained from coffee dried much less than this. It should be remembered that the great point to aim at is an even sample. For this purpose, perhaps, more care might be taken than is usually done to float off, not only "empty," but half-formed or imperfect beans. A Ceylon planter recommends that a piece of iron should be fixed in the spout of the pulper so as to separate, not only floaters, but all beans which are not of full weight; and that the latter should be classed as No. II Parchment, and tails and floaters kept separate from that. It is also of importance to pulp as clean as possible, so as to have little tails, and to wash these out daily, and not leave them to be washed up once a week. All but the very best parchment should be kept back, and sold separately at the end of the season, and coffee from "white cherry" should never be mixed with any other. This last sold very badly this year, and would have spoilt any sample with which it was mixed. Lastly, the whole of one despatch should be dried to the same weight, to facilitate the completion of the work on the coast and ensure even drying. If parts of one lot are drier than others, the whole must be kept exposed in the sun till the wettest parts are dry, and the drier may suffer from too long exposure.

A question has been raised as to whether it would not be wise to revert to the old method of packing in cases instead of double bags, as a means of preserving the appearance of the bean. This was also raised in 1885, and experts reported:—"As to packing, we have not hitherto (*i.e.* after an experience of some eight years,) found any disadvantage in double bags as compared with cases, and both have been tried separately and together, while our buyers prefer bags to cases as the bulk of our coffee goes to the Continent. We have no reason to suppose that coffee suffers in bags as we had plenty of good colour in bags." All planters of experience will agree with the Wynaad Committee that no method of estate curing (or coast curing either!) will put colour into coffee, but any great carelessness in curing will rob coffee of such colour as it may possess. This leads to the conclusion that there are many other things necessary to produce a good bean than good curing. But a consideration of these methods must be left for a future occasion.—*Madras Mail.*

A SUBSTITUTE FOR INDIARUBBER.

[TO THE EDITOR OF THE "SPECTATOR."

SIR,—In the *Spectator* of September 23rd you write in reference to the suggestions of Mr. Thornycroft that steam-roller traffic should be encouraged by Mr. Chaplin to carry loads of twelve tons at four miles an hour, that "a substitute ought to be found for indiarubber" as it is so expensive. The late Alfred Nobel invented this substitute, and he invited me to see specimens at his home at San Remo shortly before his unexpected death. He showed me samples of roofing for buildings, for tires of bicycles, for heavy

carriages, tubes, rings, and tobacco-holders exactly the same as those which are sold all over England, and which turn inside out. Mr. Nobel asked me to tear his imitation gutterpercha, and also the real articles, which were side by side. I tried and found it impossible to even damage most of the articles he had made, and that even the tobacco-pouches and elastic rings were tougher than the articles made of indiarubber. I was very much astonished. Mr. Nobel said: "Mind, there is no indiarubber in these things. I have flavoured them with it, so that it will be supposed to be real." As a fact, the real and false melt much the same. My late friend said: "There is a larger fortune to be made out of this invention than I and my friends have made out of dynamite. If you have any money invested in guttapercha forests or manufactories get out your money. More certainly than beetroot sugar destroys cane-sugar will my invention gradually kill the guttapercha trade." Mr. Nobel added that "next" year he intended to put up works in Italy and to employ fifteen hundred men to make this substitute, which would be called "Nobel's guttapercha." It would seem as if Mr. Nobel carried his secret to the grave. Because I know nothing whatever about these matters, and my late friend knew, this might have been the reason why he showed me his inventions. I can never forget a thing that Mr. Nobel did that afternoon. He said: "I will show you an invention which I will never reveal because it might do much injury, though sooner or later some one will find out the same secret." He then took some grey stuff out of a tin box, added a few drops out of a small bottle and said: "Now, in one hour's time this towel and this old coat I slightly touch with the mixture will take fire and burn violently. Happy that the *pétroleuses* of the Paris Commune did not know my secret." My late friend put the towel and old coat on an old chair in the garden. I forgot the circumstances during his most interesting conversation, but at the expiration of an hour Mr. Nobel said: "It is time; come and look," and within five minutes the coat and the towel blazed up furiously. I am satisfied that Alfred Nobel invented a perfect substitute for indiarubber, which could be produced at half the cost of the real article, and unless his brother knows the secret, it is as unfortunate that the invention is lost for the present as it is fortunate that the Greek-fire mixture will remain unused. As regards Mr. Thornycroft's suggestions, he must remember that to carry, say, sixteen tons dead weight, most country bridges and culverts would have to be inspected yearly, and very many rebuilt. And the number of carriage accidents would become too numerous for newspapers even to note them, in addition to the almost daily cyclists' mortuary list.—I am, Sir, &c.,

GANDOLFI (Duke).

Blackmore Park, Hanley Castle, Worcester, Sept. 26.

ASBESTOS IN CEYLON.—Some three months ago we reported the local discovery of asbestos, and now we see it mentioned that Messrs. S Peter Soysa and H Francis Fernando, two well-known merchants, have come across the material in one of their plumbago mines in the Galle District. Specimens have been submitted to an analyst who has given it as his opinion that this mineral exists in large quantities in the vicinity of Messrs. Soysa's and Fernando's mines.

THE CONSOLIDATED ESTATES COMPANY, LIMITED.

Our absent Editor writes:—I send you the Report of the Consolidated Estates Co., Ltd. (Messrs. Arbuthnot, Latham & Co., General Managers). It is, I think, a fairly satisfactory document: as one "City" man said to me the other day, "the time for eight per cent. dividends all round is past in Ceylon and a good thing, too, as preventing over-production." I will try and look in at the meeting of the 11th, and hear what is said:—

Authorised Capital £100,000, divided into 5,000 Preferred Shares of £10 each entitled to a Cumulative Preferential Dividend of 8 per cent £50,000, 5,000 Ordinary Shares of £10 each £50,000 Total £100,000.

Eighth annual Report of the General Managers, to be submitted to the Shareholders at the General Meeting, to be held at 34, Great St. Helens, E.C, on Wednesday, the 11th October, 1899, at 11'30 a.m.

The General Managers have the pleasure to submit their Eight Annual Report and Balance Sheet, together with Statement of Accounts for the Crop Year ending 30th June, 1899.

The profit and loss account shows a balance (including £70 4s brought forward from last year) of £6,617 6s 6d after paying interest on the debentures, and a interim dividend of 4 per cent. on the preferred shares. Out of this sum the general managers propose to replace the £250 taken from reserve last year, leaving a balance of £5,367 6s 6d, and to appropriate this amount as follows, viz: To pay a balance dividend of 4 per cent. on the preferred shares, making 8 per cent. for the whole year, which will absorb £1,480; to pay a dividend of 5 per cent. on the ordinary shares, requiring £1,950; * to set aside for redemption of 5 per cent. of the debentures at 103, £2,266; carrying forward the balance, viz., £671 6s 6d. The following shows the result of the year's working, viz: Net proceeds of crop—1,368,986 lb tea at an average net price of about 6½d per lb realised £37,242 2s 1d; cocoa, cardamoms and cinchona bark, £1,167 15s 6d; surplus on estimated value of produce on hand 1897-98, £86 2s 7d; interest on account, £138 12s 11d. Expenditure on estates—Messrs. George Steuart and Co.'s drafts—R390,315 at an average of 1s 4 11-32d per rupee, £26,584 11s 3d; balance of coast advances, £237 11s 11d; bonus to superintendents—R7,500 at 1s 4 3-16d, £505 17s 2d. The weather during the past season, though somewhat better than that of the preceding year, has not been very favourable for producing leaf; and consequently the crop shows a slight short fall as compared with the estimates instead of an increase as was hoped when the last annual report was issued. Prices of tea have fluctuated considerably. At one time they showed a material rise, but afterwards fell away and touched the lowest on record, though they have since somewhat recovered with the result on the whole that the tea has realised a net average of 6½d per lb. against 6¼d per lb. last year. The following figures giving the actual results of crop and expenditure as compared with the estimates in the last annual report will be interesting to the shareholders and

will serve to show with what accuracy the estimates are prepared under the careful supervision of the company's Ceylon agents, Messrs. George Steuart & Co., viz.: Crop expenditure—estimate R395,659; actual result, R393,803. Crop of tea—estimate 1,392,500; actual result, 1,368,986 lb. Capital expenditure—estimate £5,000 (about); actual result, £5,112 11s 2d. The estimates for the new season have again been prepared with caution, and are as follows: Wategodde—expenditure, R101,690; crop, 340,000 lb. tea. Hoonocotua—expenditure, R71,714; crop, 240,000 lb. tea. Ellagalla—expenditure, R28,441; crop, 92,000 lb. tea. Tallagalla—expenditure, R56,748; crop, 230,000 lb. tea. Warriagalla—expenditure, R56,521; crop, 180,000 tea. Rutland—expenditure, R49,288; crop, 167,000 tea. Sorana—expenditure, R49,374; crop, 177,000 lb. tea. Totals—expenditure, R513,776 at 1s 4½d equals £28,016 1s 8d; crop, 1,426,000 lb. tea. Also 9,000 lb. cardamoms and 20 cwt. cocoa from Warriagalla and 20,000 lb. cinchona from Rutland. Exchange during the past season has been rather more unfavourable than for the previous year, the cost of the rupee having been 1s 4 11-32nd (for three months' bills) against 1s 4 1-16d in 1897-8. It is no doubt within the knowledge of shareholders that the Indian Government have adopted the recommendation of the Currency Committee and have made gold a legal tender at the exchange of 1s 4d per rupee, so they will no doubt do everything in their power to maintain this rate. No new properties have been acquired since the date of our last annual report, but 49 acres adjoining Sorana and eight acres adjoining Tallagalla have been added to those estates. The cost of the 49 acres of Sorana was provided out of the original purchase money of the estate, and the little plot of eight acres adjoining Tallagalla was paid for out of the factory and extension account.

The usual acreage statement of the Company's Estates is appended, viz:—

The usual Acreage Statement of the Company's Estates is appended, viz:—

Name of Estate.	Ceylon District.	Full Bearing.	Partial Bearings.	Recently Planted.
Wategodde	Dimbula	800	Nil	25
Hoonocotua	Kotmale	560	25	15
Tallagalla	Kalutara	397	116	70
Ellagalla	Matale	217	6	8
Rutland	Hewaheta	419	30	70
Warriagalla	Nilambe	406	85	83
Sorana	Kalutara	263	32	205
Totals		3,062	296	476

Name of Estate.	Ceylon District.	Reserve for Suitable Tea.	Grass Waste, Water, &c.	Total Acreage.
Wategodde	Dimbula	Nil	70	895
Hoonocotua	Kotmale	45	117	762
Tallagalla	Kalutara	92	23	700
Ellagalla	Matale	13	201	445
Rutland	Hewaheta	85	59	663
Warriagalla	Nilambe	63	624*	1,361
Sorana	Kalutara	176	94	770
Totals		474	1,188	5,496

During the current season it is proposed to plant up 174 acres with tea, viz., 52 acres on Tallagalla,

* of which 192 acres are planted with Cardamoms and Cocoa.

* By the articles of Association it is provided that five per cent of the debentures must be redeemed before any Dividend can be paid on the Ordinary Shares.

68 acres on Rutland, 45 acres on Sorana, and nine acres on Ellagalla; also 40 acres with cardamoms, viz., 20 acres each on Warriagalla and Ellagalla. The capital expenditure during the past season for the purposes indicated in the last annual report amounted to £5,112 11s 2d, being a slight excess over the estimate, owing partly to the purchase of the eight acre plot on Tallagalla, and partly to the cost of additional machinery on Sorana to provide for the increased intake of leaf. The greater part of this expenditure, together with the balance at debit of the factory and extension account last year, has been provided for by an issue of £7,000 in 5 per cent. debentures, all of which were sold at par. For next season the capital expenditure is estimated at about £3,000 which includes the cost of opening up the 174 acres tea and 40 acres cardamoms above referred to, as well as some expenditure for machinery, &c., rendered necessary by the expected increase of leaf. Some anxiety is being felt in regard to the blight which has attacked some Ceylon tea properties very severely. Happily very little damage has been done to the Company's estates, and the general managers hope that the preventive and remedial measures which they have authorised will be sufficient to ward off or eradicate the pest. The Company's Ceylon agents have specially recommended a more liberal application of manure to keep the bushes in good heart (as apparently the weakly bushes are chiefly attacked), and this may cause some expenditure in addition to the estimates, though it should also result in some increase of leaf, but the general managers have thought it prudent under the circumstances to carry forward rather a larger balance than usual.

NEW DIMBULA COMPANY, LIMITED.

A general meeting of the members of the above-named Company was to be held at 52, Gracechurch Street, London, on Wednesday the 18th inst., to receive the Liquidator's report showing how the winding up of the Company has been conducted and its property disposed of, to hear any explanation that might be given by the Liquidator, and to pass a resolution as to the disposal of the books, accounts and other documents of the Company.

The resolution to be submitted, was as follows:—

“That the accounts submitted to this meeting shewing the manner in which the winding up of the Company has been conducted and its property disposed of, be and are hereby approved; that the Liquidator be and is hereby discharged from his office and that the books, accounts and other documents of the Company now in possession of the Liquidator, be handed to the Secretary of the new Company to be destroyed at his discretion after the expiration of one year.”

52, Gracechurch Street, London, E.C., 7th October, 1899. A. CRABBE, Liquidator.

The following is the report, for season 1893-99:—

The Directors have satisfaction in reporting that the re-organisation of the Company was completed in March last, and they now submit the accounts for the financial year ending June 30th, 1899.

The year under review has been exceptional in many ways, exceptional drought was experienced and culminated in a sharp frost on March 7th, which affected a considerable area of the lower fields; the South-west monsoon broke early and

was unusually severe, the effect being a very considerable shortage in yield, which, however, was more or less general throughout Ceylon.

In the face of the unfavourable climatic influences, the Directors are glad to learn that the Estate is in excellent order, and with ordinary weather there is good promise of the current year showing satisfactory results.

The accounts now presented show a surplus of £18,051 19s. 11d., made up of Dividend Fund, £12,878 8s. 9d., and Profit and Loss, £5,173 11s. 2d., after writing off the amount of Tea Extension, viz., £305 5s. 4d., and the amount of the Factory and Machinery Account, viz., £22 1s. 0d. The Directors propose a dividend of 20 per cent. per annum for the year ended June 30th last, 5 per cent of which was paid in March, and the placing of £1000 to form the nucleus of a Reserve Fund.

The Directors wish to record their appreciation of the care and attention paid to the Company's interests by Mr. Dick Lauder and the staff in Ceylon. Mr. Dick Lauder is at present in England, and the Directors have had the advantage of conferring with him on the management and prospects of the property. By order of the Board,

A. CRABBE, Secretary.

SOUTH TRAVANCORE TEA COMPANY, (LIMITED).

The third annual general meeting was held yesterday at the offices, Philpot-lane. Mr. T C Owen presided, and, in moving the adoption of the report, stated that for the year to June 30 last the outturn of tea had been 337,961 lb. (being 37,961 lb. above the original estimate), against 242,046 lb. last year. The average price realized had been 6.03d per lb. as against 5.55d last year and 5.85d the year before. The gross profits had been £3,339, against £1,304 last year and £1,672 the year before. After writing off the whole of the preliminary expenses and the cost the debenture issue, amounting to £521, and after providing £250 for the debenture sinking fund, the net profit had been £1,794, which with the amount brought forward left £1,980 out of which the directors proposed, after meeting the preference dividend for the year, to pay dividend at the rate of 5 per cent on the ordinary shares, leaving £468 to be carried forward. The motion was seconded by Mr. R F White, and adopted. The chairman afterwards proposed the payment of the dividend mentioned on the ordinary shares. For ordinary shareholders, he stated, had received no dividend since the first year after the company started, but their financial position certainly justified a dividend on the present occasion. The motion was seconded and adopted. The chairman expressed a hope that the board would be able to pay an increased dividend next year, the preliminary expenses and the cost of the debenture issue having been extinguished, and the amount carried forward representing half-a-year's dividend on the preference shares. The directors were proceeding carefully as regarded the question of extensions. During the past year they resold two outlying portions of land to the vendor for £1,985. The area under tea now amounted to 722 acres, of which 700 acres were in bearing, the remainder being the young tea. The present price of tea showed an average of 3d in excess of that of the corresponding period of 1898, and the quantity of tea which the company had was larger by between 8,000 lb. and 9,000 lb.—*London Times*, Oct. 3.

LONDON CHARGES OF TEA COMPANIES.—II.

(The Investors' Review, Sept. 23.)

THE TEA CLEARING HOUSE.

In this article we propose to deal exclusively with the warehouse and dock charge upon tea, about which there is so much complaint, and to start with cannot do better than quote the schedule of rates supposed to apply to every package of tea that goes through the Tea Clearing House. This is as follows:—

CHARGES ON TEA.

To apply to all parcels by ships reporting on and after July 1, 1888.

	Per package, weighing gross						
	130 lb. to 129 lb.		90 lb. to 89 lb.				
	s	d	s	d	s	d	
Landing and housing rate	..	1	10	1	6	1	4
Management rate	..	2	3	1	10	1	8
Bulking and taring	..	1	8	1	5	1	3
Bulking, taring, or weighing net separately	..	1	3	1	0	0	11
Rent per week	..	0	0	0	0	0	0

The above charges will be subject to a discount of 10 per cent to importers only.

For determining the class under which the break is chargeable, the average gross weight must be ascertained. When the fraction of the average weight is half a pound or more, the dock companies or warehouse-keepers take the benefit. Thus, the average of a break being 79½ lb gross, the whole break will be rated at 80-89 lb, but the average being less than 79½ lb, the whole break will be rated at 60-79 lb.

For the sake of bringing the table into manageable shape, we have deleted the rates upon certain exceptional sizes which are seldom used by importers. The general size of the packages is from 90 lb to 129 lb, and in all calculations made in these articles we have taken the rates upon these weights as our basis, allowing the usual deduction of 23 lb for the weight of the tare. The charges of most importance to the importer are "management rate"—i.e., the working of the tea—"bulking and taring," and "rent." The management rate includes the landing and housing rate, and a large importer has defined the services rendered for this charge in the following terms:—

"Landing, wharfage, conveyance to warehouse, housing, sampling for importer and broker, sorting to marks and descriptions, weighing, examining for damage, laying down for broker's inspection, and attendance on broker, laying out in showroom for public sale, attendance while on show and sampling, adjusting to weights after sale, coopering, nailing down, trucking and piling for delivery, reweighing and delivering to land conveyance. The rate also includes furnishing warrants and landing accounts."

SAMPLING AND SORTING.

Although this sounds formidable, an examination will prove that the greater portion of it represents work which is quite superficial. For instance, in "sampling for importer and broker" only one chest in a break is sampled, and when it is considered that a break consists more often of fifty chests than less, it is apparent that this entails no great amount of work. "Sorting to marks and descriptions" is for the convenience of the

wharf in delivering. "Weighing" is only weighing the chest gross as it arrives. "Examining for damage, laying down for broker's inspection, and attendance on broker, laying out in showroom for public sale, attendance while on show and sampling," are quite small items in dealing with a large number of chests. "Coopering and nailing down" applies to the sampled chests only, and although the rate includes furnishing the warrants, it does not include the warrant stamp (3d per warrant).

BULKING AND TARING.

"Bulking and taring" are rates that do not apply to every package. Teas are not infrequently bulked on the estate, and when this is done they are very rarely rebulked. In regard to taring, according to the Customs regulations, a certain number of chests in every break must be tared from the gross weight of the package, in order to ascertain the amount of duty to be collected. Should there be a variation of more than a couple of pounds in the weight of the chest, nails, and lead—i.e., the tare—each chest of the entire break must be tared, involving the heavy charge of 1s per package throughout. In regard to "rent," all teas are sold on a "three months prompt," and rent is charged for these thirteen weeks, less five weeks, the rent for which is included in the "management of rate." In most cases buyers take delivery of the tea within two or three weeks of the auction; but, however soon they may do this, the eight weeks' rent charged upon the tea, to make up the three months, has to be paid by the importer.

THE LONDON RING.

We have been at pains to explain the actual charges complained of by producers, and will now proceed to point out why they are considered onerous, but before doing so must first draw attention to the fact that the whole of the bonded tea warehouses in London are in a "ring." Treating the London and India Docks Joint Committee as one body, there are nineteen tea warehousing firms in the Tea Clearing House, which clearing house has a large number of subscribers, including all the principal buyers and brokers in the trade. According to the rules of the Clearing House, "No subscribers shall be entitled to warehouse or deposit tea with, or employ in connection with tea, any dock company or tea warehouse-keeper who is not a member of the Clearing House, or to purchase or sample any tea from the warehouse of any non-member." The "ring," therefore, is most complete, for should a dissatisfied body of importers attempt to start a co-operative warehouse of their own, they find that they have the whole of the tea trade banded against them under the rules and regulations of this clearing house. We shall have more to say about this matter later on.

THE MANAGEMENT RATE.

Returning to the subject of the charges, it is clear, both from internal and external evidence that they are excessively high as consideration for the services rendered. First we will deal with the internal reasons that lead us to this conclusion. There is a charge, not given in our table, but sometimes required, for "reshowing for public sale" of 1s 4d per package, and if this is added to the "landing and housing rate" of 1s 6d per package, we get a combined rate of 2s 10d per package for performing exactly the same services as those

covered by the "management rate," excepting that each package has to be handled a second time. For this second handling a charge of 1s per package is thus demanded, which is absurd when the small amount of labour and time involved is taken into account. Then "bulking and taring," if done together, are charged at 1s 5d per package, but if done separately the two operations cost 2s per package. Now the sole difference produced by dividing the operations into two is that each package of tea has to be opened and closed twice instead of once, and for this additional opening and closing of a chest of tea the charge of 7d is made. Just imagine what wages workmen with all the skill produced by handling thousands of these chests in a year would earn if they were enabled to charge the warehouse-keepers anything like this price for their time and labour!

THE WAREHOUSING OF TEA, PROFITABLE.

Secondly, we assume that the warehouse charges are exorbitant, from this external or public reason—there is the keenest competition amongst those engaged in the warehousing business to secure the handling of tea. However, much warehouse charges in other trades may be cut it is admitted on all sides that the warehousing of tea is the most profitable. Hence it affords a fine broad margin, and in spite of the most stringent regulations against the "cutting" of rates, or the granting of special privileges to individuals or companies, we believe that a great deal is done by warehouse-keepers in both directions in order to obtain new business. We know for a fact that discounts greatly in excess of the official 10 per cent have been allowed to certain companies, and this has sometimes been done in a fashion that verges on the dishonourable. However that may be, the questionable habit certainly flings the door open to fraud on the part of managing directors and other officials of tea companies. One case in particular is in our recollection. We have carefully altered the figures, but the actual results were proportionately as we state. Let us assume that the company in question handled 20,000 chests of tea in the year, the dock charges would have been nominally £4,392, upon which the fixed 10 per cent discount would have come to £439. As a matter of fact, £1,098 in discount was allowed, and the £661, or rather the proportionate actual figure, was paid over in sovereigns so as to avoid unpleasant documents in the nature of evidence that the bond of the "ring" had been ignored. The officials of the company that received this extra money were practically told, "We don't care what you do with this money; but do not let the fact that this extra discount has been granted leak out." Subsequently, complaint was made that the company's officials, acting in perfect honesty, had put down the true amount paid by the company for dock and warehouse charges, and not the amount allowed by the rules, in its accounts. This led to awkward questions being put to the warehouse-keeper by his brethren as to why the rates worked out so low. What his answer was we do not profess to know.

THE IRON BOUND "RING."

It follows that abuses of the most serious kind are fostered by this combination to enforce high charges on tea, and an iron-bound "ring" and the practices known to be adopted to dodge its exactions are calculated to cast a slur upon the

whole body of gentlemen connected with the trade. So grievous have the complaints become that many of the warehouse-keepers would welcome a reduction in rates, or rather an increase in the discount allowed. We believe that a motion to this effect was proposed to the members of the Tea Clearing House not long ago, but the suggestion was rejected mainly owing to the energetic opposition of the representative of an important warehouse-keeping firm. Yet we are informed on very good authority that this very firm has granted a discount considerably higher than the official 10 per cent in order to obtain new business or retain some of its old. We, therefore, think that importers are fully justified in asking for a liberal revision of, or an increase in the discount upon, these charges to at least 25 per cent. The business would even then pay very well, and there would not be the sore and angry feeling prevalent that one tea company may be paying the official rate, while another is obtaining a secret and dishonest reduction, or, worse still, that some official may be personally benefitting by corrupt and corrupting discounts to the detriment of the company he represents. Energetic action on the part of the tea trade as a whole in regard to this matter is rendered difficult by the very nature of the ownership of tea warehouses; but this is a large matter in itself, and we will deal with that branch of the subject next week.—*Home and Colonial Mail.*

PLANTING NOTES.

COLONIAL GOVERNMENT GEOLOGISTS: CEYLON NEXT?—We read in the *London Times* of Oct. 6, that Mr. W. H. Twelvetrees, F.G.S., has recently been appointed to the position of Geologist to the Government of Tasmania. During recent years Mr. Twelvetrees has devoted considerable attention to the Geological formation of Tasmania, with special reference to mining operations. Can Ceylon boast no scientist who has been performing similar work here and one who may become a valuable member of the coming Geological Survey Department? Mr. Oldham's advice, that no special work with a view to mining operations should be undertaken by the servants of Government, will scarcely, it appears to us, be that followed in Tasmania.

CINCHONA PLANTERS will be interested to learn that a new species of cinchona has been discovered. Mr. Standen, the Director of the Government Cinchona Plantations in Madras, is declared to be the discoverer; but he will, no doubt at once deny the bold impeachment. However, we have the authority of the *Bombay Gazette* for the statement, in a leading article in its issue of the 17th instant, that Mr. Standen has reported that "further attempts should be made to cultivate sedgers from seeds obtained from Java," that "sedgers" should be grafted on succimbra, etc.; the "original sedgers" give the "phenomenal return of 741 pounds per acre per annum." Verily, the wiles of the "printers' devils" and the troubles caused by illegible writing are legion. It is perhaps hardly necessary to state that our contemporary is really alluding to ledger seed through out its lengthy leader.—*Madras Mail*, Oct. 19.

Correspondence.

To the Editor.

THE 4-D IMPORT DUTY ON TEA.

DEAR SIR,—As a regular reader of the Ceylon papers and being deeply interested in your island's chief industry, I feel compelled to notice some points wherein the local opinion differs materially, from that held by those residents in England.

First, I will take the 4d import duty upon tea into Great Britain, for it seems to be the opinion in Ceylon that by reducing or abolishing this, that the market will at once be flooded with common foreign teas, and there also appears to be an idea that the last reduction by Mr. Goschen's, tended to lower prices to the producer, in some unexplained manner. It is very difficult to understand how such opinions have been formed.

A country pronounces a decided preference for a certain class of teas and this has most decidedly shown itself in Britain for those of a British growth. Reduce the duty and I fail to see how the taste will be in any way altered. It is a distinctive choice between two classes of tea. The duty as above referred to came down 2d, yet the relative position of China, as against British grown, has in no way altered except to the further detriment of the former.

A family drinks either, tea, coffee or, cocoa ; and it is reasonable to suppose that any reduction of the duty on tea would mean a falling off in the consumption of the other two articles. It is generally stated that during the past two years, cocoa has been much more extensively used, and that even coffee is obtaining more attention ; attributable no doubt to their present cheapness. To my mind the position of these three articles will always be depended upon their relative cheapness, and according to this, they will either individually give way, or, supersede one another. It is entirely an economic question. When tea and coffee forty years ago more nearly equalled one another in price, their relative consumption was more equal ; now tea is so much cheaper, it has outrun coffee. In like manner the coarsest plucked Ceylon and Indian would always undersell cheap China, from the fact that the latter needs more to make a cup ; each pound of which will have to pay duty. In other words, to make a gallon of tea, China tea will have to pay fifty per cent more duty.

I have not the data to go fully into the question just now, but would it not be fairer to consider British-grown teas, as instead of being opposed only against China, as arranged against China tea, cocoa and coffee ? You, Mr. Editor, have figures that could show the relative consumption of all these in the British isles, the subject could thus be considered in its wider light, for they are without doubt all convertible articles, according to economic value, I believe.

Political economists one and all tell us that reduction of price increases use ; so without doubt the reason why consumption has doubled within the last 30 years is that the sale price has gone down to less than half, helped in a measure by lower duties. It is quite inconceivable to an economist, that any other result can ensue.

If there be a want in London, it is a greater unanimity of opinion among producers, as against distributors and consumers, notwithstanding what may be said to the contrary. It is no-

body's business at present, so the individual and proverbial sticks are broken singly. For instance, last year a large quantity of inferior China tea was rejected from entry into America, as unfit for human food which promptly found its way into London, where it was sold, distributed and consumed, without molestation, there being no sufficiently authoritative machinery to interfere.

Then again,—the largest tea distributor in the world advertizes teas as follows—1s, 1s 4d and 1s 7d per lb., the last being declared *the finest tea the world produces*. Now let us follow these prices. Collectively they work out to an average of less than 1s 4d per lb. Take off 4d duty ; 3½d (a very low allowance) for retailing ; 1½d for blending, packing, advertizing and distributing and 7d gross is left for the producer or 6d net. I doubt if Ceylon can on an average over some years put its tea in London under 5d net, if any reasonable provision is made for wear and tear of property. If these calculations are right 1d per lb., is left as profit for the grower ; thus capitalizing all tea land coming within these limits, say at 10 years purchase and 400 lb., to the acre, at a value of under £17 the acre. No, the reasons for the fall in the price of teas, lies not to the blame of reduced import duty but, to far more direct causes, which I may enter upon later.

It was to support this *first appearance of unanimity* among producers in London, that I, much on the grounds and principles of a party government, supported the 1 lb. draft ; although I considered a better proposal could easily have been found.

SUUM CUIQUE.

THE PROPOSED COFFEE ASSOCIATION.

A SCHEME FOR DIRECT SUPPLY.

9, New Broad Street, London, E.C.,

2nd Oct., 1899.

SIR,—As I find that many coffee planters in your district, as well as in the Federated Malay States and in the Dutch East Indies, are manifesting a great interest in the movement I initiated recently for the organisation of an association of producers of coffee, with the object of stimulating the consumption of the article and generally to protect the interests of those engaged in the industry, I beg that you will grant me space in your columns to reply to the numerous correspondents who have addressed me on the subject. I will thus be enabled to give fuller particulars with regard to the objects and progress of the association. I should explain that I was led to take up this matter, in the first instance, in view of the heavy losses which are being sustained by the producers in Brazil and Central America, with which countries my paper, the *South American Journal*, has been for so many years associated. Consequently the final programme of the Association have only been published in the prospectus in the Spanish and Portuguese languages. These are now being largely circulated in the countries mentioned. The Government of Brazil has manifested a great interest in the scheme and has asked me to supply a large number of pamphlets to be distributed officially. The Consuls of the coffee-producing countries of Central America and of Mexico have also sent out quantities of pamphlets to their Governments, and many merchants in London, Hamburg, Havre and elsewhere, have sent copies to their correspondents. I send you herewith specimen copies.

It is obvious, however, that the success of the proposed Association will be more assured if the coffee growers throughout the world should take part in it.

The Editor of the *Indische Mercur*, of Amsterdam, has kindly offered his co-operation in bringing this matter before his countrymen in Java, Sumatra, etc., where about sixty of the leading planters have already intimated their approval of the scheme.

Probably this letter may lead to the planters in Ceylon, &c., taking some definite action in the matter. As explained in the Spanish prospectus, the original idea was to form an Association principally for propaganda purposes, to impress upon the public the peculiar merits of coffee and to instruct them how to prepare it. It was suggested that this institution should be supported by a small levy, voluntarily or legally, imposed upon each bag of coffee exported.

Upon going into the matter more closely, however, I soon perceived that this plan was encumbered by so many practical difficulties that to carry it out to a satisfactory issue would be almost impossible. These I have alluded to at length in my pamphlet. Amongst them I may mention the delay which would necessarily have to take place before all the coffee-producing countries of the world could be got to agree to the assessment; the impracticability of arriving at a general agreement as to its amount, the difficulty of its collection and of being able to estimate in advance the amount of revenue likely to be derived from it; the danger of official interference in the management, and many others, which will immediately occur to business men.

It became evident that the Association could only succeed if founded upon a commercial basis.

Fortunately it will be easy to do this under the conditions which now exist, and are likely to prevail for some long time to come in the coffee markets of the world. It is well known that the retail prices have not yet fallen in any degree proportionate to those which rule in wholesale quotations; also that coffee is sold largely adulterated in most European countries. From these circumstances it results that there is a splendid profit to be made by any Association, or Company, which will take up the business of coffee-roasting on scientific principles upon a large scale, whilst by the issue of coffee, guaranteed pure, at moderate prices, all adulterations could be driven from the market, whereby consumption of coffee will be greatly increased. I have gone carefully into this matter, and have made elaborate calculations as to the profits, which are most alluring. My estimates have been verified by people who have had great experience, and it is probable that, whether the planters give their support or not, there will soon be several large roasting factories established in England, using the machinery which I have discovered to be the best, as by it a great saving is made in the process.

It will be much better, however, if these factories are owned and controlled by an Association of producers. If started by commercial speculators, the interest of the proprietors will be to keep the wholesale prices of coffee as low as possible, whereas the producers, having a wider view, could devote some of the profits to propaganda, which would ultimately lead to a more general consumption of coffee.

If I find that there is a real interest taken in this business I shall have much pleasure in publishing the full detailed prospectus in English. The plan at present is to form a Company with a capital of £60,000 in shares of £1. each.

There is another important function which an association of coffee-producers could perform, to the great advantage of its shareholders, namely that of acting as their commercial agent; as the consignee of their coffee and the supplier of their stores, I have perceived this ever since I arrived at the conclusion as to the best plan of organising the company; but I have not sought to emphasise the point as I hoped and desired that I would have the support of merchants on this side in my efforts for its promotion: As, however, these gentlemen have now shown themselves to be either apathetic or covertly hostile to the scheme, there is now no object in keeping it dark, especially in a letter addressed to planters. Many of your readers must know from experience that their European correspondents do not always take the pains they ought in order to secure the best prices for produce con-

signed to them. In too many cases it is simply handed over to a broker to be "slaughtered," at any price it will fetch. A co-operative association of planters however, formed upon the lines I have set forth, would have its own large body of consumers which it would reach directly and many intermediate commissions and expense would be saved. Besides this, all the profits now derived by merchants from sale commissions or purchase of supplies would come into the treasury of the association and back into the pockets of the planters themselves in the shape of dividends. I hope the considerations I have mentioned will be sufficient to lead the planters of your district to take an active interest in the scheme.—I am, yours &c.,

JOHN SAMSON,
Joint Editor and Director, *South American Journal*.

MOSQUITOS—SPECIES ANOPHELES AND CULEX.

London, Oct. 3.

SIR,—The readers of your paper may like to make search for mosquitos, and they will have no difficulty in finding a good selection and so be able to ascertain if there are any of the Anopheles species among them or if they are all of the Culex species.

The detail of work performed on the West Coast of Africa is now published and the reports sent home are so simple and practical that I make free to quote a few remarks from them.

When the mosquito is found on the wall you have to note if his body, with the tail, is parallel with the wall; if so this species is the Culex and does not carry the germ of malaria; whereas if a mesquito can be found with the head pointing into the wall and the legs sustaining the body in this position and vertical to the wall, that is to say the body projecting at right angles from the place on which the insect is resting, then it belongs to the Anopheles variety and it should be carefully destroyed and a note taken of its existence.

The report gives particulars as to where the Anopheles variety is to be found. The Anopheles is a puddle-breeding mosquito: it requires puddles to breed in, but puddles of a certain kind; hence the importance of the subject. They were found in shallow roadside puddles containing water weed in the middle of the town; then some in a tub. The principal sources yet discovered consist of little pools lying in small flat areas in the towns: here the larvæ are in large numbers and are evidently in presence of the conditions most suitable to their existence. Although search has been made, as yet very few puddles have been discovered to yield this larvæ.

The whole report is most interesting reading and no doubt it will soon be in the hands of the public.—I remain, Yours truly,

THOS. CHRISTY, F.L.S.

TANNING BARK.

Oct. 20.

DEAR SIR,—In your comments on "Our Import and Export trade" in the *Observer* of 14th inst., you refer to the bark supplied by me to Colombo tanners as that of *acacia dealbata*; and as the same note appears in the 1898-99 Directory, I write to put you right on the subject. *Acacia decurrens* is the variety I cultivate for bark (and fuel). The bark of *acacia dealbata* is very poor in tannic acid as reference to your copy of Maidan's "Wattles and Wattle Barks" will show you. In a few years' time "acacia bark" should appear in a list of Ceylon exports as I sell large quantities of seed every year. Southern India is also taking it up.—Yours faithfully,

A. J. KELLOW.

THE CEYLON TEA INDUSTRY.

(Pioneer, Oct. 21.)

From an address by the Lieut.-Governor of Ceylon to the Legislative Council of that island, in opening the winter session, it appears that, in spite of the ruinous influences of a one and fourpenny rupee, the tea industry in Ceylon is in a sounder and better position financially than ever: and the limit of development is not yet reached. Big as is the present area under tea, large tracts of new tea-land have still to come into bearing. Hitherto the energy of those interested in increasing the consumption of Ceylon tea in foreign lands has always availed to keep the demand well abreast of the supply; hence no anxiety is felt regarding the disposal of the increased production of the future. Not every garden of course is doing well: some estates indeed are now working at so fine a profit margin that any appreciable fall in price must throw them out of cultivation. But unstable concerns of this sort are few in number and form the exception to the general rule. The Lieut.-Governor did not pause in his jubiliations to inquire why tea planting pays so much better in Ceylon than in India, but he may have realised that the answer to the question does not lie on the surface. One thing however is patent to anybody,—that whereas Ceylon planters command an abundance of cheap labour, Indian planters are always crying out for coolies. In every productive enterprise the labour supply must be the dominating factor, and so long as the teaming millions of Bengal remain loath to leave their village homes for distant tea gardens, Indian planters will continue to be handicapped.

OTTERY TEA COMPANY OF CEYLON.

REPORT OF DIRECTORS.

The Report of the Directors was submitted as follows:—

The Directors have now the pleasure to submit to the shareholders their Report and Accounts for the year ended September 30th, 1899.

The Crop secured was 141,555 lb. against an Estimate of 160,000 lb., the shortage being due in great measure to unfavourable weather.

After deducting R1,000 from Reserve Account, as arranged last year, to pay for part of the amount spent on Manure, viz., R2,827.60, the Tea has cost laid down in Colombo cts. 27.31 per lb., or without Manure cts. 26.02 as against cts. 25.05 last year.

The nett average price realised was cts. 46.91 as against cts. 42.40 last season, which may be considered very satisfactory.

After making provision for the Interest on Mortgage, &c., the balance of profit available amounts to R24,466.52. Of this amount R8,940 was absorbed by the payment of an interim dividend of three per cent to 31st March last, and the Directors now recommend that a final dividend of five per cent be paid, absorbing R14,900, that a Bonus of R500 be paid to the Superintendent, and that the balance of R126.56 be carried forward to the next Account.

In the terms of the Articles of Association Mr. W. Kingsbury resigns his seat on the Board, but, being eligible, offers himself for re-election.

An Auditor will also have to be appointed for season 1899-1900.

PRODUCE AND PLANTING.

TEA AND COFFEE IN THE UNITED STATES.—Statistics issued by the New York Coffee Exchange show the remarkable increase in the consumption of coffee in the United States. Formerly a 10 per cent gain in consumption from one year to another was regarded a maximum increase, and even this was the exception and not the rule. But the New York corres-

pondent of the "Grocer" properly points out if Americans would use Ceylon and Indian tea instead of China and Japan growths, then they would have a cheaper beverage than when using coffee, for one pound of good British-grown tea will make sixteen gallons of beverage at a cost of about 1½d per gallon. Slowly, but, it seems, surely the people begin to learn how to make a right use of Ceylon and Indian tea, but there is an aversion to using them alone, and so the majority of such tea is used for blending. The imports of tea for three years, ending June 30, were as follows: 1899, 74,088,153lb.; 1898, 71,957,715; 1897, 113,347,175lb. The imposition of a duty of 10 cents per lb. and the Tea Exclusion Act have also hurt the tea industry, a point disputed by those who favoured the tea law establishing standards. The imports of coffee were as follows: 1899, 831,820,341lb.; 1898, 870,514,455lb.; 1897, 737,645,670lb. Coffee is relatively the cheaper beverage, which accounts for the fact that it is growing in popularity, while tea is 25 to 50 per cent higher than it was three years ago.

AUSTRALIA AND THE POUND DRAFT QUESTION.—Trade opinion in Sydney are elsewhere was, as a rule, in sympathy with the effort of tea producers in their recent struggle to secure the abolition of the one pound draft. The impression in Australia seems to be that Indian and Ceylon producers should not only have been in thorough and complete harmony on the subject, but careful preparatory measures should have been taken both in London and India and Ceylon before the move was made.

THEY WILL HAVE TEA.—It will interest tea producers to learn that tea is so popular with the public that any attempt to restrict its supply in the cup by those who prefer to push the sale of intoxicants is met with an outcry. Cyclists have complained loudly of the difficulty they experience in some parts of the country in inducing rural Boniface to supply tea. Numerous letters have appeared in cycling and other journals on this subject. It is suggested that the Cyclists' Touring Club should "take up the cudgels and fight this matter out."—*H. and C. Mail*, Oct. 6.

INDIARUBBER IN QUEENSLAND.

The following from the *Brisbane Courier* will be of interest to those on the Northern Rivers who may contemplate taking up an industry that if carefully attended to may lead to an increase in the articles of production from this colony (New South Wales):—"The news from Cairns that a number of local men are arranging to begin operations in the manufacture of indiarubber is important. The raw article can be obtained from indigenous trees in the shrub, and is said to be of first-class quality. What is perhaps more important, the supply is inexhaustible. One of the chief values attaching to the recent New Guinea concession was the practically unlimited quantity of rubber there obtainable. To find, therefore, that a similar condition of affairs exists within easy distance of a port like Cairns is to say the least encouraging. Then, as regards the industry itself, its outlook is as bright as it possibly could be. The marvellous demand for bicycles of late years has given an immense impetus to the rubber trade, Indiarubber being also a highly perishable article is another important factor in the question of supply and demand. The demand will always exist, so the supply must be kept going. There is one consideration, however, which these Cairns men will find obtruding on their notice sooner or later. That is the question of chief labour in collecting the article. This must be considered when it comes to competing with others. In New Guinea, for instance, labour is cheap and on the spot. Here in Australia we have practically none of this native labour. The nearness to a port

for shipment may counterbalance this advantage which New Guinea rubber traders would derive from a handy labour supply. Our Department of Agriculture has during the year been trying by a series of articles to direct attention to this industry. Its progress will be watched with much interest. It will also place another string on the Cairns bow in raising that town into a place of much importance in the future."—*Sydney Mail*, Oct. 7.

THE INDIAN TEA INDUSTRY.

In his remarks regarding the position and prospects of the Indian tea trade, Mr. O'Connor, in his Annual Report, concerns himself chiefly with the question, whether the demand for China tea in the British market is likely to undergo a further reduction; but he also touches, incidentally, on the effect of the closing of the Mints on the trade. In connection with the question of the effect of the closing of the Mints, he appeals to the fact of its not having brought about even a momentary pause in the substitution of Indian for Ceylon tea as "another proof, if one were wanted, that a bad currency system does not promote trade, and that a good currency system cannot injure it." Here, however, he seems to us to miss the real point at issue. No one imagines that a bad currency system promotes trade or a good one injures it. Most of those who complain that the closing of the Mints has injured the Indian tea industry would probably maintain that the currency system if introduced was not a good, but a bad one. But, admitting for the sake of argument that it was as good a system as that which it replaced, there still remains the question whether the transition from one the system to the other was not calculated to injure the industry, at least temporarily. Regarded as a permanent fact, one rate of exchange is, doubtless, as good for trade as another. But it can hardly be doubted that a rise in exchange must have an injurious effect on the profits of the producers of a commodity like tea for export to a gold standard country, pending adjustment, which, whether it is brought about through contraction of production, or through a reduction of the cost of production, is a more or less tardy process. The fact, moreover, that the closing of the Mints brought about no pause in the decadence of the China tea trade, is no proof that the Indian industry was not injured by it. All that it necessarily shows is that the injury, if any, was not great enough to produce that particular result. On the whole, it may be regarded as morally certain that, if the rupees were suddenly to be depreciated to such an extent as to enable India to undersell China, she would have a much better chance of obtaining an entry for her tea into foreign markets than she has at present.—*Statesman*.

COCONUTS IN THE PHILIPPINES.

There are several species of cocoa palms growing in the Archipelago, but the ordinary coconut tree (*Cocos nucifera*) is the most important. The Indians make use of it in a good many ways, but only the principal ones need be enumerated. The kernel of the nut they use for food, while the liquid the shell contains makes a refreshing drink. If allowed to stand for some time, this liquid forms a very agreeable milky juice that is realised not only by the natives, but by Europeans as well. After this juice has

coagulated, it is mixed with sugar and made into bonbons, known as cocoa sugar, and also into various other delicacies. According to a recent report of the United States Department of Agriculture, by tapping the central bud that crowns the coconut, a kind of wine, called *tuba*, of an agreeable pungent taste, is produced. This *tuba*, when allowed to ferment, produces vinegar, and when distilled, a kind of brandy, that is highly relished by the natives. From the husk of the coconut the Tagals make ropes and cords, and a material for calking their boats. From the woody shell they carve spoons, cups, beads for rosaries, and many other articles. The leaves they use to cover the roofs of their houses. Roofs made in this manner are thick and tight, but they have the disadvantage of burning readily, so that in the towns and villages where the houses are thus covered, conflagrations spread with great rapidity. The veins and smaller ribs of the leaves are used to make brooms, the midribs serve as fuel, and the ashes are utilised in making soap. The trunk of the palm is made to serve as a pillar to support the houses that its leaves overshadow. Oil barrels, *tuba* casks, and water-pipes are fashioned from hollow sections of the trunk. From the roots the natives extract a red dyeing material, that they chew in place of the areca palm nuts or *bonga* when the latter cannot be procured. Large quantities of coconut oil are manufactured in the Philippines. This oil is much prized by the natives. The men and women both use it to anoint the thick growth of hair that adorns their heads, and it thus finds a ready sale at remunerative prices. It is also used in the lamps that take the place of gas-burners in the streets, and in those used by the natives and Chinese in their houses. Manila exports annually about 150,000 pesos (£25,000) worth of coconuts to China and British India, and about 30,000 pesos (£5,000) worth of coconut oil to China.—*Journal of the Society of Arts*, Oct. 6.

CACAO IN THE PHILIPPINES.

"Theobrama Cacao" (Food of the Gods) as Linnaeus called it, a native of Central America flourishes in these islands in the hot damp regions.

It is said to have been imported into the Philippines towards the end of the 17th Century from Mexico, where it has been in very ancient use. Outside the tropics, the tree will grow in some places, but gives no fruit. The Philippine quality is very good, and compares favourably with that of other countries, the best being produced between latitudes 11 and 12 N.

The cultivation of Cacao is an extremely risky and delicate business as, often when the planter's hopes are about to be realized, a slight storm will throw down the almost ripened fruit in a day. A disease sometimes attacks the roots and spreads through the plantation. It is natural therefore, that no one should dedicate his time exclusively to the cultivation of this product at the risk of almost instantaneous ruin. Usually, the Philippine agriculturist rightly regards cacao as a useful adjunct to his other crops. Small quantities of it are sent to Spain, but the consumption in the colony, when made into chocolate by adding sugar, vanilla, cinnamon, etc., to counteract the natural bitterness of the bean is considerable. To make chocolate-paste, a large quantity of sugar is added varying to one third of its weight to equal parts, whilst one pod of vanilla is sufficient for 1½ lb. of Cacao. As a beverage it is in great favour with the Spaniards and half-castes and the better class of natives.

The cacao beans or kernels lie in a fruit something like a gherkin about five inches long and three inches in diameter, and are of a dark reddish colour when ripe. The fruit contains from 15 to 25 beans, in regular rows, with pulpy divisions between them, like a water-melon. The kernels are about the size, shape and colour of almonds, obtuse at the end, and contain a fatty/oily matter to the extent of one-half their weight. In order to make "soluble cacao" as sold in Europe, this fatty substance is extracted.

The beans are planted out at short distances in orchards, or in the garden surrounding the owners dwelling. The tree, in this colony, does not attain a great height—usually up to ten feet—whereas in its natural soil it grows up to 30 feet at least. Like coffee it bears a fruit in the fourth year, and reaches maturity in the sixth year. The fair annual yield of tree, if not damaged by storms or insects, would be about three pint measures of beans, which always find a ready sale.

If all went well, and present prices, more or less, were maintained, large profits might accrue to the planter, but it rarely happens (perhaps never) during the six months of fruit ripening that losses are not sustained by hurricanes, diseases in the tree, the depredations of rats and other vermin etc. Practically speaking, cacao-planting should only be undertaken in this colony by agriculturists who have spare capital, and can afford to lose a crop one year to make up for in it the next, of planting to be taken up by hand-to-mouth colonists who must seek immediate returns.

In the aspect of a cacao plantation there is nothing especially attractive. The tree itself is not pretty. The natives who grow the fruit, usually make their own chocolate at home by roasting the beans over a slow fire, and after separating them from the hulls (like almond skins, they pound them with wet sugar etc. into a paste, using a kind of rolling-pin on a coneave block of wood. The roasted beans should be made into chocolate at once, as by exposure to the air they lose flavour. Chocolate is often adulterated with roasted rice and vily nuts. The roasted Pili nut alone has a very agreeable almon taste; the cacao bean itself, in its pure state, is extremely bitter and unpalatable.

In Manila there is a steam power manufactory which partly supplies the capital with good chocolate, and which will receive our attention in a subsequent article.—*Manila Times*, Oct. 4.

SELANGOR PLANTERS' ASSOCIATION.

The following are parts of minutes of a General Meeting held in the Selangor Club, Kuala Lumpur, on Saturday 30th September. Present:—Messrs. W. W. Bailey, (Chairman) J. D. Toynebe, C. Meikle, E. V. Carey, L. Dougal, E. B. Prior, (members of Committee) H. Huttenbach, H. M. Darby, E. F. King, F. B. Hicks, E. B. Skinner, W. Brooke, W. Irvine, A. Barnwell, F. Newman, A. Cathcart, H. C. Rendle, J. H. Power, T. S. Dumbreck, W. McD. Mitchell and Tom Gibson, Hon. Secretary.

QUIT RENTS ON COFFEE ESTATES.

Mr. DOUGAL proposed and Mr. C. MEIKLE seconded the following resolution, *viz*:—

"That in view of the distressed condition of coffee planting in the State, the Government be asked to remit the quit-rent on all blocks of 200 acres and upwards until such time as prices improve." Mr. Dougal said that the present depressed condition of the planting community was only too evident, and although it might appear that the question of quit-rent was a small matter, still every little helped. In approaching Government now and asking for this help we do not forget what Government has already

done for us, such as help rendered to fight the caterpillar pest, remission of export duty and Hospital fees etc., but all the same he felt confident that this assistance would also be granted us if asked for.

Mr. MEIKLE reiterated what Mr. Dougal had said as to the present depressed state of planting and assistance already rendered by Government to the planters, and also thought our request would be granted.

Mr. HUTTENBACH said he would be only too glad if Government could be induced to let us off the quit-rent altogether, but was afraid they would not do so, and he would suggest that we ask Government to let the quit-rent remain in arrears, making the debt a first charge on the Estate, and when times improve the amount due could be paid up without inconvenience.

Mr. DOUGAL said he thought it would be most objectionable to have a debt such as this hanging on our heads.

Mr. HICKS suggested an amendment that Government be asked to remit the quit-rent on the unopened portions of Estates until better times.

The CHAIRMAN said he was glad to see that the general feeling was that we should not ask too much; he was also certain that Government would not care to keep a debt hanging over us, but the amendment seemed to meet the case admirably.

Mr. MEIKLE proposed and Mr. NICOLAS seconded the following resolution, *viz*:—"That the attention of Government be again drawn to the unsatisfactory condition of the coconut trees in the Kuala Lumpur and other districts where the ravages of beetels are still very marked—where insufficient steps are being taken to keep this pest in check and that Government be asked to see that the Coconut Trees Preservation Ordinance be more rigorously enforced." Mr. Meikle said that for the present coffee had gone to the bad and coconuts were looked upon by many as a safe investment, and a good deal of capital was being sunk in planting coconuts in Selangor.

Mr. NICOLAS said he had much pleasure in seconding Mr. Meikle's resolution and agreed with all he had said as to the unsatisfactory way in which the Ordinance had been carried out.

THE COOLIES QUESTION.

The next point to be considered was a resolution proposed by Mr. Huttenbach as follow. "To cancel the agreement which prohibits members of the S.P.A. from engaging Tamil coolies locally without the goodwill and permission of their former employers" and the Chairman asked Mr. Huttenbach to name his seconder.

Mr. Hicks said he would second it. Mr. Huttenbach said the object of the agreement he proposed should be cancelled was to protect planters who get their coolies from India and to throw obstacles in the way of coolies who apply for employment in the country and of planters who engage their labour locally. Now he had always engaged his coolies locally and never had any difficulty in getting all the labour he wanted. It had been suggested that the reason of this was because he was so favourably situated when on the Selangor Estate, but even now they come and offer themselves at Batu Tiga which is out of the way, unhealthy and expensive.

Mr. Prior said he was surprised to hear any member make such a proposal as Mr. Huttenbach had done. The agreement, which had been unanimously passed by a general meeting only a few months ago, was calculated to do a great deal of good and had done good and to ask us to cancel it now was asking us to make fools of ourselves.

Mr. Darby agreed with Mr. Prior that the agreement was much needed and had done good.

Mr. DOUGAL said they had all heard Mr. Huttenbach say that he got all his labour locally and could always get more than he required and under the circumstances he thought Mr. Huttenbach was very lucky, but in his opinion instead of Mr. Huttenbach making a boast of this, he thought it was a thing he need not be proud of. When coolies know that they will be taken on by an employer if they offer their services

they are only too ready to give in their names, with or without any reasonable excuse and leave the estate.

Mr. CAREY said he thought we were inclined to take Mr. Huttenbach too seriously, as he could hardly imagine that Mr. Huttenbach really meant all he had said.

The motion on being put to the meeting was lost, no one voting for it but the proposer.

TELEPHONES.

Mr. HUTTENBACH proposed and Mr. PRIOR seconded the following resolution:—"That Government be asked to connect the outstations and various estates in the districts by telephone with Kuala Lumpur."

Carried unanimously.

The next business before the meeting was to elect a member of Committee in place of Mr. Dougal who is shortly leaving the State for the old country.

On a ballot being taken for a representative of the S. P. A. in the U. P. A. Committee, in place of Mr. Dougal, Mr. G. Shepherd was elected.

AN AUSTRALIAN TEA BUSINESS.

(Special to the Ceylon Observer.)

SYDNEY, OCT. 1.

Griffiths Brothers are a household name in Sydney and district, being one of the largest tea firms in a city, which is conspicuous for stores, selling that popular article of consumption. They have erected handsome premises opposite the Town-hall in George-street, at the top of which is a railway signal, and the trade mark of this firm is seen half-way down the street. The firm believe in advertising and in all parts of Sydney and suburbs placards announcing Griffiths' teas and coffees meet the eye, while they have adopted a rather novel method of bringing their name before the public. Near every station on all the railway lines for a good distance from Sydney are placed finger-posts telling the traveller how many miles he has to go before reaching their well-known firm. Their store is a very handsome one, and is made attractive by a number of China and Japan curios, while on the walls are several handsome paintings, giving a very good impression of Ceylon tea estates in the hill districts. The other afternoon a representative of this journal called at Messrs. Griffiths Brothers; and made the acquaintance of Mr. Greenhill, the buyer and taster of the firm, who readily consented to say a little about the tea trade, in which his firm are engaged, which is chiefly to the public, without passing through the hands of agents. They blend Ceylon, China and Indias together, but sell each country's teas separately as well.

Ceylon tea, said Mr. Greenhill, plays a very important part in our business. I suppose on the whole Ceylon takes up a third of the output of our trade. I do not think we exceed that. Some of the finest grades come into this market.

Asked what estates were the favourites he replied hastily, Agra Onvah and Middleton. St. John's were seldom met with on this market, but "Tymawr" is frequently met with.

Mr. Greenhill complained of the advance in price in the lower grades of Ceylon tea, and said that during the last six months there had been an advance of fully 20 per cent. On the other hand he endorsed what the representative of another firm in this city had said about Ceylon not getting up to the quality it used to. India tea would do very well for blending purposes, and this could be obtained at lower rates. Of course what

Tea was used depended on the man, who manipulated the blends.

What is the prospect of Ceylon tea here?—Ceylon tea will go ahead if brought back to the average quality it was three to five years ago, but if not it will go on the wane. China is coming ahead. The average price of Ceylon tea is higher, the quality is lower.

Messrs. Griffith Bros. have branches in Melbourne, Adelaide, Perth and Fremantle as well as the capital of New South Wales. Melbourne, which also supplies Tasmania, is the headquarters of the firm, but Sydney has the largest output.

Our representative had seen in a western paper an advertisement announcing the distribution of tea-seed among farmers, etc., and he asked for a few particulars about it.

Mr. Greenhill said it was a kind of a hobby. Mr. Griffith had got tea to grow pretty well in his garden at Bayswater, just outside Melbourne, and they had sent seeds to some of their clients. They had about 300 applications, but they had had barely time to judge of results. He thought it would never pay to grow tea here on account of labour difficulties. If they had coolie labour they might; but, owing to the objections of the working classes, the various Governments in the colonies refuse to allow alien labour to be introduced. The development of tea takes a number of years, but if the labour difficulty was overcome, and they looked ahead a quarter of a century the chances were a certain amount of tea might be produced in the colony for commercial purposes.

MR. E. E. GREEN "COCCIDAE OF CEYLON."

We have already published several notices of this book, and are glad to find it is still receiving at the hands of the reviewers at home and elsewhere the attention it deserves. The following *critiques* are from two papers of recognised value in scientists' circles:—

(*Natural Science*, October.)

The Coccidae constitute an aberrant group of the Hemiptera, contradicting all ordinary definitions of the order and class to which they belong. Hemipterous hexapods, yet in the female sex wingless, and in many genera legless as well. The very methods by which they must be studied are peculiar, and as such distasteful to the ordinary entomologist.

So it has happened that these creatures, though numerous and peculiar, have been greatly neglected. But in recent years, as though outraged by such persistent scorn, they have risen in their might and played havoc with our fruit trees and other crops, not to mention ornamental plants; wherefore we have been obliged to recognise their existence.

Studies usually begun with economic ends in view have led us far afield. It becomes plainer every day that the Coccidae are not only extremely numerous in species, but offer an extraordinary series of peculiar forms, whose organisation, as related to their environment and habits, is of the greatest interest from a purely biological standpoint. The opportunity to advance both economic entomology and pure science is too good to be neglected once perceived; and so we find a new body of students arising, calling themselves coccidologists, and dignifying their study by the name of coccidology.

Of these latter-day students assuredly E. Ernest Green is second to none. Beginning his researches during the previous decade he at first proceeded slowly. The literature of the subject was difficult

to obtain, and when obtained threw little light on the almost unknown coccid fauna of Ceylon. But Mr. Green, not discouraged, resolved to study every species *de novo*, whether described or not; acquiring his knowledge first-hand from nature, as though he might be Adam in the Garden of Eden. This method, in the hands of an intelligent worker, is sure to be successful, and it was eminently so in the case of Mr. Green. He not only prepared descriptions, but also elaborate drawings of every species in all its stages, so far as they could be obtained. This done, a thorough examination of the various publications on Coccidae had to be made before the apparently new forms could be reported as such; but this revealed comparatively few identities. In Part I. there are thirty species described, of which seventeen were new; in Part II. are twenty-nine species, all but three discovered by the author. It often happens, on receiving a paper describing so many new species, that one can immediately detect some synonymy; but I do not know of any "bad species" among the forty-three above mentioned, and doubt if there are any. The descriptions are good, and the plates most beautiful. There is an introductory portion on the general principles of coccidology, including a new classification of the sub-families and full directions for collecting and preserving material. There is also a chapter on the insecticides and other means for destroying Coccidae which injure cultivated plants. In the last-mentioned chapter the interesting fact is brought out that practically all the injurious coccids in Ceylon are those described from elsewhere and presumably introduced into the island. The truly native species, almost without exception, have proved to possess no economic importance; though of course these very species, carried somewhere else, may yet become notorious.

An unfortunate conservation, as it seems to the present writer, is shown in regard to genera. The species assigned to *Aspidiotus* represent at least five very distinct groups, which are at least of sub-generic value. *Aonidia* is made to include very diverse forms, including three distinct generic types. Similarly the twenty-six species assigned to *Chionaspis* are by no means truly congeneric; for instance the first six, *aspidistrae*, *theae*, *albizziae*, *muscaendae*, *rhododendri*, and *serobicularum*, belong properly to *Hemichionaspis*. The generic classification of the Coccidae, however, is at present in a transitional state, and an author cannot be blamed if he hesitates to propose changes while yet uncertain what those changes should be.

Simply as an illustration of good methods this work ought to be examined by zoologists who do not expect to study Coccidae; while for the coccidologist it is of course essential. Under these circumstances it is to be regretted that the manner of publication is such as to make it extremely costly. The only edition has coloured plates, which of course are expensive, while the colouring does not greatly add to their value for scientific purposes. It would have been excellent to have a coloured edition of small size, if there could have been an uncoloured one at a more moderate price. But the chief trouble is that the publishers insist upon receiving the full subscription (£5) for the work in advance, though it must take at least several years to complete it. The work, of course, is intrinsically worth all that is asked for it, and more; but the fact remains that zoologists are not commonly blessed with superabundant means, and are reluctant to part with a five-pound note under the circumstances just mentioned. Surely if the conditions of sale were rendered easier the subscriptions would become so much more numerous that the amount received would be considerably greater than at present. T. D. A. COCKERELL.

(*Entomologist's Monthly Magazine*, October.)

THE COCCIDÆ OF CEYLON: by E. ERNEST GREEN, F.E.S. Part i, pp. i—xii and 1—103, with 33 plates (1896); Part ii, pp. xiii—xli and 104—169, with 30 plates (1896). London: Dnla and Co.

It is now somewhat over thirty years since Signoret commenced his "Essai sur les Cochen-

illes," in which he demonstrated by pen and pencil that these to many easy very unattractive insects, the females of most of which live under a sort of fixed carapace (the "scale") for most of their lives, possessed, when examined microscopically, beautiful structure, and that the outline of the pygidium, with its curious denticulations (together with the spinnerets, &c.), furnished valuable generic and specific characters. For many years Signoret found few disciples, and died before the full effects of his work manifested themselves. We think we may fairly claim that to our venerable colleague Mr. Douglas (now in his 85th year) by his papers in this Magazine, was due the initial movement that has since spread over the whole world by leaps and bounds, and has in several instances (such as *Icerya Purchasi* and *Aspidiotus perniciosus*) occasioned government solicitude, and the establishment of paid official entomologists, whose duty largely it is to look after these apparently insignificant scale-bugs. There are at the present time many workers in this field, and their publications are distributed over nearly every medium, and must number thousands of pages annually, whereas about thirty years ago there was nothing. Prominent amongst the workers at the present day is Mr. Ernest Green, the author of the book now under notice. Members of Mr. Green's family have long been associated with Ceylon, and have also been known as entomologists: they saw the ruin of the coffee-trade in the island (by a fungus), and the substitution of tea-planting; it was but natural that our author, as an entomologist, and with a knowledge of the disastrous results of the ravages of Coccidae in other parts of the world, should have watched with much care their effects on the tea-plants, and in so doing his attention has been directed to the group as a whole. Mr. Green, at the solicitation of the Planters' Association, while retaining his interest in his former occupation, consented to devote himself entirely to watching the insect enemies of the planter, and to devising and testing remedies. In addition to his acquirements as an entomologist, Mr. Green possesses the art of delineating (mostly from microscopical specimens) insects and dissections of insects in an exquisitely delicate manner, and one need only glance over the numerous plates in the book before us to see that the work is that of a master hand, incapable, we might venture to say, of being surpassed, and the figures have been faithfully reproduced by chromo-lithography (most unfortunately the paper for the plates is of a smaller size than the text). The letter-press is of the fullest possible nature, with (in Part i) a concise summary of the general habits and structure of the group. The generic and specific details are complete, and the tables of genera are made to include those not yet found in the island. Mr. Green estimates that about 200 species inhabit Ceylon, many are apparently endemic, others again are cosmopolitan or introduced. Much interesting detail is given on the natural insect enemies of Coccidae, and it was news to us that the larvæ of one of the *Lycaenidæ* (*Spalgis Epius*, Westw.) feed entirely on "mealy bug."

To Part ii is appended a long chapter on remedial measures and insecticides. It is acknowledged that this is largely drawn from American sources, and the author hopes that amongst the remedies some may be found suitable for application in Ceylon should occasion require. Much stress is laid upon the necessity for quarantine, and in this connection it is stated that all the species that have proved noxious in the island have either been certainly imported or are of general distribution. No undoubtedly endemic species has caused any anxiety. Did space permit we would touch upon some curiosities of Coccid life in the work before us. Without doubt it is the most important work that has yet appeared on the subject: it is not often one finds scientific attainments and iconographic skill of the highest

order so happily combined. Putting on one side the matters of labour and time, the cost of producing such a work is great. It is not too much to ask that naturalists who can afford to subscribe to it will do so, and public libraries should possess it.—R. McL.

THE FUTURE OF THE CEYLON TEA INDUSTRY.

LONDON, Oct. 6.

I HAVE had the opportunity of discussing this all-important question during the present week with several representative authorities, all more or less interested in the welfare of our staple industry and the important trade based upon it. I will mention no names, because I have not yet completed my circle of enquiry and observation. But I may at once give you a resumé of the information so far placed at my disposal and of the conclusions I have attempted to deduce. And first, it is cheering to remark on the general confidence maintained in the future of Ceylon and its "tea." The check given to over-production by the enhanced rupee, and the recent fair supply of labour have undoubtedly strengthened the position; while the disastrous experiences in Darjiling, affecting not a few well-known "gardens," has once more attracted attention to the wonderful exemption of the planting districts of Ceylon from earthquake, cyclone or hurricane and so far tended to enhance the estimation of

PLANTATION PROPERTY IN OUR ISLAND.

On the other hand, I find myself always asked "What about these

BLIGHTS,

of which we hear so much in the papers and in correspondence of late?" Now my reply has been uniformly and honestly reassuring; for I firmly believe that, while there was occasion at first to rouse the attention of planters in certain districts to the need of "watching and working" towards checking the evil, and while I felt strongly that both Mr. Willis and Mr. Carruthers took too light-hearted a view in what was no doubt a preliminary (as well as inadequate) Report; yet, during the present year, planters, it seems to me, have rushed to the other extreme and are making too much of the "blight" enemies with which tea has to cope at certain times and in certain districts. I have had placed before me reliable evidence that not a few are inclined to attribute to "blight," injuries or discoloration of their tea-bush leaves, due to the puncturing of insects, to climatic, local and temporary causes. Just as some men at the outset refused to recognise the presence of the grey blight, even when pointed out to them,—so, of late, the other extreme is seen in many superintendents discovering blight in every trivial attack of minor enemies from which no product is free. I do not for a moment say that there are not, in some parts of Ceylon, attacks—and serious attacks—of what Dr. Watt points out to be the worst enemy of our brethren in Assam; but I do maintain that they are far less widespread than has been recently supposed; that they are often very

temporary and due to causes (such as too long delay in pruning) easily overcome; and that the time has come now for planters to be very careful in their observations and cautious in reporting "blight," before they are fully convinced that the real "Simon Pure" is amongst them. Even then, of course, the fight, which can be made in defending and clearing so hardy a bush as tea, is very satisfactory as compared with any other sub-tropical product with which we are acquainted.

All this, however, only shows the importance of

A CRYPTOGRAMIST OR MYCOLOGIST

being at work among the Ceylon planting districts; and it is satisfactory to know that the authorities are fully alive to this fact. Negatively, in showing where there is no blight, his work may be nearly as important as positively in experimenting where blights exist and in writing out the life-history and practical remedies for such evils. With, in addition, the presence of an Entomologist, in the person of one so specially qualified as

MR. E. E. GREEN

—himself a practical planter—and the prolonged engagement of

MR. KELWAY BAMBER

as Chemical Analyst and general adviser, surely the Ceylon tea planter may look the whole world in the face, and more especially the commercial (capitalist) world of London, and maintain that everything possible is being done to maintain the industry and the value of properties in the Colony itself—a colony, moreover, where there are the greatest possible conveniences for thorough examination and careful experiments—Ceylon in this respect beating both Java and Northern India with their far more scattered and diverse planting interests.

The next division of my subject for the present, should be the continued progress made in opening

NEW MARKETS

and in this connection I am pleased to read Mr. Renton's encouraging *ad interim* report; and no less to remark on the important fact brought out by your Hcwaheta correspondent, that coffee, even at its present unprecedentedly low price, is by no means so economic a drink as tea, if the test be the quantity of enjoyable, or average beverage got from the same weight of each product. Discussing this point with a tea merchant in the City interested in the American market, he pointed out that good coffee could be sold in the United States at one-fourth to one-fifth the price of good tea (in view of the duty on the latter and other causes); but I at once replied that, even taking this somewhat extreme comparison, tea gave *eight* times the return that coffee did, in a reliable refreshing beverage! This fact must be pressed home on practical Americans as well as on all careful housekeepers on the Continent of Europe (where their name is legion,) and I am sorry I did not embody it in my little French slip of instructions printed at Vichy, in addition to the note I gave on the greater economy of using Ceylon, rather than China,

tea. This latter fact arrested the attention at once, of quite a number to whom the circular was given at Vichy and in Paris; and no less during the late B. A. Excursion in Northern France and Belgium. I am convinced that by means of useful literature, popularly distributed, and judicious advertising, great progress can be rapidly made in winning the Continent of Europe for Ceylon tea, the proximity of the Colombo market to Odessa, Trieste, Genoa, Marseilles as well as Antwerp and Hamburg being another great advantage, when once a direct trade is fully developed.

But now I come to another phase of my subject and one which is, perhaps, of more immediate interest in tea circles in London at present. I refer to the arrangements connected with the receipt, handling and selling of our staple product in this,

THE GREATEST TEA MART IN THE WORLD.

The agitation over the one-pound draft, although it may be thought by many to have ended abortively, and even disastrously, for the time, has undoubtedly resulted in one great good, by bringing a full light of enquiry and criticism to bear on all the arrangements connected with the importation and selling of tea, and some of the details, I find, were quite unknown to men of not a little experience in the trade. I have not yet seen my friend, Mr. Brooke, the well-known, experienced, practical head of Messrs. J. A. Hadden & Co.; but I am assured that the system which he induced the Customs to sanction (and which he brought out so fully in his letter of protest) was quite unknown to most of his brethren, or some of them would not have proposed a change equivalent to, perhaps, four-pence a chest, in the weighing, at the risk of incurring a charge of five-pence for taring the same chest! The whole question of warehouse arrangements is now under the careful consideration of the joint Committee of Indian and Ceylon Tea representatives (they held a meeting yesterday) and not a little novel information is likely to be obtained as to the process attending "overtakers,"—surplus tea not put back in chests—*not*, as always supposed, because of careless repacking preventing its admission, but under a regularly adopted system which must have been worked to the great advantage of some unknown parties, neither planters nor merchants. Then, again, the strange fact is likely to be brought out that certain Indian Tea Companies, having protested, and insisted on a strict account of all their tea, have not suffered, like the bulk of their brethren, from this "overtaking" arrangement! Clearly there is great room for reform and for putting all the warehousing, weighing gross and tare, bulking and repacking arrangements, on a consistent, equitable and economic footing, and I trust this may be the final outcome of the present inquiry.

But now I come to an aspect of my subject which has been discussed freely in my presence, *pro et con*, by brokers and merchants during the present week and regarding which I may send you more information by another mail. Every change and reform has the object of "economy" more or less in need, and it may be permitted here

to offer a few general remarks on this aspect of the question. The position of the tea-growing industry has, during the past two or three years, necessitated the exercise of strict "economy" in all matters of expenditure, but the equally important question of

"MARKETING THE PRODUCE"

to the best possible advantage, has received but little, if any, general attention. The very considerable decline in values, as compared with, say, ten years ago, is doubtless mainly due to increased production. This increase was induced by the steady fall in the sterling value of the rupee; and so long as the fall continued, it compensated growers for the lower range of values established. But it would be well for producers to consider what other influences may have contributed to this lowering of values. The practice of putting up to public auction all Indian and Ceylon teas as fast as they arrive, regardless of the immediate requirements of the trade, has undoubtedly (in the opinion of good authorities) had, very frequently, a depressing effect on prices from which recovery has been extremely slow. This it is now sought to overcome by the formation of a Committee to regulate the offerings of Indian teas, which certainly is a step in the right direction; but unless the members of the Regulating Committee are able to gauge fairly closely the extent of the current consumption of the article, and unless the whole of the Indian importers consistently back up the Regulating Committee, it is to be feared that the movement may not prove as full and complete a remedy as is desirable. It is pointed out to me that, during the past ten or twenty years, very important changes have occurred in the methods of the

HOME DISTRIBUTING TRADE.

Formerly, I am told, when the China leaf held the market, the dealer was practically the only purchaser for the home trade, the "Blender to the Trade" being unknown. And it is of importance to bear in mind that nearly the whole of the China tea sold in the London market passed by "*private contract*"—very little, and that only to close up shipments, etc., being offered at auction. The dealers in those days carried very considerable stocks; and as they were able to obtain reasonable profits on the basis of Mincing Lane quotations, they had no inducement to lower market values. With the present-day wholesale blender and packet man the case is quite different. He has his standard blends, with fixed prices so far as his customers are concerned; and inasmuch as his purchases at auction cannot be followed, as can those of the dealer by his grocer clients, his profit is the greater the more he can knock down Mincing Lane values. We have also, apparently, to accept the fact that the blender and packet man have been eminently successful in cutting into the trade of the old-time dealer and family grocer, for whom the grower may be excused for having as great a reverence as has the modern buyer for the old-established "pound draft!" It must not be imagined that, to start as a "blender to the trade" or as proprietor of a "packet," is necessarily equivalent to banking a fortune. Many have

failed where few have succeeded, and the latter doubtless owe their success to exceptional business capacity and enterprise, for which all credit is due to them. The fact, however, remains that the London Tea Market is dominated by a few,—a comparatively very few,—large wholesale blenders. There are, of course, numerous other buyers, for the trade of the dealer has not yet been completely wiped out; but the possible operations of these few very large buyers is an additional and hampering element which all others have to take into consideration. The great influence on the market of the large buyers is also felt by sellers of Calcutta or Colombo-bought teas, as also, it is asserted in nine cases out of ten, by growers who do not accept the best bid at auction, and who “take out” any break. The general policy, it is alleged, is, as far as possible, to render the character of the auctions “without reserve” sales, and to discourage all teas not put up on growers’ account, presumably because a grower is more squeezable than an importer who has a merchant’s cost to cover and profit to fight for. The essence of public auction, of course, is that there should be free and unrestricted competition for the article exposed for sale; and anyone with any knowledge of the subject, I am assured in some quarters, can hardly contend that these conditions apply to the tea auctions in Mincing Lane, except on the rare occasions when any particular grade of tea may be in very short supply.

That the conditions obtaining in the London market are felt to be unsatisfactory seems to be proved by the suggestions which have from time to time been put forward by producers. It has been proposed many times that growers should combine to distribute the produce themselves; but presumably such proposals have been made without consideration as to the enormous extent of the trade, and of the very large capital and personal which would be necessary. The first desideratum, however, would be a complete combination of growers, which would practically amount to a “pooling” of the produce. If this could be secured, there would be no object in going much further, for the existing distributing companies and firms would be available as a means of distribution, and that on very reasonable terms, even on the basis of their present profits, taking them all round.

Another suggestion is that in place of sending all teas to London several other centres should be fixed on, such as Manchester, Glasgow, Leeds, etc. Assuming, however, that the initial difficulty could be overcome of sending to each centre exactly the class of tea required for the districts it would serve, the competition would be less than it is at present; for, although all the very large buyers might be represented, only a proportion of the smaller ones could be expected to attend the sales at each centre.

The great obstacle in the way of reverting to the system of “private contract” is the large number of breaks now put on the market. To some extent this might be improved upon without much trouble on the estates, but not to the extent necessary to admit of the change indicated, unless the whole system of packing teas for the London

market be revised. Breaks of at least 200 to 300 chests, *i.e.* of each grade of tea, would have to be the *general rule*, and the larger the break the better—especially of the principal grades which might run up to 500 or 600 chests. Such breaks could only be secured by bulking together teas of the same character from different estates, and this could only be undertaken by large companies or combinations of proprietors. Such a change would be very difficult of arrangement, except perhaps gradually.

So long as sales by public auction cannot be avoided, it is undoubtedly to the seller’s advantage to place his teas on the market where they are most likely to meet with the greatest competition, and the Calcutta and Colombo markets would seem to answer this requirement. Several of the large London buyers have representatives on these markets, and in addition there are buyers for direct shipment to Australia, America, Russia and other parts of the world; while there are also merchants operating for the Mincing Lane market. But it is pointed out these latter are at present at considerable disadvantage owing to the action of the large buyers in London. It is, however, not going too far to say that, if the whole of the Indian and Ceylon crops were respectively sold in Calcutta and Colombo, the competition of merchants prepared to take merchants’ risks would be a most important factor in counteracting the overweighing influence of the large London buyers, and that the London stocks of tea, not in grower’s hands, would be very much more generally held, which could not fail to have an advantageous effect on prices.

As a means, therefore, of improving the grower’s position in the matter of marketing their produce, it is now suggested for consideration:—(1) that a more extended use be made of the Calcutta and Colombo markets, especially by gardens unable to pack large breaks; and (2) that for London very large breaks should be made up wherever possible, and be placed on the market for sale by *private contract*. The excessive cost of working teas in the London warehouses is now (as I have already said) engaging the attention of importers, and doubtless this matter will be dealt with earnestly at an early date, when the charge for bulking will receive attention. With an appreciable reduction under this head, it would be easier, both for the large plantation companies and for import merchants, to bulk together teas from different gardens, and so appreciably diminish the number of breaks. The grower is, of course, entirely free to select his own market; but there are two parties to a contract of sale, whether it be public sale or private contract. It is hinted, however, that certain of the buyers would probably prefer to see private contract the customary condition; but in any case that it would not be introducing a radical change, as the bulk of China teas are still sold privately and private contracts of Indian and Ceylon are not unknown.

With an overstocked market the seller is at a disadvantage in endeavouring to make his voice heard. There are indications that the demand for British-grown teas is approaching the supply more nearly than has been the case for some years, and, therefore,

I am told, it would be well for producers to endeavour at such a time to put matters on a sound footing even though there may be less immediate necessity for doing so than has lately been the case. On the other hand, I have had grave doubts expressed to me as to the principle and practice of "private contracts" being advantageous to the producers. It is asserted by not a few, that there is nothing like open competition to determine values and secure fair prices; that private offers and contracts induce suspicion and jealousy; and that prices must always in the long run be governed by the laws of supply and demand. Still it is admitted, even by the strongest opponents of a change, that private contracts are useful and feasible even now in certain cases; that is, when a dealer, having bought an invoice, is offered and agrees to take two or three more invoices of the same tea—not as yet put in auction—at the same prices as the invoice offered in sale. With this exposition of both sides of the question, I must now leave the matter for the consideration of the tea planters and merchants of Ceylon, assured that, if a change is desirable, it will find advocates amongst their number, ready to do what they can to improve the present condition of affairs.

THE IMPROVEMENT OF COFFEE—II.

(By a Planter.)

There can be little doubt that the quality of coffee must be put into the bean on the tree, before it can be developed by the very best method of curing. The most important quality is the flavour when roasted, and coffee bought for the Home trade is always tested by roasting. For the Continent, coffee is chiefly bought on its appearance, it being presumed that boldness and evenness combined with colour ensure a good flavour. As regards East India coffee, it is certainly the case that no coffee that does not combine all these qualities can be expected to realise a high price, either for the Home, or export trades. The flavour of coffee depends entirely on soil, climate, and species. All East Indian Arabica, Mecha, and most Central American coffees rank as mild coffees, while all Brazilian and Liberian coffees rank as rough coffees. English Companies have recently introduced Indian methods of pulping and washing into Santos, and claim to have increased the price some 4s a cwt. This leaves it, however, at 30s a cwt. against 52s. for middling East India, in the first half of this year. We may conclude, therefore, that something in the climate of, or in the variety of plant cultivated in, Brazil produces a distinct flavour which, fortunately for us, is considered decidedly inferior to the coffee we produce. Further, within India itself, as is the case with wine in France and Germany, the produce of certain Districts and Estates is decidedly superior to that of others. As regards the District, this superiority is probably due to the dryness of the climate and the elevation above sea level, while in the case of the Estate it must be due to soil. In both cases, probably, some of the superiority is due to the variety of plant cultivated. Admitting that the improvement of the produce of any particular Estate or District is limited by the above conditions, it remains to be seen what can be done to obtain the greatest improvement possible in the produce of any given Estate or District.

It will be generally allowed that the quality of the bean in a crop of any size depends on the vigour of the tree, and that careful handling and pruning to keep the tree open, and thorough cultivation to keep the soil sweet, are essential conditions of such vigour. For the latter purpose drains,

1 feet deep by 1 foot wide and 10 feet apart are preferable to digging the soil, as it is found that too frequent digging interferes with the roots too much. The Wynaad Committee of 1885 found that shade improved the colour of coffee, and shade is now almost universal, though it was introduced chiefly to ward off attacks of borer and leaf disease. Lastly, the use of manure is also almost universal now; but, when we come to consider the effect of manure on the quality of the bean, we enter on a very difficult question. For there are two very disturbing factors in calculating the effect of manures: firstly, the law that the larger the crop the worse as a rule is the quality of the bean; and secondly the variation of the season, which may cause a deterioration in the bean in spite of every care bestowed on the cultivation of the tree. The following results obtained by the Wynaad Committee in 1885 seem to show that the price depends entirely on the size of the crop, and not on the manure used:—

Sample.	How manure.	Crop cwt. per acre.	Leaf disease	Price per cwt. for A. coffee
				s. s.
No. 1	Young coffee never manured	4	Little or none	61/
No. 2	Cattle manure once in 2 years	5½	Severe in parts	50
No. 3	Bones and poonac once in 3 years	5½	Severe	56/
No. 4	Manure yearly ½ cattle; ½ bones and poonac	3½	Severe	69/6
No. 5	Once in 2 year best cattle; best artificial	3½	Slight	56/
No. 6	Small part cattle manure yearly	2½	Very mild	64/ 65/
No. 7	Once in 3 years chiefly artificial	3	Mild	56/6
No. 8	Highly with cattle and artificial	7	S	57/6

An Agent wrote to the Committee:—"I have already got prices for a good number of Estates, and it is very curious how they vary, and still more curious how the coffee from well cultivated Estates has fetched a much lower price than crops from poor semi-abandoned ones." The explanation of this also is, probably, that the crop from the semi-abandoned was much smaller than from the well cultivated Estates. Recently complaints have been made as to the poor quality of crops from Estates on the Nilgiris and Shevaroyes, heavily manured with chemical manures. The deterioration is more probably due to the heaviness of the crops, and to excessive drought, than to the use of chemical manures. A dry climate favours a good bean, but there must be enough moisture during the formation of the berry to develop it properly. Possibly the application of too much nitrogen, and of phosphates in a form which the tree cannot readily assimilate may have had something to do with the deterioration—for the former manure might force a heavy crop unsupported by the letter. The writer's experience is that a steady application of steamed bone-dust, combined with the proper proportion of nitrogen in poonac or cattle manure, does undoubtedly improve both the quantity and quality of the crop over a series of years; and that purely chemical manures do not support the tree under a heavy crop as manures of organic origin do. Some of the most successful Estates in Mysore and Coorg rely chiefly on manures of organic origin. The main point to attend to is to promote the vigour of the tree by the use of suitable phosphates with the proper proportion of nitrogen to make the phosphates most efficacious, and not to force on the tree a heavier crop than it can mature properly. The Wynaad Committee concluded that, though it cannot be said that manures affect the colour of the bean directly, there can be no doubt that high cultivation improves the boldness and weight of the bean. These again are intimately connected with colour, and in

this way manures seem essential to obtaining and maintaining colour in the bean. The Committee admitted, however, that colour depends in a great measure on climatic influences, which vary from year to year, and on the lightness of the crop. Another 13 years of leaf disease have convinced most planters of the necessity of regular manuring, and also of following Mr. Elliot's advice of concentrating high cultivation on the best fields. That policy has, however, been in full swing ever since the crisis of 1882-85, and has been supplemented by planters putting their inferior lands under cinchona, pepper, and tea. These, though not exactly methods of improving coffee, are very efficient methods of improving the coffee planter's finances when one of the crises, to which coffee is periodically liable, occur.

There is yet another way in which planters may try to promote the vigour of the coffee tree, on which the quality of the bean so largely depends. This is by the introduction of new varieties of coffee, either by importation from other countries, or by the selection of pedigree seed, or by hybridisation. The first has been freely tried without any benefit, except in one instance, that of Nalknaad coffee seed. Attention has been drawn to the marvellous results obtained in wheat and cotton by the cultivation of pedigree seed, *i. e.*, sowing seed only from exceptionally vigorous and heavy cropping plants, and again taking seed only from the most vigorous progeny, till after several generations an entirely new, hardy and heavy cropping variety is established. But sufficient attention has not been paid to the fact that, though it is easy in the case of annuals to grow rapidly enormous numbers of successive generations from which to make the necessary selections to establish new varieties, it would entail a very heavy expense over a long series of years to do this in the case of a plant like coffee, which takes three years to come into bearing and seven years to reach maturity, and requires virgin land if it is to be grown successfully on a large scale. In America, or in the British or Dutch Colonies, large or small, this would be done by State officials; but the Government of India has not yet learnt the importance of liberal scientific aid to agriculture, although India is more dependent than almost any other country on that industry for its revenues. The same is true of hybridisation, but fortunately it has chanced that individuals have already obtained results in this line, though more by good luck than anything else. It will, of course, take some time to establish by careful selection a fixed variety; but the following results, reported at the Conference of hybridisation experts held at Chiswick in July last, are full of encouragement for planters in dealing with hybrid coffee. It was stated that varieties are perpetuated in crossing, and not as a matter of fact obliterated; that, although in the first or second generation nothing new may be seen in some cases, yet often in the third and fourth generation 58 and 75 to 80 per cent. of the variety desired may be obtained that hybrids are not as a rule infertile and, when they are, it is due to some special circumstance.

In this connection it would be well if coffee planters followed the example of their tea brethren, and tested the results of their experiments in the cup. For, though the grocer buys largely by appearance and even values his coffee by the even appearance of the roasted bean, yet there are not wanting men who are pointing out that the surest way to promote their business is to buy entirely on the flavour of the roasted bean, and who are urging grocers to disregard appearance when the flavour of the roast is good. If this method of valuing coffee becomes universal—and it is said to be the coming revolution in the coffee trade—we shall hear less of the superior appearance and evenness of Central American coffee, and, provided our coffees hold their own for flavour, we need not fear a little unevenness or even lack of colour—such, for instance, as is common in Mocha coffee.—*Madras Mail.*

INDIAN AND CEYLON TEAS.

SECOND ARTICLE.

A fortnight ago we published an article dealing with the progress made by British-grown teas in the regard of the tea-drinkers of the world; we now turn our attention to the working of tea companies in the year 1898-9.

First, we will briefly survey the Indian Companies. Last year the lot of tea growers in India was not a happy one. Exchange remained consistently high, 1s 3½d to 1s 4d being the average figure. Freight was also an expensive item, of which the chairmen of tea companies, with one accord, have complained to the sympathetic shareholders at the meetings held during the past few months. Then, again, the crop in India did not realise the anticipations of planters, who had computed the yield at about 158 million pounds. As time went on it was seen that this figure would not be reached. Unpropitious weather was experienced in some districts, and, as a matter of fact, the actual crop was 153 million pounds, of which about 135 millions came to this country. The Cachar and Sylhet gardens suffered severely from drought, and their tea was poor, realising not more than 6d per lb. on an average. Assam, Darjeeling, and Dooars teas, on the other hand, were of pretty good quality, and realised satisfactory prices.

The total paid-up capital of 31 companies is £4,487,308, and the total profit £291,589, an average of 6.275 per cent., which is a sufficiently satisfactory result, all things considered. The average profit per acre of mature plant works out at close upon £2 18s.

Turning now to Ceylon, we give a table showing the dividends paid in 1898 by fifteen representative Companies, as compared with the dividends for 1897.

Company.	Paid up Capital.		Dividends on ordinary Shares.		
	Preference.		Ord.	1897	1898
	£	%	£	%	%
Alliance ..			65,260	6	7
Burnside ..			17,600	7	2
Ceylon Proprietary ..	26,127	5	78,380	5	4
Ceylon Tea Plantation ..	81,080	7	167,380	15	15
Eastern Produce & Est. ..	753	5	299,135	7	7
Galaha ..	60,000	6	50,000	2	4
Imperial ..			90,000	4	4
Kelani Valley ..			18,765	10	5
Nuwara Eliya ..			200,000	6	6
Penawal ..	5,300	7	17,000	2	4
Portmore ..			40,000	12	12
Scottish Ceylon ..	9,000	7	41,000	10	10
Standard ..			59,500	15	15
Sunnygama ..	15,000	6	50,000	6	3
Yatiantota ..	45,000	6	90,000	2	4

The dividends paid on ordinary shares, it will be noticed, were lower in 1898 than in 1897, for the most part. In Ceylon, as in India, the effects of high exchange were felt, and freights to the home market were rather high, although in this respect competition at Colombo places Ceylon in a better position than Calcutta. The crop was below estimates, and the quality was only fair. There was not much development work done by British tea companies. In Ceylon, there is not much room for the extension of plantations; most of the land has been planted, and the Government has practically ceased to lease out land. Some of the existing companies have a little land not yet under tea, but the acreage is small and we may take it that the rapid increase in production which has taken place during the last decade will almost cease. The output of Ceylon tea is about at high water mark. In India there is, of course, abundance of land ready for planting; the great difficulty there is the supply of labour, which, it may be said *en passant*, is the reason why tea-planting in Fiji, where has climate and soil are specially favourable, the never been successful,

The prospects for the current season in both India and Ceylon are very promising. As regards crop, quality, and price they are better than the last two years. In fact, 1898 may be set up as an example of a bad year, when adverse circumstances reached a climax—over-production, lack of labour, and low prices combined against the planter. It may be safely anticipated, therefore, that an improvement will be manifest in the immediate future, although he would be a rash man who would prophesy that never will such another season as that of 1898 be known. Too much importance must not be attached to the earthquake which has been reported from India. First impressions of a disaster of this kind are generally exaggerated. The earthquake had only affected a very limited area—a few gardens in Darjeeling—and the effect upon the total Indian crop will be exceedingly slight.

The tea industry is in a healthier condition at this moment than it has been for several years—healthier, indeed, than it was three years ago, investors were rushing at every tea share they could get. Tea companies have gone through the refining fire of adversity, and have learned much from the experience. Profits are more carefully dealt with; development and extension are not undertaken lightly, but with caution and prudence. The fear of over production has no solid foundation, for on the Continent of Europe, in America, in Australia, and in South Africa, there are markets for practically limitless quantities of British tea, requiring only energetic and untiring work. In tea companies, we are convinced, may be found safe and profitable investments, but investors must, in these, as in all securities, exercise much caution. Entirely new gardens should be shunned, for five or six years must elapse, under the best circumstances, before paying returns can be made. But to well-established going concerns, with reserve estates, attention may, with advantage, be turned.—*Investors' Guardian*, Oct. 7.

CEYLON TEA.

The following advertisement appears in the *New York Evening Post* of Sept. 28:—

THANKS TO HEALTH AND ENERGY RESTORED
BY THE USE OF
CEYLON TEA

PRESENTED TO THE SHIP AT COLOMBO, OUR
GREAT ADMIRAL ARRIVED TWO DAYS
AHEAD OF TIME. IF YOU FEEL
SLOW, TRY A CUP OF THIS
PURE, MACHINE-MADE TEA.

PRODUCE AND PLANTING.

THE GEOGRAPHICAL DISTRIBUTION OF THE TEA PLANT.—At the International Geographical Congress recently held at Berlin, Mr. J. M'Ewan read a paper on the geographical distribution of the tea plant. The subject should be popular among tea-drinkers in all countries, and the paper will doubtless be read with interest when it makes its appearance in three languages in the official report of the Congress. It is a curious and interesting fact that almost the entire production of tea is raised within an area confined by 40 degrees of latitude and 50 degrees of longitude, and it is no less remarkable that the consumption shows itself to have strictly geographical limitations. Outside of the domestic consumption of China and Japan, regarding which no reliable statistics can be obtained, the principal tea-drinkers, according to Mr. M'Ewan's researches, are the people of Great Britain, Ireland, and of the British colonies, the people of the United States and those of Russia.

RUSSIA AND CHINESE TEA.—It is a difficult matter to change the taste of a nation even in regard to tea. Although Indian and Ceylon growers have made strenuous efforts to gain a market in Russia, prejudice in favour of Chinese tea is their strongest enemy. The Russian scoffs at innovation, and believes firmly in the tea which comes from China overland. Although in recent years much of the tea consumed in Russia has made the sea voyage from Chinese ports to Odessa on the Black Sea, Russians maintain that tea transported by sea loses much in flavour and quality. In consequence of this the largest tea merchants still continue to receive the bulk of their stock by the overland route. Early in January the caravans arrive in Tomsk. Between the first and the twentieth of the month 19,000 sledges full of tea are expected, each sledge containing five packages of about 130 lb. each. The tea is packed not in cases but in stiffened oxhides. Five sledges are tied together and drawn by one horse. The last sledge of each group contains hay and barley, which the horse of the next group quietly munches as he travels. In consequence of this arrangement the caravans lose no time. From the Chinese tea-growing districts to Tomsk is a year's journey by caravan.

PLANTING IN FIJI.—The Fiji Blue-Book for the past year is a record of great prosperity. The revenue was £94,164, or nearly £20,000 more than that of the previous year—on account mainly of a large increase in the Customs revenue—while the expenditure was £72,574, or, including extraordinary public works and a sum put aside for public works during the current year, £87,594. The great increase in the Customs revenue is largely due to a new tariff which came into force during last year, but also in part to an increase in trade. The tariff, which was 10 per cent. *ad valorem* on certain articles, is now 12½, and certain duty-free articles have become dutiable. The imports consist mainly of food-stuffs, clothing, hardware, and machinery, while the exports are sugar (about two-thirds of the whole), copra, and green fruit. The two latter will probably increase in the future, as large areas have been planted by the natives with fruit and coconuts. The population at the end of the year was estimated at 121,738, of which 3,927 were Europeans, 12,320 natives of India, and over 98,000 Fijians. The death-rate amongst Europeans is exceptionally low, the colony possessing "probably the most healthy tropical climate in the world." Beyond the municipal boundaries of Suva and Levuka there are few roads fit for wheeled traffic, though there are bridle paths everywhere. A properly metalled road from Suva to Rewa, thirteen miles, has been commenced, but communication almost everywhere is by water, and this has lately been much increased and improved. There is room for considerable extension in the cultivation of such products as coffee, cocoa, vanilla, limes, ginger, &c., a market for all these existing in Australia, and the Assistant-Colonial Secretary says there is an opening in this direction in the colony for persons with the necessary experience in tropical agriculture and a certain amount of capital.

PLANTING ON THE GOLD COAST.—Planting operations on the Gold Coast receive useful encouragement from the Government. In the agricultural district, says a newly issued colonial report, the planters take the cocoa and coffee to the Government botanical station, where the Government pays them half the supposed market value of the products, less a small sum to cover freight and other charges. The cocoa and coffee are then sent home, and when sold the balance of the money is paid to the producers. In this way not only do the planters receive full value for their articles, but they get enough money on the first sale to Government to enable them to continue their work, and they are therefore not compelled to sell to shippers on the coast at a low price or await the return of their money from the bankers in England. This is a plan that might be imitated elsewhere.—*Home and Colonial Mail*, Oct. 13.

KORALE TEA ESTATES, LTD.

The following is from the report of the directors, to be submitted at the third annual ordinary general meeting of shareholders, to be held at the office of the company on Thursday, Oct. 19th.

The directors now submit the report and accounts for the year ending June 30th, 1898, which have been duly audited. The net amount at credit of profit and loss account after providing for general expense is £2,494 15s 1d. To which should be added the balance brought forward from June 30th, 1893, £218 16s 10d; to dispose of which it is proposed to pay a dividend of five per cent, which will absorb £2,394 5s; directors' fees, £150; and to carry forward a balance of £169 6s 11d. In presenting the third annual report, the directors have pleasure in pointing out to the shareholders that though the expectations held out on the formation of the company have not yet been fully realised, the position of the company has improved, the net profit from the estates this year being £870 in excess of last year. Though the rates of freight and exchange have ruled higher than in the previous year there has been no loss on rice, and partly owing to improvement in manufacture and partly to the healthier state of the tea market, better average prices have been secured for the tea from all the estates than in the previous year. Mr. R C Haldane having retired from business and ceased to live near London, Mr. H C Dowling has been appointed secretary. Mr. W S Bennet retires from the board in accordance with the Articles of Association, and being eligible, offers himself for re-election. The directors continue to adopt the policy of working the estates as economically as is consistent with good cultivation, and to increase the value of their properties by planting up more of their reserve land, and when the 300 acres not yet in bearing reach maturity they confidently expect that the position of the shareholders will be much improved. The directors express their satisfaction with the work of the agents and staff in Ceylon, and look forward to being able to declare the full dividend next year.—*A. & C. Mail*, October 13.

PLANTING NOTES.

A FINE RUBY.—The Ruby Mines Company, Limited, of Mogok, have been fortunate enough to discover a very fine ruby, which gives promise of being a very valuable stone. It weighs 75 carats and looked at in the rough state is perfectly flawless and clear. It is valued now at over twenty-five thousand pounds sterling.—*Burma Times*, October 21st.

CHLORIDE OF LIME AND INSECT PESTS.—The *Indian Planters' Gazette* states that if chloride of lime is spread on the soil or near plants, insects and vermin will not be found near them. By its means plants are easily protected from insect plagues, by simply sprinkling upon, or brushing over, their stems with a solution of it. The solution should be $\frac{1}{2}$ lb. of chloride to a pail of water, and the mixture one ounce of chloride to eight ounces of lards.

THE GARDENERS' MAGAZINE.—The object of this magazine is to represent gardening, agriculture, Horticulture and the allied sciences in all their branches. At present "The Gardener's Magazine, will be issued once a month. Any amount paid as subscription will be thankfully received by the Publisher; and those who will pay anything for its support will receive ornamental and flowering plants from the Agricultural and Horticultural Nursery at their option.—Its address is 8 Gopal Nagor Road, Calcutta.

RUBBER EXPORT FROM BRAZIL.—During the first six months of 1899 the total amount of rubber exported from Brazil was 9,441,988 kilogrammes, of which 3,103,452 kilogrammes were sent to Europe, and 6,338,536 kilogrammes to the United States. According to quality there were 5,271,167 kilogrammes of fine rubber; 733,288 kilogrammes of demi-fine; 2,599,759 kilogrammes of sernamby; and 897,774 of caucho.—*South American Journal*, Sept. 30th. [A kilogramme is slightly over 2 lb.—*ED. T. A.*]

A NEW FORAGE PLANT.—The *Sacalina* (*Polygonum Sachalinense*), is being tried in the Provinces of Buenos Ayres and Entre Rios. It is a native of Siberia and is credited with possessing a number of desirable qualities, being said to grow on any soil and in any climate, to be unaffected by extremes of temperature and to resist a prolonged drought. Cattle eat it greedily, green or dry, and it is highly nutritious, owing to the amount of nitrogen it contains. Such a list of virtues ought to insure for it a pretty extensive cultivation.—*South American Journal*, Sept. 30.

COFFEE AND COCONUT PLANTING IN SELANGOR.—Coffee and coconut planters will be interested in the extracts, which we publish on page 347, from the minutes of a meeting of the Selangor Planters' Association. Coffee planting seems to be in a bad way in that part of the world and help is sought from the Government in the way of remitting the quit-rent. An appeal is also made to Government to take steps to preserve coconut plantations from the ravages of beetle pests. The labour question is also a prominent one there as elsewhere, and the Selangor planters should take a leaf out of the Ceylon book with regard to co-operation and federation.

Ceylon Rainfall.

THE P. W. D. METEOROLOGICAL OBSERVATIONS FOR SEPT 1899.—We append this Monthly Return of rain from which it will be seen that the highest fall was at Padupola in the Central Province, 28.04 inches, and the lowest at Naula, in the Eastern Province, 0.10 inches.

A SUBSTITUTE FOR INDIARUBBER.—We give in full the letter (see page 338) in the last Spectator from a retired Italian Duke, about a possible substitute for "Indiarubber." Our absent Editor writes respecting it:—"I have little fear of the raw product being superseded. Quinine, even when £1 an ounce, was never superseded, much as we heard of laboratory work." It will, however, be interesting to note if the surviving brother of the late Mr. Alfred Nobel, the inventor of the substitute, makes any use of his valuable fraternal legacy, the fruit of an ingenious mind.

COLOMBO PRICE CURRENT.

(furnished by the Chamber of Commerce.)

Colombo 31st Oct. 1899.

VETERINARY NOTES.

A case of cancer in a dog was brought to me for treatment about the 15th of June, with the history that the animal was landed only a couple of days or so ago. The animal was twice before operated on in England.

I noticed the sheath enormously swollen, with a bloody discharge of the characteristic symptom of cancer in penis, was noticeable. The case was taken in hand, and operated on by me, and the cancerous portion entirely removed. I informed the client that this operation would not readily effect a cure, if the animal was not castrated; for when the growth was cut away, the cancer would have more room to spread, and so the necessity of an operation for castration was brought home to my client, who agreed with great hesitation, thinking that the animal being old, might not be able to stand the operation; besides, the owner of the dog (Col. Webster) was away.

The dog underwent the operation, and being a pet animal the effects of the operation were very much felt, but with difficulty he came round. Soon after the wounds of castration were healed, I examined the sheath and found another crop of cancer which had to be removed, but with less difficulty than in the former instance. I did not see the animal after this till he was brought to me on the 13th September, when I noticed just a bit of growth at the root of and inside the sheath; this too I removed. Finally, the animal was brought to me on the 16th October, when I hardly noticed any growth or bloody discharge.

The operation of castration not only prevented the spread of this baneful disease, but helped a great deal in the cure.

Though the method of firing and blistering of the out-of-date farrier has now given way to the more rational treatment of the modern Veterinary Surgeon, branding or the use of the actual cautery is still admitted to be indispensable under certain circumstances. It is therefore not fair to put it down as being a relic of a barbarous age, but it should be recognised that though at one time it was practised indiscriminately it is now adopted in extreme cases under expert veterinary advice. This is how matters stand in advanced countries where the necessity for veterinary control over the treatment of animals is recognised, but in Ceylon it is found that laymen are the censors when questions of "cruelty" in the form of branding are to be decided, and this leaves matters in as unsatisfactory a state as under the old system, so that it becomes a question with us whether the native empiric cattle doctor who is allowed to practise his "profession" without let or hindrance is a better judge of the necessity of branding or the inexperienced laymen who generally sit in judgment on him. The only equitable way of settling the question of cruelty or otherwise in cases of branding, when there is reason to suspect cruelty, is by referring the matter to an expert.

"MANGO LODGE," CINNAMON GARDENS,

DEAR SIR,—I herewith send you a copy of a letter received from George Murray, Esq., of Pallekelle. I would like to add that the material used in this case was not pure but glycerinated

bile, and the animals had, as a matter of necessity, to be worked in an infected area, after inoculation, and before the usual 10 days were elapsed. From Mr. Murray's report, the mortality in this case of inoculation was only 20 per cent. Let me quote a para. that previously appeared in the *Ceylon Independent*:—

"Mr. Hoole, Government Veterinary Surgeon, who returned a few days ago from Kandy, reports that active steps are being taken by the Government and Municipal authorities there to check the spread of murrain. It appears that the inoculations at Pallekelle Estate have unfortunately failed, judging from the percentage of inoculated animals that got the disease and succumbed to it. The Superintendent, Mr. Murray, is however, unremitting in his efforts at combatting the outbreak, and it is to be hoped that the system of isolation and disinfection, which is energetically carried on on this estate will have its desired effect."

It will thus be seen that it was hardly fair to characterise inoculation at Pallekelle as a *failure*.

Yours faithfully,

(Signed) A. CHINNIAH, *Vet. Surgeon*.

(Copy of letter referred to.)

PALLEKELLE, KANDY,

12th October, 1899.

Dr. CHINNIAH,

Alston Lodge, Cinnamon Gardens, Colombo.

DEAR SIR,—I regret the delay in replying your letter, owing to my cattle conductor having left me, and I could not have found out earlier how many of the cattle you inoculated died. Two bulls died out of the ten you inoculated.

Yours faithfully,

(Signed) G. MURRAY.

ORIGIN AND FORMATION OF ORGANIC MATTER IN PLANTS.

(Continued).

By the term respiration we understand the phenomena of the absorption of oxygen and the evolution of carbon dioxide. Respiration occurs in all plant organs, and is a function of such importance that when interfered with by the exclusion of oxygen the death of the plant results. If the roots, buds, moistened seeds, and branches of a plant be placed in a flask, and a current of air free from carbon dioxide be passed over them and then led through a solution of barium hydrate, the latter will become milky, due to the formation of barium carbonate, thus showing that the vegetable matter has evolved carbon dioxide. The leaves throw off carbon dioxide except when they are exposed to the light and respiration is masked by assimilation. During the night or in dense shade they throw off carbon dioxide. When the relation between the oxygen absorbed and the carbon dioxide evolved is carefully determined, it is found that this relation is considerably modified by the temperature to which the leaves are exposed. In a low temperature the oxygen absorbed is usually greater than the carbon dioxide evolved, while in a high temperature the reverse is true, that is, there is more carbon dioxide evolved than oxygen absorbed. Since one volume of carbon dioxide contains exactly one volume of oxygen, it is evident that when the volume of carbon dioxide evolved is greater than the oxygen absorbed the plant is losing oxygen. This explains how the glucoses which are found in the pods of colza are transformed into the fatty substances of the seed, and how inosite and its derivatives formed by chlorophyll action in caoutchouc trees give a resin which is devoid of oxygen. The nature of this transformation has not yet been

explained, but the above observations indicate that these substances, like starch, cellulose, and sugar, are derived from forenic aldehyde, which as already explained, is assumed to be the primary substance from which all plant substances are built up. The formation of acids in plant tissues is explained more easily than that of fatty substances and resins. When starch or sugars are subjected to the action, of dilute nitric acid, oxalic acid is produced. Similar treatment of other saccharine bodies results in the production of tartaric acids. Plant acids are due to a partial oxidation of neutral substances. When the carbohydrates oxide at a low temperature, or the penetration of oxygen into the tissues of the plant is interfered with by the structure of the organs, combustion of the neutral substances is not complete, *i.e.*, they are not reduced to carbon dioxide and water. In this case, the oxygen combines with the substances to produce acids. For example, considerable amounts of oxalic acids and oxalates are found in the juice of the cactus, especially the prickly pear, which is but slightly permeable to air. When, therefore, the volume of oxygen absorbed is greater than of carbon oxide evolved, it may be assumed that oxygen has been fixed by organic compounds in the plant to produce acids. These acids, then, are derived from neutral substances by oxidation, and, consequently, trace their ultimate origin to the decomposition of the carbon dioxide in the chlorophyll cells. In the experiment to which attention was called at the beginning of this article it would have been impossible to grow peas without adding a few cubic centimetres of an infusion of fertile soil to the sand. If this precaution were not observed with the peas, or if the seed of some non-leguminous plant were used, the experiment would be a failure. The seed would produce a sickly plant which would soon die of starvation due to the absence of one of the elements—nitrogen—necessary to its development. Although the leaves of plants grow in an atmosphere four-fifths of which is nitrogen, they are entirely incapable of directly utilising this element.

The process by which the free nitrogen of the atmosphere is utilised by plants has only been explained in comparatively recent years. Hellriegel and Wilfarth in 1886 reported experiments which demonstrated the ability of Leguminosae to attain normal development in soil absolutely deprived of organic matter, the only precaution necessary being the addition of a small amount of an infusion of fertile soil. A few weeks after the addition of the infusion the roots of the leguminous plants were covered with tubercles, which microscopic examination showed to be filled with micro-organisms.

Breal has shown that inoculations may readily be made with these organisms by pricking a tubercle with a needle and then inserting it into a growing root.

The tubercle bacteria have been cultivated and their products have recently been brought into commerce under the name of "Nitragin," which is used for supplying these organisms to soils which are deficient in them. The growth of leguminous plants in sterile sand depends upon the presence on their roots of tubercles filled with these organisms. Through their agency the plant is supplied with nitrogen for the production of

nitrogenous matter, so that if the mineral elements are present in sufficient quantity the plant makes normal growth. The plant profits by the nitrogen furnished by the bacteria, while the latter utilise the carbonaceous matter supplied by the plant, thus establishing a symbiosis. Although the process of fixation of nitrogen by the organisms and its utilisation by the plant has not yet been clearly explained, we can understand how that, notwithstanding the great quantities of nitrogen carried away from the soil with every cutting of lucerne or clover, the amount of nitrogen in the soil increases rather than decreases.

MEMS. ABOUT FRUITS.

The proper manipulation of trees in transplanting is a subject about which most people know very little. It is not uncommon to see trees furnished with masses of roots and planted with the utmost care, prove failures. Those who have had the greatest experience in this matter advise that fruit trees with the roots pruned back are more successful than trees with the ordinary supply. We generally find severe pruning of roots practised in transplanting coconut palms, but the same practice is avoided when fruit trees have to be dealt with. Why this difference in the treatment of transplanted trees?

It is well known to gardeners that an injured root is a source of decay in a transplanted tree, and that the best thing to be done under the circumstances is to remove the injured portion by means of a clean cut. A clean cut wound is easily healed over but not so a jagged one. Now in transplanting it is idle to expect that the roots—however carefully they may be treated—will escape injury. After transplanting, it is not until the roots throw out new white fibres that they are of any use to the tree, and it is well known that these fibres are sooner developed from pruned than from unpruned roots.

The selling price of plantains in the London market does not appear in the usual price lists of tropical produce. It is, therefore, interesting to find in an Exchange, a note to the effect that in July last though the arrival of bananas in London was heavy, the demand was equal to the supply, and the price ranged from 7 to 10 shillings per bunch.

It is astonishing with what pertinacity a name, no matter how enormous and absurd, will stick to a thing after once it has come into general use. Professor Van Denan, the well-known pomologist, referring the name "grapefruit" as applied to the pomelo, expresses the hope that intelligent fruit growers would abandon the absurd and inappropriate name "grapefruit" and use in its stead the proper name "pomelo." "What relation," he asks, "can there be in that large citrus fruit to the grape? Every one that knows anything of pomelo, except it be the most ignorant tyro in pomology, knows there is none. Then why perpetuate such nonsense? The fruit is called pomelo or pumelo in its native East Indian home; and it is called the same in the books on pomology; yet,

because some ignoramus in Florida once started the outlandish name "grapefruit," many persons stick to it in the face of the known facts to the contrary. Pomelo is short, euphonic, plain, historic and sensible. "Grapefruit" has none of these facts in its favour. In the name of common sense and intelligent pomological usage, I beg of everyone—growers, shippers, dealers, consumers and rural editors—to talk, speak, write and print the true name pomelo in referring to this one of our luscious fruits."

The following details of the sale of a small shipment of pine apples received from the West Indies by Messrs. John Haddon & Co., of London, will be of interest to fruit growers:—

	s.	d.	£	s.	d.
40 pines @	1	1	=	2	3 4

It is very desirable that there should be a reform in the nomenclature of fruits and trees, and that loosely applied names should be altogether dropped and correct names adhered to. Dr. Watt gives the following synonyms for *Citrus decumana*, pomelo, shaddock, pompelmos (or pampelmouse), forbidden fruit and paradise apple besides grape fruit. The Sinhalese name (which is commonly used in Ceylon) is *Jambola*, which has to be distinguished from Jamobalan, the Indian name for *Eugenia jambolana* also known as *Masan*. We cannot, however, fully agree with Professor Van Denan as to the pomelo being particularly "luscious" and (as he calls it in another place) "delicious."

It is the experience of many that nitrogenous manures encourage a rank sappy growth of wood in orange trees, and in young trees actually retard fruit bearing. What the tree mainly needs is potash, and if fruiting some phosphate also. This will furnish material for producing a moderate amount of wood and plenty of fruit. The point in orange growing is not to encourage too much annual growth, which if moderate and if plenty of potash and phosphate be supplied will keep the tree much healthier than if over supplied with nitrogenous fertilizers. Too free use of animal manure for oranges is therefore to be avoided,

In Jamaica the planting out of oranges and pumeloes in regular groves, budded from the best varieties, is being extensively done, and some of the groves of young budded trees are now beginning to bear. The export of oranges and pumeloes for the year ending 31st March, 1898, amounted to, oranges 88,013,091, value £134,673, against 99,691,900, value £123,715 this year, and pumeloes 8,989 barrels and 5,620 boxes, value £7,983 15s. 9d. against a value of £7,649 this year.

"If chloride of lime be spread on the soil or near plants, insects and vermin would not be found near them." By its means plants will easily be protected from insect plagues, by simply brushing over their stems with a solution of it, or sprinkling upon. It has often been noticed that a patch of land which has been treated in this way remains religiously respected by "grubs," while the unprotected beds around are literally devastated. Fruit trees may be guarded from the attacks of "grubs" by attaching to their trunks pieces of tow smeared with a mixture of hog's lard and chloride of lime, and ants and grubs already in possession will rapidly vacate their position. Butterflies again will avoid all plants whose leaves have been sprinkled over with this chloride of lime. Directions:—1 ounce of chloride to 8 of lard, $\frac{1}{2}$ lb. of chloride to a pail of water.

Citrus trees require very little pruning. The first year should see them take proper shape, and if well cared for they will expand and develop symmetrically without much subsequent pruning. A little pinching back here and there as the tree starts off the first year is ordinarily sufficient. Make the trees head low and compactly. Don't put any ignoramus who professes to know it all, to butchering your trees as I have seen done recently, where a man went through a healthy, flourishing young grove, and left only skeletons behind, setting the trees back more than a year's growth and fruiting. If you do not know how to do it yourself, or cannot get a man of experience to advise you, you had better not prune at all, concentrate your energies on thorough cultivation and fertilizing, and the tree will do the rest.

MILK AND MILKING.

That the milk last obtained in the ordinary milking of a cow is much richer than that first drawn, is well known to all observant dairymen. We have in the Australian *Farm* a report of a Danish experiment, with judicious remarks about milking generally.

The experiment was made with milk drawn from a number of cows, and collecting the quantities of the different qualities as given below—

1. Milk from the first streams, 172 lb., gave 1 lb. of butter.
2. Milk from the middle streams, 38 lb., gave 1 lb. of butter.
3. Milk from the last streams, 27 lb., gave 1 lb. of butter.
4. Milk from the last drops, 12 lb., gave 1 lb. of butter.

This shows that the after-milk is very rich in butter elements, and therefore very valuable.

Straining the cow's milking capacity to its utmost will develop the udder toward rendering as perfect service as possible.

The milking hours should be regularly kept and the cows milked in a fixed succession—if possible by the same hands. If the milking starts too early the animals are not prepared for it; if too late, they grow impatient, and may even suffer considerable pain. In either case the animals are sure to yield less milk than ordinarily.

Any inconvenience suffered by the milch cow will result in a loss of milk.

Any unusual condition of the udders and teats calls for immediate attention. Soreness of any portion, sores of a peculiar character, and obstruction of the milk ducts should be promptly treated.

Cows with diseased udders are likely to be affected with some contagious sickness, and should therefore be placed apart from the remainder of the herd. Their milk cannot be gathered in the same buckets and pails as are used with the other cows until health is restored.

Whenever a "hard milking" cow is found the narrowness of her milk canals may be obviated by rolling the teats between two hands. The passing of a straw into the milk canal is disastrous to the animal, and may cause inflammation of the udder. On being milked after the first calf, many cows are very sensitive to the milker's touch. Nothing but patience and gentle treatment will avail in such cases.

A dirty udder should be cleaned with warm water before milking and rubbed dry with a clean cloth.

Inflamed udders have been successfully treated with water as hot as can be borne by the hand, and applied frequently."—*Cape Agricultural Journal*.

AGRICULTURAL EDUCATION.

It has been the experience in all countries that Agricultural Educational establishments have serious difficulties to contend with at the outset. Practical agriculturists, and especially those who have been more or less successful cultivators, are always ready to serve at schools of agriculture; while the difficulty of securing a good attendance at classes, where no prospects of employment are held out to students, is another drawback.

The Principal of the Poona College of Science in a letter to the Director of Public Instruction, Bombay, says regarding the agricultural classes:—

I regret to have to report a very unsatisfactory state of affairs. While our new Engineering and Forest classes are so crowded this year, that I have some difficulty in providing room for them all, there is only one student in the new Agricultural class, *viz.*, a man who has been sent from the Central Provinces with a scholarship of Rs. 20 per mensem, and one extra or private student, a Parsee, in the Diploma class. In order to induce fresh men to join, I offered this year three scholarships of fifteen rupees, ten rupees, and six rupees, respectively, to men attending the junior Engineering class, if they would take up Agriculture instead; but only one man applied for the exchange, on the condition that he be given the first scholarship, so I did not accept the offer

The reason for the failure of these classes is, without doubt, the definiteness of their future prospect. The L. C. E. graduates never fail to get fairly remunerative posts, and the Forest Rangers can look forward to success, seeing a number of past students already employed in the Forest Department. But there have not been many instances of similar success among the Agricultural diplomates up to date. He also suggests that Government should annually publish in March or April the number and nature of appointments which will be guaranteed to students who obtain the diploma in Agriculture, and that the scholarships be reduced in number and raised in value.

A Government Resolution has been issued, stating: His Excellency the Governor in Council regrets that the Agricultural classes in the College of Science, Poona, are languishing for want of students. The state of things is the more deplorable, as by Government Resolution, Revenue Department, No. 2178, dated the 26th March, 1898, it was directed that holders of the diploma in Agriculture granted by the Bombay University under the revised Regulation shall rank with graduates of the University, and shall be allowed all the special privileges enjoyed by the latter in the matter of the admission to, and promotion in, the Revenue Department. Government understand that these advantages are not generally known. The Principal of the College of Science should, therefore, be requested to give as wide publicity as he can to such information as he considers likely to attract students to the Agricultural course. The proposed revision of the number and value of the scholarships attached to the agricultural classes is approved, and the Director of Public Instruction should be requested to notify the change to all Head Masters of High Schools, and call their attention to the chances of employment offered to men holding the diploma in Agriculture. The necessary action as regards suggestion (c) made by the Principal will be taken in the Revenue Department, which should be requested to forward a copy of the orders that may be issued to the Political Department for similar action as regards Native States in this Presidency.

After reading of this state of things in India, we consider the Colombo School of Agriculture has done well in keeping up its classes under the very trying circumstances in which it has been placed, with no incentives to students in the way of scholarships, no adequate funds for satisfactorily carrying on its work, and with the worst possible soil at its disposal for practical operations. And yet the Ceylon Government has not yet thought fit to adopt the initiative set by the Indian Government and offer suitable employment to students who have had an agricultural training.

NOTES ON EXHIBITS FOR PARIS.

1. EDIBLE BIRDS' NESTS.

Among the Exhibits being collected for the Paris Exhibition are some about which many persons know little, particularly as regards the origin of certain products which may be familiar enough in the commercial form. It has therefore

been suggested that a series of notes giving information with reference to these articles might prove of interest to our readers, though it will no doubt be found that a number of them are familiar enough to some persons though but little known to others and *vice versa*.

At present the collection received for transmission to Paris is not a very large one, but still there are a few exhibits which appear to be more or less unfamiliar to visitors, and about which the following notes will give them some information:—

The birds which construct the edible nests are found chiefly on the Pigeon Islands (North Cunara), Vingarla Rock, and Sacrific Rocks, on the coast of Malwan (Ratnagiri District), at Tavoy and Mergui, and in the Andaman and Nicobar Islands. *C. nidifica* is known also to occasionally visit Darjeeling, Assam, and the Nilgiri Hills, and to breed on most of the islands on the coast of the Malabar and the Concan round the Bay of Bengal to the Burmese Coast and the Malay Peninsula. *C. linchi* is the principal species of Java, known locally as tintye. In most of the regions where these birds are found, there are caves which afford shelter and protection. These caves occur chiefly in limestone formations, and are often several miles from the coast; at other times they have to be entered by boats.

Mr. Portman, in his report of the Andaman Island Edible Birds' Nests, says:—"I have observed two kinds of swallows, both of which build in the caves. The larger bird has more white in his plumage, and builds a nest of twigs and grass, &c., glued together, and attached to the rock by a peculiar mucilaginous matter. The smaller bird builds a nest of white mucilaginous matter entirely, and it is this nest which is so much sought after. The nest is built in the form of a small bracket attached to the side or end of the cave, of a semi-circular form, with a radius of about $1\frac{1}{2}$ inches, and regarding the matter of which it is composed opinions differ."

"In Borneo, from which country China obtains the majority of her birds' nests, the better qualities of nests are found in caves in the interior in crystalline limestone rock, only an inferior quality of nests being found on the seashore. These remarks apply equally to the Andamans; and I have no doubt that when the interior of the islands is explored, many more nest-yielding caves will be found. All our present knowledge is derived from the Malays, who, through fear of the Andamanese, did not dare to search the interior. The explorations should be confined to hilly country, where the crystalline limestone formation predominates.

The greatest difference of opinion prevails regarding the nature of the material of which the nests are formed. Early writers used to contend that they were made of a sea-weed which the bird collected for the purpose and chemically changed in some mysterious way. Ure (Arts, Manufactures, and Mines) says: "The nests are made of a particular species of sea-weed which the bird macerates and bruises before it employs the material in layers so as to form the whitish gelatinous cup-shaped nests so much prized as restoratives and delicacies by the Chinese. On

the other hand, many recent writers discredit this theory and believe that the gelatinous material is either the natural saliva of the bird or a substance brought up from the stomach for the purpose and derived from the natural food of the nest, viz., insects. In support of this opinion they point out that the better qualities of the nests are found in caves far removed from the sea. Some of the nesting caves of Borneo are 140 miles from the sea. Mr. de Roepstorff points out that there are no edible nests in the Nicobar Settlement, but a few miles off in a richer tract of country where insect life abounds they are plentiful. "It is thus," he says, "in places where the food of the swallow is plentiful, that they exist under the most favourable circumstances, and where the nests are best." In the Ratnagiri District *Gazetteer* it is stated "the swiftlets breed in March and April, in caverns of the rocks, the nests being made of inspissated saliva, in the form of white gelatine, pure white when fresh, but when old brownish and mixed with extraneous substances." Mr. Portman remarks: "The swallow is supposed by some to make this matter, which resembles isinglass, from a species of sea-weed (fucus) resembling Carragen, an Iceland moss. I have often seen this sea-weed, but have never seen the birds on the sea-shore gathering it. Another theory is that the bird excretes this matter from his own throat during the breeding season." I am unable to give any decided opinion in the matter, but the natives have a theory that the birds bring it down from the sun."

(To be continued.)

PRINCIPAL FIBRES USED COMMERCIALY.

BY DR. CHS. RICHARD DODGE.

Of the two dozen species of commercial fibres used in the United States, twenty figure in the list of imported raw products. Taking into account, also, the imported manufactures from fibrous substances and some of the rougher manufactures from fibres or fibrous substances produced at home, the complete list of American commercial fibres may be swelled to thirty species, many of these being unimportant. There are six bast fibres, as follows:—Flax, *Linum usitatissimum*, China Grass, *Boehmeria nivea* (including Rhea, *B. tenacissima*); hemp, *Cannabis sativa*; jute, *Corchorus capsularis* and *C. olitorius*; Sunn hemp, *Crotalaria juncea*, and Cuba bast, *Hibiscus tiliaceus*; all excepting the last being spinning fibres, the Cuba bast finding employment in millinery. There are two surface fibres: Cotton, *Gossypium spp.*, and Raffia, *Raphia ruffia*. The list of structural fibres numbers 15, representing Agaves, palms, and grasses, as follows: Sisal hemp, *Agave rigida* (varieties); Manila hemp, *Musa textilis*; Mauritius, *Furcroya gigantea*, and New Zealand flax, *Phormium tenax*, cordage fibres; Tampico, or Istle, *Agave hetera cantha*; Bahia piassaba, *Attalea funifera*; Para piassaba, *Leopoldinia piassaba*, Mexican whisk, or Brown root, *Epicampes macronra*, and Cabbage palmetto, *Sabal palmetto*, brush fibres; Crin végétal, *Chamae, rops humilis*; Spanish moss, *Tillandsia usneoides*, Saw palmetto, *Serenoa serrulata*; Coconut fibre, *Cocos nucifera*, upholstery and matting fibres;

Esparto grass, *Stipa tenacissima*, for paper manufacture and vegetable sponge. *Luffa aegyptica*, as substitute for bath sponges. The two species of palmetto and the Spanish moss for vegetable hair are wholly produced in this country. As to the sources of supply of these fibres, flax is imported chiefly from Belgium, Russia, Holland, Italy, the United Kingdom of Great Britain and Ireland, and from Canada. China grass or ramie comes from China (in small quantities). Hemp is derived from Russia, France, Belgium, Germany, Austria-Hungary, Italy, the Netherlands, and British East Indies (the latter in trifling quantity); jute from India, and Cuba bast from the West Indies. The imports of cotton are chiefly produced in Egypt and Peru, though small quantities may be derived from other countries. Raffia, used as agricultural tie bands, comes from Africa.

The sisal hemp supply is produced in Yucatan, small quantities being produced in Cuba and the Bahamas. Manila hemp is a product of the Philippine Islands, Cuba hemp being a trade variety. Mauritius or aloe fibre comes from Africa, and the source of supply of New Zealand flax is indicated by its name. Tampico, or Istle, is a Mexican product, and the Bahia and Para piassabas, or "bass" fibres, are collected from Brazilian palms. There are other species of bass (see Bass in Catalogue) derived from African palms, which formerly never came to the United States, and now, if at all, only in trifling quantities. Broom root is a Mexican product, the root of a tall, wiry grass. The two palmetto fibres are produced from uncultivated species of Florida palms, while the *Crin végétal* is derived from an allied palm growing in Algeria. The vegetable hair from Spanish moss is prepared in South Carolina and other Gulf States, while coconut fibre comes from the East Indies. Esparto grass is produced in Algeria, Spain, and Portugal, and vegetable sponge comes largely from Japan. Other commercial species that might be enumerated are imported in a partially prepared state or as manufactures. Such fibrous substances appear in the form of straw plait from Italy, Japan, and China chiefly, the eastern floor mattings and basketry from various substances. In this account, however, only the raw fibres are noted. The fibres produced in this country in commercial quantity are cotton, hemp, flax, palmetto fibre, and vegetable hair from Spanish moss. Hemp and flax production should be largely extended; jute production and the growth of sisal hemp, pineapple, and bowstring hemp are possible. Cane fibre can be produced in large quantities, and there are doubtless other kinds that might form the basis of local fibre industries. The paper materials other than Esparto are not considered in this category. The native fibrous substances that might be employed in lieu of cellulose from our forest trees, for paper pulp, would make a long list, at the head of which might be placed the waste fibre from a million acres of flax produced only for seed. A day is surely coming when the question of securing new pulp materials will present itself, and it is to be hoped that from the long list of native species of fibrous plants enumerated in this work something will be found that will supply at low cost a better

paper material for common use than wood pulp, which has nothing to recommend it but availability of raw material and cheapness.

THE PROGRESS OF AGRICULTURAL CHEMISTRY.

The following is taken from an account of Prof. Maercker's address before the German Chemical Society, and gives his views with reference to Plant Food, Soils, and Manures, subjects of so much importance to agriculturists:—

In supplying nourishment to plants we must know what substances are necessary, and in what form and quantity they should be provided. Little progress was made in our knowledge of the subject till the quite recent introduction of the method of water-cultures of Sachs, Knoop, and Nobbe and the method of sand-cultures of Hellriegel permitted of the conduct of experiments in pure media, and thus rendered it possible to ascertain not only what substances are essential for plant life, but also the part played by each substance in the plant cell. Thus we know now that phosphoric acid is essential for the formation of nitrogenous substances in the plants, because the albumens, which are of fundamental importance in the transformations of substances in plants, result from an intermediate phosphoric acid compound, as is indicated by the regular occurrence of lecythin in protoplasm. Again, iron is an essential constituent of chlorophyll and sulphur of albumen, and hence must be supplied to plants. The true function of calcium was for long doubtful; its action is now known to be of a medicinal character, since it serves to neutralize the poisonous oxalic acid, which is always an intermediate product of the oxidation of the carbohydrates. It was formerly thought that calcium fulfilled some important function in the leaves, being chiefly found in the foliage of plants. Since, however, the leaves are also the chief seat of the oxalic acid, this distribution of the calcium is easily explained.

The part played by potassium has only within the last three years been explained by Hellriegel, who, by exact experiments with beet-root, showed that the amount of sugar in the beet stands in close relation to the amount of potassium provided for the plant. P. Wagner has made the interesting observation that the potassium may be partly replaced by sodium.

The exact value of magnesium to plants is not yet well understood, but it appears to be of importance in the formation of the nitrogenous substances of seeds, as in these considerable quantities of magnesium phosphate occur.

Nitrogen is an indispensable plant-food, for it is an essential constituent of albumen.

In addition to the quantities of mineral substances required by plants to enable them to exhibit a healthy growth, further quantities are found to be essential to satisfy what has been termed, though not very aptly, the "mineral-hunger" of the plant. This is best explained by an example. E. Wolf found that for the production of 100 parts of oat-plant (dried), 5 parts of phosphoric acid was necessary, when the remaining mineral substances were supplied in excess to

the plant. By other similar experiments he showed that the following quantities of mineral substances were necessary for the production of 100 parts of oat-plant :—

Phosphoric acid	50 parts
Potash	80 "
Lime	25 "
Magnesia	20 "
Sulphuric	20 "
		1.95 parts

A total of 1.95 parts of mineral substances is therefore necessary in the case of the oat-plant. However, there is no oat-plant in nature which contains so little as 1.95 per cent. The minimum is 3 per cent. The difference, 1.05 per cent, is the measure of the "mineral-hunger" of the plant, and represents the mineral substances which does not perform any special function. This excess of mineral substance may be supplied in the form of some indifferent substance, such as silica. The observation is of considerable interest to the farmer, for it shows that it is not economical to manure crops with pure substances.

Having ascertained in general what substances are necessary as plant-food, the agricultural chemist has next to apply this general information to the manuring of soils which are more or less deficient in certain ingredients. It has been found, unfortunately, that the chemical analysis of a soil is of little use as a guide unless accompanied by what may be termed a "mechanical analysis," by which he meant chiefly a determination of the amount of finely-divided constituents present in the soil. It is only the finally divided earth which presents a sufficiently large surface for the exercise of the solvent action of the water and its dissolved carbonic acid. There is one case, however, in which chemical analysis alone is of the greatest importance, *viz*, when only traces of some necessary element are present in a soil. Here there is no question of the need for a manure containing this substance.

If, on the other hand, large quantities of an element are present, it does not follow that there is a sufficiency in the soil even when the latter is in a satisfactory state of division, for the substance in question may be present in an insoluble or refractory form. This is commonly the case with nitrogen, which exists in the soil chiefly in the form of a mixture of indefinite nitrogenous substances known as humus or mould. These substances sometimes easily give up their nitrogen to plants, but in other cases are very refractory. The uncertainty as to their action is indeed so great that certain peaty soils are known which consist almost entirely of humus, but contain, nevertheless, an insufficiency of available nitrogen.

Phosphoric acid affords another illustration. The soluble phosphoric acid of the manure is absorbed by the soil as dicalcic phosphate, which is comparatively easily soluble in the soil-water. With time, however, it may change in the soil to the insoluble tricalcium phosphate, or even to iron or aluminium phosphates, which are still less soluble.

In the case of calcium, chemical analysis has been found to be of considerable service in determining what manuring is required, since calcium

is chiefly valuable in the form of carbonate or humate, and these are easily estimated in the soil.

Since then the direct method of soil-analysis is an insufficient guide to manuring, it is fortunate that chemists have been able to develop successfully an indirect method. This is the cultivation method, by which plants are allowed to grow in the soil under examination, after taking care to provide a sufficiency of all plant-food stuffs except the one, *e.g.*, phosphoric acid, whose presence in available form is being tested. The plants are then analysed, and the results compared with the analyses of the same plants grown on soils provided with all the necessary plant-food stuffs. As an important result of the method it has been found that different plants take up very different quantities of the same mineral substances. On this is largely based the system of rotation of crops, where the second crop is so chosen that it chiefly removes the ingredients of the soil which have been left by the preceding crop.

With the aid of the cultivation method it has also been possible to draw up the following table which represents the relative values of the different nitrogen compounds for plant food.

Nitrogen of Saltpetre	100
" " Ammonia	85-90
" " Albumen	60

This table may be made use of in determining the nitrogen value of a manure.

The cultivation method may be used for testing the value of manures of all kinds. Thus it was by a few cultivation experiments that Wagner in Darmstadt first showed the very great value for agricultural purposes of the "Thomas" Slag, produced as a bye-product in the manufacture of iron by the basic process of Thomas Gilchrist. The million tons of phosphate meal annually produced in Germany is now wholly utilised by the agriculturist, and its preparation for the farmer has become an important offshoot of the industry.

Similarly the demonstration by the cultivation method of the value of potash salts in manures has given an enormous impetus to the potash industry.

Speaking generally, the method gives us complete control over the fertility of a soil in so far as this depends on manuring. One consequence of this has been that our views as to the value of agricultural land have completely changed, for whereas formerly sandy soils were generally considered poor, they are now by means of a system of intelligently directed manuring, made to give yields which are scarcely inferior to those of the best soils. The beet-sugar industry, which formerly could only be conducted in the best soils, has now been extended with marked success to sandy soils.

AGRICULTURAL EDUCATION IN FRANCE.

The system of agricultural education in France is reported to be most perfect, and just at this time when a Commission is sitting with reference to the question of establishing a Department or Board of Agriculture for the island, an account of the French system of agricultural education should prove both interesting and instructive reading.

We have just received, through the courtesy of a high official, a copy of a Report (only the series of Diplomatic and Consular Reports) on this very subject, written by Mr. H. Austin Lee, Commercial Attaché to Her Majesty's Embassy at Paris. From it we learn that though various efforts in the direction of agricultural education were made in France during the latter half of the eighteenth century, it was not until 1822 that the first agricultural school was founded by Matthieu de Dombastle, at Boville, near Nancy. This school was quickly followed by others: in 1829 by that of Bella at Grignon, one of the most flourishing institutions of the present day, and in 1830 by that of Riffel at Grandjonan. The introduction of the present system of agricultural education, however, dates from 1875-76. When Minister of Agriculture, Monsieur Méline, in his official report published in May, 1898, advocated the institution of a "Superior Council of Agricultural Education," which was organised by the decree of May 27th, 1898. It is charged with the supervision of all institutions, &c., affording agricultural education, founded or subsidised by the Ministry of Agriculture, and has a voice in all matters relating thereto. It meets at least once a year and forwards a report to the Minister of Agriculture, comprising its views respecting improvements to be introduced into the system as a whole. Of this Council of thirty, fourteen officials, including the officers in control of the various sections of the Agricultural Department, heads of the Veterinary, Forestry, Irrigation Departments, Directors of Forestry and Agricultural State Schools and Presidents of Agricultural Societies, are *ex-officio* members. The rest of the members are nominated from amongst the agricultural and scientific notabilities of the country and others. They are appointed for four years, one-half of their number being renewed every second year. Fifteen members of the Council form a permanent Commission which meets to consider urgent matters whenever summoned by the Minister of Agriculture.

The inspection of agricultural education has also been lately organised. There are now officers known as Inspectors-General and one inspector for each of the eight districts into which the country has been divided.

The Inspectors-General are charged with the organization of the general agricultural show at Paris, the supervision of district agricultural shows, and the inspection of the "Institute Agronomique" and the National Agricultural Schools.

The Inspectors are charged with the supervision of the establishments affording agricultural education in the general districts other than the abovementioned, with that of the departmental and special professors. They also organise and preside over the district shows. They are subordinate to the Inspectors-General.

The corps of inspectors are recruited from qualified professors of various agricultural institutions.

The State expenditure on agricultural education, under this system, is, as may be expected, considerable. The votes for National Institutions aggregate £77,434, and for institutions subsidised by the State £75,026, or a total, for the year 1899, of £152,460. The receipts from fees and sale of

produce in general establishments, giving as the figures for 1897, are between £12,000 and £13,000.

Agricultural education as it exists in France may be divided into four sections, viz., Elementary, secondary, higher and general.

Under elementary agricultural establishments are classed (a) the Farm Schools, and (b) the Practical Agricultural Schools.

Of Farm Schools there are fourteen at present, though at one time there were about five times this number. The decrease is attributable, firstly, to the increase of "practical schools," and secondly, to the growth of private establishments taking paid apprentices. But though their present importance is comparatively small, it would appear that these Farm Schools still supply a distinct want. These institutions can scarcely be called schools. The farm is a private speculation. The Government pays the salaries of the staff of teachers, 7½d. per day towards the upkeep of each apprentice, and gives usually a bonus of £12 on leaving to those who gain their diploma, and £8 to those who do not. The teaching is gratuitous, the apprentices are boarders, and the course varies from 2 to 3 years. The age of admission varies from 14 to 16, and the average number of apprentices is about 20.

The staff usually consists of a Director, a teacher, superintendent (who is also accountant), a gardener, nurseryman, overseer of practical work and Veterinary Surgeon and drill master; besides special instructors for any special local cultivation. The teaching is mainly practical, and the Director makes use of the services of the apprentices as he deems advisable.

The theoretical studies, which occupy about one-third of the time, are of a very elementary character. They include the revision of subjects taught in the elementary schools, horticulture, arboriculture, and general notions respecting surveying and levelling, agriculture in its widest sense, "first aid" to sick animals, and book-keeping.

Admission is obtained by examination in primary subjects, but those holding the primary education certificate are exempted from examination.

The objection that has been brought against these schools is that the Directors (who are the owners or lessees of the farm) are often apt to look upon the apprentices somewhat in the light of labourers placed at their disposal by the State, and to make them work merely with a view to their own ends, the question of teaching taking only a secondary place. A shepherd's school on the same principle exists at Rambouillet.

The practical agricultural schools may be said to fill a gap between the national schools, intended to give a secondary practical and theoretical education to the sons of larger landed proprietors, and the farm schools intended to give almost entirely practical teaching to the sons of labourers. They were established with a view to catering to the important peasant proprietors and small farmer classes.

These schools may be defined as farms of the better class, carried on with a view to profit, taking paying pupils who are taught the theory and practice of the special types of agriculture in the district of each school. The plan would appear to be successful for the number of these institutions existing, viz., over 40.

The object of these schools is stated to be "to take the child as he leaves the primary or superior primary school, to give him thorough practical and theoretical training, and then to send him back to the agricultural family, which he will not again leave." The practical school does not pretend to make finished agriculturists, but furnishes them with the means of becoming so by giving them a solid foundation of essential agricultural knowledge. The scheme devised for these schools has the merit both of simplicity and of economy to the State. The Director is either proprietor, tenant, or manager for some company department, or commerce. In the two latter cases he usually undertakes the farming at his own risk against an almost nominal rent. The initial cost of adapting the farm for the purposes of a school is borne—except in rare instances—by the proprietor or lessee alone or in conjunction with the department. The owner, however, often provides the whole of his cost, being repaid by the department by annuities. The State is in no way concerned with such matters, nor participates in the management or the agricultural venture. When the school is founded with the sanction of the Minister of Agriculture, the Government undertakes to provide the salaries of the Director and staff, a small sum for general expenses, and usually from £100 to £200 for Scholarships, some of which are, as a rule, also offered by individual departments.

The average course of study is 2 years, the average number of students 30 to 40.

The average fees are £20 for boarders, £10 for half boarders, £2 for day scholars. The scale of charges is fixed by the Minister of Agriculture. If qualifying and where needed a competitive examination precedes admission; a certificate of elementary education exempting from examination. The direct supervision of each school is in the hands of a committee of officials and unofficials. The staff usually includes a director, three professors, a teacher-superintendent, Veterinary Surgeon, over-

seers for Agricultural, and horticultural work, and Military superintendent.

The pupils receive theoretical and perform manual labour alternately morning and afternoon; the practical portion of the tuition being supplemented by numerous excursions, which give occasion for object lessons in agricultural matters.

Whilst there is much diversity in the practical training, the theoretical tuition is of a fairly uniform type, including:

1. Agriculture, zootechnics (the study of the habits and characteristics of the different kinds of live-stocks, and then classified according to age, race, &c.) rural legislation and economy, and rural engineering.

2. Physics, chemistry, technology, and meteorology.

3. Botany, zoology, geology, horticulture, entomology, and the study of useful and harmless insects.

4. Superior primary instruction, civil law, mathematics, surveying, levelling, and book-keeping.

5. Hygiene and "first aid" to animals.

A weekly examination is held in each subject, and pupils are practised in laboratory and the work of the microscope.

We are then given a short sketch of two typical practical schools, viz., those at Berthonval in the North, and Ondes in Southern France.

The average cost to the State of Practical Agricultural Schools would appear to be between £800 and £1,000. A certain number of schools afford instruction of a special character, such as the manufacture of cheese and butter. Poultry Farming and Horticulture, e.g. the Practical School of Poultry Farming at Sanvic, near Havre, and the Milk Industrial School at Poligny.

Here we close our review of this interesting report, reserving our notice of secondary, higher and general agricultural education in France for future issues.

* The TROPICAL AGRICULTURIST *

◇ MONTHLY ◇

Vol. XIX.

COLOMBO, DECEMBER 1ST, 1899.

No. 6.

“EUCOMIA ULMOIDES” OLIVER: A NEW GUTTA-PERCHA PLANT.

By M. M. J. DYBOWSKI AND G. FRON.
(Specially translated, from the “Revue des
Cultures Coloniales,” for the *Tropical
Agriculturist*.)

UTTA-PERCHA is, as is known, produced principally from trees belonging to the Sapotaceæ and growing in sub-tropical regions. It is therefore interesting to know that a plant, belonging to quite a different botanical group and growing in regions with a temperate climate, can also yield gutta-percha. We refer to a species studied by M. M. Oliver and Weiss and described in the bulletin of the Linnæan Society of London in 1892, under the name of the *Eucomia Ulmoides* Oliver. Having only incomplete specimens at his disposal that botanist was unable to make an exact study of the plant. However, he ranks the *Eucomia* among the Euphorbiaceæ, near the crotonoids, and notes, in the different organs of the plants, the presence of lactiferous vessels, the contents of which become particularly visible when, having broken a portion of the stalk or the leaf, one carefully separates the two parts. M. Weiss undertook the anatomical study of the stalk and leaves, more particularly the development of the lactifers. He affirmed their presence in great abundance in the “parenchyma cortical”* of the stalk and their resemblance to the vessels holding the latex of the *Euphorbiaceæ*. Having measured the proportion of elements soluble in chloroform in the cortical region, he obtained a yield of 3 per cent.

Having noticed the analogy that exists between the leaves of palaquium and those of the *Eucomia*, when on carefully breaking the leaves, one exposes the contents of the lactifers, we have been led to try to apply

to the different organs of the plant, the procedure recommended by M. Jungfleisch for extracting gutta-percha from the leaves of palaquium. We experimented first on some fresh leaves of a single plant of the *Eucomia* in the *Jardin Colonial*. The leaves are 8 to 9 centimetres long and 4 to 5 wide. They are oval, pointed at the end, finely dentate, have short stalks, and in length resemble those of our common elm. Operating upon 20 grammes of dried leaves, we obtained 0 gr. 45 of products soluble in “toluène”* which corresponds to a return of 2 gr. 21 per cent. This return is poor, if one considers that the fresh leaves contain 70 per cent. of water. The bark seems to contain a notable proportion of matter produced by the lactifers. But the plant which we possess being still very young, we have not been able to take any branches away for examination. A second series of observations was made upon the fruits. The fruit is a samara, the length of it being from 3 to 3½ centimetres, and the width about 1 centimetre. 200 fruits weigh about 13 to 14 grammes. The extract of matter soluble in toluène has given us the following results:—1st attempt, 15 grammes soluble in toluène 4 gr. 09; 2nd 15 gr. gave 4 gr. 12. That is a proportion of 8 gr., 20 to 30 gr. of matter. This corresponds to a yield equal to 27·34 per cent. We operated on fruits not dried. The fruit contains a small proportion of water, equal to 7·4 per cent. The product obtained is of a brown colour with metallic reflections on the surface. Plunged in hot water, it becomes soft again, stretches out in thin flakes like gold beater’s skin, and under pressure will take the impress of metal. In cooling it loses its suppleness and becomes quite hard.

We have submitted the samples to M. Léaute, an authority on the subject, and he authorizes us to say that he considers them of good quality....Experiments are being made in the *Jardin Colonial* as to the methods of propagating the plant, which is at present only known in the North of China. Seeds are uncertain and often slow of growth but cuttings seem to give the best results. Cuttings will strike root in any season, but spring seems to be the most favourable for budding... The plants has lived in the open air in Paris through the winter. Further experiments on the plant are being made which will determine if it would be worth while to extract gutta from the branches or the bark.

* [That is, the soft spongy cellular web which fills the spaces between the different fibres and tissues in the leaves, young stalks and fruit.—Ed. T.A.]

* [“Toluène” is a colourless liquid obtained by the dry distillation of Tolu’s balm, a balm produced by a tree of the *myrsperme* genus.—Ed. T.A.]

COFFEE IN QUEENSLAND.

THE LATEST REPORTS.

Experiments with coffee growing have been made from time to time—often at long intervals—ever since the foundation of the colony. Thirty years ago the then Government tried to galvanise the industry into life by offering growers special concessions, but though small plantations were laid at Buderim, near Maryborough and other places, no one seems to have persisted in the cultivation either earnestly or extensively. One gentleman, near Mackay, has continuously grown a few acres of it for over 20 years, at time with very handsome results. During the past few years a wider interest has been taken in coffee culture. On the Russell River, near Cairns, Mr. W. R. Lewis has established the Mount Graham plantation. Some 16 years ago he visited Mackay and was much impressed with what he saw on the plantation of Mr. Costello (the gentleman first referred to); he decided to give coffee growing in his own district a thorough test. The result has been a complete success. He has now 15 acres under crop, and the Mount Graham coffee is to-day a well-established commercial commodity, finding a ready sale locally at a remunerative price. In the Cairns district there are now 400 acres planted as against 159 of the previous year, and 50 of the year before. At Kamerunga, a few miles from Cairns, at the foot of the coast range, there is a State nursery where many varieties of the tree have been carefully cultivated for years. To show how the industry is spreading, it may be mentioned that from the nursery during the year 1894, 110 lb. of coffee seed were distributed among 72 intending growers, while in 1896, 116 farmers received 1,300 lb. Besides this the nursery in the same time sent out 2,250 coffee plants, all the samples of coffee grown from them being of excellent quality. The progress of Cairns is best illustrated by the coffee output, which rose from 16,962 lb. in 1897 to 40,678 lb. in 1898, the majority of the trees bearing then for the first time. Three years ago planting at Mackay was begun on the largest scale yet attempted in Queensland. The Mackay coffee Estate Company commenced operations, and has now some 100,000 trees planted. Altogether at Mackay there are now 115 acres under crop, which will begin to show returns this year. The old trees which had been bearing for years have been replaced with young plants. That coffee of a very superior quality can be grown at Mackay has been abundantly proved, as, apart from Mr. Costello's experience, for years past coffee trees at the Mackay State Nursery have borne crops which old and experienced planters, who have spent years in Ceylon, India, the West Indies, and Brazil, have publicly declared they never saw excelled considering the age of the trees. Another feature of the trees grown in North Queensland, which is maintained by experts to prove beyond all doubt the super excellence of the local conditions—temperature, soil, rainfall, &c.—is that they will bear full crops in their fourth year, whereas in other coffee-growing countries a full crop rarely appears until the tree matures, and that is, attains its full growth in its sixth or seventh year. It is affirmed that its early fecundity is neither detrimental to the quality of the coffee nor the subsequent life of the tree. North of the tropic line is generally considered the natural home of the coffee plant, but experience has shown that it can be cultivated much further south with almost equal success. In the neighbourhood of Maryborough, there are now about 300 acres planted; and the success which has attended its cultivation at Buderim Mountain has induced selectors on the Blackall Range to put in some trees.

Experiments there have shown that the climate and soil at certain altitudes are very favourable to their propagation. Recognising the importance of this growing industry, and the great scope the northern portions of the colony afford for its expansion, the department has procured the services of Mr. Howard Newport to instruct the planters new to the industry in the best method of planting, caring, &c. Mr. Newport has had 11 years' experience in India, where he managed a large plantation at Melrose, Yercaud, in the presidency of Madras. He has also had considerable experience of coffee-planting in Ceylon. Mr. Newport corroborates the testimony of Indian and Ceylon planters as to the eminently favourable climatic conditions of North Queensland for coffee culture, and he brings Queenslanders the cheering news that, though the industry is yet only a very small affair in the colony, the most flattering reports have gone abroad respecting the quality of the coffee and the big field there is in North Queensland for the expansion of the industry. He says that planters in India have begun to look upon Queensland as a dangerous rival in the production of the finest-grade coffee, of which they at present are the largest producers in the world, and practically have the monopoly of that class of trade.

"Will coffee-growing pay?" is a question frequently asked. It is answered always in the affirmative by practical growers. What it will pay depends, as in all other industries, upon how economically it is worked, the quality of the article produced, and the market prices. It is only to be expected that where there have been so many isolated amateur efforts under so many different conditions there should be considerable diversity of opinion on a good many points. On one point all are, however, unanimous—that good coffee can be grown in Queensland, and that good yields can be confidently anticipated. What it will cost to grow is a matter that has not been settled definitely in such a way as to be capable of general application. It is generally admitted that it can be grown in a small way more profitably than on a large scale, where the question of labour enters largely into the consideration when the crop is ready for harvesting. So far, the areas harvested have been small, and the labour employed of different kinds. Whilst one man employed aboriginal labour, which is naturally cheap, others got through the whole of the berry picking with the help of their families. A child of about 12 years, it is said, can pick 25 per cent. more in a day than a man. But all men have not large families of young children, nor can aboriginal labour everywhere be found, and it is asserted that white adult labour would be too expensive for the work performed. In India, Brazil, Ceylon, and other coffee-growing countries there is abundance of cheap native labour. It is contended that if Queensland is to compete successfully with them the labour employed must also be cheap, so that it would seem that the labour of the Queensland coffee plantations of the future will have to be obtained, as in the case of the sugar plantations, from the Polynesian Islands. The experience of the Mackay Coffee Company during the next and following seasons should furnish a good guide as to whether the coloured labourer is as useful and essential among the coffee trees as he is among the sugarcane. But whatever may be the profit in operations on a large scale, there is no doubt of coffee being "a poor man's crop." It is an easy one to grow. Mr. Newport and other experienced planters state that any man of ordinary intelligence can easily and quickly learn all that is necessary to plant and tend the trees, pick the crop, and cure it ready for the market. It requires no heavy labour, nor any very expensive mills and machinery. It keeps indefinitely, and to a certain extent improves with age. In one of a series of letters contributed to the "Queensland Agricultural Journal" on coffee cultivation, the manager of the Mackay Coffee Estate, an ex-Indian planter of very considerable experience, wrote as follows:—"The requisites necessary for the preparation of the product of the mill are so simple

and so unexpensive that they are within the reach of all." It must have occurred to those who have followed these articles from the beginning that it is not necessary for every grower to erect a mill for the own crop. One mill in each district is ample for all purposes, as coffee in the parchment state will stand holding for an indefinite period, provided it has been sufficiently dried nor need the farmer apprehend that such delay will cause depreciation in its value, for the contrary is the case. The farmer in Queensland can choose his own time for sending his parchment to the mill, where could either sell for cash, or have the article cured, packed, and shipped for him. The same principle is carried out in most of the coffee-growing countries, and should answer equally well here." Of the great profits to the small grower there seems to be no room for two opinions. If, as before observed, he has a family of active children, he needs but little paid labour in the berry-picking season. On this point, Mr. T. A. Bromley, Pialba, in a paper read before an agricultural conference held at Rockhampton last year, said:—"I have five acres under coffee, and the reason I have not more is that I am testing coffee-growing experimentally on approved lines. . . . Now, about labour, and that is a great point. My quiver is full, and I have a big little family. When it comes to picking with the assistance of a few children from round about, I can sip through the job very well. Children are by far the best pickers." In giving an estimate of the money return that might be expected from coffee-growing, he continued:—"By taking the price mentioned as a basis (10d. per lb.) the net return per acre would be over £50. Of course, it would not do to consider that a state estimate, as in practice you might get a long way below it. However, I am satisfied there is no other crop will pay so well, not even sugar." Dr. Thomatis, of Caravonica Park, Cairns, who has been growing coffee for years, and who, eight months ago, was awarded a special prize for his coffee at the Marseilles Exhibition, is very emphatic on the subject of profits. In a paper he read at the agricultural conference held in June last at Mackay he said:—"A small farmer with a growing family can grow a few acres of coffee with the certainty of realising from £30 to £40 per acre, without the necessity of employing labour outside his own family."

As very little is generally known about coffee growing, I will here give an idea of what amount of capital a man would require arriving in Queensland prepared to embark in the industry for the purpose of making a living out of it. The cost of securing the land would very considerably, according to the conditions under which it was taken up—as a homestead selection, agricultural farm, or freehold land purchased outright. There is land coast open for selection all along the Queensland coast. The Brisbane Land Commissioner informed me a short time ago that there were 50,000 acres of scrub land on the Blackall Range, within 50 miles of Brisbane, suitable for coffee or fruit growing, and open to selection at 2s 6d an acre as homestead leases to the first persons that came along. A few miles back from the coast at Mackay, Cairns, and other northern ports, freehold land may be purchased from £2 an acre upwards. Excellent sites sheltered from the strong winds which prevail at certain periods of the year can be chosen on the slopes of the coast hills which, from their irregular conformation, are unsuitable for general agriculture, but which are all that could be decided for coffee culture. Taking the case of the site chosen, being freehold land, it may be put down as a general average that £3 an acre would be the cost of purchase. The cost of cutting and burning off the scrub would not exceed £4 an acre. To grub out the heaviest stumps might take £3 or £4 more an acre, but this operation, to a man of limited means, is to a certain extent unnecessary, as the stumps may be allowed to rot away, as they will do in time. One of the illustrations shows the dead timber still standing in the plantation. Digging holes for the ants would increase the outlay by another £4. The

whole cost of preparing the plantation would be about £12 an acre. Taking for instance a plantation of 30 acres the expenditure would be something like the following:—

Cost of land, about	£90 0 0
Clearing (if heavily timbered) and planting, about	360 0 0
Farming appliances, say	30 0 0
Fencing, say	60 0 0
<hr/>	
Total cost of planting 30 acres	540 0 0

There would be other contingent expenses; a dwelling-house, &c., a couple of horses, and other items the cost of which would depend largely on the settler's taste and disposition; and the expense of living, keeping down weeds, and tending the young trees for three years until they began to bear would also have to be taken into consideration. Of course if he has been accustomed to manual labour much of the above outlay would be avoidable with the help of one or two kanakas or a couple of sons fit for field work. Opinions differ as to how many trees should be planted to the acre; the estimates range from 700 to 1,100. Experienced planters state that 1,000 are not too many where the soil is rich, the land well cleared, and economy of space has to be considered. At the end of three years the first berries appear, yielding approximately one-fourth of a full crop. In the fourth season about a half-crop may be expected, and in the fifth year the trees are in full bearing. Each tree will yield 2 lb. of parchment coffee, which means for 1,000 trees 2,000 lb. of parchment. Taking the mean between the various estimated costs it may be set down that the cost of picking will amount to $\frac{1}{2}$ d per lb. of berry from the tree, or to 3d, per lb. of parchment coffee. During the past few years the selling price of the coffee locally has ranged from 7 $\frac{1}{2}$ d to 12d. per lb.; as importers pay 9d per lb. on the average for inferior coffee from Fiji, it seems a fair average to estimate 9d as the ruling price of the local product, and at that figure European merchants have offered to buy Cairns and Mackay coffee in unlimited quantity. This would leave a balance of 6d per lb. to the producer, which, at a yield of 2,000 lb per acre is £50. Out of this return all incidental expenses would have to be deducted. Discounting all the estimates, disregarding the fact that growers in North Queensland have netted from £40 to £60 per acre, allowing for an increase in the expenditure, a fall in the price of coffee, and setting the net gain as low as £20 per acre, then the owner of a 30-acre plantation would find himself at the end of five years in receipt of an income of £600 a year. One ceases to wonder at the enormous fortunes Indian and Brazilian planters have made.

Last year Queensland grew only about one-fifth of the coffee consumed in the colony, so that the intending planter has not only the balance of the home consumption to supply, but he has open to him the whole Australasian market. There is a big future ahead of the industry in Queensland. The local conditions cannot be surpassed anywhere, and there is plenty of available cheap land. The trees bear earlier and heavier crops than in other coffee-growing countries; the foreign planter opens his eyes in astonishment—it is not in his experience; and the plant so far has been free from the dreaded leaf disease which has played havoc with the plantations in India, Brazil, Arabia, Ceylon, and other countries. The growth of the plant in Australia gives new experience owing to its adaptability to soils and climates to which in the previous history of the tree no parallel can be shown. Finally, the climate is healthy; yellow fever and other epidemics common in other countries are unknown; and the planter lives in the midst of British civilisation surrounded by his own countrymen.—*Cydney Mail*.

RHODESIA AS AN AGRICULTURAL COUNTRY.

By MR. M. A. LINGARD, SECRETARY FOR AGRICULTURE.

Anyone who has travelled through Rhodesia, and regarded it from the point of view of a practical farmer, cannot fail to recognise that whatever attractions it may possess in the shape of its minerals, it has undoubtedly vast possibilities in the way of agricultural industries. Too many observers have been content to base their opinion upon a hasty journey through the country by stage coach, and have come to the conclusion that because so little land is actually under cultivation, it is not as a whole fitted for farming. It must not be forgotten, however, that Rhodesia had had its full share, if not more than its share, of actual difficulties and obstacles to progress; and the scarcity of stock suited to arable cultivation has been keenly felt. The locust disease fungus will, it is hoped, do much towards abating the locust pest; the native troubles are a thing of the past, and rinderpest is rapidly disappearing from our stock. Now that the country is in a more settled state, and the conditions of existence are becoming day by day more easy, alike to the farmer and the artisan, there is good reason for the belief that a steady and increasing demand will be created for the produce of the soil, which will stimulate the agricultural industry of the country. Another result of the unsettled condition of the country, and the drawbacks which have had to be encountered, has been that farming, so far as it was carried on, was regarded more or less as a speculation, and the prices realised at times for forage, etc., have been so high that the money that would otherwise have been re-invested in agricultural wants have been diverted to other channels.

In making a general review of the agricultural outlook of Rhodesia, the most important feature to be considered is of course the nature and formation of the soil. Generally speaking, the country may be described as both fertile and well watered, and admirably adapted, not only for breeding stock of all kinds, but also for raising cereals and other produce of the tropical and sub-tropical climate. That this is no mere theory, is amply proved by the results attained by the natives, whether Mashonas or Matables. These tribes were the possessors of vast herds of cattle, which roamed about on the abundant pastures; and though their equipments for tilling the ground were necessarily of the rudest kind, they had no difficulty in raising mealies, sweet potatoes, rice, beans, tobacco, and in fact all kinds of produce. How much more than can be done by skilled agriculturists with all the latest farming appliances, a requisite amount of capital, and a sufficiency of native labour? With a comparatively small capital an energetic farmer should have no difficulty in earning a comfortable livelihood for himself and his family, and making provision for the future; that is if the farmer is prepared to put his own hand to the plough. Unfortunately in the past our farmers have shown a tendency to rely too much upon native labour, and have not always given the requisite amount of superintendence, and the natural result is that the crops were neglected or improperly handled.

It has been asserted by some critics that owing to the long duration of the dry season in this country the effects of drought would be certain to discourage any serious attempt at farming. But on examination, this argument falls to the ground. With a soil which contains so much lime, and is formed on a granite bed the effects of drought are not so keenly felt as might be anticipated, and the decay of the rank vegetation which grows so abundantly forms an excellent manure for the soil, and leaves the ground ready for cropping without the aid of artificial dressing. With such natural advantages as are possessed by Rhodesia, as regards both soil and climate, a thorough system of agriculture, assisted where necessary by irrigation, should yield good results, equal to those

attained in other countries, such as Canada or Australia. Little has yet been done in the way of cereal growing as the demand has necessarily been limited. Most of the oats and barley grown here have been used for forage, which at present yields a handsome return. The only kind of agricultural pursuit that has been gone into on any considerable scale is market gardening, and here the results have been very gratifying. If other colonists were to pay a visit to the markets of Bulawayo and Salisbury, they would probably be surprised to note the extent and variety of the crops raised, and their general excellence in quality. At present the market gardens are principally carried on by Indians in the neighbourhood of our large towns but with the near development of the mining resources of the country there is still scope for a further development of this remunerative resource, with which poultry and dairy-farming can be carried on at the same time. More attention might also be paid to fruit growing in a region the climate of which is so admirably adapted to almost all kinds of sub-tropical and tropical fruits. This is a want that is very much felt throughout the country.

It is somewhat difficult to present a sketch of what kind of cereals and other crops would thrive best in any particular locality, but after paying a visit to Mr. Rhodes's estate at Inyanga, in the Umtali district, one is left in no doubt that with a plentiful supply of water, farming on a systematic basis can be successfully carried on, both as regards cereals, vegetables, and fruits. As regards the pastoral industries, it must be admitted that since the conquest of the country many serious obstacles have had to be overcome. The various diseases and troubles to which stock is subject in this country have quickly developed and spread throughout the territory, but with the measures that have been adopted by the Government to stamp out rinderpest and pleuropneumonia, together with the able advice of the Veterinary Department of the Cape Government, which is always at our disposal, there is every reason to hope for better things in the near future. It is not easy to pronounce more definitely on this important subject, as qualified men find it difficult to arrive at any definite conclusion as to why stock in this country should be so susceptible to so many diseases. However, it is to be hoped that with the introduction of a stronger and purer breed of stock the cattle will be able to throw off many of the minor ailments. There seems to be no question that the cattle reared by the natives are much more liable to many of these troubles than stock bred in the south or elsewhere, and doubtless this is due largely to the in-breeding practised by the Kaffir tribes. Indeed, it is not unlikely that this has proved a source of weakness in the past, and that to it may be ascribed the rapid transmission of the fatal scourges which have carried off so many cattle and horses. The remedy appears to lie in the importation of a better and harder class of stock, which I hope will be undertaken at no distant date.—*Cape Times*.

THE ALKALOIDAL CONTENTS OF CINCHONA.

According to an article appearing in the *Journal de Pharmacie et de Chimie*, the following are the usual limits of alkaloidal content in various groups of bark:—1. *Succirubra* from Java, 6 to 8 per cent. of total alkaloid; quinine sulphate, 2 to 3 per cent. 2. *Loxa*, from St. Thomas, 5 to 6 per cent. of total alkaloid; quinine sulphate, 2 to 2½ per cent. 3. *Loxa*, from Nilgiris, 4 per cent. of total alkaloids 1 to 1½ per cent. of quinine sulphate. 4. *Calisaya* from Bolivia, 5 to 6 per cent. of total alkaloids; 3 to 4½ per cent. of quinine sulphate. There is room for Nilgiri bark to improve, and it is to be hoped that one effect of Mr. Standen's recent visit to Java will be an increase in the alkaloidal content of Indian grown cinchona.

REMEDIAL MEASURES AND INSECTICIDES.

By E. E. GREEN, GOVERNMENT ENTOMOLOGIST.

(Continued from page 300.)

Kerosene Emulsion.—Soap is often combined with other ingredients. Of these kerosene emulsion is the best known and most widely used. As its efficacy and its effect upon plant life very greatly depend upon the preparation of the mixture, great care should be taken to accurately follow the directions. The formula in general use is:—

Soap	$\frac{1}{2}$ lb.
Kerosene	$\frac{1}{2}$ gals.
Soft water.. .. .	1 gal.

'Dissolve the soap in the water heated to boiling, then add the kerosene (to the hot mixture), and churn it until a creamy fluid results, which thickens on cooling, and adheres to glass without separating into oily particles.'

Whale-oil soaps are preferable, but any kind may be used. I have personally made a very successful emulsion, employing the common country soap, which seems to be particularly well adapted to retaining the oil in an intimate mixture, and which, in this combination, loses its own objectionable properties. The most important part of the process is the *churning*. This must be most thoroughly carried out. It can be satisfactorily managed by repeatedly drawing up and expelling the mixture through an ordinary garden syringe or a force-pump. A more lengthy method is to stir the mixture vigorously with a whisk of twigs. The liquid should be boiling hot during emulsification, and then, if kept in a cool place, it is said to last for a year or more without separating. If insufficiently churned, the mixture will afterwards become separated, and the oil collect at the top. A properly compounded emulsion will mix with water in any proportions.

For use against scale insects a strength of one part emulsion to ten of water is found to be effective. As in all preparations of which petroleum is an ingredient, it can be more safely used on cloudy days. When used in hot sunshine, it is liable to burn the foliage and injure the tendershoots of the plant, but the danger of injuring is much less with a properly prepared emulsion than with mechanical mixtures of kerosene and water. Mr. Marlatt, in some 'Notes on Insecticides,'* gives the following particulars of experiments which show that kerosene emulsion can be used of considerable strength without causing appreciable injury to the plants. But it cannot be recommended for general use at a greater strength than mentioned above. Mr. Marlatt writes: 'About the 1st May, when the foliage was in the vigour of its early growth, a number of plants—peach, Japan quince, elm, pine, and strawberry—were treated with the following strengths of kerosene and whale-oil soap emulsions, made after the standard formula: Diluted (1) with 2 parts of water, (2) 4 parts of water; (3) 9 parts of water, and (4) 14 parts of water, or the emulsion at $\frac{1}{3}$, 1-5, 1-10, and 1-15 strength. The application was very thorough, and the limbs and twigs were thoroughly wetted by immersion in the insecticide. The treatment was made on a very bright, warm day, in the early afternoon. No rain occurred for four days, after which there were heavy rains. No injury whatever developed in the case of the pine, strawberry, and elm with any of the strengths used. With peach the injury was trifling, a very small percentage, perhaps one or two per cent, of the leaves turned yellow and fell to the ground, but I am inclined to believe that this was merely the normal spring shedding of the leaves, which is seen in nearly all plants. In the case of the Japan quince, however, with the two stronger mixtures, namely, those with one-third and one-fifth kerosene emulsion, a few yellow spots appear on the leaves, and later,

upon handling the limbs treated with the strongest mixture, about one-fourth of the leaves were found to fall off readily. These leaves, while looking comparatively healthy and green, had evidently been injured more than their surface appearance indicated. With No. 2 this peculiarity was almost unnoticeable, and with Nos. 3 and 4 no injury whatever was shown, nor did any further injury manifest itself throughout the season in the case of any of the plants treated. These experiments would indicate that the kerosene emulsion can be applied in much stronger dilution to tender foliage of growing plants than has hitherto been supposed.'

On the other hand, there are well-authenticated reports of plants seriously injured, or even killed, by the use of too strong a mixture, and the application during sunny weather is attended with danger. In my own experience I have found the tender shoots on a recently pruned tea bush to be completely killed back by a comparatively weak mixture applied during sunny weather.

When the foliage of a plant is attacked, the applications should be made by means of a spraying machine. In the case of pruned trees, when the pest affects the bark only, the liquid can be applied with a brush or a piece of rag to the stems and branches. Care must be taken that the liquid is not used in sufficient quantities to run down and saturate the roots of the plant, or grave injury may result. When employed with proper precautions, there is no doubt that we have in kerosene emulsion a very valuable remedy against scale and other insect pests.

Milk may be substituted for the soap in the manufacture of kerosene emulsion. The formula given by Hubbard is:—One part milk (sour milk is said to be as suitable as fresh for the purpose), to two parts kerosene. Heat the milk nearly to boiling and mix with the kerosene. Churn the mixture violently until a thick creamy fluid is obtained. For use against scale insects dilute with nine or ten times the quantity of water.' I have been unable to find any definite statements as to the comparative effectiveness of the milk and soap emulsions. It is possibly a question of cost. In some countries a gallon of milk may be cheaper than half a pound of soap; but in most places it is probable that the balance of advantage will be on the other side. The active insecticidal properties of soap itself must surely be an additional advantage.

Kerosene.—Much diversity of opinion exists as to the use of pure kerosene or a mechanical mixture of kerosene and water. It is undoubtedly effective as an insecticide.

But in to many cases it is equally fatal to plant life. Reports are very conflicting. In some cases spraying with the undiluted oil has been unattended by any injury to the tree, while particularly successful in killing the scale. In other cases even large trees have succumbed under the treatment. One cause of injury is said to be the collection of oil at the base of the tree, the roots being apparently much more sensitive to injury than the exposed parts. As a precaution, earth should be banked up round the base of the tree, and only sufficient oil should be used to moisten the surface of the foliage and bark without any surplus to run down the stem.

Mixtures of kerosene and water have been largely employed in America, and elaborate machines devised for ensuring the proper mixture of the two ingredients. But under any circumstances their effectiveness does not compare favourably with a properly compounded emulsion.

Referring again to one of Mr. Marlatt's reports,* I find it stated that 'kerosene mixed with water is not nearly so powerful an insecticide as the kerosene soap emulsion. It does not remain nearly so long on the plant, and is not nearly so effective an insecticide at the same strength of oil. The heavier soap or milk emulsions kill more effectively, which is, perhaps, explained by the heavier liquid actually

* *Insect Life*, vol. vii, p. 116.

* *Bulletin*, No. 9 (New Series), U.S. Department of Agriculture (Division of Entomology).

bringing more oil in contact with the insect, and also by its greater permanency.' Taking everything into consideration, neither keosene, nor mixtures of the oil and water, can be recommended for general use—at any rate in the Tropics.

Resin washes.—These are used extensively in California to remove scale insects from fruit trees. The formula (taken from *Bulletin*, No. 9 of the U.S. Department of Agriculture) is as follows:—'The summer wash usually contains twenty pounds of resin, five pounds of crude caustic soda (seventy-eight per cent.), or three and a half pounds of the ninety-eight per cent., and two and a half pints of fish oil. The winter wash contains thirty pounds of resin, nine pounds of crude soda, and four and a half pints of oil. The ingredients are boiled in about twenty gallons of water for two or three hours, hot water being occasionally added until fifty gallons of solution are made. This, for both formulae, is diluted to one hundred gallons before application to trees. Greater efficiency is believed to come from long boiling of the mixture, and it is preferably applied hot. It is used on deciduous trees for the black and San José scales, and on citrus trees for the red and black scales; but the dense foliage of the latter renders thorough spraying difficult except for young trees, and fumigation is much preferred. An improperly made resin wash is also apt to spot the fruit of the orange.' I have no personal experience of either this or the following insecticide.

Lime Salt and Sulphur Wash.—This has been employed against the San José scale in America. Though undoubtedly effective in some parts of the country, it appears to have completely failed in others. Mr. Marlatt writes:—'Our experience with this wash in the East (Eastern States) had thrown doubt on its real efficiency as an insecticide, and it has been clearly demonstrated that under the climate conditions east of the Alleghanies it is almost valueless. In California, however, after a careful study of the facts in the field, I am compelled to admit that the demonstration of its usefulness against the San José scale is complete, and the benefit of its application to orchards is most manifest. In the vicinity of Pomona, California, unsprayed orchards were badly infested with San José scale, while in adjoining sprayed orchards the scale was entirely killed, and the trees were rapidly recovering and showing vigorous and healthy new growth. In contiguous orchards also of the same kinds of trees, similarly treated so far as cultivation is concerned, the trees which had been subjected to yearly spraying were at least one-third larger than untreated trees. This wash is of value also as a fungicide, protecting stone fruits from leaf fungi, and is also a protection against birds, the Common California linnnet doing great damage to buds in January and February. The wash is almost invariably made and applied by contractors, and costs about five cents per gallon applied to the trees. It is a winter application, being applied in January and February.

'Along the coast region and in Northern California, where moisture conditions prevail, this wash is very much less successful, bearing out somewhat the experienced of the East, and doubtless explained by the similarity of climate in the districts mentioned with that of the Atlantic seaboard.

'In making this wash the chief consideration seems to be prolonged boiling. The wash itself is practically a sulphide of lime, with much free lime and salt carried with it. Prolonged boiling will result in taking up temporarily additional sulphur, and will perhaps add to its caustic properties if it is applied very hot; on cooling, however, it reverts to the simpler tri- or bi-sulphide of lime. The proportions of the ingredients and the method of combining them vary slightly in different sections. The following is the ordinary formula: Unslaked lime, 40 pounds; sulphur, 20 pounds; salt, 15 pounds. One-fourth of the lime is first slaked and boiled with sulphur in 20 gallons of water for two or three hours; the remainder of the lime is slaked, and together with the salt, is added to the hot mixture,

and the whole boiled for half an hour or an hour longer. Water is then added to make 60 gallons of wash. This wash is applied practically every year, or as often as the San José scale manifests itself in any numbers.'

Carbolic Acid.—Crude carbolic, phenol, Jeyes' fluid, and similar compounds, all have insecticidal properties. Carbolic acid itself has been found inefficient except when applied in such strength as to seriously damage the plants. I find that phenol and Jeyes' fluid (which appears to be much the same thing) are effective against *Orthezia*, 'mealy bugs,' and most species of *Lecanium*. A mixture containing 1 part of Jeyes' fluid to 20 of water, applied to a *Thunbergia* bush attacked by *Orthezia*, was fatal to more than 90 per cent. of the insects, but resulted in the death of the terminal buds of the plant. It had no bad effect upon the more mature leaves and shoots. The application did not, however, prevent the subsequent hatching of the eggs in the ovisacs of the dead insects. Weaker solutions were proportionately less effective.

In a 'Report on the Green Scale Bug, *Lecanium viride*,' published in 1886, I have mentioned that phenol applied to the ground around the roots of the coffee tree appeared to cause the disappearance of the scale. But subsequent experiments have not corroborated this result, and I must suppose that the apparent benefit in the earlier experiment was due to some other cause. Single experiments are practically useless. They are liable to be vitiated by adventitious circumstances. Until similar results have been obtained from repeated experiments, no confidence can be placed in any treatment.

Tobacco Water.—Steep 5 lb. of refuse tobacco (stems, &c.) in 3 gallons of water for three hours. Strain the decoction and add sufficient water to make 7 gallons.' The mixture will kill soft-bodied species that are unprotected by a covering scale, such as *Lecanium viride*, *Pulvinaria pasidii*, and *Dactylopius citri*. It has little or no effect against the *Liaspidine*.

Lime Water.—In the early days of the 'green coffee bug' I used a very thin wash of quick-lime and water. The mixture is inconvenient or difficult to apply as a spray, as it quickly clogs the nozzles and valves of the machine. I applied it with large brushes to the affected coffee foliage, and it was certainly fatal to every insect with which it came in contact. The bugs turned from green to a bright orange colour within five minutes of the application. But many individuals necessarily escaped, and the benefit was only temporary. No damage to the trees was observed, but the lime had such a caustic effect upon the hands and arms of the coolies employed in the work that it had to be discontinued.

Strawson's Mixtures.—I have recently had the opportunity of experimenting with a mixture supplied by the Strawson Company for use against the Teamite, and have found it very effective against scale insects of all kinds. It is one of the few insecticides that I have found of real value against *Orthezia*. Applied as a spray in the strength of 1½ lb. to 4 gallons of water, it not only kills this insect, but prevents the hatching of the eggs also. This is apparently effected by the blocking of the aperture of the ovisac, and so preventing the emergence of the young insects. The mixture (as supplied) is of a soapy nature, and it is the soap that is probably the active agent in the destruction of the scale insects. The ingredients are naturally kept secret by the manufacturers, for which reason I am unable to recommend its use as a spray for tea during the plucking season, but for the removal of scale insects upon other trees it will be found of value, and I have frequently used it advantageously to clean the stems of *Pruned* tea. It is particularly effective also against the ants (*Oremastogaster Dohrni*) that give such trouble by building their nests in the tea bushes. These nests always enclose a colony of scale insects (usually *Lecanium formicarii*), and to prevent the recurrence of the ants it is most necessary to get rid of the bugs that attract them. For application to

the stems of trees a large paint brush can be used in place of the spraying machine.

McDougal's Insecticide Wash.—This is another very useful patent insecticide, also of a soapy nature. As the ingredients are kept secret, the same objection applies to its extensive employment upon tea plants. It is equally effective against scale insects. The two mixtures (Strawson's and McDougall's) were tested upon *Orthesia* with similar beneficial results. It is used as a spray.

The above two insecticides may be safely employed 'against green bug' or mealy bug' on coffee, and would be found very beneficial in checking these pests where they are confined to a small area. The treatment would be too expensive over a large acreage, and would be useless unless applied very thoroughly.

Adhatoda.—A decoction made by steeping the leaves of *Adhatoda vasica* (an Indian plant) in water is said to have proved beneficial against various insect pests in India, but I can find no record of its effect upon scale insects. Dr. Watt (Reporter on Economic Products to the Indian Government), who first brought into notice the properties of the plant as an insecticide, states that it has a distinctly paralysing effect upon many insects. But he appears to have found it unsatisfactory and uncertain in general use. The plant grows in Ceylon. In Trimen's *Handbook of the Flora of Ceylon* it is said to occur in the 'low country, common in hedges and waste places, especially in dry regions, but usually planted, and scarcely a native.' I obtained a few leaves and made a strong decoction from them. The amount of material was insufficient for extensive experiment, but leaves affected by various insect pests were dipped into the mixture. I was surprised to find it absolutely ineffectual. Even such soft-bodied insects as aphides, when thoroughly wetted with the mixture, were as lively as ever the next morning. Possibly the Ceylon-grown plant does not acquire the insecticidal properties noticeable in the Indian plant.

It may here be as well to mention a few other supposed remedies for the cure of scale bug, that are really quite valueless for the purpose. The beneficial results that have been attributed to them are probably due to some fortuitous circumstance, such as the treatment having been applied at a time when the pest was declining from natural causes. Such errors of observation have led to much waste of time and money.

The application of 'Mana grass' (*Andropogon nardus*), was at one time considered a cure for the coffee bug (*Lec. coffee*). Nietner, in his *Enemies of the Coffee tree*, mentions that it was customary to bind the grass round the stems of the trees. I have repeatedly tried this plan, at various times of the year: I have tied the grass round the stems as directed, have spread it on the ground, and strewn it over the foliage. But in no case have I been able to observe the very slightest benefit from its use.

Soot is another article that has been greatly overrated as an insecticide; and wood ashes may fall under the same category. These substances are, doubtless, useful in dealing with slugs and snails, their astringent and absorptive properties acting upon the mucous surface of such animals; but when applied to dry insects, such as caterpillars and scale bugs, they fail to adhere, or, when adhering to act in any way prejudicial to the insect.

Lime, when applied dry, has little or no effect, unless there happen to be moisture upon the insects. Even then its action will be very partial and unsatisfactory.

Powdered sulphur is also quite useless against scale insects.

Many other substances have been made the subjects of experiment; but, as they are either far too costly or otherwise impracticable it is useless to enumerate them.

In the foregoing notes I have endeavoured to gather together the most reliable information on the subject of insecticides applicable to the treatment of Coccid pests. I present it to my subscribers, hoping that from amongst the various processes some treatment may be found to suit any case that may come under their notice.

INDIGO—A THREATENED INDUSTRY.

TO THE EDITOR OF THE "TIMES."

Sir,—My attention has been drawn to your special article on the above subject in your issue of the 4th inst., and to a letter in your issue of the 7th inst. from Messrs. Mewburn and Ellis, who give some details and comparative statements which require correction.

The indigo industry in India has up to the last few years occupied an almost anomalous position in this century of scientific progress an invention. Cultivation and manufacture have remained practically the same as they were at the end of the last century.

The industry has, on the whole, been a paying one until this recent competition of an artificial product, and planters as well as agents were content to let things remain as they were. There have been chemists of an inventing bend of mind who have of late years occupied themselves with indigo manufacture and endeavoured to improve the same and increase the yield of dye from the raw material. But the encouragement they received has been too limited and was confined to a few individual planters. The industry generally, as well as the financing agency houses and the buying trade discouraged all improved methods of manufacturing processes necessitating the use of chemicals, and indigo known to have been made by any such improved methods was prejudiced at the indigo sales, if not altogether boycotted, so that enterprising planters lost courage and dropped all improvements in manufacture, even those of established merits.

The buying trade had also, up to lately, rested upon a most primitive basis of buying, dating also from the last century; valuations were and are still being made on comparison with standard samples of certain supposed values, and the buying trade was therefore suspicious of any alterations in the methods of manufacture which might produce an equally good looking article but of perhaps less dyeing value.

All this is now rapidly changing. The indigo industry is ripening, and is now more prepared than it was a few years ago to benefit from the scientific progress of our century.

The buying trade is more and more abandoning the buying on comparison with standard samples, and buys now to a great extent on analysis, paying a certain amount per unit of indigotine, which varies slightly according to the mechanical conditions of the paste.

Indigo planters have rallied together in face of this threatening competition, are now employing distinguished chemists, and are taking practical steps to improve their methods of cultivation and manufacture.

The financial agency houses are realizing the seriousness of the situation, and are taking the lead to help their constituents in the only way in which they can be helped—viz., to establish experimental factories where improvements in manufacture and cultivation can be worked out and tested.

It is not generally known that only about one-third of the dye in the plant is obtained by the ordinary methods of manufacture, and that, moreover, waste to the extent of 20 per cent. of the ultimate output occurs therein.

There is, therefore, an ample margin for improvement in the manufacture alone, besides the progress which can be made by improved methods of cultivation and drainage and the use of new and selected seed.

The chemistry of indigo manufacture is till somewhat obscure; the dye in the plant is not present in a merely extractable state, like theine in tea leaves, but has to be developed from certain basic products, which is most profitably done by a prolonged fermentation of the plant, the agency being then microscopic life. This has made improvements in manufacture difficult, for chemists are rare who are conversant with and thoroughly understand the conditions of low microscopic animal and vegetable life, and who in addition possess the necessary perseverance, the necessary inventive power and gift, to devise experiments, to carry them out, and to interpret correctly the results. But such chemists will doubtless be found, and the benefits which the industry will derive from their work will be more

important and wide-reaching than even the most sanguine of planters hope for at present. One of the leading agency houses is already fitting out one of their factories in Behar to test next season a new process for which an outturn or more than double the quantity of dye is claimed, and, in my opinion, improvements will not even stop at this.

Messrs. Mewborn and Ellis are therefore wrong in thinking that the cost of making indigo in India will not decrease in the same proportion as they expect the cost of the artificial indigo to decrease. The cost will, on the contrary, decrease to an extent which will enable the natural indigo industry to meet the competition successfully, and come out of it victoriously.—Yours obedient servant,

EUGENE C. SCHROTKY.

Wiesbaden Villa, Sonneck. October.

PLANTING IN THE GOLD COAST.

The annual report for 1898 from the Gold Coast Colony puts in some very strong pleas for railways. With improved transport we are assured the output of rubber could be trebled, money would be saved, and better employment could be found for human beings than using them as beasts of burden—for at present the rubber has to be carried to the coast on men's shoulders. The export of timber is further handicapped by the lack of transport facilities, and that with such facilities more trade might be done is evidenced by the increase in the timber business in those districts which have water communication. Moreover, the mines in the Colony can never be properly developed so long as all the materials and machinery have to be transported on the heads of natives. Happily, one Government railway is already under construction, and surveys for six others have been made. Five of these lines will tap the mining districts.

In the nine months there were 621,116 tons of foreign refined beet sugar imported into the United Kingdom, and 311,237 tons of raw or unrefined beet, making together a total quantity of 932,353. The total quantity of sugar from all parts was 1,084,711 tons. Another proof is thus afforded of the almost entire possession by beet root sugar of the English market. The British public is providing work and wages for vast populations in Germany and France. Java and the Philippines show a great falling-off, and practically nothing comes from Cuba and Porto Rico. Peru and Brazil also show a large decrease, proving that all cane countries are suffering, so far as the English market is concerned, from the bounty competition. On the other hand, Mauritius and the East Indies have sent more than they did last year, but their actual totals are very small. The British West Indies have sent less, viz., 35,000 tons or rather more than ten per cent. of their total crop, probably in the form of Demerara and Trinidad crystals. During three months we only received 4,000 tons of West India sugar. The raw cocoa imported amounted to 38 million pounds, the home consumption for the nine months being 26 millions. The imports of prepared cocoa were 3,700,000 lb, or not much more than half of last year's imports for the same months. The home consumption, too, has fallen off, being under four millions of pounds against more than four and a half millions in 1898. This looks as if the home manufacturers were using more of the raw cocoa, and we were becoming less dependent upon the Continent for our prepared cocoa supplies. The quantity of raw cocoa in bond is 19 millions of pounds, much about the same as last year, but the prepared cocoa in bond is only 468,000 lb, against 1,451,000 last year. This may partly account for the recent strong market, and be a reason for the continuance of favourable prices. The shipping of war stores to South Africa should also be regarded as supporting the cocoa market. It should, however, be noted that a large quantity of raw cocoa is re-exported, viz.: nearly nine million pounds. The prepared cocoa exported is small, only reaching 572,000 lb, which was, however, considerably,

in excess of the two preceding years. The amount of new cocoa consumed per head of the population was 0.80 in 1898, showing a gradual increase since 1884, when it was 0.39. Prepared cocoa, too has increased in consumption from 0.03 in 1884 to 0.16 in 1898. The 0.20 of 1897 was evidently a record year, and due to special causes. On the whole, with an increased consumption, however slow and steady the prospects of cocoa are fairly good, and there may come a boom some day when the true virtues of this food will be more popularly recognised.—*Planter.*

A FAMOUS LADY ORCHID GROWER.

Mrs. George B. Wilson, of Philadelphia, according to the "Boston Traveller," (Sept), owns the largest collection of orchids in America, but she has unfortunately lost quite recently several fine specimens. The writer says that for the past ten years this gorgeous orchid flower has been Mr. Wilson's hobby. Always and admirer of orchids, about 1894 she decided to go into orchids thoroughly, and began a study of this millionaire's emblem, sending all over the world for specimens of its myriad varieties. Europe, Asia, North and South America, and the isles of the sea were explored, each for its particular production. At important orchid centres agencies for Mrs. Wilson were established which from time to time have furnished her with rare and valuable plants together with information regarding their cultivation. In this way more than 10,000 orchids have been brought together at the Wilson mansion in Philadelphia. In its line this assemblage is one of the most famous and most extensive in existence. A few years ago the collection as it, then stood, was greatly improved by the addition of that belonging to the Erastus Corning estate of Albany, which it had taken 40 years together. All of the great florist firms have professional orchid collectors. They brave the fastnesses of the forest of the Amazon and Orinoco rivers and are exposed to the deadly fevers and miasmas of swamps where the anacondas and boa-constrictors are the least of the evils to be encountered.

Mrs. Wilson's collection is assembled in seven great glasshouses that were erected in the rear of the Wilson mansion at the cost of thousands of dollars. Upon entering the main conservatory, in the centre of which is a grove of the palms, the East India house is found to the left. Passing from this house the next is that of cypripediums, containing over 300 specimens. Beyond is the Mexican house, which is literally a mass of bloom. Many of the plants carry from two to six spikes of brilliantly coloured blossoms. Conspicuous among them is the rare *Laelia dawsoni*, bearing several flowers of a most exquisite type. Another prominent one is the *Laelia anceps alba*, measuring over four feet square. The Cattleya house has a fine showing of blossoms, and provides a distinctive charm in its superb specimens. Taken in its entirety, the collection fills seven houses, and it is conceded to be one of the most valuable in America. Many of the smaller plants cost from 300 to 500 dollars each, and others of the unique varieties would fetch thousands even at forced sale. Perhaps the most interesting feature of Mrs. Wilson's collection is the assemblage of varieties that come from the Philippine Islands. The Spaniards made the collectors pay a licence for hunting orchids there, but despite that method of coaxing ducats from American pocket many unique plants came from the group. Under the new regime, when Aguinaldo and his followers shall have ceased to struggle, the influx of plants from Uncle Sam's new domain will without doubt be greatly increased. Mrs. Wilson is now in Mexico, directly overseeing the work of her agents there who are searching for Mexican orchid wonders. Her superintendence is not a sinecure, nor is it the work of an amateur. The owner of this giant orchid collection is fully conversant with the habits of pet plant and of the laws which govern them. She has made a scholarly study of the flower, and believes in putting the knowledge she has acquired into practical application. When at home, everything is under her own personal supervision.

RHEA: HISTORICALLY AND PRACTICALLY CONSIDERED.

I think it highly probable that there is no plant in the vegetable kingdom to-day around which centres such a wealth of failure, historical and abiding interest as that commonly termed rhea. Probably many are not aware of its hoary-headed antiquity as disclosed by Chinese classics.

It should, however, be understood at the outset, there is probably no more difference between so-called China grass and rhea than there is between the China form of the tea-plant and that of Assam.

The so-called China grass is of itself a singularly unfortunate and misleading term, as the *Chu Ma* of the Chinese, or *Boehmeria nivea* of the botanist, has no more to do with a grass plant than has the apple with the pear for example. Those acquainted with original tea literature will remember how even so distinguished a botanist as Sir William Hooker pronounced in favour of a *rhea viridis*, that it to say a plant exclusively used for green tea as distinct from black.

And to-day we have a past president of the Society of Engineers setting out the misleading distinction of terming *Boehmeria nivea* a species of nettle indigenous to China and India, and *Boehmeria tenacissima* as a valuable textile plant. As though both were not textile plants, both *Boehmeria's* both very closely allied so much so in fact as to probably constitute no other difference than the temperate and tropical form of one and the same thing.

The distinction, however, between the tropical and temperate form, otherwise China grass so-called, and ramie or rhea, is a material one practically, and demands the careful consideration of the planter. Dr. Watt has endeavoured to show that the hot plains of India are no place for the temperate China type. And this may be, and probably is quite true, although it by no means always follows. For instance, a mountain home was supposed to be necessary for tea originally obtained from the China mountain districts, but subsequent history has abundantly proved the tea-plant will thrive in all elevations from 7,000 feet down to sea level. *Phoenix dactylifera* otherwise the date palm is another case in point of a plant that will thrive abundantly in tropical and subtropical regions, even up to some frost and snow. Very few plants, however, will do this, for instance, the Assam so-called hybrid tea-plant is a sorry thing at high elevations, and there is not wanting evidence that *Boehmeria nivea* demands its own climate. From a perusal of the literature of the subject and the undoubted fact that in years gone by direct imports have been made from China and elsewhere, there can be little doubt the China and tropical forms of rhea have got confused until many mix up the two indiscriminately, and this will be a source of disappointment and failure to experimenters if not understood, and a clear distinction drawn between the tropical and temperate form or type.

It is a fair inference in nine cases out of ten that a plant that has grown for untold centuries in temperate China with its comparative dry climate will be certain to fail in many places in India and conversely the tropical form under opposite conditions; the practical man and planter should therefore ascertain for certain which form he is dealing with—the China type or the tropical type termed *Boehmeria tenacissima*. In 1843 a reference was made to Dr. MacGowan, then resident at Ningpo, as to the identity of the Rungpore plant with the China kind, whereupon Dr. MacGowan provisionally named the China plant *Canabis sinensis*. This however was entirely wrong, and shows how easily a learned man like Dr. MacGowan may go astray in putting down *Boehmeria nivea* as a *Canabis*. We are less concerned, however with the doctor's mistake than his exceedingly interesting and comprehensive note on the plant in general.

In this note the doctor goes on to say the "*Chu Ma* is found from Cochin China to the yellow River, and from Chusan to the farthest west that researches

can at present go, it is cultivated in many places, visited by the author, and grows even on the walls of Ningpo; it is mentioned in the Chinese classics and was undoubtedly cultivated a thousand years before our era; it is mentioned in the Shu King as an article of tribute from the central part of China in the time of Yu, B. C. 2205."

Here then we come face to face with a plant with a mighty record in time, but as if 2205 B. C. were nothing, Dr. MacGowan goes on to say:—"Doubtless it came into use in far more remote times,"—the *Chinese Herbal* says its origin is unknown.

Hence it will be seen in rhea we have a plant with one of the oldest records extant.

Leaving classical China on the subject, we come to India and Roxburgh—that Father of Indian Botany as Dr. Watt very fittingly terms the learned and withal very practical Roxburgh. In 1809 we find Roxburgh writing to the Secretary to the Board of Trade:—"From the receipt of the first sample sent to me by Mr. Ewer of Beucoolen, I saw its quality was uncommonly interesting, and promised to be superior to every other vegetable fibre I had seen. I was therefore, more than usually solicitous to obtain the plant, and in 1803 four plants were received into this garden; since which period a thousand plants have been raised."

Then the doctor adds this significant remark:—"But to this day I have not discovered a ready way to clean the fibres." Here in a nutshell, after 96 years, is still the central difficulty—an expeditious, cheap, effective and satisfactory cleaning machine. We imagine the century cannot produce the equal of so long and deplorable a failure of mechanical genius than is illustrated in the failure of at least thirty years of intermittent effort to produce a satisfactory decorticating and cleaning machine for rhea.

Roxburgh strongly recommended cultivation to the fullest extent, but remarked that this would be limited for a long time, as no good seed has yet been produced in India.

In 1833 Major Jenkins sent samples of the fibre from Cachar to Calcutta and subsequently from Assam.

Colonel Burney sent samples from the Shan Provinces of Pevela and Youkzouk, while Resident at Ava. Major Macfarquhar sent samples from Tavoy on the Teuasserim Coast. In 1836 Colonel Burney remarked it was cultivated by the Shans, the Siamese, and Chinese all of whom were loud in its praise for its fine texture and durability both as cloth and cordage. Mr. Landers, travelling amongst the Shans, also observed the same thing.

In 1847 we find Dr. Campbell, superintendent of Darjeeling, lighting on the plant at Rungpore in Bengal. "Here" says Dr. Campbell "it was cultivated with much care along the banks of the Teeshta River under the name of *kanbhura*." He goes on to say, "I never saw the plant before and as winter crops are rare in that part of the country, it was an object of additional interest."

Subsequently samples were sent to Calcutta, and a Mr. Henley visited Rungpore and endeavoured to purchase a quantity, but could only get a small bale, for sending home for sample, and Dr. Campbell says "The natives would not sell, and cultivated it for the manufacture of towing lines and fishing nets: on account of its proved superiority for fishing nets and for enduring water without injury longer than any known substance.

Mr. Henley expressed the opinion that machinery could be produced for the separation and cleaning of the fibre with great facility and economy; until then it was hopeless to expect the fibre to be produced at a low price. It is a curious commentary, after practically half a century, that the same opinion holds good to-day. Here briefly stated is the first half-century of rhea under European observation.

There was a unanimous verdict of its great strength durability, and fine texture and suitability to withstand water longer without injury than any other known substance during this period. Samples were

sent to England, and its merits instantly recognised by British manufacturers.

And so the subject went on gathering interest and enquiry until the Government of India—recognising the great obstacle to expeditious cleaning in their notification of January 1870—offered a prize of 5,000 for the production of a machine that should clean the fibre at a cost of £15 per ton, including all process of cleaning, wear and tear of machinery, and provided the cleaned prepared fibre fetched £50 per ton in the London market. Notwithstanding this liberal prize, which was again renewed in 1877 in the shape of £50,000, both trials were a failure, and no machine came up to Government conditions.

Since then two or three score of patent have been taken, and more than a dozen distinct processes invented, all claiming to have solved difficulty. Among the most recent, is the Ferguson process—the Macdonald-Boile—the Eyssen—and, lastly, Mr. Dear has turned up with yet another machine of Automatic pretensions. According to the *Financial News*. Mr. Ferguson has spent £30,000 on his process, and now merely wants £500,000 to place it on a commercial footing: it is possible Mr. Ferguson will be found wanting that some of money for some time to come yet.

Some time ago Mr. J. R. Boyle wrote from the Imperial Institute saying one firm would purchase to one thousand tons at £12 per ton in London with the fibre in its own integument. Mr. Boyle may rest assured that "one firm" is by no means alone in desiring 1,000 tons of rhea fibre at £12 a ton in London; seeing the eminently handsome difference between £12 and the price of the finished article and taking full note of the fact that at least half the cleaning has to be done in India.

Notwithstanding the many failures, it may be confidently predicted the time is not far distant when all difficulties of manufacture will be a thing of the past. The subject is now become one of very keen interest to a greatly increasing number in widely divided places, and without a doubt it is understood a splendid fortune awaits the first inventor of a really effective and reasonably priced process for dealing with rhea. A fibre acknowledged on all hands to be one of the finest if not in the language of Roxburgh, the finest of vegetable fibres, must come to the front, and assert, its merits and if this should be so—and there is not the shadow of a doubt about it—India should not be behind in the matter. When all difficulties of manufacture have passed away, it will be solely a question of quantity, production, in short a planter's question.

PRACTICAL CULTURE OF RHEA.

At the every outset I must revert to the types and emphasise the paramount importance of clearly understanding which is which. manifold errors and failures will be avoided in India by understanding clearly there are two types, which for cultural purposes are widely distinct in their climatic demands.

I note rhea seed figures in the admirable catalogue of the Himalayan seed stores: it is Italian-grown, and the "true rhea" so stated. But I must take leave to point out this Italian-grown seed is undoubtedly the produce of *Boehmerianivea*, which is the true temperate China plant, from which so-called China grass is made, and for cultural purposes wholly distinct from Roxburgh's type, named *Boehmeria tenacissima* and which is the Samatra plant, and no doubt identical with the tropical form subsequently found at Rungpore in Bengal and Assam; and doubtless the rhea being extensively grown in the Island of Ceylon, is the tropical type, and therefore not *Boehmeria nivea*, but Roxburgh's *Boehmeria tenacissima*, which is the vigorous, rapid growing, very long fibre type, in short the tropical type as distinguished from the temperate or at all events sub-tropical type.

When this point is understood an enormous amount of confusion and prospective failure will disappear. To plant this the true China type in such places as Assam for instance, is the best way to fail; in point of fact it

is on record that a number of Assam planters have tried rhea culture and failed; at all events abandoned the culture. I have not seen it stated which type was used or exactly why the culture was abandoned, but if *Boehmeria nivea* was used, then we need seek no further for the why of the failure.

This is a case in which there is not much in a name but a very great deal in clearly distinguishing between the tropical and temperate type of practically the same thing, whether it be *Boehmeria nivea* or *Boehmeria tenacissima*; they are both first class, identical, fibre-yielding plants, but amenable to totally differing climatic conditions.

There is very little doubt that *Boehmeria nivea* would flourish well in sub-montane tracts along the foot of the Himalayas and up to 3,000 feet elevation in these places there is no possibility of swamping, drainage is good, and it would be an expensive matter to lay on irrigation if desirable from some of the many water ravines descending from higher elevations. There is this additional advantage, *Boehmeria nivea* is an abundant seeder, and could be so produced in any quantity for those trying *Boehmeria nivea*. Dr. MacGowan, on the Chinese method, dating from time immemorial, may be briefly stated with advantage. Dr. MacGowan says: "The seed is sown in May." [This would be a bad month in India; I would suggest the beginning of the monsoon or March as better for this country.] "Loose dry soil is to be selected, the ground to be well ploughed, manured, and broken up finely. Then divided into beds, eight yards by one yard wide; then raked levelled and watered down and left for the night. On the morrow the beds are to be loosened up, raked and firmed down again; then two or three tea-spoonfuls of seed is mixed in a bowl of earth and sown broadcast over the beds and raked in subsequently a frame work is made, and as soon as the seed commences to germinate, and come through the soil, the young plants are protected from the hot sun—of June and July—by mats. The matting must be kept moist by day and taken off at night for the young plants to receive the dew of heaven." [A consideration of the Indian climate in the submontane districts during May, and up to the burst of the monsoon suggests a different time for sowing to that of China namely, just before the burst of the monsoon when the soil is hot and the ensuing rains create a rapid germinating medium otherwise February should be selected.] "The beds must be constantly weeded. When plants are three inches high they should be taken up and transplanted four inches apart. In the following May they are to be taken up and planted half a yard apart." [This will never do for India, the transplanting in May; it would be better to do this in March, and possibly February would be still better.] Then follows instructions to water every few days for the first decade and at ten days intervals; subsequently in the second year, the plants will be mature for cutting. Regarding manures the doctor says:—"Never use swine's dung as it is 'saltish' and hurtful to the *Ma*."

Further:—"In many cases fresh earth, pulverised bricks, ashes, etc., are used as manures." He also mentions a heavy mulch to protect the young plants from the cold of winter—this however would be of less moment in India than China.

Ten years is given as the age of unprofitableness, but even at that age it is remarked the plants may be taken up and planted forty inches apart in well prepared and heavily manured land.

Elsewhere Dr. Macgowan remarks the plant "is found at the base of hills and dry places."

The first cutting takes place in June and the last end of September or October. The stems grow seven or eight feet high and give three crops a year. "It not unfrequently happens that the crop is in some places remarkably small, and some other times the produce is very great without assignable cause." This remark should be duly noted; we can scarcely suppose in the case of China it would be climate, but more probably some peculiarity of soil; however this may be, it is to be noted the rhea plant is amen-

able in an eminent degree to suitability of soil and climatic conditions.

From the last cutting the finest cloth is made; after each cutting, it is mentioned, the plants are watered and manured: obviously this is a detail of considerable importance in the production of subsequent crop, probably the watering would not in consequence of the monsoon season be needful in India, but the manuring could not fail to be of considerable service.

From this it will be seen the Chinese pay great attention to cultivation, preparing the ground well manuring it, and manuring at every cutting or three times a year; great pains are taken with the seedlings too; all this tends to show in an unmistakable manner that rhea for commercial purpose must have a thorough culture, and disposes of the stupid somewhat prevalent notion that rhea will grow anywhere and anyhow; the fact moreover that the plant is cut down three times a year inducing a three-fold demand on the soil in the one year will ever constitute the rhea plant a rapid soil exhauster, and the Chinese have recognised that fact very well by manuring at ever cutting. This is an important fact to remember. Commercial rhea will always mean a thorough and systematic culture, and this fact should be forced home with the manufacturers from the planters' standpoint and low prices stoutly resisted.

Mr. Henley, who made a special visit to Rungpore in 1847 in order to obtain a quantity of the fibre from the Rungpore fishermen states:—"It however requires a rich free soil and plenty of manure." No doubt the Rungpore plant was identical with Roxburgh's *Boehmeria tenacissima*, and it is so called by Mr. Henley, and in the matter of soil and manure it would reasonably appear to differ nothing from the sub-tropical China type. But in all other respects, as regards requisit climatic conditions, we must again accentuate the great difference between the two forms. I may venture to sum up what we believe will be found satisfactory conditions for *Boehmeria nivea*—the China type only:—

Planting localities.—All suitable spots as regards soil from the base of the Himalayas up to three thousand feet elevation; or any other parts in India giving from 1,000 to 3,000 feet elevation.

Soils.—There is an absolutely unanimous consensus of opinion that rhea requires a free, easily worked, friable soil, and this is quite comprehensible when we have in mind the fact that the rhea plant is a herbaceous perennial plant of rapid growth, and therefore requires a soil in which the roots can move about freely and rapidly. Within the areas noted there are numerous places giving a considerable depth of rich porous vegetable soil admirably suited for this class of plant.

Drainage.—This should be beyond all possible doubt good. Lands liable to be submerged or swamped, or even to lay wet for any length of time, should be studiously avoided. There is ample evidence in the shape of the wild forms taking no exception to great rainfalls where the drainage is perfect; rhea land should be such as to allow of heavy monsoon rains draining rapidly away. Here again the Himalayan slopes offers a drainage not by any means always available on the plains.

Given approximately these conditions, I am confident *Boehmeria nivea* would for the most part thrive abundantly.

In support of this view I may briefly note *Boehmeria frutescens*. Of this kind Dr. Campbell wrote in 1847—"It grows wild and abundantly in the valleys through the mountains of Eastern Nepal and Sikkim, at the foot of the hills skirting the Terai; to the elevation of 1,000 or 1,200 feet, and within the mountains up to 3,000 feet elevation." This is the *Pooah* of Darjeeling and Sikkim, and the *Poee* of Kumaon and Gurhwal, and *Boehmeria frutescens* of botanists indigenous to the sub-montane Himalayas from Gurhwal to Sikkim Hills. And also of Japan; but I may remark I have seen this plant in many places in Kumaon growing luxuriantly at between four and

something over five thousand feet elevation. Dr. Campbell states that it grows to seven or eight feet high with stems the size of a pencil to that of the thumb, but he could no where find it on the plains and the hill-men considered it a hill plant.

Samples of the fibre of this kind were sent to the Flax and Hemp Committee, and pronounced by Captain Thomson equal to the finest flax and the best thing he had seen in India for sail cloths. I regard this as the wild form of the sub-tropical type, and no doubt the bon-rhea that grew wild all over Assam is approximately the wild form of the tropical type.

Dr. MacGowan also says of the China plant:—"Foot of hills and dry places: the fatal error is and has been the distribution of this type over the scorching plains of India. Those who intend rhea on the plains should undoubtedly confine their attention solely to the acclimatised tropical form such as the Rungpore, Assam and Malay plant."

Provided the soil is rich and drainage perfect, this is the type of rampant rapid growth, great size and length, such for example that grows so well in certain parts of Ceylon with its mean annual temperature of 78 degrees.

CONCLUSION.

Here then is the *Chu Ma* of the Chinese, the rhea of the Assamese, the *ran* of the Shans, *kunkhura* of Rungpore, Bengal, ramic of the Straits Settlement, *calooe* of Sumatra. For all practical purposes this is one and the same thing under greatly differing climatic conditions. It has been shown that the China plant is of enormous antiquity, probably quite five thousand years: in all probability the Bengal and Assam type has been indigenous for many centuries, and likewise the Sumatra stock. As for the wild forms it would be rash to speculate on their age.

During these lengthened periods each stock has become acclimatised to its respective environments, so that to-day they are amenable to advantage to a sub-tropical and tropical climate only; and the great mistake is to make these terms convertible; and mix the climatically wholly different forms together, and assume either one or the other is interchangeable for any parts of India. A misapprehension of this essential point cannot fail to be a source of failure in rhea culture.

HIMALAYENSIS.

—*Pioneer* Nov. 8.

VANILLA.

BOTANICAL OBSERVATIONS.

Vanilla is the generic name of epiphytical orchids indigenous to tropical America and Asia. During their first stage of development they strike root and obtain nourishment from the ground, then they creep up trees to a height of 30 or 40 feet by sending out thread-like roots from knotty stems. The stem is from 2 to 3 centimeters thick; the leaves grow in to long rows and are long, green and fleshy. Clusters of blossoms grow out at the angle between stem and leaf they are large and fleshy, and of a whitish yellow colour and pleasant odour. Following the blossoms come cylindrical pods, 8 or 10 inches long, which split on one side and are filled with a number of small black seeds. The latter suggest sand, they are imbedded in similarly coloured pulp. The fruit is yellow when ripe. On drying, it turns black, and forms the well known spice. The number of members of this family is not yet established; indeed some difference of opinion exists whether these are species or only varieties. It has not yet been exactly determined which kinds of fruit are utilized either in the trade or at the place of production. In Mexico 4 useful kinds are known:—*Vanilla*, *V. sylvestris*, *V. planifolia* and *V. pompona*.

In Guiana:—*Vanilla guianensis*, with large yellow blossoms and long fruit. In the province of Bahia:—*Vanilla palmarum*. In Brazil and Peru:—*Vanilla pompona* and *aromatica*; the latter notwithstanding its name, having the least pleasant odour.

The search for useful varieties is still progressing. The director of the Botanical Gardens in British Guiana is just making the experiment of planting all the varieties indigenous to the whole of Guiana on his trellises (? misprint for Gelangestretch of land) in order to determine which can be recommended for planting and generally how to graduate their values.

If there are still many questions to be solved about the Vanilla family, we do at least know definitely that the earlier theory, that most of the Vanilla of Commerce comes from the *V. aromatica* is a mistake. *V. planifolia* should take its place.

This kind furnishes the most valuable fruit, and is therefore brought into cultivation wherever Europeans are concerned in the Vanilla culture. What part the other kinds play in the production of the article of commerce it is impossible to say, even approximately.*

The *V. pompona* seems to be rather important, for their short, thick pods, easily recognised, are always on the market (though in small parcels), indeed they have received the distinctive name, Vanillon.

Its value is considerably less than that of *V. planifolia* fruit, frequently only one quarter.

Apart from the useful varieties, the Vanilla family has only a purely botanical interest, for the blossoms do not possess the wonderful colour which distinguishes most orchids and ensures their high rank in horticulture.

GENERAL SURVEY OF THE PRODUCTION.

Vanilla was introduced into Europe in the 16th Century from Mexico, which was the chief place of production at that time, as it is at the present day.

The total crop of this state was given as 108,500 half kiols, in the last published Statistics for 1880. One cannot take this as literally true, for the official machinery does not allow of an exact estimate being taken. The output of Vanilla is still very considerable and is not exceeded by that of any other country. The chief seat of the industry is in the State Vera Cruz, the next in Oajaca. The village Zentilla in the latter State is said to produce the finest Mexican Vanilla.

The Vanilla culture is also more or less developed in the States of Tabasco, Yucatan, Chiapas, on the Isthmus of Tehuantepec and in a few places on the West Coast as well as in the hinter land of Acapulco and Mazatlan.

As a rule, 5 kinds of Mexican Vanilla are recognised:—

- (1) Vanilla *fin*a or *primira*, the pods are at least 24 c. m long.
- (2) *Chica prima* is shorter and thinner.
- (3) *Zucate*
- (4) *Rezacate* and finally
- (5) *Basura*, mark degrees in size.

The last named is not only the smallest, but is spotted, and often damaged. These varieties differ not only in size, but often in the contents of the pods.

In Guatemala, the Vanilla is not cultivated for purposes of commerce; the Indians, however, collect the wild fruit in the forests of the North West Coast, and bring them on the market at the Capital (and as far South as Panama, *J. H. II.*)

A few hundred pounds are exported from thence in some years, in others no pods are exported. In the rest of Central America nothing is known of the culture of Vanilla, or of collecting the wild fruit. (*This is incorrect as I have seen it otherwise in Veragua, J. H. II.*) It is little better in the West Indies, where deficient experiments in planting have been made, but soon abandoned. Here and there a few hundred shrubs are cultivated, the out-put is used for home

consumption. Guadeloupe alone exports small quantities to France, the annual amount varying extraordinarily. The exports amount in one year to 150 kilos, in the next to 1,500 kilos. In the year 1880 it amounted to 2,656 kilols.

Although wild Vanilla grows luxuriantly and abundantly in the forests of Venezuela and Guiana, its culture is completely neglected. Attempts have recently been made in British Guiana to revive it. The Brazilian Vanilla does not enjoy a good reputation; this is a consequence of the neglect of preparing the crop. A considerable part of the fruit is collected from wild shrubs, and is consequently of little value. What I have previously said about this country's Cocoa applies accurately to its Vanilla. The Vanillon, alluded to above, comes from the most part from Brazil. It is almost all used in France. During the "fifties," a series of bad harvests seriously damaged the sugar industry in Reunion, and caused the planters to turn to Coffee and Vanilla cultivation, with such results that this island has become, after Mexico, the chief source of this species.

Not only that, the methods of cultivation have been brought to the highest degree of perfection in Reunion and we must turn there to learn how the industry has advanced. The exemplary French statistics afford us also a dependable insight into the advanced and present position of Vanilla culture—an example which awaits imitators in this special branch.

The Statistical Tables show that in 1866, 223 hectares were planted with Vanilla shrubs, furnishing a total crop of 15,494 kilos. In 1871, the area covered was 593 hectares, and the harvest 25,547 kilos. In 1874, area 1,563 hectares, and harvest 43,959 kilos. At the beginning of the "eighties," the average harvest amounted to 5,000 kilos, and the area of cultivation about 1,800 hectares. The latter cannot be sharply defined because it is increasingly the custom on this island to plant the shrubs in suitable places scattered over the ground. This is especially the case with the small landed proprietors who are mainly attracted to this industry. That is readily comprehensible, for the cultivation of Vanilla is suited to the "small people" owing to the great value of the product, rendering the possible maintenance of a family of modest wants on a bit of land too small to allow of Sugar or Coffee cultivation. A further advantage is, that is not requisite to employ machine power or labour beyond that of the family, if working on a small scale. The French have likewise introduced the cultivation to Tahiti, but according to the latest intelligence, only 30 hectares were planted, of which 2,000 kilos, of fruit formed the average crop. The example of Reunion was soon imitated by the neighbouring island of Mauritius, but with less energy, for both before and since, sugar has been regarded as the staple article of the island. Statistical estimations of the export are available, not of the production. From 1865 to 1873, the export amounted on an average to 5,000 English pounds (equal to 4,500 half kilols.), from that time the export increased to an average of 12,000 pounds per annum. Mauritius possesses a few other orchid species, the leaves of which may replace Vanilla for the perfumer. *Angreecum fragrans*, which when crushed emits an odour which powerfully reminds one of Vanilla—some profess to recognise an admixture of the odour of Tonquin (?) beans. The leaves of Paham orchids should be mentioned, yielding an aromatic tea which is so much valued that this plant has been introduced into St. Helena and Madeira and the leaves into France. The leaves of *Orchids fusca* emit a similar aroma. About 1810, the cultivation of Vanilla was introduced into Java, but it has only engaged attention in recent times. Planting has been energetically taken in hand in Ceylon. It is still a question, however, whether the enthusiasm will prove lasting, and whether this Island will form an important source of Vanilla. Vanilla thrives well in Madagascar, and is even cultivated on a small scale. The output is trifling, and, since the war with France, has completely ceased. The refreshing action of Vanilla is due to an alkaloid named Vanillin, so closely allied to benzoic acid that it was

* Vanilla *pompona* produces a pod almost identical with that of the *Vanilla grandifolia*, a native of Trinidad and the mainland, and the species producing the kind known as West Indian Vanillons in the markets, (*J. H. II.*)

previously considered identical with it. Vanillin often crystallises out on the pods in the form of fine needle-shaped crystals—sometimes only years after picking.

The crystals notoriously influence the value of the article; they are regarded as a measure of quality. This measure is occasionally misleading, as is demonstrated by the fact that the finest Mexican Vanilla contains only 1.70 per cent.; Vanillin, Mauritius Vanilla, 2.45 per cent.; Java Vanilla, 2.75 per cent. and yet the first is by far the most valued. The explanation lies in the volatile oil which gives the special aroma, the products of Java and Bourbon being accompanied by another oil of pleasant odour. The percentage of Vanillin varies from 1 to 2.75, with but few exceptions.

Vanilla is usually packed in air-tight tin boxes in which it will retain its aroma for years. The quality may be estimated from the following points of view:—The longer and darker the pod, and the greater the quantity of crystals formed, so much the better are the goods. They should feel oily, and should emit a fresh, strong and pleasant odour. The pods in a box should be equal in length, not broken or in any way damaged. It must be preserved in air-tight vessels, as the aroma rapidly volatilises. These conditions are not always compiled with in the retail trade; one result thereof is a regrettable frequent adulteration of old odourless Vanilla with benzoic oil, which is said to restore the odour and oil of almonds to give the suppleness. The most hardened deceivers go so far as to strew Vanilla with salt to imitate the Vanillin crystals.

A product of the plant, unknown in Europe, but prized in South America, is a juice which trickles from the fully ripe fruit, and is caught in vessels hung beneath.

MANURING OF TROPICAL PLANTS—RICE.

The two varieties of this plant—viz., water rice and upland rice—require different soils and different climates. The first variety is more generally cultivated, and requires a moist, clay, soil, that can stand the necessary watering. Lighter soils should at least have a loamy, impermeable subsoil. Upland rice, on the other hand, can be grown on a soil not quite so rich; it stands dryness much better, and thrives also in less warm climates.

The following quantities of plant-food ingredients are removed from one acre* :—

	Potash.	Phosphoric Acid.	Nitrogen
By an average crop of			
2,676 lb. grains ..	28.1 lb.	16.3 lb.	26.2 lb.
2,676 „ straw ..			
446 „ chaff ..			
By a good crop of			
4,014 lb. grains ..	45.7 lb.	21.9 lb.	39.2 lb.
4,460 „ straw ..			
624 „ chaff ..			

Very thorough investigations have been conducted by Prof. Kellner† and others in Japan, as the fertiliser requirements of water rice. In order to determine the exhaustion of nitrogen, phosphoric acid, and potash in the soil, a fertiliser trial was inaugurated, in which each plot received the following quantities of fertilisers to the acre :—

Plot	No fertiliser.	phosphoric acid	potash	— lb. nit.
1	2	89 lb.	89	89
2	3	89	89	89
3	4	89	89	89
4	5	89	89	89

Nitrogen was applied in the form of sulphate of ammonia, phosphoric acid in the form of double superphosphate, and potash in the form of carbonate. The development of the plants corresponded to that of the previous years; the plants which had received a complete fertiliser grew best of all, showing a nor-

mal green colour; next came the plants to which no potash had been applied. The plants to which no nitrogen had been given were of a light green colour. Phosphoric acid seems to have a very beneficial effect upon the growth of the plant, for the plants which had not received phosphoric acid differed but little from the unfertilised plants; they were of a dark green colour, but very small. The average yields from three check plots (the size of the plots is unfortunately not given) were as follows* :—

	(Yields given in ounces.)			
	Straw.	Fullgrns.	Empty grns.	Total.
No fertiliser ...	10.2	7.5	0.1	17.8
Without nitrogen	16.8	12.0	0.2	29.0
Without phos- phoric acid ...	13.1	9.5	0.2	22.8
Without potash	22.2	14.6	0.4	37.2
Complete fertiliser	27.5	20.3	0.3	48.1

Investigations were also conducted, to determine the quantity of nitrogen available by the rice-plant when green manuring with a legume (*Astragalus lotoides*, Lam.) is resorted to.† *Astragalus* was sown in the autumn, and fertilised with different quantities of lime. In the beginning of May, when the plant was in full bloom, it was cut, weighed, and then turned under. The yield of green material was as follows :—

Quantity of lime applied per acre	0lb.	89lb.	178lb.	356lb.
Yield of astragalus per acre	8,991lb.	16,573lb.	16,341lb.	13,451lb.

The conclusion can thus safely be drawn, that *astragalus* responds well to lime fertilisation, though 89 lb. per acre were sufficient for the soil in question. The leguminous plants analysed 12.23 per cent. dry matter and 0.369 per cent. nitrogen; the plants from the plots fertilised with lime contained 2,266 lb. dry matter and 69 lb. nitrogen per acre. In addition to the green manuring, 98 lb. of phosphoric acid in the form of phosphate of soda and 89 lb. of potash in the form of carbonate were applied. The yields from the separate plots were as follows :—

Fertilisers Applied per Acre.	Yields per Acre in lb.			
	Straw.	Full Grains.	Empty Grains.	Total Yield.
Potash and phosphoric acid without nitrogen	0.478	3.631	0.029	0.849
Potash and phosphoric acid, green manuring without lime	0.556	5.141	0.037	0.973
Potash and phosphoric acid, green manuring with 89 lb. lime	0.747	5.653	0.047	1.315
Potash and phosphoric acid, green manuring with 178 lb. lime	0.736	5.497	0.049	1.291
Potash and phosphoric acid, green manuring with 356 lb. lime	0.767	5.764	0.041	1.348
Potash and phosphoric acid, complete fertiliser with 473 lb. sulphate of ammonia	0.870	5.692	0.068	1.416

Green manuring increased the yield considerably especially on the plots that had received lime. The complete mixture of artificial fertilisers produced just as good yields as the green manuring; as in green manuring the nitrogen in the atmosphere can be utilised, this method is naturally less expensive and hence more profitable.

A similar experiment with green manuring was conducted with another nitrogen-gatherer—viz., indigo (*Indigofera tinctoria*)—in the botanical garden at Buitenzorg, Java.‡

The indigo was grown during the East-monsoon, and as much as possible ploughed under during the rainy season. For the sake of comparison, two fields were manured with 205 and 410 lb. of lime per acre respectively, while a fourth was left unfertilised. The yields were as follows:—

	From 1 Bonw=1.7 acre.	From 1 acre.
Green manuring...	58.4 picul	4,596 lb.
410 lb. lime ...	56 0	4,407 "
205 " ...	52.8	4,156 "
No Fertiliser ...	48.0	3,773 "

Field experiments on a more extensive scale have been conducted in Italy, the results of which are given in the following table:—

Fertilisers applied per Acre.	Yields per Acre in the first year.		Yields per Acre in the 2nd year.		Profit or Loss from yields of both years after deducting cost of fertilisers.

* Jahrbücher der "Cattedra ambulante" von Professor Tito Poggi, Rovigo.

FERTILISING EXPERIMENT WITH RICE.

By Professor Tito Poggi* on the Vendramin Farm (Po Valley).

The highest yield was obtained where all three of the plant-food ingredients had been applied, and on these plots a very good after effect was produced in the second year. Phosphoric acid proved very beneficial, especially upon the yield of grain.

Professor Poggi, Rovigo, makes the following recommendations for the quantities of fertilising materials to be applied per acre:—

	For New Fields.	For Exhausted Fields.
Sulphate of ammonia ..	89.0 lb.	178 lb.
Acid phosphate (16 per cent.)	222.5 "	356 "
Muriate of potash ..	44.5 "	89 "

267 to 356 lb. plaster or slaked lime should be applied to soils deficient in lime. In case of light soils the quantity of murate of potash applied per annum should not be less than 89 lb.

However, too much potash should not be applied to water rice, as this ingredient produces a luxuriant formation of straw at the expense of the yield of grain. American rice-planters always recommend large quantities of potash for upland rice, holding that this is necessary to obtain a heavy yield of grain.

Mr. C. K. McQuarrie, of De Funiak Springs, Florida, holds that the presence of empty husks of upland rice is due to a deficiency of potash. He makes the following suggestions in regard to the planting of upland rice on the rather light soils of Florida:—

If a crop is going to be made on new land, it should be well ploughed during the previous winter, and harrowed over and over again, until all the sod is broken up. At the last harrowing 400 lb. of kainit per acre should be scattered broadcast. When ready to begin planting, furrows should be run with a bull-tongue plough, about 3 feet apart. In these furrows scatter about 300 lb. fertiliser per acre, containing phosphoric acid and potash, not less than 8 per cent. of each. This fertiliser must be well mixed with the soil by dragging a chain in the furrow. The seed must be sown liberally, as at least 25 per cent. of the rice generally grown is nothing but empty husks. After the plants are up, treat the crop to a little top-dressing of nitrate of soda. If the crop is planted in March or beginning of April, we can always depend on getting a second crop from the stubble of the first crop. This second crop is generally not so good as the first, but if fertilised when the first crop is cut it will repay us for our trouble.

Rice must not follow itself on the same land, as it greatly impoverishes the soil, but if we want to continue it on the same land green manuring and a liberal application of potash are absolutely essential. The leguminous plant should be sown early in the spring, and can be ploughed under in time for the first planting.—*Queensland Agricultural Journal.*

WOOD-PULP.

The utilization of the waste products of our Indian forest is a most important problem, but in many cases even where the uses such material can be put to are known, there are serious difficulties to be overcome. In the case of wood-pulp, however, it is indeed to be wondered at that no enterprising capitalists come forward to develop the industry in this country.

In Europe the manufacture of wood-pulp has been going on steadily for many years, but so great is the demand for timber there, the manufacturers are able to obtain only a comparatively small supply of the raw material required. The consequence is that although new uses of wood-pulp are discovered every day, the industry has not expanded very considerably.

It is in America, both in the United States and Canada, that wood-pulp is creating a veritable revolution in the mercantile and manufacturing world. So much so is this the case that "The Times" says:—

"The extraordinary development of the single manufacture of wood-pulp which only a few years ago was practically unknown and is now used not only for making paper but for clothing and an immense diversity of other articles, is a sufficient indication of the practically limitless extension of the already widely varied use of timber." "Cotton," it is said on the other side of the Atlantic "was once called king; but king Cotton is a lesser potentate than king Timber must soon become."

All the American papers are full of accounts of the wonderful development of the industry in that country, and of the constantly increasing uses to which wood-pulp is now put. It is in fact this industry that has brought home at last to the people of America the urgency of making State reserves, protecting them from fire and managing them systematically; for, as long as lumber only was exported

from the forests the younger and smaller trees were left, but now that the wood-pulp man has appeared no trees escape, as he utilizes all the trees left by the lumber man.

The *New York Tribune*, referring to the numberless uses of wood-pulp and the inroads caused on the United States' Forests say:

"Printing paper alone eats an enormous hole in our national forests yearly, and the future extent of that requirement can only be conjectured. The huge procession of railway cars all over the country run, to some extent, on paper wheels; carpenters are beginning to use boards of paper handsomely veined requiring no planing, twice as durable as the wooden variety, and costing only half the money. The builder is introducing paper bricks, showily enameled, which will not burn, and possess many advantages over those of burnt clay. The ship-builder introduces masts and spars of the same substance, which is likewise used for telegraph and telephone poles and flag-staffs. These are not fanciful experiments but serious business procedures, justified by the superior durability of the articles so produced. The same quality is claimed for the paper horseshoe recently invented and now extensively used. An enumeration of the purposes for which this surprising protoplasm has come to be employed would stretch into a catalogue and new ones seem to be discovered every day."

Verily we are approaching the day referred to in the chorus of the old song.

'Paper hats, paper coats, paper boots and shoes.

Patent paper, sailing ships and patent paper crews.

On the paper market there'll be a paper strain, And every one, both young and old, will have paper on the brain.'

The chief wood used for pulp is spruce but silver fir is used in the Vosges mountains. Poplars, which have a short fibre, are also used but more especially for mixing with spruce pulps to give the paper a more even surface. Of spruce there is an unlimited supply in the N.-W. Himalayas, from the Bhagirati to Afghanistan, also in Sikkim and Bhutan. It grows chiefly on Northern and Western slopes between 7,000 and 11,000 feet. The species is of course *Abies Smithiana*, very closely allied to the common European spruce, *A. excelsa*. It attains a maximum height of some 225 feet, and a girth up to 16 feet. The wood is white like that of *A. excelsa* and weighs about the same *viz.*, 32 lb. per cubic ft. on the average.

In the Jaunsar Division alone there is a huge stock of magnificent trees, which is unsaleable at present as there is no demand for it. So much so is this the case that wherever it happens to be found growing near deodar, it is ruthlessly killed by girdling and allowed to rot, so as to favour the valuable deodar. I roughly estimate that from this Division, were the spruce put under systematic management, an annual outturn of 1,50,00,000 cubic feet, or about 5,70,000 maunds, equal to about 21,000 tons by weight, could be obtained. If a large quantity like this were exported it is probable that it would pay the Forest Department to sell the wood at Dagpathar on the Jumna for about eleven annas a maund.

Wood ground mechanically yields, I believe, one-third of its weight in pulp (dry) and this the paper mills would, it is supposed, willingly purchase for at least R3 per maund delivered on the railway, as their agents in the bazaars are now scouring the country for old pieces of paper of all kinds which have to be sorted, washed and bleached before being of any use. For this the agents give R2 per maund and they must get a good commission for all their trouble.

Fifty-seven thousand maunds of spruce would yield some 1,90,000 maunds per annum, or 633 maunds per diem (taking 300 working days=one year) of mechanically-ground pulp and this should sell for R5,70,000.

There is not likely to be any difficulty in disposing of this quantity as the demand for paper in

this country is steadily on the increase, more or less in proportion to the spread of education and trade. Moreover, if good raw material were readily obtainable by the paper mills they would not be so keen on making arrangements, throughout India, to collect all the waste paper, however inferior its quality may be.

The probable annual receipts and expenditure for such an outturn would be as follows:--

<i>Receipts.</i>		R.
By sale of 1,90,000 maunds of pulp, delivered at Dehra Dun Railway Station @ R3 per maund		5,70,000
<i>Expenditure.</i>		
		R.
Purchase of 5,70,000 mds. of spruce @ 11 annas per maund	...	3,91,875
Wear and tear of machinery and buildings @ 10 % on R1,50,000	...	15,000
Manager's pay @ R800 per month	...	9,600
Mechanical Engineer's @ R150 per month	...	5,400
3 Foremen @ R50 each per month	...	1,800
3 Do @ R30 each per month	...	1,080
60 Workmen @ R6 each per month	...	4,320
Carting 1,90,000 maunds of pulp to Railway at 3 Annas per maund per 26 miles	...	35,625
Miscellaneous charges	...	5,300
Profit on capital of R5,00,000, <i>i.e.</i> 20 % per annum	...	1,00,000
		R. .. 5,70,000
The Capital required would be as follows:--		
Cost of Machinery	... R. 80,000	} R. 1,50,000
Setting up, leading water and erection of buildings	R. 70,000	
Working Capital	R. 3,50,000
	Total	R. 5,00,000

This is the prospect which seems to await any capitalist enterprising enough to take up the business; and, if mechanically-ground pulp is able to give such a profit, what would the profit be on chemically-prepared wood fibre for paper and cloth? For, although it is somewhat more expensive to manufacture, the yield is as much as 60 to 66 per cent. of the weight of the wood against 33 per cent. of mechanically-ground pulp. Doubtless Government would be prepared to meet any capitalist willing to start the business, with an agreement to give him the first refusal *via* Dagpathar, at a certain rate for a certain number of years, as well as to lend him a plot of land for his factory with a right to lead water from the river to propel the machinery, so that he could make his own calculation as to whether it would pay him or not. Government at the same time would benefit by the opening out of a market for spruce, for which there is now no demand.

There should be no difficulty in getting water power sufficient to drive all the machinery required for the factory as, I believe, the fall of the Tons river at the foot of the hills is about 45 feet per mile. Should a market for spruce be in this way developed, it would most probably pay the Forest Department to grow spruce on a rotation of 30 or 40 years.

The Canadian pulp factories have bought up large areas of forest land which I am informed they are treating on a 20 year rotation, but then the growth of American spruces, especially the Douglas spruce, is very rapid; *vide* the table published in "*The Indian Forester*" for May 1899.

The trees in the plantation of spruce near Deoban in the Jaunsar Division made in 1874, when the plants were put out at one year old, now average 20 feet in height and 4 1/2 inches in diameter; but the plantation is not densely stocked and the locality is one with an Eastern aspect, while spruce does not apparently grow thereabouts naturally. So if

is expected that with a rotation of 30 or 40 years, in places suited to the species, it would give a suitable sized tree for pulp purposes. When once a regular young forest was formed, the age at which the mean annual increment per acre culminated would be determined, and that age fixed for future rotations. It is very possible that, if experiments were made at the factory, it would be found that silver fir could also be utilized, in which case it would be advantageous to grow a mixed forest of spruce and silver fir.

It is, indeed, to be hoped that a market will soon be developed for spruce, as it is too heart-rending a sight to see all the grand trees now growing being absolutely wasted; and, as mentioned before, being girdled and allowed to rot wherever they interfere with deodar, even though the latter be seedlings, a few years old.

P. H. CLUTTERBUCK.

Jainsar, May 1899.

THE NILGIRIS.

[FROM OUR OWN CORRESPONDENT.]

Since the Madras Government abandoned the commercial aspect of its cinchona experiment and adopted the philanthropic, it has ceased to give the public any information regarding the manner of working its cinchoua plantations on the Nilgiris, which is to be regretted. But notwithstanding this circumstance occasional reports fall into the hands of members of the Press, and we learn what is being done. It is from such a stray copy for 1898-99 that I am in a position to give you the following account, which I hope will interest your planting readers.

This is the second year of the experiment of Government purchasing bark from private planters for working up in its Nedduvottun quinine factory, and it is one of larger transactions. In 1897-98 only 108,934 pounds were bought for this purpose, but in the year under review no less than 405,074 pounds were purchased at Rs3,120-4-8. From the Government plantations 101,307 pounds of dry bark were taken, but from the combined sources only 461,941 pounds were used up in the factory to produce the 12,603 pounds of sulphate of quinine and the 7,238 pounds of febrifuge turned out by it, costing at the rate of R7-11-7 including, and R2-4-6 excluding, the value of the bark per pound of alkaloid; or taking quinine alone, it cost R9,9-6 to produce a pound, that in sale transactions is valued at R18. Though this is not the price at which quinine is issued to public institutions, charged at the rate of R15 per pound. The quantity of quinine issued by the Cinchona Department during the year to all buyers was only 4,629½ pounds, or something more than a third of what was manufactured. A fact attributed to the falling off in the demand for quinine from Bombay and from the Punjab during the year, having been supplied by the Bengal plantations instead of by the Madras, as heretofore.

Mr. Standen says that the Nedduvottun Factory as at present equipped, can work up to 450,000 pounds of bark per annum. The actual expenditure on the Department 1898-99 was R1,94,603-14-1 and the actual receipts for the same period amounted to only R91,039-2-8 the balance having been provided out of a special grant by the Government of India of R1,02,000 made for the purchase of private bark.

The year was also marked by the resumption, after a long period, I think of 20 years, of extension of cultivation on the Government plantations so much condemned by the planters as a breach of faith on the part of Government with them. The extension at Pykara, on the Hooker Estate, measures 80 acres and is completed, but there is a further extension being made in the same locality or another 80 acres which will be noticed in the report for 1899-1900. Referring to the raising of nursery plants for this purpose and for replanting failures, Mr. Standen notices a disaster that was dealt with successfully by his superintendent at Dadabett. It was found that a

number of small thread worms girdled the roots of the seedlings and caused their death. The insects were found in the baskets in which they are established before planting out, and the damage done by them was revealed by the microscope. To destroy the worms the baskets, plant and all were immersed in a strong solution of salt and placed in beds covered with saw dust that had been sprinkled with kerosine oil. The result was that no worms were to be found in the soil in the baskets afterwards, but lest the soil itself might be thus affected it was used, after being burned, for subsequent nursery purposes.

Dadabett is the Government cinchona plantation of the greatest age, and it is satisfactory to note here that the oldest trees are the healthiest, the most vigorous, and the most ready to respond to cultivation and manuring. Speaking of the want of success in planting operations in previous years, Mr. Standen attributes it to soil exhaustion, for such operations are quite satisfactory when carried out on new land; and this led him to recommend that land with cinchona, on being cleared after uprootal, should be replanted with fuel trees.

Similar appearances were observed at Nedduvottun, the oldest parts of that plantation being the best and here the replanted land growing the only sickly trees.

From the statistics attached to the report I gather that the entire number of trees on the Government plantations on the Nilgiris aggregate 1,675,103; that between stripping and coppicing since the commencement of this enterprise by Government as many as 3,402,634½ pounds of bark have been taken and either sold or worked up into quinine and febrifuge. That the plantations, as they stand, represent a surplus of receipts over expenditure of R13,80,403; that in 1875,76 expenditure exceeded receipts by R11,22,117, which has been overtaken by the present surplus. This, I suppose, means that since 1875, the plantations have been working at a profit, the aggregate to date being R25,02,500, a highly satisfactory result, if it does not only exist on paper.

For the year under review, Mr. Standen says that a profit was realized of R35,377-3-8.

Mr. Standen early in the current year visited Java by order of Government, and concludes a lengthy, interesting and suggestive report with the following five practical suggestions, which will commend themselves to growers of cinchona who wish to be abreast of the times in the details of their industry. The suggestions are—(1) That further attempts should be made to cultivate ledgers from seed obtained from Java. They should be grown at an elevation of from four to five thousand feet, in rich, well drained soil, and the richest trees only should be propagated from. (2) The grafting of ledger on succirubras at low elevation and of officialis on succirubras at higher elevations should be tried.

(3) Officialis seed should be taken only from trees showing a high percentage of quinine. (4) Succirubra bark should be shipped in the form of quills; and (5) high cultivation should be adopted and where the lay of land and nature of the soil are suitable the ground should be terraced before planting.—*Planter.*

UNITED STATES EXPERIMENTAL TEA GARDEN.

The only tea plantation in the United States, at Summerville, S.C. The estate, known as Pinehurst, covers 700 acres, of which fifty acres are devoted to the cultivation of tea. The first "Rose Garden" was planted in 1890. In 1894, 151 pounds of tea leaves were harvested; in 1895, 333 pounds; in 1896, 600 pounds; in 1897, 648 pounds; in 1898, 1,200 pounds. On the basis of 900 plants, the production per bush is almost five ounces of tea. This tea has a distinctive character, and retails in the local market at \$1 per pound. It compares favourably with tea bringing 25 cents at pound in lines in the New York Market—*Planting Opinion*, Nov. 11.

TEA AND OTHER PRODUCTS—SPECIALLY
CACAO IN THE WEST INDIES.

LONDON, Oct. 13.

My enquiries, I am bound to say, do not in their results, give much encouragement to the proposal to substitute "private contracts," to some extent, for public sales. The very large number of lots to be dealt with is offered as a strong objection by a broker with long experience in the China and Indian tea trade; but that might be obviated, to some extent, by larger breaks, as indicated in my last, if the big Companies and proprietors so arranged. A more forcible objection is the difficulty of getting at the chief buyers and of disgusting the smaller men who would in a manner be shut out from "private contract" business; while they participate in all that goes on in the public auction room. There is, however, another side; and I have been favoured with opinions worth quoting—thus one merchant writes:—

There is, I believe, a very general impression that huge profits are made by the London buyers. I don't think this is the case to an undue extent; but, on the other hand, I think that the public are getting too good value for their money in many cases. I enclose the advertisements of three of the big blenders in the *Grocer* of 2nd inst. all offering a blend at 9½d per lb. *duty paid* (4d) and carriage paid. There can be no profit on this, even if the commonest stuff of any sort that can be picked up be supplied. This is only a "method" of the trade to enable these people to get at the higher priced trade out of which they can make a profit. Besides these three, there were on 2nd Sept., about six or seven other firms with a 9½d blend. In this week's *Grocer* Brooke Bond's advertisement does not appear; but both Kearley and Tonge and Lipton's are still offering their 9½d mixture, although there is hardly a leaf of Indian or Ceylon tea to be had at less than 6½d as it lies in bond. The profits earned by these big concerns represent in most cases a return on years of energy expended in building up the business. The enclosed advertisement from a recent *Standard* throws some light on the ins and outs of tea distribution, and the cutting from *s of a Time* few weeks ago, *re John Rees*, shows that everyone does not succeed in the business! These points may be useful to you in dealing with the question of a Growers' Distributing Co., to manage which successfully a "genius" would have to be discovered. If a few of the big Companies—C. T. P., Eastern Produce, Anglo Ceylon, &c.—were to give the "private contract" system—with large breaks—a trial, I think they would not find it as difficult as would at first sight appear.

Again, it is quite realised that a change, even though partial to sale by private contracts," involves very big interests, and is a big question altogether, requiring careful consideration at the hands of the leading importers and agents, as well as by the planting and mercantile community of Ceylon. I may have some more opinions to give from this end later on.

Meantime as we are congratulating ourselves on the check to further extension of tea-planting, with the risk of over-production, I find the following advertisement in *The Times* of 12th Oct. :—

Ceylon Tea Land, 4,000 to 5,000 acres in one block, elevation 2,000 to 3,000 feet. Good water power and rainfall. Exceptional chance. Little land now available at this elevation.—A. F. S., Z. 442, The Times Office, E.C.

The initials "A.F.S." would seem to point to a well-known retired planter, and I should guess that the block referred to must be situated in Yakdessa or the upper end of the Kelani Valley.

Turning from Ceylon, to the

WEST INDIES,

one may ask, can any good thing be found in that much-tried part of the world? Well it seems an enterprising Scot who knew little or nothing of the Tropics, until he happened to read "Tropical Lands" by A. Sinclair (copies to be had at your office), sought an interview with the author who advised him to go with his capital to the island of

TOBAGO

and there it seems he (Mr. W. Archibald) is in a fair way to make a fortune! Here is an extract from a letter which has been placed at my disposal:—

I did not return home till the end of June this year from the West Indies and I am glad to say all the time I have been away I have enjoyed very good health. I am very well satisfied with all my investments in Trinidad and Tobago. One of my cacao estates gave me a return of nearly 30 per cent. I bought another cacao estate in January in Upper Caroni for a little over £4,000 and I expect this will pay me even better than the other. We had a very severe drought after the crop and this property did not suffer nearly so much as the others. I have had my hands full in Tobago. I have built a pretty large house there, which will be finished by the end of next month. The house is exactly 400 feet above sea level, with splendid view of the hills at the back and sea in front. Water is laid on all over the house, and I am putting in acetylene gas; so when all is finished, it should be fairly comfortable, and I hope you will come out and pay me a visit, and see Tobago. As to planting, I have got about 50 acres in cacao, about 10 acres of coffee, [The coffee grown in Tobago (Arabian small bean) fetches the highest price in the New York market.] 5,000 nutmeg trees and before the end of the year will have over 5,000 rubber trees planted. The difficulty is getting steady labour to keep the young cultivation clean. I am getting over coolies from Trinidad and hope to get a larger area planted next year. Since I bought my estate in Tobago last year, things are booming, a number of estates have changed owners at higher values. A Mr. Thornton from Ceylon has bought an estate "Alma" for £1,600. This property, I believe, could have been bought last year for £800. He proposes, besides planting, of erecting a large bungalow for a sanatorium and run a coach from Scarborough to Alma. Messrs. Howard and Ord bought the adjoining estate to mine shortly after I bought mine last year. They are acting for an English Rubber Syndicate: they have already planted, I believe, about 50,000 rubber trees. Those trees planted under shade are doing well, but in the open growing very slowly. There are still many *good estates* to be had in Tobago. I have the offer of one now—500 acres—for about £700 called "Caledonia" with 1,000 cacao trees bearing and 5,000 non-bearing, 200 young nutmeg trees, and I understand the soil is very rich. So if you know of any one who wants a cheap estate, I will be glad to get and give all information. I am thankful to say we have escaped so far all the hurricanes. We are in a measure out of the latitude of them, although, I think, in 1845 they had a slight one in the northern side of Tobago.

I suppose Mr. Thornton is our old friend of the Kelani Valley and Dikoya, who has travelled a good deal in his day. It is certainly surprising, in the face of such an ex-

perience, that West Indian sugar planters should sit still and whine to Mr. Chamberlain; while inexperienced newcomers like Mr. Archibald should walk in and win—and most deservedly, in view of the enterprise displayed,

KNAVESMIRE ESTATES CO., LIMITED

REPORT ON THE KNAVESMIRE PLUMBAGO PROSPECTS.

Messrs. George Stewart & Co., Colombo.

Gentlemen,—Acting on your instructions I proceeded to Kegalla and thence to Knavesmire on the 25th April last to inspect the last named for plumbago. Mr. Daniel met me and shewed me every attention and kindness, and with him I went over the estate next day. The first point examined was a shaft sunk on a vein of plumbago some 60 feet vertically, above the stream marking the Northern or North-West boundary of the estate. Before proceeding further I may say that the shaft in question is altogether too large for the requirements of prospecting or even for fairly extensive working above water level, and this is an important matter when working mines in cultivated land.

This shaft is some 15 feet deep and I noticed with satisfaction that the vein had improved considerably even in this short distance. In the present bottom of the shaft the vein is some 6' to 8' wide, not all mineral, but the larger portion is plumbago and of very good quality, and as depth is attained, there is little doubt the vein will improve, will become more compact and less impregnated with foreign matter, but even in its present condition it is a vein of plumbago not to be despised, as it would pay for extracting even now, if properly worked either by shaft or tunnel. For the better development of this vein and others that will be mentioned later on, I should recommend a tunnel being put in at right angles to the strike of the veins, from some convenient point below the before-mentioned shaft; and while on the ground I pointed out to Mr. Daniel a site that I think would answer the purpose admirably. A tunnel at the point indicated would intercept the vein some 40 feet below the top of the shaft, and the distance to drive to the first vein would not exceed 75 feet, and this through most favorable ground for working. Beyond the vein sunk upon in the shaft traced three other distinct plumbago veins running parallel with the first named, and all showing more or less good indications and one in particular shows excellent prospects.

All these veins can be tapped by the tunnel I recommend and the distance would not exceed 150 feet further driving.

As each vein is intersected, drivages on their course would be put in hand to prove the vein in lengths, and to open up the ground for stopping, and to do this the main tunnel need not be stopped more than a day or two for the starting of each drivage on the veins. Ventilating shafts will necessarily have to be sunk at various points as the main tunnel proceeds, but these need not be large nor would they be of an expansive character, and as they would all be sunk on the veins they would probably pay for the labour spent upon them, and possibly leave a profit. Such shafts as I have mentioned are also required for laying the veins open for convenience of removing the mineral; so there are two objects in sinking them. The veins here strike S.-E. and N.-W. and the dip S.-W. varying from 20 to 40 degrees about. To the North-West the strike of the veins soon take them out of the limits of the estate, but to the S.E. there is a clear 400 yards. I should judge that these veins can be worked upon within the Knavesmire

boundary and before the limits of the estate are reached in that direction there will be quite 120 feet vertical of mineral veins above the tunnel, which with four veins to work upon, means a large area of mineral ground.

In conclusion I may say that I have a high opinion of the prospects of opening up a payable plumbago industry at Knavesmire, and I can with confidence recommend the further exploration of the property.—I am, Gentlemen, your obedient servant

(Signed) LEONARD TREGAY.

NORTH MYSORE PLANTERS' ASSOCIATION.

A REDUCTION OF WAGES.

At an extraordinary general meeting of the Association held at the Balehonour Club on Monday, the 23rd inst., the following members were present:—Messrs. O Scott Skirving, president, F Clifford, H Edington, C Danvers, E Lund, D MacMillan, H Morthey, C Wood, L Kingchnrch, H G Bonner, N Seton, D Allardice and T J Parton, Hon. Secretary, proxies from Messrs. C Harvey, C H Browne, C P Reed and H Bidie. The proposal "That coolies pay be reduced to three annas and six pies to men, and two annas for women" was carried. An amendment to the following effect, proposed by Mr. H Edington and seconded by Mr. F Clifford, "That advances be abolished, that men be paid three annas and six pies, and women two annas and six pies, and that the commission to maistris should not exceed 10 per cent" was rejected. It

was further decided that as only 50 per cent of subscribing estates was represented at the meeting, all members of the Association should be supplied with voting papers on the proposition and the amendment, in order that they might have the opportunity of ratifying or rejecting the above proceedings.—*Madras Mail*, Oct. 23.

A SHADE IN CRAZE.

(Communicated.)

With reference to the remark of "Finem Respice" in the *Ceylon Observer* regarding shade for tea, it should be generally known that when tea was first planted in Cachar and Sylhet, shade was deemed requisite; this false impression prevailing down to the autumn of 1860 and among some planters even to ten years later. Even Dr. Jamieson of the N.W. Botanical Gardens in his remarks on Fortune's report, shews an inclination to adhere to the fallacy. In 1860, a Kew man, who had had subsequent Indian experience at Sibpur under Dr. Anderson, put in an appearance in Cachar, and to the surprise of the few men then in the district, took up a block of grass land entirely destitute of timber. Previous to this, Silcoorie, the two Jaliugas, and one or two gardens in the Chutla upon which a large amount of timber had been left standing, exhibited an array of straggling bushes the result of constant drip. So marked was the success of putting plants out in the open at Doodputli that, in 1861-62, down came the timber in all directions, the improvement becoming apparent within a few weeks, in the filling out of the stems and branches, and greater development of vegetation. Shade in Assam has never been resorted to since; and as we happen to know something of the Wynaad and Southern India in general, we would strongly deprecate, in the interest of proprietors there, as also in Ceylon, its adoption for tea. At certain exposed spots in the Nilgiris we know that many planters have endeavoured to counteract the effects of the violent wind that sweeps across coffee plantations when the plants are blossoming by planting belts of *Acacia dealbata*, but the remedy, owing to the tendency of the roots if these plants to ramify in all directions, has proved worse than the evil it was hoped to mitigate. How high may he ask does "Finem Respice" intend to permit his *hevea* to run? Like all plants of the rubber yielding species the para requires and draws from the soil all the properties it possess and will be found to flourish best upon land occasionally subject to submergence, as is demonstrated on the upper water of the Amazon, Orinoco and some of the streams in the different Guineas. The rubber is found under similar conditions on the Congo and Gambia, sufficiently proving it to be a most exacting plant; so that any variety put down between the rows of either tea or coffee can only be at the expense of the latter.

All true caoutchouc yielding plants are vines; we think that fact was established years ago by Sir W. Hooker, father of the present eminent botanist, when curator of Kew. Any plants put down between the rows will open up the soil, but as such plants as para develop, they will most assuredly uproot the weaker plant. As far as mere planting goes Assam has been demonstrated to be the land par excellence for tea, neither Ceylon or any part of Southern India being able to compete with in the full average of either quality or outturn, and though quite willing to admit that conditions of cultivation must necessarily differ under different aspect of climate, elevation, rainfall, etc., we unhesitatingly affirm that wherever tea is considered unable to get along without shade that locality is utterly unfit for the plant. This is the reasons it has failed in both Trinidad, Jamaica and other of the West India Island.

We do not belong to the "creeper" fraternity,* but our botanical experience dates from the winter of 1854, in addition to what we learnt by a pretty close attendance at Kew; whatever knowledge we possess has been acquired in hill and plain, in the West Indies, and in almost every district in India from Cape Comorin to Mussoorie and Karachi to the Salween. "Finem Respice" adduces five reasons for planting para rubber between the rows, everyone of which emphasises what we intimate in regard to his having got hold of an unsuitable locality for tea. Crowding plants together upon a hillside or land subject to a rush of water may prevent wash, certainly, but will inevitably choke the plants so jammed in, and to open up the soil by this means would expose it to the first contingency. If a plantation needs a wind guard, the sooner it is abandoned for some less exposed site the better; if people will go up into the clouds for the sake of a pleasant climate like many of the Nilgiri planters have done, they must be prepared to put up with such exigencies as the proceeding entails. Instead of mitigating fungoid growth and lessening the number of insects, the merest tyro knows that the denser the vegetation the greater will be the development of these parasitical pests. Paragraph (f) would seem to imply the intention of permitting the plants between the rows to attain full dimensions, which would ensure the destruction of either tea or coffee. The concluding remark as to para not being umbrageous enough to require lopping raises a suspicion, in our minds, that "Finem Respice" has got hold of the wrong plants. If leaf is wanted from tea, or coffee cherry is expected to mature, lopping will have to be adopted, the effect being a free distribution of the gum all round, which can hardly prove beneficial to either fruit or flush, and it will assuredly kill the rubber plant as the same process did in Assam and the Upper Valley of the Chindwin.—*Calcutta Planter*, Oct. 23.

MALABAR-WYNAAD PLANTING NOTES.

WYNAAD, Oct. 25.—The weather has been cloudy, muggy and showery during the past fortnight or three weeks, and a good deal of very heavy rain has been recorded. But notwithstanding this, we are still about 10 per cent. below our average to date.

Leaf disease has not attacked Arabica coffee more acutely than usual, except on certain well-defined fields of estates, where the blight seems to recur regularly towards the close of the S W Monsoon. Upon Liberian trees, the rust has, however, been severe, and the coming season's Liberian crops will probably prove disappointing. On the other hand, Arabica is furnished with an abundance of vigorous young wood, and, given a good season, next year's crops should equal, or exceed, those of 1893-99.

Prices of food grains in the local Bazaars do not appear to have been enhanced by the exports from the West Coast ports to Bombay and estate labour has no difficulty in supporting itself on the usual subsistence allowance. Coffee picking has been commenced, but it seems doubtful whether bushel picking will commence much before the middle of next month, except on a few favoured properties, which enjoy exceptional climatic advantages. The low prices which have been realised for some months past from the majority of tea gardens in Wynaad, has proved a disappointment to those who confidently anticipated that with the splendid soil all over the plateau (as compared with Ceylon) prices would rule high, with the advent of experienced.

* "Creepers" are unknown in Assam. They are purely a Ceylon production—*Ed., Planter*.

TEA PLANTERS FROM THE "SPICY ISLE."

But, as a matter of fact, the averages, quoted in the public price lists of tea sales, indicate that the teas exported from factories which are under the sole management of Wynaad men, realise better prices than the breaks shipped to London from places "bossed" by ex-Ceylon tea planters. As an instance, one property in particular, which enjoys the advantage of being under the control of its resident proprietor, and which disposes of a great deal of its coarser grades of teas locally to native merchants at 5s. a pound, (a figure that such tea would probably not realise in Mincing Lane) rarely exceeds 6½d per pound. A leading Ceylon planter, well conversant with the Wynaad, recently expressed the opinion that "improved manufacture" would insure Wynaad teas fetching at least 2 annas a pound in excess of recent prices. There would appear to be a prospect of a further influx of Ceylon planters shortly, and it is to be hoped that these gentlemen will be competent to introduce a more profitable standard of manufacture—should they invest locally.

While the Mysore Planters' Association appears to deplore the gradual depreciation of Nalknad coffee, and its susceptibility to leaf disease, it is noteworthy that where the Coorg bush has been tried in South Sylhet, and in the Straits Settlements, it has not as yet shown signs of the blight in those localities.

Interest in the profitable cultivation of rubber trees in the Wynaad seems to be increasing, but excepting where information is available from Ceylon newspapers, very little appears to be known of the peculiarities of either the *Castilloa* or *Para* varieties.

Local buyers are now offering to take the growing pepper crops at R220 per candy, whereas last year's sales did not exceed R180.

The Honourable Mr. G Acworth recently passed through the Wynaad, and appears to have been very favourably impressed with the appearance of the tea properties owned by a leading West Coast firm.—*Madras Mail*, Oct. 28.

THE KINTYRE TEA ESTATES COMPANY, LIMITED.

The following is from the report of the directors, to be submitted at the general meeting, to be held on Wednesday, Oct. 25th, at 12-30 o'clock, at the offices of the Ceylon Association in London, 61 and 62, Grace church Street, E.C. :—

"The estimated tea crop for the season was 460,000 lb., but this has been largely exceeded, the total secured amounting to 498,532 lb., or upwards of 60,000 lb. more than were harvested during season 1897-98. The average cost of production was estimated at 26'81 cents, but a considerable saving on this figure was effected, the actual average cost being 24'66 cents. The directors think these results very satisfactory, and they show careful and economical working. The net profit on the sales of the company's produce amounts to £5,770 4s 4d, and after paying directors' fees, income-tax, and the usual commission to estate superintendents, there remains a balance at profit and loss account of £5,149 1s 3d. The board have authorised the payment, half-yearly as usual, of the preference dividends, absorbing £1,000; they have set aside £500 for wear and tear of buildings and machinery; and they now recommend the payment of a dividend of 8 per cent. for the year on the ordinary shares, which will absorb £3,600 and leave £121 11s 11d to be carried to next account. A bungalow was built for the superintendent on Ayr estate, and the expenditure therein, with some item

for the factory, &c., amounting in all to £488 14s 1d, has been charged to capital account. The average yield of tea, in full bearing was 570lb per acre, and the gross average price realised in London was 7.90d per lb. The sum of £44 12s 10d has been written off the coast advances, as the Ceylon agents advise that the amount is not likely to be recovered. The superintendents have certified that the remainder of the coast advances may be considered good and recoverable. The estimates for the current season point to a crop of 480,000lb of tea, to cost 26 cent per lb, and by the latest advices good progress had been made on each estate towards realising the above quantity.—*H. & C. Mail*, Oct. 20.

HORNSEY TEA ESTATES COMPANY, LTD.

The following is from the third annual report, 1898 99 :—

The directors beg to submit the report and audited accounts for the year closing June 30 last. The crop has weighed out 172,139lb, against last year 146,226lb, giving an increase of 25,913lb. The directors have during the last year sold most of the crop in Colombo, and the result has been satisfactory. The London sales have amounted to only 21,735lb, and the balance of the crop sold on the other side realised an average of 45.40 cents, equivalent to a London price of 8½d per lb. The cost of production, including manure, has been 31.12 cents, against last year 36 cents, or, in sterling, 5d per lb Colombo, against 5½d per lb. Turning to the accounts, it is to be noted that the profit on working account is almost double that of last year, the result of better prices and a larger crop; expenditure being very little in excess of the previous year. During the twelve months the coast advance account has been reduced by £154 14s 0d, leaving the very moderate amount of £178 16s 11d outstanding. After paying all fixed charges, and preference dividend for the twelve months, and providing for the £126 3s 2d carried forward to debit last year, there is a balance at credit of profit and loss of £561 12s 4d. The directors propose to write off £310 from preliminary expenses account, pay a 2 per cent. dividend on the ordinary shares, taking £240, and to carry forward £11 12s 4d to credit of next year.—*Ibid.*

PRODUCE AND PLANTING.

TEA ACREAGE IN TRAVANCORE.—In consequence of the misleading character of the figures with reference to the area of tea in Travancore published by the Government authorities for the period of 1897-98, which were so excessive as almost to cause a scare in Mincing Lane last year, considerable interest has of late been shown in the matter. We understand that there are about eight thousand acres of three years old tea, and about the same quantity of two years old, in addition to which Kanan Devan Hills Produce Company has put out some six thousand acres, which will no doubt lead to an increase in the crop from this district at no far distant time. The total crops have been as follows:—1893, 1,931,000 lb.; 1894, 2,022,000 lb.; 1895, 2,214,000 lb.; 1896, 2,226,000 lb.; 1897, 2,532,000 lb.; 1898, 2,610,000 lb. The crop during the current season will probably reach three million lb.

THE TEA BUYERS' ASSOCIATION.—This Association, the outcome of the dispute over the pound draft questions, has amalgamated with the Wholesale Tea Dealers' Association, or perhaps it is more correct to say that the latter has merged into the former.

RUBBER CULTIVATION.—According to the views of Senor Horta, who has recently issued a pamphlet on "Rubber in Guatemala," the climate most appropriate for the growth of the rubber tree is that of the Tierra Caliente, or hot coast lands, at an altitude not exceeding 1,500 feet, and the trees should not be planted in the sun, although the contrary opinion is held, and has been expressed by some authorities.—*H. & C. Mail*.

SCOTTISH TRUST AND LOAN COMPANY OF CEYLON, LTD.

The following is the report by the Directors of the Scottish Trust and Loan Company of Ceylon, Ltd., to the twenty-second Ordinary General Meeting of Shareholders, held at the Company's Registered Office, No. 123 George Street, Edinburgh, on Thursday, the 26th Oct. :-

The Directors present their Twenty-second Report, being for the year to 31st August, 1899.

ESTATES IN THE COMPANY'S POSSESSION.—The Estates of the Company, along with most estates in Ceylon, experienced the effects of the abnormal season 1898-1899, and the yield of Tea fell short of the estimate. Notwithstanding this, the year's working shows fair results.

The Company's Estates now comprising 1,581 acres of Tea in bearing, 151 acres in partial bearing, and 293 acres of young Tea—in all 2,025 acres. Coffee cannot be depended upon for substantial returns; the crop being precarious, and the market at present much depressed.

FACTORIES, BUILDINGS, AND MACHINERY.—The Capital outlay includes the extension of Annfield Factory, wire shoot for Rahanwatte, the planting of new land, and upkeep of Tea not yet in full bearing.

DEBENTURE DEBT.—The Debenture debt remains at the same amount as at the close of last year. The sole remaining Bond will mature and be paid off at Martinmas 1899.

ACCOUNTS.—The Balance at the credit of Profit and Loss Account is £7,065 14 5

And the Directors propose—

To pay a Dividend of
5 per cent per annum,
free of Income Tax. £2,250

Note.—Two and a half per cent of this was paid as an Interim Dividend at Whitsunday 1899.

To pay Bonus of 5 per cent free of Income Tax 2,250

To transfer to Reserve Fund 1,000 5,500 0 0

Leaving £1,565 14 5

to be carried forward to next Account.

By the death of Mr. William Bowden Smith, the London Agent, in October 1898, the Directors sustained the loss of a sound adviser in all matters relating to the practical working and welfare of the Company, and they desire to place on record an expression of the value of his services. The vacancy in the London Management thus caused has been filled by the appointment of Mr. A. Gordon Dickson and Mr. William G. Smith as Joint Agents.

The Director have pleasure in intimating that during the year under review they appointed by Mr. W. Herbert Anderson as Resident Director in London, with a general supervision of the Company's affairs. Mr. Anderson's long practical experience as a Ceylon Planter has already proved of much value to his colleagues. In terms of the Company's Articles of Association, Mr. Anderson falls to retire from the Board, and be re-elected by the Shareholders at the ensuing General meeting.

The Director retiring by rotation is Mr. James Haldane, who is eligible for re-election.

The Auditor for the current year falls to be appointed.
FRANCIS A. BRINGLOE, Secretary.

CEYLON TEA AT ZANZIBAR.

We have decided to give this product a trial, because of the healthy appearance of the tea bushes at Miss Thakeray's shamba, Mbweni, planted by Sir John Kirk. These were pruned down in October and flushed well, bearing enough new growth in two months to form a plucking surface

and leave six inches of pruning wood. Half a maund of Horagalla, Ceylon, Assam Hybrid, has been obtained and planted in the new nursery at Mpapa and is growing well. This should give us enough plants for six acres, planting five by five, and leave a margin for supplies and distribution. I don't think that Zanzibar will ever enter the lists as a tea producing country, even if low-country varieties are found to flourish here, as the labour-supply is too small and uncertain. The plentiful supply of organised labour in Ceylon is one of the chief reasons why that country has taken the lead in this industry, while Natal is an example where the comparatively adverse conditions of labour have operated unfavourably. In our present unstable condition of labour we could not do more than grow a few acres for local consumption and perhaps induce Arabs and natives to cultivate a few trees for their own use. Another point to remember is that tea is a declining market and is probably already overproduced.
—Zanzibar Gazette.

THE CONSOLIDATED ESTATES CO.

LONDON, Oct. 14.

I see the *H. & C. Mail* attempts no report of Mr. R. A. Bosanquet's really very sensible and suggestive remarks at this meeting; while it rather bungles what I said in mixing up Rubber and Shade Trees. After very aptly expressing thanks for all connected with the work of the Company, Mr. Bosanquet alluded to his recent visit to Ceylon and to what he saw of the need for liberal cultivation; but he felt that manuring must be judiciously carried out, and he did not quite believe in "bones" for tea. He illustrated the need of taking action against tea pests betimes, by what occurred in the case of coffee; but by no means indicated the cases were alike.

I am much interested in the home campaign to induce all publicans to supply "tea" among other refreshing drinks! Support of this movement would repay Ceylon planters much more than wasting time and thought over the abolition of the Tea Duty—of which, even if desirable (which most people doubt), there is not the remotest chance, with war in South Africa.

CEYLON GREEN TEAS IN CANADA.—Is Ceylon really exporting any green tea, or is its fair name being used as a handle for the ready sale of green teas from other sources? The following is an extract we have received from the agents of the "Salada" Ceylon Tea Co. at Montreal, dated October 4th:—"You may be interested to hear that we have just had a visit from Mr. Wm. Mackenzie, who has induced our firm to take hold of Ceylon green teas, and after talking the matter over the matter with our principal and Mr. Mackenzie (who were here together on Saturday last) we have decided to go into them, and we believe that there is a great future before them. We believe, in fact, that instead of climbing a very steep hill, as we have done in displacing Japan teas with Ceylon blacks, we have a comparatively easy path in Ceylon greens, and propose to push them for all we are worth." Mr. Mackenzie's next communication on this subject should afford food for reflection to planters who are not now turning out green teas at all.

TROPICAL CULTURE IN AUSTRALIA.
THE LABOR PROBLEM.

Below we quote one of the leading articles, which appeared in the Sydney *Daily Telegraph* of Monday, October 23, in which the benefits, which will accrue to North Queensland agriculturists when Federation is established, are pointed out and attention is also drawn to the success which has already attended the cultivation of many products, which we, in Ceylon, are interested in. One of the chief difficulties in the way seems to be the labour question, as the prejudice against the introduction of "colour" is very strong in Australia, not only on account of labour, but also from the fear of a half-caste race springing up in the community and the article in question comments on this point. No trade will be regarded as worth having if it involves any menace to the principle of a "White Australia." Fiscal difficulties are also alluded to, but the article itself is well worth perusal:—

TROPICAL CULTURE.

It can hardly be questioned that Federation and the extensive import duties which will accompany it will open a field for tropical cultivation, and Northern Queensland and probably the Chinese in the Northern Territory will be enabled to reap a harvest out of the

needs of the southern markets. Hitherto it has only been a question of tropical labor which has stood in the way of the extension of such cultivation, even with the southern markets alienated by high duties. But with those markets freed and protection against the world outside Australia, there will be added inducements of a very powerful description to cater for consumers within the commonwealth. In New South Wales the sugar industry can thrive upon £3 per ton protection, and in Queensland it can hold its own even without the favoritism it is certain to secure at the hands of the Federal Parliament. Last year Australia turned out enough sugar to cover its entire consumption, and it may therefore be taken as beyond controversy that in the case of this most important of all tropical products the problem of internal production has been already fully solved. But sugar by no means covers the entire field. Those who perused the Queensland Financial Statement delivered by Mr. Philip on the 3rd inst. must have been struck with the amount of attention now being directed in that colony towards other forms of tropical culture. In 1896 Queensland put 138 acres under coffee, and last year this was increased to 432 acres, while in 1899 a further considerable extension has been notified. Queensland is already in a fair way to supply her own market, and with similar duties on imports into Australia she may look forward to supplying a very much larger one. Rice cultivation is entirely in its infancy in Queensland. But the area of 863 acres in 1898 was double that of 1897, and the yield was over 44 bushels to the acre. It may be argued that rice stands specially in need of colored labor, but the crop is highly prolific, and even a halfpenny per lb. duty will be found a great incentive. Queensland is also turning her attention to tobacco cultivation, more particularly to cigar tobaccos, and is likely to make a better show than the southern colonies have done. In times past Queensland has grown good cotton, arrow-root, and other tropical products, and of the suitability of the soil and climate to such crops there can be no question. The difficulty has been to offer sufficient inducement to growers, and there are many directions in which a large and protected market will act as a powerful stimulant. That through the entire range of tropical culture the labor problem is pretty certain, sooner or later, to crop up is a point we shall not now attempt to discuss. It has to be recognised that the United States, with its £200,000,000 worth of tropical culture annually, and its entire command of the cotton markets of the world, could never have reached its present exporting and internal manufacturing power without the negro. The presence of the negro, however, has created a growing racial trouble, which renders even this trade dear at the price. We may take it for granted that no such price will be paid here, and that no trade will be regarded as worth having if it involves any menace to the principle of a "white Australia." But that will not be the question now in Australia. The problem is that of supplying a favourable internal market with products upon which already high import duties are levied, and there is really no reason why even the great revenue-yielding import of tea should not be covered by the northern producer. Thus Federation is more than likely to bring in its train a very extended utilisation of the tropical north, much more so than is at present understood. But from a revenue standpoint there will be serious trouble. The duties now paid upon tropical imports are high, and play a large and important part in our State finances. It has always been a safe source of income to levy high duties upon such products in the southern colonies, because internal supply was impossible. It will be different in the future, and the prospect appears to be that gradually, but surely, internal markets will command a growing share of attention to the possible detriment of production for export. That Australia must continue to export largely is beyond question, because the interest on her indebtedness has to be covered in that way, but there is at present a very large excess

of exports, which enables us to pay for our extensive imports, and that may be affected. This is one of the problems which Federation will open up in the probably not distant future, and it bids fair not only to at some important points direct employment into other channels, but gradually to alter the system of taxation. We shall have in the future to depend less upon Customs duties; more upon excise and direct taxation, as is now the case in all the older countries of the world. In a country differing so vastly as Northern and Southern Anstralia there are a number problems of a similar nature which are bound to arise.

ENGLISH TEA IMPORT DUTY.

The following is the return forwarded to us by the Planters' Association of Ceylon. It was unavoidably crowded out from the *Observer* on Monday:—

Year.	Quantity of China tea consumed annually in the U. K.	Quantity of Indian and Ceylon tea so consumed.	Total quantity so consumed.	Average rate of duty	Average price in bond.	Average quantity consumed per head.

* The importation of Ceylon tea in large quantities commenced in 1883.

TEA GROWING IN MEXICO.

About 300 Japanese colonists located two years ago in the southern part of Oaxaca, near Jimillepec under authority of a concession granted by the Mexican Government. The colony has been experimenting in tea-growing and has made such a success that 5,000 more Javanese men and their families are to be brought to Mexico to join the original colony. — *Glasgow Weekly Mail*, Sept. 23.

A VISIT TO THE SEYCHELLES.

IMPRESSIONS OF A CEYLONESE.

Mr. J. R. Dissanaïke, who returned to Ceylon the other day by the steamer "Khaudalla" from Bombay, is a son of Madaliyar A. Dissanaïke, the retired President of the Village Tribunals. After a course of training at the Ceylon Technical College and after some experience in survey and other connected work, under Government, he left two years ago for the Seychelles islands, accompanied by, and as assistant to, Mr. Waddell, of the Ceylon P. W. D., who was seconded for service in these islands in the construction and repairing of roads and otherwise improving the internal communication of the islands. Unfortunately, Mr. Waddell had to resign before he could have accomplished much, owing to ill-health; but Mr. Dissanaïke was able to continue to the end of his term, the climate (which much resembles that of Ceylon) agreeing with him. A correspondent, who had a talk with Mr. Dissanaïke, informs us that he learned from him that there are now in Mahé, where the latter was stationed, nearly twelve miles of good road, besides many more miles of bridle and footpaths. The majority of the inhabitants, (creoles and niggers) however, are slow to use them, especially for transport purpose, as they are prejudiced in favour of their boats which are called "perogues" and which are "gulled." The old roads traversing the island are more like footpaths than roads, owing to the steep gradients over which they pass, due to the rocky and mountainous nature of the islands.

CORAL MACADAM

is chiefly used on the roads, with occasionally some metal, which is of a very hard character indeed.

To Mr. Dissanaïke the islands presented a very lovely and picturesque view as he approached them by steamer from Bombay and what was most remarkable to him was the pretty and varied colour of the water within the reefs near the shore, due to the coral formations of different tints. The view of the town of Mahé from the harbour is also very picturesque, dotted as it is with houses and other buildings on hilly prominences here and there. The houses are built of timber, on raised masonry pillars, a few feet above the ground, with shingle roofs; but accidents by fire are very rare. With the vegetation of Mahé. Mr. Dissanaïke was quite at home—most of the trees and vegetables found in Ceylon growing there, such as coconuts, jak, breadfruit, oranges, pineapples, bananas, pink apples (jambus), lime, tamarind, sugarcane, manioc, sweet potatoes, bandalai, etc. Coffee, cacao, cinnamon and cloves also grow there; but the latter two products appear to be neglected, especially the cinnamon, the natives not knowing how to prepare it for the market, or the uses which it is put to. Lime and tamarind are scarcely used by the creoles and negroes, and consequently are allowed to rot under the trees. Some of the fruit and vegetables are exposed for sale in the town; but in the interior there is very little demand for them, except manioc and sweet potatoes, which, with fish, is the principal diet of the creoles and niggers.

COCONUTS,

too, go very little into human consumption and are chiefly prepared into oil for export; while a portion of

the oil is also used in the local soap-manufactory in the immediate neighbourhood of the town.

The chief industry in the Seychelles is, of course,

VANILLA GROWING

which is mostly in the hands French settlers, creoles and niggers, though there are plantations belonging to Europeans. The vine is grown on supports for which live trees six to seven feet high are utilized, and comes into bearing in two or three years when handled in the usual manner.

Beside the creoles and niggers, the population of Mahé include English and French settlers. All seem to be peaceful and contented and are very hospitable to strangers. Serious crime is seldom or never heard among them, although there is a chief court and police court in the town—in fact during the two years' of Mr. Dissanaïke's residence in the island, he did not hear of a single case of homicide.

The people are chiefly Roman Catholics, and the French priests, who minister to them, take a great deal of interest in the education of the masses, and have several schools and churches all over the island. There is also a Government school in the town, beside two Protestant Churches—one in the town and the other in the country. The language chiefly spoken in the island is French, but the creoles have a peculiar dialect of their own.

Rice is the

STAPLE FOOD

of the settlers, but the creoles and niggers mostly live on manioc and sweet-potatoes and fish. In the town a couple of bulls are slaughtered twice a week—on Wednesdays and Saturdays—and the meat is sold at fifty cents a lb. Pork and turtle flesh can be had in abundance and pigs are reared in large numbers. Fish is very cheap and in point of relish is superior to the kinds found in Ceylon. Hardly any mutton or goat flesh could be had, while chicken and eggs too are scarce. A kind of bird's eggs of a smaller size than hen's eggs are brought at a certain season in the year, from a neighbouring island, and they are sold at Mahé, at about half a cent each. Turtles, when caught, are kept in a pond near the shore, which at low tide runs quite dry, and then the poor creatures undergo much suffering. There are no hotels except a boarding-house kept by a creole woman; but the respectable portion of the community seldom or never patronize it.

There are no rivers in Mahé, except streams not more than four or five feet at their widest parts; and the people chiefly depend on these for their water supply, though the town is served from a tank a few hundred feet about it, by pipes; but often trouble is experienced with the latter.

There are pretty seashells to be found all over Mahé, while coco-de-mer is the principal natural feature of Praslin, the next biggest island in the group.

Steamers plying between Bombay and Zanzibar call at Mahé once a month for passengers and cargo; but not unfrequently men-of-war of different nations pay visits to Port Victoria, when the town presents a more animated scene than usual, with "Jack ashore."

CEYLON FISHING CLUB.

ANNUAL REPORT.

(For the season ending 30th September, 1899.)

The annual report of this Club was read at the general meeting held on the 26th November, 1898, by the then hon. Secretary, Mr. S M Burrows, when accounts of the Club to the end of October, 1898, were submitted, and the same office-bearers were unanimously re-elected for the ensuing year. Two general meetings have been held since: one on the 8th February and the other on the 14th April, 1899. In view of the resolution passed at the general meeting of the 26th November, 1898, fixing the closing of the open season for Trout for the 30th September, the accounts and the report

are made up to the end of September, instead of October as heretofore.

FINANCE.

2. The accounts of the Club up to 30th September are appended to this report. (Appendix A.) The financial position of the Club is satisfactory. The balance standing to the credit of this Club on the 30th September, 1899, is R364.69. A statement of probable revenue and expenditure for the ensuing year is also appended to this report. (Appendix B.)

THE OUT-TURN OF OVA.

3. Three consignments of ova were received from England during the year; two consignments of 29,000 each of the ordinary brown Trout ova (Fario) at a cost of R648.76, and one consignment of 10,000 rainbow Trout ova (Irideus) at a cost of R216.19. The total out-turn of fry from the first two consignments was 11,670 fry, distributed as follows:—

4,230	"Hatchery Stewponds," Nuwara Eliya.
2,500	Mr. Farr, "Horton Plains."
1,500	Mr. Ross-Clarke, "Calsay," Nanuoya.
1,000	"Queen's Cottage Stewpond."
840	Nuwara Eliya Streams.
700	Mr. Brown, "St. Leonards," Udapussellawa.
500	Mr. Cuff for Maskeliya Club.
200	Mr. J Fraser, "Abbotsford," Nanuoya.
200	Mr. Cuff, "Patna Streams," Maskeliya.

11,670

RAINBOW TROUT.—(*Salmo Irideus*.)

4. Out of the 3rd consignment, that of rainbow Trout ova, only 1,510 fry were available for distribution; this small out-turn is attributed mainly to the faulty packing of the ova, to which was due the fact that a very large percentage of the ova were found squeezed into pulp on arrival here. The healthy ova, however, hatched out very well, the percentage of deaths being few. The young Rainbow fry have thriven very well, and it seems probable that the introduction of this variety will prove a decided success. There are two disadvantages in importing Rainbow Trout ova: (1) that the ova hatch out within 25 days of fertilising, and so it is difficult to get them delivered from Guildford in time, a certain percentage of the ova having hatched out and died before reaching Nuwara Eliya; and (2) the ova reach Ceylon rather late in the season, when the rains may have commenced, the temperature of the water has risen, and no precautions can prevent the deposit of some sediment on the eggs which is fatal to their hatching out. One-half of the consignment of the Rainbow ova was ordered out for Mr. Wilson-Wood, who paid half the cost of the consignment, viz. R126.66. The distribution of the Rainbow fry was as follows:—

801	Mr. Wilson-Wood, "Drayton," Kotagala.
324	"Hatchery Stewponds," Nuwara Eliya.
150	Mr. Farr, "Horton Plains."
75	„ Ross-Clarke, "Calsay," Nanuoya.
75	„ Brown, "St. Leonards," Udapussellawa.
75	„ Lyall, "High Forest," Maturata.
10	„ J. Fraser, "Abbotsford," Nanuoya.

1,510

The notes made at the time when this consignment of ova was unpacked are appended in Appendix C, a copy of which, it is suggested, should be forwarded to Messrs. Andrews & Andrews for their guidance with the orders for the forthcoming season.

It is suggested that two consignments of Brown trout, 20,000, and one consignment of Rainbow

trout, 10,000, be ordered for the coming season from Messrs. Andrews & Andrews of Guildford.

STEWPONDS.

5. In compliance with the Resolution No. 3, passed on the 16th November, 1898, most of the young fry were turned into Stewponds, of which three new ones, A, B and C, were constructed at the hatcheries, two on the Horton Plains, two on Calsay, Nanuoya, one at St. Leonards, Udapus-sellawa, and one at High Forest, Maturata. The upper pond on the grounds of the Queen's Cottage was also utilised for the purpose.

At the Hatcheries, 4,230 Brown trout fry were placed in four stewponds, and 324 Rainbow Trout fry in two stewponds. These stewponds were emptied on the 1st, 2nd and 4th October, immediately after the close season had commenced, with the following results. The number of Brown Trout fry was 796, the greatest length being 7 inches, and the average was 4 inches, their age being then 7½ months. The number of Rainbow fry was 170, and the average length was 4½ inches their age being then 6 months. The whole seemed healthy, and in fair condition, the Rainbow fry especially being very game, thriving excellently on their diet of fresh water shrimps: there was, however, a great diversity in the growth of the consignment, a number having hardly grown at all.

At the time when the Brown trout fry were turned out into the stewponds, the daily mortality was serious; and it is probable that they were not, as a whole, in healthy state. Whenever any fry show signs of weakness they are attacked and eaten by the healthier fry, and it is probable that numbers were thus disposed of when quite small. Very few dead were detected. The Rainbow fry on the other hand were always healthy while in the troughs, an admixture of earth every few days to the sand at the bottom of the troughs seeming to neutralise the ill effects of the pollution of the water arising from the decay of food which had not been eaten. In the stewponds, too, they did not fight like the Brown trout, nor are they such depraved cannibals.

A fissure occurred in the bottom of stewpond E, through which may fry escaped into the small stream adjoining it, where they were seen working their way down to the river. One thousand fry had been placed in this pond, but when drawn only 53 were left.

OUT-TURN FROM STEWPONDS.

(A.) NUWARA ELIYA.

6. (I) The result of the out-turn of fry into Pond A, the first of the new upper ponds.

Consignment received on 12th February, 1899. 1,250 fry put into the pond about 15th April.

This pond was drawn on 2nd October, 1899, 236 fry were taken out in good condition, great variations in growth.

19	...	7" long
30	..	6" long
50	...	4" to 5"
137	...	varying from 4" to 2"
<hr/>		
236		

This pond was probably too crowded. Six were put back; all the rest were put into the Nuwara Eliya river.

There were three very small fry which have not grown at all since they were put in April, these have been returned to the troughs.

(2.) The out-turn of the Brown trout fry put into B, the second of the Upper Pond was as follows:—

Consignment of Brown Trout ova arrived on the 12th February, 1899. Put out into the pond about the 15th April, 1899, 1,750 fry.

Pond drawn on the 4th October, 1899. 325 fry were taken out.

20	about 7" long
50	do 6" "
100	do 5" "
100	do 4" "
55	do 3" and 2" long
<hr/>	
325	

All appeared to be healthy. They were distributed as follows:—

- 223 Nuwara Eliya Main Stream.
- 96 Hawa Eliya Stream.
- 6 Back to the Pond.

325

(3) The out-turn of the Brown trout fry put into the Stewpond D, in front of the Hatchery, was as follows:—

Consignment of Brown trout ova received on the 12th February, 1899. Put into Stewpond about the 1st May, 1899. About 230 fry were put in.

Pond drawn on the 4th October, 1899. 182 fry were taken out in good condition.

10	about 5" long
100	" 3" to 4" long
72	" 2 to 1½"

182

They were all put into the Nuwara Eliya Stream.

(4.) The out-turn of the Rainbow Trout fry put into C, the large new Stewpond was as follows —

Consignment received on 25th March, 1899. 250 put into Stewpond on 6th May, 1899.

Pond drawn on 1st October, 1899, 150 fry were taken out in good condition. Great variation in growth. Greatest growth (15 fry) 7"; smallest growth (25 fry) 2"; average growth about 4½"; six large fry (6" long) left in Pond.

The remaining 144 were distributed as follows:—

- 72 between the Tavern and Rose Bank Bridge
- 47 Hawa Eliya Stream.
- 25 Sita Eliya Stream.

144

6 back into the Pond.

150

(5.) The out-turn of the Rainbow fry put into Pond E at the back of the Hatchery:—

Consignment of Rainbow Trout ova received on the 25th March, 1899, and put into Stewpond about the 10th of August, 1899. 23 fry were put in.

20 fry were taken out on the 4th October when the Pond was drawn.

4	about 5" long
10	" 3" "
6	" 2" "

20

the Queen's Cottage pond is largely due to the fact that a pair of Kingfishers settled by the pond, and that otters infest the pond and cannot be kept out through want of fencing.

(B.) HORTON PLAINS.

Mr. T Farr reports as follows regarding the fry placed in the Horton Plains Stewponds, viz.—1,500 Brown Trout fry and 150 Rainbow fry. (1,000 Brown Trout fry were turned into a stream falling into the Horton Plains River.)

9th August, 1899.

DEAR SIR,—In reply to your letter of August 8th, I do not think the time has yet arrived to transfer the trout from the ponds to the river, therefore I can only by observation guess at the number of fish in each.

They may, so far, I think, be considered a success, and I should estimate the pond into which 1,500 fry were placed as containing say 500 to 700, and the rainbow fry should turn out 50 per cent of the number put in.

I may mention that the growth of fry in both the ponds is very uneven—some of the fish being very strong and of good size whilst others have grown very little.

The Rainbow Trout appear to have grown better than the Faro.—Yours faithfully,
(Signed) T. FARR.

(C.) OTHER STEWPONDS.

(1.) Calsay, Nanu Oya.—Mr. Ross-Clarke reports of the "Calsay" Stewponds, where 1,500 Brown trout fry and 75 Rainbow fry were placed, as follows:—

July 25th, 1899.

DEAR SIR,—On the 19th instant I emptied my two stewponds with the following results:—

the Top Pond contained 196 trout
the Lower Pond " 305 "

out of 700 and 800 put in; the following day I took 209 up to Ambewella and turned them in there in good condition, 40 were turned into the Rajah Patna stream, several 5 inches long, and the average about 4 inches.

I returned 250 about an average of 2½" to the Stewponds, where they ought to thrive well now that the bigger fish are gone.

I am of the opinion that the larger fish were preying on the smaller latterly, hence the perhaps rather small out-turn. During the five months I only found some ten dead ones which were picked out, they were in very good condition and appeared to have died from enlarged liver, with the exception of one which had his tail bitten off.

The Rainbow trout are doing very well and are of a fair size, one dead and one was found so far. I propose keeping the 250 in the Ponds for another three months or so, or until they reach a size of 4" or 5."

These are the figures:—

Took out of Top Pond	...	196	
" " Lower "	...	305	
Turned into Ambewella Stream			209
" " Rajah Patna "			40
Returned to Stewponds			250
Escaped			2
		501	501

Yours faithfully,

G. G. ROSS-CLARKE.

PRODUCE AND PLANTING.

KEEPING THEIR PACKERS UP.—In this review of the trade of India during 1898, Mr. O'Connor proffers comfort to Indian tea planters. He points out that last year the outturn of Indian tea was the largest on record, giving a total of 157 million pounds, being more than double the quantity exported thirteen years ago. When a limited market is found in conjunction with an unlimited supply, the inevitable result is a heavy fall in prices. Yet Mr. O'Connor would not have Indian planters despond. He recalls the fact that it took Indian tea twenty years to drive Chinese tea out of the market, and he reminds us that Indian tea is at present consumed in a comparatively limited area. A very large proportion of the white race of the world does not yet consume tea. Mr. O'Connor warns the planters—by the way, they are well aware of the fact—that in their efforts to force their way into these huge untapped markets they must be prepared for a struggle as strenuous as that undertaken by them when they entered the lists against China tea. But with courage and perseverance there is no reason why they should not forge ahead.

REALLY!—The writer on "Trade Topics" in "The Grocer" has the following:—"Now that the pound tea draft question is settled, it is not surprising to learn that those who proposed its abolition are, feeling the results of their ill-advised attempt to abolish it. At a meeting of one of the large tea-producing companies the other day, the chairman said there was no doubt that the falling-off in trade which they had experienced was due to the agitation in connection with the question. It would, of course, be wrong to rejoice too loudly over the victory which has been achieved, at the same time it is satisfactory to note that those who stirred the matter up have learned that they cannot attack the distributing trader with impunity. It is certain that only a few even now fully realise the importance of the issues involved in that struggle, but it is to be hoped that it will be very many years before we shall again witness such an attempt to interfere with the rights of such a large body of traders, as is the retail food distributing industry of this country." It should be noted that his majesty, the "distributing trader," must not again be disturbed in his beneficent work of distributing tea at very profitable prices to the consumer, and any further attempt to interfere with his right will—well, it is too awful to contemplate what might happen, so we will consider the incident closed.—*H. & C. Mail*, Oct. 27.

THE PUBLIC SALE DAYS.

A report has reached us to the effect that certain parties are agitating for some alteration of the days for the public auctions of Indian and Ceylon Tea in Mincing Lane. It is perhaps too much to expect that any state of finality will ever be reached in regard to tea matters, but as the changes proposed are in our judgment rather opposed to the best interests of the whole body of buyers and, therefore, indirectly antagonistic to the interests of the sellers, we make no apology for examining the arguments put forward pro. and con. more especially as we took considerable interest in the arrangement of the present system, and consider it too satisfactory to be rashly disturbed.

From a circular emanating from the secretary of the Tea Buyers' Association we learn that the present practice is objectionable to some of its members, but whilst we do not claim for the present arrangements absolute perfection, we should have been glad to know why and where-in it is objectionable, and this is not stated. There are manifest advantages to buyers in

knowing at the beginning of the week how much tea is to be offered during that week, as it will be evident to any one that no buyer will operate freely on Monday if he is not absolutely certain that similar tea from the same garden will not be in print the next morning for sale on Thursday. Such things have happened before today, when every importer of tea was a law to himself; and when, perhaps, well satisfied with the sale of his tea effected on Monday, he cheerily ordered another invoice to be offered on Thursday. Buyers generally do not like to be treated in this manner, and we think that over a course of years the importer would find such a course of action would destroy confidence. Take the Assam Company method of procedure for example. For years past they have regularly offered a catalogue of tea once a fortnight. Buyers know they will not have any more for another fortnight, and it is matter of notoriety that the relations subsisting between the Assam Company and their regular buyers in public sale is of a most friendly character. No doubt there are difficulties to be encountered in every human arrangement, and the efforts of those at the point of action should be to minimise those difficulties by effecting some general plans which on balance of advantages against disadvantages will show the largest surplus on the credit side. It is for this reason that we strongly deprecate any disturbance of the present system.

An ideal plan would possibly be to have one large sale at the commencement of each week, and no more for the remainder of that week, but in short winter days that would be clearly impossible, even if physically within the capabilities of buyers and sellers to get through a week's work in one day. But the next best thing is to have a large sale catalogued for Monday, and get on with its disposal as far as possible on that day, concluding automatically at four o'clock, and finishing what is left unsold on the following Wednesday. Buyers then know exactly what they have to deal with in the week, and the confidence they feel in the position of affairs enables them to act freely and boldly, which is clearly in the interests of the sellers. Gradually but surely during the last twenty years the tendency has been for less and less tea business to be done towards the end of the week. To offer a sample in a country town on Friday or Saturday means either that the local buyer has supplied his wants on the earlier days of the week, and now prefers attending to his own customer's wants; or if he does entertain samples the upset in a majority of cases is that he says he will wait to see what comes out of Monday's sale. Hence in the eyes of Mincing Lane dealers public auctions on Thursday and Friday, the purchases in which have to be forced on unwilling country buyers on Friday and Saturday are by no means favourably viewed.

For this reason we strongly maintain our opinion that the present system is the best that has yet been devised. If any small change were to be made it should rather be in the direction of discontinuing Thursday's Indian tea sale, and allowing whatever portion of the Ceylon sale of Tuesday was left over, to be finished on Thursday. But we deprecate such action as the Tea Buyers' Association contemplate in holding a large sale of Indian tea on Thursday; for the reasons we have assigned above we think it is foredoomed to failure.

—*H. and C. Mail*, Oct. 27.

THE KINTYRE TEA ESTATES COMPANY, LIMITED.

The third ordinary general meeting of the shareholders of the Kintyre Tea Estates Company, Limited, was held at the offices of the Ceylon Association in London, 61 and 62, Gracechurch street, on Wednesday, Oct. 25.

The CHAIR was occupied by Mr. G. A. Talbot, Chairman of the company.

The SECRETARY read the notice convening the meeting.

The CHAIRMAN, in moving the adoption of the report and accounts, said: The report which has been circulated among you will, I presume, be taken as read. It is with no small satisfaction that we are able to present this report to you, for if you look back upon the history of tea during the past three years you will observe that circumstances have occurred which have made it almost impossible to realise the estimates made when the prospectus was issued, and I think you will agree with me that in paying 8 per cent on the ordinary shares we have fully anticipated what was promised last year, and what many other companies were unable to perform. The circumstances which have led to the reduction of profit in tea are chiefly in the fall of price on the London Market, a rise of 2nd in the exchange, which has increased the cost of production by 3d per lb, and so reduced the profits, and the unfavourable weather of last year. The circumstances, though at the time they were looked upon as misfortunes, have really been blessings in disguise, for the fall of price on the London Market has tended to increase the consumption, and the rise in exchange has certainly stopped the further planting of tea in Ceylon, besides giving investors the advantage of what may be looked upon as a fixed exchange. This, in my opinion, is very much better than the uncertain one which was common when this company was formed, when the finances of India were more or less demoralised, and when it was felt that something of the kind was greatly needed. As regards the bad season, it has been the cause of the great bulk of cultivation being checked. When I was in Ceylon during the early part of this year I saw a good deal of tea planted on old worn tea-land that had been abandoned. There is no doubt that this tea must go out of cultivation, and if this is so, we must regard the production of tea as having reached its limits. This is a benefit for those who are able to produce tea, for with a gradually increasing demand, our prices are bound to be on a firm basis. Next we come to last year's working. There was a great deal of anxiety about what were called tea pests, but we are glad to tell you that in spite of this fear, we produced 570 lb. per acre as against 519 lb. for the previous year. Then a word about the cost of production. This has been reduced to 24 2-3 cents per lb. f.o.b., which, considering that this company holds two-thirds of its estates in Ceylon on the high-lying ground, I think you will agree with me is very good indeed. Our agents and our superintendents on the estates deserve our warmest thanks for their careful management, for it is chiefly through them that these better results as regards costs have been obtained. I must mention, however, that I think it will be extremely difficult, and, perhaps, impossible, to maintain this low cost, for, with the extensions in manuring that are desirable and the renewal of buildings, this rate, which is an extremely low one, may be exceeded. The amount of our profits, therefore, the rate of production

being fixed, depends on the price on the London market, as is the case with all producers. I think we may confidently expect that the prices will not diminish, in fact, we may reasonably hope that they will considerably improve. I now move the adoption of the report and accounts, and before putting it to the meeting I shall be very pleased to answer any questions, any shareholder may wish to ask.

The proposal was seconded by Mr. W. Nevett. In reply to questions from Mr. Fort, and Mr. Gibson, both of whom, in the course of their remarks, congratulated the company on its results, the Chairman stated, as regarded the great discrepancy between the income-tax for last year and for this year, the explanation was that on the one side the income-tax was worked on a three years average, and on the other that the previous two years income-tax came into the calculation. The cost of shipping the tea in Colombo is half a cent. per lb.

In reply to a question by Mr. Gibson as to the advisability of having an interim report and dividend, the Chairman said that he did not think they could hold out any hope as regarded the interim report. It was quite an unusual request, and he did not think it would be of much utility, in fact, if they took last year as an example, when there was a very bad season it would go very much against the shares. As regarded the interim dividend, it was customary for a good many tea companies to pay one, but he did not think either that it influenced the shares, or that it benefited the shareholders. However, the directors would consider the suggestion.

The CHAIRMAN then proposed that a dividend of 8 per cent should be paid on the ordinary shares. This was seconded by Mr. Baumann, and carried unanimously.

On the proposal of the CHAIRMAN, seconded by Mr. Nevett, the retiring director, Mr. Baumann, was unanimously re-elected.

Mr. Fort proposed, and Mr. Gibson seconded, the re-election of the auditor. The motion was carried.

The proceedings closed with a vote of thanks to the Chairman.—*Home and Colonial Mail*, Oct. 27.

THE WYNAAD TEA COMPANY, LD.

The following is from the report to be presented at the fifth annual meeting of shareholders, to be held at No. 20, Eastcheap, at the office of the Ceylon Tea Plantations Company, Limited, on Monday, 30th Oct. :—

The directors, in presenting to the shareholders the profit and loss account and balance-sheet for the year ending March 31, 1899, wish to explain that the reason the accounts are for eleven months only, is due to a request made by the managing director in India that the financial year in future shall finish at the end of March, instead of the end of April as heretofore. The working for the past season has resulted in a net profit of £728 2s 9d, after crediting the block account with the proceeds of tea sold from the Cootacovil Estate; this profit the directors propose to write off the debit balance of last season. The coffee crop turned out fully 51 tons, and was the largest gathered for some years, and the directors were fortunate in having sold it at the high figure of 78s c.i.f., before the great fall in the value of coffee took place. The pepper crop of about 14 tons was also sold for arrival at the satisfactory price of 45s 6d

per cwt., whilst the first pluckings of tea, viz., about 15 lb., from the Cootacovil estate from the 1895 plantings, realised an average of 7½d per lb. The net proceeds of tea, coffee, and pepper during the season 1898-99, after deducting proceeds of Cootacovil tea which has been carried to block account, amount to £3,957 2s 7d, and the expenditure in India to £2,413 11s 7d, leaving a credit balance of £1,543 11s on the season's operations in India. The manager in India reports condition of the estates as most satisfactory, and that the tea leaf is coming in so fast that further machinery for rolling and firing is necessary. He expects to obtain more than his estimate of 78,000 lb for the current season. According to present appearances, Mr. Walker estimates this season's coffee at 18 to 20 tons, and the pepper crop at about 20 tons. The prospects for 1900-1 are so promising that the directors confidently look for a yield of about 150,000 lb made tea, and a coffee crop of about 40 tons, whilst the pepper crop is likely to be quite equal to this season's yield, but, of course, these are only estimates which may be influenced favourably or otherwise, according to the weather. The directors have much pleasure in stating they have now completed arrangements with Messrs. R. and J. Henderson, of 7, Mincing Lane E.C., to finance the company as from April 1 last. These gentlemen have also undertaken to subscribe for the balance of the £8,000 6 per cent. debentures not taken by the shareholders. The directors and Mr. Walker have subscribed for £500 each, and the shareholders are now given the opportunity of securing a good 6 per cent investment with the option of turning their security into 10 per cent preference shares any time prior to the date of repayment of the debentures. The acreage under cultivation remains the same as last year. Dr. Innan retired from the direction during the early part of this year, and according to the articles of association, Mr. J. C. Sanderson retires from the board, and being eligible, offers himself for re-election.—*H and C Mail*, Oct. 27.

SUGAR AND OUR NORTH-CENTRAL DISTRICTS.

—In the note, written in connection with the lecture delivered by Mr. Ferguson in London, the local "Times" has the following comment :—

Sir C. Clement Smith's suggestion at the debate at the Royal Colonial Institute yesterday that sugar and palmyra should be tried in the North-Central districts is, doubtless, good advice as regards palmyra, but sugar requires a rich soil. The subject of cotton cultivation might also be considered in the near future; and the Agricultural Department may do good work in following the railway line through the Wannai and the rest of the comparative unknown country south of the peninsula.

NEPENTHES DISTILLATORIA.—Growers of these plants should include this interesting species in their collection. It was the first species brought to the knowledge of botanists, being found in Ceylon in 1674 by a Swedish physician named Grimm. Dr. Trimen, in his "Flora of Ceylon," says that it grows in large quantities around Colombo, usually in very wet places. He also says the stems are very tough, and are used as ropes. The pitcher is about four and a-half inches in length, one side being flattened between two ciliated ridges. The colour is for the most part green, but is thickly set with small dark-coloured glands. The lid is at first pressed down over the mouth of the pitcher, but later it stands erect. This species is, I think, synonymous with *N. khasiana*.—*F. T. S. in—Amateur Gardening*, Oct. 21.

REFORM IN THE TEA TRADE.

(Produce Markets' Review, October 21.)

DOCK CHARGES.

Some time back we printed a short comparison of the charges made by the London Docks and Wharves upon Tea, especially upon Indian Tea as compared with Indian Coffee. We now append a fuller table of the charges on each, calculated so far as possible upon the same basis, and it will be seen that a ton of Tea costs £4 0s 2d, and the same weight of Coffee costs only 17s 2d, or less than a quarter of the charge on Tea.

DOCK AND WHARF CHARGES ON INDIAN TEA IN LONDON.

Charges on one ton of Indian tea landed and sold at public sale, taking 20 chests to a ton :—

	£	s.	d.
Landing and Housing Rate, 1s 6d per chest	1	10	0
Public Sale charges, 4d per chest	0	6	8
Bulking and Taring each chest, 2s per chest	2	0	0
Thirteen weeks' Rent, 3d per chest	0	10	10

	4	7	6
Less 10 per cent	0	8	9

	3	18	9
Weight Notes	0	0	8
Warrant Stamps	0	0	9

£4 0 2

Note.—The Landing and Housing Rate comprises : Landing, wharfage, housing, separating into chops, weighing, average taring, furnishing lading weights, examining and turning out and in for damage, mending, laying down for private inspection, lotting, nailing down, placing in delivery pile, and delivery by land.

DOCK AND WHARF CHARGES ON COFFEE IN LONDON.

Charges on one ton (16 bags) Indian coffee, for the same period as tea, sold at public sale. There are no charges for arranging coffee for public sale.

	s.	d.
Consolidated Rate, including bulking and sampling, 8½ per cwt	14	2
Sorting and Lotting, 1½d per bag	1	8
* Seven weeks' Rent, 6d per ton	3	6

	19	4
Less 12½ per cent	2	5

	16	11
Warrant Stamp	0	3

17 2

If there is no bulking done the consolidated rate is 6d per cwt.

The Consolidated Rate includes : Landing, wharfage, weighing, gross, mending, housing, or piling, accounts of landing weights, original warrants, six weeks' rent free ; weighing on delivery, and delivery.

Least it should be thought that the comparison with Coffee is of an exceptional nature we have compiled the following table, showing what the charges are for the consolidated rate on other articles

of grocery produce, and it will be seen from this how enormous is the surcharge upon Tea :—

CONSOLIDATED RATES PER TON ON VARIOUS GOODS COMPARED.

Indian Tea (placed on about the same basis)	56s
Coffee	14s 2d
Refined Sugar	4s 6d
Currants	7s 6d
Valencias (½-boxes)	12s
Tapicca	8s 6d
Rice	3s 9d
Salmon (in tins)	4s
Sardines	5s 6d

It seems to us impossible to account for the extraordinary difference in the charges upon Tea, except on the supposition that an antiquated system of business has lasted longer than in any other goods, owing to the absence of competition, and of modern methods of trading in Tea. Thirty years ago the wholesale price of Tea in bond, on the average, exceeded 1s 9d per lb., while it is now less than 8d, and, probably, if we went back sixty years the difference would be still more striking. Yet, as compared with the charges of a generation ago, we believe the dock and wharf rates on Tea in London to be, if anything, higher than they were then.

TEA BONDED WAREHOUSES.

It is always said that competition is the life-blood of business, but if so, the Tea warehouses are in a bad way, for there is no competition whatever between them. A good many years back the system of secret discounts to importers was introduced, which was responsible to a very great extent for the cutting down of the wages, which led to the great Dock Strike of ten years ago. The system of discounts is in itself a most objectionable one, for there can be no object in sending a bill for £100 and on a subsequent occasion returning £10 or £25 out of it, unless it be that the original invoice is intended to be forwarded to some one who is not to receive the discount. After the Dock Strike, the dishonest nature of the system became so apparent, that the Dock Companies felt themselves obliged to publish their discounts in their rate books, so that the Tea growers, when they sent Tea to this market, could have an opportunity of seeing that only the proper prices were charged to them. The publication of the discount, however, was with the condition that it should not be given away, so that beyond the Tea planters knowing that they are charged 10 per cent more than their agents really pay, there is no gain to them in the publication, as is the case with similar pickings in freights and insurance charges.

TEA CLEARING HOUSE.

In order to bring about greater fixity in the charges on Tea a sort of Trade Union was formed, at the time we speak of, between the importers, the warehouse-keepers and the wholesale trade. By this arrangement a Clearing House was established, which somewhat facilitated the daily work of getting Tea through the Customs, and the members agreed, first, that they would only buy Teas lying at specified warehouses, and secondly, the warehouse-keepers agreed that they would only charge certain rates, allowing a discount, first off the importers' charges, and secondly, off the dealers' charges, in both cases on the conditions that these discounts should not be given away. The Board of Customs was also brought upon the

scene, and has since practically refused to fully license new bonded Tea warehouses, so that as a matter of fact, it is practically impossible at the present moment to obtain a new bond for the warehousing of Tea in London.

The result has been unsatisfactory—though at the time well intended, because the object was to protect the minimum wages of the dock labourers. The combination has now clearly become injurious owing to the changed circumstances of the case. The distributor can no longer afford the enormous charges made, and the whole trade, whether importers or wholesale or retail distributors, recognise that the cost of distributing Tea is enormously out of proportion to that of distributing any other article of grocery produce. After carefully considering this question, we can only arrive at the conclusion that this state of things is due simply to tradition, and that simplification and much greater cheapness are possible in dealing with Tea.

CUSTOMS RESTRICTIONS AND SUPPORT OF THE COMBINE.

The first step towards modernising the Tea trade is to obtain greater elasticity in the Customs regulations. In the first place, what reason exists for insisting that the duty on Tea shall only be payable at bonded warehouses? It is obvious that this at once limits the trade to those happy warehouse-keepers who were the parties to the Tea-clearing warehouse scheme. So far as we can judge, there is no reason whatever why the Customs should not gladly welcome the payment of duty on Tea over the ship's side, as is (we are told, but we do not know) the practice with other goods. A covering amount should be paid as the cargo was put over into lighters, and an officer should then attend at the destination of the Tea (at the cost of the owner, of course) and collect the balance, if any be due or return it if the duty be overpaid. To the commercial mind it appears that this would be an obvious gain to the Revenue; but the authorities, on the other hand, appear hitherto to have thought it more advantageous to insist on Tea being warehoused—to take charge of it in detail, and to look after each particular chest for months and years at a time. It is quite clear that until our present restricted Tea warehouse system is broken through, our Indian and Ceylon planters will not have a fair chance in this matter of charges. They should at once bring pressure publicly to bear on the Customs, to insist on sufficient new bonds being granted to ensure free competition in Tea warehousing—at present a highly profitable monopoly.

The *Investors' Review* has lately shown in a series of articles how largely the planters' agents in this country are interested as owners or shareholders in Tea warehouses, and therefore in the maintenance of the present system. The matter will thus be a difficult one to fight, more especially as the wholesale Tea trade have also become interested, through the discount system, in the maintenance of the existing plan. We think, however, they are open to reason on the matter, for their gain from this source is absolutely trivial when compared with the complications and high cost of the system of selling Tea, which are rendering the wholesale Tea trade so difficult.

WEIGHT NOTES AND WARRANTS.

Apart from warehouse charges in themselves, there are many details in the working of the trade which are quite of an exceptional and unnecessary character. There has been no change in the

number of packages entered upon a warrant since the time that Tea was three times its present price, and this seems simply absurd. The old system was to have six chests upon a warrant, and the present proportionate document, therefore, should have placed on it eighteen chests or thirty-six half-chests, as representing the former value of a much smaller number of packages. The warrant in Tea is still accompanied by a weight note, a system which has been given up in every important branch of the grocery trade, though it is still kept up in some minor commodities such as spices. The issuing of a weight note, of course, means that the work in connection with Tea is done twice over, for which there can never have been any reason that we can see, but which is, at any rate, a simple waste of time and of money at the present moment. We are aware that the weight note in its present form is considered to be necessary as a security for the deposit paid on the purchase of Tea. We are not, however, aware that any particular sanctity is attached to the deposit system in itself, as it also has been abandoned in the large grocery trades. Supposing it, however, to be continued, security might readily be given by a coupon attached to the warrant. The weight notes are not only unnecessary in themselves, but they embody an immense number of equally futile details. For instance, they give full import particulars in excessive detail, either in writing or printing, which also appear on the warrants. In addition to this, the weight note is supposed to bear three separate signatures, and often does so, and it then forms a separate contract for the sale and purchase of each six chests, being signed by all the parties. In addition to this, each weight note works out, in detail, for every six chests of Tea, the weight and price at so much per pound. From this result the deposit is deducted separately, and the lot money, 4d, is then separately added to the total. The weight notes give the particulars of the country of origin of the Tea, the name of the importer, the date of importation, the variety of Tea, the name of the ship, the name of the captain, the port of origin, the name of the selling broker, the date of sale, to whom the warrant is issued, the date of the prompt and of the commencement of rent. Several of these particulars are repeated twice over upon this valuable document—the weight note—though they all appear on the warrant also. What could be more childish and absurd than all this? There is no doubt that a very considerable economy in money may be effected by enlarging the number of packages on the warrant and by abolishing the weight note altogether. This is a simplification which forms, in our opinion, the initial step towards the cheapening of the distribution of Tea. To those accustomed to modern systems of trading, the weight note appears simply a farcical, though unfortunately a costly, absurdity. If the Coffee trade can be conducted with the utmost ease without such documents, why cannot the same be done with Tea?

DELIVERY ORDERS FOR CLEARING.

Further great simplification might be caused by using delivery orders for clearing and delivering tea, as is done in other trades. There is, however, a considerable practical difficulty in this matter in the case of tea. Many years ago Mr. Gladstone, as Chancellor of the Exchequer, in one of his great Budgets freeing trade from Customs imports, unfortunately made a detailed change which was worked a great

deal of mischief, by imposing a penny stamp on delivery orders for goods issued on warehouses where rent is taken. Tea at that time was delivered in great detail to the retail buyers, who kept stock in bond in London, often for long periods, in the charge of the wholesale dealers. This system still continues, and the quantities in which tea is cleared are proportionately smaller than is the case with other articles of grocery produce. Representations were made to Mr. Gladstone as to the injurious bearing of the penny stamp on delivery orders in the case of tea, and it was agreed that the warrant stamp of 3d should, as a compromise, cover all deliveries made on the face of that document. It has been argued over and over again at the Board of Inland Revenue, that the stamp having been paid on the warrant as a compromise for separate deliveries, a penny stamp should not be required when separate pieces of paper are used for delivery orders, instead of the deliveries being written oil on the warrants themselves. The authorities at Somerset House, however, held a different opinion, and it has not been considered worth while to go to law to test their right to make the charge though it appears to be very doubtful. The result of this is the maintenance of an extremely complicated system in the clearing of tea. The warrant, with the order to deliver written upon it, has to be lodged at the Clearing House, from whence it is sent on to the wharf, and subsequent to the delivery of the tea, the warrant is returned to the Clearing House, from whence, in due course, the wholesale dealer fetches it back. The delays and expense caused by this little obstacle to business, devised by the perverse ingenuity of our Revenue departments, are inconceivable to those who have been accustomed to the broader, easier, and far cheaper system used with all other grocery goods. If it were not for this stupid piece of obstruction on the part of our Government to a rational system of delivery, there would be no necessity whatever for such an institution as the Clearing House, and the home trade would not only move as smoothly again but be conducted at much less cost.

DELAYS IN GETTING WARRANTS.

The warrants and weight notes are not only obsolete and obstructive in themselves, but there is a quite objectless delay in obtaining them. In all other trades that we know of payments for warrants as they are required are made to the actual holders of the documents. A notice is sent them in the morning that such-and-such warrants are required. They are at once sent on by hand to the applicant, and handed over in exchange for a cheque. In Tea, this is not the case, and endless loss of time and temper results. The importers should do one of two things: either trust their brokers with their warrants if they cannot manage the details themselves, or else accept direct payments. Their can be no doubt that the second is the proper plan to adopt, and it is surprising that the wholesale Tea trade have not long since insisted on the removal of this great hindrance to business. It is true that a poor compromise was adopted some years back, by which it was arranged, that when payments were made to the brokers before noon, the brokers would procure the warrants from the merchants by 2 p.m. This plan constantly leads to a day being lost in the delivery of Tea, to the loss of both the wholesale

and the retail buyers. We, are, of course, fully aware that one cause of these delays, is the fact that such a large proportion of warrants are pawned by their holders. When they are their own property there is no objection to this than to any other legitimate pawnbroking operation. But when the pawners are not the owners of the goods other considerations arise, and after the sale of Tea, the original owners have no right to leave it in pawn than they have to mortgage some one else's house.

THE PUBLIC SALE SYSTEM.

The system of disposing of Tea almost exclusively by public sale lends itself to much criticism. It will be seen above that the cost of arranging Teas for public sale is no less than 4d per chest, so far as the docks and wharves are concerned. For the work done, the charge is not out of the way, but the question is whether the whole system might not be greatly simplified and more closely approximated to other cognate trades. First, there is the payment to the brokers for the hire of rooms, and for the printing of the catalogues, and for their distribution, often to a very unnecessary extent. Tea catalogues are printed in a different way to those current with other groceries. We do not know whether the system of printing and the sort of paper is more or less costly, but this deserves looking into. There is one very obvious source of waste in Tea catalogues, which are often very small documents, but in which two pages are always given, first for the names of the brokers and rough particulars, and next for the conditions of sale, which are given in full in every catalogue. These particulars it is surely unnecessary to print in every catalogue in detail, especially when, as they often do, they take up from 20 to 50 per cent of the paper used. The catalogues are not, it is true, in such minute detail as was the case years ago, but it is questionable whether this does not still admit of a great deal of simplification.

The brokers' charge for public sales, in addition to their brokerage, is 9d per lot of six chests. It would be interesting to compare this with the public sale charges on other Mincing Lane produce, and the materials could easily be collected. On 2,000,000 chests a year sold publicly, 9d for six chests represents a cost of £11,000.

A great deal of the work connected with catalogues is due to the separation of the teas into miserable little lots, which are supposed to be of different qualities, though the teas are very frequently all plucked at the same time, from the same bushes, and on the same gardens. Owing to the inefficient appliances in India, Indian teas have, as a rule, to be rebulked in London, and while this operation is being conducted, we feel sure it would be in the interests of every one concerned—planters, importers, and dealers alike—to put an end to these separations, and to make larger breaks for one average sort of tea. The cost to the wholesale trade of distributing these trifling lots is out of all proportion to the profit to be obtained upon them. Probably the old days when China teas reached us in breaks of 300 to 600 chests, which could be judged of by a single small sample, will never return, but the Indian tea trade will never be in a satisfactory condition until a minimum parcel of one quality should be represented by quite 100 chests. This cannot be done till teas are bulked at the gardens, and so tared that each chest does not require to be turned out here for separate taring, at an enormous cost to

the grower, which only entails unnecessary labour on the home trade, with no advantage in return.

HUGGER-MUGGER AUCTIONS.

The system of sampling the public sales on the part of the trade is a very cumbrous one. In other business the samples are on show in the broker's sale rooms, but that is mostly in the case of commodities where elaborate tasting is not so essential as it is in the case of tea. It has been suggested that it would be more convenient if the public sale samples were sent round to the trade in time for the sales, by the bonded warehouse-keepers and payment taken for them at some average price, or so many pounds of "returnis" given. At present the whole number of the representatives of the wholesale dealers attend at the different bonded warehouses, and the supply of the separate samples to them creates an immense amount of expense and of waste of time. We do not suggest this as a definite solution but only as one that might be considered, now that the new Tea Buyers' Association is engaged in going into all such questions. As it is, the time allowed the trade for valuing is quite insufficient, and only the largest houses can cope with the samples, and then only hurriedly. The interests of growers must often be seriously affected by this excessive haste.

As we pointed out some time back it appears certain that much of the present great depreciation in the value of tea, as compared with former years, is due to the system of unrestricted public sales. Whether the teas are or are not wanted, they are pushed upon the market in constantly increasing quantities, and fall to a dead level in price in consequence, because it is not worth while for anyone in this country to stock more tea than they can possibly help. It is our firm conviction that what the Indian tea planters have been long trying to do, that is abolishing what they erroneously call the Mining Lane monopoly, is the source of half their troubles. In former days when the varieties and qualities of tea were far less than they are now, it was worth the while of an intermediate class, acting as merchants here, to buy up suitable teas, and to wait for markets, so that the prices were equalised. At present this class of dealers practically confine themselves to hand-to-mouth purchases, for they can always get plenty of supplies at auction, and there is no reward whatever for holding larger stocks than are sufficient for a few days' trade. So far as we know, there is no other article whatever, which taste and fancy so largely enter into, which is sacrificed in the same way as Tea is, in this hugger-mugger without reserve system. In years past we have strongly advocated public sales for Tea, as the only way to fix values, and to this we fully adhere, if they are supplemented by large private transactions, conducted in a more leisurely way. The Indian and Ceylon trade can never be on a satisfactory basis until the public sale system is largely supplemented in this fashion.

BULKING AND TRADING IN INDIA.

We alluded above to the great cost inflicted upon the Indian planters, through the necessity for bulking and for separately taring their Teas in this country. Some progress has been made with regard to bulking abroad, but it is inconceivable here why the system has not become universal. Years ago we heard the old excuse about the dampness of the climate and the difficulty of keeping Teas; but if the facts are as alleged, the difficulty can easily be remedied by such simple appliances

as hot-water pipes. Then again, as regards the taring of the teas, the smaller gardens no doubt have to rely on rough native labour, and this is given as an excuse for the chests not being cut to scale. The excuse seems to us totally insufficient, and we can only ascribe the continuance of the existing system to ignorance. In these days when metal chests can so easily be obtained, as well as the beautifully-made "Venesta" and other artificial wood chests, uneven tares seem simply inexcusable. It pays our Sugar refiners to import ready-cut wood for such a cheap commodity as theirs, and when a single manufacturer requires 40,000 or 50,000 cases a week of the size of a tea chest, it surely would be worth the while of Indian planters to import either the "Venesta" packages or wood cut in proper shooks from other countries, in places where the native labour and the appliances are so deficient as they appear to be in a vast number of cases. The planters also go far to necessitate rebulking in this country by the excessive subdivision of their teas into different sized leaves. This can only be effected by a costly system of sifting, in addition to the exposure of the tea to friction, which breaks a large portion of the leaves, and turns them into comparatively waste dust or broken leaf. We have long held that the planters would do far better to buy a reasonable-sized grocers' bulking and cutting machine, and then make much larger breaks of an average quality. The cost would be less, and, we believe in the long run, the relative price would be higher.

INCREASING PRODUCTION, LOWER PRICES, AND THE ARTIFICIAL RUPEE.

The production in India, Ceylon and Java, is consequently increasing, for the fresh plantings are year by year coming into bearing. Even if another tea plant were not planted for the next five years, the increase would still continue from previous sowings. The consumption of tea in this country has reached its limit, and the next great consuming country—the United States—uses only something like one-sixth of what we use, and is at present greatly wedded to the flavoured China teas. The same is the case in Russia, and although we hope, and believe, that Indian and Ceylon teas will readily make their way in both these countries, the demand cannot be important for years; its progress is not quick, and the increasing supplies must therefore continue to deluge this market. The action of the Indian Government in artificially fixing the exchange value of the rupee at the rate of 1s 4d, when the intrinsic value of the coin is something about 11d, is also most injurious to the Indian tea planters. In these depressing times it must to a large extent tend to ruin our own growers, or to divert the trade to the common tea of China, because China owing to the unrestricted exchange for the dollar, enjoys an advantage of 2d in every pound of tea. While the possibilities of economies in the trade are great, we fear that the possibilities of decreasing prices are even greater, so that the question should be actively taken in hand. It is, therefore, obviously to the interest of the whole trade to take up tea reform in earnest. It is possible that the result of the coming depression will be the extension of something like the Central Factory system. If so, the small gardeners would cease to manufacture tea, and would sell the green leaf to the larger operators, who can work better and more economically than the small growers. This is the system which long usage has established in China, and it is already beginning in India. These latter

changes, however, are matters for the future, and the present necessity is for a simplification and modernisation of the tea trade, such as will greatly reduce the present unnecessarily high cost of distribution.

CONCLUSION.

In the above remarks we have given a short outline of the main changes required whether at home or abroad, for it matters little which section of the trade is benefited so long as expenses can be lessened. The necessity for reform must come home very forcibly to the producer, in consequence of the present great depression in values. It is true that, for temporary reasons, very common teas have recently very considerably advanced, but we do not think that this can possibly last for long with the supplies coming forward. If it do so, and the price of common Indian tea is maintained, we shall shortly be swamped with common China Congou, which will bring prices once more down to a lower level. If there is no hope for a rise in the price of tea, but rather a strong prospect of a further fall in it, the only way to save the planters from ruin is economy in production and distribution. The mixture of the two branches of the trade in the above remarks is apparent and not real, for we hold that the whole tea trade is organised far too expensively, for the present scale of prices, and that economies in cost in any direction will benefit all sections alike.

WILD AND PLANTATION CINNAMON FOR EXPORT.

The following circular has been issued by the Customs:—

H. M. Customs, Colombo, 9th November, 1899.

It having been brought to notice that wild cinnamon has been entered for export as cinnamon, it is hereby notified that from this date the description "Cinnamon" will not be admitted at the Customs and Exporters must declare the bark as being either "Plantation Cinnamon" or "Wild Cinnamon."

The attention of Ships' Agents is requested to the rule that the description of goods in the "Outward Contents" must correspond with the description in the boat notes.

H. L. MOYSEY, Principal Collector.
The Steamer Agents, Colombo.

SNAKES FOR THE PARIS EXHIBITION.

The Portuguese barque "Atlantico," from Para to Brazil, has reached New Orleans with a cargo consisting entirely of snakes, valued at fifty thousand dollars. They were gathered along the Amazon River, and include Boa constrictors thirty-three feet long. They will be shown at the Paris Exposition. French snake-charmers own the collection, which represents the labour of twenty-five years spent in gathering the rarest specimens from America, Asia, and Africa.—*East African and Uganda Mail*, Oct. 20.

THE MINERALS OF CEYLON.

Mr. Archibald K. Brown, a mining expert of considerable experience and influence, who is at present on a visit to Ceylon is anxious to obtain a concession from Government and if it is granted to him he points out that it will cost the Government nothing, as he is willing to bear the whole cost of prospecting operations throughout the island. From a contemporary we learn that Mr. Brown has already been to the Colombo Museum where he was favourably impressed with a good many specimens of the stones and ore he

saw there, and he has interviewed some of our local experts. He was a little surprised that so little was known in Ceylon about its mineral capabilities.

MORE LIGHT ON THE TEA QUESTION.

We have already referred more than once to the complaint made by cyclists and others as to the difficulty frequently experienced in getting tea served at country inns. A correspondent now comes forward with what he claims to be an explanation of the reluctance of inkeepers to supply anything except beer and other alcoholic liquors. He says it all comes of the tied-house system. Many a publican has tried to improve the character of his trade by selling something else than intoxicating drinks, and as surely as he succeeds the sale of beer falls off. Then comes the brewer's agent, who reminds the publican he is there to sell beer, and that if he allows the brewer's interest to suffer, someone else will be found to do the work better. Many a publican is said to have been turned out of his house for this reason, and this correspondent declares that it is because the publican is afraid to supply it that people find it so difficult to get a cup of tea in a tied public house.—*Home & Colonial Mail*, Oct. 27.

PLANTERS' MEETING IN CENTRAL AFRICA.

(*Central African Times*, Sept. 30.)

In response to several requests an informal meeting of the Chamber of Agriculture and Commerce was called for Monday afternoon, 18th September, to meet the Mlanje planters who had come in for the Agri-Horticultural Show.

The Chairman in his opening remarks explained the object of the meeting and stated that it was a quite informal and not a regular meeting of the Chamber. It had been suggested that a meeting between the Mlanje men and the Chamber would lead to good results as there were many questions of common interest which were ripe for discussion.

Mr. Bradshaw then referred to the name of the association and stated that he was in favour of a Planters' Association such as they had in Ceylon and India. He did not doubt that the Chamber had done good work in the past, but he thought it would be much better for the country if it were a Planters' Association. At present there was a certain confusion of interests, whereas planters as a body would be more able to do good work for the industry. If a purely Planters' Association were formed he would be one of the first to support it for all it was worth, but he did not see his way to support the Chamber on its present footing.

The matter was then discussed by those present. Mr. Moir said he agreed pretty much with all that Mr. Bradshaw had said. He recognised the good work which had been done by the Chamber and he thought it had fully justified its existence. At the same time if it were thought that it would better fulfil its functions as a Planting Association he was also quite willing to go in with the proposal.

Mr. Israel agreed with the proposal to change the name and thought that it would be better to have two separate Chambers, one for the trading interest and one for the planting interest.

Mr. Moir then referred to the new Mining regulations and pointed out how they would affect certain titles. The position of such titles was not clear and he suggested that the Chamber Committee should go into the matter and make it clear otherwise it might seriously affect the titles of many holders of land.

The Chairman pointed out the danger to the growing tobacco industry in B. C. A. by the proposal of the Rhodesian Legislative Council to tax tobaccos.

Several other matters, such as Labour going south and the need of the natives being made to work for their taxes, or the tax being raised were referred to, and after an interchange of views on these and other questions the meeting terminated.

COCHIN MARKET.

Cochin, Nov. 11th.

C. N. OIL.—As anticipated in our last this staple has made a slight advance, and the closing quotations today are R88.12 to R89 per candy. A large quantity of oil is booked for New York by one of the steamers of the Indian-American line due next month. The market in London is also firm and Cochin oil is quoted at £29 10s 0d. for spot and £26 10s 0d. for January-March shipments c. i. f. per ton.

COIR YARN.—By the English mail of 20th ultimo particulars of a public coir sale held in London on that date were received. The quantity of Cochin yarn brought forward was only 212 bales and two ton in dholls and the prices realised were decidedly in seller's favour. Locally supplies arriving from the interior continue to meet with a good demand, but prices shew no change.

ROPE YARN.—Contracts are reported at higher rates and the market is firmer. We quote today assorted R36.46 per candy baled weight.

COIR ROPE.—Extreme prices were realized for the small quantity of Cochin rope offered at the last sale owing to limited stock. Early shipments from this side will most probably shew very favourable result. We quote here today R8 to R8.8 per cwt.

COIR FIBRE.—Picked R19.20 per bale of 200 lb. —*Cochin Argus*, Nov. 11.

RUBBER CULTIVATION IN CEYLON.

M. Fernand Vivier has arrived in Colombo by the M.M. ss. "Tonkin" from Singapore, and is proceeding home by the ss. "Polynesian." He is interested greatly in the process of extracting rubber from young stems, and of preparing it by a purely mechanical process the bark of young trees. He (with his partner, M. Emile Deiss,) is dealing with a new process and has taken bark (specimens of which can be seen at the *Observer* Office) from the *Willoughbeia firma*. M. Vivier is now on his way to Paris, but will return to Ceylon in January, when he hopes to be able to meet planters and merchants interested in rubber cultivation in Ceylon with the view of introducing the new process which, he claims, will add materially to the pecuniary advantages to be derived by those concerned in the cultivation of rubber trees.

MINOR PRODUCTS REPORT.

CARDAMOMS.—The moderate supply in auction today met a poor demand, and a small proportion found buyers at about 2d per lb lower rates. The following were the prices paid:—Ceylon-Mysore, good bold pale, 3s 8d to 3s 9d; medium ditto, 3s 2d to 3s 5d; small to medium, 2s 5d to 2s 10d; small pale, 2s 3d to 2s 4d; very small pale, 1s 10d to 1s 11d; shelly and split, 1s 8d; seeds, 1s 8d to 2s; wild Ceylon, 10d; Ceylon-Malabar were not in demand.

CINCHONA.—The average percentage of sulphate of quinine in the bark to be offered at Amsterdam on November 2nd, is 5.32 per cent against 5.25 per cent in the September auctions, 5.60 per cent. August, and 5.2d per cent for the ten auctions of 1898. The 6,141 packages to be offered contain 561,330 kilos of Java bark, with a total of 26,850 kilos (939,750) oz. The only offering in auction was a parcel of six bales red bark, dull broken quill, for which 4½d was refused.—(From the *Chemist and Druggist*, Oct. 28).

CEYLON TEA.

THE NEW TARING ORDER :

HALF-POUND AND MORE TARERS TO BE USED.

LONDON, Nov. 15 (received 12 p.m.).

The Customs have decided to issue an order for Taring teas with an added half-pound weight in the scale: and increasing the number of tarers taking for averaging. The order takes effect from the 1st December.

"CORN" RUBBER.

FROM a French paper of date in October, we make a translation of what seems to be the latest information respecting "corn" rubber. In view of the great demand for the article, few products are more adulterated in various processes of manufacture than rubber; and here we have one of the processes by which it is hoped to get a substitute:—

For some years a kind of rubber has been made from Indian corn (*maïs*); now it is corn which will soon give the precious substance. Corn-rubber looks remarkably like the ordinary reddish-brown rubber, but it has not yet been found out how to make it as resistant to heat as its predecessor. Corn-oil, which is the first constituent of this false rubber, is not readily oxidized; and, without knowing whether this is a fault or a good quality, they say that, thanks to this peculiarity, the new product will always preserve its suppleness and will not crack. The public has not yet been able to judge, as this rubber has not reached the trade; chemists wish to continue their researches until success is assured. The corn-oil is taken from the germ of the grain and not from its cover. The starchy and glutinous parts of the seed served in the manufacture of starch or of glucose while the oil of the corn was practically useless.

Hence it is thought that the new rubber could be put on the market at 33 centimes (3d.) per lb. Already it can take the place of rubber in cycle tyres or linoleum or for cheap toys; but will not do for scientific or industrial apparatus.

It was started in Chicago and will probably make its *début* at the Paris Exhibition.

In another Paris paper, there is the following reference to gutta-percha of some local interest:—

THE CULTIVATION OF THE EUCOMIA.

M. Dybowski, Director of the Garden for the Colonies, has given the Academy of Science an interesting note on the possibility of obtaining a very superior gutta-percha from a shrub native of the North of China, called *Eucomia*. Hitherto the production of this article (which fetches often 12s. the lb.) has been confined to the islands of Sunda. The *Eucomia* can be grown in very temperate climates. The gutta extracted from the fruits is of very good quality, and the fruits contain 28 per cent of gutta. The leaves and branches also contain it and can be utilized.

THE CAROLINA TEA COMPANY OF CEYLON.

SEVENTH ANNUAL REPORT.

The following has been published as the annual report:—

Your Directors beg to submit the Balance Sheet and Profit and Loss Account for the year ending 30th June, 1899.

The surplus of £8,236 11s 8d is proposed to appropriate as follows:—

Net Profit ..	£8,236 11 8	
Amount at Credit of Ordinary Shares ..	112 18 1	£8,349 9 0
Debitent Interest ..	£2,450 0 0	
Dividend on Ordinary Shares at 7 per cent per annum ..	3,500 0 0	
Proposed to place to Reserve Fund ...	1,200 0 0	
		£7,150 0 0

Balance carried forward to the credit of the Ordinary Shares ..	£1,199 9 9
---	------------

The actual tea crop from the Company's properties was 961,757 lb. as against an out-turn for the previous year of 939,491 lb., in addition to which 32,862 lb. tea were made from purchased leaf.

The cost of the tea free on board Colombo, was 4'6d per lb., as against 5'10d for the previous season.

The average gross sale price in London was 7'65d as against 8'02d in 1897-1898.

The fall in price as compared with last year was to some extent owing to the disorganization of business brought about by the dispute between buyers and importers on the subject of the condition of Auction Sales. This has now been arranged, but importers of teas generally have suffered in the matter.

The crop of cocoa has increased from 441 cwt. to 555 cwt.

The season's working of the estates shows a very substantial increase in profits over those of the previous two years, notwithstanding that the average sale price of the teas has declined, proportionately with the drop in values of Ceylon teas generally, and in the face of a continuously advancing average rate of exchange. This result has been obtained by means of increased crops, as also by large economies effected in expenditure on the estates and in Colombo.

Your Directors are pleased to add that these economies have been arrived at without at all interfering with the continued thoroughly satisfactory condition of the properties.

The following statement will be of interest as showing the progress of the estates:—

Season.	Tea in full and partial bearing. Acres.	Actual Crop from Company's estates. lb.	Cost per lb.	Average Sale price. Gross.
			d.	d.
1895 ..	1,987	916,715	4'43	8'35
1896 ..	2,046	930,066	4'88	8'26
1897 ..	2,116	939,491	5'10	8'02
1898 ..	2,233	961,757	4'61	7'65

The total area of land now under cultivation is 2,602 acres, comprising:—

Tea in full bearing ..	1,784 acres
Tea in partial bearing...	449 "
Tea not in bearing ..	208 "
	2,441 acres
Cocoa, Coffee, &c ..	161 "
	2,602 acres

The sum of £1,200 has been added again to the Reserve Fund, bringing up the total of this account to £8,400.

Your Directors have resolved to carry forward a large sum this season, having under discussion at present representations from the General Manager in Ceylon that considerable additions be made to accommodation and machinery at the principal Factory of the Company, to provide for the proper manufacture of the constantly increasing crops of tea.

Your Directors have to express their entire satisfaction with the working of the staff in the Company's employ.

The thanks of the Company are due to the Colombo agents for a modification in their scale of charges to the advantage of the Company's which has been accepted by the Directors.

It is with great regret that the Directors have to report the resignation, owing to failing health, by General Hopkinson, C.S.I., of his seat on the Board. It is not proposed in the meantime to fill up this vacancy.

The Directors retiring by rotation are Mr. C A W Cameron and Mr Evelyn Heseltine, who being eligible, offer themselves for re-election.

C. A. W. CAMERON, Chairman.

London, 18th October.

MESSRS. SCHIMMEL & CO. OF LEIPSIK AND NEW YORK.

THEIR ASSOCIATION WITH CEYLON.

We have received by the German mail a report from the above firm, which opens with the remark that: "the progress of all branches in the German Empire, continues unabated;" reference is made to the operations of the Company in the United States, Brazil, Mexico and South America, as well as Europe: and they add:—

We would further mention that, taking into account the importance of the English market, we have opened, from the 1st of October, a branch office at 27, Mincing Lane, London, E.C., under the management of Mr. H. Breitenstein, late manager to Messrs. Volkart Bros. of Galle, Ceylon. This branch will be exclusively devoted to the sale of the products of our Leipzig and New York works and to the general furtherance of our interests in Great-Britain.

With regard to cardamom oil, the following particulars are given:—

E. J. Parry contributes a paper on the oil of Malabar-cardamoms. The author has prepared and examined the oil obtained from two different varieties, known respectively as Ceylon-Malabar and Ceylon-Mysore-cardamoms, and has found them identical in point of odour. Their physical properties, also, were almost the same.

CINNAMON.

This occurs in the course of the report:—

The quotations of cinnamon chips have, during the last few months, gradually risen in Ceylon to 3½d. per lb., and the exports are nearly double those of the corresponding period of 1898. This would imply, either that active speculations are carried on, or that new openings have been found for this article.

The exports of chips were:—

	Jan. to	July	lb.,
from 1st	25th	1899:	1,159,761 as against
" 1st	" 25th	" 1898:	677,656 "
" 1st	" 25th	" 1897:	666,454 "
" 1st	" 25th	" 1896:	450,348 "

This increase seems to have been at the cost of a reduction in the exports of quills, which, in the above named period, fell from 1,123,653 lb. in 1898 to 886,132 lb. in 1899.

The shipments of chips were distributed as follows:—

To United Kingdom 444,349 lb.; to Germany 349,096 lb.; to United States 28,000 lb.; to Austria 105,926 lb.; to Italy 100,320 lb.; to Belgium 95,760 lb.; to France 1,750 lb.; to Holland —; to Spain 18,200 lb.; to Australia 15,120 lb.; to Turkey —; to Africa 1,240 lb.; Total: 1,159,761 lb.

According to these figures, Germany now occupies the second place. The bulk of the German imports, of which a full third comes to our firm alone, would appear to serve for the preparation of Ceylon cinnamon oil.

CITRONELLA OIL.

Since our last Report, the value of this important article has slowly declined by a further 10 per cent, and has now reached the lowest point within our knowledge.

The new variety of citronella oil, which we have recently introduced, is being distilled in Java exclusively for us. Its cost is almost twice that of Ceylon oil, but the last-named cannot be compared with it, and, in respect to strength and sweetness of aroma, it throws all other varieties into the shade. As a result, this oil has found so many buyers, that there can be no question of the accumulation of considerable stocks.

CHINA AND JAPAN TEAS.

—China Overland Trade Report, Nov. 4.

RUBBER AND PLANTING IN BRITISH CENTRAL AFRICA

MLANJE, Oct. 21st.

THE CULTIVATION OF RUBBER

would seem to deserve the serious attention of the capitalists, for there appears to be no limit to the demand and increasing uses to which this product can be put; and in the course of years, not very many I should say, the present supply must become very limited. I have read with much interest the articles appearing in your *Tropical Agriculturist* from time to time on this subject. I shall now venture with a few remarks on the subject myself.

Central Africa, from what I know of it, and what I have read, does not furnish a vast or unlimited supply of rubber vines or trees. The whole country from north to south, and from east to west, is a bush-grass field, as one may call it, covered with native grasses with single fire-proof trees standing in it from 10, 20 to 30 yards apart and on many places thinner; and the bulk of the country has no trees at all. The forests are few (very limited in extent) and usually only in gullies and strips on the sides of the higher ranges of mountains. Stanley's dark forest, of course, is an exceptionally large piece of the continent.

Now the bush country contains no rubber-yielding vines or trees except by the sides of some streams which have a small bulk of trees left by natives to conserve water, so it is not difficult to see that the supply of

RUBBER FROM AFRICA CANNOT LAST

especially owing to the wasteful way in which it is collected.

There are only two vines in British Central Africa from which rubber is collected by natives, viz:—*Landolphia Florida* and *Landolphia Pertersiana*, very small delicate vines, only to be found in forest which the bush fires don't run through. Traders are offering 1s to 1s 6d per lb. for this rubber and engage squads of men to search every nook and corner for it, regardless of the method of collecting.

The Negro finds a vine or two, climbs the trees to which they are attached, cuts the vine in sections, even the very primary roots he cuts, and carries away the whole thing to the nearest path, or his camp, where he slices away at the bark just as he fancies, till he get a small ball of a few ounces (the rubber coagulates as fast as exposed, and is gathered at once) and off he goes in search of more. The primary roots being cut, and the root bulb removed, the vine is done for, as no shoots ever spring from the roots left in the ground. Some useless and, it would appear to me,

UNWORKABLE RUBBER REGULATIONS

have just been published by H. M. Commissioner for B. C. A. What is wanted is to restrict the collecting of rubber altogether, except by license under proper supervision: even then I question very much whether the Congo Free State, B. C. A., and the South African Co. will permit the destruction and ultimate extinction of the "goose that lays the golden egg" in their territory.

I do not think many years are wanted to exhaust the rubber supply of East, Central, and West Africa, though West Coast exports have fallen off greatly during the past few years. We have several large forest trees here, which yield rubber, and one large vine that is not tapped by natives as the caoutchouc does not readily coagulate.

One of those trees answers to the description of *Kickxia Africana*, a West African rubber tree; another I take to be *Ficus Elastica*. The yield of the latter would seem to be very large. I set two men to work on a large tree in my forest; and in about eight hours they brought in over 1 lb. of rubber each in the

evening. It took the whole day to coagulate. The men cut slits out of the bark, which is very thick, and allowed the rubber to collect and set in them. I have sent rubber and herbarium to Kew for identification.

The vine rubber, &c., I have also sent to Kew. I was always struck with the enormous amount of caoutchouc this vine yields: it simply runs out of a cut in the bark for any length of time, and I was

LED TO EXPERIMENT

with some from what I read in your *T. A.* I went to the forest with two men and from one vine, in the course of a few hours, we returned with two quarts of caoutchouc. Into one quart, I stirred half a tumbler of water, in which one tea-spoonful of J. T. Morton's tartaric acid was dissolved. After a little stirring, the contents coagulated the same as butter would come in a churn. I then went to the bath-room and washed the rubber, squeezing it and working it in my hand for some time, till all the refuse was washed out, when I had a piece of beautifully pure rubber quite white. When exposed it turned reddish grey in colour. The other quart I boiled pure and simple without the addition of any acids. In a quarter of an hour, stirring all the time, I got the same result. Gradually the rubber stuck to the stick until all was collected. This seemed to take place gradually as the water evaporated until I had one lump like very thick porridge, which I tumbled out on a board, poured water on it, and worked it about till I had

A LOVELY PIECE OF RUBBER

much nicer looking than what was made with the acid—more elastic with a pretty bluish transparent look about it. I am sure the above treatment is simple and inexpensive enough, and perhaps better results may be got than by the use of patent machinery. I shall try the churning; but as the use of my dairy churn is prohibited, I shall have to construct one for myself. I shall let you know the result in due course.

The abovementioned vine is very hardy, easily propagated from seed, and only takes about ten years to become fit for tapping, with a stem a foot in diameter. I am thinking of

PLANTING IT ALONGSIDE ALL THE SHADE TREES

in a coffee clearing on which native shade was left, although the coffee is a decided success so far up to 18 months old. I do not think the rubber vines would do any harm; and, of course, it is always better to have two strings to one's bow.

I have frequently read in the columns of your *Tropical Agriculturist* about hybrid coffee. Why, it is as common as anything here. From

SOME ORANGE COFFEE

imported by the Church of Scotland Mission by Gardener or some other person, we have got it hybridised on, I suppose, every estate in British Central Africa. At all events Mlanji has got it in every shade from the real orange to nearly approaching the dark green of our

Coffee Arabica. I have often wondered whether this variety would resist the attack of leaf-disease. I could send some seed to any one in Ceylon who may wish to try it. From a small-leaved West African coffee we have several hybrids. The narrow-leaved coffee that my P.D. in Dimbula used to point out as a mail coffee, and give orders to reject when counting the plants, is also here, and has got hybridised with the Arabian variety.

I got some Liberian coffee seed from the Blantyre Mission in 1892 and put it into a nursery, and remember a few of the seeds came up; but what became of the plants I never found out from my assistant who did not know much about coffee. After some years I discovered several of the Maragogipe or hybrid variety of coffee trees in a field of about 140 acres; but how they came there I do not know, for I never got any seed or plants of Maragogipe from anywhere, and can only surmise that a Liberian plant must have existed somewhere and got

HYBRIDIZED WITH THE ARABICA.

I have not had much experience of tea-making. In the early days of hand work, I got some lessons from the late A. Cameron when on his rounds and turned out fairly good tea, which sold at 50 cts. per lb. in Colombo. But what puzzles me here is, I sometimes make a break of tea which is quite better; and if any of your experienced planters or your worthy self would tell me what is the cause of better tea I would be much obliged. I see nothing in T. C. Owen's book about it, and never remember turning out better tea in Ceylon. I have an idea that it is the withering or fermenting that has to do with the bitterness as it is only occasionally it turns out better. The crop is just over in British Central Africa and said to be a large one, and it would need to be, for the past two years have been very short.

THE RAINS

have been seasonable this year and our coffee is blossoming early: we have a grand show of spike on the trees at present. Early blossoms always do well in British Central Africa, so that I may safely say prospects are good for 1900 crop. H. B.

ANALYSIS OF A COCONUT.—Dr. Bachofen, of Mr. Baur's Laboratory, has produced an analysis which should be of much interest to coconut-growers. The chemical constituents are most precisely detailed, while the amount of each important ingredient in the soil, removed by 1,000 nuts, is also added for reference. The latter should be extremely useful in the analysis of soils under consideration with a view to coconut-planting. In the former the most noticeable points are that Potash and Sodium Chloride are the chief constituents of every portion of the coconut; and that the dry matter exceeds the moisture only in the Shell, (by 69.60 per cent) while it is less in the Husk and Kernel by 31.12 and 5.6 per cent respectively.

OUR PLUMBAGO INDUSTRY.

CROWBORO', Oct. 27.

A merchant largely interested in our one mineral of commercial importance, although he knows nothing of Ceylon, has been placing some enquiries before me as follows:—

"Plumbago, which a couple of years ago, could be bought at £25 a ton is now up at £75 per ton, a corresponding increase having taken place in the inferior qualities. To what is this owing? Are the mines exclusively in native hands or are they subject to any control from European or American buyers? Are the different qualities of plumbago taken from different mines? Does the working of a mine require much capital? I am told that the principal expenses is timbering. What is the present output? And is the supply likely to run short? Perhaps you can say what probability there is of the present abnormal prices being maintained. Could a large consumer depend upon receiving a regular supply all the year round? At present it seems to be very scarce as well as dear."

My answer was that he (my correspondent) as using plumbago, ought really to know more about the cause of the rise in price than I, a Ceylon man. That, we have heard, is the greatly multiplied requirements for crucibles in view of increased armaments of the United States, and European Powers. But I must enquire about all this on my return to town, or it is possible some light may be thrown on the matter after my lecture on the 7th November. A trebling of price is certainly phenomenal; and I see the total export this year is not to be less than 600,000 cwt. in all probability, or 33 per cent above the last year's export! Thirty thousand tons at an average of £40 to £50 a ton will mean an enormous amount of money to divide among the Ceylonese mine-owners. Probably not less than twenty million of rupees! How much of this will go into the hands of the labourers? Some years ago, Mr. de Mel had one mine that gave him £2,000 profit a year for eleven years. With prices trebled, he and other fortunate plumbago pit-owners must be making very large sums. Let us trust they see to the comfort and safety of their workmen and their proper remuneration. It would be interesting to know if any mines are worked on the co-operative system? Then surely the Government should make "hay" for the general revenue while the sun is shining. The royalty on 600,000 cwt. expected will be only R150,000 or not one per cent on the value; but that cannot be helped. It is the royalty from plumbago dug on Crown lands that should yield more revenue at such a time, or the sale outright of such land.

Turning to the question of my correspondent, I was able to tell him as an exception to the native owning of mines, the case of the late Mr. Tottenham (how far-seeing was our friend to bring out a Mining Engineer to develop his property when he did), and that since then other English capitalists had entered the field. As regards the supply running short, I ventured to say that I saw no reason for its doing so; and that in fact with the advent of a Geological Survey Staff early next year, there ought to be a fresh impetus given to plumbago mining; but as to the price keeping up, that

is a matter, I suppose, for which the answer must be sought in London or New York rather than Ceylon.—Now should be the time to get intelligent progressive Ceylonese like the Messrs. de Mel, Fernando and some others in plumbago, to confer some lasting boon on their countrymen—why not provide a YOUNG MEN'S INSTITUTE FOR COLOMBO?

PRODUCE AND PLANTING.

AMERICAN TEA BUYERS.—Our New York contemporary, "The Commercial," has the following on the influence exercised by the American tea buyers on the London market. It says: "The London market, the great tea mart of the World, was until lately controlled by a few large buyers, who, by agreeing between themselves to remain out of the market for a sale or two, could readily depress prices. These buyers were, and are, by force of circumstances necessarily 'bears,' because the tea they buy is put up in packets and sold at fixed prices, to which the consuming public has been educated. It can be readily seen that with every change of the market to a higher basis, the price of the packet to the consumer could not be changed, hence the packet tea buyer must purchase at a low price or sustain a serious loss. In this connection a leading dealer in packet teas said yesterday: 'With the American business an important factor in the London market, such a combination becomes unavailing at once, as there are always ready buyers of Ceylon and India tea here when London prices go below a certain limit. Formerly China tea, at 8 cents a pound, came into competition with the pure teas of Ceylon and India, which cost 12 to 13 cents to land. Through the strict enforcement of the standards by the United States Government, those inferior "compounds" are entirely excluded, and China tea cannot be bought under 12 to 13 cents a pound, which brings the two classes of tea practically to a parity, and at the same time the more desirable for blending or any purpose is the machine made tea of Ceylon and India. Thus, it will be seen that the operations of the American buyers immediately nullify any contemplated "bear" movement in London, as the offers to buy at a price for export to America are always in evidence there. The result will be that possibly after one or two bear attacks the combination will have to fall into line and buy at market prices in self defence. With the consumption of Ceylon and India tea increasing here, in Great Britain and, in fact, all over the world, the trend of price is upward, and after the British "bear" combination has been compelled to buy at current values, the American buying interest will have to raise its limit also, and in that way values will reach a still higher level. Certainly it is that prices are looking upward, and there is nothing in existing conditions that would make shrewd tea buyers hope for or expect lower values. Another strong factor which tends to lessen the influence of the "combine" of packet tea buyers in London upon the world's market is the great number of orders now sent direct to Colombo and Ceylon from houses in America, Russia and Australia." By the way, apropos of tea in America, it may be mentioned that two-thirds of the total tea importations of the United States go in through New York, and amount to nearly 60,000,000 lb. a year. Although Americans are not especially known as a tea-loving or tea-drinking people, they consume 90,000,000 lb. of tea annually.

TEA CULTIVATION IN THE UNITED STATES.—The "New York Commercial," commenting on the report of the tea crop of the Pinehurst tea estate, Summer-ville, S.E., says "The 'Commercial' has from time to time published opinions of members of the tea trade in this city to whom samples of the Pinehurst tea were submitted. These opinions varied but little regarding the quality of the product. In all cases it was described as inferior to

the best quality imported, and equal to the grade sold at from 22 to 27 cents per pound. Some doubt was also expressed regarding the possibility of tea growing ever becoming profitable."

TEA IN FRANCE.—There is clearly scope for further and energetic operations in connection with the sale of tea in France. A correspondent of "The Grocer" calls attention to the fact that many tea-rooms have been opened which announce the sale of tea in liquor and in leaf, and most of them advertise themselves as "Five O'Clock Tea Rooms." He says: "I called at one of the newest of these—a very small shop—the other day, and found that the business was being run by two young ladies, daughters of an English clergyman. I tried their tea, and must confess that if the same article were served in Regent Street or Piccadilly the trade done by that shop would be very small. The tea was of a very thin and flavourless description, especially when mixed with milk and sugar. I purchased one of their packets of tea, which was sold to me at the rate of 4s per lb. and on examining it I found the tea was such as would not find a very ready market in England. I submitted it to an expert, who assured me that it would be worth about 7d per lb. on the English market; to that has to be added about 2s 3d for duty and 'octroi,' bringing the cost of the article up to about 2s 10d a lb. Curiously enough, it bore the name of a Swiss merchant, from whom I understand it had been obtained. It is a pity that the French taste for tea should not be educated with something better than this, because there can be little doubt that if the French consumers were taught how to make tea properly, and were taught how to appreciate a good cup of tea, a very great trade might be done in this article in France. There is, I am informed, an attempt to popularise tea in connection with the Indian and Ceylon sections of the Exhibition, but the restriction which has been laid down by the authorities that it shall not be sold within the precincts of the Exhibition is one which will very greatly handicap exhibitors. No doubt many of your English merchants have turned their attention to France as a country into which tea might be profitably introduced, but the failure which has attended their efforts in the past doubtless accounts for the slowness of English merchants at the present day to make a fresh attempt. As, however, there will be a great number of English-speaking tea-drinkers in Paris next year, no doubt a good opportunity will afford itself of making a fresh attempt. In the Exhibition year of 1889 some Englishmen did make the experiment of providing tea served in the English fashion, which met with a limited amount of success; but the numbers of English-speaking visitors next year it is expected will be greater than ever, and so it must be for the consideration of English merchants how far they will make another experiment in this direction."

COFFEE ADULTERATION.—Coffee suffers in the matter of adulteration as compared with tea. The fraud, which is made in Germany, has found its way into Yorkshire, and, according to the Government analyst, it is most difficult, even on close inspection, to distinguish the doctored maize from the genuine coffee berry.—*H. and C. Mail*, Nov. 3.

SHEVAROY PLANTERS' ASSOCIATION.

The following are from proceedings of a meeting of the committee of the Shevaroy Planters' Association held in Yercaud, on Monday, the 6th instant:—

Present:—Messrs. W J Lechler, Thurston, Short, Rev. M Anderson, Messrs. C Rahm, C G Lechler, S B Nicholson, Rev. J M Kempf, Mr. R Gompertz, (Chairman and Hony. Secy).

Read circular 89-99 from the Secretary, U. P. A. S. I., re exhibiting and selling Indian coffee at the Paris Exhibition, and enquiring what our Association is prepared towards the expenses. Resolved:—"That the Secretary, U. P. A. S. I., be informed

that this Association is prepared to subscribe R200 towards the expenses of advertising and dispensing Indian coffee at the Paris Exhibition, provided that other Associations will subscribe in proportion."—*Madras Mail*, Nov. 17.

LANKA PLANTATIONS COMPANY, LTD.

Report presented at the Nineteenth Ordinary General Meeting of the Lanka Plantations Company, Limited, held at the Office of the Company, on Wednesday.

1 The Directors now submit their Report for the twelve months ending 30th June last, together with the Balance Sheet and Accounts of the Company made up to that date and duly audited.

2 The season was unusually favourable for Coffee. The crop shipped to London amounted to 722 cwts., and realized £2,843 10s 2d. Last year, the crop shipped was 247 cwts., and realized £1,072 11s 8d. The acreage under Coffee alone is nominally 134 acres.

3 The total crop of Cocoa gathered on Yattawatte amounted to 1,665 cwts., and realized £5,509 18s 10d, against 1509 cwts. last year, which realized £4,866 1s 9d. The cost of seven acres new land, and the net expenditure on clearings not yet in bearing, are charged to capital account. On the same estate 420 lb. Cardamoms were gathered, realizing £40 4s 9d.

4 The Tea received from the Company's estates amounted to 769,578 lb., and has been sold at an average of 7.44 per lb. net, realising £23,862 4s 4d. Last year the company received 731,593 lb. which was sold at an average of 7.45 per lb. net, and realised £22,840 18s 1d. The season was generally unfavourable and the yield fell short of the estimates.

5 The average rate at which drafts were negotiated on account of the season's crops was 1/4, 9-32nds per Rupee against 1/4, 3-32nds last year.

6 The following statement shows the acreage and state of cultivation of the company's estates on the 30th June last;—

Estate.	Coffee.	Tea.	Cocoa.	Grass.	Chena & Patana.	Forest and Timber Trees	Total.
Ampittia-kande, Arn-hall	20	444	..	4	167	70	705
Fruit Hill	..	227	10	..	237
Fordyce, Garbawn, Gona-galla & Paramatta	..	794	..	7	..	135	936
Rappahan-nock	..	522	..	31	30 1/2	90	473 1/2
Rillamnille	..	232	6	20	258
Thotulagalla	114	264	63	114	555
Yattawatte	*751	95	294	82	1,222

* 68 acres interlined with Liberian Coffee 134 2,283 751 137 570 1/2 511 4,866

7 The net profits for the past year amounted to £9,544 2s 7d, to which must be added the sum of £614 6s 11d, the balance brought forward from the year 1897-98, making together £10,188 9s 6d.

8 Having already paid a half year's interim dividend on the 6 per cent. Preference Shares to the 31st December, 1898, amounting to £426

6s 0d, the Directors recommend payment of the Dividend on these shares to 30th June last, requiring (less property tax) a similar amount, and having deducted £1,247 1s 8d, being one-tenth of the sums charged to Suspense Account during the ten years ending 30th June, 1898, and (in anticipation) the tenth of such sums for the ten years ending 30th June, 1899, amounting to £1,136 14s 4d, they further recommend a dividend of 8s per share, being 4 per cent. (free of income tax) on the Ordinary Shares, amounting to £6,000, carrying forward a balance of £952 1s 6d to the next account.

9 The Director who retires on this occasion is Mr. George Allen, who, being eligible, offers himself for re-election.

Mr. John Smith, the Auditor, also retires and being a Shareholder offers himself for re-election.

CEYLON AND INDIAN PLANTERS' ASSOCIATION LTD.

SECOND ANNUAL REPORT, 1898-99.

The Directors beg to submit their Report and Audited Accounts for the year closing 30th June last.

The past twelve months have proved somewhat better for the tea industry in Ceylon. With the exception of Kandaloya Garden, all the Estates give a larger profit than for the corresponding period. Kandaloya tea is now being sold on the Colombo market with better results than would be obtained here, and the Directors hope that next year this portion of the Company's property will do more, to increase the profits than it has done hitherto.

The crop has not weighed out as much as expected, but is still 46,664 lb. in excess of the previous year. Estimates for this year anticipate a further increase of 68,000 lb. of made tea, or a total of 740,000 lb., for an expenditure very little exceeding the past year's.

It will be noted that in the accompanying analysis the average sale price has been more, and the cost of production less than last year, except in the case of Kandaloya.

The Directors during the year have paid off the Mortgage and issued Mortgage Debenture Stock for £45,000 at 5 per cent secured on the whole of the Company's properties.

The Directors desire to record their thanks to Mr. George Greig and the Staff in Ceylon for their efforts in promoting the welfare of the Company during the period under review.

The Accounts show that after paying Interest and preference dividend and manager's commission, there is a balance at credit of Profit and Loss of £1,834 6s 9d, the Directors propose writing off £450 from preliminary expenses, £400 from machinery account, and £150 from debenture issue account, and to pay a dividend on the ordinary shares of 2 per cent absorbing £800, carrying forward the small balance.

Both Directors' and Secretarial fees have been surrendered.

The Auditors, Messrs, Singleton, Fabian & Co., beg to offer themselves for re-election.

Directors—C A REISS, C F DICKINSON.

CENTRAL TEA COMPANY OF CEYLON LIMITED.

Report of the Directors submitted at the fourth annual ordinary general meeting of shareholders held at 20, Eastcheap, E. C., on Monday the 13th Nov.:-

The Directors have the pleasure to submit the general balance sheet and profit and loss account for the year ending 30th June, 1899, duly audited.

£ s. d. £ s. d.

The net amount at Credit of Profit and Loss Account, including the balance brought forward at 30th June, 1898, and after providing for General Expenses, Directors' Fees, Income Tax, &c., is	..	935	7
Dividends on the 6 per cent. Preference Shares were paid for 1898/9 (less Income Tax) amounting to	..	1,305	0 0
It is proposed to pay a Dividend of 6 per cent. (less Income Tax) on the Ordinary Shares which will absorb	..	1,073	0 0
And to carry forward to next year a balance of	..	557	7 7
		<u>£2,935</u>	<u>7 7</u>

The Directors trust the results of the year's working of the Estates will be considered satisfactory by the Shareholders.

The gross average price realised for the tea was 7-87d per lb., as against 7-75d per lb. last season, and the rate of exchange was 4 19-64d as against 1s 4d.

The yield of tea was 331,427 lb., being 377 lb. per acre over a plucking area of 879 acres.

The acreages of the Estates are as under—

Estate.	Tea.					Total acreages.
	In bearing.	Partia bearing.	New clearings.	Cardamoms.	Forest Grass and Waste.	
Kabragalla	.. 431	61	16	32	397	937
Somerset	.. 387	..	13	..	33	433
(Including Easdale and Loxa).						
Total	.. 818	61	29	32	430	1370

Under clause No. 24 of the Articles of Association Mr. J. Sanicroft Holmes retires on this occasion from the Board, and, being eligible, offers himself for re-election.

The Auditors, Messrs. Harper Brothers, Chartered Accountants, also retire from office, and offer themselves for re-election.

TEA MACHINERY.—Amongst the announcements of Messrs. Crosby Lockwood & Son's new and forthcoming publications is the following:—

Tea machinery: A Descriptive Treatise for the Use of Planters and Others. By A. J. Wallis-Taylor, A.M. Inst. C.E.E., Author of "Refrigerating and Ice-Making Machinery," &c.

TO ALL PARTS OF ASIA, AFRICA, AMERICA AND OCEANIA.

Seeds & Plants of Commercial Products.

Castilloa Elastica Cervantes.—Orders being booked for the coming crop of seeds available in March and April, selected seed from very old trees. R. N. Lyne, Esq., Director of Agriculture, Zanzibar, writes under date 24th August, 1899:—"Please send me 200 seeds of *Castilloa Elastica* for further trial; the seeds of *Castilloa* you sent me last August germinated very well." Price and particulars in our Circular No. 32; special quotations for large orders according to quantity; immediate booking necessary to avoid disappointment.

Hybridised Maragogipe Coffee.—A larged-beaned superior variety of Coffee in demand; orders booked for the coming crop of seeds, February and March delivery. Price according to quantity on application.

Hevea Brasiliensis (Para Rubber).—Orders being booked for the coming crop available in August and September, 1900. This is the only crop of seeds in the year. All orders should reach us before the end of July to avoid disappointment, as we have to make arrangements in time; guaranteed to arrive in good order at destination. We have already booked a large number of orders. A Sumatra Planter writes, dating 9th March, 1899:—"I consent to the price of £—— per thousand. I herewith order 50,000 upon condition that you guarantee at least 33 % seeds germinating." Plants can be forwarded all the year round in Wardian cases. Price and particulars as per our Circular No. 30. A Borneo planter writes dating, Sandakan, 17th August, 1899:—"The last lot of Para seeds turned out very well."

Ficus Elastica (Assam and Java Rubber).—Seeds supplied by the pound with instructions; price according to quantity. This tree grows equally well in high and low land, in forest and grass land, its cultivation being extended largely by the Indian Government. For price of seeds with particulars as per our Circular No. 33.

Manihot Glaziovii (Ceara or Manicoba Rubber).—Fresh seeds available all the year round; price as per our Circular No. 31. It is superior to Mangabeira rubber and second to Para rubber.

Urceola Esculenta (Burma Rubber) and Landolphia Kirkii (Mozambique Rubber).—Seeds and plants, both are creepers.

Cinchona Seeds.—Different varieties.

Sterculia Acuminata.—(Kolanut). Superior quality, seeds and plants; price on application, packed to stand the transit well for several months, a hardy tree, cultivation easy.

Erythrina Lithosperma.—Thornless variety, new crops of seeds ready in December, May and June. Price according to quantity on application.

Seeds and Plants of Cinnamon, Nutmeg, Clove, Sandlewood, Pepper, Cardamom, Vanilla, Arabian, Liberian and Maragogipe Coffee, Cacao, Tea, Coca, Fibre, Medicinal and Fruit Trees, Shade and Timber Trees, Eucalyptus various varieties, also Palms, Bulbs, Orchids, &c.

Our enlarged Descriptive Price List of Tropical Seeds and Plants of Commercial Products for Foreign Countries for 1899-1900 are now being forwarded to applicants in different parts of the world. Also Descriptive Price Lists of Seeds and Plants of Fruit Trees, Bulbs, Tubers and Yams, and Orchids.

"SOUTH AFRICA."—The great authority on South African affairs, of 25th March, 1899, says:—"An interesting Catalogue reaches us from the East. It is issued by William Brothers, Tropical Seed Merchants, of Heparatgoda, Ceylon, and schedules all the useful and beautiful plants which will thrive in tropical and semi-tropical regions. We fancy Messrs. Williams should do good business, for now that the great Powers have grabbed all the waste places of the earth, they must turn to and prove that they were worth the grabbing. We recommend the great Powers and Concessionaries under them to go to William Brothers."

A leading Planter writes from *New Hebrides* under date 17th January, 1899:—"I shall like a few more of your Catalogues to distribute through these Islands, as I feel sure many would place themselves in communication with you, did they know where to write for Seeds and Plants."

Our New Descriptive Price Lists of Seeds of Shade Trees for Coffee, Cacao, Tea, Cardamoms, &c., Timber Trees, Trees for Avenues, Hodges-Wind and Shelter Belts, Ornamental Trees, Shrubs and Climbing Plants; and Seeds and Plants of Palms, Calamus, Pandanus, Cycads, Tree and other Ferns, Crotons and Dracinas, now being prepared and will be ready shortly.

Agents in London:—MESSRS. P. W. WOOLLEY & Co., 33, Basinghall Street.

Agent in Colombo, Ceylon:—E. B. CREASY, Esq.

Telegraphic Address:

WILLIAM, VEYANGODA, CEYLON.

J. P. WILLIAM & BROTHERS,

Tropical Seed Merchants,

Lieber's, A.I. and A.B.C. Codes used,

HENARATGODA, CEYLON.

WYNAAD TEA COMPANY, LIMITED.

The fifth annual meeting of The Wynaad Tea Company, Limited, was held at the company's office, 20, Eastcheap, E. C., on 30th Oct., Mr. J. C. Sanderson presiding. The secretary having read the notice convening the meeting,

The CHAIRMAN, in moving the adoption of the report and accounts, said:—You have all had a copy of the report and accounts, so I presume I may take them as read. As explained to you in the report, the accounts are only for eleven months, the reason being that our managing director in India wished that our year should end at the same time that the financial year of all other tea companies ends, viz., at the end of March. The net profit of the working for the past season, after crediting the block account for the tea which had been picked from the Cootacovil Estate, is £728 2s 9d and this profit the directors are going to write off the debit balance of last year. They regret they cannot give you a dividend; but, of course, while that debit balance exists we cannot declare one. We hope that it will all be wiped away next year, and that there will be something to the good. Besides the credit which we have taken for the tea, there are legal charges to the extent of £231 13s, which have been outstanding for some years, but which are now all wiped off, so that I think (and I hope you will agree with me) that this year's report is decidedly the most favourable one we have had for some time. The crops for the past season turned out very satisfactorily. The coffee crop was the largest gathered for some years, being fully 51 tons, and the director were very fortunate in selling it at a very high price before the fall in coffee took place. The pepper crop was also sold at a profit, fetching 45s 6d per cwt, while the first pluckings of tea, which amounted to about 15,000 lb. from the Cootacovil estate from the 1895 planting, fetched an average price of 7½d per lb. With regard to the present position of the estates the manager reports that their condition is highly satisfactory throughout, and the prospects for this year are encouraging. The tea leaf is coming in so fast that we shall have to put in more machinery, and according to the letter which we have received today we are some 7,000lb ahead of estimate. The estimate, as the report tells you, is 78,000lb for this season, and with by far the heaviest month, of the year to come we have in the first six months received nearly half the estimate. The shrubs are flushing splendidly, and they are in a very healthy condition. The estimate for the pepper crop this season is about 20 tons, and we are just on the point of selling it at considerably more than the price realised last year. With regard to the coffee crop, it will probably be from 18 to 20 tons, but the market is rather too uncertain for us to forecast what we shall get for it, although we think it will come on a better market. The outlook for 1900-1 is very promising. The coffee trees are making splendid wood, so that we may expect a considerable increase over this year's crop, and the tea yield will be much more, because we shall have the first hundred acres in full bearing, and we shall also pluck from the second hundred acres. Under these circumstances the directors confidently look for a yield of about 150,000 lb. I do not want to hold out too sanguine a view, but I think we have turned the corner, and that the time is coming when we shall all be repaid for our long waiting. Before asking you to adopt

the report and accounts, I shall be very pleased, with the assistance of Mr. Walker, to answer any questions any shareholder may wish to put to me. I have now great pleasure in moving the adoption of the report and accounts.

The resolution was seconded by Mr. Labouchere.

In reply to a question from Mr. Summerhays, the CHAIRMAN stated that the proceeds of the tea were credited to the block account and not to the revenue account, because the tea was not in full bearing.

In reply to a question from Mr. Donald Andrew, Mr. WALKER stated that with the exception of a short period at the beginning of the year they had had no difficulty in getting labour, in fact, there was far more labour than they could employ. They had lost no tea through scarcity of labour, so that he thought they could fairly say that they would be able to get all the labour they might require.

The report and accounts were then unanimously adopted.

On the proposal of Mr. LABOUCHERE, seconded by Mr. Andrew, Mr. Sanderson was unanimously re-elected a director of the company.

Mr. KNOTT proposed, and Mr. Goodwin seconded the re-election of the auditors (Messrs. Lovelock & Co.). The motion was carried unanimously.

The next business of the meeting was to consider the resolutions for financing the company by borrowing money secured upon debentures.

The CHAIRMAN in proposing these resolutions said:—You will no doubt remember that last May we had a meeting, and a resolution was passed giving the directors power to raise £10,000 in debentures to carry on our properties and to pay off a large block account which we owed. There were certain informal matters which interfered with carrying this proposal through, and one, the most important, was the question of taking away all our borrowing powers. Those shareholders who understand the working of tea will know that the business has to be carried on by means of agencies, and that we have to borrow money for the upkeep—that is the cultivation of our crops until they are marketed. The resolution as it stood would have debarred the directors taking powers to borrow money for this purpose. We have since reconstructed the resolution, and I now beg to bring it to your notice. I am sorry to say that we have had to change our agents, and it is with great regret we have done so, for we have experienced every consideration and assistance at their hands. It was, however, hardly within their province to take up debentures in another tea company, so they informed us that if we could make other arrangements they would not stand in our way, that is to say they very kindly allowed us to break our contract in the middle of the season. We have therefore arranged with Messrs. R. and J. Henderson to take the balance of any debentures that the shareholders do not wish to take. The directors have subscribed for £500 each, and you may be sure it is considered a very good and safe investment as otherwise your directors and Messrs. R. and J. Henderson would not be willing to take them up. Our property is a valuable one; an independent valuation which we had made in 1897 amounted to £40,000, and since then the value has been increasing by a part of the acreage of tea having come into cultivation, and the coffee and pepper crops having greatly improved. I repeat, therefore, that with these fine and valuable properties as security, it is a very good and

safe investment for the debenture holders. Messrs. R. and J. Henderson wish first to give the shareholders an opportunity to take the debentures, because they carry the condition with them that they can be exchanged for 10 per cent. preference shares any time prior to the date of repayment, so the shares may become of great value. Those, therefore, who help the company through the pressure at the present moment will not regret it hereafter. I do not think that I have anything more to say, so I will proceed to move the following resolution:

"That in lieu of the authority to borrow £10,000, conferred upon the directors by the resolution of May 27, 1899, the directors be, and they are hereby authorised, from time to time to borrow for the purposes of the company sums of money not exceeding in the aggregate £10,000, to be secured by debentures charged upon the company's property in such manner as the directors think proper, such debentures to bear interest not exceeding six per cent per annum, and to be repayable at par at the expiration of five years from the date of issue, with the option to the company of repayment, in the meantime, at a premium of £2 10s per cent., upon six months' previous written notice, and to confer upon the holders thereof:

"(a) The right to receive notices of general meetings of the company, and to attend and vote at such meetings in manner provided in the case of shareholders by the articles of association of the company.

"(b) The right during the said period of five years to exchange such debentures or any of them for fully-paid 10 per cent. preference shares of the company, notwithstanding the terms of clause 6 of the articles of association."

The CHAIRMAN said that he must here explain that, according to the terms of clause 6 of the articles of association, any issue of new shares should be offered to the shareholders pro rata. As they had only about £4,000 left of the preference shares unissued, and they intended issuing £10,000 debentures, there would be a difference between that sum of £6,000, which might have to be issued hereafter. The second resolution was:

"That the directors be and they are hereby further authorised from time to time to borrow upon the security of the crops and produce of the company's estates any sums of money required for the purposes of the company."

These resolutions were seconded by Mr. Donald Andrew.

Mr. SUMMERHAYS then said that, as the legal adviser of the company, and also as a small shareholder, they might like him to make a few remarks. From a legal point of view the case was an extremely simple one. Here was a company to all appearances on the eve of prosperity, but in order to make its position absolutely secure it was necessary to raise a substantial sum of money, viz., £10,000 to give full effect to its powers and to make the most of a very valuable property. It seemed the best way of accomplishing this object in the interests of shareholders was by raising money upon the issue of debentures which form the first charge upon the company's estates. This is a case in which the shareholders should first be considered, and in which they should have the first opportunity of taking up these debentures, more especially considering the special

advantages which were to accrue to the debenture holders. It might not suit the views of a good deal of the company's share holders to add to the present holding of preference shares, and for the very good reason that money could be raised for the purposes of the company which would come in front of those shares, but on the other hand, if those shareholders now came to the assistance of the company they were only helping towards this, and they got the very best security for their money. They got a first charge for this relatively small sum of £10,000 upon £40,000, so that their security, became undeniable. This was not all. They also got the special condition of being able, while these debentures were accruing, to surrender their debentures which gave 6 per cent. interest, and taking 10 per cent. preference in their place. He could conceive of very few securities more advantageous than that which was offered in the first instance to the shareholders, and afterwards to the public. The method of procedure was perfectly simple. He might mention, as a small shareholder in the company, that he was so convinced of its being a safe investment that it was his intention to recommend it to his Indian clients. It was an essential part of this scheme that debenture shareholders might exchange their debentures for preference shares, so that it was really necessary to alter the sixth article of association. However, it was the spirit of the thing that was the main principle. If any difficulty should arise two meetings would have to be held, and then the position of debenture holders would be secure.

The resolutions on being put to the meeting were unanimously adopted. The chairman then proposed a vote of thanks to the staff in India for their hard work and efficient management. This was seconded by Mr. Summerhays and carried unanimously.

On the proposal of Mr. Labouchere, who said that, as next year they would probably meet the offices of Messrs. R. and J. Henderson, this was the last opportunity the directors might have of passing a vote of thanks to the Secretary, Sir Wm. Johnston, for the eminent way in which he had done his work. He had pleasure in proposing the vote of thanks. The proposal was seconded by the chairman and carried unanimously. A vote of thanks to the chairman concluded the meeting.—*Home and Colonial Mail*, Nov. 3.

GOOMERA (CEYLON) TEA ESTATES CO., LTD.

DIRECTORS' REPORT.

The Directors herewith beg to submit the fifth annual report and balance sheet for the year ending June 30th, 1899.

The accounts, after paying debenture interest writing off the balance of preliminary expenses out-standing, and paying 3 per cent. on the preference shares, show a balance to the credit of profit and loss of £353 2s 8d. Out of this a final dividend of 3 per cent. has been paid on the preference shares, leaving £203 2s 8d. to be carried forward to next year.

Although considerably better than last year, the result of this year's working has not been as satisfactory as hoped for. There has not been a good market for medium teas, such as the Company produces, during the year. It is hoped that the young tea now coming into bearing will add

materially to the yield and the profit of the Company in the immediate future.

The estates of the Company are reported to be in thoroughly good order. During the past year some of the machinery has been renewed and the factories put into good repair. Extensions have been made to both of them in view of the young tea about to come into bearing; this latter expenditure has been charged to capital account.

During the year Mr. C. J. Rowe and Mr. F. A. Macrae died, and in accordance with the Articles of Association, Mr. B. F. White was appointed in the place of the former and Mr. A. Valentine Holland was appointed in the place of the latter.

THE "KNOCK-OUT" IN THE TEA MARKET.

(COMMUNICATED.)

In spite of many assurances to the contrary from those interested, for sometime it has been generally known that a unity of action existed among the larger buyers of tea, which has now assumed the shape of The Tea Buyers Association, with the object of buying collectively at the public sales and acting on the lines of what is generally known as "a knock-out." There is no doubt about it, and after all it is only an outcome of the modern mode of doing business. Anyone who likes to go to Ingram House, 165 Fenchurch-street, can see the title in the porch:—

THE TEA BUYERS ASSOCIATION.

Most of the following was compiled in January, 1899, by one who had previously devoted some months to studying the Tea Trade in all its branches, from arrival of its produce in London to its retail—comparing it with the other large industries, such as brewing, distilling, iron, cotton, leather, &c.; in search of any information likely to be of service in improving the system of selling tea.

In carrying out this, his endeavours have been to adhere as closely as possible to simple facts and direct conclusions, and so avoiding all that is remote, or complex.

The Tea Planting Industry of India and Ceylon is now suffering depression from four causes:—

1st. An arbitrary action of the Indian Government, affecting so-called exchange.

2nd. Occasional and periodic rushes of tea from India and Ceylon upon the London market, necessitating some order and regularity in the quantities offered for sale weekly.

3rd. The want of definite and reliable information on the quantities of tea produced and likely to come forward from India and Ceylon.

4th. The same collective care in selling that is exercised in buying teas.

Temporary over-supply seriously brought down the price in the tea market during the early part of last and this year; and although the statistical position of all teas, a little later, shewed the stocks to be almost identical with those of 1897, yet there was no reversion to the prices then ruling, at least for Indian teas. Ceylon, by extra fine plucking, has barely (1898) maintained its average price. It is observable, however, that a return to what economists call an equilibrium of the market, does not re-establish a relative and permanent recovery of price.

There is also every indication that the market has hitherto periodically suffered far more from the irregular manner in which produce has reached

it, than from over-production, although this position has been very nearly reached.

Some years ago, when consumption was smaller, the public sales market in Mincing Lane was frequented by a proportionately larger number of tea buyers than now: tea was brought in smaller parcels obtaining livelier competition.

PUBLIC SALES.

Now in spite of the so-called sales by Public Auction, everyone knows that by far the larger proportion of tea now sold in Mincing Lane goes from seller to buyer without any public competition whatever, it evidently being arranged beforehand who shall be the purchaser. Formerly, the statistical position of the tea market was no more favourable to growers than it is now; the present market, however, has ceased shewing the same response to improved statistical conditions as it then did.

Although the excessive supply of tea brought to sale during the past few years, has gradually been worked off, assisted by the increased consumption of foreign markets, yet there is not the reacting buoyancy that the market should in consequence possess.

Nor is any one prepared to dispute that the buying of teas in Mincing Lane has fallen into fewer hands, and that the results obtained are not so satisfactory as formerly.

Also few will admit that the market responds now as formerly to supply and demand; for, from a grower's point of view, whatever be the cause, the fact remains of the existence of some adverse influence somewhere. Consequently, if the present order of things continues unaltered, the open market is not likely to adjust itself in any adequate degree.

The following table shews that something besides supply, demand and over-production have been influencing the downward tendency of tea prices, for the past 15 years, although probably the chief cause has been the irregular supply of the market.

HOME CONSUMPTION OF TEAS.

Memo shewing the total home consumption of all teas, including India, China, Ceylon and Java; also stock at the close of each year; with average of price and the proportion of stock to consumption over 15 years, in intervals of three years, from January 1st to 31st December in each year:—

Year.	Home consumption in lb.	Total stock at the end of each year.	Average price.	Proportion of stock to consumption. per cent.
1898..	235,414,185	101,638,000	8'35*	43
'95.	221,731,490	103,480,302	9'63	46
'92...	217,135,679	98,244,217	10'07	45
'89...	185,578,298	113,189,357	10'79	60
'86...	178,809,197	103,157,446	11'77	57
'83...	170,780,777	118,060,000	12'46	69

The foregoing table proves that just the opposite has happened to what would be expected. A proportionate reduction of stocks should be followed by a corresponding rise in prices and a proportionate increase of stocks by a fall.

This surely shews that some other influence must be at work, for there is no natural response to supply and demand.

The progression of the figures from '43 to '69 are gradual over 15 years, so the result can scarcely be considered accidental.

* 8'35 is only approximate.

As a matter of fact, judging from all ordinary experience, the markets were proportionately over-stocked 15 years ago, than they are now.

It is no use hiding the fact, that the influence of the regular arrivals of Ceylon teas throughout the year has in a measure stopped the necessity of so large stocks—a secure condition which, if less assured, would be more to the advantage of tea-growers.

MARKETS.

Probably buyers have noticed that tea has gone steadily down for the past 25 years and so do not care to stock against a falling market. Reverse the order, even by the slightest degree, and the opposite will happen and this latter is urgently wanted.

CLOSING THE MINTS.

In spite of Great Britain's boast of Free Trade, the Indian and Ceylon tea-growers have suffered from the arbitrary action of the Indian Government, in protecting its own exchanges at the expense of exporters, by closing the mints, which has been disastrous to tea-growers.

Without going unnecessarily into details, it may be considered that between the natural value of the rupee and its present forced value, that 1d per lb is added to the cost of production, which, roughly speaking, is almost equivalent to 4 per cent profit on the average standing capital value of the tea property of India and Ceylon—a very serious loss of itself, but far more serious when regarded in its capitalized form.

If trade were conducted free of undue influence, from either buyer or seller, these unsatisfactory relations would soon readjust themselves; but with buyers becoming fewer in number, representing larger collective capital and working on larger lines, there appears to be evidence that they have undoubtedly obtained some undue influence over the market.

Within the last twelve months it was mooted that further amalgamations and the offering to the public of certain large distributing Tea Companies was probable, which would still further reduce the number of public buyers at sales.

Indeed it is not necessary to hide the fact, that for this purpose capital is easily procurable, expenses of management saved, and additional power attained with every probability, that these conditions will increase rather than diminish in the near future.

For, doubtless, in these large concerns with special organization, there arises a most careful scrutiny of where money can be saved or made; they also command the most efficient and skilled men, and with their increasing magnitude, opportunities in their dealings for keeping down prices will not be neglected.

As compared with butter, bacon, sugar and other groceries, tea is sold at a much higher profit by retailers, further evidenced by the gratuitous offerings to those who will only purchase their teas. Growers, if united, might have something to say on this; indeed they would actually possess a power right through the trade, which, even if not used, would at least exercise some control.

PRICES OF TEA.

Unlike wheat and other annuals, the production of which can stop at the close of any season, tea does not come into heavy yield until four years after planting operations have begun, by which time it has attained a value which necessitates continued cultivation: consequently, from this

cause among others, it is apt to arrive with considerable irregularity in the market and this produces falls in price, quite unexpected and unprovided for.

There is also a time in each year, usually during June and July, when it may be expected that the London market will become inactive owing to the bulk of new Indians shortly expected; and it is at this period of the year that the heavy shipments of Ceylon arrive. The consequent fall in prices, that takes place then, exercises its influence on prices throughout the remainder of the year.

Those who have studied economics know that the measure of price of the first transaction has a most material effect upon those which follow, and this principle is acknowledged by all traders.

If so, what can be expected from sellers in a market, who use no systematic and general means of regulating the quantity of tea offered for sales and allow large and ordinary arrivals to take their place indiscriminately without attempting their regulation?

What would be thought of a man who rushed Company shares on the Share market without any regard, at the time, whether they were wanted or not? What principle is right in an individual, must also be right in an industry, having similar pursuits and interests.

Doubtless, the permanent price of tea, from year to year, is ruled more by the *lowest price* of the market at the beginning of the season than by any other cause; and if these periods could be tided over without any material fall, a better price, until these circumstances occurred again, might be insured.

IRREGULAR ARRIVALS.

The effect of these irregular arrivals being thrown thus upon the market is bad enough on produce; but upon the capital value of property and upon the tea share-market, it may truthfully be said that recognised stability is destroyed; and there is every reason to believe that, unless some permanent equalising control can be brought to bear, this condition of things will most assuredly be *more frequent in the future* than it has ever been in the past.

Owing to the small margin gradually remaining to tea-growers to go and come upon, the collapse of prices, which takes place almost yearly, assumed a very serious aspect during the early part of last and also this year. This, however, might have all been moderated by the slightest equalisation of the quantities of tea thrown upon the market, from both Ceylon and India.

No fair critic would allow that, in the public auction sales, the buyer and seller are upon equal terms. The buyer can, at any sale, buy or not, just as he chooses; he claims the right of re-bulking, objects to non-sampling breaks, claims right of objection on every conceivable point, not the least of which is a regular outcry of "quality falling-off," whenever the market becomes a little over-supplied, leading to endless, and often useless, correspondence between London and the tea gardens.

Against these the individual seller has but one redress, a futile one; if the bid be unsatisfactory, he can withdraw his teas, but as, under the present condition of the market other sellers are easily found, he is no better-off. Individually, he is powerless, on the other hand; combined growers would have it practically their own way.

The buyer can always arrange his purchases so as to obtain a marginal profit on his re-sales,

which no ordinary circumstances are likely to upset, while with the seller, everything is against a fair marginal profit at all commensurate with his outlying capital and yearly cost of production; so the only way this can with any permanency be retained must be by some collective means.

PROPRIETORS NOW RESIDENT IN LONDON.

The present system was unavoidable when the grower and proprietor lived abroad; but now the proprietary of tea-gardens chiefly rests in London, it is time more up-to-date and equitable terms of business were instituted between buyer and seller. If for no other reason, at least to be prepared for differential actions of Government and adverse defensive measures of trade.

It might be asked why sellers should not exercise the same controlling influence over the markets of wheat, sugar, coffee, cocoa, etc. The reply is: other markets compete with London in these, but London practically has the monopoly of British-grown teas; neither are these other products so favourably situated for the purpose, their growers being too much scattered.

Anyhow British tea-growers have object lessons before them, in closed mints and sugar bounties; so may rest assured that any satisfactory countervailing influence will not arise unless they take a lesson from the owners of *British industries* and either rise as one man and protect themselves, or allow the *interests of the consumer* to be alone considered, as with the West Indian sugar industry.

ASSOCIATIONS IN LONDON.

Tea-growers or their representatives do business with brokers, dock-owners, etc., *who all have their unions or associations*; and there are also very distinctly arranged understandings among tea-dealers and grocers; perhaps, not so definitely arranged, *but they exist*, or, as they know very well, trade would not be so advantageously done: unwise competition would as soon, with tea growers, make their business unsteady and insufficiently profitable.

Political economists lay down a maxim, that what is division of labour in the individual becomes Free Trade in the State: so surely it is within the legitimate function of the seller, to regulate his sales to the requirements of the market, without infringing the laws of Free Trade; and if so individually with division of labour, collective action does not alter the principle but merely increases the numbers in operation.

Indeed, no principle of Free Trade is infringed and the evidence of one of the first Professors of Political Economy, on combining to regulate the sales of the tea market, is that it would be wise rade to do so.

It is certain that the ordinary operation of natural trade cannot fight against the differential impositions of the Indian Government, any more than a man who does not fully protect his own business, can expect to compete with another who defends his at every turn.

No matter how necessary for the financial arrangements of India, it is not likely that the protective action of the Indian Government would have been so widely approved, were it not that it gives immediate benefit to the official classes

and to British investors in Indian finances. If the measures taken by India were necessary and so right, a similar course under the circumstances by the British Tea Industry *will not be less right*; federated too, it will have sufficient power to carry out the measure.

SOMETHING MUST BE DONE.

Under any circumstances, as British growers are at present placed, with a practically differential tax against their own products, with continued falls in price, irrespective of favourable statistical conditions, *something must be done* to prevent this continual downward tendency of the market. Last year, between May and August, tea fell $\frac{3}{4}$ and *there is no reason, as the market is at present constituted*, that it should not continue doing so unless some collective means are adopted to meet the situation.

SUUM CUIQUE.

A REPLY TO "SUUM CUIQUE."

Colombo, Nov. 22.

DEAR SIR,—Your article appearing in today's paper signed "Suum Cuique" is indubitably a most interesting and able communication. It brings into prominence the leading features of the position of tea and the factors that effect its price.

I think, however, that the table of comparison of prices and proportion of stock to consumption is not carried far enough to prove that stock has no, or even little, effect upon the prices which the "Buyers' Combination" is prepared to pay. This is not fault of your correspondent because the proportion of stock to consumption has only lately, namely, at the end of 1898, dropped materially below the proportion shewn in 1892, which was, (I quote his figures), then 45 per cent against 43 per cent in 1898; the effect of this falling-off of stock at the end of 1898 has been that during the current year the average price of tea has risen, and if the Calcutta export falls off a little and we do not go ahead too fast, there is no doubt whatever that the price of tea will still further advance; but these are big "ifs." But, as your correspondent says, the constant flow of tea into the consuming markets (there is no off-season now to give a buyer a chance of holding) prevents any distributor feeling that he is bound to stock; and the markets, are therefore, immediately affected by an excess in the offerings over and above the immediate hand-to-mouth demand. I think that sellers and buyers are agreed that there is no more sensitive market than the tea market, nor any market where the prospects of supplies are more studied and the effects more anticipated or discounted; but as the trade are forced to buy every year during the months of September, October, November, December, and January, 20 per cent more tea than they can deliver, it is not to be wondered at that however sanguine the buyers may be as to the cheapness of the article, there is bound to arrive a time each year when the price is forced down below the level which the estimate of the crops warrant.

The position would be improved for the planter if there were a buffer between him and the distributor such as there is in every other large article of produce; I refer to merchants, speculators, men who seeing that a position was unwarrentable as regards prices, could have facilities of

buying and of holding the "Umbrella" during the downpour of tea which occurs during the months named above.

It is not the business of a planter to speculate. His risk and duty is to make tea, and to sell it at once and obtain his money quickly; and the agency houses in London and elsewhere recognise this and wisely sell on arrival, and, in my opinion, no combination of Tea Companies could be formed of sufficient strength to regulate supplies so as to keep the price of tea up during the heavy months of the year.

If a body could be formed, among the various owners and Companies—each proprietor subscribing *pro rata* according to the number of acres under bearing, to a sufficient amount to enable the body to sustain prices when they fell below a level warranted by the whole position of tea—why then prices would not fall below their proper level.

Such a company would have to keep itself well informed of every movement in the trade; it would have to know what the export from India was going to be; what the out-turn from Ceylon would be, how Dealers' Stocks were working off; and watch any increase in the export of China, caused by the keeping of the prices of British-grown tea too high; its operations would have to be guided by the deliberations of an experienced Committee, and directed by a smart tea expert.

Granted that these conditions are obtainable, in combination with a few others, which I will not weary you with now; and, there is no doubt in my mind, that they are obtainable: then the mere announcement that the "Planters' Protection Society" was going to buy, would so reassure the trade, and tighten things; that it is more than probable they would have to buy nothing, the competition of the alarmed distributor would prevent the Company buying at low prices.

If the Company did buy a few thousand chests, the operation would not only have prevented the Market falling, but when the months of light supply came along, it should have an opportunity of making a profit on them; and pay a dividend—a dividend wrenched from the man of the insatiable distributor.

London Warehouse charges.—There is an agitation very justly in progress, to reduce the London Warehouse charges; some years ago the London Warehouses used to compete for business and in doing so they would cut their prices; some would offer 25 per cent discount, others 50; and 75 per cent has been known; this was suicide for them, so they met together and made a scale, and bound themselves under large penalties to not accept business under the scale. The result was that tea found its way into the Dock Warehouses and the last state of many of the outside Warehouses was worse than the first. What did they do?—with commendable enterprise, they bought tea gardens, and floated Companies; and even bought tea when it was cheap in Colombo and in Calcutta. The result of the buying and flotation of tea gardens, has been that the warehouses have tea to warehouse, and make a fine profit out of the business; the result to Ceylon has perhaps not been an unmixed evil, for one of the factors of the boom in tea estates a few years ago, was the anxiety of the wharfinger to obtain tea to warehouses. These facts, sir, would tend to show the difficulty of fighting the London Ware-

houses on the subject of their charges, they being so intimately mixed up with the proprietorship of much of the tea in this island, and regarding a dividend as quite secondary to charges "fine and large."—Your humble and obedient servant,
DIRECTOR.

THE BRITISH TEA-INDUSTRY.—A most exhaustive study of the tea-trade appears on page 414, one which is well worth the attention of all planters who are at all concerned in the subject. The letter is the third of a series from a veteran correspondent, signing "Suum Cuique," who has devoted months of reflection and enquiry to the question. Two important conclusions are arrived at—we cannot today touch on all the points he passes in review—which are:—(1) that, the permanent price of tea from year to year being ruled by the lowest price at the beginning of a season, efforts should be directed towards tiding over these periods without any material fall, the constant tendency of the market of recent years having proved a downward one; and (2) that some collective means must be adopted to prevent this downward tendency. Every one knows or ought to know that, even if advisable at all, the reduction or abolition of the British tea-duty is an impossible object to aim at, this time of heavy war expenditure; and that whatever decision, on the matter, if any, is arrived at by the Planters' Association next month will be an academic one merely. The Indian Tea Association, the minutes of whose meeting of October 31st, are unfortunately crowded out today, have set about the right line of attack—namely, that upon excessive dock and warehouse charges. And, it will be seen from them tomorrow, the London Committee of the I.T.A. have been asked to bring matters to a definite issue. We cannot believe that any practical good can be attained at Kandy by discussing the Tea-Duty on Tuesday week, whereas if Ceylon joined hands with India over dock and warehouse charges, some effective means of cheapening the cost of supplying tea to the London market might be secured. Meanwhile everything must be done to develop the Colombo Market as far as possible for there is ample scope in this direction, and it would be a curious reflection on the tea island if the foreign buyers we have welcomed here, were at any time to find they could not obtain all their requirements at this growing source of direct supply to the countries they represent.

INDIAN TEA EXPORTS.—Statistics published by the Indian Tea Association, with reference to the exports of Indian tea from Calcutta, show that in the month of October last the sailings to Great Britain increased to 21,692,976 lb. as compared with 21,466,999 lb. in the same month last year. More noticeable increases took place in the sailings to Australia and New Zealand, the figures being 1,763,291 lb., and 426,867 lb. respectively, and to America, the latter total being 1,495,391 lb. in comparison with 583,316 lb. in October 1898. The sailings to other places show a slight falling off, 1,216,278 lb. having been exported in October last year and 1,031,405 lb. in this.—*Pioneer*, Nov. 18.

Correspondence.

To the Editor.

ALL ABOUT RUBBER.

Botanical Department, Trinidad,
Sept. 22, 1899.

GENTLEMEN,—Always the first in the field to collect and disseminate information likely to be of use to the planting interest, you have only acted up to your traditions in issuing "All about Rubber" 1899. The book is a perfect compendium of information on the rubber question, and affords me my first look at the latest circular of the Ceylon Botanical Department, and of Mr. Parkin's Report. I have no time today to point remarks at length, but I may say that I am unable to follow some of the propositions of Messrs. Biffen and Parkin.

I cannot see where the evidence comes in, which makes the Ceylon *Castilloa* a different species to that in Trinidad. Surely it is possible to follow the recognised method of sending specimens to some large herbarium for identification, rather than to guess them different, to explain differences in the latex. I might as well declare the Heveas different because that of Ceylon has "no pronounced odour or taste," while our *Hevea brasiliensis*, is readily distinguished by a strong odour of stale saltfish; as can the prepared Brazilian article. I cannot reconcile Mr. Parkin's views on coagulation with my own. If coagulation is brought about by the "separating of the proteid matter from solution which entangles in its meshes the rubber particles so to form a clot," how is it that on analysis of rubber prepared by another method it "just showed a trace of nitrogen" only. The latex of Ceylon "does not behave" like the latex Mr. Biffen describes, so it is made out to be a different species. "Cream left on" the surface of water, after all proteids are washed out, will coagulate naturally, that is to say, it will be "brought into a mass" curdled, or solidified. "All about Rubber" should be in every Rubber-planter's hand, because it is right that they should be conversant with the different views afloat, and the course of the various experiments.—I am, yours faithfully,
J. HINCHLEY HART.

CEYLON TEA IN CANADA.

Montreal, Oct. 4.

DEAR SIRS,—Richmond is the Province of Quebec, in which province there is a population of one million five hundred thousand souls, eighty per cent of these being French, who use almost exclusively China and Japan teas. "Salada," our own specialty, is being pushed on this ground vigorously, and has been very kindly received by the English-speaking portion of the population, and we are gradually (though very gradually) getting some support from the French element. The paper above referred to will give you an idea of what we are doing in the way of advertising. This is only one of a series of seven subscription papers that have a large circulation throughout this province, and our red advertisement appears in each of them the same as copy sent you, and is an innovation in newspaper advertising and a striking one too. Besides these papers we are advertising in many others in this province, both by display advertisements and readers, together with an extensive display of enameled window signs, and an almost lavish distribution of samples. This good work is backed up by travelling representatives that are on the road continuously covering every town, village and hamlet. Some day we hope to have succeeded in converting a large proportion of the French-speaking people

to the use of the better and purer teas from your island in which we are mutually interested. Of course beyond this Province are the provinces of Nova Scotia, New Brunswick, Prince Edward Island, and Cape Breton; all of these places we are doing a large and growing business in, and have lately opened up in Newfoundland. We shall feel obliged if you will mention these advertisements in your next issue.—Yours very truly,

GEO. MANN, Manager for Eastern Canada.,

The "Salada" Tea Co.,

[Planters in Ceylon will be glad to hear of the work that is being done to specialise their tea, more especially among the less easily convertible French-speaking population of the Dominion. The advertisements are of a most striking and attractive nature.—ED. T.A.]

A COCONUT ANALYSIS.

Colombo, Nov. 21.

DEAR SIR,—I beg to enclose report an analysis of a Coconut and shall be obliged if you will give it publicity in the columns of your paper.—Yours faithfully,
A. BAUR.

REPORT,

Though there exist several analyses of parts of of the Coconut, no one seems to have undertaken the task of getting a complete analysis made with a view of ascertaining the actual demand made by the coconut upon the mineral constituents of the soil. Yet this knowledge is of paramount importance to those going in for manuring owing to the different customs which prevail, either of exporting the whole or only part of the nut.

I am glad therefore to have the opportunity of supplying those interested with a complete analysis executed by Dr. F. Bachofen, in charge of my Chemical Laboratory. Together with the analysis will be found a table showing the quantities of the more important constituents removed by 1,000 coconuts from the soil. A. BAUR.

INDIAN TEA ASSOCIATION.

Abstract of proceedings of a meeting of the General Committee held on 31st October, 1899. Present: Messrs. H S Ashton (Chairman), H C Regg (Vice-Chairman), W Brown, A C Lawrie, R Magor, M R Quin, A Tocher, and T Traill, Mr. R R Toynbee was absent from Calcutta.

Proceedings of the last meeting of the Committee, held on the 3rd October, having been approved in circulation, was confirmed. Proceedings of the Assam Branch of the Association for the month of September were to be recorded. Letters of 22nd and 29th September, and 6th and 13th October, from Mr. Ernest Tye, Secretary, Indian Tea Association, London, were brought up, after previous circulation for final consideration. The principal matters to which Mr. Tye referred in these letters were:—

(a) *Bonded Warehouse Charges in London.*—With his letter of 22nd September, Mr. Tye enclosed copy of a letter dated, 21st September, addressed by the London Committee to the Tea Clearing House Committee in reference to this question. In this letter the London Committee laid stress on the onerous nature of the charges levied upon teas by the warehouse proprietors, and strongly urged that substantial reductions should be made. In his letters of 6th and 13th October, Mr. Tye referred at length to the General Committee's letter, No. 561-O. of 13th September, in which the whole question of the warehouse charges was fully discussed. He stated that a Special Sub-committee of the London Branch of the Association had been appointed for the purpose of negotiating with the Tea Clearing House Committee with a view to a reduction of charges. The London Committee had also considered the question of the organization of opposition warehouses on the principle of co-operation. It was pointed out that this principle had been adopted for some years by several of the largest London tea Companies who had subscribed capital for the purchase of Butler's wharf. Other warehouses might be established on the same principle; and possibly a license might be granted by the Customs authorities if the combination were sufficiently strong to guarantee, say, two hundred, or two hundred and fifty thousand chests. If the warehouse were not in a position to offer the facilities provided by the Tea Clearing House, there would be a difficulty with the tea trade; but this might be met by either purchasing or hiring one of the existing bonded warehouses. If, in raising the requisite capital, the amount subscribed by each shareholder was approximately in proportion to the quantity of tea sent by him to the warehouse, the rates could be fixed on any scale, because it would be the same thing to the shareholders whether they received the benefit of their co-operative working in the shape of low charges, or as a return in the shape of profits. Companies selling their teas in Calcutta would, however, be unable to control the warehousing of their produce on arrival in London. Precautions similar to those taken on boardship to prevent contact with other produce have to be taken in the warehouses. This necessitates separate buildings; consequently a warehouse which could depend upon a full supply of tea would be at a considerable advantage compared with one which could only utilize a portion of its tea space and could get no return from the balance. For this reason the London Committee believed that some of the existing warehouses had difficulty in working to a profit.

The question was considered by the Committee, and the Secretary was directed to address the London Committee again in regard to its urging them to bring matters to a definite issue. In this letter attention was to be drawn to the suggestion made in the General Committee's letter of 13th September that a scheme for establishing co-operative warehouses should be formulated in

London, an enquiry was to be made as to whether it was proposed to devise such a scheme, and it was to be recommended that this should be done.

The Secretary was also directed to write (in continuation of his letter No. 569-O. of 14th September) to the twenty-six Calcutta tea companies named in the proceedings of the meeting held on the 15th September. In this letter the remarks made in the letters from the London Committee were to be incorporated, and it was also to be stated that they were again being addressed on the subject in further reference to the establishment of co-operative warehouses.

(b) *Area of Tea under Cultivation.*—With his letters of 22nd and 29th September and 13th October, Mr. Tye forwarded copies of correspondence between Mr. J E O'Connor, C I E, the Director-General of Statistics, Mr. A G Stanton of Messrs. Gow, Wilsen and Stanton, and himself in regard to the difficulty of obtaining accurate returns of the area under tea in several districts in India. Mr. O'Connor drew special attention to the case of Travancore. In that district the total area under tea was returned as 30,073 acres in 1897, while in 1898 it was given as 19,634 acres. On the other hand the outturn was given in 1897 as 2,545,913 lb. while in 1898 it was returned as 8,413,860 lb. Mr. O'Connor also stated that 84 gardens in Assam had withheld the information for which they were asked in connection with the matter. The London Committee suggested that the Association in Calcutta should give all the assistance possible to Mr. O'Connor in order to enable him to procure more reliable figures.

The question was discussed, and it was pointed out that it had engaged the attention of the Committee in connection with the Report issued by the Director-General of Statistics on the 1st November, 1898. Some correspondence had ensued between the Statistical Bureau and the Association, with the result that it had been suggested to the Director-General, that if practicable, before publishing the figures in his next report, he might place them before the Committee for verification. No reply had been received to this letter and it was accordingly decided to write to the Director-General of Statistics pointing this out; and stating at the same time that the Committee would glad to do everything possible to procure more accurate returns. It was also to be suggested that the names of the 84 Assam gardens referred to should be furnished, as it would be difficult for the Committee, without that information to take any steps in regard to them.

The Secretary was also instructed to address the United Planters' Association of Southern India and the Planters' Associations in Travancore, drawing their attention to the matter and laying stress on the importance of reliable statistics being furnished to Government in all cases.

The Chairman undertook to interview Mr. O'Connor in regard to the question.

(c) *Scientific Officer.*—It was stated in the letter of 13th October that the London Committee had again considered this question. In view of Mr. Kelway Bamber's re-engagement with the Ceylon Association, they asked for the views of the General Committee as to whether a scientist should be selected in England. The Chairman of the Association in London had undertaken to make enquiries, and the necessary arrangements would be made by the Committee there if desired.

The matter was considered, and on reference being made to the replies received from the various local Associations to the Committee's Circular letter No. 31822 O of 12th June, it was seen that a majority were in favour of the engagement of an agricultural chemist.

The Committee were also of this opinion, and it was accordingly decided to write to the Association in London, stating that their offer to select a scientist in England had been accepted, and asking that enquiries be made at once regarding an agricultural chemist. It was also to be pointed out that it would be necessary to consult the Government of Bengal and the Administration of Assam before anyone was finally engaged.

Considered file of papers in connection with the Bill to consolidate and amend the law relating to emigration to Assam which was introduced into the Imperial Legislative Council on the 13th October. Copies of the Bill had been forwarded to the Assam and Cachar Branches for their consideration. The Assam Branch had arranged for a special meeting of members in November to discuss the Bill, and steps were, it was understood, also to be taken in Cachar for the due consideration of the measure. Mr. Buckingham, C.I.E., Chairman of the Assam Branch, had been appointed by the Government of India as an Additional Member of the Imperial Council to participate in the discussion of the measure. The Committee then proceeded to the formation of a Special Sub-Committee to examine and report upon the provisions of the Bill. It was agreed that the Sub-Committee should consist of five members and Mr. Begg and Mr. Magor accepted seats upon it. It was further agreed to ask Mr. A. Topping, of Messrs. Macneill & Co., Mr. W. Warrington, of Messrs. Finlay Muir & Co., and Mr. C. de C. Richards, of Messrs. McLeod & Co., to act. A letter of 20th October from the Chairman of the Assam Branch upon certain of the provisions of the Bill, and a letter of 24th October with enclosures from Messrs. Begg, Dunlop & Co., were to be referred to the Sub-Committee for their consideration. Considered letter of 28th October from Messrs. Shaw, Wallace & Co., covering papers in original in regard to a case in Cachar in which an application had been made under Act XIII of 1859 for the arrest of certain absconded coolies. The Magistrate had refused to issue warrants for the arrest of the coolies on the ground that the advance of one rupee made under each contract was not sufficient to make the contracts binding. Messrs. Shaw, Wallace & Co. stated that it appeared to be a custom on many gardens to make an advance of only one rupee, deducting the sum at the termination of the contract. There appeared to be no decision of the High Court upon the point and they thought it was a question upon which the Association might obtain a legal opinion. After some discussion the Secretary was instructed to forward the papers to Messrs. Sanderson & Co., the Solicitors to the Association, with a request for an expression of opinion upon the points in question. Considered letter No. 4491-T., of 27th October, from the Director-General of Telegraphs, in reply to the Committee's letter No. 611-O., of 10th idem, in regard to telegraphic news for the mofussil. With the last-named letter, the Committee forwarded a letter of 2nd October, from Mr. J. Buckingham, C.I.E., the Chairman of the Assam Branch, suggesting the establishment of a regular system of wiring the latest telegraphic news to Assam. Mr. Buckingham estimated that at least forty stations in the Assam Valley alone would be only too glad to avail themselves of the opportunity of getting the latest telegraphic communication, provided they had not to pay deferred rates. He proposed that for all telegrams conveying English or Indian

news, "press" rates only should be charged. This proposal was supported by the Committee in their covering letter.

In his reply the Director-General of Telegraphs stated that he was not empowered to grant the concession asked for. He, however, drew attention to Rule 109 and footnote, Section 11 of the *Telegraph Guide*. He pointed out that under that rule if in any district served by a telegraph office, whether by hand or postal delivery, four subscribers combined, and desired each to be provided with a copy of a telegram containing a summary of news, the cost to each subscriber would be practically the same as that of a telegram addressed to each subscriber at press rates. If more than four subscribers desired copies, the cost to each would be less than press rates. Such telegrams would have to be drawn up and sent by an agent independent of the Telegraph Department.

The Secretary was instructed to forward a copy of this letter to Mr. Buckingham, with a request for his opinion upon the proposal referred to by the Director-General of Telegraphs, and asking whether the Committee could do anything more in the matter.

H. S. ASHTON, Chairman.

—*Indian Planters' Gazette*, Nov. 11.

THE COMING FIBRE INDUSTRY.

There can be little doubt, judging from present appearances, that the profitable growing of agaves for the production of fibres in India is merely a matter of time. A few years back little was known in this country concerning these plants and their great economical value. Thanks to "Forester" and others they have, during the last few years, been brought prominently forward, and now that a machine is invented which can be worked by a couple of natives after a few hours' practice and turn out fibre at the rate of 1½ tons per hour, there is every prospect that during the next few years we may have an industry which may rival in dimensions that of the Bahama Islands themselves. Although a good deal of information upon the subject has been furnished from time to time to the press, there are still a large number of enquirers into such details as to the very best agave to grow, the probable cost of planting, yield per acre, &c. As I have for the last five years given considerable attention to the subject with the view of planting up waste land, perhaps a few of the facts regarding the cultivation of the plant may not come amiss at a time when a great many zemindars and planters are seeking information on the subject.

THE AGAVE GENUS.

There are numerous species of the agave genus, and they are nearly all *monocarpic perennials*, that is they grow on for an indefinite number of years producing leaves only and then flowers. They only flower (poll) once in their lives as when they flower they die. The usual period between the very young state and the throwing up of their flowering poll is between seven and fifteen years, but this would appear to entirely depend on the nature of their environment.

SISAL HEMP.

Sisal hemp is produced by more than one species of agave, but one recognised as producing the very best agave fibre is *Agave rigida* var. *sisalana*. This is the species which has been introduced into this country, and considerable care has been taken to import only the true variety. *Agave sisalana* is the name that Dr. Perrine gave to the plant known to the natives of Yucatan as Yaxci. Another variety cultivated in Yucatan is named *Agave rigida* var. *longifolia*. This variety produces equally as valuable

a fibre as the one known as *sisalana*. As a matter of fact they are the same plant in every particular, with the exception that *longifolio* is armed with side teeth which renders it more difficult to handle and cannot be conveniently planted so closely as the *sisalana* variety, which is wholly, or almost wholly, destitute of side teeth, and only armed with a sharp spine at the point of the leaf. There are several other varieties of the *rigida* type cultivated in Yucatan, and also some varieties of the *Furcroyas* and the fibre all goes under the name of *Sisal*. But although the produce of these different plants go under this name in the market, they are of different value, and the fibre of *Agave rigida* var *sisalana* is now recognised by experts as producing the very best agave fibre for white ropes, and which is only second to real Manilla hemp itself, and some assert that in some instances it is even superior and commands a better price than the latter.

One of the Kew papers upon vegetable fibres states that in the report on fibre plants by the late Director of the Botanical Department, Jamaica, it is mentioned that with regard to the value of *Agave rigida* and its allied forms as the sources of the sisal hemp of commerce, there were two important points deserving attention. The first was the universal increasing demand which exists in all countries for this fibre; and the second was the drought-enduring character of the plant and the simple and economical treatment which it requires at the hands of the cultivator. It has been stated that in regularly-planted areas there should be 400 plants to the acre; but it should be pointed out that this statement applies to Yucatan, where the majority of the plants under cultivation are fully armed with side teeth and cannot be planted closely. The selected variety, which was named *sisalana* by Dr. Perrine can be planted very much closer, and it is said by those who have tried this variety in India that 6 feet between the plants in the row and 8 feet between the rows gives ample room for the full development of the leaves which can be easily harvested owing to their being unarmed. Young plants from 1 foot to 2 feet high when planted commence to yield in the fourth year. It has been stated that the same plants continue to yield for fifty or sixty years. It may be said at once that no reliance should be paid to such a statement. Their yielding period is between their fourth year and the time they flower, and that period may only be four or five years, and it may extend to twelve or fifteen years. The great rule to be kept constantly in practice is to plant a young sucker whenever a plant commences to yield leaves. The leaves of the older plant will in no way interfere with the growth of the younger one underneath, as whenever the leaves of the big plant come down to a horizontal position they are ripe for cutting, and the leaves left on are always more or less pointing upwards. Where young plants are planted for the first two or three years they will grow suckers from their roots. These ought to be always removed, as they take strength from the parent plant. If they are put in a nursery by themselves they will always be there ready to plant when required. If this supplying rule be strictly observed there can be no reason why a plantation will not last twice fifty or sixty years, as the agave is really a "scrub jungle," and the roots of plants which have perished are in a continual state of decay, and by adding humus to the soil through the process is really one of Nature's land reclaimers.

To give some idea of the probable returns from a sisal hemp plantation it may be stated that each plant from 4 to 5 years old is found to yield on an average 25 to 35 leaves per annum, and these leaves will give 1½ lb. of clean fibre; this amount has been actually got by hand clearing, from leaves grown upon waste land in Assam. Eight hundred plants to the acre of the smooth-edged *sisalana* variety will not prove a single plant too many, and this would mean 1,200 pounds of clean fibre to the acre. This may be taken as a fair calculation; much depends

upon how the plantation is planted and the details of management.

COST OF GROWING.

The actual cost of growing and preparing the fibre would naturally vary according to the locality in which the plantation was situated, but in any part of India it must be very much cheaper than it is in the West Indies, where the price of labour is so much higher. The land upon which the agaves are grown in Yucatan is of a gravelly, stony and in some places of rocky character, and they thrive best and give most fibre in comparatively arid districts. Moist or rich land is considered unsuitable, and it has been proved in this country that, although the plants grow luxuriantly upon such lands, the yield of fibre is comparatively small and of less strength than it is when grown upon what is usually called barren or useless land.

HARVESTING.

The proper time to harvest the leaves is when they have nearly come down to a horizontal position on the rosette. But the leaves take no harm if they are left on the plant for three months after coming to this position so long as they are cut before they commence to turn yellow, as after this the fibre is apt to be discoloured which detracts from its appearance and consequently its value. As the leaves are not ripe till they come down to the horizontal position or nearly so, it is always the outer leaves which are cut first. The leaves are cut and made into bundles of 50 each, and 30 such bundles is reckoned a fair day's task when carried out to the edge of a cart road. The machine should be placed near a supply of water, and one machine (of the latest invention) is ample for 200 acres. After the fibre has passed through the machine, it is hung up in the sun and thoroughly dried, but care must be taken that none of the green juice is left on the fibre when exposed to the air, or it is bound to be discoloured. If a high degree of whiteness is desired it is left out all night to bleach and during next day carefully turned. The fibre is made into bales by means of a screw press, and great care is taken to have these bales as tidy as possible, and the fibre ought to be kept straight in the bales. Proprietors of gardens are reticent of risking money in experiments, but, as far as can be judged from the data available, those who have land lying idle upon which they have to pay rent will be consulting their own interests by giving this industry their careful study and attention—L, in *Calcutta paper*.

THE BRITISH TEA-INDUSTRY: A REPLY TO "SUUM CUIQUE."—An excellent reply to the letter of "Suum Cuique" appears on page 418, and a notable suggestion is made for the keeping of prices up to a proper level. It is surmised that if a body of proprietors (including Companies) could be formed, each subscriber subscribing according to his property, to enable prices to be maintained at a high level when the downward tendency became marked, such prices would not sink. The qualifications of the "Planters' Protection Society," as it is named, are further detailed; and it is shown that this body could withhold supplies when there was a rush of imports, and sell them again at a profit when deliveries became lighter. Some pungent remarks on Warehouse Charges are also made, and we commend these to the attention of the Planters' Association, which we yet hope to see directing its main attention, ten days hence, to this topic, while submitting the Tea-Duty *pro forma* for discussion as invited by our Indian friends. "Director" shows some of the difficulties of the attack. Will not some planter's ingenuity come to the rescue with a plan of campaign?

CEYLON LAND AND PRODUCE COMPANY
LIMITED.

ANNUAL REPORT.

Report of the Directors, submitted to the fifteenth annual general meeting of Shareholders held at the Registered Office of the Company, Leadenhall House, 101, Leadenhall Street, London, on Monday, the 13th day of Nov. 1899:—

Your Directors have the pleasure to submit the Annexed Profit and Loss Account and Balance Sheet for the Crop year ending 30th June, 1899, duly audited.

The amount at credit of Profit and Loss Account is £11,978, 11s 10d, which, with the sum of £321, 12s brought forward from last year, leaves £12,300, 3s 10d to be distributed.

On the 22nd July last an Interim Dividend of 7½ per cent. on the ordinary Shares and 3 per cent. on the Preference Shares was paid, and your Directors now propose to pay on the 15th day of December, 1899, the balance of the fixed Cumulative Dividend on the Preference Shares (3 per cent.) making 6 per cent. for the year, and 7½ per cent. on the Ordinary Shares, making 15 per cent. for the year, and in addition, a bonus of 5 per cent. on Ordinary Shares—all free of Income Tax. It is also proposed to transfer £4,000 from Profit and Loss Account to Reserve Fund, increasing that account to £17,500, and carry forward the balance of £1,532 16s, subject to the Directors' remuneration for the year under review, and to the payment of Income Tax, &c.

In accordance with a Resolution of the Board, a call of 10s per Share was made upon all Members holding Preference Shares upon which only £3 10s had been paid, and the same was payable on the 30th March, 1899.

Your Directors regret that owing to unfavourable weather the total crop of Tea fell short of the quantity estimated, though the intake slightly exceeded that of last financial year. It will be observed on reference to the Statistics herewith that the plucking area was increased from 1,676 to 1,754 acres. Your Directors, however, desire to point out that this additional acreage was only in partial bearing.

With regard to Cocoa, your Board are pleased to note that the Estimates were exceeded, though, owing to the wet weather prevalent when this product was being prepared for Market, a lesser percentage of "good red" kinds was obtained.

A welcome rise in the price of Tea has been recorded, whilst freights have ruled on the average somewhat lower than during 1897/98. Average Cocoa values, for the reason above stated, are less than last year.

Your Directors desire to inform the Shareholders that during the past three years the total expenditure on Manure and its application amounted to over £60,000, the whole of which has been charged to Revenue.

It is a source of gratification to your Directors that, though the cost of production tends to increase by reason of the higher rate of exchange plus a more liable cultivation, they are able to assure the Shareholders of the continued prosperity of the Company, and they are of opinion that the outlook for the future is bright.

TEA.—At the beginning of the year the quantity available for shipment to Great Britain for 1899 was estimated in Colombo at 93 million lb. against rather over 96 million lb. actually exported in 1898. So far as can be judged at present, the amount sent to this country during the current year will not exceed that of the for going one, and the Indian crop being also likely to prove of moderate dimensions, the statistical position of all Tea may be considered satisfactory, especially in view of the larger deliveries which have been going on recently, both for Home and Foreign use.

A check was given to business by the dispute which arose in the early part of the summer, between Importers and the Trade, regarding the 1 lb. draft, and Public Sales were virtually suspended in consequence for three or four weeks. This caused some accumulation of Imports, which however have now been about worked off, and the Auctions are rapidly resuming their normal size.

Prices ruled above those of 1898 for the first six months of this year, but latterly have not been quite so favourable. For the 964,500 packages passed through the Mincing Lane Sale Rooms from 1st January to 31st ult. the average is 8d per lb., compared with 7½d. per lb. in the corresponding ten months of 1898 for 984,300 packages.

During the spring months quality, as is usually the case, shewed a falling off, many of the Teas being deficient in strength and flavour. Later on a general improvement was manifested, and some very desirable invoices were received which attracted considerable attention.

That the use of Ceylon Tea in other countries than Great Britain is growing, is evidence by the shipments from London to outside quarters, and as will be seen by the undermentioned figures, business direct from Colombo with Russia, America and Australia, for the first nine months for the year, marks an increase.

TO AUSTRALASIA.		
1899.	1898.	1897.
11,967,000 lb.	11,259,000 lb.	9,524,000 lb.
TO RUSSIA.		
2,719,000 lb.	1,915,000 lb.	325,000 lb.
TO AMERICA.		
2,344,000 lb.	1,870,000 lb.	707,000 lb.

COCOA.—The marketing of this article has been subject to many peculiarities this season, mainly attributable to the effects of unfavourable weather on the greater portion of the Crop, which has given a larger proportion of inferior and ordinary kinds than in any previous season. The effect of this was shewn in the scarcity of good and fine red parcels almost throughout the entire Crop, and in consequence, there was a considerable rise in the price of the finer grades, with a corresponding decline in those for the less desirable kinds, the result being that the general average is at a lower level. At the same time it may be pointed out that higher prices have been obtained for really well-prepared lots than for the past few years. Manufacturers generally are becoming more favourably impressed with this growth, and the increasing consumption is more than sufficient to deal with any likely large increase in the production of the island. Your Directors look favourably upon the future of this article. The out-turn of the Company's Crops was, as stated above, affected by the weather, and was much below our usual high standard of quality, but in the realisations full advantage was taken of the exceptional Market movements.

Acreages.—The following Statement shows the approximate acreage of the Company's Properties at date:—

Name of Estate.	Tea.				Total Acreage.	
	1 yr.	2 yrs.	3 yrs.	4 yrs. & over.		
Alloowiharie Group ..	—	117½	50	47	2,450½	
Andangodde Estate ..	—	16½	39½	120½

1,386½						

N.B.—Coconuts are planted through Tea, Cocoa and Coffee. In the absence of detailed surveys these figures, as mentioned above are approximate only.

Your Directors greatly regret having to inform the Shareholders of the death of Wm. Keiller, Esq., and Sir N. A. Staples, Bart. The vacancies thus caused have been filled in accordance with the Articles of Association by Alex. D. Wilson, Esq., of Messrs. Chapman, Wilson & Co., 23, St. Mary Axe, E.C., and Lewis A. Lewis, Esq., of Messrs. Lewis and Noyes, 14, Mincing Lane, E.C.

The prospects of the Tea crop for 1899/1900 are so far, favourable, the intake to 30th September being in excess, as compared with the Crop at same date last year. Your Directors hope that the Estimates of Cocoa will be realised, but at the moment it is practically impossible to speak with any certainty.

Your Directors have decided to issue the balance of the 6 per cent. Cumulative Preference Capital, viz., 2,150 Shares of £5 each, at a premium of 12s 6d per Share, and the attention of the Shareholders is drawn to the Secretary's Circular accompanying this Report.

Mr. Alex. D. Wilson, by rotation, retires from the Directorate, but being eligible, offers himself for re-election.

Mr. James B. Laurie, the Auditor, also retires, but he is eligible, and offers himself for re-election.

JAMES WILSON, Chairman. ALFRED E. LOCK, Secretary.

(CIRCULAR ACCOMPANYING REPORT.)

Dear Sir or Madam.—I am desired to inform you that by Article No. 6 of the Company's Regulations, it is provided that—

“The Capital of the Company is One Hundred Thousand Pounds, divided into Twenty Thousand Shares of Five Pounds each, where of Ten Thousand are Preference Shares, and Ten Thousand Ordinary Shares. The Preference Shares are and shall be entitled to receive out of the profits of each year a Cumulative Preferential Dividend of £6 per centum per annum on the Capital paid up thereon, and no more than such Dividend and the surplus profits of each year shall (subject to the right to create a reserve fund) be divided, in payment of Dividends on the Capital paid up on the Ordinary Shares.”

I am further desired to point out that on the 30th June, 1893, the Company had in its possession a total area of 4,554 acres, out of which 2,780 were under cultivation at the then book cost of £96,958. At the close of last financial year 3,836 acres in all had been planted up, excluding the area under Coffee, and the total extent increased to 5,264 acres, the book cost being £116,414—in other words, during this period a sum of £19,456 has been added to Capital Account, the major portion of which (£17,500) will have been provided out of the profits of the Company.

In view however of the further expenditure needed to bring the clearings into full bearing, and to provide for the building and equipping of Tea Factories to be erected on the Strathisla and Alloowiharie Groups, the Directors beg to offer to the Preference Shareholders, in proportion to their present holdings, the balance of the unissued 6 per cent Cumulative Preference Capital, viz., 2,150 Shares £5 each, at a premium of 12s 6d per Share. * * *

The amount due in respect of the Shares will be payable in instalments as follows, viz:

On 1st December, 1899 ..	£1 10s 0d	per Share.
1st January, 1900 ..	£1 10s 0d	”
1st February 1900 ..	£2 12s 6d	” (including premium).

The Dividend at the rate of 6 per cent per annum will accrue as from dates of payment; pre-payment of the whole sum will be accepted, the Dividend being calculated at the rate of 6 per cent per annum also.

Interest at the rate of 7½ per cent will be charged on instalments, after they become due, during the non-payment thereof. Failure to pay any instalment will render the previous payments liable to forfeiture. Interim Dividends are generally payable in July, and Balance Dividends in December.

I am, &c., ALFRED E. LOCK, Secretary.

STATISTICS FOR PAST 10 YEARS.

NORTH BORNEO TRADING COMPANY (LIMITED.)

Here is a report from *The Times* of a Company in which we, in Ceylon, should take some interest, in view of its pioneering with "rubber":—

The second ordinary general meeting was held at Winchester-house. Mr. A. J. Scrutton presided, and, in moving the adoption of the report, said that he would leave it to Mr. C. P. Bennett, the managing director, to explain the present position and the prospects of the company. Mr. Bennett, who seconded the motion, stated that they had 103,500 acres of land, which stood in the balance-sheet at 12s per acre. There could be no doubt that the land, which was located round the Bay of Sandakan, was some of the finest in Borneo, and as it was held for a period of 999 years it might be regarded as practically freehold. The total outlay on the development of their estates was £1,241 in the period covered by the accounts—from July 1, 1897, to December 31st last. Of this amount £723 was for rubber cultivation on the Sekong plantation. He rather hoped to see this item still larger in the next balance-sheet, because if they got good rubber they would obtain very satisfactory results from the investment. The 27,050 shares, credited with 8s paid up, which appeared in the balance-sheet as unallotted, had, since December 31st last, been applied for and issued. On the whole, he thought that the shareholders should be satisfied with the gross profit of £2,694, seeing that, during the first six months of the period covered by the accounts, no business was being done. Mr. Roberts, the manager, was in England, and the work of reconstructing the old company was being carried out. Judging by the figures received lately from Mr. Roberts, he believed that the accounts for 1899 would show much better results than those now presented. On the 10th ult., the board were informed that China was now prepared to take more timber than the company could ship, so that they were not exactly in the position of having to seek for fresh markets. However, a good look-out was being kept for other markets in the East, and only lately they concluded a contract for 20,000 cubic feet of timber for Manida, and other orders could be had almost for the asking on favourable terms. They had succeeded in overcoming the shipping difficulties which stood for a long time in the way of the company's progress, and he expected that there would be a considerable increase in their output in the immediate future. Their company, and he believed, all the other Borneo trading companies were now

receiving every consideration on the part of the Chartered Company. The motion was unanimously adopted.

PRODUCE AND PLANTING.

TWADDLE ABOUT TEA.

The fact that the consumption of tea is increasing rapidly in the United States is perhaps the chief reason why certain people whose hobby it is to attack everything that is popular hasten to assert the danger of tea drinking. One of the latest diatribes against tea is attributed to Dr. Kellogg, the founder of a sanatorium at Battle Creek, in Michigan. Tea according to this investigator, is a

most dangerous drug. He tells of servant girls arrested in the streets of Boston for being drunk and disorderly who had tasted no alcohol, but who had "chevered tea constantly"; also, of an old lady in Minneapolis who drank thirty or forty cups a day and ended her life in a lunatic asylum. But even worse than these cases are those in which tea plays a more silent and insidious part. Among women it produces a kind of mania, "the mania for acting the persecuted saint. Among men, unlike the much condemned alcohol, it produces fear. One patient who was suffering from tea poisoning in this way never passed a high building without looking up to see if something was going to fall upon him. Then the relentless Dr. Kellogg goes on to argue that tea is responsible for sleeplessness, and, in fact, most of the ills which flesh is heir to. We have heard all this so often that it has ceased to be funny. There is another kind of mania than that produced by drinking tea, and it appears to be brought on by the knowledge that a number of people drink tea in moderation and find pleasure and comfort in doing so.

RUSSIAN GROWN TEA.

The Official report as to the results of the tea crops on the experimental tea plantation in Tchakva, near Batoum, shows that all the three crops collected produced exceedingly good tea. The Commission appointed to report classified the tea under two qualities, and came to the conclusion that the first sort could be sold retail at two roubles a pound. As the best Russian tea is sold at two roubles eighty copecks a pound, the two-rouble tea corresponds to tea at about 2s 3d in Mincing Laue. The Tchakva tea was appraised more highly because it was manufactured on the Indian and Ceylon method rather than the Chinese.—*Home and Colonial Mail*, Nov. 10.

SOUTH INDIAN PLANTING NOTES.

OOTACAMUND, Nov. 25.—Mr. Barber, Government Botanist, is under orders to proceed to Vizagapatam to report on the sugar-cane disease, which is prevalent in that District.—*Madras Mail*, Nov. 28.

COORG PLANTING NOTES.—Nov. 24.—Crops began to ripen up early this season owing to the early blossom last February, and some fly-picking was done towards the end of October; but no full picking was commenced till the middle of the current month. Every care is being exercised the whole country over in the curing of the coffee, for which there is more opportunity with the present small crops than when, like last season, crops are large and things have to be done at high pressure. There is every reason to hope that Coorg coffee of this season's growth will go a long way to re-establish its reputation for quality which it had so largely lost last season. The samples of beans already gathered are very fine. There has been a better demand for East Indian coffees in the London market lately.—*Madras Mail*, November, 28.

WYNAAD PLANTERS' ASSOCIATION.

The following extracts are from proceedings of a General Meeting held at Meppaddi, on the 8th instant:—

COFFEE ROBBERY.—Read letter from the Superintendent of Police, Calicut, asking for information as to the best time to send up the extra constables to prevent the theft of coffee. Resolved, that the Superintendent be thanked for the trouble he has taken

in the matter, and that he be informed that the Association considers that the 1st November would be the best date on which to send up the constables.

U. P. A. S.—(1) Paris Exhibition.—A subscription list towards the Paris Exhibition Fund was circulated; the total amount collected came to R645. (2) The Secretary was requested to ask the Secretary, U. P. A. S. I., for a copy of the draft of the new labour ordinance; and the Committee were asked to meet to discuss it at the earliest opportunity.

ALLEGED COOLY-CRIMPING.—Read copy of letter from the Ceylon Labour Federation re-alleged crimping from Ceylon. Proposed by Mr. R. Lamb, seconded by Mr. M. D. Taylor, that this Association point out that it is not within its province to interfere in the matter referred to by the Secretary of the Ceylon Labour Association in his letter to the U. P. A. S. I., dated 13th September, 1899.—*Madras Mail*, Nov. 28.

ROADSIDE FRUIT IN EUROPE.

The cultivation of fruit trees along the highways of France is being extended each year. The Government having first set the example, the communes in certain departments adopted this practice as a source of revenue, so that now roadside fruit cultivation has become an important branch of national industry. It is not, however, only in France that fruit trees have been planted along the roadside. The United States Consul at St. Etienne says that in Germany, Belgium, and the Duchy of Luxemburg, the system has been greatly developed, giving satisfaction to the State as well as to local interests. On the Wurtemberg roads, for instance, the fruit harvest from this source produced in 1878 over £40,000, and last year the returns had more than trebled. The annual revenue derived from the national roads of Saxony planted with fruit trees, rose from £1,800 in 1880 to £8,400 in 1892, furnishing a total sum of £68,000 for the 13 years. In Belgium, according to the statistics of 1894, over 2,875 miles of roads were planted with 741,571 fruit trees, which furnished the large sum of £400,000. In France the production of fruit trees is estimated at £12,000,000. In Westphalia, in the Duchies of Baden and Saxe Weimar, in Alsace-Lorraine, Switzerland, &c., the *employes* of the Administration of Roads and Bridges and the road supervisors, are instructed in fruit culture. In some of the southern departments of France the roads are bordered with cherry trees, producing the small fruit called *merise* (wild cherry), much appreciated for making wine *suigeneris*, preserves, and even alcohol. In the Tououraine, plum trees predominate, while in the Allier, the walnut trees transform the roads into shady walks. In Auvergne the chestnut tree flourishes; while in Normandy, place is naturally given to the apple tree. Some twenty years ago, the picturesque roads of the north-east of France were lined with stately poplars; but although ornamental, their roots went far and wide, rendering the adjacent meadows sterile, and ploughs were continually stopped by offshoots lying almost at the surface of the soil. The farmers appealed in such strong terms, that the communes decided upon the fall of the poplar, and soon axes and saws were brought into requisition, and the roads cleared of these trees in favour of the humble but more useful *mirabelle* (small plum), to the great satisfaction of the villagers. Thousands of baskets of this fruit are sent to Paris daily. Some thirty years ago the distillation of the *mirabelle* was unknown in the country districts, the people plucked it as food for their pigs, but to-day they have learned to make more profitable use of it. They distil it in large quantities, and find a ready market for it. A quart of this alcohol, slightly perfumed, sold five or six years ago for only about 10d. or 15s. to-day it brings not less than 2s. or 2s. 6d., while in Paris the best kind cannot be obtained under about 4s. 3d.—*Journal of the Society of Arts*,

RUBBER CULTIVATION IN GUATEMALA

According to the views of Senor Horta, who has recently issued a pamphlet on "Rubber in Guatemala," the climate most appropriate for the growth of the rubber tree is that of the Tierra Caliente, or hot coast lands, at an altitude not exceeding 1,500 ft., and the trees should not be planted in the sun, although the contrary opinion is held, and has been expressed by some authorities. Senor Horta gives as his reasons for this opinion: (1) The nature of the rubber tree; (2) experiments made in Guatemala; (3) the fact that by planting in the shade there is complete security and a satisfactory result. Experiments in Guatemala have shown that rubber plantations in the open do not develop nor give a profitable yield, and planters have suffered serious loss on this account, not only in this country, but also in Tabasco, Chiapas (in Mexico), and in British Honduras. By planting in the shade it will always be an easy matter, if special conditions of the soil so require to remove superfluous shelter. Under these circumstances it is not necessary to consider the manner of cultivation suggested by some persons, namely, that of planting rubber in the sun and using the trees as shade for coffee or cacao. This mode has been tried and, has given very unsatisfactory results, not only in Guatemala, but also in Tabasco and British Honduras; in some cases it was necessary to destroy the rubber tree and substitute others giving better shade, and in other cases the entire plantation had to be abandoned. It is a mistake to cultivate together such plants as coffee and rubber, which require distinct climatic conditions, soil, and atmosphere; the result invariably is that neither acquires a proper development. The yield of rubber trees has been estimated by some agriculturists as high as 3 lb. yearly from the sixth year; Senor Horta does not consider that trees should be tapped before their ninth year, and says that, according to his personal experience, 1 lb. of rubber, say 2½ lb. to 3 lb. of milk, is a good annual yield. According to him, the milk may be extracted twice each year, during the rainy season, about two months after its commencement, and again towards its close; the most propitious time being when the tree has dropped its leaves, and when the sap is most abundant and most active. He adds that, if agriculturists would devote themselves to giving great attention to the study of the nature and conditions of life of the rubber trees, to the progress of its sap, to the stimulants and fertilisers that might be advantageous to it, it is probable that this yield might be greatly increased.

SPRUCE GUM IN RAMIE, U.S.A.

The gathering of spruce gum as a side issue of lumbering during the less active months in Maine has grown to be quite a large industry. The crop for the past year was the largest on record and the last consignment of six tons was delivered late in August, bringing the total for the year to nearly thirty tons, valued at about \$63,000. The process of collecting the material has many interesting features. During the winter, when the snow in the woods is not too deep, a "hunter" goes from camp to camp picking out good-looking trees that have a supply of gum clinging to the bark. He makes a note of each tree, making it by cutting into the bark with his axe. In the spring, when the snow has melted he leads a party of pickers over the same territory, and they clean the trees of the gum that has accumulated. The instrument used for picking purposes is of fine surgeon's steel, tempered to such a degree that it can be bent to almost any shape and not break. This is necessary, for on many of the trees the gum is hanging to the bark in such a manner that to attempt to remove it with anything but a crooked blade would be useless.

The gum as it is scraped from the tree is taken in a large basket to the nearest lumber camp and left for the coming of the "chaser," whose duty it is to see that the gum is delivered to the "boss"

who has sent the expedition out. When the gum arrives at the latter place it is spread on a carpet and the whole neighborhood takes a hand in sorting the good from the bad, the light-colored from the dark. Then it is "blowed," a huge bellows not unlike those used in a blacksmith shop being used for the purpose. The gum is then ready to be bagged and sent to the city dealer, who in turn disposes of most of it to chewing gum manufacturers. —*New York Manufacturer.*

CEYLON LAND AND PRODUCE COMPANY (LIMITED).—On page 422 we give the report for the year ended June 30th, which states that the amount at credit of profit and loss account is £11,979, which, with £321 brought forward, leaves £12,300 to be distributed. In July an interim dividend of 7½ per cent on the ordinary shares and three per cent on the preference shares was paid, and the directors now propose to pay the balance of the fixed cumulative dividend on the preference shares, making six per cent for the year, and 7½ per cent on the ordinary shares, making 15 per cent for the year, and in addition, a bonus of five per cent on the ordinary shares—all tax free. It is also proposed to transfer £4,000 from profit and loss account to reserve fund, increasing it to £17,500, and carry forward £1,533, subject to the directors' remuneration for the year under review, and to the payment of income-tax, &c. The directors have decided to issue the balance of the six per cent cumulative preference capital—viz., 2,150 shares of £5, which are offered at a premium of 12s 6d per share to the preference shareholders. We congratulate all concerned upon the result of the years' working.

CEYLON TEA IN RUSSIA.—It will be good news to planters to learn that the Russian firms in Colombo have been conferring with English firms doing business with Russia in Ceylon tea, with a view to a meeting in the early future at which it is hoped some arrangement may be reached whereby the scope of such business may be generally enlarged. The meeting, we understand, will most likely be held at the Bristol Hotel on November 27th, though the date has not actually been fixed. The ground for such a meeting is, we understand, the impossibility of supplying the Russian market direct with sufficient Ceylon tea at the present time; further orders from Russia would be forthcoming were it possible for the local firms to guarantee larger regular shipments from Ceylon. The only way to enlarge the scope of the business, therefore, would be to have more teas put up for auction in Colombo. If Russian firms in Russia increase their orders, while the same quantities are put up here week after week, prices may rise by reason of the increased competition among buyers; and this would in turn check the Russian orders from home undesirable. Hence the anxiety to obtain larger local deliveries; and, following up our remarks of last evening, we must urge the local exporter to cultivate the local market with more vigour than hitherto. Prices need not go down, but a larger capture of the Russian taste will be in store for Ceylon teas, if the deliveries in Colombo are considerably increased.

CENTRAL TEA COMPANY OF CEYLON, LD.

[The following is a copy of the report.]

The Directors have the pleasure to submit the General Balance Sheet and Profit and Loss account for the year ending 30th June, 1899, duly audited.

The net amount at credit of Profit and Loss account, including the balance brought forward at 30th June, 1898, and after providing for General Expenses, Directors' Fees, Income Tax, &c., is

£	s	d	£	s	d
			2,935	7	7

Dividends on the 6 per cent. Preference Shares were paid for 1898-9 (less Income Tax) amounting to

1,505	0	0
-------	---	---

It is proposed to pay a Dividend of 6 per cent (less Income Tax) on the Ordinary Shares which will amount to

1,073	0	0
-------	---	---

And to carry forward to next year a balance of

557	7	7
<hr/>		
2,935	7	7

The Directors trust the results of the year's working of the Estates will be considered satisfactory by the Shareholders.

The gross average price realised for the tea was 7-87d per lb., as against 7-75d per lb. last season, and the rate of exchange was 1s 4 19-64d as against 1s 4d.

The yield of tea was 331,427 lb., being 377 lb. per acre over a plucking area of 879 acres.

The acreages of the Estates are as under—

Estate.	Tea.					Total acres.
	In bearing.	Partial bearing.	New clearings.	Cardamoms.	Forest Grass and Waste.	
Kabragalla ..	431	61	16	32	397	937
Somerset ..	387	..	13	..	33	443
(Including Easdale and Loxa)
Total ..	818	61	29	32	430	1370

Under clause No. 24 of the Articles of Association Mr. J. Sancoft Holmes retires on this occasion from the Board, and being eligible, offers himself for re-election.

The Auditors, Messrs. Harper Brothers, Chartered Accountants, also retire from office, and offer themselves for re-election.—By order of the Board,
WM. JOHNSTON, Secretary.

MINOR PRODUCTS REPORT.

CITRONELLA OIL.—Quiet and unchanged, with small sales at 11½d per pound in tins, and 11¼ in drums on the spot.

SPICES.—A quantity of Cinnamon-chips, offered without reserve, sold at 7d to 8d per pound for pieces, quillings at 5½d per pound, featherings at 4d to 4½d per pound, bark and common chips at 2nd to 3d per pound.—*Chemist and Druggist*, Nov. 11.

UNITED COFFEE GROWERS' CO.

The statutory meeting of The United Coffee Growers' Company, Ltd., was held in the Assembly Room, Coonoor, on Wednesday. A statement was placed by the Directors before the shareholder, in which they were informed that the land for the erection of the buildings has been acquired in Coimbatore, but the building will, it is hoped, be completed in from two to three months' time; that roasting, mixing, and grinding machinery, as

well as a tin-making plant, has been ordered from the Continent, and is now on its way out. It is estimated that this machinery will be capable of dealing with 400 to 500 tons of coffee per annum, which amount by the addition of another roasting machine, can be increased to 800 to 1,000 tons per annum, the engine-power and the tin-making machinery being sufficient for this additional output. The services of a gentleman who has been through a regular course of instruction in London and on the Continent have been secured. The Company has spared no pains to put itself into a position to place the best article on the market at the lowest price. A statement of the financial position of the Company was made by the Directors and was found to be in every way satisfactory. This being a Statutory Meeting, no other business was transacted. The Annual General Meeting of the Company was fixed for July, 1900.—*Madras Mail*, Dec. 1.

PRODUCE AND PLANTING.

ADULTERATED TEA.—It is to be regretted that the Commissioners of Customs, in their reference to the examination made by their analyst on imported teas before they are taken out of bond, do not state where the teas of doubtful character upon which they report come from. It is not difficult for the expert to guess, but the public, not so well acquainted with the tricks of certain growers and manipulators in the Far East and in Germany, possibly imagine that Indian and Ceylon teas are sometimes adulterated. The report of Mr. W. Cobden Samuel, tea analyst, is as follows of the 938 samples analysed: 70 samples of green tea faced, 20 samples of green tea unfaced, 46 samples of green tea capers, 595 samples of black tea, congou, 160 samples of black tea dust, 47 samples of black tea siftings. Of the total 854 were, on analysis, considered satisfactory, and the importations represented by them were accordingly delivered on this certificate of the analyst. The remaining 84 samples represented teas of doubtful character, the results of analysis of which were reported to the Board for their decision, with the result that the whole of these, representing 1,603 packages, were restricted to exportation or for manufacture of caffeine. In regard to samples of tea examined by public analysts, it was stated in the annual report for 1896-97 that of the 4,289 samples examined in the previous five years only four had been reported against. In 1897 one sample was condemned, but during the past year, out of 486 samples taken, as many as fifteen were adulterated, while eight more were returned as of inferior quality. Many of these were of the variety known as caper tea, and were reported to contain excessive quantities of mineral matter. Respecting this revival of an old and somewhat ingenious method of adulteration, which consists of the addition of stones and sand to tea in order to increase its weight, the analyst for the country of Derby writes: "The practice is defended by interested persons on the ground that the mineral matter is unavoidably introduced during the process of the preparation of the tea for the market. This contention, however, cannot be sustained, as genuine tea practically never contains 1 per cent. of mineral matter in the form of sand, while sand and stones are present in the proportion found in the samples under observation, these foreign substances must have been purposely introduced, and possibly caper tea is chosen as the chief medium for the operations because the shape of the leaf after its preparation for sale is favourable for the concealment of the stones. The tea certified by me to contain 4 per cent. of sand and stones was sold at the high price of 3s 8d per lb. and the adulteration, which was actually in the excess of the amount certified by me, was obviously of a fairly remunerative character,

Legal proceedings were taken in five instances of tea adulteration, and two fines were inflicted.

ADULTERATED COFFEE.—Of the 1879 samples of coffee examined 10 per cent were condemned. As usual, many samples were reported to contain large quantities of chicory.

TEA REFORM AND DOCK CHARGES.—With reference to the comments on this subject which have appeared in the *Produce Markets Review*, and which we have reproduced, that journal remarks in its issue of last Saturday that these comments have led to a good deal of criticism, especially on the subject of the dock charges. "Our figures," it says, "were compiled from the dock books themselves by one whose sole occupation it is to look after such matters, but the items are most obscurely given by the companies, and it is indeed impossible for any one except an expert to make head or tail of them. Our object was, however, to secure absolute accuracy, and as we find on close scrutiny that some of the items (notably the bulking and taring, in which, after reference, we believed we were right) are inaccurate, we append a corrected statement of dock charges on Indian tea in this port, and a comparison of them with those on other goods. This comparison is the important point and not fractional differences in details. The errors affected by our critics, which we gladly correct, affect this comparison to the extent that we overstated the Indian tea charges comparatively 3s 6d per ton, they working out at 52s 6d instead of 56s. Warrants and weight notes were not included by us in tea, which would practically cover this small balance, but we are content to take the smaller figure. What possible reason can there be, except gross mismanagement and monopoly, for the charges on Indian tea being four times more than those on Indian coffee? To satisfy our critics we now give the following corrected charges on one ton of Indian tea landed and sold at public sale taking twenty chests to a ton: Landing and housing rate, at 1s 6d per chest £1 10s; public sale charges, at 4d per chest, 6s 8d; bulking and taring each, chest, at 1s 5d per chest, £1 8s 4d; and ten week's rent, at 3d per chest, 8s 4d; giving a total of £3 13s. 4d. From this a discount of 10 per cent. is deducted, leaving a balance of £3 6s, and then again to this has to be added the charges for weight notes and warrant stamps, which are 8d and 1s respectively, thus giving a net total of £3 7s 8."

COMING DOWN HANDSOME.—The Tea Trade Section of the Mincing Lane branch of the Lord Mayors Transvaal Widows and Orphans' Fund has made a hearty response to the call for subscriptions. Tea companies, growers, agency firms, importers, brokers, dealers, distributors, and warehouse-keepers are doing their best to swell the fund, which already reaches £8,000. The tide of subscriptions flows bountifully, thanks to the energy of those who are working in the good cause. We hope shortly to publish a list of the subscribers.—*Home and Colonial Mail*, Nov. 17.

THE CEYLON LAND AND PRODUCE COMPANY, LTD.

LONDON, Nov. 17.

Being in the City, I looked in at the annual meeting of that very prosperous institution—

THE CEYLON LAND AND PRODUCE CO., LD.

—to find the Chairman (Mr. James Wilson) and his co-Directors and the Secretary (Mr. Loch), and four or five shareholders taking the Report as read; while Mr. Wilson (having a heavy cold) handed his address to be read by his son. It was both practical and interesting.

As last from Ceylon I ventured to second the adoption of the Report, congratulating the shareholders on continued prosperity, due largely to judicious management, but also to the low rate at which their fine properties stood in the Company's books, showing the prescience of the original founders of the Company and of Mr. Wilson. I called attention to the great extension of cacao-planting now going on in Trinidad in supersession of sugar, as a reason for some caution, and thought care should also be taken in planting coconuts among tea. At the same time I corroborated the view that, with attention and liberal cultivation, there was no reason for alarm in regard to tea blight or cacao canker.

Mr. SETON (the well-known tea share-broker, &c.) followed with some weighty remarks, as an expert on the financial position of the country, arguing that it was a pity with so many shares not fully paid, additional capital should be called up, and dealing also with blight from experience in Assam.—Capt. Brebner and another shareholder took the same view about the calling of new capital, and it was also suggested that the Company should get a quotation on the Stock Exchange.

But the CHAIRMAN and Mr. SETON both showed that this was really not worth the trouble it involved and indeed it might require the remodelling of the Company *de novo*; while the CHAIRMAN also showed that they could not call up the balance of capital due on shares without paying off debentures and the time had not come for that yet. He also mentioned that the coconut palms on Peradeniya were prosperous and seemed to do no harm to the tea; that the cacao now being planted was *Forastero* and he called on Mr. Lewis (of Messrs. Lewis and Noyes, cocoa brokers) to refer to cacao.

This Mr. LEWIS did in a very reassuring way, saying he did not think West Indian cocoa would ever compete with the Ceylon article which had special qualities of its own. That great efforts had been made in Trinidad to prepare similar quality, but without success, and he had no fear for the future.

(Still, it is a fact that the price of Ceylon has fallen from the maximum a good deal, and that it is not now rated in value so much above the West Indian cocoa, although the price is still satisfactory.—Mr. Lewis also mentioned that Ceylon cocoa was used for special purposes by the manufacturers. Altogether the discussion was an interesting and instructive one, as regards tea, cocoa, coconuts and rules of finance).

Thanks were duly moved to the Chairman and Directors, and, on my suggestion, the resolution was extended to include the Visiting Agent and Estate Managers in Ceylon; and I testified to Mr. Anderson, of Peradeniya, being one of the most reliable and hard-working planters in the island. This was readily agreed to, and the Chairman promised to convey the unanimous thanks of the meeting to Mr. Anderson and the different superintendents.

One announcement made by the Secretary (Mr. Loch) gave general satisfaction, namely, that a register of shareholders was to be kept open for inspection at any time.

Correspondence.

To the Editor.

COLLECTIVE ACTION FOR TEA GROWERS.

LONDON, Nov. 17.

DEAR SIR,—Those who have carefully investigated, admit that a combination exists among buyers, which is undoubtedly evidenced by their strong Buyers Association at Birmingham and what is soon started in London, extraneous evidence too has come from America, shewing conclusively that an arrangement has existed among the larger buyers in London, for some years.

LOSS BY FALL IN EXCHANGE.

What is unsatisfactory in the position of tea just now is the loss the interest has sustained by exchange. If this were recovered, profits would average 4 per cent. more than at present, but so long as the buyers are strengthened by their Associations; unless met by similar methods; it is difficult to see how a permanent recovery can be accomplished. Organization must always, in the long run, beat what is not organized; discipline what is indisciplined.

REGULATION OF SUPPLIES.

Supply and demand will undoubtedly in time fairly adjust prices, but in the lengthened process of the swing, first credit and then capital go. By a system of regulation, now almost universally adopted by the various industries of Great Britain, the great extremes of the crude supply and demand process, are eased and a more moderate result ensues. It has been found that by allowing the price of any product to fall to a low level, that it is next to impossible to re-establish it. This, of course, applies more to imperishable, rather than perishable commodities, and in this respect tea is favoured. When Pattison's Whisky Company failed, the trade arranged that the stock should not be thrown on the market, simply, in case it should establish a lower price. Thus within the process of supply and demand, the extremes produced are modified, a more average result ensues, investors know better where they are; and an industry is better established and accredited.

So far everything goes to shew that the organization is only on the side of the buyers, the seller, using no means of meeting them; in this the produce markets of Great Britain stand alone.

THE INDIAN TEA ASSOCIATION'S MEASURES.

Since most of the foregoing was written the Indian Tea Planters' Association in London has wisely regulated its sales, and if Ceylon would only do the same, say, from 1st May to 31st October, prices would be improved. Since "regulation" has come in, it is only necessary to compare now much better, relatively, Indian teas have sold than Ceylons. A very casual glance over sale lists will prove this. It should be the endeavour of Ceylon to begin regulating their sales from May next.

The beneficial result of regulation by the Indian growers is shewing itself in an earlier return to better prices and against a less favourable statistical position at the same time last year.

A TEA PRODUCERS' ASSOCIATION MUST BE FORMED.

The only way of meeting buyers on equal grounds now; is for a Tea Producers' Association of London to be formed and after due attention has been made, to regulation of sales of all teas, to bear the following in view.

To facilitate also the production of tea to its requirements, the Association should have a record department, wherein should be kept at the disposal of members, complete statistical and general information, with compiled tables made therefrom. These should be as complete as possible so as to have some influence in preventing unwise extensions.

EDUCATION OF THE PUBLIC.

There should also be some effort made at educating the public, for already, although the less discriminating are satisfied, those who can pay for their teas have little opportunity of obtaining the choicest blends and of which, most know nothing.

There is a large grocer in an important provincial town who buys wholesale 1s 1d, 1s 2d and 1s 3d, teas which he retails respectively at 1s 4d, 1s 8d and 2s per lb. Indeed a close investigation shews that such anomalies exist small sides.

OBNOXIOUS REDUCTION IN VARIETY OF TEAS.

The worst feature, from a producer's point of view, is the growing efforts to reduce teas to only two or three kinds; when there should really be as great a choice as there are of wines. Against this the strongest stand should be made. So far as has brought the staple down to an indiscriminate mass, without distinctive flavour, or character, a practical blending of port, sherry, and claret to a general average. To anyone with a palate for what is delicate and choice it has no attraction and the fear is that amongst our customers, who are prepared to pay for a choice article, that they will sooner or later revert to coffee and chocolate. Unfortunately this catering for the masses, in cheap teas in packets, has drawn in the thrifty, though well-to-do, housewife to purchase 1s 4d instead of 2s teas, and until some effort is made to shew the distinction, things are likely to become worse rather than better. From cottage to palace, one and all are buying cheap teas in a manner never known before, not from choice, but ignorance.

Medium teas have little value in the public market. Large quantities of low-priced are blended with a strain of anything likely to make them pass muster. Buyers recognise two kinds, high and low, but are determined to throw the bulk, the medium teas out of competition, consequently, whether by a preconcerted arrangement or not, they fall to the buyer without any apparent public competition whatever.

THE PUBLIC BUYS AS IT IS TAUGHT.

There are people who will say, the public buy what they want. This is a mistake, those of the public who have an opportunity of judging are not satisfied. The bulk are led by advertisements and what appears in the interested public papers, and which the Association should refute—for instance it is advertised everywhere, "that the best tea the world produces" can be bought for 1s 7d; personally, the writer considers this 1s 7d tea dear at the money, and not what a gentleman or lady should have on their table. He also recognises among well-to-do people, that good China is gaining ground; which can only

be accounted for by a natural reaction from the strong pungent tea of the masses, being so indiscriminately used in the drawing rooms of many of the wealthy.

HOME ACTION MUST BE TAKEN.

With a Tea Producers' Association in London, that would fairly face all these questions, of regulation of sales, collecting accurate and complete statistics, instructing and educating the public and having machinery to touch the trade in every part, there is nothing to fear in the future of the tea industry. On the other hand, if producers believe that the falling of the distributing of their teas into fewer hands, as has happened more or less with almost every industry, means that they are to make no action themselves, they will have a rude awakening.

SUUM CUIQUE.

CARDAMOMS AND (ALOE) FIBRES.

Bambragalla, Rattota, Dec. 3.

DEAR SIR,—In your para "Tea and Cardamoms," in the *Observer* of the 1st instant, I see that a brother planter has corroborated what I stated in my letter to you of the 26th November. I know several small fields once planted with cardamoms, which are now growing good tea; but I do not know and never heard of any land which failed to grow tea well having been planted with cardamoms and I am quite sure that cardamoms would not bear in such land. The article by "L," in a Calcutta paper was about aloes not about rami. "L's" experience of growing aloes has been very different from mine. My experience of growing aloes, the large kind with spines on the edges of the leaves, is distinctly adverse to growing them in poor useless land. Twenty years ago I thought they could be grown on any kind of land, so I planted up 15 acres of useless land with them (the large kind) and kept the field free of weeds for two years; but finding that the plants made little or no progress I abandoned it. Some of the plants continued to live for years afterwards, but never became large, though plants put in fairly good soil grew to the usual size.—Yours faithfully,

R. B.

JADOO.

KANDY, NOV. 29.

DEAR SIR.—Can any of your readers tell me, from *bona fide* EXPERIENCE, if Jadoo is good for strawberries, as regards the bearing of fruit.

E. F. T.

DEAR SIR,—In reference to "E. F. T's" query *re*-Jadoo I may say from experience that this is a nutritious and convenient—because light and clean—form of soil, which is especially useful for plants grown in pots in rooms and verandahs. As regards its application to strawberries, however, it would no doubt be found to be productive of healthy growth for a time, provided it did not get too soon washed away by the rain; but, from a commercial point of view, it is very doubtful whether it would thus pay. Jadoo is a light spongy sort of soil, similar to decayed coconut fibre. At one time it was thought to be the medium *par excellence* for nursery-beds for tea, coffee, &c., but apparently it has not as yet stood this test.—Yours truly,

X.

THE TEA DISPUTE AND RESULTS.

(From a Home Correspondent).

LONDON, Nov. 17.

H. M. Customs has at last given its decision with regard to the Dealers and Importers' petition regarding the terms of agreement come to in August last, and has issued its order. * * * It will be seen that this is distinctly an advantage in favour of the Importers.

It remains to be seen what steps the Buyers will now take to secure the "overtakers." I understand they have taken Counsel's opinion which is that they are legally entitled to them: but Importers have an opinion to the contrary effect. Perhaps, the best course would be to settle this by a friendly "test" case.

Notwithstanding the adverse criticism of the few that the draft was badly engineered, it appears to me that the result obtained has fully justified the efforts of the Joint Committee. The Importers have scored in the matter of Customs weighing, while Buyers have gained nothing.

The regulation of sales of Indian teas has been an unqualified success: the system adopted is working smoothly and has undoubtedly saved the market from being flooded with tea at this time of the year. Although Ceylon teas do not require regulation, the course adopted has been the means of keeping up the market for Ceylons as well as Indians.

The Associations are quietly working the warehouses, regarding a reduction of rates, and this is, I believe, in a fair way of being obtained. The docks, however, do not see their way to fall into line with the other warehouses which are prepared to make a reduction.

Should they persist, and the others do not break from the "ring," the inevitable result will be that a planters' warehouse will be started.

Another result of the "Tea Dispute" is that an Importers' Association is being formed. The draft of its constitution has, I learn, been drawn up by the Joint Committee of the Indian and Ceylon Associations; but will not be submitted to those interested until the Committee have thoroughly matured the scheme.

The amount of time given by the members of the Joint Committee to the *great dispute*, and all these other questions affecting the Tea Industry on this side, has been a severe tax on busy men. In my opinion, those growers and importers who did not support the Committee, and more especially those who seceded after signing the agreement, should be heartily ashamed of themselves. No doubt, however, they will gladly accept all the advantages that others have fought and gained for them. You will remember it was the same with the voluntary tax and export cess for pushing our teas. A miserable minority who could not see beyond their noses, protested, but all the same reap the advantages with others. It is always good to have an opposition, but, when the fight has once begun, we should stand shoulder to shoulder, as our country is now doing in this Transvaal war.

Ceylon Rainfall.

THE P. W. D. METEOROLOGICAL OBSERVATIONS FOR OCT. 1899.—We append this Monthly Return of rain from which it will be seen that the highest fall was at Padupola in the Central Province, 43.07 inches, and the lowest at Kekanadura in the Southern Province, 1.29 inches.

THE TEA GARDENS ON THE CAUCASUS.
—The report of the Russian Government on the results of the tea crops at the experimental tea plantations near Batoum shows that all three crops produced exceedingly good tea. The first sort could be sold at two shillings and three pence. The tea is prepared by the Ceylon method.—Pioneer, Nov. 27,

COLOMBO PRICE CURRENT.

VETERINARY NOTES.

ACTUAL CAUTERY OR FIRING.

HIS form of treatment well-known in Ceylon by the name of "Firing" or by the commoner expression "Burning," has by unjudicious use created a prejudice in the minds of many.

The lameness caused by sprains and exostosis is common enough in animals, and especially the horse, which though destined by nature to do fast work, is often worked without moderation, and this form of lameness requires the use of irritants in the shape of liniments, blisters or even the actual cautery to stimulate and check the growth of calcareous substances in case of exostosis, and also to stimulate and produce absorption and mechanical support in cases of sprain.

In serious cases of lameness by exostosis, blistering is often attended with only a partial success, and the use of the actual cautery will in many instances indicate in a short time the advisability or inadvisability of continuing further treatment. The advantages of the actual cautery over other forms of treatment are that it is acute and effectual, and that the cicatrix left serves as a mechanical support for the part that has undergone the operation.

No doubt it leaves a blemish. In cases of acute lameness caused by exostosis, point-firing is much preferable, because it does not cause much blemish; but in cases of sprains, blistering and firing should be resorted to only when other forms of treatment fail.

SUCCESSFUL OPERATION OF NEURATOMY IN A CASE OF NAVICULAR DISEASE.

A case of lameness was reported to me by a well-known horse owner, and from the history of the case I had very little difficulty in telling him that the animal was suffering from navicular lameness. I also informed him that I believed neuratomy to be the only treatment that could be adopted with success. I explained to him the evil results that usually follow neuratomy, but assured him that in the hands of good horsemen and under proper shoeing and care they could easily be prevented. I further explained that the operation is a very painful one, but considering the chronic pain the animal suffers daily, the tension pain caused by the operation can never be considered cruel. Accordingly, it was agreed to operate on the animal.

The animal underwent the operation on the 25th September, and owing to want of a well-trained assistant, it was operated upon without general anæsthesia. I found it rather difficult in carrying on my work with the use of a magnifying glass, but it is important to be able to pick out the nerve from the other vessels that run along with it, and which are very often severed by mistake.

It is also usual to tie up the nerve before it is severed, and in this connection I should like to emphasise that only loose knots should be used and not a surgical knot. If the operator learns that he has made a mistake by securing an artery or vein, it will be a herculean task to untie a surgical ligature when it is jammed up.

I have found sutures hardly of any help when it is aimed at bringing only the severed skin in juxtaposition; for in the absence of highly organized muscular tissues, sutures generally fail, and so the wound was left unsutured, and I am glad to say in this case union was prompt and good.

The animal is now quite free from lameness.

D. A. CHINNAH, *Vet. Surgeon.*

Greatest amount of rainfall in any 24 hours on the 20th inst. was 3.77 inches.

Mean rainfall for the month .52 in.

Recorded by Mr. J. A. G. RODRIGO.

OCCASIONAL NOTES.

Before the present number of the *Agricultural Magazine* is out, the office of Director of Public Instruction for Ceylon will have changed hands, Mr. Harward, the present holder of the office giving over charge to Mr. S. M. Burrows, C.C.S. We cannot let this opportunity pass without recording our high appreciation of Mr. Harward's régime as the head of the Department of Public Instruction and of the liberal spirit which he shewed in all his relations with the School of Agriculture and its kindred institutions.

The new Director comes with a reputation not only as an administrative officer, but also as an enthusiastic educationalist. What is, however, of more importance to us, Mr. Burrows has been known to evince the greatest interest in agricultural improvement, whether as regards land cultivation or stock-breeding; and for this reason we accord him a specially hearty welcome in his dual capacity of Director of Public Instruction and Agriculture.

It is currently reported that the Agricultural Commission appointed by H.E. the Governor have decided to recommend that a department of Agriculture and Irrigation be established for Ceylon, and that scientific experts in the persons of the Director Royal Botanic Gardens, the Entomologist and Veterinary Surgeon (officers already holding appointments) as well as an Agricultural Chemist and Cryptogamist (to be appointed) are to be "attached" to the Agricultural Department.

We take over from *Farm and Dairy* an interesting case of milk-prosecution, the details of which should be of special interest to dairymen. It is said that the defendant will appeal, and we shall be interested to know the final issue of the case.

It has been shown by numerous analyses that soils abandoned for centuries to natural vegetation in which grasses predominate are quite rich in nitrogen. There are mountain meadows in France which during the open season are grazed by milch cows, and although this involves the removal of a considerable amount of nitrogen, and no fertilisers are used, these soils constantly increase in nitrogen content. While soils which are continuously cultivated frequently contain not more than $1\frac{1}{2}$ to 2 parts per thousand of combined nitrogen, permanent meadows contain 5, 7, 9, and even 10 parts per thousand. The prairies of Western America are also well stocked with nitrogen. It is interesting to trace the origin of this nitrogen. Although the investigations of Ville and Atwater and those at Rothamsted and Grignon had proved that free nitrogen intervenes in the phenomena of vegetation, the process of fixation of nitrogen in the soil was not understood until explained by Berthelot, who showed that nitrogen is fixed in the soil by bacteria. Winogradsky cultivated certain of these bacteria in sugar solution, and found that they decomposed the solution, forming butyric and acetic acids and evolving carbon dioxide and hydrogen. They are therefore very similar to, if not identical with the organisms studied by Maquenne and Dehérain in 1882, and which decomposed sugar as explained above. The latter investigators, however, had no idea at that time that the ferments were able to fix the nitrogen of the air, and the investigation is mentioned simply to call attention to the fact that these ferments are very widely diffused, since they were found in all the soils studied. These organisms are all anaerobic, and it would seem surprising that they should grow in a medium so thoroughly aerated as arable soil; but this has been explained by Winogradsky as follows:—The organisms which fix nitrogen are capable of action only when associated with certain common species of organisms which are capable of oxidising organic matter, and which thus surround the anaerobic forms with an atmosphere changed with carbon dioxide and deprived of oxygen. Winogradsky further suggests that the hydrogen set free in the decomposition of the carbo-hydrates furnishes ammonia which is assimilated by the micro-organisms and used in the formation of tissue. It is not, therefore, simply the nitrogen which has recently been drawn from the air which is utilised by plants. They assimilate also the nitrogen derived from vegetable and animal remains. The work of Pasteur has shown that the action of micro-organisms is necessary to the transformation of the complex organic substances of the tissues of living plants into the simple forms which may be assimilated by plants. Without these organisms life would be impossible, as Pasteur himself has said, because the work of death would be incomplete. By their intervention the complex substances are burned, the carbon passing into the form of carbon dioxide, the hydrogen into water and the nitrogen into ammonia; and in these different forms the matter is again carried into

circulation. It often happens that vegetable matter remains for a long time in the form of humus; but even in this form it is utilised by plants. The humus is constantly subjected to the oxidising action of the lower organisms, and undergoes gradual decomposition. The ammonia produced by the decomposition of the humus is assimilated by plants as well as the readily available product of oxidation, nitric acid. Schloesing and Müntz 20 years ago showed that nitrates are formed in the soil by the action of organisms. More recently Winogradsky has demonstrated that the action of two different organisms is necessary for the transformation of ammonia into nitrates; one converts ammonia into nitrites and the other completes the oxidation, producing nitrates. We thus see that micro-organisms seize upon the nitrogen of the air and convert it into organic compounds; they convert vegetable matter into humus, and then breaks down this humus, producing ammonia and finally nitrates. At every step they perform a useful work, and are valuable auxiliaries of agriculture. There are, however, other organisms which interfere with the work of beneficial kinds. Bréal observed several years ago that there is an aerobic organism which decomposes nitrates and sets elementary nitrogen free. This organism is abundant in vegetable débris, especially in straw. It is also encountered in the excrement of domestic animals. The extent to which the losses of nitrogen in arable soils is due to the action of this denitrifying organism and the conditions most favourable to its action are questions which require further investigation.

NOTES ON EXHIBITS FOR PARIS.

EDIBLE BIRDS' NESTS.

(Continued.)

Portman is quoted by Dr. Watt as having published an interesting account of collecting the nests as pursued in the Andaman Islands:—

"Before the arrival of the swallows, and as soon as the weather is sufficiently settled, say, about the first week in November, all the caves in the islands should be visited and thoroughly cleaned, the portions of old nests and débris being removed. After the arrival of the birds, and as soon as it is ascertained that they have built their nests, all the caves should be visited and the nests collected and brought in. The date of this visit, and, indeed, the number of collections, during the seasons are fixed by the time at which the north-east monsoon rain ceases. Being unusually late this year (1885-86), we did not commence nest-collecting till the end of February, but with a dry December the collection might commence on the 15th January. As the collection of nests from the present known caves takes about a month, and the swallows rebuild their nest in six weeks or so, the collectors should wait about ten days in Port Blair, and then go out again, taking care to observe exactly the same order in their rounds. The nests may be collected until the commencement of the rains, when the collection should cease, and the birds be left to breed. Although the great demand is for the white nests, still it may be remarked that the fucus attachments of the grass nests, and the old nests

gathered in November cleaning, may be sold locally at R5 per seer, and should, therefore, be collected. Each collection averages about 52 lb. of nests." He then proceeds to state the number of men employed by Government to collect the nests, adding: "The six collectors are supplied with torches, rough ladders, axes, and dahs, also with a large clean bag lined with linen slung to the side, and an iron implement, about a foot long, with three prongs at one head, and the other end being shaped like a cold chisel. These men detach, with this implement, nests from the sides and roofs of the caves, placing them carefully in their bag, from which, at the end of the work, they are transferred to a box provided with a lock."

In cooking the nests, they are first soaked in cold water for two hours, when they swell up and become soft. They are then easily picked to pieces and cleaned. After this they are boiled in clear chicken-broth until dissolved, a process occupying about two hours longer. The usual allowance is one nest (value R1) to a tea-cup of soup. Any clear soup may be used. The nest is absolutely tasteless and flavourless, but Mr. Portman does not consider them to be particularly strengthening or useful in any way.

Particulars are not available regarding the full extent of the Indian trade in nests. The merchants are Chinamen who reside in Rangoon. They recognise three classes:—

- No. 1. Large, pure white nests averaging from R110 to R115 per viss = $3\frac{1}{2}$ lbs.
- No. 2. Clean but slightly coloured nests, averaging from R100 to R140 a viss.
- No. 3. More discoloured and dirty nests.

The refuse sells at from R5 to R15 a seer. Balfour states that $8\frac{1}{2}$ million nests are annually imported into Canton, and that nests of the first quality fetch from £5 to £6 the lb.; those of the second, 9s. 4½d.; those of the third, 3s. 1d. McCulloch says that the second quality fetches £4 14s., and the third £2 15s. The bulk of the more expensive nests are sent to Pekin for the use of the Court. The Japanese do not use the nests, but they prepare from a sea-weed an artificial nest called Dschin-Schan, which they export to China. Of the Ratnagiri District it is stated the right to collect nests is farmed out to Goanese. The Andaman contractor used to pay R3,000, but last year, owing to the contractor having thrown up his contract, the Government worked the nesting and realized £4,900.

In Ceylon *Collocalia nidifera* is widely distributed with the exception of the North and North-Western Provinces. It does not confine itself to any one altitude, even its building station extending from the seaside to the highest hills. These swifts select for their breeding places large dark and gloomy caverns, in the darkest parts of which they build their famous nests. These may number only a few or thousands, and are not always made of the same substances. The Ceylon nests are considered to be very poor in nutritive properties in comparison with those of Java, Borneo and China, having much less glutinous matter in their composition. The nests are closely built together against the face of some overhanging rock, and if one may judge by the

accumulation of guano below them, the same nest is used frequently. The nests are often found among the refuse on the floor of the caverns where these birds build. According to Dr. Trimen the isinglass-like matter which so largely enters into the composition of these nests, is most probably secreted by the glands situated on either side of the gullet, and which if pressed in a bird just shot emit a viscid matter.

The bird itself is an insignificant-looking little creature, of a somewhat smoky colour, darker on the head, wings and tail than on the other parts of the body. The Japan and Borneo representatives of the species are blue, but the two are said to be identical. The article is prepared for export to China by the natives of that country, who pay Government a small annual sum for the exclusive privilege of collecting the nests in certain caves, chiefly in the Morawak Korale of the Southern Province. The yearly value of this article of export does not exceed R4,000.

As regards the Guano, Dr. Watt says:—"There is no reason why India might not meet its own demands for Guano, if not open up an export trade in the article." Mr. de Koepstorff, referring to the Nicobar Islands, said, "I am certain that I can produce bird nests and guano to the value of at least one lakh of rupees per annum"; to which might be added the possible supply from the Andamans. There is no reason why all the guano procurable in Ceylon should not be conserved and utilized for manuring purposes.

RINDERPEST AND ITS REMEDY.

Captain Leonard Rogers, I.M.S., who has been holding the post of Imperial Bacteriologist in India during the absence of Dr. Lingard on sick leave, has published a most interesting paper on his researches in connection with the treatment and prevention of rinderpest. He does not claim to have fathomed the subject to its bottom, as may be seen by his opening remarks, but no one interested in cattle in this country can read his paper without feeling that very important and practical advances have been made. He commences thus:—"During the last three years a large amount of research work, with a view to discovering methods of protective inoculation against rinderpest, has been carried out in South Africa, with the result that several methods, differing more or less completely from each other, have been discovered and put into practice in that country. Differences of opinion as to the value of these divers methods were inevitable, and as, moreover, the conditions with regard to the prevalence and severity of the disease in India are very different from those of South Africa, it has been deemed necessary to test these methods carefully at the Muktesar laboratory and to apply the results obtained in actual outbreaks reporting with regard to what steps should be adopted to check the enormous loss of cattle from this disease which annually occurs in India. At the same time some new lines of inquiry have been opened out, although any great advance on the discoveries recently made in South Africa as a result of several years' work by numerous observers can hardly be expect-

ed. As it was not until January, 1899, or four months ago, that these experiments were commenced, no definite conclusions have as yet been arrived at, so only a brief outline of the work that has so far been carried out can be given in this report, reserving for a future occasion a full examination of the question. He then goes on in a most lucid manner to deal with the various methods of inoculation for rinderpest that have been in vogue in South Africa. It is of interest to note that the original method by Professor Koch, of inoculating the animals it was desired to protect with the fresh bile of an animal suffering from rinderpest, was borrowed from the natives of South Africa. There were many objections to this method, and, therefore, other means had to be resorted to. One of these was the injection of a large quantity of defibrinated blood of an animal which had suffered from rinderpest. The inoculated animal was then exposed to natural infection, contracted a mild form of the disease and was thereby rendered permanently immune. This plan was a great advance and formed the basis of the serum treatment to be presently mentioned. The principal objections to it were the large doses of the blood required, and the risk of transmitting malaria with the remedy.

The method which has been adopted in South Africa with the most encouraging results was one discovered by Messrs. Turner and Kolle. It consists in injecting a small dose of a powerfully protective serum into one side of the animal, at the same time, that a dose of virulent rinderpest blood is injected into the opposite side. The protective serum is obtained by repeated injections of gradually increased doses of virulent blood into an animal which has had rinderpest. The serum of the animal so prepared is thus made powerfully protective. The inoculated animal then goes through a mild attack in 90 per cent of the cases tried, and is, thereafter, permanently immune. Only half per cent of the animals so treated die. The latest report states that in Rhodesia over 100,000 animals had been inoculated with a loss of less than one per cent, the disease being thus stamped out of the country. Dr. Rogers goes on to say: "It might be thought at first sight from the above description that it only remains to put into practice in India the methods which have been so successfully used in South Africa, but a moment's consideration of the great differences between the intensity and distribution of the disease in the two countries will suffice to show that the problem is not quite so simple. . . In India the disease has been present for centuries, and consequently a certain degree of immunity has been gradually acquired, so that the disease is usually rather of an endemic than of an epidemic type, and is attended with a lower mortality, and has much less tendency to spread widely and rapidly than was the case in South Africa, although at times it assumes a more epidemic character."

What is most wanted is a method which will produce an immunity as rapidly as possible, as the outbreaks will seldom be reached until they are at their height, while, if it is to gain the confidence of the villagers, care must be taken not to run any risk of any material mortality among the inoculated cattle, or of a too

severe degree of illness, even at the expense of a less durable immunity, which is of much less importance in this country than it was in South Africa, for the reasons already pointed out. The religious susceptibilities of the people must also be reckoned with, and for this reason alone the bile method of Koch, which necessitates the slaughter of some 7 per cent of the animals, at from the sixth to the eighth days, in order to obtain bile for the protection of the others—a protection, moreover, which is only a temporary one—is practically out of the question in India. The glycerine bile method is next reviewed and rejected, because of the slowness of its action, and the necessity for a second injection ten days after the first. Captain Rogers rightly urges that the simplest possible method will be the best in this country, and he considers it probable that "the serum method or a modification of it, so as to give but a very slight attack of the disease with a sufficiently long consequent immunity, will be best suited to the conditions met with in this country, especially as the protection will be obtained in a very few days. Moreover, the serum in larger doses can be used as a curative measure in early cases of the disease, if a sufficient quantity is available, a matter of the greatest practical importance."

The writer then goes on to give a full account of the experiments he has conducted with Indian cattle, which will well repay perusal by all who are interested in cattle. Here, however, a bare outline is all that we have space for. We may, therefore, pass over the interesting, though hitherto commercially unprofitable, results of the various other experiments, to deal with what promises to be a most important advance, so far as the interests of the Indian agriculturist are concerned. The method of Turner and Kolle, which we have described above, was carried out in the Muktesar Laboratory—which was recently burned down—with the result that 30,000 cubic centimetres of serum were manufactured in a comparatively short time. The serum so obtained was then tried experimentally on cattle, with the most gratifying results. It was discovered that whereas cattle from the plains were comparatively easily protected from rinderpest by the serum, the hill cattle required much larger doses to protect them. It was, however, merely a question of dose, and given large enough doses, the hill cattle could be as effectively protected as the plain cattle. In each of the experiments mentioned above the rinderpest test was carried out by the injection of a dose of virulent blood subcutaneously, the most certain way of producing the disease in an unprotected animal, and yet, given sufficient doses of the serum, the cattle showed no signs of the disease. A most interesting and important feature of the inquiry was the practical application of the method to the cattle of infected villages. The villagers readily assented to the experiments being carried out, and allowed blood to be taken from a diseased animal for the purpose. The result was most gratifying, since not one of the inoculated animals contracted the disease, while of the uninoculated a number suffered from rinderpest, and several died.

From what has been said it will be obvious that though Captain Rogers neither claims nor has attained finality in his results, he has nevertheless

done enough to show that the method he advocates is a practical one, which promises to very materially diminish the great mortality from rinderpest in this country. It will, however, be first necessary for Government to obtain a sufficient organisation to put into practice the important outcome of the experimental work we have alluded to.

AN INTERESTING MILK PROSECUTION.

The first prosecution of any importance to the milk-vending trade reached a definite stage last week, when a Sydney Dairyman was fined at Newtown, by Mr. Isaacs, a Sydney P.M., for selling milk below the strength laid down in the Public Health Act.

The case was commenced six weeks ago and concluded last week. William Liddell, Inspector under the Health Act for the Borough of Marrickville, proceeded against Alfred Wedlock, registered dairyman, of Marrickville, for that he did by his servant, John Wedlock, sell to the said William Liddell an article of food, to wit milk, the same not being of the quality of food demanded by him in terms of section 62 of the Public Health Act of 1896. Mr. Ralston, instructed by Messrs. Norton & Co., appeared to prosecute; and Mr. Ferguson, instructed by Messrs. Deane and Deane, appeared for the defendant. Evidence was given by the inspector of the purchase of the milk and the submitting of the same to the Government Analyst for analysis. In answer to Mr. Ferguson, the inspector stated that defendant's cattle were in excellent condition, and had the appearance of being well fed. The dairy premises were kept in splendid order. The cows were stall fed, and appeared to receive every care and attention.

Mr. Hamlet, Government Analyst, stated that he had made an analysis of the milk in question. The milk was below the standard notified by the "Gazette." The deficiency of total solids was .47 per cent. The fat was deficient .45 per cent. The solids not fat were deficient .02 per cent. The material difference was in the fat. He could only account for the absence of the fat by its abstraction by dilution or skimming. The standard given was a low one, and in favor of milkmen. He had received a number of authentic samples from veterinary inspectors. He had seen samples actually taken from the cow, which he had analysed, and found that they averaged 3.8, sometimes over 4, and evening milk up to 5. These samples had been taken at all times of the year and in all weathers. As a result of these investigations he fixed the standard approved by the Board of Health. Morning milk contained less fat than evening milk. Cold, wet weather practically made no difference in the quality of milk. He took samples from his own cow which averaged 13 per cent of solids and over 4 per cent. of fat. The fat in the milk comes from the food that the cows take. It would take six hours to make a complete analysis of milk, and could only be done by an expert. The English standard for solids had gradually fallen from 9.5 to 8.25. They had no standard for fat in England.

For the defence, evidence was given by the defendant that he spared no effort to get the best cattle and the best feed for them, irrespective of price, in order to make his dairy a model one,

The milk was delivered to his customers direct from the cow, and he at no time had ever received the slightest complaint from any of the 400 persons he served. Other witnesses corroborated the testimony of the defendant as to the milk being delivered to the customers direct from the cow, and that complaints were at no time received as to the quality of the milk supplied.

Henry Wilson, manager of the dairy department of the Fresh Food and Ice Company, stated that he had acted as judge at many Shows. Defendant exhibited his cows, and won prizes with them. The method of feeding described by defendant, and the nature of the food mentioned, was as good as it could be for stall-fed cattle. Of course, grass was the best of all food for milk purposes.

Mr. Ferguson submitted that to be an offence under the Act it must be one of adulteration, and the evidence showed the very opposite. The milk was sent out direct from the cow in a pure state, and that was what the Act required of the vendor, and nothing more. If in this case a fine was imposed the defendant was injured in the eyes of his 400 customers, not one of whom, if they were in Court and heard the evidence, would believe that they had received anything else but pure milk.

Mr. Isaacs said that whatever might be his decision he was satisfied that the milk had not been tampered with after it left the cow, and before it was delivered to the consumer.

Mr. Ralston submitted that all he had to prove was that the milk was not up to the standard provided by the Government. That had been done, and he asked for a conviction.

Mr. Isaacs said he considered that the only question he had to decide was whether this milk was up to the standard fixed by the Government on the recommendation of the Board of Health. He, however, stated expressly that he considered that this milk was sold as it was taken from the cow, and that defendant had done his best—and more than 99 out of every 100 milk vendors did—to supply his customers with milk of the best possible quality. He was sure that defendant's *bona fides* was perfectly clear, but as the milk was not up to the required standard he would convict the defendant and order him to pay a minimum penalty of 5s., with 21s. professional costs, and 10s. 6d. analyst's fees added, in default levy and distress. The defendant intimated his intention of appealing to the Supreme Court on the decision.

The points relied upon by Mr. Ferguson, the defendant's counsel, in his appeal are as follows:—

The Public Health Act of 1896, s. 62, provides (*inter alia*) that: "Every person who to the prejudice of the purchaser sells any food or drug which is not of the nature, substance or quality of the food or drug demanded by such purchaser shall be liable to a penalty not exceeding £20."

Section 63 provides that "Any person who sells a food or drug shall deliver the same to the purchaser in its pure state." A breach of this section is deemed an offence under the preceding section.

Wedlock, the defendant in this case, was charged under the 62nd section with selling to the prejudice of the purchaser an article of food, to wit, certain milk, the same not being of the quality of food demanded by him.

Section 53 of the Act empowers the Governor, on the recommendation of the Board of Health, to fix limits of strength and purity for articles of general consumption, but it does not go on to make it an offence to sell articles which are not in conformity with this standard. In pursuance of this section the Governor has fixed the standard of milk as follows:—Natural milk solids to be not less than 12 per cent, of which the fat shall be three-and-two-tenths per cent. Wedlock's milk fell short of this standard in butter fat and other solids, and the magistrate held that this constituted an offence under the Act, although it was proved to his satisfaction that the milk was sold as it came from the cow, without anything added to or taken from it; that the cows were of the best possible quality, fed in the best possible way, and that everything possible was done by the defendant to get the best milk.

The defendant's contention was that though the law authorised the fixing of a standard, there was nothing in the Act to make it an offence to sell milk which deviated in quality from the standard, and that having sold pure milk fresh from the cow he had thereby supplied a customer who asked for milk with milk of the quality demanded by him.

FIBROUS PLANTS.

(Continued.)

While 30 or 40 species of plants supply the world's demand for commercial fibres, hundreds of fibrous plants could readily be enumerated, the simple fibrous matter in many of which to outward appearance is just as good as the fibre of the commercial species widely cultivated. There are many wild plants for instance which produce fibre stronger and better than jute. Such plants have been the subject of constant enquiry, and in considering them as a source of fibre there are many points to be taken into consideration. We should enquire whether the plant is capable of successful cultivation, what its uses will be in manufacture, what commercial fibre it will replace or be a substitute for. In fact this latter point is the most important to be settled, for the present commercial fibres represent in a sense those that have stood the test of experience, and until these are crowded out by new conditions, or through what might be termed evolution in the economic arts, they will have no chance. The only opportunity which may be afforded these secondary forms is in the creation of special uses to which they may be peculiarly adapted, for which the standard forms known to the market are not so well fitted. Should a fibre be "promising" it would need to be subjected to chemical and microscopic study to determine the length of the ultimate fibre cell, the proportion of cellulose, and any other elements which would give it its rating among textiles. By such technical study we are enabled to obtain direct knowledge of the species, and in a measure to avoid long and costly economic experimentation.

Experiments for the developments or extension of vegetable fibre industries under Governmental

auspices or direction have been instituted at different times in many countries, and such experiments date back nearly one hundred years. In some instances these have been confined to testing the strengths of native fibrous substances for comparison with similar tests of commercial fibres, as the almost exhaustive experiments of Roxburgh in India early in the present century. Another direction for Government experimentation has been the testing of machines to supersede costly hand labor in the preparation of the raw material for market, or in the development of chemical processes for the further preparation of the fibres for manufacture, or in microscopic and chemical investigation. The broadest field of experiment, however, has been the cultivation of the plants, either to introduce new industries as sources of national wealth or to economically develop those which require to be fostered.

The introduction of ramie culture is an example of the first instance, the fostering of the almost extinct flax industry of our grandfathers' days an illustration of the second.

The United States Government has conducted experiments or instituted enquiries in the fibre interest at various times in the last fifty years, but it is only since 1890 that an office of practical experiment and inquiry has been established by the Department of Agriculture, that has been continued through a term of years. This is known as the Office of Fibre Investigations. The work of this branch of the Department of Agriculture has been mainly directed towards the development or introduction of those fibres which we do not produce commercially, but which are capable of cultivation in the United States, and which will add to our national resources. This work has been prosecuted by the importation and distribution of the seeds of fibre plants, by encouraging and directing field experiments, by testing fibre machines and by affording information, both through personal correspondence and through a series of publications.

CIRRHOSIS, CHRONIC INTERSTITIAL HEPATITIS, OR CHRONIC INDURATION OF THE LIVER.

This is a chronic disease in which the liver becomes hardened, it may be increased or diminished in size, depending on the particular phase of the morbid process. The interstitial or connective tissue takes on a slow form of inflammation, and a very active over-growth, which leads to a general compression and atrophy of the secreting cells, and a hindrance to the flow of blood through the liver. The liver is hard and tough, giving, in many instances, a distinct grating sound when cut; the cut surface presents a variable appearance depending on the particular stage of the pathological process. "When cirrhosis is old, the surface of the liver is granulated and irregular, sometimes covered with new membranes; the serous membrane is thickened, whitish and opaque. At the beginning the colour of the liver is nutmeg-brown; later it turns light yellow, and the organ becomes anæmic. On section we find a fibrous network formed by the

thickened connective tissue, a network the principal traces of which circumscribe more or less large fields of the atrophied hepatic parenchyma, whilst its ramifications separate the various hepatic lobules. . . . With these alterations of the liver we find also a passive hyperæmia and a chronic catarrh of the stomach and intestine, ascites, anasarca, congestion of the meninges, and hæmorrhages in different organs.*"

Chronic inflammation of the liver, although very prevalent amongst horses which graze on the veld in some districts of the Colony, is not so frequently met with amongst cattle which feed solely on the veld, although many cases do occur, such as has already been referred to. The disease is very common, however, amongst cattle which are either wholly or partially fed in the stable, especially amongst milch cows. In some instances cases of chronic hardening of the liver are met with in which no previous history of any acute attack can be obtained, but in the great majority of cases, in which the animals have been under close observation by the same owner for some considerable time, the animals have suffered from one or more previous attacks of the illness, which indicated the presence of acute congestion or inflammation of the liver. A rather unusual case of this character occurred recently. The patient was a pure bred red polled cow which was imported about six months ago. She calved, either on board the steamer or immediately after her arrival, and suffered from derangement of the digestive organs for some little time after. She recovered, however, and appeared to be doing fairly well, until about three months after, when she had an acute attack of inflammation of the liver. She made a slow and somewhat irregular recovery from this attack; her appetite remained delicate, and her bowels somewhat irregular. Latterly, however, her owner reported that she was doing much better and feeling well. This continued until about five days before she died, when she became suddenly ill, and manifested symptoms of acute constipation. Suitable aperients were administered, but after four days' illness she began to strain violently. When examined the day that she died by Mr. Spreull, she was found lying down with her head turned round on her shoulder persistently; her breathing was quick, and she strained continuously as if wanting to expel something; her temperature was 106.2. The rectum was inflamed, and contained a mixture of blood, slime, and a little very black fæces, but no injury could be detected. The stomachs were not full, nor was the abdomen tympanitic. She died very suddenly. The postmortem examination revealed the gall-bladder but ductus choledochus—the bile duct leading from the gall-bladder enormously enlarged and distended to its utmost capacity; its contents measured fully one gallon. Its wall were much thickened and inflamed, but the ductus choledochus—the bile duct leading from the gall-bladder to the duodenum—was not obstructed, but narrowed. The greater portion of the contents of the gall-bladder closely resembled the white of an egg in its character and consistence and was of a light lemon colour.

* Friedberger and Frohner.

There was a sedimentary portion which formed about a tenth of the whole; this was of a yellow colour and flacculent in its character, corresponding to the yolk of the egg. The liver was very hard, grated when cut, and was smaller than normal. The cut surface presented a grey mottled anaemic appearance, and the thickened bands of connective tissue could be plainly seen with the naked eye. The first, second, and third stomachs were normal and full of food of a soft consistence, due principally to the medicines administered. The fourth stomach was inflamed, and numerous petechiae on the rugae or folds of the lining membrane. The duodenum was but slightly inflamed, but there was severe congestion and inflammation of the rest of the small intestines. They contained a blood-coloured watery fluid. The caecum was not much inflamed, and there was little inflammation of the colon, but the coats of the large bowels were infiltrated from $\frac{1}{4}$ to $\frac{1}{2}$ an inch thick with a pale yellow serous fluid. This infiltrate was abundant in the mesentery and loose tissue around the coils of the large intestines. The rectum was inflamed and the abdominal cavity contained about half-a-pint of a pale sherry-coloured fluid. The spleen, kidneys and lungs appeared normal. The urinary bladder was full of urine of a rather deeper colour than natural. The heart was pale but firm; there were large blood extravasations under the endocardium of the left ventricle, and numerous punctiform haemorrhages under the epicardium.

Symptoms.—As already remarked, animals may be affected with cirrhotic livers in an advanced stage without manifesting any prominent symptom indicating its presence, but there is generally irregularity of the bowels—constipation alternating with diarrhoea; a somewhat delicate and variable appetite. In one herd of dairy cows which I had under observation for some time, and in which over twelve consecutive cases occurred at comparatively short intervals, one prominent symptom which was noted on close observation was frequent grinding of the teeth. These cows ate and ruminated very much as usual, their appetites were not so keen perhaps as they should have been, and their faeces were rather firmer than natural, considering the food which they were receiving, but with the exception of this occasional grinding of the teeth, which was observed a number of days before any other symptom became manifest, an ordinary observer would not have detected anything amiss with these cows. In this particular instance the grinding of the teeth was perhaps due more to the indigestion which was associated with the cirrhotic liver, than to the pain and uneasiness caused by the condition of the liver itself, as in nearly all these cases the acute symptoms were ushered in by diarrhoea and a catarrhal condition of the stomach and bowels, which we found great difficulty in controlling. In the more ordinary cases the animal continues to feed and ruminate as usual, until it suddenly manifests symptoms of acute indigestion and liver complications, associated with constipation. After administering the usual purgative medicine, and the bowels have acted freely, the patient may appear relieved and commence to feed a little, but frequent relapses

occur, and although temporary improvement may follow the judicious administration of saline medicine, the patient, as a rule, becomes gradually more and more emaciated; dropsical swellings appear in front of the chest and between the fore legs extending towards the abdomen. In more favourable cases, by careful dieting, and the frequent use of saline medicines, the animal may be maintained in fairly good health and condition for many months. But injudicious feeding will at any time bring on an acute attack which may terminate fatally in two or three days.

Treatment.—The treatment of chronic induration of the liver, when such a condition is suspected, either from previous attacks of an acute character, or from the general symptoms, can only be palliative, and consists principally in regulating and arranging the diet, so as to avoid over-loading the stomach, and keep the bowels in a laxative condition. To maintain the latter, an occasional dose of sulphate of soda (Glauber's salts)—from half a pound to a pound—may be given, or when the cows can be tempted to eat it, about two ounces of salt may be dissolved in a little boiling water and added to a small bran mash every morning or every second or third morning as may be required. A tablespoonful of common salt should be given daily. When acute symptoms appear, these should be treated in the same manner as recommended for acute inflammation of the liver, by giving first a dose of calomel followed by repeated doses of Glauber's salts as may be necessary to keep the bowels acting. It will be evident from what has been said that when an animal has just recovered from an acute attack of indigestion, congestion of the liver, or any serious derangement of the digestive organs, it is a great mistake to force all kinds of food upon it, combined with tonic medicines, in order to stimulate its delicate and defective appetite, as is usually done. The treatment which such an animal requires is not medicine so much as a light nourishing diet of a laxative character, given in small quantities and at short intervals. A little laxative medicine judiciously administered occasionally will relieve the debilitated and congested organs, and assist their defective action. An excellent stimulant under such conditions is the carbonate or chloride of ammonium, which may be given along with gentian and ginger in the following doses:—

Powdered Chloride of Ammonium	..	$\frac{1}{2}$ ounce.
" Gentian root	..	2 drachms.
" Ginger	..	2 "

Mix in a bottle of thin linseed or oatmeal gruel, and give twice a day. The carbonate of ammonia may be substituted for the chloride if the animal is weak in addition to having a delicate appetite. But the principal consideration is the regulation and selection of the diet in all such cases. Remember that the habitual tendency of all that goes on in the animal body is always in the direction of health. This is the inherent bent of all the vital powers and processes of the animal organism. The object of medicine, therefore, is to assist this "healing power of nature," as it is called, and one of the principal means of doing that is to remove every obstacle to the free action of this health-restoring force.

If an animal is dull and depressed with a feeble appetite arising from a sluggish liver, it is not a stimulant that it wants, but a dose of opening medicine to relieve the congested liver and the inactive bowels, and by careful feeding to prevent a recurrence of these conditions.

D. HUTCHEON, C.V.S.

GENERAL ITEMS.

The *Town and Country Journal* lately published the following method of pasteurising milk:—The vessel containing the milk, which may be the bottle from which it is to be used or any other suitable vessel, is placed inside of a larger vessel of metal, which contains the water. If a bottle, it is plugged with absorbent cotton, if this be at hand, or, in its absence, other clean cotton will answer. A small fruit jar, loosely covered, may be used instead of a bottle. The requirements are simply that the interior vessel shall be raised about half-an-inch above the bottom of the other, and that the water shall reach nearly, or quite, as high as the milk. The apparatus is then heated on a range or stove until the water reaches a temperature of 155 degrees Fahr., when it is removed from the heat and kept tightly covered for half-an-hour. The milk bottles are then taken out and kept in a cool place. The milk may be used at any time within 24 hours. A temperature of 150 degrees maintained for half-an-hour is sufficient to destroy any germs likely to be present in the milk, and it is found in practice that raising the temperature to 155 degrees and then allowing it to stand in the heated water for half-an-hour, ensures the proper temperature for the required time. The temperature should not be raised above 155 degrees, otherwise the taste and the quality of the milk will be impaired. The simplest plan is to take a tin pail, and invert a perforated tin pie-plate in the bottom, or have made for it a removable false bottom perforated with holes, and having legs half-an-inch high, to allow circulation of the water. The milk is set on this false bottom, and sufficient water is put into the pail to reach the level of the surface of the milk in the bottle. A hole may be punched in the cover of the pail, a cork inserted, and a chemical thermometer put through the cork, so that the bulb dips into the water. The temperature can thus be watched without removing the cover. If preferred, an ordinary dairy thermometer may be used, and the temperature tested from time to time by removing the lid. This is very easily arranged, and is just as satisfactory as the patented apparatus sold for this purpose.

We (says the *Queensland Agricultural Journal*) have begun an industry in the Colony which is rapidly expanding and which promises ere long to rise to great importance. This is the Coffee-planting industry. Few people need be told that while many years ago Coffee-planting was the principal industry in Ceylon, at the present day coffee in that island is a thing of the past, owing to the ravages of the parasitic fungus (*Hemileia vastatrix*) known as the Coffee leaf-disease. Of late years spasmodic attempts have been made to

revive the industry, but without avail. The existence of wild coffee in the jungle operates against the planters. The disease remaining with the plants cannot be eradicated, and what was once a source of great wealth to the planters and consequent prosperity to Ceylon has had to be finally abandoned, and cinchona, (sic) and tea have successively taken the place of coffee.

The amount of water absorbed by large trees is very considerable, and hence ring-barking has a marked effect on the grass. The destruction of heavy timber over a large area of country has, notwithstanding all that has been said to the contrary, the effect of reducing the rainfall, particularly in flat country. But the water beneath the surface, which went to nourish the growing trees, is, after the latter are destroyed, left to nourish by capillary attraction the roots of the grass, which grows more luxuriantly in consequence. Not unfrequently springs burst forth spontaneously in ring-barked country, owing to the superabundance of subterranean water now no longer expended in supplying the trees.

The latest method of destruction of ants is said to be the use of gasoline. Pour about a half-pint of gasoline into the ant hill or nest, and set it afire. The gasoline will instantly spread through all the nest, and, as the heat on the surface increases, the gas will generate from the utmost recesses and the fire will cook the ants. Half-a-pint of gasoline will burn from three to eight hours, and kill every ant in the largest nest, as well as all which attempt to enter it from without.

Here is another remedy:—When it is a big mound nest, pour a little bisulphide of carbon down each hole and throw a wet bag over the nest immediately afterwards. Remove it in a couple of minutes and apply a lighted stick over each opening. The fumes explode, wreck the nest, and burn all the ants beneath. Care must be taken not to put too much bisulphide near the roots of fruit trees, as it will destroy them. Also, as it is very inflammable, no light or spark should be allowed to be near the bottle, which should be kept corked. It is well to have the lighted stick five or six feet long, though even if the nest explodes near the land no harm would be done.

A farmer, writing to the *New York Tribune*, says:—Eight years ago I lost about one-third of my crop of corn and cow peas on account of the weevil, but luckily I made a discovery that has been worth many dollars to me since. During the same year I sacked up a lot of cow peas, and about one-fourth of the sacks used were salt sacks, with the salt still clinging to them. When I was ready to market the peas I unsacked the lot, and found to my surprise that the peas in the salt sacks were in perfect condition, while those in the other sacks were almost destroyed by the weevil. When I gathered my grain crops the next fall I used salt sacks entirely with the same success. It is the custom in this section to put the corn in the barn with the shuck on, and the consequence is that a great many insects secrete themselves in the shuck and afterwards destroy a great deal of

grain. Knowing this I dissolved 1 quart of salt in 2 gallons of water, and as the corn was thrown in the barn I gave it a light sprinkling. I was not bothered with any insects that year, and of course I have continued to use the salt remedy ever since with the best of results.

It is generally thought by household authorities that brown-shelled eggs are superior to the white-shelled varieties. An investigation has been made into the relative merits of the two kinds of eggs at the Californian Experiment Station, with the result that the impression that brown-shelled eggs are richer is not borne out by chemical analysis. Further, a physical examination proves that the main points of superiority, though extremely slight, are possessed by the white-shelled eggs. But practically there is no difference so far as the food value is concerned, between the two classes.

It is a troublesome question to know what to do with the flies this summer. This is the best method of destroying them that we know of. Take half-a-teaspoonful of black pepper in powder, 1 teaspoonful of brown sugar, and 1 teaspoonful of cream; mix them well together, and place in the room on a plate when the flies are troublesome, and they will soon disappear. Cold green tea made very strong and sweetened with sugar will also, where set about the room in aucers, attract flies and destroy them.

The results of a series of experiments on the preservation of eggs are published in the *Berliner Markthallen Zeitung*. Fresh eggs were treated by twenty different methods in June, and after being allowed to remain eight months were examined at the end of February. In only three of

the methods employed did all the eggs remain sound. These were (1) covering with vaseline, (2) preserving in lime water, (3) preserving in a solution of silicate of potash. The treatment with vaseline, however, is a tedious business, submersion in lime water induces a disagreeable flavour, and the use of silicate of potash renders the shell extremely brittle so that it is expedient to pierce it with a needle before putting it into boiling water for cooking. Whichever be the method employed, it is desirable that only non-fertile eggs should be subjected to the process of preservation. Twenty per cent. of the eggs went bad that had been (1) covered with lard, (2) preserved in wood ashes, (3) varnished with shellac, (4) put in a mixture of boric acid and silicate of potash, or (5) treated with permanganate of potash. Of eggs varnished with silicate of potash or with collodium, 40 per cent turned bad. Of eggs that had been plunged for 12 to 15 seconds in boiling water, or immersed in a solution of alum, or in a solution of salicylic acid 50 per cent. were found to be bad. Of eggs rubbed with salt, or preserved in bran, or covered with paraffin, or treated with a mixture of salicylic acid and glycerine, 70 per cent. went bad. Of eggs wrapped in paper 80 per cent., and of eggs kept in salt water 100 per cent., were found to be bad.

Place 4 lb. of unslacked lime, 1 lb. of salt, and 1 oz. of cream of tartar in an earthen jar; then add 3 gallons of boiling water, stir well and allow the mixture to stand for two days, when it is ready to receive the eggs. The vessel should stand in a cool place where it is not likely to be disturbed. There should be quite 2 inches of the liquid standing above the top layer of eggs. As the water evaporates, add cold water up to where it previously stood in the vessel.

No. 7.

NEW AND OLD PRODUCTS IN ZANZIBAR.

(From Annual Report of the Agricultural
Department of Zanzibar.)

COCOA.—We have risen a quantity of young seedlings in the nursery, chiefly from seed obtained from Mr. H. Baty, Seychelles, in June. The seed arrived in capital condition, was at once germinates between blankets and planted in bam-

boo pots. Some of the plants have been transplanted out with scarcely one failure as the roots suffered no disturbance during the process, and with cacao this is most important. The Plantation which we set out in the beginning of the year from last year's seed suffered severely from the want of rain. Still many trees survived, while the gaps have been supplied. We have enough plants to bring up the total acreage under cacao to about 8 acres. The trees are being placed 14 feet apart. We have planted intermediate rows of bananas for temporary shade and we find these better than castor oil trees. The latter bear a scanty crop of leaves in the dry weather and have a straggly, unsightly growth. For permanent shade we have planted bois immortelle but these have also suffered. We are also trying *Melia azadirach* for permanent shade which promises well; it has a healthy and rapid growth when young. There are I think several species of trees on the island suitable for shade as for instance *Erythrina tomentosa* a leguminous trees which sheds its seeds freely, and a species of *Dalbergia* also freely seeding and growing rapidly. We have as yet not proceeded far enough with the cultivation of cacao to form an opinion as to its suitability for this country. It evidently requires very careful attention when young and the trees cannot be set out and left to their own resources like for instance cloves or coco-

nuts or even coffee. The tow cacao trees on Miss. Thackeray's shamba at Mbweni cropped abundantly last year, but this year the fruit shrivelled up when about the size of an areca-nut and one of the trees is now nearly dead.

Kola.—A small plantation of about 3 acres of Kola was, in March, laid out in the clearing near the police station. They survived the transplanting and the drought much better than the cacao, though they have grown very slowly. Some fresh seed planted in August and put out the October to supply the gaps has overtaken the old planting. Kolo, though it springs up rapidly in the nurseries, is evidently of slow growth. We placed them 20 feet apart shading them in the same way as the cacao. **Kolas** are subject to great vicissitudes in the London market, the price ranging from 2d to 6d or even 10d per lb. They readily fetch a high price if in small supply but fall to nothing if over produced. A good deal depends upon the condition in which they reach the market.

Coffee.—The few Arabian coffee trees which were put out last season have grown excellently and will be ready for topping in another year. Some more seed has applied for from Nyassaland. Young plants of Liberian are now coming in the nursery for a plantation of 4½ acres to be laid out this season.

Tea.—We have decided to give this product a trial because of the healthy appearance of the tea bushes at Miss. Thakeray's shamba, Mbweni, planted by Sir John Kirk. These were pruned down in October and flushed well, bearing enough new growth in two months to form a plucking surface and leaves six inches, of pruning wood. Half a maund of Horagalla, Ceylon Assam Hybrid has been obtained and planted in the new nursery at Mpapa and is growing well. This should give us enough plants for 6 acres, planting 5 by 5, and leave a margin for supplies and distribution.

I don't think that Zanzibar will ever enter the lists as a tea producing country, even if low country varieties are found to flourish here, as the labour supply is too small and uncertain. The plentiful

supply of organised labour in Ceylon is one of the chief reasons why that country has taken the lead in this industry, while Natal is an example where the comparatively adverse conditions of labour have operated unfavourably. In our present unstable condition of labour we could not do more than grow a few acres for local consumption and perhaps induce the Arabs and natives to cultivate a few trees for their own use. Another point to remember is that tea is a declining market and is probably already over produced.

Pepper.—The pepper vines at Mwera, planted some years ago by Mr. Bomanji, have seeded this year though not freely. The condition of these plants shows, I think that pepper, if properly cultivated would grow here. Still we do not propose to give this product any special attention at present. Pepper is cultivated largely in India. The Straits Settlements and Borneo where the plantations are well established, and though the market price of pepper ruled higher this year than last, it is subject to the caprices of speculation as all spices are when the supply fluctuates. Its cultivation is confined to the East Indies and thought this in itself is no reason why it should not be tried elsewhere it is a noteworthy fact that the West Indies have not found it worth their while to take it up. Unlike cloves and coconuts its cultivation requires detailed attention and if introduced here would be more suitable for wa-ha-dimu small cultivators than for Arab planters. In the East Indies the Chinese are the principal pepper-growers.

Vanilla.—The small plantation of vanilla at Dunga has survived the dry weather and is doing well. The trees lost their leaves and the plants had to be artificially shaded but beyond this the plantation has absorbed little labour. Once established vanilla looks after itself fairly well but it must be sheltered from the sun and, in the dry weather, watered twice a week. Further supplies of cuttings have been ordered and I hope to receive them in time or planting in the rainy season. The live support—castor oil (Mbono) and Frangipani—have already been laid out and are ready for their reception, and we propose to plant some in a patch of natural forest growing on this estate. The vanilla at Mwera planted by Mr. Bomanji, flowered this year and a small quantity of fruit is now growing from flowers that were fertilised. Some of this fruit is 7 and 8 inches long. The length of bean that reaches the market from Seychelles, Mauritius and Bourbon varies from 5½ to 8 inches; our beans are therefore well up to the average length. There is an other patch of fruiting vanilla higher up the Mwera valley on a plantation owned by Jack Savey, an old skip's Krooman. Arabs take more interest in vanilla than in any other new product, though there are, as yet, no indications that they mean seriously to take it up. The wild vanilla, which was described in the *Shamba* of August and November, deserves a passing notice from the fact that it is bearing fruit. In October Mr. Robertson and I visited a patch growing on the coral about a mile from the Dunga bungalow and found a quantity of fruit forming. One pod measured 5 inches in length. Some insect must have been at work fertilizing the flowers of which there were at that time, numbers, though no insects, excepting ants, were visible in the dense, stifling jungle.

Para Rubber (Hevea Brasiliensis).—The plantation of Para rubber made at Tundana, Pemba, last year has suffered severely from the drought and only a few trees are now left. These however have grown well and were over 6 feet high in October. A young plantation, of a little over 2½ acres, has been laid out at Dunga in valley to the east of the house and we have a further supply of seedlings in the nursery for another ¼ acre. All are doing well. The two-year-old trees at Dunga, of which there are about a dozen have, grown slowly. In July I tapped the large Para rubber tree growing in Miss Thackeray's garden at Mbweni, and planted by Sir John Kirk. This tree is probably 20 years old. It was flowering

in January of this year (1899). We cut V shaped conduits on three sides of the trunk to a height of about 6 feet from the ground but no juice was obtained; the tree seemed completely lacking in latex. After operating for about an hour we obtained enough milk to work up into a piece of rubber the size of a pea. I visited the tree a few days afterwards but there were no signs of further exudations. On previous occasions when I had pierced the tree with a penknife milk had flowed freely. I think, therefore, that the bad results obtained at the tapping must be due to the dry weather and the soil, which, in the locality, is dry and sandy. The result is nevertheless, disappointing, as a tree of this size should yield an appreciable quantity of rubber at any time.

Ceara rubber (manihot Glaziovii).—One thousand of these trees were planted out on the Wanda in April. The soil here is only a few inches deep but is of a rich vegetable mould. It overlies coral mixed with red sandy soil. Holes 18 inches deep were sunk through this and filled in with surface mould. The trees did well at first but the subsequently dry weather killed off all but 192. We shall replant this clearing in the rainy season, sowing the seeds in the holes which are already dug.

Central American Rubber (Castilloa elastica).—200 seeds of this variety of rubber were received in September, 92 of which grew. Some of these have been planted out in the same valley as the Para and at the same distance apart from one another, namely 17 feet. All are doing well, with the exception or a few that were attacked by mongoose. These animals also destroyed some of the young Para and cocoa plants. We were compelled to put a fence of small stakes around each tree to prevent their attack, which takes the form of biting through the young stem an inch above the ground. With the exception of Para rubber the cultivation of Central America Rubber is receiving more attention in the tropical world than that of any other variety of rubber plants. The trees are described as tall and handsome, with large spreading foliage and deep roots and have been recommended as shade trees for cacao and coffee. The trees yield rubber in 8 or 10 years and are said to thrive equally well in a dry or a wet climate. *Castilloa elastica* is of the same natural order as our Jack fruit tree. In its native country, it is undergoing rapid extermination by the native rubber collectors.

Assam Rubber (Ficus elastica).—Several of these trees are growing about the island; we have one at Dunga. *Ficus elastica* is the "rubber plant" common in conservatories at home. It is found in the rainy mountain regions of Assam and is said not to thrive in low countries. Probably therefore, it would not as a rubber producer, suit our climate.

General remarks on Rubber.—We have now five different species of rubber producing plants on the island, including the native vine *Landolphia Kirki*—Seeds of Lagos rubber, *Kickxia African* have been applied for. The unfavourable results obtained from tapping the Para rubber tree, and, similarly, from tapping the Ceara trees last year, of which there are numbers at Moweni, make it I think doubtful whether rubber can be successfully grown here. Much of the cultivable areas of this island are of the same nature as the Mbweni land, namely dry and sandy, and is adapted for the cultivation of coconuts than of India rubber. The low valleys and swamp are, in extent proportionally small, and are utilised by the natives for growing rice. Allowance must be made for the dryness of the season, though at best the rainfall is but light. I think that the results in Pemba are much more favourable notwithstanding the high percentage of deaths, though of course we have had as yet no trees there large enough to tap. The two-year-old Para trees at Tundana have far outstripped our two-years old trees at Dunga, though they have had the same dry weather to contend with. Both the soil and configuration of the land is more suitable in Pemba for the cultivation of rubber than in

Zanzibar. The soil in Pemba has a greater admixture of clay and therefore greater drought resisting properties than the soil in this island, while the low steamy valleys are numerous; the country being in fact one continuation of small hills and valleys.

If Ceara Rubber could be established on the coral it would indeed be a great gain. It is a tree that, in the opinion of some authorities, might be profitably grown in land corresponding to our coral country. After the holes are dug and the seeds planted the expenses are confined to keeping fires off, which involves judicious burning on the boundary of the plantation about twice a year.

The planting of the *Landolphia* Vice is not practicable except in the natural forests, where it is a matter of preservation rather than of propagation. And it is far more important to preserve the forest trees themselves than the rubber vines, though the destruction of the latter naturally follows upon that of the former. But a forest could be stocked with rubber vines in a much shorter space of time than that required for rearing the trees to afford the necessary support and shade. The latter in fact would be an impracticable undertaking. The rubber forests of Pemba are so thickly festooned with creepers that it is almost impossible to penetrate them, but only a small portion of these are rubber yielding vines, and they are so widely scattered that the collection of rubber scarcely pays. The whole aspect of the forest would be changed in a few years by cutting away the superfluous creepers and planting young *Landolphia* plants in their places.

China Grass (Boehmeria nivea).—A small experimental plot of this fibrous plant has been grown in the nursery. Through the long drought it received no water yet it has preserved a fresh green appearance and in 12 months has grown about 5½ feet. But no cuttings have been made as the stems have not yet ripened. A small quantity of roots of the tropical species *B. tenacissima*, Ramie or Rhea fibre have been applied for.

The following are approximately the areas to which the principal new plantation will be brought up in the coming planting season. In the case of Tea and Liberian coffee no trees have as yet been planted out:—

Cocoa	8	Acres
Ko'a	3	"
Liberian Coffee	4½	"
Tea	6	"
Para rubber	3	"
Castilloa rubber	½	"
Ceara rubber	1,000 trees	
Vanilla	uncertain	
Coconuts	About 3,000 young plants, half of which will be ready in April.	

At Machui about 3,000 plants will be ready in April and another 2 or 3,000 in November.

II — CLOVES.

Marseilles Shamba.—In addition to the Dunga plantation which this year came under our management we have had charge of two of H. H. the Sultan's shambas at Machui—Marseilles and Kitumba. The former is situated on the second range of hills which runs longitudinally through the island. The soil is a brick red mixture of sand and clay which gets very hard in dry weather. It is however superior in quality to the corresponding outcrop on the Masinigi range of hills to the westward. Kitumba is in the low alluvial district of that name which spreads out to the eastward of the Machui range. The soil is generally a red loam overlying clay. As these two shambas adjoin and were as far as possible worked together they may be counted as one.

Marseilles plantation has a historic interest worthy of note. It belonged to Khalid, third son of Seyyid Said, first Sultan of Zanzibar. Khalid affected the French and so named his estate after the Mediterranean seaport town. Another account says that a Frenchman who visited the shamba was so struck with its rich and excellent appearance that he named it Marseilles. On Khalid's death it passed to two of his sisters. The place in those days was richly

decorated according to the prevailing taste of Arabs and was frequently visited by members of the Sultan's household. When Seyyid Said died Majid, as eldest son in Zanzibar, ascended the throne, but his ambitious brother Barghash, fifth son and afterwards Sultan, conspired from the first to bring about his brother's destruction. In 1868, two years before his death, Seyyid Majid confined Barghash to his house which he surrounded with troops, but Barghash, by the help of his sisters, escaped in the guise of woman's clothes and collected his forces at Marseilles. Here he was followed and routed by the Sultan's troops who bombarded the palace and reduced it to a ruin. The final engagement was fought out in the open country in the western side of the hill, just beyond the palace, Barghash being compelled to fly back again to the town.

Cost of Clove-picking.—Clove picking began, in Zanzibar in the latter end of October. At Machui we departed from the usual method of picking and instituted a system of payment whereby we could ascertain the total cost of clove gathering. The shamba people who, according to the new *sheria*, should have given their labour four days in the week were paid for each operation. Under these circumstances picking proceeded from the first more briskly with us than with our neighbours and we were able to gather a much larger proportion of cloves. The men and women of the shamba were rated as follows:—

1 Nkoa or headman	27 pice for every 400 pishi brought in
2 Wakadammu or headmen	23 pice each
1 Storekeeper and caretaker	46 " " " "
1 Woman cleaning sweepings	20 " " " "
	15 " " " "

Total 108 pice per 400 green pishi

Pickers 3 pice per pishi, and 3 pice per day (that is one pishi gratis) for spreading out and taking in the cloves in the morning and evening and in showery weather.

Wa-geni pickers, or outsiders, 3 pice per pishi.

The number of wa-geni pickers varied from 60 to 100 a day early in the season, dropping to 40 as gatering became general. The cloves were conveyed to the Custom house for sale on donkeys at the rate of 24 pice per bag of 20 dry pishi, equal to 40 green pishi.

The total cost of gathering, not including the overseer's wages, may, therefore, be calculated as follows:—

Per 400 green pishi:—	
Nkoa etc.	108
Picking at 3 pice per pishi	1200
25 spreaders daily at 3 pice each; reckoning an average of 400 pishi picked per diem	75
Transport (10 bags)...	240

Total pice ... 1623

1623 pice at 68 pice per rupee, the local rate of exchange, are equal to Rupees 23 pice 59.

Reckoning now that 20 green pishi will when dry weigh one frasila we have:—

Total cost of gathering and conveying to market:..
R. 23 p. 59 per 20 frasila (400 green pishis) or R. 1 pice 13 per frasila.

Quantity picked per day.—"Picking" includes the actual gathering and subsequent stalking. Pickers stop gathering at 2 o'clock and bring their loads in to stalk, after which the cloves are measured, stalks not being counted. Stalking and measuring will sometimes go on up to half-past six. The average quantity picked (and stalked) at Machui in a day was about 6 pishi per head. Our best picker was a woman named Binti Kiweti who gathered 9 and 10 pishi regularly, though she lost from an hour and half each day in taking the cloves in an out. Our heaviest day was November 24th when we picked 874 pishi with

135 men: an average of 6·4 pishi per head. At Dunga our average was much less by reason of their being fewer cloves; besides having to visit more trees the people never became so expert. Our best picker brought 6 and 7 pishi, while our average was between 3 and 4 pishi per diem.

(To be continued.)

THE "CAUCHO" RUBBER OF PERU.

A published report from H. M. Consul at Pará states that the tree which produces the quality of india-rubber exported from Peru, through Pará, under the name of *caucho*, has recently been determined by M. Huber, a botanist, who is on the scientific staff of the Museum of Pará.

M. Huber lately visited the Ucayli region in Peru, and discovered that the tree was a *castilloa*, and will shortly be able to decide by comparison whether it is the same as the *castilloa elastica* of Central America, or a variety of the same genus.

It has been surmised previously that the tree might be a *castilloa*, but it is said that M. Huber is the first authority who has settled the point. With this knowledge it results that the distribution of the *castilloa* is wider than was previously thought to be the case.

Caucho is produced in the neighbourhood of the Bolivian tributaries of the river Amazon, and from parts near the said tributaries that pass through Brazilian territory.

A sample of *caucho* exists in the Pará Museum that came from the banks of the River Tocantins. It is said that *caucho* is also produced near Macapo and Mazagao, on the north bank of the River Amazon, near its estuary.

A recent statistical return on the exports of the State of Pará shows that this produce was exported in small quantities (altogether about 10 tons) from Aveiros (River Tapajos), Santarém, Alemquer and Obidos, on the River Amazon.

The total shipments of *caucho* from Amazonian ports amount to about 2,000 tons annually. M. Huber describes the process of tapping as follows:—

The trunk is almost severed in two at a distance of about 3 feet from the ground, and the tree is allowed to fall in such a manner that it is supported in an inclined position by its branches, and still holds on the part that remains standing. The sap is collected and poured into a hole made in the ground, and is coagulated by means of the juice of certain local *lianas*. The natives state that this is the best method of tapping, and that if the trees were treated in the same manner as the *heveas* they would soon be destroyed by insects, which would attack them where the bark would be injured by incision. This may be only an excuse for unnecessary destruction, which might be avoided. However, it must be considered that as these trees grow far apart from each other in their native state it must be inconvenient, if not impossible, to attend to more than one tree at a time.

Trees that have been tapped in the manner described do not survive the operation. In the course of time their places are no doubt taken by young trees that grow from seeds. The amazonian *castilloas* are found on elevated land which is beyond the reach of floods, whereas the *heveas* thrive best in the lowlands that are periodically inundated by the River Amazon.

Sir W. T. Thistleton Dyer, Director of Kew Gardens, in a communication to the Foreign Office, states that *caucho*, of which caouthouc is probably an expanded form, has been hitherto identified with "India-rubber" par excellence, the produce of one or more species of *hevea* indigenous to the basin of the Amazons and exported from Pará; it would now, however, appear that the *caucho* tree of Peru is a *castilloa*. One or more species of this genus produces the India-rubber of Central America. In South America the *castilloa* has been known to extent as far as Ecuador, where it is called *jébe*, otherwise *jeve* or *heve*. According to Aublet, this latter name

was given in Northern Ecuador to a species of *hevea*, and in founding that genus he derived its name accordingly. In the Amazon basin the name for the species of *hevea* is "Seringa," and in Central America for those of *castilloa* "Ule" or "Tuun" (see *Kew Bulletin*, 1898, pp. 141, 142.) Perhaps in Western South America the names *caucho* and *jébe* are applied indiscriminately to rubber-producing trees.

According to a report by Mr. D. B. Adamson, H. M. Consul at Iquitos, dated 24th December, 1898, and published in the "Transactions" of the Liverpool Geographical Society for the same year, Peru has two kinds of rubber producing trees—*caucho*, which appears to belong to *castilloa*, and *jébe* to *hevea* (pp. 39-40). Both Mr. Adamson and Mr. Churchill also state that the rubber is extracted from the *caucho* tree by felling.

The *jébe* is always tapped. The former process results in a district being "worked out." In consequence, according to Mr. Adamson, "many of the 'caucheros' (or rubber collectors) are working on Brazilian rivers, where the supply is yet more plentiful." It is not, however, necessary to fell the *castilloa* trees to collect the rubber.—*British Central Africa Gazette*.

NOTES ON THE "SPOTTED COFFEE-BUG" AND KINDRED QUESTIONS.

BY J. MAHON.

When the particulars of Mr. Cameron's discovery were forwarded to me for examination and report it was suggested that I should write something on the subject as soon as the facts were made public property. There are a few points, perhaps, that may be briefly touched upon to some purpose.

With the descriptions and mode of life of the insect as set forth in the pamphlet just published I find no grounds for differing, and it does not seem necessary to repeat them here. When my attention was directed to the matter our dry season was too far advanced for any very critical observations, as undoubtedly the insects' chief depredations are committed while the coffee berries are young and growing. Careful search in a couple of plantations where "spotted" and "light" bean are common failed to reveal the insect, and but little success attended a considerable hunt amongst the flowers and fruits of many native plants. This was during the latter half of July.

In Mr. Cameron's company I subsequently saw the creature at work in his gardens wherever green berries were common. That the numbers seen were not great was due, doubtless, to the vigorous measures he was taking for their destruction. I observed the insect a day or so later in greater force on the neighboring Magomero Estate but I did not find it on other Namasi plantations.

At Zomba, early in August, I met with another phase of the creature's mischievous habits, which, although it did not surprise me when I found it, is not mentioned by Mr. Cameron. Examining some beds of seedling *Coffea Arabica* (unshaded) which we raised recently I noticed the terminals and young "primaries" of many drooping, whilst some were killed. Presently I came on a few of the bugs sucking these parts in other seedlings proving them to be the cause. At the same time I took a relative of theirs, as large as a *longicorn* beetle and of a dull brownish colour, who was occupied in the same destructive work. He prefers to conduct operations head downwards always and resembles a fragment of dead branch or leaf at the first glance. This indicates that the planter's vigilance must not only be exercised over plant in bearing but actually from the time his coffee germinates. My observations lead me to the same conclusions as Mr. Cameron regarding the "spotted bug" and its congeners being the principal cause of "spotted bean" and, to a certain extent, of "empty" or "light" berry also. Concerning the latter, however, I find so much of it

with practically no traces of external attack that I am compelled to repeat the opinion hitherto expressed, namely, that "empty berry" is due to debility and want of stamina generally in the plant. But that "spotted bean" is largely due to the cause mentioned above I have no doubt.

As a matter of fact the *haustellate* group of *Hemipterous* insects are very numerous in the country, as they are in countries possessing similar climatic conditions, and it is necessary to wage incessant war on all of them. The sub-order *Hemiptera* of the class *Insecta* contains, perhaps, the greatest pests that man and other animals, as well as the vegetable world suffer from, and this *haustellate* (i. e. provided with a *haustellum* or sucker) group are the worst of an extremely bad lot. The illustration of the ravages members of this group can effect in the case of a considerable indigenous forest tree (*Bersama*, native name "Sekese.") is instructive. Anyone who has collected seeds of our native plants must have been struck with the very small percentage of good material obtainable. This is true in almost every instance. Naturally, in the case of coffee we spread a plentiful table for the "spotted bug" and its relatives, just as we harbor and foster boring beetles (and the growth of fungi) by neglecting to burn or remove every particle of dead wood in a garden. For it is a rule that insects prefer to live in close proximity to the feeding material they find most suitable. It is also true that soil constitutionally poor, or impoverished by faulty cultivation, and where growth is stunted, are natural breeding grounds for insects.

The fact so frequently observed that young, or virgin, coffee crops are practically immune from "spotted bean" coincides exactly with what entomologists point out, namely, that injurious insects select sickly, stunted, or weakly plants for their attack; while the preference "spotted bug" shows for green berries is characteristic of the group which lives on green food and whose ravenous propensities are notorious. We see this in the well-known genus *Thrips*. Planters will recollect how these latter quite defoliated coffee gardens in several districts during the last months of 1897.

Professor Alphens Packard points out that injurious insects become suddenly abundant in newly cultivated tracts where the former presence of forest, and their natural enemies, kept them under. The balance of nature appears to be disturbed and insects, multiplying rapidly, become terrible pests. In the course of time, however, they seem to decrease in numbers and the former balance is restored.

He also remarks that insects often have a metropolis where they occur in great abundance, and judging from the numbers of "spotted bug" collected by Mr. Cameron this year, his plantation would seem to be in or near a metropolitan area.

Concerning remedies for the destruction of this pest I do not consider any means more satisfactory than their collection by children, as, fortunately, the creature is extremely easy to catch, and so are other members of the group that came under observation. It would be interesting to experiment with the locust serum or which might prove effective. I feel certain, however, hand picking, with the aid of their natural enemies, will suppress them, for we have many of their inveterate enemies, (the lady birds) here. I have seen and examined the latter myself, while various genera and species are named in the lists given in Johnston's "British Central Africa."

That Mr. Cameron should have noticed the "spotted bug" so far back as ten years ago at Mandala and suspect its evil-doing then is a matter of interest, and while it is to be regretted the facts were not brought to light earlier, yet this is an instance where the adage "better late than never" is happily *apropos*. Personally my attention never was drawn to the matter during my visits to coffee estates and although I learned recently the late Mr. Buchanan wrote about the creature in the "C. A. Planter" of his day, yet that was some time prior to my arrival in the Protectorate and the question, if ever it ex-

cited any local interest, had evidently ceased to be remembered. To Mr. Cameron, therefore, all the more credit is due for so effectively resuscitating it.

SEED SELECTION. I am absolutely convinced the subject of seed-selection for furnishing new coffee gardens does not receive with us anything like the attention it deserves. Situated as the coffee industry is in this country it behoves planters to use every endeavor to ensure a high class seed being obtained for sowing. In consequence of the danger attending the importation of fresh seed and the resultant inbreeding that must ensue, it is essentially necessary that seeds used for sowing be taken from especially selected trees. To gather a coffee crop, pulp it, and afterwards take at hazard a quantity of the beans for sowing, is assuredly the worst method that cultivators can adopt, for it does not at all follow that the largest beans will eventually furnish trees capable of yielding good crops of good quality.

The planter must select from his trees at bearing time those possessing as many desirable qualities as he can obtain, then mark the trees and see that their fruit is only picked when perfect ripeness is attained and that the seeds are expressed with the fingers and not fermented, but sun dried. I have no doubt whatever that the numerous blanks and failures one meets with in every fruiting garden during May, June, and July, (and a large percentage of the "empty" berry) are due to inherent debility transmitted through a weak parent tree, for when the strain of bearing is placed on such plants they collapse. Most people are aware of the trouble and expense incurred by agriculturists at home in keeping animal and vegetable stock pure and strong, obviously we must employ similar measures in our cultures here. Reference has just been made to the tendency insect enemies have for attacking weakly or stunted plants and it follows that a vigorous plant will tide successfully over the possible unfavorable climatic periods (drought &c.) that may occur here when the weaklings will be found to succumb. In this connexion the value of new blood suggests itself.—*British Central Africa Gazette*.

AGRICULTURE IN MEXICO.

In Mexico irrigation is necessary in the greater portion of the country, and on account of the scarcity of water, a large extent of land cannot be utilised. When the owner of land has sufficient water for the purpose indicated, he retains his property, and rarely can be induced to sell, as it is of permanent value to him. For the last three hundred years large tracts of land have been owned by individuals or families, who have spent heavy sums of money for canals and dams in order to make them productive. The United States Consul-General at Monterey says that on account of this, and the attending expenses of irrigation, there are fewer small farmers in Mexico than there are in the United States. Until recently farming in Mexico has been of the primitive order, but the Mexican is an expert in irrigation, and if he can get the water, his land becomes fertile and yields generously. During the last two decades decided improvements have been accomplished through the introduction of modern improvements into farming in Mexico. The increase in production corresponds to the improvements in farming apparatus. The great railroads of the country have been important factors in this advance, enabling farmers with a surplus of production to supply those less fortunate. The cost of labour is from 6d. to 1s. per day depending on the locality. There are two crops of corn a season upon which the former averages about £5 per acre gross. Sugar cane, turned into *Piloncillo* or brown sugar, averages from £14 to £19 per acre gross; beans from £6 to £8 per acre; rice, from £7 to £9 per acre; all other products realising correspondingly high prices. Thus it will be seen that the profits of the farmer must be large. Hay is not made in any great quantity, but corn fodder is sold to advantage. Near the cities, a lucrative trade is carried on in

green barley and corn, which are cut before maturity and delivered in the cities to owners of horses and cows. Cattle breeding is, and always has been, a profitable business in Mexico, consequent upon cheap labour, low taxes, and the large tracts of cheap land which are suitable for grazing only. Until recently, no attempt has been made to improve the stock, but certain large cattle men have now undertaken to do this, and steady improvement is certain henceforth. The demand created during the late war with Spain, and the high prices which obtained in the United States, increased the price of cattle to such an extent that the northern portion of the country has become depopulated of its stock, which, it is said, will take several years to replenish. Dairy farming in the neighbourhood of large cities is lucrative, milk selling at 1s. per gallon, and butter at 1s. 6d. to 2s. per pound. Those engaged in this business make money rapidly. Fruit and vegetable farming are beginning to attract attention. Formerly this amounted to simply enough for the home market. Now an effort is to be made to supply the United States with early fruit and vegetables. The movement is in its infancy, but it is expected to grow into large proportions. Oranges, lemons, tomatoes, beans, &c., are produced in Mexico from four to eight weeks earlier than in the United States. Hence this is expected to be a profitable business in the near future. Wheat is cultivated in the high tablelands of Central Mexico, and is fairly profitable. It is not the equal of that grown in the United States, either in quantity per acre, or quality. Para and Bermuda grass give pasturage in many sections of the country. They are said to be equal to any in the world. Parts of the country are adapted to the growth of tropical products, viz., coffee, vanilla, rubber, coconut, cocoa, &c., the quality of all being excellent. It is said that the best vanilla of the world comes from the State of Vera Cruz, and the best cocoa from the State of Chiapas. The coffee of Michoacan is said to be equal to any; the tobacco of Vera Cruz is preferred by many to that of Havana, and the sugar production of Southern Tamaulipas, or Northern Vera Cruz, is said to be surpassed by that of no country save Hawaii in quantity, and it is more profitable to the producers, for the reason that seven to ten crops are the result of one planting, whereas the Hawaiian planters get only two. Taken as a whole, farming in Mexico is an inviting field for persons of capital and intelligence.—*Journal of the Society of Arts.*

STORY OF A CLOVE PLANTATION.

The experiences of the Rev. Canon John Key of the Universities' Mission to Central Africa are worth recording as they throw light upon that rather obscure question—Clove planting. There are little or no data to enable one to figure out the approximate returns to be expected in this industry; no one can say whether clove growing pays or not; the general impression is that it does not pay and the impecunious state to which many Arab planters have been reduced confirms that impression. Nevertheless we believe it to be a false one, based upon wrong data, or rather upon complications and no data at all. This story of Canon Key's, therefore, being record of actual facts, not calculations from data merely, is valuable accordingly, even when due allowance has been made for the wealth of last year's crop.

The shamba in question is known as Kizimbani about half an hour inland from Weti, Pemba. It was selected by Canon Key as a missionary site chiefly because of its situation on the Suka Road, one of the arteries which feed Weti from the north. Kizimbani contains in all 1,100 clove trees 950 of which are bearing, the other 150 being unproductive. R1,132-8 0 were paid for the clove shamba originally two and R155 for three patches of waste land adjoining; in all R1,287-8 0. Occupation was entered into in January 1898 and clove picking began on October 29th lasting until February 21st 1899, 3

pice a pishi were given to pickers, the legal measure begin used. Arabs in the locality also gave 3 pice per pishi but used the native wooden measure, always used in the plantations for clove picking both in Zanzibar and Pemba and which contains a little more than the metal one used by the shop-keepers. Canon Key gave his people 2 pice per pishi daily and barked the other pice for them till the season was finished, an arrangement which they apparently appreciated. From 20 to 40 pickers were employed and two overseers at R14 a month each.

In all 520 fraslās were obtained from the 950 trees an average of 19 2-5 lb. of cloves per tree and a return after paying export duty of 25 per cent. of R1,965. Add. R38 for 43 fraslās stems and the gross returns are R,2003.

From this total there are several charges to be deducted. Eight pice per bag for cloves and five pice for stems, amounting to R29, were paid for conveyance to the beach on donkeys and R76-0-0 for freight to Zanzibar, landing charges, sorting charges, import declaration and scale fees:—

520 fraslās Cloves	1,965
43 „ Stems	38
			Total..2,003

2 Overseers 4 months	112
Picking 528 fras.	466
Conveyance to beach	25
Freight etc.	76
Balance profit	1324
			Total..R2,003

Balance profit..1,324

Thus the purchase money of the shams, R1,267 was more than recovered the first year. After paying for digging the shamba (R100), baskets, bags drying mats, bak-hish to overseers etc. the year's profit was reduced to about R1,000. The former owner used to make R200 to R400 a year out of this shamba and Arabs now attribute these good results to "the blessing of God" though the Canon, thinks that they may be accounted for largely by the fact of his having dug the shamba over.

It would be misleading to generalize from these results because doubtless Canon Key had much in his favour; proximity to a large village and a comparatively plentiful supply of labour; a good shamba and a prolific season. The record is that of a prosperous year and stands as such for what it is worth. Still in our opinion it is worth much. The bad years that now and then occur in clove plantations, and which have contributed to their disparagement, may be accounted for by the habit of the clove tree and vicissitudes of seasons but they may be also due to improper cultivation or at any rate partly so. If clove trees will yield so roundly after years of casual management and two years of extreme drought what may not be expected from them if properly cared for?

An interesting comparison may be drawn from the results at Kizimbani and those at Machui as published by the report of the Agricultural Department for last year:—

	Kizimbani		Machui	
1. Yie'd per tree lh..	19 2 5		6 ½	
2. Cost of picking and delivering per fraslā ..	R1-4 3-10		R1-5 ½	
3. Return per fras. net	R2-7		R3-4	
4. Return per tree net	R1-5 3-5		R0 9 ½	
5. Approximate price obtained per fras. ..	R4-15 1-5		R6-3 9-10	

(Less duty and disregarding stems)

The comparison is on the whole distinctly in favour of Kizimbani even when allowance is made for the fact that at Machui a quarter of the crop was abandoned for want of labour. The large quantity of cloves to handle at Machui made it necessary to employ a staff of spreaders while at Kizimbani this work was done by the pickers at no extra cost. In calculating the yield and return per tree the good

and bad trees are all counted together at Machui but at Kizimbani the unproductive trees have been neglected.

Still when all these deductions have been allowed for, the superiority of the Pemba trees remains very evident. They date from prehurricane days and are therefore older and larger, and the soil at Wei is stronger, than at Machui.

Canon Key concludes his report by some very interesting remarks which we append:—*Clove culture*.—The Arabs plant 6 or 7 trees together; and the e often unite in a wonderful way and from one tree but knowing that several trees were planted together you can see how and where they join and the numerous branches, each "tree" having the same number as a single tree would have. In a shamba of young cloves that I bought I rooted out all except one with the result that the young trees have gained in strength.

Pruning.—I have found that many trees have overgrown their strength, hence reducing their branches has added strength to the rest of the tree. We made a mistake in the first instance in cutting away the middle branches which of course cannot bear many cloves, but this divided the tree making it difficult to climb. Lateral branches are wanted in clove trees; the upward growing branches should be cut off otherwise the tree in time will grow to wood and only bear on the sides and the top.

My own shamba I cleaned once before last clove season. Leaves and grass were dug in for manure and the rain was able to soak into the ground instead of running off the top. Nothing flourishes under cloves as the small roots spread out like a net on the top of the soil; the trees would probably be the better for their being cut. The shamba next to mine I foolishly offered to pick but the cloves were small and many dropped off before becoming mature, which made difficult work for the pickers. We made RI00 but lost more by being compelled to neglect our own shamba. Clove trees seem to die in some parts of the shamba from some cause I do not know. I have noticed that trees on the outside of a plantation suffer most [May not this be due to the outside trees receiving the brunt of the sun's rays while the inside trees shade one another? Ed.] Many too have died in the valley from want of drainage. But most trees have recovered in a wonderful way. Arabs talk of the crop this year as half of that of last but I hope to make two thirds as our shanba is doing well."—*Shamba*.

CHILEAN AGRICULTURE.

About three-fourths of the persons engaged in agriculture in Chile use machinery and ploughs of European or American manufacture, the remainder using the same style of implements that were in vogue in Egypt 2,000 years ago. A pointed stick of hard wood with a single shaf stuck in the centre serves as a plough. For harrowing, a heavy beam of hard wood, with the additional weight of the ploughman standing on it, is dragged by a yoke of oxen over the rough-ploughed farms. The reaping, according to the United States Consul at Valparaiso, is done by hand, the threshing, by forming a deep circle in the open air with straw, similar to the ring of a circus, driving in from 30 to 50 mares, posting as many men at regular intervals on the outer part of the circle, and, by means of shouting, shrieking, and lashing, driving the animals fast and furiously round and round the circle, thus treading out the wheat from the ears. This is called *la trilla*, primitive, indeed, but highly satisfactory to the simple farmers who do it, as they make this the occasion for a general feast on the farm, winding up the business of the day with copious libations of *chicha* (sweet grape cider). On each farm live a number of *inquilinos*, or farm labourers, who are allowed a house to live in, a small piece of ground sufficient to cultivate enough maize, pumpkins, potatoes, and onions for the use of their families, and where they can keep a few hogs and fowls,

grow grapes, oranges, peaches, quinces, &c. Peaches grow almost wild, as do quinces. The valley of Aconcagua is celebrated for its fine quality of walnut, honey, wax, potatoes, onions, &c. About 3,000 tons of walnuts are gathered yearly in Chile, 2,000 tons of honey, and 300 tons of wax. The *papa colorado*, or red potato, is grown in quantities, not only sufficient to supply all the midland and northern provinces, but to be largely exported to Peru and Ecuador, and sometimes to Panama and intermediate ports. They may grow in the valley is sufficient to supply all the northern provinces and nitrate regions, and to export many thousands of bales to Peru and the Brazils. Ship loads have also been sent to England. The same broad valley from Las Vegas to Los Andes is planted for many leagues, as far as the eye can reach, north and south, with the vines of the black grape, from which is made *chicha* (cider) by boiling, sieving, and fermenting grapes together with the skins. It is estimated that 1,000,000 gallons of good sound wholesome claret could be made yearly from the grape crop of this valley. Don Guillermo Brown is the proprietor of a large vineyard, and produces great quantities of first-class claret. It is called "Vino escorial de Panquehue," the latter being the name of a village in the vicinity of the estate, near which is also the large estate of Errazuriz, producing excellent wines similar to those of the Brown estate. Grape culture extends also from Huasco to Cauquenes, or about 550 miles north and south. Delicious sweet muscatel wines are made in or near Huasco (north), and semi-sweet wines are made in Tome and Cauquenes (south). There seems to be no limit to the producing capacity of the soil, which is greatly favoured by the facilities offered for irrigation by the numerous streams of melted snow which can be, and are, trained in any required direction as they rush towards the Pacific Ocean, fertilising the lands through which they pass in a constant stream. This, of course, is applicable only to the central and southern provinces. The northern portion of Atacama, and all of Antofagasta and Tarapaca are rainless regions.—*Journal of the Society of Arts*.

USES OF TOBACCO JUICE IN FRANCE.

All tobacco shops in France are compelled to keep a stock of what is called "tobacco juice, rich in nicotine and guaranteed." This is manufactured by the tobacco monopoly in Paris. The article, it is claimed possesses the following advantages:—(1) It is free from all matter susceptible of fermentation, and keeps for an indefinite period if in closed vessels. (2) It contains no resinous matter, and is almost transparent, therefore, it does not injure or clog the spraying machines, and does not stain plants or flowers or the wool of sheep. (3) It has a Government guarantee as to the proportion of nicotine it contains, which never varies. This product, it is also claimed, contains from five to six times the quantity of nicotine that may be found in ordinary tobacco juice, and that, therefore, one-fifth to one-sixth of the quantity will accomplish the object to which it is applied. For spraying purposes the product is employed in the proportion of one part of juice to one-hundred parts of water. It is stated that the spraying of plants should be done after sunset, and that they should be sprinkled with clean water on the following day. For fumigating hot-houses the proportion is one part of juice to five of water. The mixture is sprayed upon bricks or iron sheets heated to a temperature sufficiently high to produce rapid evaporation. It is claimed that insects and parasites are absolutely destroyed by this process. It is said, further more, that the proportion is most efficacious for the destruction of all insects in cattle, as well as being a preventative of all manner of parasite attacks. For these purposes the juice is mixed in the proportion of one part to twenty of water. It is recommended that the lotion be not used as a general bath but applied gradually on limited surfaces. It should not be brought in contact with sore or erosions of any kind. The benefits accruing from the use of

these mixtures are said to be greatly enhanced by mixing 100 grammes (about 3½ ounces) of soda crystals with each litre (1·7 pints) of diluted juice. Regarding the use of this product in the Alpes Maritimes, the United States Consul at Nice says that it is rapidly coming into general favour for all the purposes mentioned above. He has seen it used with complete success in curing what is popularly called "le noir." This parasitic affliction is not confined to orange, lemon, olive, and other trees, but has been most disastrous to such vegetables as potatoes, beans, peas, tomatoes, &c. He has also seen whole rows of orange trees so thickly coated with parasites that every leaf appeared coated with soot (hence the popular appellation, "le noir,") and he has been enabled to verify the fact that three or four applications of the lotion have prevented the disease from attacking new leaves, and have caused the disappearance of the black deposit upon those attacked. A proprietor of an olive grove in Nice has recently stated that the use of the juice in combating "le noir," which has destroyed many thousands of olive trees in the department, is most costly, but at the same time very efficacious. The spraying machines used to spread the mixture are the same as those employed in applying sulphate of copper to vineyards. Efforts have been made to ascertain whether the use of tobacco juice would not be more desirable in treating vines for the cure of the oidium—a parasitic disease of the vine leaves—than sulphate of copper, but it appears impossible to discover anyone who has experimented with the two treatments. It would appear, at first sight, that tobacco juice would be preferable, as sulphate has always been considered a preventive of attacks upon the grapes themselves, especially after the bunches are completely developed, whereas the oidium attacks only the bases and indirectly the vitality of the plant.

FUMIGATION OF TREES.

The fumigation of trees for the destruction of insect pests has for some time been extensively used in California and other parts of the United States. The process will probably soon come into use in New South Wales, for Mr. W. J. Allen describes in the *Agricultural Gazette* of the Colony some very successful experiments in spraying and fumigating for red and other scales on orange trees. The tree to be treated, is completely covered with a tent, and is subjected for netly an hour to the fumes of hydrocyanic acid, produced by the combination of sulphuric acid and potassium cyanide. The number of men generally employed in a fumigating gang is four or five, according to the size of the tree. One man introduces the chemicals, another looks out for the generator and measures the acid, and two or three handle the tents. Such a gang can handle from thirty to forty medium-sized tents, and cover four to six acres of orchard in a night. Fumigation is to be preferred above spraying, because the trees are not in any way damaged by the fumes, except in the case of a few of the tender leaves, while the solution used in the sprays must to a certain extent close the pores of the tree and slightly weaken it.—*Nature*.

MANGABEIRA RUBBER.

The current number of the *Kew Bulletin* contains an important article on the source of Mangabeira rubber (*Hancornia speciosa*). In consequence of certain objections to its use, the price has been but half of Para rubber. Recently, however, the price of Mangabeira rubber has advanced by reason of the improvement in the purity, and on account of its great suitability, when pure, for certain purposes. In consequence, the disparity between the price of the best sorts and that of Para rubber is much diminished. At the end of last year, a kilogramme (2lb. 3oz.) of the best Mangabeira rubber sold for upwards of 12 milreis (almost 8s.), a price not far short of that of Para rubber. An additional cause of the advance

in price is to be sought in the change in making up the rubber; for, owing to the constant watch which is necessary to guard against adulteration by addition of iron or stones put in to make weight, pieces of rubber only half to three-quarters of an inch thick and two feet long by ten inches broad, the so-called "sheets" of commerce, are welcome in the trade.

Of recent years, the exploitation of this source of rubber has taken a considerable extension. While the intelligent collectors, who start from Bahia and work towards the interior, have only tapped mature trees, improvident itinerant collectors, making their own profit out of the pressing demand of the time, have in many places mischievously drawn on the supply and threatened its continuance.

The chief centres for export of Mangabeira rubber are Bahia and Pernambuco. A large supply is brought down the river São Francisco, and so to Bahia; and from this town, in 1889, 131 tons were exported: in 1892, 4,362 bales, to the value of £22,826; and in 1893, 3293 bales, to the value of £20,362. From Pernambuco were exported, in 1896 64 tons to the value of £1,800.* A small amount of caoutchouc from the Province of Matto Grosso (probably Mangabeira rubber) is exported down the Parana through Paragnay, and great quantities from Minas Geraes are shipped through Rio de Janeiro.

Recently the Province of São Paulo has begun to demand a place in the consideration of rubber export. Regions here, such as that through which the Mogyana railway runs, are exploited, even by persons coming from Bahia for the purpose, the owners of the land receiving, in return for the permission they grant, one-third of the clear profits. A worker can collect about 6½ lbs. of rubber per diem, and receives on the spot 75 milreis (£2 9s. approximately) (per arroba 32½ lbs.). The arroba is sold in London for 200 milreis. In the first half of the year 1898 no less than 76,498 kilogrammes (approximately 76 tons) of rubber were passed over this railway, and yet the railways of Paulista and Sorocaba equally traverse the country where the Mangabeira tree grows. In consequence of the increasing trade, Santos has become an important centre for rubber, and there, as at the town of São Paulo, now exist mercantile houses whose principal concern lies in this business.

In this Province an idea of the importance of cultivating and protecting the tree is arising. Many coffee-planters are turning their attention to the sowing of *Hancornia*, and seed is already hard to procure. The Government hoping, by means of the duty on rubber (now standing at 13 per cent. *ad valorem*), to recuperate its finances, which have become disordered by the depreciation of coffee, has instructed Dr. A. Uchoa (a valcant, Acting Director of the Agricultural Institute at Campinas, to inspect the territory in question; and, further, the Congress of the State has decreed that the Mangabeira trees shall be protected, and its cultivation extended, as is advisable.

Although but little is known so far of the cultivation of Mangabeira, it may be said that there is a considerable probability of it becoming an important tree in rubber-culture. The apparently easy accommodation of the tree to soil and climate, its early and considerable yield, together with the fact that even under the rough treatment of the Indians it preserves its fruitfulness, and also the facility with which it can be cultivated, promise a future. And, taking a wide view of its possibilities, from its presence in the red coffee-growing soils of the west of the Province of São Paulo, it appears suitable for the red caribs of the German colonies of Africa, Usambara and Togoland alike, such, for instance, as occur at Misahöhe, in the latter colony. For these soils it promises to be considerably better suited than the Ceara rubber plant (*Manihot Glaziovii*), and the Para rubber (*Hevea*), and will probably give better results than *Castilloa*, than which it is more hardy, earlier maturing, and smaller.—*Journal of Society of Arts*.

* Probably an error for £18,000.

THE RUSSIAN TEA TRADE. LARGER SUPPLIES FOR COLOMBO MARKET.

In a recent issue we gave a summary of the proceedings at the meeting of those interested in the Russian Tea Trade which was held on Dec. 8, 1899, in the Chamber of Commerce room to discuss the desirability of laying before tea proprietors the possibility of increasing the quantity of tea put up for sale in Colombo. In opening the meeting,

Mr. F. M. MACKWOOD (Chairman of the Chamber of Commerce who presided) said he was glad to see so many present. The meeting was called at the instance of one or two of the Russian gentlemen in their community, who approached the Chamber as to the possibility of their being able to address those interested in the tea trade here in the hope that they might be able to offer figures and arguments which would induce the proprietors of estates and agents of Companies to sell a larger proportion of their tea in Colombo than was at present being sold. He was not called upon, he thought, to make any further remarks and he would ask Mr. Tokmakoff what he had to say to them.

MR. TOKMAKOFF'S VIEWS.

Mr. S. J. TOKMAKOFF said that it was by the kind permission of the Chamber of Commerce that they were enabled to hold that meeting that day. In his speech at the Planters' Association Meeting. Mr. Lane, the Chairman of the Association, passed some remarks upon the Russian tea market. Mr. Lane had asked "one and all of the planters who could possibly do so, to encourage the Colombo market as far as possible, for he understood that there were complaints that there was an insufficiency of tea offered in the local market to supply all the requirements of the foreign buyers who were amongst them. Although the development of the Russian market was partly due to the way these people had taken to our teas, a part was attributable to the falling off in the quality of China tea, but in view of the absolute importance of pushing the foreign markets, it was the duty of every member of the planting community to aid and assist as far as he could in developing the Colombo market."

Some of the firms who dealt with tea in Russia got complaints from the Russian tea buyers, that they (the latter) could not buy enough tea in Colombo. Consequently, they were unable to enlarge their orders, as they could not get tea enough. They certainly wished to enlarge their business and the question was how they could enlarge their orders if the Ceylon people did not enlarge the market in Colombo. (Hear, hear). If they continued to put the same quantity on the market as before and the Russian traders enlarged their orders, then the price would go up. The total consumption of Ceylon tea in Russia in 1897 was about six million lb. out of which only about 440,000 lb. were exported from Colombo. That was about 12 per cent. In 1898 it increased nearly 50 per cent, the total consumption being about 11 millions as against six millions in 1897, and of this 11 millions there were sent direct from here 2,700,000 lb. or 23 per cent. The estimate of the total consumption of Ceylon tea in Russia for the present year was about 17,000,000 lb. of which it was hoped that about 14,000,000 lb. would go from Ceylon. They would see therefore, that the consumption of Ceylon tea

was increasing (applause), and at the request of his countrymen, both here and in Russia, Mr. Mackwood had been kind enough to call that meeting so that the matter might be placed before the Planters' Association and the "Thirty Committee" to see whether they could find it possible to increase the tea sales here. He proposed that gentlemen representing the firms who dealt in tea with Russia be appointed to write an official letter to the Planters' Association and the "Thirty Committee" explaining the reasons why they wished more tea put upon the Colombo market. (Applause.)

NEW METHODS REQUIRED: DO AWAY WITH GRANTS.

Mr. HEATH, seconded the resolution. He had been in China and had some experience of the Russian trade for a good many years. He had also been in Moscow. Last year, he made a trip in the winter with the special object of trying to get orders for the Colombo market. He had just come from there, having started a branch of his firm there. He was almost invariably met by the same arguments on the part of the Russian buyers that if they put large orders on the Colombo market prices were driven up to a limit much beyond London, and therefore they could not trade to such advantage out here. Consequently they restricted their orders and took up small quantities as they required from London. He thought that if the Thirty Committee were inclined to help them in this matter, they could do a great deal of good. He was sure that, for instance, instead of giving away so much money as had been lately spent in grants, if they were to distribute some of their money to aid the Colombo market, and the planters who were inclined to sell their teas locally, it would be to the advantage of everybody, and especially to the planters themselves. They were willing to spend money on this, and they were very anxious to do business in Russia and he thought it could be very easily worked. The amount of tea that could be taken in Russia was practically unlimited. They could take the whole crop, if they could get the right kind at a reasonable price. They were quite ready, too, to take Ceylon tea, as far as he could judge by the increase of the figures. He did not think it was a partiality for China tea that it had been so popular so long. Ceylon tea, wherever it went, was taken on its merit entirely—(applause)—and he did not think it required any pushing, provided it could be got at a reasonable figure, to compete with the China teas which had been taken previously. He thought, if the planters were inclined to help in the matter, and would put more of their breaks on the market, they would certainly do no harm, and probably they would do themselves a lot of good. At present it seemed to him their great mistake was they put everything on the market in one break—pekoe, broken pekoe, pekoe souchong and did not consider whether they were suitable for the requirements of Russia. He maintained that if they liked to pick out their broken pekoes and broken orange pekoes, which were not wanted at any particular time—they could be advised by the agents to that effect—they could send them to London, but give them a show with the pekoes, and pekoe souchongs and leafy teas which were particularly required for the Russian market, and at the worst, if they did not get fair bids they could always ship them to London, and they would not be losers thereby. But he was quite sure that

if planters and local sellers would only give the Colombo market a fair amount of tea, so as to give local Russian buyers a good selection, they would find that the demand from Russia would be enormously increased, and that instead of a few millions, as at present, it would be double and treble the quantity, provided that local Russian buyers were well backed up. He was certain, that the fact of any one firm starting a branch locally and pushing the sale of tea for all they were worth did more good than all the grants given by the Thirty Committee since the time the fund was started. He believed that most of the buyers would bear out what he had said. He begged to second the motion.

The CHAIRMAN said that as regarded liberty of speech it was advisable that the meeting should take the form of a Committee meeting so that members could speak more than once and ask any questions they wished.

SMALLER BREAKS WANTED, AND MORE VARIED.

Mr. HEATH understood that very often a planter would send a break down to this market for which he wanted a good bargain and marked it "X. Y. Z." The broken pekoes people were, perhaps, suspicious of it, as they did not know the tea and no fair bids were made; but the pekoes and pekoe souchongs required for Russia got fair bids. They said that was a mistake and they would not send the whole break home because people were prejudiced in London if they knew that it had been shown in the Colombo market. To obviate that, could not some of the big concerns try half their breaks on this market and ship the broken teas home? Everyone knew that they could buy this particular class of tea for Russia so that it would be no advantage to put up these teas here. He thought that if the planters sent part of their lots to London and some of their leafy teas here, they would find that they would get very good offers, in fact, far better than in London, in many instances, provided the teas were suitable. Of course some kinds could not be bought for Russia at any price. It seemed to him to be a mistake to put up the breaks as they did at present.

RUSSIA BUYS ONE-SIXTH OF COLOMBO TEAS.

Mr. WALTHAM thought it would be interesting to mention that at the last auction 165,000 lb. or about one-sixth of the total was bought for the Russian market at prices considerably over London. The figures he had quoted were collected that morning from the various buyers in Colombo.

The CHAIRMAN said that to him two points seemed to stand out clearly on which he thought it would be quite fair for them to ask for information, at least with reference to one of them. As to the other there might perhaps be a certain amount of delicacy as trenching on individual sources of interest. The first question they were all interested in was this. They knew that Ceylon tea was increasing in quantity annually, and it would be a great comfort for them to know that there was any one country or group of countries that would be likely to take an increased quantity of tea each year so as to work off the surplus. The first question that he would therefore ask his Russian friends was this. At present Russia was supplied from the two markets, Colombo and London practically, and it amounted to so many million lb. a year. The first question he would ask was, if there were greater facilities

and greater quantities of tea put in the Colombo market would it mean that they should simply sell more in Colombo for Russia and less in London than at present, or did it mean that owing to the facilities offered here, they should actually increase the total quantity of tea sent to Russia from here irrespective of what they might do in London. In other words would they buy more tea here and less in London? If so, there was no great advantage as regarded getting rid of surplus teas. The other question was this. He could quite understand that that gentleman would not care to go into detailed figures showing that it would be of advantage to the planter to sell in Colombo in preference to London, because there were all sorts of interests concerned—there were the Russian interests in London and other things. It was quite possible that they might go more into detailed figures in addressing a letter to the Planters' Association and the Thirty Committee where communications of that description were often held to be of a confidential nature and not made public.

Mr. HEATH said, with regard to the first question of the Chairman as to whether more would be taken if more and a better selection were offered in Colombo at a reasonable price, he thought there was no doubt that the sale of Ceylon tea would be enormously increased if they could show importers in Russia, the Continent and other countries that there would be material advantages in giving orders in Colombo.

The CHAIRMAN:—The total aggregate sale?

Mr. HEATH:—Yes, certainly. But if they move round the Russian firms and tried to get orders and then found that they were not in a position to buy in Colombo, people would naturally think that they had been wasting their time and had been talking nonsense, and that these people would go back to China tea, or whatever they had been taking previously. They had to give everybody some inducement and prove to them that what they were telling them was true.

The CHAIRMAN:—In other words if you get more Ceylon tea, the Russians would take less China tea.

Mr. HEATH thought there was no doubt about it. It was a question of price. If they gave them a better article, as they thought Ceylon was, at a lower price, they would certainly take more because it suited their taste.

Mr. WALKER pointed out that an advantage in selling tea in Colombo was that they saved the London charges and that tea could be landed in Odessa for 3d as against 1½d in London. If Russian buyers were prepared to give the same price as to the seller in London they would still have the advantage.

Mr. TOKMAKOFF thought the figures he had given as to the consumption of Ceylon tea in Russia spoke for themselves, and in his opinion the increase of orders here would not decrease the London market. There had been an increase from 11 to 17 millions and very probably the consumption next year would be 24 millions.

The CHAIRMAN: I hope so.

Mr. RENTON said it had been remarked that the advent of one Russian firm here had done more to bring Ceylon tea into Russia than the Thirty Committee. He would like to ask who made the first efforts to introduce Ceylon tea into Russia. Eight or nine years

ago when it was first attempted they were told, as they were now being told in Germany and France, that Ceylon was not known as a tea-growing country. It was very much the same thing in Russia. But the Thirty Committee had made known the fact that there was an island called Ceylon which grew tea and asked all those who were in the habit of drinking tea to try the Ceylon growth. The very fact that they began in a small way to make Ceylon tea known brought before the attention of the Russian buyers and—he would not say compelled but, induced them to give Ceylon tea a trial. Now that the work had commenced and now that the Russian buyers had formed a trade for themselves it was probably no longer necessary to make grants, but he was perfectly certain that the first effort made seven or eight years ago on behalf of the Thirty Committee laid the foundation stone and had been the means of bringing the Russian buyers here (applause). With reference to what had been said as to shipping the broken teas and putting only the leafy teas on the Colombo market, could not the Russian buyers do as those in other countries did, and try to a certain extent to cure, or alter the taste of their constituents so that they might be able to buy a proportion of broken teas. If other markets, such as the Australian, English and Irish, were willing to take a percentage of broken teas, why could they not alter the Russian taste too. Surely they would learn in time that the quality of tea did not merely depend upon its appearance. Surely if it was too strong it was only a case of watering it down, was it not?

Mr. HEATH said it did not suit them at all. As buyers they had simply to buy what they were told. If a man sent an order for pekoe at 40 cents and he sent broken pekoe it would probably finish the business.

Mr. RENTON.—But could they not be induced to buy broken pekoe?

Mr. LAMPARD said that every house in London interested in the trade kept their own special buyers both for leafy and broken teas and so on; they were absolutely separate things.

Mr. RENTON was very glad to hear that; it was something worth knowing. He would like to suggest, however, to the Russian buyers that they should try to make a market for the broken teas.

Mr. TOKMAKOFF said he had sent samples of small lines and got orders for broken pekoes, and he wondered why other firms did not do the same thing. (He was understood to add that some of the biggest firms bought broken teas on the London market.)

Mr. RENTON thought it would be a drawback to put one or two or three lines of tea on the market here and send the rest home. Estates that shipped tea here would want to sell the whole lot. If they did so there would be an accumulation of broken teas in the Colombo market, for they would not be able to find buyers. If this were carried out too much broken tea would come on this market. That was a point on which he was glad to hear that Mr. Tokmakoff had tried the Russian market and to make the tea known. He feared that it would be difficult to get leaf teas sent here and broken teas sent home, estates preferring to sell all or nothing. Buyers here knew very well that teas put up in Colombo and withdrawn were tabooed in London and would never get their proper value,

Mr. HEATH thought that Mr. Thomson of Messrs. Finlay Muir & Co. would probably be able to give them some information on that point, as he understood that when they could not get the price they wanted for breaks here, these breaks were sent home.

Mr. THOMSON took exception to that remark. It was very seldom that they withdrew teas, and if they were withdrawn that did not make the slightest difference to their selling in London.

The CHAIRMAN asked whether the trade in London would be able to discriminate whether tea was not going home through third hands.

Mr. THOMSON did not think that any broker in London having printed the tea as being sold on any company's account or estate account, would question the fact at all. They would take it as estate tea.

Mr. LAMPARD said they had to study the requirements of the Russian market, and the point that weighed with him was that although there were very cheap internal rates, still with these advantages frequently tea could be bought very much cheaper in London than in this market. He was not speaking from any particular point of view about this thing, because his interests were quite equal. The same point really applied to the whole of the foreign trade which depended upon the supply of the local market. He thought Mr. Lane, the Chairman of the Planters' Association, would bear him out when he said that was a point he had been hammering at ever since he came to Ceylon. He came here chiefly with the idea of pushing the Russian business which had gradually grown to a point which made the men who dealt with it say that they must go on the same lines with regard to Ceylon as they had hitherto done with regard to China. It was the same feeling all the world over. They preferred to pay equal rates and get their goods direct, rather than get them *via* London and it must be in the interests of the producers here to study the local market. They had to study the rates of produce from here to London, and they would find that it would cost them at the cheapest a fraction over one penny. Roughly speaking it was one penny three farthings, and from here direct, it took about one half-penny per pound, and in addition to that they had more favorable internal rates for transit to Moscow. If they consider these points and allow the market to be supplied with a larger quantity of suitable tea, it stood to reason, that the trade would go forward with leaps and bounds. In studying the local market, they were not studying the interests of one particular country, but the only possible chance of getting the tea up to paying level, and that was by opening fresh markets. The danger that Ceylon had was in concentrating the supply in one particular market. If they supplied this market they would gradually get away with the surplus, and drive it into countries direct where all the surplus would be taken up and tea kept at a paying level.

Mr. THOMSON said that every house of any size was represented in one way or another by agents in this matter, as well as probably every foreign trade outside England.

Mr. HEATH thought there was no doubt that buyers on the Continent generally would far rather import their teas direct than buy in London, if they could get equally good value. He thought it would be the experience of all the buyers here, that preference was given to importing direct.

Mr. RENTON thought he could corroborate that. The CHAIRMAN thought Mr. Renton had hit the nail on the head very fairly and clearly. If they wanted those who produced tea and had the disposal of it to put only certain grades in greater proportion on the local market, and ship the remaining grades to London, it seemed to him that those remaining grades would create such a glut in the market at home that they would run the prices down of those grades quite enough to balance the relief they would have in selling their leafy teas. That was the difficulty and the true solution of the difficulty was that if the Russian buyers wanted to assist them in the matter, and they should like to assist them, by putting larger quantities of tea in the local market, and as Mr. Renton suggested by getting the Russian people by degrees, however small it might be at the beginning, to take some of our other grades.

Mr. LAMPARD thought the wisest thing to do was to print the whole invoice.

Mr. LANE said his reason for coming here was to learn as much as possible on that very important point, because, as they were all aware the Planters' Association and the Thirty Committee were most anxious to develop the Russian—and in fact all foreign—markets. Mr. Tokmakoff had made a suggestion that a letter with certain suggestions should be addressed to the Thirty Committee. That would be the best way of meeting the difficulty, because they would have in writing the views of those who were anxious to develop the market. He had been anxious to hear whether there had been any suggestion made as to the reduction of duty on tea going into Russia, and how that would help in the introduction of Ceylon tea into that country, and to cause a greater demand for their tea. It had been proved that the reduction of the duty had been of great assistance in opening up different markets in other countries, and the Planters' Association, last year, addressed the Foreign Minister in hopes of getting a reduction on the duty on the European frontier of Russia. They made no reduction on the European frontier but they made a slight addition to the duty on the Siberian frontier. The duty of 1s 10³/₄d on the European frontier fell very hard on Ceylon tea. He should like to hear from those who were likely to know something on the matter; whether they should press this subject still in the hope by reduction of duty and increasing facilities they could bring the tea within the reach of the poorer classes. He was very glad to see so many persons present interested in the market.

Another matter he would like to ask about was this. They said that the planters upcountry did not know what grades were required, but it was very difficult for them, to know, unless somebody interested in the development of the Russian market made it known. He was sure, after the report of that meeting came out and it was understood that pekoes and pekoe souchongs were the chief grades required for Russia, that there would be men—there would be lots of independent planters—who would be very glad of the hint and send their better and higher grades in the hope of securing better prices. Of course the sale of tea in the local market would depend a great deal on the prices. If encouragement was given, teas would be sent here; otherwise they would be sent to London.

Mr. TOKMAKOFF explained that all attempts to have the duty reduced on the European frontier had been unsuccessful. The Russian revenue—

nearly 60 per cent—was derived from the duty on tea.

Mr. LANE said that with a lower duty there might be double the quantity of tea used and that would make up the amount to Government.

Mr. TOKMAKOFF said they tried this about three years ago, but could not manage it.

Mr. LANE said he would be glad to know whether Mr. Tokmakoff and his friends would advise the Planters' Association to keep on pressing the point. They had already addressed the Secretary of State, and the memorial of the Association had been forwarded through the Foreign Office to the Russian minister De Witt. A small concession had been made by the addition on the Siberian frontier of two pence, but they had asked for a reduction on the one and ten pence-half penny on the European frontier. Did they think it desirable, and likely to lead to success, if the P. A. again pressed the matter back by the Chamber of Commerce and the Russian interests in Colombo?

Mr. TOKMAKOFF said he would not be sure of success, but he was perfectly sure, that if the duty was reduced the Russian Government would not lose anything, because the consumption of tea would increase.

THE STERLING COMPANIES.

Mr. RENTON thought the people they must go for were the London sterling companies. Of the rupee companies who had agencies in Colombo, fully 80 per cent of their teas were sold in the local market, and he thought most of the independent proprietors sold their teas too. Of the large sterling companies, practically the whole of their teas went to London, simply because the London brokers and directors and the bonded warehouse men were all interested, and must have their pickings out of them. (Laughter.) They should make a special appeal, not to the Directors, and not to the Secretaries of the London Companies, but to the shareholders.

Mr. G. THOMPSON said he believed his firm represented a fairly large number of sterling companies. Of the Muir companies he had persuaded them to sell half their tea locally and half in London.

Mr. RENTON said that sterling Companies he represented also sold their teas here.

After some remarks by Mr. Walthew and the Chairman as to the cost of putting down tea in Russia from Colombo and London,

Mr. G. H. ALSTON said that he had for many years endeavoured to get sterling Companies to put the tea in the local market and it was chiefly with the object of backing up his own views on this subject, that he was so pleased to see that this meeting had been called, so that they might show that other people were interested in it.

Mr. LAMPARD said the Russian firms would not, of course, pay the same rates in Colombo as they did in London, but perhaps there might be something to divide between them, something for the planters, and something for themselves.

The Hon. Mr. CAMPBELL said he did not know whether it was worth while for him to state, but he did not mind telling them, that he put one estate's tea on the local market a year ago, with fair results, and has just got permission to put another estate's tea on the local market, which would amount to about a quarter of a million lb. per annum. (Applause.)

Mr. LANE said, he supposed that application would be made to the "Thirty Committee."

The CHAIRMAN said they had received information which must be a gratification to the Russian buyers in this market, inasmuch as what they were urging them to do, had been taken up by a good many of them. In his own small way he had succeeded in getting permission to sell certain classes of tea which were serviceable for this market, allowing the rest to go home, but so far, he could not say which way the result would work. On the other hand, they had definite information of efforts which had culminated in success, some of them quite recently, efforts which had reached the point of considerably more quantities of teas being put on the market; and no doubt, if these increased quantities met with the success, with which presumably the previous quantities met, he did not think they need now have any fear of this market in course of time not being adequately supplied. He had been asked as regarded the address to the Planters' Association or Thirty Committee, to say that the following five gentlemen might form themselves into a sort of letter-writing committee, if they might put it in that way, viz., Messrs. Heath, Tokmakoff, Tchokoff, Thomson and Lampard.

Mr. LAMPARD said that as he was going to Calcutta he was unable to act, and suggested the name of Mr. Croll.

On the suggestion of Mr. RENTON, the CHAIRMAN said that the letter drafted by the committee might be put in such a way, that copies of it might be sent to those in Colombo who were interested in the matter, and had some influence as regarded the disposal of tea. If that could not be done, he might draw up a separate letter.

The CHAIRMAN in declaring the meeting closed expressed the obligation, that those present were under to the Russian gentlemen for coming there and laying their views before them.

Mr. THOMSON suggested the draft of the letter should be sent to the Chamber of Commerce, who should send it to the agents of the Sterling Companies here.

The CHAIRMAN.—I think I can say on behalf of the Chamber, that we should be quite willing to act in such a matter.

On the motion of Mr. Renton a vote of thanks was passed to the Chairman, and the proceedings terminated.

PRODUCE AND PLANTING.

LOW-PRICED TEA.—On the subject of low-priced tea, a correspondent of the *Grocer*, Mr. Hicks, of Leman-street, writes: "Some time since you were kind enough to insert some letters for me upon the position of the tea market and the inadvisability of pushing low-priced tea. I pointed out then that no provision was made for a rise in the market. The position to-day is one which is worth the attention of every grocer. The facts are that, with a low exchange some three years ago, and a considerable amount of over-production, tea reached a very low level, and a very uneconomic one. The rate of exchange has greatly increased, making it quite unprofitable to sell tea at the prices which ruled some time ago. At the same time, the consumption of tea abroad has largely increased. The stocks of China tea, which used to be a large factor in low prices, have been consumed, and as practically there is nothing to be seen on tea laid down under 6d in London there is no reason why for some time the market should be under that price. Up to the present time high prices have generally produced large supplies, but as parts of some tea plantations have actually been abandoned it does not seem as if there were any new inducements to put new ground to tea to any large extent, and until that is,

done, and the tea is ready for picking, there is not likely to be over-production. After all, the shilling canister is not one to reflect credit either to the retailer or to the wholesale man, and I think that every retailer would be studying his best interests if he threw the weight of his influence with his customers into educating them to higher things. We hear a lot of talk about cheap tea, but tea is not a particularly cheap thing. It costs a good deal to produce to place in chests and lay down ready for the grocer, and a heavy exchange adds largely to the cost; and, with so many steamers taken up for transports, freights will be exceptionally high. It is difficult to see what the advantage ever was to the retailer to have tea advertised at a price which was practically impossible to maintain. There never was any real profit in tuppenny tea, neither was there any likelihood of there ever being any; and, as most people worship the god of low prices, it would no doubt successfully divert their purchasing powers from better teas in the direction of no profit."

THE NEW REGULATIONS.—It is announced that the new regulations in regard to weighing tea by the Custom House, which it was hoped would have come into force at the beginning of October, are to commence on December 1. Under the old system producers were liable in an extreme case to a loss of 30 oz. in a chest in addition to the 1 lb. draft. Under the new regulations this possible loss in taring is reduced by 50 per cent.—*Home and Colonial Mail*.

INDIAN TEA ASSOCIATION (LONDON).

The following is an abstract of the proceedings of a meeting of the committee held on Nov. 21. Present: Messrs. D. Cruickshank (chair), R. Lyell, J. Riddell, F. A. Roberts, A. G. Stanton, J. N. Stuart, W. H. Verner, C. W. Wallace, and S. A. Went. The proceedings of the last meeting held on Tuesday, 7th inst., were read by the Secretary, and confirmed.

Copies of correspondence with Calcutta, which had been previously circulated to the members of the committee, were laid upon the table.

ASSAM LABOUR BILL.

After discussion it was decided that the following gentlemen be appointed a sub-committee to consider the provisions of this Bill.

REGULATION OF SALES.

The following has been issued to the members of the Association by the secretary, Mr. Ernest Tye:—

Referring to the general meeting of importers held on July 26th last to consider this subject, I have the pleasure to inform you that definite adhesions have been received from members and others, representing over 100,000,000 lb., of Indian tea. This represents the bulk of the Indian tea imported on garden account and also a good deal of Calcutta bough tea. The scheme adopted by the general meeting of July 26th has now been in operation since the beginning of August, and has worked most satisfactorily. I am instructed by the general committee to hand you herewith copy of the report received from the regulating committee, to which I am to ask your special attention. You will observe that in the opinion of the regulating committee the work has tended to steady the market, and my committee unhesitatingly endorse this opinion.

The following is the report of the Regulating Committee referred to in the foregoing:—

The Tea Brokers' Association of London, 118, Dunster House, Mincing Lane, E.C., Oct. 20.

The Regulating Committee beg to report as follows:—

1. That in accordance with the rules agreed to by the Indian and Ceylon Importers' Sub-Committee they were elected by the General Committee of the Tea Brokers' Association to carry out the said rules, and commenced their work on August 11,

2. That up to the present time the scheme, so far as it concerns Indian Tea, has worked satisfactorily, no opposition having been shown by importers of Indian Tea to the necessary postponement of the sale of their Teas, when so decided by the committee; and buyers have in many cases expressed satisfaction at a limit being placed to the quantity offered weekly.

3. That the committee regret that so few importers of Ceylon Tea availed themselves of the opportunity of submitting particulars of their Teas for regulation at a time when it would have been advantageous to have done so.

4. That with a view of obtaining a more satisfactory result, and one fairer to the present subscribers to the agreement, this committee would urge upon the Indian and Ceylon Associations the desirability of doing all in their power to induce those importers to join who have not already done so.

(Sd.) ARTHUR THOMPSON, Chairman of the Committee.
—*Home and Colonial Mail*, Nov. 14.

BRITISH AND BENNINGTON'S TEA TRADING ASSOCIATION (LIMITED).

At the fourth ordinary general meeting held yesterday at the company's offices, Southwark-street Mr. John H. Moore who presided, remarked that the net profits of the year were £11,756 against £10,797 for the 12 months ended September 30 1898 and this, notwithstanding the fact that considerable disadvantages had arisen owing to the high range of prices ruling in the tea market during the greater part of the year. The actual balance on profit-and-loss account available for distribution was £8,926 against £8,378 in 1898. The whole of the preliminary expenses attending the formation of the company, amounting to £1,259, had been written off, and consequently about £450 would be available in future years either for dividend or an addition to the reserve. The average net trading profits of the first three years of the company had exceeded the certified average profits of the combined businesses for the three years immediately preceding the formation of the concern, and this notwithstanding several adverse circumstances. Neither the company nor its predecessors had ever adopted the practice of weighing tea in the wrapper, and he denied that such a practice could be called "the custom of the trade." The board in May last paid dividends upon the preference and ordinary shares at the rate of 5 per cent. per annum; they now proposed to pay the usual dividend for the half-year upon the preference shares, and they recommended a dividend at the rate of 7½ per cent. per annum upon the ordinary shares. He concluded by moving the adoption of the report. Mr. George Bennington seconded the resolution which was carried.—*London Times*, Nov. 21.

DEPARTURE OF AMERICAN BOTANISTS.

The American Botanists, Messrs. D. G. Fairchild and Barbour Lathrop, of the Agricultural Departments of Washington and Chicago, respectively, whose arrival by the "Friedrich der Grosse," we chronicled on Thursday last, left yesterday for Singapore. Their hurried departure, before they were able to pursue their tropico-agricultural investigations here to any considerable degree, was owing to the necessity they were under of pushing on to Java as quickly as possible, and the inconvenience that would arise from taking a later steamer. Mr. Fairchild writes to us expressing his regret that he was deprived of the chance of spending a few days in Kandy and other parts of the island.

THE GERMAN SCIENTISTS.

Drs. Benedict Friedlaender and August Ewers, who arrived at Colombo about a month ago on a scientific expedition to the East, left the island for Tuticorin on Saturday last. During their stay in Ceylon they were busy collecting specimens and information regarding biology and the popular belief among the natives with regard to the influence of the moon on human beings. They also travelled upcountry, where among the other places visited were Mihintale and Anuradhapura. The summit of Pidurutalagala was also ascended and they seemed pleased with everything they saw. Dr. Friedlaender took a collection of Sinhalese and Sanskrit books along with him to help him in his researches. From Tuticorin they will make a tour through India and thence will proceed to the Samoan Islands, returning home after about six months.

COCOA IN AMERICA.

The imports of cocoa show a large gain over previous years. For nine months ending September 30, 1899, they were 28,926,474 pounds—a gain of over 10,000,000 pound over the same time in 1898, and 8,000,000 pounds over 1897. In only two previous years have the imports for the entire year exceeded the imports for nine months of 1899. The cocoa industry is growing fast.—*American Grocer*.

TIMBER IN VICTORIA.—Mr. Perrin, the Victorian Conservator of Forests reports that between the years 1888-89 and 1897-98, 615,603 valuable timber trees were planted by hand in permanent sites. In addition to these some 380,000 blue gums and sugar gums are thriving at Havelock, Majorca and You Yangs. These, however, were sown broadcast and thinned out afterwards. The number of applications for surplus stock at the Macedon nursery continues to increase year by year. Nearly 50,000 were distributed from Macedon during 1898. The three most popular trees for the northern plains are the sugar gum, pepper tree and locust tree, and to these may be added the tallow wood of New South Wales.—*Sydney Mail*, Nov. 25.

THE RUSSIAN TEA-TRADE WITH COLOMBO.—We have to remind all those concerned—and not a few firms will be interested in the occasion—of the meeting to be held at the Chamber of Commerce on Friday at 3 p.m., to discuss the possibility of increasing the quantity of tea put up for sale in Colombo. Planters are naturally unwilling to favour a move that might result in a lowering of prices; but it is pretty certain that the large Russian firms will not inundate local agents with further orders that will only tend to raise the prices in the Colombo market. It would, therefore, be advisable that a favourable consideration should be given to the requirements of Russian firms which are fully cognisant of the high quality of Ceylons, but which will probably continue to serve themselves with Chinas and Javas unless they can obtain increased supplies here at present prices. For this it is imperative that there shall be larger deliveries for the Colombo sales.

DIGALLA CEYLON TEA ESTATE CO., LD

The following is the report of the Directors to be submitted to the Third Annual Ordinary General Meeting of Shareholders, held at 20, Eastcheap E. C., on 5th Dec. :-

The Directors have the pleasure to submit the General Balance Sheet and Profit and Loss Account for the year ending 30th June 1899, duly audited.

The net amount at Credit of Profit	£	s.	d.
and Loss Account, after providing for General Expenses, Directors' Fees, Income Tax, &c., is	..	575	13 1
Dividends on six per cent. Preference Shares were paid for 1898-99 (less Income Tax) amounting to	..	348	0 0
Leaving to carry forward to next year a balance of	..	227	13 1
		575	13 1

The past seasons in Ceylon has not been one favourable to the production of Tea. There was a long drought in the early part of the year and too much rain at other times, and consequently the Company's crop was some 50,000 lb short of the estimate; owing to this, and to the fact that a considerable proportion of the up-keep on the 143 acres not in bearing has been charged to revenue, the Directors regret they are not in a position to pay a dividend on the Ordinary Shares.

The acreage of the Company's property is as follows :-

Tea in Bearing..	456	acres
Tea not in Bearing	143	"
Jungle..	152	"
Total	751	acres

The gross average price realized was 6.84d per lb, as against 6.17d per lb. last season, and the rate of exchange is 4½, against 1s 3 27-32d.

The total crop amounted to 192,697 lb. plucked off 456 acres, of which 134 acres are in partial bearing, giving an average of 423 lb per acre.

Under clause No. 24 of the Articles of Association Mr. H K Rutherford retires on this occasion from the Board, and being eligible, offers himself for re-election.

The Auditor, Messrs. Harper Brothers, Chartered Accountants also retire from office and offer themselves for re-election.

TEA-BULKING IN CHINA.

A gentleman for some years in the China tea trade, has favoured us with the following description of a method for bulking tea, which he says is most simple and inexpensive. Four square wooden posts grooved on two of the adjoining sides, and several planks of (say) 18 inches in breadth are all that is required. These should be made into a large box, the posts forming the corners and the planks the sides. The box should be built, raised some four feet from the ground, the bottom being made of wood having a sliding trap-door in the centre, so made that the outlet can be enlarged or reduced according to the size of the leaf to be bulked. When the box is being filled with tea the trap-door remains closed. The tea to be bulked should be spread out in layers as thin as possible inside the box, one quality on top of another, until all the tea required to be bulked is inside the box. Now open the trap-door, and the tea will run out from the top, taking a little from each layer in its downward course, the result being a perfect bulk. The bottom of the box should be made slightly on a slope from the sides to the centre near the aperture, so that the tea may get away equally. By means of a zinc tube the current of the leaf can be carried direct from the

box into a package or chest, standing on a lever scale. A sand-glass will illustrate the above on a small scale. Tea is bulked in China on the same principle as the above, but there, one side of the box is drawn away, and the packages filled from the tea that collects at the foot of the pile.—*Planter*, Dec. 9.

THE NILGIRI GAME ASSOCIATION.

OOTACAMUND, 11th Dec.—At the annual Meeting of the Association held on Saturday last in the Collector's Office, the following gentlemen were present:—Mr. C J Weir (President), Mr. C G Douglas (Honorary Secretary), the Hon'ble Mr. H P Hodgson, Mr. W L Edmiston, Mr. G Hadfield, Mr. F Hadfield, Mr. J E David, Mr. T J Kenna, Mr. J H Pascoe and Major T N Bagnall.

The Honorary Secretary presented the Report for the year ending 30th June, from which the following are interesting extracts:—

INCREASE OF GAME AND RESULTS OF PROTECTION.—On the whole we may consider ourselves tolerably successful in maintaining a fair head of game in most parts of the District, though the results of protection may not have made themselves everywhere apparent by increased numbers.

PROSECUTIONS.—The year's return of offences detected and punished under the Forest Act is the best on record since the Association began. This satisfactory result may be attributed to (1) a more liberal use of rewards; (2) better paid watchmen; (3) the great personal interest taken in preservation by some of our leading members. This last is simply invaluable.

THE NILGIRI GAME BAY.—In a former Report you were informed that two valuable registers were opened in the District Forest Office. One a game register and the other a register of shikaris well known to, and recommended by local sportsmen of experience. It is greatly to be regretted that neither has proved a success.

TROUT.—Your Committee is as sanguine as ever regarding the ultimate success of this enterprise. In Major Grant, who has left the District, and whose services in trout culture have been annually recorded with due appreciation, the Association has lost an enthusiastic fisherman. The following are his notes for the season. He has only been a few months in office. I regret to say that the whole of the *Salmo Irrodens* ova received this year was worthless. It had evidently been so for a long time, as in some cases it had altogether rotted away and only the smell remained. It was clearly the fault of the people on board ship and I attribute no blame to them who conveyed it from Madras to Ootacamund.—*Madras Mail*, Dec. 13.

TEA DRINKING IN AMERICA.—In a letter (dated Oct. 21st) kindly forwarded to us by an American visitor, from Mr. Oscar Joseph (a nephew of Mr. F. C. Loos) who proceeded to America with a view to training for the Ministry, we have the following criticism from the writer, who is now at New Brunswick, New Jersey, on the quantity of tea now being drunk in the Eastern States:—“I have not yet tasted a good cup of tea in America. In the restaurants of New York, and even in private houses, where everything else is of the best, the tea is worse than what you get in any of the boutiques on the way to Anuradhapura. I have seen advertisements of Nettley's Ceylon and Indian tea. They evidently mix the teas here, and, of course, the real flavour of our superior tea is altogether lost. The Planters' Association should wake up if they desire to save the reputation of Ceylon tea in America.”

DR. WATT IN THIS INDIA PLANTING DISTRICTS.

(By a Planter.)

In due time Dr. Watt will no doubt issue a valuable and instructive Report as the result of his observation during his

RECENT TOUR THROUGH COORG AND WYNAAD,

but as it will probably be some time before this Report appears, an account of his visit to Wynaad may be of some interest to planters. Dr. Watt took specimens of the canker on *Lagerflora cinchona*, of the disease which kills the pepper vine, of a new blight on tea, and of the fungus on Liberian coffee. It is to be hoped he will not only name these pests, but, as he has done in the case of tea blights, recommend efficient methods of combating them. He also observed a mite preying on *Hemeleia vastatrix*, and thought this might lead to the discovery of some method of fighting this pest. Liberian coffee was found to be suffering from another fungus than *Hemeleia* and it is not improbable that as many planters have thought, it is this fungus that makes Liberian sickly and liable to *Hemeleia*, which it seems to resist when in a healthy condition. Similarly, the failure of *Lagerflora* of late years may be due, not to deterioration of seed, but to a fungus which has mastered the plant. The new blight on tea is the two hundred and first to which that plant is subject; but blights are more prevalent in Assam, where plantations give 1,200 to 1,600 lb. of made tea an acre than on the Nilgiris, where tea averages only about 250 lb. an acre, and Dr. Watt thought well of the Wynaad as a tea District.

The management of tea has been so thoroughly worked out in Assam, and the results so amply recorded, that planters will be more interested in what Dr. Watt had to say on coffee. This related chiefly to the method of pruning, to the importance of growing plants which supply nitrogen to the soil, and to the advisability of establishing a hardier type of plant than the present coffee tree. Experience has taught planters that of late years the wood most certain to resist leaf disease, and to crop well, is that found on gormandisers and suckers, and that it is not possible to get the tree to crop as well at the bottom as at the top. Some fine all-estates, therefore, have their trees in the form of umbrellas, and others in the form of a cup formed of a ring of great gormandisers rising from short primaries on a short stem. Dr. Watt condemned both the umbrella and gormandiser systems, on the ground that an enormous mass of old unproductive wood, often as thick as a man's arm, and full of knots, bends and dead stags, had to be maintained in order to support a smaller extent of bearing wood. He thought quite as much bearing wood could be maintained on short primaries if the tree was trained in a pyramidal shape, such as it naturally assumes when young. In order to retain this form Dr. Watt would, as soon as the young tree has reached its proper height, cut the top pair of primaries at the joint from the stem, the next pair at two joints, the next at three, and so on till a foot from the ground is reached when he would remove all the primaries to admit a free circulation of air. From the shortened primaries young shoots should be encouraged to form a fan consisting of bearing wood and green wood for the following year the former being removed as soon as it has borne. When too much of a blow is formed, the primary is to be cut back just behind it, and when the

primaries are gone, the tree is to be collar pruned that is, cut off 2 inches below the soil. The object of cutting below the soil is to prevent the formation of any dead wood as this causes decay to eat down into the stem. Dr. Watt believes that if the trees were thus kept free of all dead stumps to cause decay and tends to check the flow of sap, and relieved of the masses of old wood they now carry, they would be much less liable to blight. He thinks the high price realised for "Faith" coffee this year is due to the system of pruning adopted on that estate. No doubt planters will experiment on a small scale on the lines Dr. Watt recommends; but many think the coffee tree will not stand such drastic treatment in these days of leaf disease, and condemn severe pruning and the stamping of old trees which often give only sickly suckers. The cutting under ground is, however, a new method, and may give better results than stamping at 6 or 9 inches above ground.

Dr. Watt was struck with the absence of nitrogen-forming plants amongst the weeds found in

COFFEE

and recommended the growth of dhal in open spaces, or among young coffee, and of *Albizia stipulated* in thick coffee. He condemned the *Erithrynas* as nitrogen-forming shade trees on account of their liability to bug. Soil destitute of nitrogen-forming plants soon becomes sterile from the absence of nitrogen-forming bacteria. Dr. Watt took specimens of the various hybrids he saw, and was much interested in the experiment. He had some useful hints to give as to the necessity of protecting an approved hybrid from fertilisation by inferior forms, which would cause degeneration in the resulting plants. It is equally necessary, however, to avoid degeneration from self-fertilisation only and good hybrids should be cross fertilised either by other good hybrids or by vigorous *Arabica* trees. Dr. Watt doubted if a cross with Liberian, now that this is so diseased would be likely to afford continued immunity from disease, and suggested breeding from the best *Arabica* trees in order to try to establish a pure blight-proof *Arabica* tree. The extraordinary vigour of the best Liberian-*Arabica* hybrids may however, preserve them from blight as all experience so far shows that such vigour is the only successful prevention of disastrous attacks of *Hemeleia vastatrix*.

Dr. Watt's visit is another proof of the

ABSOLUTE NECESSITY, NOWADAYS OF EXTENSIVE SCIENTIFIC AIDS

to agriculture being afforded by every Government which hopes to see its industries flourish. Such aid on any scale is alien to the official mind, which is mainly fixed on administrative measures. The perfection to which the *Lagerflora* tree has been brought in Java is, however, entirely due to the labours of scientist in Government employment over some twenty years, and such expensive and continuous research is beyond the means of any individual or firm. The United States maintains a whole Department exclusively devoted to the discovery and prevention of blight, and to the introduction of the best manures, the best methods of cultivation, and the best varieties of plants to grow. It requires the exclusive attention over a considerable period of a man of Dr. Watt's energy, scientific attainments, and practical ability, to establish new and valuable varieties of crop bearers, and a successful system of combating pests.

SUCH A MAN IS BADLY WANTED

now by the coffee industry of South India. Hard as Dr. Watt worked on his recent tour, it is impossible he could effect much in such a hurried visit. A beginning in the provision of scientific aid to agriculture by Government has been made in South India by the appointment of Dr. Lehmann to advise the Mysore Government, and of Dr. Barber to advise the Madras Government; but such appointments must be multiplied considerably before the many agricultural industries of South India can receive the attention which they require, and which would be readily afforded them in the United States.—*Madras Mail*, Dec. 14.

TEA TARING.

THE REFORM SUSPENDED.

The following letter has been addressed to the Secretaries of the Ceylon and Indian Associations in London by the Commissioners of Customs:—

Custom House, London, Nov. 30.

GENTLEMEN,—The Commissioners of Customs direct me to acquaint you, for the information of the Ceylon and Indian Tea Associations, that, to their great regret, they have felt it necessary to postpone, for a time, the coming into operation of the London Port Order 39-1899, respecting the taring of Tea to the $\frac{1}{2}$ lb. and an increase in the number of tarers, referred to in Mr. Prowse's letter of the 14th instant, No. 13728-1899. The date of operation mentioned in the Order is 1st December 1899, and the Commissioners hope that the period of suspension may not be long. Due notice will be given of the new date as soon as it has been fixed.

The Board desire me to briefly explain the circumstances that have rendered a postponement necessary. Throughout the correspondence that has taken place on this subject the Board have maintained the position that no action can be safely and properly taken on their part, unless it commands the general assent of the Tea Trade, both Importers and Buyers. They felt that, subject to the rights of the Revenue they could not lead the Trade but must follow it, if any change is to be made successfully in the methods of taring. Accordingly when the Indian and Ceylon and Tea Buyers' Association submitted the following proposals, on behalf of Importers and Buyers, coupled with the continuance of the 1 lb. draft, and of the present system of gross weighing, the Board felt no hesitation in agreeing to all of them that met with general acceptance, and fell within the province of this Department.

TEA TARING.

(a) If tare be to an even lb.—it will be entered as such.

(b) If it be to an even $\frac{1}{2}$ lb. or over, it will be entered at next lb. above.

(c) If it be to a smaller fraction than $\frac{1}{2}$ lb. it will be entered at next lb. below.

(d) No overtakers.

(e) Boxes (*i.e.* packages not exceeding 23 lb.) to be weighed and tared as heretofore.

(f) Increased No. of Tarers according to scale.

(g) If Teas are bulked, each package to be tared separately.

Terms (a), (b), (c) and (f) were objected to by none, and were therefore provided for in Port Order 39-1899. Term (h) was acknowledged to relate to a matter with which the Customs could not interfere. Term (e) required no action: and (g) alone presented any difficulty because it in-

involved the repeal of General Order 102-1894, and a number of leading importers petitioned the Board to leave that General Order in force.

After mature consideration, the Board came to the conclusion that the Port Order dealing with terms (a), (b), (c) and (f) ought to be issued at once, as dealing with matters no longer in controversy, and that, as (g) was disputed, it would be fairer to both sides to preserve the existing option of either averaging or separately taring bulked teas.

No sooner, however, had this decision become known than the Board received a strong protest from the Tea Buyers' Association against the separation of terms (a), (b), (c) and (f) from (g), because the separate taring of bulked teas was an essential part of the compensation which the importers were to make for the concession of a $\frac{1}{2}$ lb. taring on the part of the buyers. The latter also represented that the option of separate taring or not when tea is bulked, is no safeguard of liberty, because the buyers have practically no voice in its exercise, and the importers will always exercise it in their own favour. They moreover dwelt on the ease and therefore cheapness with which each case, which must be emptied in the process of bulking, might be separately weighed, as was the rule until 1894.

In the opinion of the Board it would have been inequitable to allow port order 39—1899 to come into operation in the face of this opposition. They have therefore postponed it in the hope that after further conference, the importers and buyers may either agree to adopt term (g) or make some other arrangements in common which will render that condition unnecessary.

The board have no bias towards one side rather than the other, but must always be the hearty well wishers of both. Their desire is for as accurate weighing and taring, and as just averaging, as circumstances render practicable, and their officers will spare no pains in contributing to the attainment of these ends. In the whole system of averaging tares, and of rounding weights up or down, which is no doubt ordinarily a matter of practical necessity, the Board would always wish to have the mutual consent of all parties concerned. The law in its full strictness recognises exact weights only.

I am to add that the Board earnestly trust that you will shortly be able to submit to them an agreement which will be fair to Buyers and Importers equally and will put an end to a dispute which is seriously jeopardizing the prosperity of one of the most important trades of the Empire.—I am, gentlemen, your obedient servant.

JOHN COURROUX.

W Martin Leake, Esq., Secretary to the Ceylon Association,

and Ernest Tye, Esq., Secretary to the Indian Tea Association, 61, Gracechurch Street, E C.

REFORMS ON THE TEA TRADE.

The following is the conclusion of the article from the *Produce Markets Review*, the first part of which appeared in our last issue:—

BULKING AND TARING IN INDIA.

We alluded above to the great cost inflicted upon the Indian planter through the necessity for bulking and for separately taring their teas in this country. Some progress has been made with regard to bulking abroad, but it is inconceivable here why the system has not become

universal. Years ago, we heard the old excuse about the dampness of the climate and the difficulty of keeping teas; but if the facts are as alleged, the difficulty can easily be remedied by such simple appliances as hot-water pipes. Then again, as regards the taring of the teas, the smaller gardens no doubt have to rely on rough native labour, and this is given as an excuse for the chests not being cut to scale. The excuse seems to us totally insufficient, and we can only ascribe the continuance of the existing system to ignorance. In these days when metal chests can so easily be obtained, as well as the beautifully made "Venesta" and other artificial wood chests, uneven tares seem simply inexcusable. It pays our sugar refiners to import ready-cut wood for such a cheap commodity as theirs and when a single manufacturer requires 40,000 or 50,000 cases a week of the size of a tea chest, it surely would be worth the while of Indian planters to import either the "Venesta" packages or wood cut in proper shooks from other countries, in places where the native labour and the appliances are so deficient as they appear to be in a vast number of cases. The planters also go far to necessitate re-bulking in this country by the excessive subdivision of their teas into different-sized leaves. This can only be effected by a costly system of sifting, in addition to the exposure of the tea to friction, which breaks a large portion of the leaves, and turns them into comparatively waste dust or broken leaf. We have long held that the planters would do far better to buy a reasonable-sized grocers' bulking and cutting machine, and then make much larger breaks of an average quality. The cost would be less, and, we believe in the long run, the relative price would be higher.

INCREASING PRODUCTION, LOWER PRICES, AND
THE ARTIFICIAL RUPEE.

The production in India, Ceylon, and Java, is consequently increasing, for the fresh plantings are year by year coming into bearing. Even if another tea plant were not planted for the next five years, the increase would still continue from previous sowings. The consumption of tea in this country has reached its limit, and the next great consuming country—the United States—uses only something like one-sixth of what we use, and is at present greatly wedded to the flavoury China teas. The same is the case in Russia, and although we hope, and believe, that Indian and Ceylon teas will readily make their way in both these countries, the demand cannot be important for years; its progress is not quick, and the increasing supplies must therefore continue to devalue this market. The action of the Indian Government in artificially fixing the exchange value of the rupee at the rate of 1s 4d when the intrinsic value of the coin is something about 11d, is also most injurious to the Indian tea planters. In these depressing times it must to a large extent tend to ruin our own growers; or to divert the trade to the common tea of China, because China, owing to the unrestricted exchange for the dollar, enjoys an advantage of 2d in every pound of tea. While the possibilities of economies in the trade are great, we fear that the possibilities of decreasing prices are even greater, so that the question should be actively taken in hand. It is, therefore, obviously to the interest of the whole trade to take up tea reform in earnest. It is possible that the result of the coming depression will be the extension of something like the Central Factory system. If so, the small gardens would cease to manufacture tea, and would sell the green leaf to the larger operators,

who can work better and more economically than the small growers. This is the system which long usage has established in China, and it is already beginning in India. These latter changes, however, are matters for the future, and the present necessity is for a simplification and modernisation of the tea trade, such as will greatly reduce the present unnecessarily high cost of distribution.

CONCLUSION.

In the above remarks we have given a short outline of the main changes required whether at home or abroad, for it matters little which section of the trade is benefited so long as expenses can be lessened. The necessity for reform must come home very forcibly to the producer, in consequence of the present great depression in values. It is true that for temporary reasons, very common teas have recently very considerably advanced, but we do not think that this can possibly last for long with the supplies coming forward. If it do so, and the price of common Indian tea is maintained, we shall shortly be swamped with common China Congou, which will bring prices once more down to a lower level. If there is no hope for a rise in the price of tea, but rather a strong prospect of a further fall in it, the only way to save the planters from ruin is economy in production and distribution. The mixture of the two branches of the trade in the above remarks is apparent and not real, for we hold that the whole tea trade is organised far too expensively, for the present scale of prices, and that economies in cost in any direction will benefit all sections alike.—*Home & Colonial Mail*, Dec. 1.

PRODUCE AND PLANTING.

RUSSIAN TEA.—The attempt at tea cultivation in the Trans-Caucasus has demonstrated that the tea-plant can be successfully grown in the country under existing climatic conditions, and further, that it is only necessary to surmount certain difficulties at present experienced in respect to the question of obtaining cheap labour in order to make tea-growing an industry of the district. A large Moscow firm erected a factory on its plantations last year, and the authorities on the estate belonging to the Imperial domains at Chakva have followed this example, and have set up a tea-making establishment of considerable dimensions. The yield of the tea crop has been good, and, comparatively speaking, fairly abundant. But the Russians like good tea, and this Trans-Caucasian tea is far below the standard of Indian, Ceylon, or China. Seeing, however, that tea can now be successfully grown in this region, writes our Consul at Batoum, in a report on Transcaucasian agriculture, "the Imperial domain authorities propose to encourage the cultivation of this plant among the peasantry, and with this object in view would gladly split up the area on their estates now planted with tea into small plots for distribution, on certain conditions, to the surrounding inhabitants to cultivate under their supervision. It is considered that a measure of this kind would induce a considerable proportion of the peasantry to cultivate tea, and as soon as it is known that fairly remunerative wages can be obtained for the collection of the leaf, a large number of women and children would willingly come forward and assist in gathering tea harvest, and by this means an important reduction in the price of labour would be likely to follow." So for the present, and for some time to come, Russia will want the usual supply from elsewhere, for our Consul takes care to point out that in the present difficult position of the labour market, owing to the absence of a good supply of labourers, it is evident that the expenses incumbent on the cultivation of tea in the Caucasus are so excessive that

if the production were to attain such figures as would enable even a small proportion of the demand to be satisfied, it could, nevertheless, not be sold at prices much below those which teas imported from abroad, and paying a heavy rate of duty, fetch in the markets of the Russian Empire.

REGULATIONS OF SUPPLIES IN SALE.

To the Editor of the *Home and Colonial Mail*.

SIR,—I have read in your last issue the report of the Indian Tea Association, in which, under the heading, "Regulation of Sales," it is stated, "that that scheme has been in operation since the beginning of August, and has worked most satisfactorily." The Regulating Committee, through their worthy chairman, Mr. Arthur Thompson, then go on to say that "no opposition had been shown by the importers of Indian tea to the necessary postponement of the sale of their teas, when so decided by the committee, and buyers had in many cases expressed satisfaction at a limit being placed to the quantity offered weekly." May I therefore ask a little space to offer a few remarks? I start with the fact that the total offerings of Indian tea in public sale in the year 1898 were 1,590,000 packages, which in round figures would average 133,000 packages a month. The contention in regard to regulating supplies has been that for month after month during every autumn the quantity put on the market bore no relation to monthly demand, but was entirely conducted on a "Devil take the hindmost" policy, thereby depressing prices by overloading buyers at one season of the year, and inducing a scarcity at another. The Regulating Committee was appointed to put this right, and it may therefore be worth while to examine the results of their labours since they started operations. The number of packages of Indian tea offered in public sale were as under:—

	unregulated.	regulated.
	1898.	1899.
August ..	124,474	135,556
September ..	170,762	177,071
October ..	238,655	232,950
November ..	193,871	206,122
	732,762	751,699

These totals explain the reason why the scheme has "worked so satisfactorily," and one ceases to wonder that "no opposition was shown to the necessary postponement (?) of the sale of their teas by importers." One would also like to be introduced to the "buyers who in many cases had expressed their satisfaction that a limit was placed on the weekly offerings." Possibly had there been no regulating of supplies this season the consequences might have been disastrous. Who can say? But no one will contend that the committee has introduced any very radical change; and now that the attention of the Ceylon tea importers is drawn to the results as stated above they will surely hesitate no longer "to avail themselves of the opportunity" of being regulated. Walk up, gentlemen, there is positively no danger.

I am, &c., D. F. SHILLINGTON.

THE CALEDONIAN (CEYLON) ESTATES, LIMITED.

The second annual ordinary general meeting of the Caledonian (Ceylon) Tea Estates, Limited, was held at the offices of the company, 78, Gracechurch Street, on 30th Nov., Sir Alfred

Dent, K.C.M.G., chairman of the company, presiding.

The SECRETARY having read the notice convening the meeting,

The CHAIRMAN, in moving the adoption of the report and accounts, said:—Although there is a very small number of shareholders present, other shareholders who are unable to attend the meeting will be interested to know what took place, so I will proceed to make a few remarks. In the first place I must express the regret we all feel at the absence of Mr. Alexander Ross, which owing to a rather serious illness. He always gives us most valuable advice, and I am sure we all miss him very much. The report will no doubt have been studied by all of you, and though we cannot call it a satisfactory one, still I think the shareholders will all admit that we have done as well as most of our neighbours, considering that we are only comparatively a young company. Our chief trouble this season has been the exceptional weather, which has reduced our crop to 489,687 lb. of tea, showing a deficiency of 67,800 lb. as compared with the estimate. This, as stated in the report, is almost entirely owing to the weather, but as Mr. Stanley Ross, the manager in Ceylon, is here, he will explain to you the difficulties he has had to encounter better than I can. His report, received a short time ago, said that the rainfall for the first six months of the season was favourable to the flush of tea, but that the first three months of this year a severe drought came on, which caused the rainfall to drop to 11 in. This was followed by an unusually heavy burst of the southern monsoon, and a rainfall of 40 inches was recorded during the last three months of the season, which seriously interfered with the pruning and flushing. These alternate periods of rain and drought make tea cultivation extremely difficult. The gross prices of the tea are given in the report, and I think you will consider them fairly satisfactory. Perhaps the average cost per pound on the different estates will be of interest to you. On the Lawrence estate it was 7.13d per lb., against 7.14d for the previous season; on the Venture estate 7.17d per lb, against 7.24d; and on the Selagama estate 5.73d per lb, against 5.24d. The exchange for the year was almost the same as for the previous year, being 1s 4 7.32d, against 1s 4 3.16d, or only a difference of 1.32d. Our average price was of course affected to a certain extent by the unfortunate dispute in the tea trade. Like other companies we had an accumulation of invoices, and some of these had to be forced on the market, with the result that we lost halfpence to 1d per lb on them. One item that seems to call for attention in the accounts is that of capital expenditure. This amounts to £4,067 since the company was started, as foreshadowed in the prospectus, and the amount has been carefully laid out in cultivating and extending the estates. Only a very small portion of it has been spent on machinery. I think I am right in saying that the expenditure on capital account will be very largely reduced, if not almost nil, next year, nor do we think that anything but a very moderate expenditure will be required for extra machinery. This capital expenditure has been met to a certain extent out of moneys received from the sale of produce, the reserved shares having been kept in hand. The market being against issuing shares for the moment, the

company thought it better to borrow money from their agents than to force shares on an unwilling market. The agents are content to advance money in this way, provided that the company can give them the necessary security, and with that idea in view it will probably be necessary to create a second charge on the company's estates, which is to cover the capital outlay pending the issue of the reserved shares, and which will be cancelled as soon as that issue is made. As regards the cultivation of the estates, Mr. Stanley Ross will tell you what a high state of cultivation they are kept in, especially Lawrence and Venture, which are two of the leading estates in Ceylon.

As regards the acreage of the estates, you will see by the report that 500 acres of tea and 140 acres of cocoa are just coming into bearing, which will enable us to present a very much better report to you next year. The Wavina estate is also planted with 21,000 rubber trees, and coconuts to a considerable extent, though it will be some time before we shall derive much profit from that source. Turning to tea generally, every one present is no doubt very familiar with the Ceylon tea statistics, but I think it as well to call attention to the satisfactory figures for the last ten months ending October 31. The imports were 44,924,000 lb., against 42,094,000 lb. for 1898, 42,330,000 lb. for 1897, and 39,088,000 lb. for 1896, and the deliveries 43,638,000 lb., against 40,865,000 lb. for 1898, 42,635,000 lb. for 1897, and 39,562,000 lb. for 1896. The average price of last week's sales was rather under 8d gross, against 8½d for the previous week, and 8½d for the corresponding week in 1898. I have nothing more to say, but, with the assistance of Mr. Stanley Ross, I shall be very pleased to answer any questions any shareholder may wish to put, before putting the adoption of the report and accounts to the meeting. I now beg to move. "That the report of the directors and statement of accounts for the year ended June 30, 1899, now presented, be and are hereby approved and adopted."

The motion was seconded by Mr. Gow.

In reply to questions from one of the shareholders, Mr. STANLEY ROSS stated that there was no cinchona grown on the estates at all, it having been cut out before the company was formed. As regarded the coffee, that also had been abandoned on the only estate where it had ever been planted, viz, Venture. This resolution was then put to the meeting and carried unanimously.

The CHAIRMAN then proposed, "That a final dividend of 3 per cent (making 6 per cent for the year ended June 30th, 1899) on the paid-up Preference share capital of the company be and is hereby declared payable on and after this date."

This was seconded by Mr. W. Gow, and carried unanimously.

The next resolution was, "That a dividend of 2 per cent on the paid-up ordinary share capital of the company for the year ended June 30th be and is hereby declared payable on and after this date."

This was proposed by the CHAIRMAN, seconded by Mr. Gow, and carried unanimously.

On the proposal of Mr. W. Gow, seconded by Mr. STANLEY ROSS, the retiring director, Sir Alfred Dent, K.C.M.G., was unanimously re-elected.

Mr. LOWE proposed, and Mr. HANSEN, seconded the re-election of the auditors, Messrs. Singleton, Fabin & Co.

The motion was carried unanimously.

Mr. LOWE proposed a vote of thanks to the Chairman, who in responding, said that he felt sure that they all join with him in giving a hearty vote of thanks to the manager, Mr. Stanley Ross and the staff in Ceylon.

Mr. STANLEY ROSS briefly returned thanks, and said that with 500 acres of tea and over 140 acres of cocoa coming into bearing, he had no doubt that they would be able to pay a much larger dividend next year.

This terminated the proceedings.—*H. and C. Mail*, Dec. 1.

A TRIP ON THE HAWKESBURY.

SYDNEY, Nov. 25.

One of the most enjoyable day excursions one can make from Sydney is a trip on the Hawkesbury River, a stream noted for its beauty, which Anthony Trollope declared

EXCELS THAT OF THE RHINE AND MISSISSIPPI, and one day last week I went this trip. My view in visiting Richmond was with the object of inspecting the

HAWKESBURY AGRICULTURAL COLLEGE,

an institution founded by the Government for the training of those who are to till the soil. As this institution is one of the best, south of the line, if not in the world, a few words respecting it may be of interest. There, over a hundred students, some from other parts of the world, including a Jap, while one of the smartest in the College at present is a Frenchman from Noumea. Boarders are charged 10s a week, the inclusive charge for board and instruction being £25 a year, part of the agreement being that they help in the work of the farm three days a week. Those who live in the district pay £2 a year, with £5 for daily lunch. Each student is provided with a bed-room and takes his meals in the large dining hall. There is a fine gymnasium; and cricket, football and other games are indulged in; electric light is laid on and there are a laboratory and a lecture hall. The institution is under the charge of Mr. Valder, the principal, assisted by several masters; while each section on the large experimental farm is under the control of a practical man, not necessarily with scientific knowledge, who is assisted by the students who are first of all taught in the classroom and then are sent out into the field to gain practical knowledge. When I arrived at the College I found that Mr. Campbell, an agricultural inspector, was coming from Sydney with 40 or 50 boys, the agricultural class at the model school, the best public school in Sydney, and so I waited to go round with them. Soon after their arrival all sat down to a substantial lunch, all of which, with the exception of tea (which, in Australia, is brought on at every meal), was produced on the farm. Afterwards the principal took us round, first of all showing us the horses, and the various machinery, and the most up-to-date methods being taught the students. We saw the sheep, which were being herded, the poultry, bees, and then from there to the dairy, where each visitor was regaled with a glass of delicious milk. Here butter and cheese are made. The cows were a very nice lot of animals, while the pigs looked in good condition. It should be mentioned that the animals, &c., reared in the farm, are many of them sent to the market and are sold as fast as they can be secure

while there is an equally ready sale for the dairy produce. In the cheese department each student is allowed a day for making a cheese, which is examined by an inspector and marked whether good or bad. The last place visited was the

FRUIT ORCHARD

where a large variety of fruit is grown, a good portion of the ground being under grapes. The fruit is preserved for the use of the College in winter. These are the principal things, which are taught in this institution, the benefit of which has already been felt in the Colony. Even in Australia the tendency is to over-populate the cities, and the Government are acting wisely in giving the younger generation the best instruction, so that they may go out to large tracts of country, which yet await cultivation, and be able by scientific methods to obtain better and quicker results than their forefathers, the pioneers in this country, did. On this farm, science is made to go hand in hand with nature, and the results obtained have not been reaped on a rich soil, but on land which no farmer would himself tackle. Visitors to the institution are always welcomed, and any one who intends starting in any branch of agriculture can obtain advice on the subject, and be told the best way of laying out the capital he has to spend.

I drove back to Richmond a quiet country town, shaded amid the trees, and caught the afternoon train to Sydney. Away in the distance one could see the Blue Mountains, but we traveled over gently undulating ground, through park like country til Paramatta, the oldest town in Australian with the old Government house, was reached. From here the suburbs begin and one was transposed in the short space of little over an hour from peaceful country scenes to the rush and bustle of city life.

LIBERIAN COFFEE ESTATES SALES.

On Dec. 13, at Messrs. Powell & Co's auction rooms in Singapore, there was held an auction of six important Liberian Coffee Estates in the Malay States, belonging to the Malay Peninsula Coffee Co., Ltd. and advertised in the *Ceylon Observer*. It is probably the most important offer of coffee estates that has ever been made in the Straits, as the estates are all well-known, and they are all more or less in bearing. There was a considerable attendance of people interested in coffee and property, and after explanation of the conditions of sales bidding was started for

Lot 1 at \$1,000. It was sold for \$3,600 to Mr. Tunnicliffe, Batu Kamuning Estate, Sungei Ujong, has 117 acres of coffee just coming into bearing, and has 1,435 acres of forest in reserve. Bidding commenced at \$2,000 and went slowly to \$5,000 and was knocked down to Mr. Jas. Millar.

Klang Lands Estate, Selangor, is of 1,341 acres of which 183 is Liberian coffee, about a third of it over four years old. There are also para rubber trees and a large nursery. The bidding for this Estate commenced at \$5,000 and rose to \$11,200 to Mr. W. Smith.

Welds Hill was started at \$10,000 and went to \$16,500 to Mr. Edlin.

Weld's Hill Estate, just outside Kuala Lumpur, is the well known old estate, with coffee varying from 17 years, and para rubber, some two years, and some ten years old.

Eveleen Estate, also near Kuala Lumpur, is 99 acres in area. The coffee is from 4 to 5 years old, and there are a number of fruit trees.

Linsum and Silian, in Sungei Ujong, are also well-known having been under cultivation twenty years. The area is 1,697 acres; coffee in bearing

covers 419 acres, and there are also pepper, sago, coconuts and 100 para rubber trees in full bearing. Bidding for Linsum and Silian Estate commenced at \$15,000 and closed at \$25,500 to Mr. R J Gann.

Kamuning Estate is in Peak and contains 5,973 acres, part of it being subleased for mining purposes. There are manager's quarters, live stock, &c. This estate was sold to Mr. T Scott for \$40,000.

BULKING TEAS IN INDIA.—It appears that in India it would be on the whole advisable if more teas were bulked on the spot instead of in London. In Ceylon factory-bulking has also been urged, but has been met with the response that very often bulking has had to be done over again when the packages arrived in London. The remedy would seem easy enough, but, perhaps, it will be well to peruse some Indian advice on the subject. The *Planters' Gazette* writes as follows:—"Not only are better prices realised as a rule of teas that have been bulked in India, but loss of weight is very considerably avoided. Planters are aware that tea properly packed will gain, instead of lose, in value, if kept in its original package untouched, while it soon loses in flavour if it is disturbed by being turned out and re-packed. The reason why small concerns, belonging, it may be, to private proprietors who sell in Calcutta, do not bulk, is because, if they waited for sufficient tea for a large break, the quality would be likely to suffer to a degree that would nullify any benefit to be derived from bulking. The interest of the proprietor of a small garden is concerned more in offering a tea with all its aroma and fragrance at perfection in Calcutta, than in considering how his tea will keep in England, after bulking in the London warehouses. The necessity for the gardens in India bulking their teas in their own factories, is becoming more, and more imperative, owing to the very large quantities that have to be sampled and tasted. The work of tasting for the sales alone has grown so much that the powers of the buyers have been heavily strained to keep pace with it. Human nature cannot do impossibilities, so unless the teas are bulked, and the size of the breaks materially increased, there will very soon come a time when the buyers will be quite unable to look at the whole of the samples, much less to taste them."

PARIS, THE CINEMATOGRAPH AND CEYLON TEA.

—In our issue of the 21st October last we put forward the suggestion that the cinematograph might well, with advantage, be employed for advertising Indian tea. That lectures illustrated with "living panoramic pictures" of every operation connected with tea, from the very first start—the clearing of the heavy forest jungle or grassland—to the time it is sold over the counter; or, in fact, drunk at the breakfast or "afternoon tea" table, would take immensely with middle classes and the proletariat, and prove one of the very best methods of advertising our teas we could possibly adopt. We are glad to note that our Ceylon brethren have promptly taken up the idea, and that the necessary steps are being taken for the representation of such views (representing *Ceylon* tea), as we suggested, at the Paris Exhibition. The Thirty Committee has, in adopting our suggestion, proved itself far more go-ahead than our Indian Tea Association in this city, which has made no move in the matter.—*Indian Planters' Gazette*, Dec. 9.

Correspondence.

To the Editor.

IRRIGATION IN CEYLON AND INDIA.

Colombo, Dec. 8.

DEAR SIR,—As one who has for many years been connected with irrigation matters in Ceylon and had opportunities both of visiting a few of the big works in India, and of becoming familiar with a good deal of literature on the subject, I would ask for room in your columns to add the results of my experience. In the first place, I would notice the recent local references to the returns from Indian works and point out not only that the figures quoted refer to a limited number of works, but further that no satisfactory comparison can be made as regards results of irrigation between Ceylon and India as our revenue and land systems are so radically different. In Ceylon all the land is considered *private* property and is now, where irrigation is provided by Government, only liable to a water rate of Rs 1 per acre; but Government has no claim on any share of the produce or of the increase due to improved irrigation.

In India, on the other hand, the land is all owned by the State and the occupier is a tenant (or at most a lessee) paying a *rent*. This is generally "settled" periodically (except in Bengal) and ordinarily considered as the equivalent to the value of half the *net* crop; but, as laid down in the "Directions for Settlement" "under Indian Governments there is practically no other limit to the demand upon the land than the power of Government to enforce payment and the ability of the people to pay," I quote further as follows:—"The principle which now obtains is that the State determines the land tax from time to time retaining power to advance it upon fresh land rendered irrigable by national works. In Madras especially, this has proved an additional source of income to the State which can be fairly credited to irrigation accounts." By this means the principle of a single tax is maintained and it is largely by taking credit for this increased land revenue that the Indian works can be considered as remunerative. But there are other considerations which help forward this view, for instance, "Prior to 1854 all irrigation works were constituted under a military board by military engineers and paid *from out of revenue*. It is difficult if not impossible to ascertain the exact outlay upon particular schemes or indeed upon the whole of them up to that time." So this outlay is excluded from consideration.

Again in Madras there were ancient native and British works which were utilised, to which "additions have been made at a very moderate cost, but the revenue produced cannot properly be compared with their recorded cost as they are very largely the result of the labour of years antecedent to British rule which cannot be estimated." (Strachey's famine and P.W. of India.)

Further no account is in this connection taken of the system of State advances made to tenants for the purpose of permanent improvements to their holdings under the Land Improvement Acts, in which the "first place is given to wells, tanks and other works for storage, supply and distribution of water." Under this, a land-holder can borrow to the extent of 75 per cent. of the value of

his land on easy terms of interest and repayment extending in some cases over 40 years and up to a limit of Rs 10,000. Under this system there is *annually* advanced a sum of Rs 200,000 in each of the Presidencies of Madras and Bombay—of which no notice is taken in the Irrigation Department.

Again there has been a large outlay in famine relief works which, I believe, finds no place in the ordinary irrigation accounts. With these preliminary remarks I pass to an examination of the last report of the Irrigation Branch of the P. W. Department of Madras (for the year ending 30th June, 1898, but published in 1899), and add some information to the figures put forward in the newspapers, so far as they refer to this Presidency.

I find the results stated as follows:—

(a) The *net revenue to the State on capital outlay (not return* as apparently stated in the papers quoted at a recent meeting) amounted to 7.88 p.c. on *ten major (productive and protective) works*—irrigating 2½ million of acres.

(b) But this is *exclusive* of the "Interest charges" amounting to over 26½ lacs, and which reduces the *net return to the State* to 4 p.c.

(c) Further out of these 10 works, four instead of yielding any surplus show a deficiency of about 20 lacs on current outlay. While those which pay handsomely and make up for this deficiency are the Cauvery, Godavery and Krishna delta systems. When there were old native or early British works, the capital outlay on what is unknown; and as it cannot be taken into account a deduction is made of a portion of the revenue "assumed to be due to old irrigation less old maintenance charges" so as to arrive at the net revenue, which it is claimed is due to the extensions and additions made under the capital expenditure shown.

(d) Other 25 "minor works for which capital and revenue accounts are kept," (irrigating 535,000 acres) yielded a revenue of Rs 16,59,000, of which "old irrigation" is credited with over nine lacs, leaving 7½ lacs as surplus revenue due to outlay of Government capital. (Under this class the capital outlay on the Buckingham canal is shown at 89 lacs, though it cost the Government £2½ millions sterling to buy out the original Company.) No "interest charges" are shown under this head, and the percentage of net revenue, due to outlay of Government capital, is put at 4.44.

(e) The two foregoing classes account for about 3½ millions of acres, but there remain another three millions of acres served by "minor works for which neither "capital nor revenue accounts are kept P.W.D." and minor works revenue department," in which there was an expenditure during the year of over 19 lacs as against a gross revenue of 83 lacs, but it is not stated if this surplus represents any return on the original outlay on the works.

(f) Finally, under head of Agricultural Work, there was an outlay of Rs 587,922 against a return of Rs 42,185.

I have not at present access to the official reports of recent years, relating to other parts of India, and in their absence must fall back on some other sources of information, though they are not quite up to date. I find these in Mr. Deakin's Indian Irrigation (a work published about five years ago), and who wrote as follows:—"Neither in Bombay or Bengal does irrigation pay the state; but major works pay 5 per cent in Panjab, 12 per cent. in Sind, and 7 per cent. in Madras." As this last figure is very slightly

under the latest report, we may fairly infer the rest of the figures may be accepted as probably still correct for the rest of India.

In view of these figures and my general acquaintance with the subject, I am unable with due humility to give my submission to the statement that "Irrigation in India pays handsomely." That a few special selected works or class of work are made to do so, is I dare say, not to be gainsaid, but the general proposition is open to doubt. I will in a further letter discuss the Ceylon figures and will stop here for today, but I trust that I have advanced sufficient to show that there are such differences between India and Ceylon that it is not possible to make a suitable comparison between the two; especially because the figures published take account of sources of profit not available in this island, and omit sundry branches of expenditure, which are included in the returns published in Ceylon, as I will show in my next letter.

Meanwhile I would only add that there is one broad ground common to the policies of both the Indian and Ceylon Government as set out by the author already quoted in the following words:—"The gigantic works undertaken by the Indian Government and those on a smaller scale in Ceylon were not a speculation in beneficence, but forced on by the terrible famines which periodically visit portions of this great territory. * * * It pays the Hindu everywhere, for without it, millions would not live at all and millions would be decimated by famine every few years. Reckoning its influence upon the railway commerce and good Government of India its value is inestimable."

In view of these remarks, which are on a smaller scale applicable to this island, one is almost inclined to enquire why any immediate and direct return for irrigation is required and why Government should not be content with the indirect benefits and returns which admittedly follow.—Yours faithfully,

E. ELLIOTT.

ANALYSES OF SAMPLES OF COCOA.

Kandy, Dec. 12.

SIR,—I herein enclose copy of Mr. Hughes' Report on samples of cocoa analysed by him in terms of recommendation made by the Cocoa Committee, that analyses should be made of the principal brands of cacao in order to ascertain if any adulteration exists, which might prejudice the interests of Cacao Planters.

The Report is a valuable one and will doubtless be perused with much interest.—Yours faithfully,

A. PHILIP,

Secretary, Ceylon Planters' Association.

Analytical Laboratory, 79 Mark Lane, London, E.C.,
November 9th, 1899.
W. M. Leake, Esq., Ceylon Association in London,
61 and 62 Gracechurch Street, E.C.

Dear Sir,—I have now the pleasure of sending you the results of my analyses of the nine samples of Cocoa sent me respectively on the 12th and 18th October. According to your letter of the former date samples marked :

	s.	d.
Cadbury's ..	9½	ozs. for 1 4½
Army and Navy ..	8	do 1 3½
Van Houten ..	8	do 1 6½
Taylor's Condensed ..	8	do 1 5
Fry's Extract ..	6	do 9½
Vi-Cocoa ..	8	do 1 4½

were purchased at the Army and Navy Co-operative Association at the prices above named.

	s.	d.
Samples Suchard's ..	8	ozs. for 1 4½
.. Rowntree's ..	8	do 1 4½
.. Epp's Homeopathic ..	8	do 7

were purchased at the Civil Service Stores.

The analyses have been carried out fully according to your instructions, the results being in sufficient detail to determine to what extent adulteration and admixture with other ingredients prevailed.

I have added a few remarks which the results suggested and I trust the analyses will be of practical use both to producers and consumers of Cocoa.

Believe me, yours faithfully,

JOHN HUGHES.

ANALYSES OF SAMPLES OF COCOA.

Purchased respectively at the Army and Navy Co-operative Society, Limited, and the Civil Service Supply Association. By Mr. W. M. Leake, Secretary to the Ceylon Association in London :—

TABLE I.

SAMPLES OF COCOA ESSENCE consisting of pure cocoa from which about two-thirds of the original fat has been removed :—

Residue left on sieve	23.65	57.26
	100.00	100.00

REMARKS.

From the above results it will be seen that in Table I., the chief variation in quality depends upon the amount of fat removed from the original cocoa, Cadbury's containing only 25.01 per cent while the sample of the Army and Navy Stores contained as much as 37.20 of fat.

Pure cocoa contains originally from 50 to 52 per cent of fat and from 2.20 to 2.35 per cent of Nitrogen. The removal of the fat renders the essence or residue richer in Nitrogen and in the other constituents of cocoa.

How far the removal of the fat should be carried off naturally an important point to be considered with a view of rendering the material digestible and palatable.

Doubtless some person will prefer cocoa rich in fat while other persons will prefer a quality from which more of the fat has been removed, consequently the selection must be a personal matter.

In Table II., the samples consist of cocoa with a slight addition of potash salts. Why potash salts should have been added is not quite apparent, as the quantity present cannot very materially affect the solubility of the cocoa, though possibly the digestibility may be somewhat improved thereby.

The figures show that there is not very much variation in the general composition of the four samples.

Table III., represents the composition of two well known mixtures consisting of cocoa and other materials.

No. 8. Dr. Tibble's Vi-cocoa contains 27.10 per cent of fat and 2.77 per cent of Nitrogen. Microscopical examination shows that the bulk of the material consists of cocoa to which small quantities of ground kola nut, malt and hops have been added.

Whatever may be claimed for it as "a restorative and stimulating food" by the makers the actual figures brought out in the analysis indicate that there is less nitrogen and more indigestible fibre than exists in well known brands of pure cocoa.

No. 9. The last of these samples contains very much less original cocoa than any of the others. The figures for fat name 26.40 per cent are very similar to those found in the previous samples, but the exceptionally low figures for Nitrogen 1.15 at once indicate that other materials must be present in the mixture.

On making a microscopical examination it is seen that considerable quantities of arrowroot and coarsely crushed white sugar are present.

Probably one-half of the mixture consists of pure cocoa with the whole of its original fat left in, whilst the other half consists of the above named ingredients.

MECHANICAL CONDITION.

The figures given under the heading of fineness and state of granulation represent the readiness with which the respective powders can be passed through a sieve having a mesh of 10,000 holes to the square inch.

GENERAL SOLUBILITY.

The claim so frequently set up by certain makers that their cocoas are soluble, cannot be in any way supported by practical tests.

From a number of experiments recently made it was clearly demonstrated that the actual amount of cocoa rendered soluble by the action of boiling water continued for half an hour in no case exceeded 30 per cent; so that it is most undesirable that manufacturers should continue to put forth claims of superiority on the grounds of solubility. Cocoa is mixible, but certainly not completely soluble in hot water.

JOHN HUGHES, F.I.C.,

Agricultural Analyst

Analytical Laboratory, 79 Mark Lane, London, E. C. November 9th 1899.

THE COCONUT INDUSTRY AT TRINCOMALEE.

A correspondent writes:—"The coconut industry, which has been much neglected, is beginning to attract attention. Mr. Lushington's estate at Nilaveli is fully planted and the plants grow very rapidly. The soil is supposed to be the best of its kind and in process of time will compare favourably with any estates in the Eastern or North-Western Provinces. The timber, that was cut on the land, is now being sold for firewood with some profit to the owner. Several other lands on a small scale have been bought from Government and are now being converted into coconut estates."

CINNAMON IN LONDON.

The information, which has come to hand by a recent mail, on the quarterly auction sale of cinnamon held in London on the 27th ultimo, helps materially to modify the impression created by the intelligence, by wire, which we published on the 28th, that spice of ordinary quality fetched the previous sale's rates. A not unreasonable deduction from that brief message would be that there was nothing to distinguish the sale in November from its predecessor of August; and that prices had remained practically unchanged. The fact is that the two sales were as different as possible in almost every particular. In August, the quantity offered (959 bales) was below the average, the offerings for August 1898 having been over 1,500 bales; last month, the offerings were far above the average, if they did not constitute quite a record. In August almost all the cinnamon offered was disposed of in the sale room; in November considerably less than one-third found buyers. In August the demand was brisk and the prices were even; but last month the tone of the market was dull, and the variation in prices was most marked. The determining factor was that the market was over-stocked, cinnamon as a luxury being specially sensitive to over-production; while that, again, was caused to a great extent by the inrush of wild and coarse bark. Both quantity and quality thus conspired to unsettle the market.

In discussing weather and crops, and in interpreting the Export Tables, we pointed out, from time to time, that the severe drought which prevailed in the lowcountry, during the first quarter of this year, followed as it was by unusual rainlessness in June-July, would tell on the export of cinnamon and of the products of the coconut palm. After the second drought we felt that it would not be possible to make good, before the end of the year, the shortage in quilled cinnamon, though the exports of chips, scraped from sticks that will not peel, might show an increase. Almost immediately after, exports of quilled bark kept going up by leaps and bounds, in a most unaccountable way, until the phenomenon was explained by the announcement that wild bark was being shipped in large quantities. The Collector of Customs insisted on having a separate heading for what is not the true cinnamon bark of commerce; but it is to be feared that, before official notice was taken of the new departure, and before the Chamber of Commerce sounded a note of warning, a great deal of the wild stuff was sent away as cinnamon, both in bales and bags. On no other ground can we explain the shipments of quilled bark aggregating 2,414,035 lb. till the 19th instant, and coming so close to the shipments for the corresponding period of last year, which were 2,400,796 lb. The immense growth in the exports of chips—1,748,317 lb., against 1,321,806 lb. in 1898, and 1,021,838 lb. in 1897, may be referred to the droughts which compelled the scraping of coarse bark which would not peel off—though not if all the quilled bark that was shipped was genuine stuff. There is reason to fear that in chips, as in bales, the

exceptionally high figures are due to dishonest dealing, and the shipment of spurious bark.

We should be glad to know that the trade in other than cultivated bark received its quietus at the sale of three weeks ago. It certainly received no encouragement at the auctions; for nearly all of it had to be withdrawn. It is probable that, up to the middle of this year, genuine cinnamon was adulterated with wild and low bark, and that high prices and a short supply encouraged the dishonest fraternity to attempt a new stroke. Nothing can check dishonest trade so effectually as the demonstration that it does not pay; and we should greatly rejoice if the new columns in our export tables would disappear, as a result of the last cinnamon sales. It is satisfactory to find that the old marks of cinnamon and the fine qualities were all disposed of, and at prices which were highly satisfactory—the finest showing advance. Even "unworked" cinnamon held its own, so that it only wants the elimination of wild cinnamon, for the market to revert to a healthy state.

The following report from the leading firm we generally quote, is of special interest at the present time:—

9 King William Street, London, E.C., Nov. 28.

CINNAMON.—The last quarterly auctions of the year were held yesterday, when about 4,450 bales Ceylon growth offered against 959 bales in August and 3,901 bales at this period last year.

The selection was not a good one, a very large proportion of the extensive supply comprising wild and low bark, nearly all of which sorts had to be withdrawn as the trade did not bid for this poor stuff.

The tone of the sales was dull but as importers met the Market, about 1,200 bales were cleared in the room.

"Worked" quill was in small supply and all sold, the top grades of fine and good at generally firm prices, and the lower qualities mostly at 1d. per lb. decline. "Unworked" went irregularly, at full rates for the better grades and easier for the inferior. "Worked" Firsts good and fine sold at 1s. 5d. to 1s. 8d.; seconds, 1s. 4d. to 1s. 5d.; thirds 1s. 2d. to 1s. 5d.; fourths 8d. to 12½d. "Unworked," first, 8d. to 1s. 3d.; seconds 8d. to 1s, thirds 7d. to 11½d, and fourths 6d. to 9½d. per lb.

CHIPS, &c.—The enormous supply of about 4,550 bags offered; mostly wild and bark that were neglected, some 300 bags only finding buyers at about late rates; cuttings, &c., 4½d. to 9d; bark and chips 1½d. to 3d. per lb.

STOCKS CEYLON.—5,859 bales against 6,116 in 1898; 4384 in 1897 and 2,100 in 1896.

CHIPS.—6,705 bags against 1,920 in 1898; 4,096 in 1897 and 4062 in 1896.

The ss. "Duke of Norfolk" with a quantity of Cinnamon on board has not yet arrived.

The next auctions are fixed for 26th Feb. 1900.

THE GEOGRAPHY OF TEA.

This is the title of the paper on the above subject read at the International Geographical Congress, held in Berlin on September 28th, by Mr. McEwan, F.R.G.S.—*Home and Colonial Mail*, Dec. 15.

PASSION FRUIT.

We are surprised to stumble upon some ignorant comments on an article on Passion Fruit, which appeared in our columns some weeks ago, in a paper which should know something above the subject. The *Fruit Grower* of November 30th has the following:—

It is notorious that we have to go from home to learn anything of ourselves. The *Ceylon Observer* in an article on passion fruit, tells us that "fairly successful" trial shipments of this fruit have been made from Australia to the London markets, "some of the samples being sold as high as 1s a dozen." We would like to have some particulars as to the "success" of these shipments. The *Observer* much more correctly sums up the situation with regard to passion fruit by saying that it is an excellent fruit for "local consumption."

In view of this extraordinary and ill-informed effusion we have been at the pains to refer to facts. Corroborating our statements, the following from the *Daily Telegraph* early this year and from the *Melbourne Leader* of March 3rd will be sufficient:—

Whatever may be done as regards oranges in New South Wales, it may be considered certain that an attempt will be made this season to send a good supply of passion fruit to the London market. This is a fruit in connection with which Australian growers need fear no rivalry. The obstacles to overcome are the ignorance of English people to the merits of the fruit, and the unaccountable prejudice some of the London fruit importers have against it. Why this prejudice should exist is a mystery, but that it does is evident from the published letters of Mr. F H Dangar. He was led to write owing to one firm going so far as to say that passion fruit had "no commercial value" in the London market, and he pointed out that this could only be from the fact that it was almost everywhere an untried novelty. The main fact remained that it carried well, hardly a pod going wrong in a large consignment, and that by many buyers the fruit was pronounced delicious wherever sampled. The loss to exporters of passion fruit last year was occasioned chiefly by London agents not thinking it worth their while to make sales. The time will come when to be agent and salesman for Australian fruit in London will require more than a mere mechanical conveyance of the cases to a sales room and an offer there to the highest bidder.—*Daily Telegraph*.

Some time back a trial shipment of passion-fruit was sent from Pennant Hills, New South Wales to London. It was a failure, the account sales showing the disposal of thirteen cases each at one shilling per case. Some later consignments, however, fared better; and Mr. F H Dangar, of Sydney, who is now in a letter to Mr. C B Cairnes, of Parramatta, remarks:—"I am inclined to think that as the fruit was not known, the waste has been unnecessarily enlarged, and fruit rejected which was perhaps slightly shrivelled. Englishmen who used to stay with me in Sydney used to call it 'heavenly fruit,' and I am certain when this is better known higher prices will be obtained. I fear that but few Australians here knew of the shipment." Mr. Dangar mentions that when he went to England last year he took a case containing 20 dozen with him from Sydney. They were carried in the vessel's cool chamber, and when opened in London not more than six pods were found to be damaged. It seems pretty certain that a few more Australian consuls like Mr. Dangar would be invaluable to our growers (says the "*Daily Telegraph*"), and that it is simply absurd to ship fruit to British fruiterers who have never seen it before, and who condemn passion fruit as worthless because the skin is a little wrinkled. English business people are the most conservative men on earth in many respects, and a small consignment of unknown fruit, with some shrivelled up,

could not be recognised by them as the first fruits of a new and possibly great trade. The pity of it—for the Pennant Hills people—is that Mr. Dangar did not meet Mr. Cooper when the latter was selling fruit at a shilling a case, while Mr. Dangar was giving a shilling a dozen for all he could get, and thinking it would be ridiculously cheap. It is quite evident that great as was the failure of the first trial the passion fruit export trade has possibilities which are in some ways greater than that of oranges, if only for the fact that they will leave the market to themselves.—*Melbourne Leader*, March 3.

PRODUCE AND PLANTING.

THE TEA MARKET IN NOVEMBER.—"During November the offerings at public auctions of Indian teas were 220,000 packages, against 210,000 packages in the same month of 1898. Some inferiority in quality was apparent as compared with earlier arrivals," say Messrs. McMeekin and Co., in their report, "and this was most marked in the case of some of the Darjeeling teas. The strong tone and active market noticed during October continued till the middle of the month, but after that buyers showed some unwillingness to purchase, and a material decline in the value of all descriptions took place. The average price for the month was 8½d per lb, as against 8¼d per lb. for the corresponding month of last year. The imports were 20,471,000lb, and the deliveries 13,689,000lb, leaving in stock on November 30, 52,985,000lb. The present position of tea generally is in marked contrast of twelve months ago, when attention was pointedly called to the manner in which both the home and the export demand were running ahead of the importations. For the eleven months expired of the present calendar year, the imports from all sources shown in the figures of the Tea Brokers' Association have increased by 5,700,000 lb. while the total deliveries only show an increase of 1,600,000 lb. and the stock shows an increase of 3,270,000 lb. on that of Nov. 30, 1898. The period of higher prices for common grades, which set in early in 1899, appears to have checked the increase in the rate of home and foreign consumption, which had been proceeding previously in a most satisfactory manner. It is probable that during 1899, the total increase in shipments, as compared with 1898, of Indian and Ceylon teas to countries other than the United Kingdom (including re-exports from there) will be about 4,000,000 lb. while the increase in home consumption may be comparatively small. The increased crop for the Indian season will probably exceed 12,000,000 lb. and Ceylon is likely to finish up with some 5,000,000 lb. of increased yield for 1899. There is, therefore, little fear of an inadequate supply unless there is a sudden large development in the demand. The regulation of the supplies printed in auction is working well from the buyers' point of view, and so long as large unoffered first-hand stocks remain in the warehouses, there can be little inducement to run the risks and incur the expenses of buying ahead of immediate requirements especially in a declining market. Of Ceylon tea the offerings were 98,000 packages, against 100,000 packages in the same month of 1898. The quality generally showed a falling off, and really fine liquoring teas were strongly competed for throughout the month."

THE NYASSALAND COFFEE CROP.—Advices from Blantyre say: "Seasonable rains have fallen in the Shire Highlands. The coffee crop amounts to 1,000 tons. It is expected that there will be an excellent crop next season, largely exceeding any in the past."

REMINDERS ARE NECESSARY.—The war absorbs so much space in the newspapers, that there is apparently no room for the insertion of the occasional paragraphs about the planters and tea planting, which at one time served to advertise Indian and Ceylon teas. It may be thought that the product of British enterprise is so popular with consumers that there is no fear of any decline in the demand. This is

so to a certain extent, but the public are fickle, and the more they see or hear about an article of produce, the more they feel disposed to take a practical interest in it. It may be noticed in this connection that one or two firms of wholesale and retail dealers, who do not make a speciality of Indian and Ceylon teas, have recently opened tea rooms in various parts of the country, where the sale of tea in the cup is combined with the sale of tea in packets. These rooms are tastefully decorated in Chinese or Japanese fashion, and ornaments from the Far East are also offered for sale. There is thus some inducement to the purchaser to try the teas of China and Japan. So long as this idea is limited in practice its effect on the Indian and Ceylon tea trade will be little or nothing. It is strange, however, that whereas shops for the sale of Chinese and Japanese articles as well as tea are not uncommon, especially at the more prominent seaside resorts, it is not often that Indian or Ceylon tea rooms are to be found. The native ware from our own possessions does not seem to possess the same charm for the British buyer, or else it is not pushed so freely as the competing article from the Far East. We have heard of a scheme for opening tea houses in London and elsewhere after the style of those in Japan. We are aware that in a feeble way some attempt has been made to establish tea rooms at which natives from India or Ceylon were employed. But the idea has not been supported, we believe, by capital to any considerable extent. It is not to be expected that capitalist unconnected with Indian and Ceylon tea will take risks that those who are interested decline, but it seems odd that if capital can be found for kindred ventures, an object which would serve a distinctly useful purpose, so far as British-grown tea is concerned, should be deemed impracticable. We are not amongst those who believe that the majority of tea drinkers care where the product is grown; value for money is the main consideration. But if a thing is talked about, advertised, and the interest in it maintained, the public are sure to demand it. That is why the need for advertisement in some form or other is particularly useful, and why there is constant necessity for reminding the public, lest they become indifferent on the subject that British-grown tea has the first claim on their attention for several reasons.

LAST WEEK'S TEA MARKET.—Teas "for price" continued in request, and were well taken at last week's rates, the lowest market quotation being still 6½d.—*Home and Colonial Mail*, Dec. 15.

COCOA IN LONDON.

Messrs. Hamel Smith & Co., East and West India merchants, report:—The demand for this article is very strong. Yesterday 20 bags of defective and very inferior were sold at 59s, and some thin and broken mixed with dust at 56s. A few weeks back such cocoa was unsaleable. Fine Ceylons would command fancy rates just now, but there are none offering. Some of the makers of cocoa and chocolate hope to have a good Christmas, as they expect the public will follow the Queen's example, and make chocolates their Christmas present.

It is expected that the Government will be buyers again next week, but if so I expect it will be mainly Guayaquil as at present there are only two sales advertised. No sales were held this week, the trade preferring to buy privately. Today's prices for Ceylon are:—56s to 59s for inferior and defective, 65s for ordinary, 68s to 76s for low middling to middling, and 87s for fine red; but prices are sure to go higher. The present stock is 6,390 bags, against 9,080 bags last year.

THE DETERIORATION OF GROUND NUTS.

The Madras Government, like the French Administration of Pondicherry, is, says the *Times of India*, addressing itself to the task of investigating the remarkable decline in the groundnut trade of the Presidency. The rapid decay of this industry has almost spelt ruin to Pondicherry, which, in addition to the great deficiency caused by the deterioration of the crop, has had to suffer the diversion of a considerable export trade to the neighbouring port of Cuddalore. The French Administration are seeking for a remedy in the direction of improving the quality of the seed, and certain superficial advantages have been obtained by the distribution of seed nuts from Mozambique and Mauritius. But although the deterioration of the seed is a factor in the decay of the industry, it is not the main one; bad farming is undoubtedly at the root of the evil. The Madras cultivator crops the same land with nuts year after year, removes all vegetation from the land, and neglects even to replenish the soil by means of fertilisers. That exhaustion of the land lies at the base of the depression is still further established by the circumstances that exotic seeds, after a year or two, suffer equally with the indigenous variety. On the suggestion of Dr. Leather, the Madras Department of Agriculture is arranging for a series of analyses to determine whether the local nut is as poor as it is commonly reputed to be. The information, no doubt, will be useful, but we should be glad to see some more practical measure in progress to conserve an industry which is well worth preserving. This is not a case of good groundnut oil being elbowed aside by inferior substitutes. The Marseilles soap boiling firms "await with impatience" the moment when groundnut oil shall again be procurable. It ought not to be beyond the powers of the Agricultural Department to direct the ryot to supply that demand.

SPRING VALLEY COFFEE COMPANY, LIMITED.

The following report was to be presented to the thirty-fifth ordinary general meeting of the Company held at No. 5, Dowgate Hill, London, on Thursday, the 21st December.

The crop of tea for the past season amounted to 396,800 lb., and this, together with 90,782 lb. bought from neighbouring estates and manufactured at Spring Valley, sold for £15,711 17s 10d, the average selling price being 7.73 pence against 8.24 pence obtained last year.

The crop from the few remaining coffee trees amounted to 234 cwts. 3 qrs. 8 lb., and realized £738 6s 1d, being at the rate of 62s 10d per cwt., against 96s 5d obtained for the 1897-1898 crop.

The total proceeds from the sales of produce amounted to £16,450 3s 11d, and expenditure in Ceylon and London to £14,314 13s 11d, leaving a profit on the year's working of £2,135 10s. To this, profit has to be added a sum of £363 6s 7d, brought forward from last year, and after debiting £26 10s for Income Tax and £900 for Dividend on the Preference Share capital to 31st July, 1899, there remains a balance of £1,572 6s 7d to be now dealt with.

The Directors recommend the payment of a Dividend of 1½ per cent on the Ordinary Capital, which will absorb £1,200 of the above sum, and that the balance of £372 6s 7d be carried forward to next year.

During the past year the sum of £3,522 11s 8d has been spent on Capital Account on the extension of the tea area and factory accommodation,

The Directors have to report that the severe drought and unfavourable weather referred to in the last annual report continued almost without intermission throughout the past season. The crop of tea has in consequence been most disappointing, the yield from the 1,217 acres in hearing having fallen to 326 lb. per acre, against 375 lb. and 440 lb. secured during the two preceding years respectively.

The climatic conditions which prevailed during the past year are not usual in the Badulla district, and, with a return to normal weather, former yields may be looked for with confidence.

The Tea Factory has been successfully completed, and the whole of our available area planted with tea and fuel, the latter on steep faces unsuitable for tea.

With the large area of tea coming rapidly into bearing, and with the facilities for manufacture we now possess, it is expected that important savings in the cost of production will be effected in the future.

Our Manager is of opinion that estimates will be more easily framed and worked to, now that the property is converted into a tea garden, if the financial year were made to terminate on the 31st December in place of 31st July. Accounts for the five months ending on the 31st December next will therefore be presented to Shareholders early in 1900 in order to bring this into effect.

The area of the estate as on 31st July, 1899, was as follows:—

TEA.			
5 years old and over	1045	acres.	
Planted November/December ..	1894	172	"
"	1895	145	"
"	1896	159	"
"	1897	194	"
"	1898	196	"
Total under Tea ..		1,911	"
Total under Fuel ..		163	"
Forest, &c. ..		257	"

Total Area ... 2,331 acres

Mr. J G Wardrop, a member of the Board, retires on this occasion, and, being eligible, offers himself for re-election. Messrs. Deloitte, Devor, Griffiths & Co., the Auditors, also offer themselves for re-election.

TEA CORPORATION, LTD. (OF CEYLON.)

Report of the Directors, and Accounts for the year ending 30th June, 1899, submitted to the annual General Meeting of Shareholders on the 19th Dec.

The Directors beg to submit herewith the Accounts of the Corporation for the year ending 30th June, 1899, which, compared with those of the previous year, must be considered satisfactory.

It will be seen by the working accounts that the gross amount of Tea produced on the estates was 1,234,442 lbs. The cost f.o.b was 26.10 cents per lb., which is nearly 6 cents or 1d. per lb. less than it was during the previous year. The average price obtained was 6½d. gross and 5.15-16d. nett per lb., this also being a great improvement on 1897-98. To the profit on Tea is added that on Sundry Produce, amounting to £592 14s., thus making a total of £8,867 19s. to be carried to Profit and Loss Account.

This account shows a profit of £4,327 1s. 9d., after the deduction of London Expenses and debenture Interest, etc. From this must be further deducted the loss on last year, amounting to £1,020 6s., leaving a nett profit of £2,706 15s. 9d. as shown in the Balance Sheet.

A dividend on the Preference Shares up to the end of February, 1898, was paid on 1st August last.

It is proposed to write off £393 9s. 0d. from preliminary expenses, thus reducing that account to #1,300.

The results of the year, though bearing a favourable comparison with 1897-98 do not come up to expectation; this was mainly owing to a serious drought in the early part of this year, followed by long-continued rains. In view of these circumstances, it is satisfactory that an increased crop should have been obtained, and that at the same time an evident improvement in the quality of the Tea has been shown.

Mr. Tatham hopes to secure over 1,250,000 lb. of Tea for the current year at under 27 cents per lb., and about 300 cwt. of Cocoa, and in his last letter to the Board states as follows:—

"I have no doubt that I shall procure my estimate and also realise a better price for the Teas than I did last year, owing entirely to the manure, which has enabled me to pluck finer and still increase my yield."

At Doteloya alone there is a considerable acreage of land admirably suited to the growing of tea. Mr. Tatham strongly urges that this should be planted up, and Mr. E H Hancock, who has visited the property, thoroughly endorses this opinion. The Directors therefore recommend, subject to the approval of the Shareholders, that an additional amount of £20,000 debenture stock should be raised for the purpose of developing the Company's property. Your Directors would not require the whole amount at once, as the expenditure would be spread over the next three years; they would therefore only call up this additional stock as occasion required. It is proposed that the stock should in the first instance be offered to the present Shareholders at the price of 90 per £100 stock.

For some months past negotiations have been on foot for working the Plumhago on the Company's estates, but in consequence of information received by the Board from Mr. Tatham, as to the value of the vein which has recently been found, the Directors have thought it advisable not to lease the rights, on the terms already proposed, without placing the matter before the Shareholders.

Mr. E H Hancock, on his return from Ceylon, joined the Board in place of Mr. H A Hancock.

The Directors retiring in rotation, are Mr. E H Hancock and Mr. T J Lawrance, who, being eligible offer themselves for re-election.

The Auditors, Messrs. Broads, Paterson & Co., also retire and offer themselves for re-election.

CACAO CULTURE.

It may be true, as stated recently by an experienced London broker in the cacao trade, that the Ceylon product does not come into competition with that of Trinidad or, we suppose, with the cacao of Mexico, Nicaragua, Ecuador, &c. But it must be, nevertheless, a fact that increased production in these Western lands tends to affect the market, unless consumption keeps pace, more especially on the Continent of Europe. We have just been reading a Report on "Cacao Culture in Ecuador" (see elsewhere) which shows that production in that South American State has been increasing since 1836 and that the crop for 1899 is expected to be close on 600,000 cwt. or fifteen times the outturn of Ceylon! This, however, must either be a great exaggeration, or the quantity required for home consumption must be very large. Hitherto, judging by shipments, we have credited Ecuador and Peru with an outturn of 360,000 cwt. and a home consumption of about 90,000 cwt. There can be no doubt that Ecuador has a great deal of land, and the perfection of climate, for cacao culture; but fortunately for Ceylon,

the labour difficulty prevents any rapid extension of plantations in the 20,000 square miles of the coast provinces which are considered to be adapted to the cultivation.

Turning to another cacao-producing country—Mexico—we direct attention to the interesting letter (given on page 483) from an old Ceylon coffee planter, Mr. F. O. Darley, so long resident in the Knuckles district. Who would not hasten to Mexico if all Mr. Darley states be realisable; but how can our correspondent explain the failure of the group of hard-headed Ceylon men who visited Mexico in 1897 and 1898 to take up land or make investments? Surely they had information, such as is now offered to us, placed before them? And yet going to see the country and the plantations for themselves, they deliberately declined to make an investment. And yet Mr. Darley tells us that a profit of £120 to £150 per hectare—£50 to £60 per acre—is to be got after an outlay of only £8 per acre for any one who will wait five years—the crops being equal to over 16 cwt. of cocoa per acre. This is, we fear, too sanguine an estimate to be at all reliable. Indeed, Mr. Darley's own figures of value of crop will scarcely allow the profit he names and surely 40 cents of a dollar (or say 10d) per lb is too high a price for Mexican cacao, being close on 90s a cwt? No doubt the United States supply a grand market for the produce of Mexico; but it must be under extremely favourable circumstances when even £50 worth of cacao per acre as the gross result is realized. So in the case of rubber; to secure £2,000 worth of rubber for an outlay of £1,600 spread over five years should be tempting enough to draw abundance of capital to Mexico; but, as we mentioned, the Ceylon visitors of 1897-8 did not see their way to recommend investments. At the same time, it may be said that if Mr. Darley's estimates are halved in their next result, they should be good enough. Sugar, it will be seen, is estimated to pay £36 an acre; and coffee is without disease. Mr. Darley must really tell us a little more about this "Paradise of the West." Let him give us his own experience—a plain unvarnished tale as a practical planter—since he first landed in Mexico. What about labour, taxes, police? Let us hear some of the drawbacks, and the reason why British and American capitalists have not long ago taken up all available land to grow products so much in request in the adjacent extensive markets of the United States.

THE SUGAR INDUSTRY.

We have received a copy of a Glasgow paper with information as to new sugar machinery prepared by a Clyde firm for the important Penang and Straits Sugar Companies, represented by the gentleman who is anxious to inspect North-Central and North-East Ceylon with reference to the location of a similar industry. It would be supposed that the further development of extensive operations in the Straits Settlements would be more than enough for the enterprise of Sir John Ramsden and his fellow-Directors and Agent; but apparently not, there being

abundance of capital available for any proposal recommended by their trusted Manager. Of course, the result of the required inspection has yet to be made manifest. But meantime we append the extract above referred to from our Glasgow contemporary; and it will be observed that Porto Rico is to receive new machinery from the Clyde, as well as the Straits Settlements:—

The well-known firm of sugar machinery engineers, Messrs. M'Onie, Harvey & Company (Limited), of this city, have just completed some specially heavy cane crushing machinery for the Penang Sugar Estates Company, of London and Penang, of which Sir John W. Ramsden, Bart., of Huddersfield, is the proprietor. The machinery consists of two sets of regrinding sugarcane mills, the rollers being 36 inches diameter by 72 inches long; these are fitted with steel shafts of great strength, having journals 17 inches diameter by 24 inches long, and are carried on side frames of extra strength, which have through side and main top bolts of heavy section of steel, the latter so arranged as to give the narrowest possible return plate. The returner is of the Rocker type, and consists of a deep beam of cast steel supported on strong brackets from the bottom of bedplate up through the side frames. The rollers run in heavy gunmetal bearings, which are cast hollow for the purpose of water circulation, thus assisting to keep the bearings cool, which is a consideration, owing to the great pressure now exerted by these large mills so as to extract all the juice out of the canes. The mills are fitted with strong, self-acting carriers for feeding the canes into the mill, also mechanical carriers for removing the crushed cane to the steam boilers. The mills are driven by powerful horizontal engines of the Corliss Frame pattern, having piston valves, the steam cylinders being 28 in. diameter by 48 in. stroke, are fitted with link reversing motion and sensitive high speed governor. The fly-wheels are extra heavy, and built in centre arms, and segments for shipment abroad. These engines transmit their power through strong double gearing to the mill; all the spur pinions of this gearing and the large pinions on the roller shafts are made of the best Siemens' cast steel; the main and intermediate spur-wheels are built, and the segments of these wheels are also of cast steel; the shafts of these wheels are of best forged steel and large proportions, suitable for the work required. The whole as erected in the works has a very fine appearance, and has just been inspected by Sir John Ramsden, Bart., and Mr. Underdown, Q.C., of London, along with Mr. Arnold, the secretary, and Mr. Turner, the company's administrator in Penang.

Messrs. M'Onie, Harvey & Co. (Limited) have also in progress another powerful plant, the first of several to be erected for the Straits Sugar Company (Limited), of London, in which the same gentlemen are interested, consisting of engine, mill, and gearing, being duplicates in all respects of these already described, but this plant is for the manufacture of what is called in the Straits "basket sugar," or Muscovado; but in place of the usual copper wall used generally in the manufacture of this quality of sugar Mr. Turner intends using a Harvey triple effect evaporator, which will be a saving in fuel and labour, as well as improved recovery in the sugar obtained. After the syrup is brought to a high density it is treated in a special manner by a patent process of Mr. Miller, the chemist of the above company in Penang. By the Miller process the syrup is kept at a low temperature, so that there is no danger of its being charred, as sometimes occurs in the usual copper wall. Thus all the water is taken out of the syrup at a low temperature, and is then run into another

vessel, where it is kept in motion until it granulates into a solid mass of raw sugar, and is used in this state by the natives in the East or sold to refiners and brewers.

The advantages claimed for this process are that no molasses are produced, that the sugar will give a high recovery, and with the low temperature at which the juice is treated in the triple effect and in Miller's patent granulators there will be less loss from inversion, as compared with the present system of making Muscovado sugar on the copper wall with open evaporation. Also the process is simple, as no vacuum pans nor centrifugals are required.

The late hurricane in Porto Rico caused great damage to all the sugar estates in that island, and a number of the estates were levelled to the ground. Three of these damaged estates are now being amalgamated to make a central sugar factory, and the work has been entrusted to Messrs. M'Onie, Harvey and Company, (Limited). The success of this new venture may induce other planters to do likewise.

A DAY'S WORK ON A CEYLON TEA ESTATE.

"Master, Wake! Master, Wake!" This combined with a tremendous banging, announced that another day's work was beginning and that my worthy appu (cook) was endeavouring to awake me to a sense of my many duties. Having eaten early breakfast, or rather confined myself to a slice of pineapple, as eating anything at that hour—5-30—is always to me impossible, and walked to the factory (the place where the green tea leaf is converted into the saleable article) about 200 yards from my bungalow, I found most of the coolies already assembled, and others being hurried along by the kanganis (native overseers) to the mustering ground. The first thing on these occasions is to make oneself heard, and having succeeded, with the help of the conductor (the head native overseer, usually English speaking), in this, the next thing is to tell off the different gangs to their various works. This is frequently a work of extreme difficulty, as the coolies often like some work very much better than others, and the way they can slip from one gang to another without being seen is wonderful. And then there are the ladies to contend against little kutties (native girls) of most innocent appearance, swearing that their feet are full of thorns and that they cannot work today, or that their great uncle died in the night and they must have three days' mourning with unlimited rice that he may be properly buried so that the various devils cannot get at him.

NATIVE FUNERALS ARE IN THIS COUNTRY made an occasion of great feasting, generally ending in all parties getting very drunk and indulging in a free fight, thus paving the way for another funeral. However, after a great deal of shouting and an occasional mild use of the stick, though this is to be deprecated, all are got into working order and marched off to various parts of the estate in charge of their respective kanganies. Then there is time to light the first pipe of the day and try to remember how many mistakes you have made at the muster in sending large gangs of coolies to works that only require a few, and *vice versa*.

This train of thought leads on to another, in which the likelihood of the manager's liver being slightly out of order, and the probable consequences when he comes on his morning's round to the various works, form a leading part,

THE MANAGER'S LIVER,

especially if he happens, to be an elderly gentleman who has spent some years in the East, is always a matter of considerable interest to assistants on tea estates. But there is not much time to waste, and as a gang of men are pruning a field near, we just visit them. This is rather skilled labour, and the best coolies are usually selected for it, as a great deal depends on a field being properly pruned. Each man has his line of tea bushes, and they are cut down to about 18in. above the ground. Great care must be taken to make the coolies cut the branches off so that when the bush is pruned the tops of the cut branches form a level surface, and all cross branches and small twigs are or should be taken off. Half the coolies come to us and say that their knives are useless, or their hands are hurt, and the other half are usually doing very bad work: so that we may count on a lively half hour with these gentlemen. Their excuses are wonderful and manifold. It is here that an intimate knowledge of the Tamil language is so useful, as when the first coolie comes up with some stupid complaint, and you are able to draw comparisons in proper coolie Tamil between the man addressing you and one who is useless, it serves to deter the rest to a great extent. Of course, there are often real cases where a man cannot do the work, and if so he is sent to the pluckers in the next field.

Having looked carefully over the pruning, and informed any coolie doing bad work of your opinion of himself, his father, mother, sisters, brothers, and ancestors generally, and threatened the most awful penalties if he does not mend his ways, we proceed to the next field, where the pluckers are engaged. Here is the main body of the coolies, mostly women and boys and girls who are not strong enough to do other works, but are usually far quicker and handier than men at plucking. They all have baskets on their shoulders, into which they put the leaf. Only the young shoots are taken, and all coarse leaf must be left alone.

THE KANGANIS ARE SUPPOSED TO GO

constantly round to see that the baskets contain nothing but good leaf, and woe betide the unfortunate assistant if the manager receives a note from tea maker (the man in charge of the factory, usually a more or less educated native) to say that the day's leaf is unsatisfactory. We stay some time with these coolies, as the work has to be carefully looked after, and so we go up and down the line of pluckers, and soon, on looking into the baskets, find several faults. Some coolies are

MISSING GOOD LEAF

that is, leaving a bush before they have taken all the young and good leaf from it, or putting big, coarse leaves, which have the effect of giving the made tea a rank, bitter taste, into the baskets. It is a most important thing to see that all the flush (young leaf) is taken, as if there is any left it stops the young shoots sprouting, and instead there is only big, coarse tea maker leaf where, if previously the bush had been properly treated, there would be young stuff fit for the tea factory. A field takes from ten days to three weeks between pluckings, depending on the weather and caste of tea. The young shoots are very sensitive to climate, and too much dry or wet weather is quite enough to stop the flush coming on. I am talking, of course, of Ceylon only; it may be different in Assam.

Having lectured the kanganyies and looked over the trees already plucked, and probably indulged in a little chaff at the expense of erring coolies, we proceed round the estate. About this time the manager usually makes his appearance on his morning's round before going to the office, and if there is anything wrong it is as well to draw a veil over the meeting between the senior and junior superintendents, more especially if the aforesaid manager has had a late night with some friends, and is possessed of a head, liver, &c. Coolies clearing up roads and drains—the latter most important in a mountainous country like Ceylon, where the rainfall is heavy and wash therefore very great—are seen, too, on our way to the next work, where a gang of men are making a nursery for some seed. This is done by making beds of earth about 6in. high and putting very fine soil on the top. A fence must be put round if there is jungle near, or deer, pig, &c., will make short work of the young plants as they are coming up. On our way back to the pluckers we take the opportunity to see if the weeds are being kept down. This is done usually by giving the kanganyis contracts about the estate of from ten to thirty acres, at about one rupee per acre: they are then entirely responsible for that piece of land as regards weeds and if many are found there they are liable to be fined; but, as they generally manage to make money out of the weeding, it does not as a rule give much trouble.

It is now 10-30 a.m., and time to weigh up the pluckers for the morning leaf. The conductor produces pocket scales and a kangani's name is called out. We open the

PLUCKING BOOK,

and find in it written the names of all the coolies belonging to his gang, as each kangani, before being taken on by the estate, has to bring so many coolies, for which he is paid what is called head money, at about 4 cents per day for every coolie that is working in his gang. On the coolie's name being called he or she steps out, and the conductor weighs her basket and tells us how many pounds of leaf she has plucked this morning, which is put against her name. All the coolies of that kangani's gang having been weighed, we pass on to the next gang, and so on until it is finished, and the leaf, put in sacks, is carried to the factory by boys. The weighing up finished, we go to breakfast, and have two hours spell before tackling the afternoon's labours, which are much the same as the morning's, and about 4 p.m. a coolie blows a horn and we go to evening muster, when all the coolies' names are taken down who have worked through the day and the pluckers' leaf weighed up a second time. If the work of anyone is unsatisfactory, it is usual to give the offending party what is called half name, that is, make a mark in the name book (commonly known as the check roll) against that coolie, to signify that he is only to get half pay for the day's work. Very young assistants, and sometimes older ones too, are often much too apt to do this for trifling faults; it should be only done when the offender really deserves it or otherwise it only tends to dishearten coolies and make them careless.

Having despatched the

LEAF SACKS TO THE FACTORY

and given any sick person medicine, and listened to any of the kanganyis' complaints, as they generally choose this time in the day to ventilate their grievances, we retrace our steps to the bungalow, and, if there is a court near, play tennis,

or cricket practice perhaps elaims us. In some districts there are a number of things to do in the way of sport, cricket, football (both Rugby and Association), and hockey being played regularly, and as there are always plenty of young men of the right sort, public school or 'Varsity many of them, there is no difficulty in getting good teams together. Some of the pleasantest days I have ever had have been when playing for my district against neighbouring ones.

The salary of an assistant superintendent is small, about 125'00 rupees, or £8, per month, but living is not expensive and this with perhaps a little help from home, should be enough, as an assistant is not expected to entertain, and he will find the subscriptions, &c., to the various sports he may go in for very small. The life, if a little monotonous, is, nevertheless, a very jolly one, as you are always out of doors, and, as most of the tea estates are in the hills, the climate is usually very good; in fact, where I am, at an elevation of about 5,000ft., it is almost perfection, and fires are very often required in the evening.

A young gentleman of good family, more especially if he is a public school man, will have a very good time, as he will find plenty of good fellows round him if he goes to a big planting district, such as Dimbula or Dikoya. After he has served his time of probation, known in the island as creperdom which is very often the hardest time he will have, and gets an assistant's billet, he will find the life on the whole a good one, though, without influence of some sort, it is not very easy to get on quickly, and for some time, he will require help from home as regards money matters.

—Field, Dec. 9.

PLANTER.

THE CEYLON TEA CROP IN 1899.

THE total exports for 1899 (according to the Chamber of Commerce figures) show a greater jump forward than for any of the past four years. The increase over 1898 is more than 10 million lb., and we have to go back to 1895-6 for a similar ratio of advance. We need scarcely say, too, that the outturn is decidedly in advance of the estimate of the Planters' Association as framed in the early part of 1899, and confirmed in September last. The comparison between estimates and results may be seen from the following:—

ESTIMATE.

P. A. Estimate of Total Crop (1899) ..	lb.	126,500,000
Local Consumption	1,500,000
Total shipments	125,000,000
of which to United Kingdom	93,000,000

Leaving for other Countries	32,000,000
ACTUAL RESULT.		
Total Export 1899 (Chamber of Commerce)	129,894,156
To United Kingdom	103,948,124
Other Countries	25,946,032

For 1898 Total	119,769,071
To United Kingdom	96,133,833

Other Countries	23,635,238
--------------------	----	------------

Increase to other Countries .. 2,310,794
 It will be observed that the United Kingdom got well-nigh 11 million lb. more tea than

was estimated, while the shipments to "other countries" did not reach anticipations by 5 million lb. "Thank heaven for the London market" being able to take off so much, one is inclined to say, in the face of such figures. Of course, if by increasing the offerings in the Colombo market, more tea could be diverted to "other countries," and especially to Russia, not a day should be lost on the part of proprietors or their agents—where free to make the change—in supporting "Colombo" and testing the statement that such tea would be bought at profitable rates for direct shipment. Meantime, it is of interest to note the distribution, and comparison between the two years, for "other countries." In the first place it is difficult to understand how the P. A. Committee came to estimate less for 1899 to the United Kingdom than was actually delivered in 1898; and in the second place, the total to other countries only showing an advance of 2,310,780 lb. is distinctly disappointing. From the details given by the Chamber, it will be seen that there has been a comparative decrease to Austria, France, Germany, Spain "India" (for Persian Gulf, etc.) and Africa; while to America and Australia the increase is by no means equal to expectations. To Russia the direct shipments compare as follows:—

1899	3,949,740 lb.
1898	2,714,003 ,,
Increase	1,235,737 lb.

It is said that if a larger quantity of tea had been sold in Colombo, more would have gone to Russia; but it must be remembered that 37½ million lb. were offered in Colombo in 1899, of which only 31 million were sold; and as shown, only 26 million sent to other countries than the United Kingdom. Let us hope that 1900 may show a much better result, more especially in regard to America and the Continent of Europe. The Chamber's comparison is as follows:—

EXPORTS OF CEYLON TEA TO OTHER COUNTRIES,

	January 1st to December 31st, 1899.			
	1899. lb.	1898. lb.	Increase lb.	Decrease lb.
Austria	8,321	14,873	—	6,642
Belgium	14,424	13,590	834	—
France	98,952	100,001	—	1,049
Germany	346,959	352,252	—	5,293
Holland	30,211	26,351	3,860	—
Italy	13,521	6,730	6,791	—
Russia	3,949,740	2,714,003	1,235,737	—
Spain	18,700	44,650	—	25,950
Sweden	78,088	42,471	35,617	—
Turkey	18,733	73,974	—	55,241
India	567,616	1,091,559	—	523,943
Australia	15,606,833	15,126,891	479,942	—
America	3,080,002	2,180,188	899,814	—
Africa	288,239	372,242	—	84,003
China	1,384,490	1,185,445	199,045	—
Singapore	83,813	59,867	23,946	—
Mauritius	100,248	33,299	66,949	—
Malta	257,232	196,852	60,380	—
Total	25,946,032	23,635,238	3,012,915	702,121
Increase			3,012,915 lb.	
Deduct Decrease			702,121 ,,	
Net Increase			2,310,794 lb.	

Referring to past year's estimates and results, we take over the following from our

Handbook and Directory as of interest at this time:—

CEYLON TEA EXPORTS.

	Estimated by Planters' Association. lb.	Estimated by Messrs. Forbes & Walker. lb.	Exports as per Chamber of Commerce Re- turns. lb.	Exports ac- cording to Customs Returns. lb.
1899	125,000,000	125,000,000	129,894,156	—
1898	120,000,000	124,000,000	119,769,071	122,113,573
1897	119,000,000	120,000,000	110,054,567	114,466,318
1896	101,000,000	105,000,000	108,141,412	110,095,358
1895	90,900,000	89,000,000	97,939,871	98,581,060
1894	88,000,000	90,000,000	84,591,714	85,376,322
1893	77,000,000	78,000,000	84,406,064	82,269,353
"Observer" Office Estimates.				
1892	80,000,000*		71,153,657	72,279,984
1891	68,000,000		68,274,429	67,719,371
1890	46,500,000		46,901,554	45,799,512
1889	32,000,000		34,048,065	34,345,859

It may be explained that the Customs enter the exports as each shipment is put on board a vessel in the harbour: while the Chamber only takes cognizance of the vessels and cargoes as they clear from the port.

A NEW INDUSTRY.

A Cityman writes under date London, 15th December:—"Talking to a man down Mincing Lane, with whom I have been connected in the Indian Bird, Bristle and Cow Tail Hair trades, for a good many years, the idea struck me that perhaps Ceylon might find it to her interest to do a trade in these articles. So I send you a report of each to show the prices realised at the last sales. The Bristle report is hardly a fair one as it does not give any description, but I can say Bristles are now selling very high. They must be stiff, and well washed, the different lengths tied up in bundles with strings of about 1½ to 2 inches in diameter. It is a large trade and pays well as the demand for fine Bristles exceeds the supply. They come over in cases of about 100 lb. Cow Tail Hair is sent press packed in bales of 3,400 lb. Anyone wanting to see if they can do anything with these articles, had better send a sample per sample post, which I will get valued free of charge with pleasure; then they send a small trial shipment, if the valuation seems satisfactory. In this way no one can lose much even if the experiment does not pay." The report is as follows:—

"I enclose Hale and Son's, Bird and Bristle report of prices obtained at public sale for these articles from India and elsewhere. Could not your people do something in these lines to their advantage? Cow Tail Hair well washed and free of skin sells at 10d lb. which I believe leaves the Indian trader a large profit, as they were content with 5d not long ago. If your readers want any further information I shall be pleased to send it, and will get any samples they care to send, valued and reported on free of charge."

* Planters and merchants whom we consulted were greatly out in their anticipations for 1892: in consequence of the very large increase of 22 million lb. between 1890 and 1891, it was felt to be quite safe to put on another in case of 12 million between 1891 and 1892: but the result only showed 4½ million lb. of increase by the Customs figures.

TO ALL PARTS OF ASIA, AFRICA, AMERICA AND OCEANIA.

Seeds & Plants of Commercial Products.

Castilloa Elastica Cervantes.—Orders being booked for the coming crop of seeds available in March and April, selected seed from very old trees. R. N. Lyne, Esq., Director of Agriculture, Zanzibar, writes under date 24th August, 1899:—"Please send me 200 seeds of *Castilloa Elastica* for further trial; the seeds of *Castilloa* you sent me last August germinated very well." Price and particulars in our Circular No. 32; special quotations for large orders according to quantity; immediate booking necessary to avoid disappointment.

Hybridised Maragogipe Coffee.—A large-beaned superior variety of Coffee in demand; orders booked for the coming crop of seeds, February and March delivery. Price according to quantity on application.

Hevea Brasiliensis (Para Rubber).—Orders being booked for the coming crop available in August and September, 1900. This is the only crop of seeds in the year. All orders should reach us before the end of July to avoid disappointment, as we have to make arrangements in time; guaranteed to arrive in good order at destination. We have already booked a large number of orders. A Sumatra Planter writes, dated 9th March, 1899:—"I consent to the price of £——per thousand. I herewith order 50,000 upon condition that you guarantee at least 33 % seeds germinating." Plants can be forwarded all the year round in Wardian cases. Price and particulars as per our Circular No. 30. A Borneo planter writes dated, Sandakan, 17th August, 1899:—"The last lot of Para seeds turned out very well."

Ficus Elastica (Assam and Java Rubber).—Seeds supplied by the pound with instructions; price according to quantity. This tree grows equally well in high and low land, in forest and grass land, its cultivation being extended largely by the Indian Government. For price of seeds with particulars as per our Circular No. 33.

Manihot Glaziovii (Ceara or Manicoba Rubber).—Fresh seeds available all the year round; price as per our Circular No. 31. It is superior to Mangabaira rubber and second to Para rubber.

Urceola Esculenta (Burma Rubber) and **Landolphia Kirkii** (Mozambique Rubber).—Seeds and plants, both are creepers.

Cinchona Seeds.—Different varieties.

Sterculia Acuminata.—(Kolanut). Superior quality, seeds and plants; price on application, packed to stand the transit well for several months, a hardy tree, cultivation easy.

Erythrina Lithosperma.—Thornless variety, new crops of seeds ready in December, May and June. Price according to quantity on application.

Seeds and Plants of Cinnamon, Nutmeg, Clove, Sandlewood, Pepper, Cardamom, Vanilla, Arabian, Liberian and Maragogipe Coffee, Cacao, Tea, Coca, Fibre, Medicinal and Fruit Trees, Shade and Timber Trees, Eucalyptus various varieties, also Palms, Bulbs, Orchids, &c.

Our enlarged Descriptive Price List of Tropical Seeds and Plants of Commercial Products for Foreign Countries for 1899-1900 are now being forwarded to applicants in different parts of the world. Also Descriptive Price Lists of Seeds and Plants of Fruit Trees, Bulbs, Tubers and Yams, and Orchids.

"**SOUTH AFRICA.**"—The great authority on South African affairs of 25th March, 1899, says:—"An interesting Catalogue reaches us from the East. It is issued by William Brothers, Tropical Seed Merchants, of Henaratgoda, Ceylon, and schedules all the useful and beautiful plants which will thrive in tropical and semi-tropical regions. We fancy Messrs. Williams should do good business, for now that the great Powers have grabbed all the waste places of the earth, they must turn to and prove that they were worth the grabbing. We recommend the great Powers and Concessionaries under them to go to William Brothers."

A leading Planter writes from *New Hebrides* under date 17th January, 1899:—"I shall like a few more of your Catalogues to distribute through these Islands, as I feel sure many would place themselves in communication with you, did they know where to write for Seeds and Plants."

Our New Descriptive Price Lists of Seeds of Shade Trees for Coffee, Cacao, Tea, Cardamoms, &c.; Timber Trees, Trees for Avenues, Hedges Wind and Shelter Belts, Ornamental Trees, Shrubs and Climbing Plants; and Seeds and Plants of Palms, Calamus, Pandanus, Cycads, Tree and other Ferns, Crotons and Dracinas, now being prepared and will be ready shortly.

Agents in London:—MESSRS. P. W. WOOLLEY & Co., 33, Basinghall Street.

Agent in Colombo, Ceylon:—E. B. CREAMY, Esq.

THE HEAVIEST-YIELDING TEA PLANTATION IN CEYLON—IF NOT IN THE WORLD?

Mariawatte plantation near Gampola—opened originally in tea by the late Mr. David Reid with Messrs. Rutherford, Tod and Mackay as partners and now owned by the Ceylon Tea Plantation Company, Limited—has brought much credit to the Tea Enterprise of Ceylon as well as much profit to its fortunate proprietors. It covers a considerable portion of the site of Royal Gardens belonging to the Kandyan Kings, which came into possession of the Byrde family, and by them was cultivated by coffee, but never with much success. This is explained by the easy undulating, almost flat, character of most of the fields, which does not at all suit a fruit crop like coffee; while tea revels in flats where the soil is fairly good or well-manured. In the assets of the late firm of Messrs. Byrde & Co., the Gampola lands were put down for a mere trifle, so little did the experienced coffee planting valuers anticipate that they would ever include the richest tea plantation in Ceylon. But such a few years later proved to be the case, and it will be seen from the interesting return appended—which we owe to the Company's Manager—that tea reaching now to 20 years old shows no sign of falling off, but rather gave an increase of crop during the past year. Mariawatte began to be a show-place for visitors interested in tea about 1885-1888, and we can recall Assam proprietors (of whom we had many calling in those days) declaring to us, after an inspection of the estate and of other upcountry places, that they were quite satisfied *tea could not last in Ceylon*—that 8 or 10 years more would see both the bushes and the soil exhausted! Twelve and fourteen years have already passed and yet Mariawatte continues to flourish exceedingly; while we have heard of no abatement of vigour in the tea of Looecondura, Hewaheta, which includes one of the oldest fields in regular cultivation in Ceylon, namely 30 to 32 years of age. This is very satisfactory in reference to the permanence of the industry, which, indeed, is based on a shrub, regarded by the Kandyans as a regular jungle plant, and not a temporary visitor like coffee. Meantime here is the return which has just come to hand and which will, as usual, be embodied in our *Handbook*—

CACAO AND THE AGRICULTURAL SOCIETY OF TRINIDAD.

Botanical Department, Trinidad.
E. Tripp, Esq., Secretary, Agricultural Society, Port of Spain.

Sir.—I beg to forward herewith a report upon a portion of diseased Cacao recently forwarded to this Department by a prominent planter, who reports that many trees are affected.

The Fungus now reported upon is quite distinct from those formerly described as *phytophthora omnivora* and *nectria bainii*—but is a species of the latter genus, which is thought to be identical with that attacking the Cacao trees in Ceylon.

The treatment recommended by Mr. Massee is simple and I would strongly urge that it should be followed by our planters wherever the disease is seen. I should be glad to have the report laid before the Society.—I am, yours truly, J. H. HART, F.L.S.

DISEASED CACAO BARK FROM TRINIDAD.

The bark is killed by a parasitic fungus, a species of *Nectria*. The sketch in the letter that accompanied the bark represents the conidial-Fusarium-stage, and the densely clustered, bright red spots on the outside of the bark are the ascigerous condition. These latter, which appear after the conidial stage, had probably developed during the journey.

The symptoms appear to be absolutely identical with the Cacao disease in Ceylon, but as no scientific report has yet appeared, it is impossible to state whether the West Indian *Nectria* is specifically identical with the one causing damage in Ceylon.

Damp, stuffy, conditions favour the disease, and as *Nectrias* are wound fungi, care should be taken to minimise the number of bark wounds.

Cut out diseased portions and wash the wound with corrosive sublimate in methylated spirit, afterwards cover with tar or other suitable material. The conidial form which appears under the form of small white patches, should be sought for, and destroyed as above.
G. M.

2-11-99.

The above is—Mr. Massee's report.

Received from Director Royal Gardens Kew, November 29th, 1899.

J. H. H.

(Port-of-Spain Gazette, Dec. 7, 1899.)

CORROSIVE SUBLIMATE FOR CACAO BARK DISEASES.

TO THE EDITOR OF THE PORT-OF-SPAIN "GAZETTE."
Sir,—Mr. Massee's report accompanying Mr. Hart's letter, published by Mr. Tripp in today's *Gazette* will be read and welcomed by the cacao proprietors of Trinidad.

It is satisfactory to know, on the authority of Kew Gardens, to which we owe so much, that the cacao-bark disease is due to the parasitic fungus "*nectria*" and that corrosive sublimate will eradicate it, and planters will gladly turn to the remedy.

It is well, however, that directions should be given for the use of such a powerful disinfectant and poison; and pending such directions from the Botanical authorities, it should be generally known that corrosive sublimate corrodes metals, and can only be used in glass, porcelain, or vulcanite vessels—In solu-

tion, one in 1,000,000 will hinder the growth of anthrax bacilli, while one grain in five gallons of water will entirely prevent their growth. A solution of one in 500 is irritating to hands and skin, and probably one in 5,000 is quite strong enough for ordinary solutions.

—I am, Sir, Your Obedient Servant.

FITZGERALD PROCTOR, M.R.C.S., England.
Port-of-Spain, Dec. 6th, 1899.

TEA CORPORATION LIMITED (OF CEYLON.)

The annual general meeting of the Tea Corporation, Limited (of Ceylon), was held at Winchester House, Old Broad-street, on Tuesday, the chairman (Mr. Cyril Gurney) presiding.

The SECRETARY (Mr. E. T. Bartlett) having read the notice convening the meeting,

The CHAIRMAN said: Gentlemen, you have all received the accounts for the year ended June 30 last, and I think that I shall best explain the results of the year's working by going shortly through them. With regard to the working account, you will see that the gross amount of tea produced on our estates for the year under review was 1,231,442 lb. This was by no means so large a crop as we had hoped to secure, the shortage being mainly due to the long drought and subsequent exceptionally heavy rains which greatly interfered with the cultivation in the latter part of the year; it is satisfactory, however, to find that we have an increase of quite 100,000 lb. on the crop of the previous year. With regard to the price the tea sold for—it fetched an average of 6½d. per pound gross, or just under 6d. per pound net, after deducting all the usual expenses, which amounted to less than 1d. per pound. The net price of just under 6d. was a great improvement on the previous year, and we are pleased to be able to say that we have—after much trouble—been successful in effecting a great change for the better in the quality and make of the tea. As you will have seen from the report, Mr. Tatham hopes to show a further improvement in quality this year, from being able to pluck finer, while at the same time increasing the quantity; we hope, therefore, with favourable markets, to show a continued improvement this year in the price our tea fetches. With regard to this I should like to emphasise what has already been referred to in the report—viz., the increased return that may be looked for as the result of manuring. As soon as your directors got possession of the estates they instructed Mr. Tatham to apply manure where it was most needed, and though this is, of course, responsible to some extent for the improved quality of the tea plucked this year, we have not yet experienced the full benefit of this expenditure. During the year covered by these accounts we have spent a considerable sum in manuring other parts of the estates, the results of which will continue to be felt for the next two or three years. The whole of this expense has been charged to profit and loss account. The total profit carried to profit and loss account is £8,867 19s, from which must be deducted rent, office expenses, salaries, directors' and trustees' fees, &c., amounting to £1,057 4s 4d, also interest, £3,356 18s 8d, &c., leaving a balance of £4,327 1s 9d carried to the balance-sheet. With this sum we have written off the loss of last year, amounting to £1,620 6s, paid £1,950 preference interest, and propose to write off £393 9s, from preliminary expenses, carrying forward £363 6s 9d. With regard to the year beginning on June 30 last, we expect to obtain fully

1,250,000 lb. of tea. At present, in spite of bad pluckings in July and August, which was due to previous heavy rains, we have an increase on 1898-99 crop, and Mr. Tatham is quite sanguine that the estimate will be fully obtained—indeed, unless something unexpected happens there seems little doubt that we shall have an increase over last year. The cost of production is estimated a trifle higher than last year, but this includes a liberal expenditure for manure, which, as I have already said, your directors consider a profitable expenditure; but we have sent out instructions that every economy is to be exercised consistently with good cultivation and management. Sales of this year's tea during the last three months show that on an average a higher price has been obtained than in the same period of last year, though there has been no corresponding increase in the average price of Ceylon teas. In view of these figures, your directors have reason to take a much more hopeful view than they could this time last year, and think the shareholders may look forward to still better results being shown in the future. You will remember that at the last meeting we said that we hoped to be able to arrange for some reduction in our agents' charges; we are pleased to say both they and Mr. Tatham have agreed to a reduction of the terms upon which they undertook the business, which will decrease the expenditure in this and future years. I think our best thanks are due to Messrs. A. Gibbs and Sons, and our agents and manager in Ceylon, for their liberality in meeting us in this matter. With regard to the proposal to raise £20,000 additional debenture stock, we think that this would prove of great value to the company's property. I should like to explain, however, that we do not propose to raise the whole of this at once, and so increase the fixed charges of the company by £1,000 a year; but we think it is of great importance to the future of the company that their property should be fully developed. At present there is a considerable acreage, especially at Deteloya—about 800 acres—which is entirely unproductive. This, if planted up, would, we think, prove of considerable value to the company and add materially to the capital value of the estates, besides enhancing profits, which would benefit the shareholders. Mr. Hancock, who has lately returned from Ceylon, can give you further information with regard to this. If the shareholders respond, the directors are prepared to do their full share in subscribing for the money. You will probably remember that in the report last year, and also in the more recent circular which was sent to shareholders, mention was made of indications of valuable deposits of plumbago on some of the estates. We instructed our manager to take in hand prospecting on the estates which it was thought contained veins which it might prove profitable to work, with the result that on three estates plumbago was found. On one of these—viz., Nahaveena—the outturn was very small, and only paid the expenses of working it; but on the two others—viz., Springwood and Lauderdale—plumbago was found of good quality and in fair quantities. These estates were worked, and resulted in a profit of about £250 on an output of 35 tons. It is impossible, however, to go on working these veins without some capital expenditure. Your directors were approached by parties on the spot and by responsible people in London with a view to their leasing the mineral rights over the company's

estates. There was, however, considerable difficulty in arranging terms with the latter. The company who wished to lease the rights were, we are given to understand, prepared to lay out considerable sums in systematically developing plumbago on the various properties; but they naturally required a long lease of the mineral rights, so that they might have some chance of recouping themselves for their initial outlay. A lease of twenty-one years, with the option of renewal for another twenty-one years, was the period they required. I did not think your directors would be justified in leasing the mining rights of the company for so long a period without putting the matter before the shareholders. We, however, arranged a provisional agreement, by which this company would receive certain royalties on the gross output of the mines, which we were prepared to submit for the shareholder's approval. We have, however, lately received from Mr. Tatham advices that the main vein, consisting of very good plumbago, which was always believed to exist on Springwood Estate, had been found, and we therefore, told the company we had been in negotiation with, that in view of these later advices, we could not conscientiously recommend the shareholders to confirm the agreement we had provisionally made with them, and we asked them if they would give more liberal terms which we could put before you. They declined, however, to amend their offer, and the negotiations have therefore recently come to an end. We have every reason to believe that valuable veins of plumbago do exist on the Company's estate, which will prove a valuable asset. The question is, What is the best way of dealing with them? Having stated so much, we should like to take the sense of the meeting as to whether it would be advisable to lease the mining rights, or whether we should endeavour to work the veins ourselves. In conclusion, I should like to say that I think the thanks of the shareholders are due to Mr. Tatham for having so energetically carried out the wishes of the board, and he has constantly succeeded during the last year in much improving the position of the Company, and also Mr. Low, the manager of Springwood and Barra, to whom the discovery of the plumbago is mainly due. I beg to move the adoption of the report and accounts.

MR. E. H. HANCOCK seconded the motion. He said he was on the Springwood property in July last, where the plumbago was found. It was of good quality and indicated some larger veins in the neighbourhood. It would put this company, he thought, in a very different position in the future. Judging from the telegram just received, it should encourage them to work the plumbago themselves. There was always a certain amount of risk in mining, but at present this mine did not run very deep. It was only 60 ft. from the surface when he was there. The only thing that prevented their working it very much quicker was that they had no pumps, and were baling out in buckets. It had never been worked scientifically at all, but he thought that after a little outlay by making a moderately deep shaft and erecting pumps they could keep it free from water and that such a valuable vein they had better work themselves. He did not think that plumbago had ever been scientifically mined in Ceylon. There was only one place he knew of where they were attempting to do it and that was upon one of Lipton's estates; but what they were doing he

did not know, because Liptons kept the matter very quiet. He believed they had spent a lot of money, but he did not know the return. With regard to the other estate in the neighbourhood, Landerdale, the indications there of plumbago were the best he had ever seen anywhere, and he had no doubt they would find a good and valuable vein. Seeing that they had this good vein, he had come to the conclusion that they ought to work it themselves, and not to part with it unless they could get a very tempting offer. The chairman had said that Doteloya they had about 800 acres. He did not say that all that would be valuable for planting out, but he had no doubt they could pick out some 600 acres. If they were to plant that they could do it much cheaper than other people, because they had the labour on the spot, and could practically make a new estate of 600 acres at small expense, which would add considerably to the capital value of the company. It was virgin land, and they would have an estate of 600 acres adjoining their other estate, which would give them good value without using manure. There was no doubt that their proper course would be to open up that land, although he did say that they could do it all at once. They could do it, perhaps, at the rate of 200 acres per annum, according to the amount of labour they could spare from the other estate, and in a few years that land would place the Company in a very sound position.

MR. LEWENZ asked how many acres of the whole property were under cultivation.

THE CHAIRMAN: About 3,000.

MR. HANCOCK added that he was quite satisfied that on those estates where manure was required it paid. He had tested that.

The motion for the adoption of the report and accounts was then carried.

THE CHAIRMAN invited an expression of opinion as to the development of the plumbago—whether the shareholders were in favour of developing the property themselves or leasing it.

After a long discussion, in which Mr. Mozley, Mr. Lewenz, Mr. Shand, Mr. Preston, Mr. A Bull, and others joined,

THE CHAIRMAN said that for the last few days they had been getting it about half a ton a day. The average had been about £25 a ton. Of course, they had to take from that the cost of getting it out. For this year they had had to write off the loss of last year, and it was that that had handicapped them, otherwise they had earned sufficient to cover the whole of the preference interest. A certain amount of preference interest had been paid this year. As to the prospectus, they had made the tea very much at the same price as mentioned in the prospectus, and sold it at the same price, and the difference between the year's working and what the prospectus put forward was a fall of about 2d. in exchange. The difference in exchange had made a loss to this Company of £2,500.

On the motion of Mr. Foss, seconded by Mr. Preston, the following resolution was carried: "That the board be authorised to spend a sum not exceeding £500 upon working the plumbago, provided that they be advised by a mining expert that it is advisable to do so."

THE CHAIRMAN then moved: "That the board be authorised to issue, subject to the debenture trustees' consent, an additional amount of debenture stock, not exceeding £20,000."

MR. HANCOCK seconded the motion.

SIR C LAWSON submitted a direct negative: "That the board be not authorised to issue any more debenture stock."

Upon a show of hands, the motion of the Chairman was carried by 12 to 6.

The retiring directors (Mr. E H Hancock and Mr. T J Lawrence) having been re-elected, the auditors were reappointed.

A vote of thanks to Mr. F. Tham (the managing director in Ceylon) and to the agents (Messrs. Anthony Gibbs and Sons) terminated the proceedings.—*H. and C. Mail*, Dec. 22nd.

THE INDIAN TEA ASSOCIATION (LONDON.)

The following is an abstract of the proceedings of a meeting of the committee held on Tuesday, December 19th, 1899.

Present: Messrs. D Cruickshank (in the chair), C C McLeod, J Riddell, F A Roberts, A G Stanton, J N Stuart, W H Verrier, and S A Went.

The minutes of the last meeting, held on Tuesday, December 5th, were read by the Secretary and confirmed.

Correspondence with Calcutta, which been previously circulated to the members, was laid upon the table.

The revised estimates, showing available crop (140 millions for London) and also the quantity of tea entered for export to the United Kingdom, taken from the Calcutta Customs daily entries, for first half of December, 11,200,000 lb., against same period last year, 5,710,000 lb., making a total from April 1st, 1899, to December 15th, 1899, of 129,792,000 lb., compared with 116,757,000 lb. for same period last year were noted.

WAREHOUSE CHARGES.—The Secretary and Mr. McLeod reported having seen Mr. Poock, who was unable to say that any definite decision had been come to by the Tea Clearing House Committee. He had promised, however, to write to the Association as soon as it had been approved by the Chairman.

CONDITIONS OF SALES.—It was noted that a meeting had been fixed to take place this week between the buyers and Special Sub-Committee of India and Ceylon to discuss this question.

SCHEME FOR A DOCK TRUST FOR THE PORT OF LONDON.—A letter was read from the Secretary of the London Chamber of Commerce inviting the Association, in conjunction with the Ceylon Association and the Tea Buyers' Association, to nominate two members to jointly represent the tea trade on the sub-committee that has been formed to consider this question. It was decided to request the Chamber to allow a nominee to be appointed for each section.

WORK IN AMERICA.—A cheque was signed for £159 19s 11d, being remittance to New York in payment of India's share of advertising British grown teas in the United States for the month of November.

At the close of the meeting of the General Committee a meeting of the Paris Exhibition Committee was held to meet Mr. Langdale and a gentleman from the India Office, in order to discuss plans and arrangements for finishing the Indian Tea Courts in preparation for the opening of the Paris Exhibition on April 15th, 1900.

ERNEST TYE, Secretary.

—*Home & Colonial Mail*, Dec. 22nd.

PRODUCE AND PLANTING.

TEA IN THE UNITED STATES.—The imports of tea for the first ten months of 1899 were 63,913,718 lb., against 54,887,062 lb. for the same time in 1898, and 79,310,181 lb. in 1897. Of the total imports Japan

furnished 29,782,657 lb., or 43½ per cent.; China, 32,840,467 lb., or 47·8 per cent. of the total imports. From these figures it will be seen that British tea-growers have a big task if they are to displace China and Japan teas in the United States. In the first place, as the New York correspondent of the "Grocer" points out, Americans are not partial to the beverage, and probably because of climatic influences. In the next place, nine out of ten consumers care little for niceties of flavour, and are satisfied with a hot beverage so long as there is no objectionable feature. The Americans are yet to be educated up to an appreciation of fine flavour; and to some extent this is true of coffee.

THE RUSSIAN TEA EXPERIMENTS.—An expert points out with reference to the tea growing experiments in Russia that tea production there on a commercial basis is an impossibility. It cannot be produced in the Caucasus to sell at such a low figure in Russia as imported Indian and Ceylon teas do, even after paying the import duty of 1s 10½d per lb., which the local production entirely escapes. In addition to that fact there is no comparison in point of quality.

NEW FIBRE IN BRAZIL.—A correspondent of the "Jornal do Commercio," of Rio de Janeiro, draws attention to the fibre of the guaxima, which grows wild everywhere, but is found in large quantities on the low lands near the sea. It is believed that this fibre would prove an excellent substitute for jute, which is all imported, and when cultivated prove the basis of an important industry. The threads are long and very strong, and will resist the action of water, the fibre being used by fishermen on the coast for their nets, which last for years if soaked in a tincture of aroeira bark. The process of elaboration of the guaxima fibre does not require long maceration in vessels, as is the case with jute; immersion for a few days in running water being sufficient to loosen the green outer bark with the hands, after which the rods are exposed to the sun in order to dry the woody part; this then contracts and allows the fibres to be easily separated. A sample was to be sent to England to be spun and woven, and its uses and application thoroughly investigated.—*Home and Colonial Mail*, Dec. 22.

TEA IN AMERICA IN 1899 AND PROSPECTS.

—The correspondent of the London *Grocer*, writing from New York on November 29th, has the following rather discouraging deliverance in reference to our staple and its prospect of being more largely consumed:—

The imports of tea for the first ten months of 1899 were 63,913,718 lb., against 54,887,062 lb. for the same time in 1898, and 79,310,181 lb. in 1897. Of the total imports Japan furnished 29,782,657 lb., or 43½ per cent.; China, 32,840,467 lb., or 47·8 per cent. of the total imports. From these figures it will be seen that British tea-growers have a big task if they are to displace China and Japan teas in the United States. In the first place Americans are not partial to the beverage, and probably because of climatic influences. In the next place, nine out of ten consumers care little for niceties of flavour, and are satisfied with a hot beverage so long as there is no objectionable feature. The Americans are yet to be educated up to an appreciation of fine flavour; and to some extent this is true of coffee. It is a significant fact that in the older settled sections and wherever wealth abounds such articles are bought on their merits, while in the newer sections anything seems to go. New England pays the highest price for coffee; so do the Middle States; while the West and South are the large consumers of low-priced coffee. The great field for British growers of tea to exploit is in the large cities. The consumption of tea is about 95,000,000 lb. per annum, or 1·28 lb. *per capita*, that of beer 15 gallons, coffee 18·4 gallons.

A VISIT TO HAKGALA GARDENS.

(By a Newcomer.)

Such a visit must be always a treat to any lover of plants, and especially so when shown round by the courteous Superintendent. The weather on our visit was perfect: the sky cloudy to temper the sun, but no clouds over the vast Uva amphitheatre of hills except to wreath the Namunukula peak. The grassy platform in the Gardens, from which this view is obtained, has been enlarged and a fitting wooden pavilion built where visitors can sit to a table to partake of their refreshment in face of the panorama—thanks to Mr. Nock's thoughtful attention.

Among the plants there is a new species of lily which Mr. Nock has named after Lady Ridgeway: the flower is cream coloured. The wedding flower ("Morea Robinsonia" after Lady Robinson), has been, I regret to learn, nearly eaten out by porcupines. The fern, of which the natives make a curry, is interesting economically and the successful growth of the "selaginella," picked up near Horton Plains, is interesting to Botanists. The new scientifically arranged plots, when fully carried out, will afford further interest. I need not refer to the gratification afforded by a walk under the giant pines, eucalypts and "cupressus" and amongst the 30,000 plants of all degrees from the lycopodiums to the tree ferns, among which that peculiar to Ceylon (*Alsophylla crinita*) still is queen. On account of climate as well as interesting and beautiful surroundings, surely nowhere in Ceylon is a walk more enjoyable than in the Hakgala Gardens under the magnificent masses of rocky cliff towering 2,000 feet above the visitors. Long may Mr. Nock live, to superintend and preside over Hakgala!

[Mr. Nock, we suspect, will sympathise with the young lady—was it Miss Canning?—who, helping her brother to canvass the electors of Liverpool, so won their regard, that they all shouted as she appeared on the hustings:—"Miss Canning for ever"—only, however, to be answered with a smile and a bow,—“No thank you—I don't want to be *Miss Canning* for ever"! So, our correspondent must know that Mr. Nock can scarcely desire to be at Hakgala for ever, unless, indeed, his good services are recognised by a corresponding increment of salary.—ED. T.A.]

TEA PLANTING AND LABOUR PROSPECTS.

ONE of the most competent authorities in the island writes to us:—

"Tea has been doing wonderfully well in the last few months and blights have all but disappeared. They will be showing up again, however, when the dry weather sets in unless the manure which has been freely applied of late keeps them in check. Heavy manuring is all very well if one can be certain of the necessary labour to reap the benefits thereof, but risky otherwise and there is a feeling that with so much Railway Construction on hand coolies may become scarce. Advances are already rising."

With two or three millions of people suffering from famine in India, it does seem

strange that there should be any scarcity of labour in Ceylon. The time has surely come for opening fresh districts of supply, and it is possible that the pioneers in this direction would not only benefit themselves, but local industry generally. The Railway contractors (including the Government) will certainly be bound to do something in this direction.

TEA IN AMERICA.

New York, Jan. 6.

It will be noted that last month's deliveries are up to the normal consumptive requirements of the country, being on a basis of 100,000,000 pounds annual consumption. There is not much life to invoice trading, Jobbing demand fair. Market steady. The following table shows, among other items, the stock of tea on hand in the United States on June 1st, 1899, and the estimated stock on June 1st, 1900, together with the amount of visible supply on December 1st, 1899, and the total tea exports from China, Japan, Ceylon and India to North America during the season of 1899-1900:—

	Pounds.
Stock of tea on hand in the United States on the 1st of June, 1899	28,200,000
Estimated total export from all China, Japan and Ceylon and India season 1899-1900, to North America	
Green tea	15,000,000
Japan	42,000,000
Formosa	15,000,000
Foochow and Amoy	4,500,000
Congou, Shanghai	5,500,000
Congou, Foochow	5,500,000
India and Ceylon	12,000,000
	99,500,000
Withdrawals, June to Oct. 31.	36,935,456
Withdrawals, est., for November	8,064,544
	44,000,000
	83,700,000
Deduct direct shipments to Canada	22,000,000
Deduct re-exports and rejections	1,700,000
	23,700,000
Visible supply for United States, December 1st. 1899	60,000,000
Six months' consumption to June 1st, 1900, at 7,000,000 pounds per month, estimated	42,000,000
Stock of tea in the United States June 1, 1900, estimated	18,000,000
— <i>American Grocer</i> , Dec. 6.	

A COFFEE-PLANTING CONTRACTOR on a plantation near Jaboticabal, São Paulo, met with a very disheartening experience a few days ago. He had managed to save 6,000\$, which he deposited in a glass jar and then concealed it in the chimney of an unused stove in his house. One day while he was out in the fields, a black woman from a neighboring house asked his wife for permission to use the stove to make soap, and with the result that when the husband returned he found his precious savings in ashes. It was hard luck, but he should have found a better savings bank.—*Rio News*.

Correspondence.

*To the Editor.*MEXICO AND ITS PRODUCTS BY A
CEYLON PLANTER: CACAO; RUBBER;
SUGAR AND COFFEE.

TABASCO, MEXICO.

DEAR SIR,—As promised you some months ago, I now send you a general description of this part of Mexico and its products. From San Juan Bautista, the principal trading town and Port for this district, to the Grijalva Coy.'s land, some 45 leagues, the land is chiefly level and slightly rolling with a very deep loam soil and there are many very fine cacao and sugar plantations to be seen along the road, owned by Mexicans and Spaniards and some few rubber plantations of small size also. The states of Tabasco and Chiapas are noted as being the home of cacao—"theobroma cacao"—the soil and climate being particularly adapted to its culture and I have found many trees growing wild and bearing a good crop in this land. The local method of planting is to clear the land, plant the cacao madre 20 by 15 feet or thereabouts and maize the first year, and the second year, or so soon as the shade from the madre is sufficient to plant cacao plants 15 feet apart between the row of madre. The only cultivation it then gets is two weedings a year with machetes and the greater part of the year there is a heavy carpet of weeds three feet high, which shuts out all ventilation and in consequence there is great deal of moss on the cacao trees. The cacao bears in five years, and the pods are gathered in the roughest manner, being torn off the tree by a blunt hook or forked pole generally destroying the eye at base of stalk and consequently much future blossom. The shrub is never pruned, but notwithstanding all this, it bears good and paying crops, about 50 pods per tree. Of course, there are some few plantations where better care is taken and on these the yield is larger: on some trees in the district of Macuspana 200 pods have been gathered from trees.

The cost of land, clearing, planting and weeding for five years, if properly done, is about \$200 (two hundred dollars silver) say £20 for each hectare (2½ acres). The cost of gathering, curing and sacking the crop is about \$4.00 (four dollars) per carga (60 lb.) say 4,500 to 5,000 lb. per hectare; value of crop on the plantation 40 cents per pound leaving a net profit of some \$1,250 to \$1,500 per hectare. Besides this, vanilla can be grown on same land as a side crop which makes quite an addition to the profits.

RUBBER (*CASTILLOA ELASTICA*), like cacao, is indigenous to the soil and is found growing wild here and when cultivated there is no more profitable tropical product or one so easily and cheaply produced; and some attention is now being paid to its cultivation by Mexicans and Americans. It may be planted in the open clearing or under shade: it appears to thrive and grow equally well, under both conditions. Seed may be planted at stake, plants, or stumps, all have done equally well, planted by me. The cheapest way to form a plantation is to clear out the underbrush and any decaying trees likely to fall, and plant through the jungle 12 ft. apart. Another way is

to clear and burn off and then sow maize, planting rubber seed at stake 12 by 12 or 15 by 15 ft. Maize can be grown for two years making four crops which will pay for keeping the land clear. A plantation of 100,000 rubber trees so planted will cost at end of five years, including price of land, some \$15,000 or \$16,000—say £1,600. The fifth year a tree here, if properly taken care of and properly tapped, will yield from five to six lb. of juice equal to two lb.: pure rubber which at \$1 per pound is worth at least \$200,000 from 100,000 trees. I have seen trees that have been tapped for 20 years still yielding and the tapping had been done most barbarously. The cost of upkeep and production is small: one man will tap 20 trees per day. The juice is then put in a barrel and a solution of five oz. of sub-carbonate of sodium in water sufficient to cover the whole mass, which is churned up with a paddle every once in a while, and after 36 hours the water is run off: this is repeated until the rubber becomes white. This certainly is the enterprise for the small capitalist in Mexico.

SUGAR CANE.—There are many fine plantations on this river. The yield on some is 60 tons per acre. I have seen some cane-fields which I was assured by their owners were 35 years old, still yielding handsome returns, and they had had little or no cultivation all those years. From the best information I can get the average yielding here about is 50 tons cane per acre, which yields 70 per cent. juice in cane, 15 per cent. of sugar in juice, besides the molasses which is made into rum, white sugar is worth eight cents. per pound, molasses one cent per pound. 750 lb. molasses make one barrel rum worth \$10. So that taking the product at only 45 tons per acre and upkeep and expenses of making sugar and rum at \$20,000 for 100 acres, it leaves a profit of some \$36,000 per 100 acres. The cost of machinery is considerable and for that reason the small capitalist cannot enter the field as he can in rubber and cacao.

COFFEE produces heavily and there is no leaf disease, or any other so far as I can see. There are also many other products that can be grown with profit, as side crops on cacao or rubber plantations; but I will not enter into them in this letter, as I feel I have already trespassed too much on your valuable space.—Yours very truly,

E. O. DARLEY.

CEYLON GREEN TEAS.

Toronto, Dec. 8.

DEAR SIR,—We note your comments in reference to our letter to you, in the weekly issue of the *Overland Observer* of Nov. 6th; and we beg to say that Ceylon is exporting Green Teas today, we have them on hand, we have sold a considerable lot, and we have more close to hand and still more on order for regular shipments from Messrs. Whittall & Co., of Colombo, who will be glad to give you any information, we have no doubt, about what is being exported in Ceylon Green Teas.

We believe there is a big market here for those teas, otherwise we would not have commenced a campaign in their favor. We believe the Ceylon Greens are well-worthy of the planters' attention.—Yours truly,

P. C. LARKIN & Co,

SPURIOUS OR WILD CINNAMON.

Colombo, Jan. 6.

SIR,—In support of the action originally undertaken by the Chamber of Commerce, I beg to enclose copy of letter from Messrs. Darley, Butler & Co. to the London Produce Brokers' Association. At foot of letter I append particulars of the result of effort to sell the wild cinnamon shipped.—Yours, &c.,

R. W. NUNN,—Secretary.

RESULTS OF SALE REFERRED TO.

2,280 bales offered, none sold, stuff valued before sale at 4d to 5½d per lb., vainly sought buyers after at 2½d. Principal marks offered were:—

H. M. S. & Co.	... 325 bales
D. B. C.	... 920 "
M. D. J.	... 214 "
M. A. K., D. S. S. and U. L. M.	

Later news quotes ½d per lb. offered for some of the above.

The Chairman, General Produce Brokers' Association of London, Commercial Sale Room.

SPURIOUS OR WILD CINNAMON.

London, Dec. 1st, 1899.

DEAR SIR,—As importers of Ceylon Cinnamon we wish to call the attention of the General Produce Brokers' Association of London to the importation of various kinds of bark not in fact cinnamon under the classification of cinnamon, and to ask that the Association will, if possible, take up the matter with a view to preventing such bark, whether imported as quills in bales or as chips in bags being included in the imports, deliveries and stocks of cinnamon and cinnamon chips.

There is no doubt that the shipments of this spurious cinnamon from Colombo have done much injury to the trader in genuine cinnamon, and we commend the following facts to your consideration:—

(a) It is estimated that some 3,000 bales of quills of spurious cinnamon have been shipped from Colombo during the present year, the bulk of which has come to London and appears in the imports of cinnamon; probably the bulk at the present time remaining in stock.

(b) Though some of the barks so shipped as cinnamon are of a genus belonging to the same family (Lauraceae or laurel family) as genuine cinnamon, they are not of the same genus making them in fact quite distinct from genuine cinnamon, while some belong to an entirely different family altogether—in the one case the difference in genus differentiates the bark entirely from genuine cinnamon, in the other there is no connection at all.

(c) The use of such bark, if it is used at all, must be for the purpose of adulteration. In this connection we would ask you to ascertain from those who are selling this spurious cinnamon the relative value compared with genuine cinnamon. In order to give you all the information we can, on the subject we enclose herewith:—

(1) Copies of correspondence in Ceylon including a report from Mr. A. Schulze to the Chamber of Commerce.

(2) Letter from the Secretary, H. M. Customs, to the Secretary of the Ceylon Association in London, in reference to action which the Customs' authorities may take here.

We are indebted to the Secretary of the Ceylon Association in London, for these documents, and are assured of the support of the Association in any steps that it may be desirable to take to protect the Cinnamon Trade of Ceylon.—We are, &c.

DARLEY & BUTLER,

CACAO CULTURE AND DISEASE:
PRICES AND PROSPECTS.

LONDON, Dec. 22, 1899.

DEAR SIR,—I enclose two cuttings out of the "Port of Spain Gazette" (Trinidad, W.I.) re diseased cacao bark from which the Trinidad planters seem to be having a good deal of trouble just now. As the remedy seems highly poisonous, I consider Dr Proctor's (who is also a cacao planter) letter very *expos.** If, as Mr. Masee says, the disease is caused by damp, stuffy conditions, this strengthens my idea that many people grow their cacao under much too damp circumstances; under the idea that the damp humid banks of the Brazilian rivers are the habitat of the original trees, many seem to think cacao cannot be too damp and hot. It is a great mistake, which, however, the Ceylon planters seem fully alive to. I also enclose my notes on the London Cocoa Market.

One of my cacao planting friends in Trinidad writes me that, judging from all the estates he has visited, there will be practically no cocoa about for Christmas; except, perhaps, a little, small proprietors scrape together; the promising pcds that were coming on a little time back having turned black. Another reliable authority bears this out by saying he does not expect London will see any appreciable quantity of Trinidad cocoa until the middle or end of February, so evidently the crop will be a full month late." The weather, when the mail left was showery and generally more promising for agriculturists.

The Government not being buyers, no sales were held last week, and I don't think we should have had any this week, but for the desire of one broker to realise some cocoa belonging to a Guayaquil house who is in difficulties; but prices are firm to 1s higher all round, and considering it is Christmas week, it has been a busy one.

Privately a fair quantity of Ceylons have been sold, anything at all decent being quickly taken up, and even inferior stuff sells better. Prices privately have ranged from 63s 6d to 68s for common to fair native, up to 76s for good red. Fine red still commands fancy rates, and at this week's sale some good bold, rather dark break sold at 85s, good small 60s to 65s, and fair red 75s, 73 bags good dull red Java, very whitish in break also fetched 85s, which I consider a high price. There is no doubt any falling-off in production this year, which in the face of 1899's bumper crops, is not unlikely, will cause some excitement among buyers, especially if the war continues, and the Government are steady buyers, which seems likely to be, for I see by the press, every soldier carries 4oz. cocoa paste as "emergency rations," besides what is given out in lieu of tea and coffee.—Yours truly,

H. H. S.

WILD OR SPURIOUS CINNAMON.—With reference to the correspondence in the other column sent us by the Chamber of Commerce, surely no one, after this exposure of the pecuniary as well as intrinsic value of the stuff shipped as wild cinnamon, will repeat the operation? We suppose 2d a lb. is required to cover cost of shipping, freight, charges, &c.—so that to get only ½d must mean a heavy loss. Such a trade should surely die out at once?

* See page 478.—ED. T. A.

BANDA NUTMEGS AND MACE.

BY O. KAMERLINGH ONNES.

BEING AN ACCOUNT OF THEIR HISTORY, CULTIVATION, TRADE AND USE.

(Compiled with the aid of data placed at our disposal by the Crediet-en Handelsvereeniging "Banda" Amsterdam.)

I. HISTORY.

INTRODUCTION.

Oh, it will not take you long, we do not ask many hours to bring the gracious reader out to the Moluccan Archipelago 300 years back, and ship him safely home instanter.

We perfectly understand any man's eagerness to use his time well, and we won't make him grumble. So any one even in the busiest moment of his life, may feel safe and commence to read.

But he must bear in mind one thing. He should be fully aware that he has to know somewhat more about Banda produce than he knows just at present, in order that he may pass the rest of his days all the happier for it.

For whoever, clearly realizing that he may have in great abundance at penny price what others longed for, wrote poetry on and even shed blood for, what man would he be that, remembering the *History of Spices* and, enjoying exquisite dishes, should not feel happy that he lives in the present time?

In fact though we admit the possibility of any type, there is no such man, and whilst we agree with the rest, let them agree with us and give their best and kind attention to what we have to say about Banda nutmegs and mace.

* *

300 YEARS BACK IN HOT HASTE.

Spices had come to Europe long before the Dutch dared to open a direct trade with the Indies. We do not know exactly how many years it is since the trade of spices commenced, but we may take it that the Arabs were amongst the first to value nutmegs and mace either at the beginning or near the middle of the Ninth Century. Their learned doctors mention them. History even goes so far as to show that one of them Ibn Amran, highly esteeming the *Nux Moschata* for its medicinal properties, loses his head by a too liberal use of his spice-box.

Some hundred years later we find the *Karoun Aromatikon* having made its way into the pharmacopoeia of Europe, and since then it soon spread over different markets. Its price remains excessively high on account of the charges incurred by the route used in those days for all Indian produce.

Carried from the Moluccas to Aden, crossing the desert land-route and following the Nile down to Alexandria, it is easily understood that heavy charges enhanced the price of a product which had to change hands so often before it could so much as reach one of the European gates of Eastern trade, whilst these themselves were

not at all reluctant to make money out of every open door monopoly, which by chance or cunning had fallen into their hands.

About 1400 Genoa and Barcelona are the principal markets for spices. But the attention of the North of Europe as well has been directed—though on a lesser scale—to those far-away countries, visited by Marco Polo. Others follow him, describing the marvels of their visits to Asia, in colours to bewitch even the most sceptic. A rage for spices springs up in Europe and continues through the century.* Direct shipping trade with India begins here.

To the Portuguese falls the honour of having first traded into the Far East. In 1511 Albuquerque visited Banda. A few years later the Spaniards under Charles V. went out to the Moluccan Archipelago. The interests of the two nationalities collide. Then follows war, which ceases however for the moment, when the Spice Islands are sold by the Spaniards to Portugal. Columbus discovers the New World and the Holy Father settles everything in peace, reserving the West to the Spaniards and the East to the Portuguese. Under the reign of Philip Portugal being united with Spain, the world might have come to peace for ever, but for the excluded North interposing its veto. The rage for spices kindles a fire which will last for centuries, dividing Europe and bringing war as well here as in the unhappy Indian territory, endowed by Nature with the trees that bear gold.†

Profit had been heaped up, and continued pouring into the lap of the daring Portuguese and Spaniards, but profit won so freely, soon called opponents into the field. Rivalry, the ever watchful stimulus of trade had opened the eyes of the North. Yet what most of all caused these Nations, especially the Dutch, to compete with the Portuguese and Spaniards in India, was the unlucky move by which the latter closed Lisbon against the Dutch mercantile navy.

Seeing its usual store of supply cut off and its second-hand profit endangered, Dutch Commerce took the alarm and at once made efforts to meet its opponents on an equality.

In 1595 the first Dutch vessels are sent out under Corn. Houtman, to trace the unknown path to India, risking their poor ships round the Cape of Good Hope. Their enterprise is crowned with success. Corn. v. Neck, Warwyk, and v. d. Hagen, follow. In 1599 Banda is visited by Jacob Heemskerck.

The *Oost-Indische Compagnie* famous for its rapid development and unprecedented display, commences its operations in Indian Waters. Soon the love of monopoly excludes all others from the field of commerce. India like Europe is disturbed by war amongst the Nations, trading in those days sword in hand and the guns loaded on board their merchant-ships.

In the Moluccan Archipelago the foes of the Hollanders generally make common cause with the natives, who are shut out from the profitable trade of spices themselves. This constant struggle however does not disturb the Company's sphere of influence, on the contrary it leads to a

* St. Johns.

† Lans.

permanent form of administration, which reaches its highest pinnacle when Coen, one of the boldest and most clear sighted governors that ever served the Company's cause in the East Indies, proclaims Batavia the centre of the Dutch forces.

Holland had become one of the first powers in Europe; but the wonderful possessions of the Dutch East-India Company in India are of a strictly private character, governed by officials controlled by the Company only, and the State itself has not the slightest intention to join the distant isles to the Mother-country. Monopoly in the Moluccan Archipelago is all that is desired, and the Company's officials know perfectly well how to safe-guard its interest in this respect.

We need not enter into the Company's struggle for self-preservation which on many occasions might have been deemed entirely hopeless, if the opponents in Europe had been fully possessed of the facts which have since been brought to our knowledge. If however we may pass in silence the details of war between the Dutch and other European nations, we may not wholly do so with regard to the struggle between the natives and the Dutch in India, which fills many an inglorious page in the history of those days.

As a rule writers of the present century have criticised the policy of the *Oost Indische Compagnie* in a most severe way, especially with regard to the hard measures carried out in the Banda islands, and we shall certainly not defend any of these unscrupulous acts which were forced upon the Bandanese in order to maintain the Monopoly of spices in Indian Waters.

It is clear however that in judging of past times, the critic has to bear in mind first of all that in the beginning of the 17th century the ideas about humanity in war were radically different from what they are now. Secondly, equity should allow for many an act of bloodshed provoked by the constant treachery of the Asiatic tribes, seemingly eager to grant any amount of privileges, solemnly pledged when they considered themselves compelled to submit, but as eagerly scouted, as soon as they thought the moment fit to do so, either on instigation or by instinct.

No doubt the self-evident want of understanding of two races so different in character, religion and tradition, must be taken into account when judging any shortcomings on either side which, originating in the slaughter of the isolated Dutch forces and constant mutinies, ended in a complete submission of the monopolised islands and almost wholesale massacre of the Bandanese in 1622.

Whatever we may have to say in these matters and wherever our sympathies lie, there is this testimony which speaks clearly in favour of the Dutch rulers, that when in later years the political fall of Holland caused the nation to neglect the Indian Archipelago, the natives complained about their being left to themselves and protested for fear of being wholly abandoned by those whom they had learned to consider their regular masters.

When in 1796 the Spice Islands became English for the first time (they were brought under the English flag for another short period once more in 1810), the natives still continued to consider them-

selves as subjects of the Dutch and they hoisted even then the Dutch flag on all festive occasions.*

This single fact appeals to every impartial critic. It exonerates neither the rash acts of cruelty nor the merciless despotism exercised by the Conquerors, but it goes far towards excusing them.

What we needs must blame looking back over so many years is the general blindness of those who, pretending to govern India on sound mercerical principles, did not even see that the miserable Monopoly was the cause of endless war and should in the end drain Indian resources.

As unwise as the man in the fable who killed the goose with the golden eggs to get all the profit at once, the rulers of India, alarmed at the number of trees "that bear gold," rashly cut down so many that they drove the people away and wealth with them.

By restricting the cultivation of nutmegs and mace to *Banda Neira*, *Lonthoir* and *Ay*, the monopoly caused a great deal of injury to the Moluccan Archipelago. By compelling all the produce—nutmegs and mace—to come to Europe, it crippled the trade, which had ever found its natural outlets in Asia. Severe control and constant vigilance of course could do something to maintain the monopoly in the days of the Company's utmost glory, but it is easily understood that against the unnatural law, smuggling was ever on the alert for an opportunity to detract the much cherished spices from the Company's stores either with or without the connivance of the Company's own officials.

Though estimates differ it is not at all inadmissible that over one-fifth of the yearly Banda produce of nutmegs and mace was diverted by smuggling in Indian waters, and such notwithstanding the excessive punishment inflicted upon the offenders.

Besides the regular loss caused by smuggling, there was another which very often swallowed the profit for years, viz., the *volcanic eruptions* alternating with storms or parching drought, causing heavy loss of full-bearing trees, whilst moreover the scarcity of hands in years of abundant crops is met with in nearly each of the volumes, which deal with this part of the Company's arduous administration.

If we could separate the Moluccan administration from the complex of the Company's extensive household reaching South as far as Australia, and Eastward as far as Japan, including the stations at the Cape, in Ceylon and on the Coast of Malabar, a deficit would be shown by many years, that were considered extremely profitable by the shareholders in former days.

Leaving aside the years of enormous profit in the Indian trade, which may be reckoned to have lasted till 1693, there remains a period of more than one Century when the returns hardly cover the expenses, nay even entail a loss, and we may safely state that the Moluccas were for a good deal the cause of the disastrous end of a management, commenced under the auspices of inexhaustible wealth.

* George Windsor Earl.

† La Perouse, Crawford.

With a staff of a good many more than 19,000 Europeans in India (1770) of which nearly 3,300 in the Moluccas, the Company's Administration must no doubt have been far too intricate to allow many, either to appreciate its real state, or to foretell its future career but for grave blunders on its part.

Involved in every war which threatened Holland, bound to assist the State either with salt-peter and ships or money or both, the *O. I. Compagnie* had of course more to do than simply to administer the Indian territory. Her greatest fault was the waste of produce ordered to be burnt in Amsterdam, or destroyed in the Moluccas, conforming to strict orders from the Company's headquarters. Their eyes were closed against everything that should have been taken as a warning to break with the cutting down of trees (*hongt-expeditions*) and slavery. They were wilfully closed against everything that savoured of free labour and free trade, and they would remain so even for many and many years in favour of the old prejudices. When in 1798 the Company's bankrupt household showing a deficit of 120 millions was handed over to the State, the government did not know how to act better than to continue the Monopoly of Spices, which even managed to drag on its miserable life till 1870.

We need not wonder that, whilst in Europe at the end of the 18th Century the Revolution changed everything, the ideas in India moved very slowly only. Of course there were some persons in India and even amongst the highest officials that pleaded for a complete opening up of the islands for trade, but the advice they sent home did not find much favour. Under the administration of Holland as well as under that of England, proposals concerning the Banda Isles to this effect met in the Mother country with too little knowledge of India's wants.

When in the second period of English possession of the Banda-group (1810—1816) Governor Raffles declared himself an absolute foe of monopoly and asked the English government to sanction a change, he complained that the Bandanese knew just as little of England as the English knew of the Banda-group. If on commercial principles—Raffles wrote—it may be deemed advisable that the spices shall be collected into few hands, let the gardens or their produce be farmed out. Let the East-India Company or any Association of Europeans enter into the speculations, but let the British government preside,

This advice was quietly passed by. England did not take any real interest in the Banda-group itself, except that its produce should be directed to England instead of to Holland as before. When the *Treaty of Breda* in 1816, once more restored the Banda possessions to Holland, no material change whatever had been made in their administration.

Mercus, the Dutch Governor-General, after his visit to Banda pleaded for the abolition of the Monopoly. Van den Capellen, who visited Banda after him in 1824, though much impressed with the desolate state of the impoverished islands, did not dare to abandon the venerable monopoly system sanctioned by a usage of 200 years.

Some change however had been introduced. In 1819 slavery [slaves had been emancipated nomi-

nally in 1812 under the English] had been definitely abolished in the Moluccas by the Hollanders, and though for the moment the difference between slaves and "adscripti glebæ" (*perkhoorigen*) is still less essential than it pretended to be, this first reorganisation was to smooth the way for broader views of lawful trade also.

In 1853 the port of Banda was opened to the flag of every friendly nation. However as the produce was still monopolized by the government, merchantmen knowing that they would not find any cargo, of course did not call.

In 1862 the expeditions of extermination (*Hongt-tochten*) were abolished, and for the future the young nutmeg trees are allowed to thrive in any of the islands of the Moluccas. Very likely the unforeseen rise of Penang and Singapore as Spice-markets, supplied by the produce cultivated on English territory (Malacca) helped to open the eyes at last. Only three years later the first parcel was sold in Banda Neira in free auction.

The destruction of the nutmeg by disease in the Straits in 1866, which made prices go up till 1871, fortunately did not alter the liberal policy of the Dutch government. On the contrary the government now fully convinced that the Moluccas wanted the stimulus of free trade, urged the estate owners (*perkeniers*) to make themselves independent from the monopoly system. At first few of them seemed to appreciate the change, being far more willing to continue their unprofitable connection with a buyer as the government, instead of being thrown upon the open market. With the prices ruling very high just then, the energy pent up so long, seized from a few examples the profit which can be made. One after the other of the planters made himself free, and on the 1st of October 1873 at last every vestige of the monopoly of spices had been buried in the past.

Applications for opening up *Rhun* and *Rosengain* reached the government.

Already the next year the *Colonial Reports* of Netherlands India stated that the abolition of the Monopoly of Spices had proved a boon, having awakened more interest in the cultivation, both labour and money being supplied on a larger scale than before by the planters in the Banda Islands.

Since then the free cultivation of nutmegs has not always been so profitable, and especially of late years competition in every part of the globe, combined with low prices have put the energy of the planters to a severe test.

It may be safely asserted, however, that as the Banda nutmeg and mace still enjoy the highest reputation in the market, the care bestowed upon their cultivation as well as the large sums spent on it, must ensure a reasonable profit. In fact there are signs that prices will improve, cultivation having nearly reached its maximum in Banda. The days may be over when the produce of Banda was synonymous with the "trees that bear gold"; its gardens still bear the promise of wealth ready to fall into the hands of those who know to cultivate well this part of the wonderful East Indian Archipelago.

II.—CULTIVATION.

NUTMEGS AND MACE IN THE BANDA-GROUP.

A glimpse at the map of the Banda-group makes it clear that the islands are remnants of

a volcano, one-half of which has sunk beneath the surface of the water. Of this volcanic formation there still remains one active crater the *Goenong Api*, literally Fire-mountain, which ever keeps its neighbourhood in awe of new eruptions, though fortunately the days of destruction which marked the 16th and 17th Century have been great exceptions in the latter part of this century. The Bay of Banda itself is part of an extinct crater; over the whole Archipelago we meet with the same geological formation. Nevertheless, danger has always been overlooked in the Moluccas by the Natives as well as by the Conquerors, owing first of all to the much-prized spices, with which Nature gifted the islands, but no doubt also to the charming impression which the islands, and especially *Banda Neira* and *Lonthoir* leave upon everyone who visits them. The aspect of the islands simply surpasses everything which tropical vegetation offers in the usual way. In the *Guide through the Archipelago* issued by the Royal Mail Packets Co. of the Netherlands India, the pages 186 etc.* give a most picturesque description of the voyage from Amboina to the Banda-group as follows:—

“As a crowning effect of the trip to the Moluccas, as a finale of all the incomparable natural phenomenae between which the steamer smoothly conveys its passengers every night, the silhouette of the Banda islands with the high *Goenong Api* rises above the brilliant easterly horizon on the morning after the departure from Ambon. Everything is delicate and fine in this enchanting group of islands, which reminds us of nothing so much as of scenic decorations on a gigantic scale. The sea is more intensely blue, the green is deeper and more brilliant, the yellow and grey stripes on the smooth slopes of the ash-cone are more marked, the clouds of morning are more ethereal than anywhere else.

“It is still early in the morning when the steamer runs past the islands of *Rhun* and *Ay* on starboard, whilst on the notherly horizon the rocky masses of *Swangi* loom up, but by the time the steamer reaches the harbour, we are well on in the morning. The rapture which the lover of nature experiences on entering this unique bay baffles all description. On passing between the steep cliffs the steamer skirts the coast so closely that one can almost grasp the impending branches of the dense forest, when suddenly we find ourselves in a glassy lake enclosed by high precipices, from which with hardly any shore at its foot the *Goenong Api* rises its gigantic cone. But even more striking than this threatening volcanic funnel is the view straight ahead of us, where we discover a little town built against the slopes of a verdant rocky island, above whose white houses and terraces a mediæval castle towers high.”

The European dwellings in Banda testify by size and condition to the welfare which the cultivation of nutmegs has spread amongst the planters. They are however far from making an impression of luxury. All the large houses are built of bricks, but very low, reminding us of the

danger of eruptions [the one of 1852 caused serious damage to all the buildings].

According to the same authorities the aspect of the nutmeg gardens is perfectly unique, yea we may fancy ourselves in the holy woods of which the poets sang.

“Not a trace of wilderness and yet everything grand and luxuriant. The eye glances along an unintercepted view of the magnificent nutmeg trees with their crowns of foliage of shiny dark green leaves between which the dead-yellow fruit are hanging in abundant profusion. The dark red mace glows in the recesses of the opening fruit. And over these dense orchards huge *canary-trees* move their dark green crowns in one interwoven protecting leafy roof, borne as on columns by trunks of a girth such as hardly ever seen in Java.”

The interior arrangement of an estate house is extremely simple: a front-gallery, inner-gallery or hall, into which open all the private rooms, and a backroom which is practically the sitting-room. Society life in Banda is of course rather monotonous, one of the principal diversions of the colonist and his family being the tropical sky-gazing (*klimaat-schieten*). Meanwhile a reception-day on the estate is a very pleasant event. The invited guests meet at noon at the profusely provided rice-table, which is followed by the siesta. After the usual Indian ablutions, the guests meet in full dress, pumps and gloves being “de rigueur.” Supper follows at 7 o'clock and the well-spent day is finished up with a dance, varied by theatrical or musical entertainment. Families are usually very large, ten to sixteen or more children being no exception. In religious matters the colonist is exemplary tolerant. A special trait of the colonist's character is his pronounced love of the House of Orange, chiefly dating from the festive visit of the late Prince Henry, the happy memory of which is revived on every occasion.*

Another Indian specialist† describing the nutmeg gardens in Banda says: “The agreeable scent which is wafted from the wood invites us irresistibly. The high canary-, warringin-, and teak-trees act as a protection against heavy showers and gales for the conical nutmeg trees, whose foliage is formed by pointed leaves hanging down from branches shooting out regularly. Between the shiny foliage sparkles the ripe open fruit of which the dark brown nut is the kernel, whilst the bright-red mace envelops the nut as an elegant network. Occasionally we meet in the wood with bamboo bushes and other jungle vegetation. Sweetly blows the cool air, invigorating and bracing is the scent of the nutmeg, whilst the wood echoes with the merry voices of men and women gathering nutmegs, and children picking canary-nuts, mingled with the various sounds of the cooing nut-pigeons (*manoek faloe*), parrots, the Indian nightingale (*baikolie*), the canary-yellow *karajamoe*.”

A peculiarity of the nut-pigeon inhabiting the Archipelago is that they swallow the fruit bodily and discharge the nut whole and undigested. This curiosity, which no doubt leads to the distribution of the plant, was formerly connected

* Dr. D. F. v. Bemmelen and G. B. Hooyer.

* v. d. Linden.

† Prof. v. d. Lith.

even with its sex as shown in Vogels' remarkable passage*: "If the bird that drops the nut is a male, the tree growing from it will be a male too; if the bird is a female, the tree will be a female as well, whilst if the bird happens to be still a virgin, the tree that grows from the swallowed nut will be one of the best in the woods.

Whilst nature produces 100 male against 100 to 200 female trees, it is a fact that only the females yield fruit. On the whole the latter bear fruit when ten years old, but their produce at that age is still small. In the years immediately following, the produce increases rapidly, gradually again more slowly, until the highest point of production is reached between the 20th and 25th year, continuing, undiminished during 25 years. Only then, about its 60th year a decrease may be noticed. Many trees however reach a much greater age, some of them are said to complete a century.

The nutmeg trees bear blossom and fruit without intermission, in every stage of ripeness, and so the nuts may be gathered all the year round. The greatest abundance however falls during the months of July and August.

The nutmeg itself is the kernel of the fruit, which is pearshaped, of the colour of a peach and consists of four parts; the outer fleshy part, then the membranous substances, covering the shell of the nutmeg and known to Commerce as mace, then the shell, and finally the kernel or actual nutmeg.

The greatest care is required in gathering and handling the fruit. Twenty-four hours after the opening of the fruit, a sure sign of its ripeness, the nut will drop to the ground, thus injuring the mace-network and deteriorating its proper quality as its lying on the soil makes it apt to become wormy. On the other hand the closed fruit may be still unripe, and knocking these down would be still unjudicious.

Work commences at 5 o'clock in the morning at the ringing of a bell, when men, women and boys and girls over 16 years, go out into the woods, armed with the *gaa-i-gaa-i*, a long stick with a prong at the end to break off the ripe fruit and a basket to carry the collected nuts.

The wood is the all in all to the labourers. It is his place for work and recreation. It is his club and even the spot where the young man seeks his future wife when the overseer is out of the way, notice of whose approach is kindly given by the friends of the young couples imitating the call of the nut-pigeon as a danger-signal.

Apart from the romantic side of these proceedings, the practical advantage becomes evident when we know that love-making contributes greatly towards the rapid filling of the basket, the boys helping all the pretty girls most assiduously, in order to secure for them the premium awarded for extra-diligence, (a practise which has followed up the rotten used in the days of Monopoly).

While the owner may thus be profiting by the romantic disposition of his young staff, it is quiet on the cards that his overseers are not overanxious to intrude where the voice of the *manock faloer* is heard. The only drawback of this arrangement is that the boys do not regard the boundary of the

estates too scrupulously, thus filling with the produce of one estate the baskets of the other. We cannot vouch for the veracity of the statement, but it is asserted, says Mr. v. d. Linden, that an estate-owner who one year happened to engage an unusually attractive female staff, thus saw himself unexpectedly rewarded with a superabundant crop, whilst on the neighbouring estates many complaints were heard about the scarcity of fruit.

Work in the woods finishes at three in the afternoon when the collected fruit is delivered at the *pagger* where the warehouse, drying-house and other out-houses are located. On entering, all the pickers, males as well as females, squat down in the open gallery to separate the ripe fruit from the unripe (*kérangs*) and portion them out in little heaps. After the inspecting and sorting of the fruit, the nuts are taken to the drying-shed (*rookkombuis*) where a low fire is constantly kept smouldering. Here the nuts are spread out and dried on a second flooring of split bamboo (*para-para*) constructed at not less than 12 feet* above the fire on the floor. After about 6 weeks, during which time the nuts are repeatedly turned over, they may be considered dry, which is heard when they begin to rattle.

In the drying-sheds the nuts should not be overheated, merely to accelerate the process of drying them, as they are very rich in oil (35%) which would ooze out. The temperature in the drying-sheds varies as a rule between 35° and 40° C. (95° till 104° Fah.), care being taken to avoid fluctuation, a precaution which explains why the walls of the drying-sheds should be so thick. A temperature above 45° C. is considered injurious by Dr. Janse, the eminent scholar who was sent out in 1897 by the Dutch Government to institute a special inquiry into the growth of nutmegs and its requirements.

The smoke which formerly was looked upon as necessary, is not essential; the smouldering fire being preferred because it assures the best, *i.e.*, a slow process of drying. A change in the venerable, old proceeding was repeatedly urged. Meanwhile, Dr. J. remarks that the use of machinery is not free from objections, the nutmeg being an article which is valued according to its "*face*" value, necessitating the greatest care for the preservation of its outward appearance.

When dried too quickly the nut cracks, when exposed to an excessive temperature it shows spots in consequence of the oil finding its way out.

When the nuts have been sorted they are limed, which is not done to rob the nut of its productive power as people used to think in the days of monopoly, in order to prevent cultivation elsewhere, but only to safeguard the nut against getting worm-eaten, or in case a worm should have got in already, to fill up its hole and kill it.

There are two systems of liming, the wet and the dry. In the dry process the nuts are treated

* Warburg.

† v. d. Linden.

* Van Gorcum (Colonial Museum, Harlem.)

with dry lime-powder either by rubbing them between the hands or shaking them in barrels. In the wet process the nuts are thrown into the newly slaked lime upon which they are spread over the floor to dry. Dr. Janse mentions having seen on his visit to Banda that small basketfuls of nuts were dipped into the slaked lime and the nuts heaped into little piles.

In order to ensure the best appearance for the mace, a careful treatment is equally required. It loses of course when dried the bright purple hue, which it possesses in its natural state, but the orange colour should be as vivid as possible.

In contrast with the nut, mace contains only 7 to 9 per cent of etherial oil, but it holds an abundance (23 per cent) of aromatic balm.

Immediately when the mace is loosened from the nut, the fresh substance is spread out during the night on matting or flat wickerwork. When the weather is fine it is cured in the sun in a few days. During the process of drying it is trodden flat in order to facilitate the packing and avoid its breaking when in a perfectly dry state.

The only work on the estates now remaining is the packing and forwarding.

We might now pass to a review of the nutmeg and mace trade, taken into Europe and its principal emporiums Amsterdam and Rotterdam, but we consider it necessary first to refer to the places of inferior produce and the diseases to which the plant is subject outside Banda.

ATTEMPTS TO ACCLIMATIZE NUTMEGS OUTSIDE BANDA.

When in 1839 the Government gave its sanction and assistance to transplant the nutmeg trees from Banda and Amboina to the other parts of the Dutch Archipelago, cultivation began to spread and the plant was also introduced into *Minahassa* (North Celebes). What the natives produce in *Ambon* is of less importance than that in *Minahassa*. Its cultivation dates especially from the great destruction caused in the Banda Islands by the gale of 1778. Cultivation of nutmegs in *Ceylon* dates from 1798, that around Singapore from 1819.

In the French *Mascarenes*, off Madagascar, nutmegs were imported about 1770. Though at one time the cultivation raised favorable expectations, it has since dwindled into nothing, the cyclones having been the chief obstacle.

Even poorer results were achieved on the plantations in *Madagascar* and in *Zanzibar*.

Lately an attempt has been made to acclimatize the nutmeg tree in *German West Africa*, but thus far in the botanical gardens only.

In South America, *French Guyana*, where the plant was introduced by the French in 1772, it did not flourish. From there it was brought to *Brazil* in 1809, where it is found even now in solitary specimens only. Also in *Dutch Guyana*, *Venezuela*, *Mexico*, the *West Indies* and on the *West Coast of South America*, the nutmeg trees have never yielded a produce of any importance. Though during a short period the English plantations in *Trinidad* seemed likely to thrive, the ultimate success was poor.

POOR RESULTS OUTSIDE BANDA.

Everywhere in these regions, either the winds or the unforeseen continual droughts have disillusionised the planters there, and after all the naturally appointed place for the nutmeg produce of the world remains in Asia, and especially in the Moluccan Archipelago, where it has found for hundreds of years, together with the soil suitable for the plant, the favourable climatic dispositions without which the "trees that bear gold" cannot be expected to yield ever-abundant crops.

DISEASES OF THE NUTMEG TREE.

Like every other plant of tropical culture the nutmeg tree is subject to many diseases. Of these we may name:

1. *The Bark-disease* which without any previous symptom destroys part of a plant, sometimes in a day. Such a tree may be saved by cutting away the affected parts. The disease generally attacks the stems, it being a great exception that the branches alone are attacked. However great the ravages may have been elsewhere even destroying the gardens entirely, as in 1860 round Singapore and Penang, the bark-disease has never shown itself in the Banda islands.

What is indeed bark-disease says Dr. Janse, but what Dr. Warburg has treated as a separate malady, is the *white ant-plague*. White ants are not injurious to sound trees, but on the least symptom of decay in a tree, they muster in their thousands and the affected tree is hopelessly doomed. They seem to have a particular aversion to hog-dung, but to have rather a predilection for cow-dung.

As another case of bark-disease Dr. Janse mentions the *root fungus*, which is practically the same disease only appearing below the surface.

2. *The Premature Opening of the Fruit*.—Of the losses which a planter suffers regularly every year, the premature opening of the fruit may be considered the principal cause. In this case the nutmeg is either totally unfit for the market or it gets wrinkled. In bad years the loss owing to this cause amounts to half or even three-quarters of the crop. It is known either as *boeka poetih*, *boeka moeda*, *pala reboes*, *boeka massaq* or "*Kerang*," when the premature opening is caused by a fungus.

3. *Star-spotted fruits*.—This disease also brought about by kind of fungus according to Dr. Janse, is classified by Dr. Warburg as *nutmeg cancer*. It is rarely met with in Singapore but raged severely in Penang.

4. *White thread cancer* (*Benang poetih*), *Black thread cancer* (*Benang hitam*) are diseases which specially attack the leaves and branches.

5. *Parasite plants* (*kajoe menoempang*) and *Animal Parasites* (*Boor-boor*, *gani*, etc.) as well as *Blight* and *Fieldmice* are amongst the plagues to which weak trees are more or less exposed.

Though we cannot enter into further details which would ask a good many pages, this condensed enumeration of plagues and diseases easily accounts for the disastrous results that have overtaken sooner or latter the cultivation of nutmegs outside the Indian Archipelago.

GOOD AND BAD YEARS ALTERNATING.

Banda-Crop: According to Valentijn the total produce reached in 1634, 666,747 lb. (Amsterdam) *nutmegs* and 183,720 lb. *mace*. During the decade 1662-72 the yearly produce is estimated: 458,951 lb. *nutmegs* and 117,229 lb. *mace*. In 1710 Siberg puts it at 704,000 lb. *nutmegs* and 176,000 lb. *mace*. In 1778 the total produce sinks as low as 30,000 lb. *nutmegs* on account of a disastrous gale. The years 1785-1792 give poor results 22,459 lb. *nutmegs* and 7,504 lb. *mace*. In 1809 Daendels shows better results again 350,000 lb. (first estimate) 475,000 lb. (final estimate) *nutmegs*. In 1816 volcanic eruptions bring the figures according to Dr. Bleeker down to 127,239 lb. *nutmegs* and 31,809 lb. *mace*. The following years show better results, Especially 1860 proved a very good year, the produce being then estimated at 1,072,765 lb. *nutmegs* and 275,586 lb. *mace*. In 1867 the yield is only half of that in 1860. The next years show rather abundant crops and especially 1876 with 1,341,000 lb. *nutmegs* and 332,000 lb. *mace*. But in 1878 on account of excessive drought the crop is very poor once more, the yield being 464,000 lb. *nutmegs* and 164,000 lb. *mace*. Next year the results are much better, and 1881 is again a year with a very large crop 1,322,000 lb. *nutmegs*. In the following years the crop is good and repeatedly (1887, 1888) even abundant. In 1889 the crop is poor again 566,000 lb. *nutmegs*; whilst from the years after that up to 1895, that of 1893 beats the record with the large crop of 1,400,000 lb. *nutmegs* and 352,000 lb. *mace*.

The fact that good and bad years alternate at unforeseen intervals on account of drought or territorial (volcanic) disturbances, is shown by the foregoing list of figures.

(To be continued.)

THE GOLD MINES OF INDIA.

It was stated in a previous number of *British Indian Commerce* that coal and iron were not, by any means, the only minerals which abounded in India. The next to them in practical value is gold, and as the India Government has finally decided to adopt a gold currency and standard, the Indian gold mining industry has acquired greatly increased importance. At what historical period the searching for gold was first attempted in India is a matter of some interest. The gathering of this precious metal at and near the surface was doubtless begun in India, as in other countries, at a very early period. It was stated by Mr. S. U. Syed Ali Birgrami, a distinguished native metallurgist, in his essay on the "Iron Industry," that a human skull was found, in the Wundli Gold Mine in the Deccan, 210 feet below the surface. The ancient native miners in India did like the Romans in Spain, most skilfully work out the surface gold, but were stopped from going deeper by the influx of water. In the recently published book on "The Gold Mines of the World," written by Mr. J. H. Curle, who has visited nearly all the mines of every country, the author says: "In regard to India, several of the world's greatest mines are found here." This is very high testimony. As the mines in India which are now being chiefly worked are those of Mysore, some of which have proved to be extraordinarily prolific, and those in the Nizam's territories, namely, Wundali and Raichore, Mr. Curle appears to have been greatly impressed with their richness. The former working of the Mysore mines was doubtless profitably carried on by Tippoo Sultan and his predecessors who, it has been historically recorded, had a vast accumulation of golden treasure which had been extracted from the Mysore mines when he ruled the country. A great portion of the treasure doubtless fell into the hands of his captors when he was defeated by the English forces. These mines were probably then worked by slaves, but up to about 1870-71 they appear to have laid dormant or nearly so. Previous to that time there were always native searchers for gold, in and near the Wynaad. There were the "Pannirs" and "Korumbars," two native

racers, who washed and dug for gold, obtaining about four annas worth each per head a day. In other parts of India, as well as Mysore, there were always searchers after precious metals. In most of the streams on the western coast of India, gold is found associated with black magnetic iron sand. The iron sand is used in native iron furnaces, or as dust for spreading on written documents to dry the ink instead of using blotting paper. On the seaside, near Beypore and Calicut, there is always an accumulation of this precious black sand, and with it are particles of Gold. The chloride of sodium in the sea water decomposes the impurities with which the gold is associated. In Queensland, Australia, on the sea coast, where the large rivers empty themselves into the sea, after heavy floods which cover the low swampy lands, a similar muddy, black sand accumulates, and is very carefully collected, with profitable results, in the shape of fine gold in considerable quantities, and of the highest value because of its purity. Between the coast of Beypore and the Wynaad Hills on the low lying ground there are many traces and remains of ancient gold mines once worked, but now abandoned for no other apparent reason than the want of enterprise. The native minors could only go down to the water-bearing strata, where they would be drowned out for want of drainage appliances, which is no longer a difficulty. The searching for gold mines, though no exact rules can possibly be laid down, is not, however, so very complicated or mysterious an occupation as may by some be supposed. There are certain geological and mineralogical, as well as topographical rules, which, if carefully followed, will indicate the possibility of gold being discovered. Such were the data which enabled the late Sir Rhoderick Murchiston to indicate that gold would probably be found in certain parts of Australia and South Africa, though its existence was very well known beforehand in both cases, but the technical rules upon which Sir Rhoderick built his theory were strictly correct.

As regards the Indian gold mines, the late Sir Richard Owen, Director-General, of the Natural History Museum, owned a coffee estate in the Wynaad, which, during the ten years of his ownership, had cost him a thousand a year. Getting tired of his bad bargain, and his canny Scotch manager having retired and set up an estate of his own on his accumulated savings, the Professor wished to sell the property, and on transferring it to the buyer, he said: "If you will examine the rivers on the estate you will find gold"; and gold was actually found; but when the samples were shown to the leading merchants in Madras they attached no importance whatever to the discovery. That was in 1862, and it was not until 1875-76, when the India gold mining mania raged, that there was a rush for mining properties, and fancy almost fabulous—prices were offered for mining rights in the Wynaad. Unfortunately, too often and too freely were such prices paid, without any guarantee that the properties contained paying gold. Amongst other properties was that of Sir Richard Owen, for which £1,500 was originally paid to him; for this the modest sum of £100,000 was asked, but not obtained. The surface outcrop of the lodes of quartz did, nevertheless, yield 11 dwts. of gold per ton, worth 40s. From 1875 to 1888 a great number of Indian gold mining companies were started, with an aggregate capital of many millions sterling, and very exorbitant prices were asked and paid for mining rights. Large fortunes were acquired by promoters and speculators, but when the boom was over most of these companies fell into the hands of "wreckers," and were wound-up. One company, for example, which had bought its rights for £40,000 cash and some fully paid-up shares, had no more money to send out a competent agent to test or work the mine, and it had, therefore, to be wound-up, and the right abandoned. Yet there was clearly traceable on that estate six or eight good quartz reefs, which assayed 10 to 12 dwts. of gold per ton, worth 40s.

This was a capital period for retired Indian Army officers and civilians, who rushed to the front as directors, managers, and experts, with about as much knowledge of gold mining as a cow (or say a calf) knows about the differential calculus.

There are very few gold mines put upon the market which could not yield a good return for capital actually expended in working them, but when two-thirds of the capital is taken as purchase price for the same, the returns must be very poor indeed, except in very exceptional cases. A gold or any other mine should never yield less than from 10 to 20 per cent., for, of course, as the mine is worked, it becomes of less and less value till exhausted. The original cause of the *furor* in the Indian gold mines was that one of them, the "Alpha," which belonged to a large mercantile firm in Bombay, which failed with debts of over £2,000,000 sterling and ruined a Glasgow bank, was as extravagantly over valued by the liquidators, who declared the mine in India would return all that was due to the creditors and the bank as well. On the strength of this statement there was a rush of Indian gold mines.

It is a remarkable fact that 80 per cent. of the gold of the world is obtained from the beds of gravel, which contain small particles of fine gold, worth not more than 10d. to 2s. 6d. per ton of stuff. These gravel beds exist in many countries, but Russia, California and Australia are the most famous. Such deposits formerly existed in Spain, whence the Romans obtained one million sterling's worth of gold annually. The remains of their stupendous mining which still exist show that they were worked by hydraulicing, as in California, and they surpass anything done in that country at the present day. There are doubtless, similar deposits in some part of India which are as yet unexploited. The most certain indication of the existence of gold is when it is found in the gravel of the various streams, as in the Wynaad; and the quartz veins, which exists in the Silurian schists, in the same locality precisely as gold exists in North Wales. It has, however, been well ascertained that the presence of "Trap Dykes," such as occur on the western Coast of India, when they are found traversing the schistose rocks, that *dislocation* or contact apparently creates the quartz lodes which contain gold. These lodes almost invariably run north-east and south-west, the gold being secreted in small veins and pockets, sometimes visible, but more frequently not. This gold is often very pure, but is more generally associated with silver, copper, zinc and iron pyrites; and it requires considerable experience and familiarity with mineralogy, as well as chemical knowledge, in order to determine not only the presence of the gold, but also the value of the ores. Very poor ores can now be profitably reduced.

The gold at and near to the surface in India has, of course, long since been gathered. Deep mining has been limited by the accumulation of water in the pits, but in many parts of India gold has been, and is still, obtained in some of the rivers, as from the Sona river (Gold River), which comes out of the Himalayas in Northern India. The gravel is still washed for gold to a very limited extent. Much of the fine gold work done in Delhi by the sonars (gold smiths) is made from gold brought across the Himalayas from Thibet, in the shape of small ingots about the size of the finger. Traders bring this over with goat's wool and borax, which they exchange for wheat and warm woollen clothing.

It is a curious fact that true granite has never yet been found in India. Trap and schistose rocks are plentiful, some of them like stratified granite, and frequently so called, which is a misnomer. It is in those schistose rocks where gold is found, and these are plentiful enough from the Himalayas to Cape Comorin. Were these gold mines properly and inexpensively worked, they would yield a fair profit, if they were not overweighted with capital, too often the custom nowadays. To carry on a gold mine from an establishment in London 7,000 miles distant, reliance

must be entirely placed upon the energy, skill, and integrity of an agent. India is not the country for enterprising and energetic Colonists in the usual acceptance of that term. As to the best mode of dealing with the mines, it has been suggested that they should be worked by convict labour. This was the custom with the Romans in Spain, where the descendants of these people still exist as a separate race, and still wash the rivers for gold after 2,000 years. The difficulty of dealing with convict labour would be the setting of task work, one of the best stimulants to Indian as well as other workmen. One the other hand, finding occupation for convicts without encroaching prejudicially upon the legitimate tradesman has been a question in India as well as other countries. Gold-mining would not compete with the ordinary tradesman prejudicially. Gold-mining is not, as a rule, a profitable occupation. In California and Australia, in the best of times there, if the results obtained were divided equally amongst the successful and the failures, it would not give a fair day's pay for the labour, and if all the gold mines of the world belonged to one syndicate or company the balance on the year would be on the debit side of the account, hence the almost nominal intrinsic value of gold, and, therefore, its suitability as a standard. The same, however, cannot be said of silver, the cost obtaining which fluctuates greatly between *nothing* and twenty pence per ounce, while gold remains at £3 17s. 6d.—*Indian Agriculturist*.

CACAO CULTURE IN ECUADOR.

The history of Ecuador does not record when the cacao plant was introduced into the country, but it is stated that the production in 1741 was from 35,000 to 40,000 "cargas" of 81 lbs. each. It is believed that cacao came originally from Mexico, where it was cultivated by the Aztecs long prior to the Spanish conquest. In Mexico it was called "caeri" or "cascara quahuil," and the product was called "chocolatl," from which the word chocolate is derived. It is produced in five provinces of the coast of Ecuador, Los Rios, El Oro, Guayas, Manavi, and Esmeraldas. The soil best adapted for cacao plantations is one that is deep and moist, the root of the tree growing vertically downward to a considerable depth. Silicious clay is especially preferred on account of the phosphoric acid and potash required by the bean. Banks of navigable rivers are selected generally because of the transportation facilities, but important plantations are found at considerable distances from waterways. Cacao is planted from fresh seeds. Four or five are put in each hole, which are five yards apart, in rows. Formerly they were two or three yards apart, but experience has shown that this method does not give the plant sufficient air, light, and nourishment. The United States Consul-General at Guayaquil says that the cultivation of cacao in Ecuador is limited to caring for the plant until it reaches maturity, then cleaning and weeding once a year. In the first few years the plant is pruned occasionally, in order that it may "run to fruit" more quickly. Manures have never been used, even when the ground has been cultivated over a century, and no irrigation is practised. The sediment, spread over the lands by the rains during the rainy season, and the decaying vegetation, appear to afford sufficient nutriment. In some haciendas, however, the proprietors pile up leaves and other vegetable matter found in the vicinity of the tree at its foot, and also rub down the bark with coarse cloth to destroy the adhering parasites. In the primitive manner in which it is grown and harvested, cacao yields a good return on the capital invested, but if scientific methods were adopted there is no doubt that the increase in production would be large. In the sixth or seventh year the tree commences to bear, but the pods at this time are very small and scarcely repay the effort to gather them. In the tenth year the tree reaches full maturity. It then produces on an average 1 lb. of dry cocoa of good

quality. There are many trees which produce more, especially those which are isolated, some of which have yielded at one picking as much as 7 or 8 lb. In the province of Oro (Machala), 1½ to 2 lb. per tree is the estimated yield. The tree is in bloom during the entire year, but most of the blossoms fall before fructification, which occurs twice a year, the time varying with the locality. The cacao tree grows to a height of 20 or 30 feet; its leaves are evergreen and lanceolated in form; the base of the main trunk attains a thickness of 8 to 10 inches; the bark is hard and of greenish coffee colour. The blossom is very small, pinkish white and wax-like in appearance. It grows directly out of the main trunk and branches. If it fructifies, the petals fall off, and from the stamens, in the course of from fifty to seventy days, an oblong pod is developed. This pod is of golden colour, and contains some twenty to thirty-five grains of cacao, enveloped in a gummy liquid which coagulates on exposure to air. The outer rind of this pod is dark or golden yellow in colour, and very hard, a sharp instrument being necessary to cut it open. Its size varies according to the kind of cacao, from 8 to 15 inches long by 2 to 6 in. thick. The outer rind is marked by longitudinal furrows, more or less pronounced, which indicate the interior arrangement of the seeds. Both the outer rind and the gummy contents of the pod are porous, and blacken in colour as soon as picked, and in Ecuador are of use only to fertilise the soil upon which they are cast. As soon as the pods begin to ripen, they are removed with pruning knives, very sharp, and attached to the ends of long poles, which are lengthened by joints as often as required. As the twigs are very tough, the blow with this instrument must be strong and well aimed, and the labourers must be experienced on account of the particular skill that is required and the fatigue that attends handling heavy poles sometimes 30 feet high, with the face continually upturned. Whenever they can be reached the pods are cut off with a machete. A good deal of cacao is lost by the carelessness of the labourer, and his disinclination to deal with the pods in the upper branches. The pods are heaped in piles by one set of labourers, while another cuts them open and extracts the contents. A sharp pruning knife is used, and the seeds are often damaged through carelessness. For extracting the gummy substance and the seeds, an implement made of an ox rib is used. The drying is done on open platforms made of split bamboo and palms, where the cacao is exposed to the sun during three or four days, and in order that it may dry uniformly and well, labourers are employed to tread it out with bare feet. If not well dried the bean is apt to ferment; and if excessively dried it shrinks and finally turns black. The dryers are provided with covers for protection against rain. Attempts have been made to introduce drying machinery (steam), but at present not one plantation in Ecuador uses it. When dried in the primitive fashion stated, a great deal of pulp yet adhering to the grain, the cacao is put into sacks and sent to Guayaquil to be sold in its natural state. Some merchants, it is said, attempt to deceive the buyer by washing an inferior bean in achote, which gives the skin the appearance of first-class cacao, but this practice is severely condemned by honest merchants, and is seldom followed, nor is reddish earth used in Ecuador as it is elsewhere for the purpose of preserving the grain from decomposition, and of increasing its weight. Reaching Guayaquil, the cacao is subjected to the cleaning process. Splinters, dirt, and defective beans are eliminated, and the adhering clusters of beans broken apart and dried several times before shipment. During this process the cacao loses 4 to 5 per cent, in weight. The sacks for foreign shipment contains from 60 to 70 kilogrammes (132 to 154 lb. net). The largest portion of the crop is bought in advance by Guayaquil merchants engaged in this business, who lend considerable sums of money during the year for current expenses of cacao estates. Large capital is necessary, and the number of merchants engaged in the business is limited. The profits of a plantation depend chiefly on the quality of

the land, management and proximity to market but ; it may be reckoned approximately at from 40 to 50 per cent. per annum on the capital invested which will continue for an indefinite period, cacao trees lasting for several generations. The price of land varies greatly, and depends on the caprice or need of the seller. Land adapted to cacao cultivation covers an area of some 19,600 square miles in the coast provinces of Ecuador. A very small proportion of available land is now under cultivation, although there are large tracts adjoining important estates. The chief impediment to the rapid development of cacao plantations in Ecuador is the system of "peonage conciertos," or slavery in all but name, which is in vogue, whereby labourers are bought and sold openly for debts. The production of cacao in Ecuador has been increasing since 1836, and the crop in 1899 is expected to be nearly 3,000 tons, the chief producing province being Los Rios, these following in their order of their importance : Guazas, El Oro, Manvi and Esmeraldas. —*Journal of the Society of Arts.*

Major Bagnall caught a male trout weighing 4 lbs. —"he fought well, and was in good condition." Others have been caught at the same spot. There is no certain evidence of trout having been seen in Pykara river, but Captain Campbell, R. A., who was fishing above the bridge in July, thinks a small trout came at his fly. Carp seen to be thriving there. Captain Beadnell has had most success, as he caught 15 lbs. weight of fish in three hours one day. Major Bagnall believes these fish to be Mahseer and wants opinions. Apart from fish, the "Nilgiri Game Bag" shows that all sorts of animals have fallen victims to the guns of different shikaris during the past five years, namely ibex, sambar, panthers, bisons, bears, and tigers. The last bear was shot at Kullakombay, in September last; and in 1899 there have been as many as nine tigers shot, the largest of which measured 6ft. 6 inches. Certain rules were fixed at the meeting in regard to the preservation.—*N. Times*

GAME AND FISH ON THE NILGIRIS.

There is always a good deal of general interest to be found in the pages of the annual reports of the Nilgiri Government Fish Preservation, Association which held its annual general meeting at Ooty, on Friday. The year is said to have been a very successful one in the way of the preservation of these two sources of sport that yields "supplies" for the table. The first article in the report describes what has been done during the year in the way of the "destruction of vermin"; but the word "vermin" here is used in a very special sense. For instance, the creature that is primarily set down as vermin is the otter; and it is so called because the otter is the great enemy of trout—a species of fish which the Association have long been trying to cultivate in Nilgiri streams. But the Nilgiri streams—in the words of the reports—"swarm with the pest, and our promise of trout greatly depends on the destruction of the vermin." Something was done during the past year: for seven otters were killed, which is the second best record. Of other "vermin," 11 wild dogs, 141 wild cats, and 62 mongoose were accounted for, which was a record in every case.

The report regrets that, in spite of protection, immature game not infrequently falls a victim to the "chapter of accidents" or; worse still, is killed by inexperienced sportsmen, who trust entirely to their shikaries, and are unlucky enough to get hold of unscrupulous men who only care to secure meat add trade on the inexperience of their employers and urge them to kill game that should be left for another day. The report represents that if the Association can but succeed in making things too hot for the careless or unscrupulous shootist, and especially for the worst class of shikari, it will be possible to write more definitely and satisfactorily of the results of protection. Actual poaching by the Badaga population has undoubtedly been checked; and at the present moment the most confirmed poachers are Kurumbars from Malabar, who make raids on the Kundahs and manage to evade detection, and wonder, no doubt, why they shouldn't be allowed to capture the game as freely and unrestrainedly as their father and forefathers did before them!

As for the culture of trout, Major Grant, v. c., who was an enthusiastic fisherman, has gone; but in Major T. N. Bagnall the Association has found "a keen all-round sportsman, who has gone *con amore* into the business of trout culture in a workmanlike fashion, which promises great things for the future." Hitherto the importation of trout ova has not been very successful, and Major Bagnall reports, in amusing fashion, that the whole supply received during the year was worthless, the fact being that in some cases "it had altogether rotted away, and only the smell remained." For the rest, he reports that Burnfoot Lake unquestionably contains trout though he has never seen one himself. Some have been seen in Avalanche river; but still they have never appeared to Major Bagnall. In Emerald Valley river, on the 23rd of June,

he runs to execute the order, for he well knows for such an outing there will be no lack of volunteers.

Before daylight machella team and men for loads are ready. Cook, plate-washer and boy are also ready with baskets of grub, cooking utensils, tent, &c., &c. By 7 o'clock off goes the caravan, after being directed to make for the Ruo—Portuguese boundary.

After giving instructions about estate work during my absence, I tumble into my "machella," manned by two sturdy negroes, one at each end of the pole; and off they trot like a pair of tandem ponies at the rate of about five miles an hour. These men are relieved by others belonging to the team as we jaunt along. After two hours the Ruo is reached: here is a good-sized stream about 80 yards wide, with little water, however, at present, the weather at this season of the year being very dry. We easily crossed.

Now having reached the wilds or

COUNTRY OF THE WILD BEASTS

—"cherombo," as the natives call it—my team of machella men are returned as there are no village paths ahead to run on comfortably. After a cold roast fowl and some curry and rice, washed down with a cup of delicious Ceylon tea, a start is made through the bush—a straight line is made for "Chiperone" mountain seen in the far distance through a hazy sky. We had not gone far when we came upon elephant tracks running in every direction. Some of the tracks bore evidence of large herds having been on the march during the rainy season. Elephants arrive in this "Malolo" country about March and leave when the bush fires begin in July and August, during which time the grass is high and the rivers are flooded, so that people cannot easily get about to disturb the noble beasts as they roam freely during those months. Confident of safety, although quite near to native villages on the opposite bank of the Ruo—the river being seldom fordable, and there are no boats as the people have no use for them—I had not gone far before a man arrived in great haste to say

THREE HIPPOS

were in a large pool in the river and we must go back and have a shot at them. The hippos are somewhat like your rogue elephants, take any number of bullets, and unless struck on the vertebra or right on the brain-pan itself, one need not expect to get them. Upon arrival at the river bank the strictest silence had to be maintained, for when a noise is made the beasts disappear and walk away under water, for goodness knows how far, and by creeping over the shallows to the next deep pool, which may be a mile or more away, escape unobserved. Upon peeping through the bushes three grand pig-like heads were seen, every one turned towards us, only eyes, nose and ears showing above water. A steady aim at the nearest one's ear and bang went a solid Lee-Metford bullet into the head somewhere, for it didn't hit the water. All three heads disappear, only leaving the ripple on the surface where they had been, and all is still as death again. Silently waiting with the rifle ready, silently watching the water, for another shot, is rather monotonous; about 20 minutes later, however, two heads appear about 80 yards down the river and commence blowing and grunting, making a thundering noise—too far off to shoot, however; so I had to make tracks for the spot,

OUT FOR A SHOOT IN BRITISH CENTRAL AFRICA.

(BY AN EX-CEYLON PLANTER.)

HIPPOS—ANTELOPE—ZEBRAS—ELEPHANTS, &c.

To relieve the monotony of the regular routine of daily work on the plantation, a run out now and again for a bit of camp life does one a power of good.

On 8th October I called my negro boy to send for my "Kapatu" (conductor in Ceylon) to get ten men for "machella," hammock slung to a strong bamboo pole, and ten men for loads to start at 6 a.m. tomorrow. To see the happy grin on the "Kapatu's" face at the prospect of "Nyama" (meat) is amusing. Without a word off

but too late, of course. After about five minutes' waiting one solitary head appears and bang goes a bullet into his eye; down goes my game again only to re-appear; this time done for, floundering heels overhead. "Hit this time" shouts the nigger: "Nyama, nyama" (beef, beef) and the greatest excitement prevails amongst my men. I was meantime not idle, for I charged and fired, as fast as I could, altogether eight shots, and still the beast went on turning over and over; for about 10 minutes this performance went on, till the pangs of death overtook the monster and he sank to the bottom to rise no more. Although I waited fully two hours, I never saw the other two again. How long they can remain under water I cannot say, but the natives say they can sleep lying on the bottom of a pool like the "crocks."

Next morning at daybreak all were astir and we soon made tracks for the river to find at the bottom of the pool, floating against the rapids in shallow water, the carcass of our hippo: the huge beast looked in the distance like a floating whale. All hands were soon at work, skinning and cutting up, great sport going on amongst the willing workers at this job, much to the amusement of onlookers who had congregated from the near villages on the prospect of a piece of meat, for there is nothing the African loves or worships more than "Nyama." No matter what the quality is, the savage eagerly seizes any scrap as the work progresses, skewers it on a stick and roasts it very slightly before a fire or on the smoke and ashes, tearing it to pieces with his horny fingers and devouring it with the greatest relish. The whole day was occupied skinning, butchering and despatching loads of meat to friends and relations in the villages. By evening there was hardly a vestige left except

MY TROPHY

—the head which was slung on a pole and despatched to the estate. Next time I go hippo shooting, I shall try what effect a dynamite cartridge has, thrown into the pool, to rouse the sleeping hippo who won't rise when wanted to. At day light next morning all were active. By way of experiment I tried a stick of hippo meat, but found it too rank in flavour, stringy and porky for my taste. We struck camp and marched in the same direction as yesterday. After two hours' tramp through the forest,—something like your Park country, but instead of the short lawn grass so easy to walk upon, we have a burnt off guinea grass field intermixed with scrub,—we got into a long dambo, that is a damp hollow with short tufty grass like the Uva Patanas.

ANTELOPE.

In the distance, about half a mile off, a herd of "sable" were visible. Skirting along the edge of the forest, I got to within 100 yards, when I could see they were on the alert fidgeting about all in a heap with the leaders of the herd always facing me. No delay now, my only chance, and bang right into the finest bull's chest; a stampede, of course, resulted upon the report of the rifle and there was just time for another couple of shots before they were out of sight. Upon examination of the spoor, we found two were wounded. A party of men started on the track of each. I followed the biggest and had not gone far, before I heard a grunt or a fierce snorting noise: a plunge forward and out bounded my wounded bull, full in view, head erect, with magnificent horns sweeping over his majestic neck. One

bullet well forward on the shoulder-blade laid him low with a forward bound. The other "sable" was tracked for a long distance, but the wound must have only been a flesh one for we never came up to the beast; so we gave up the hunt and camped near the water about a quarter of a mile distant.

THE SABLE ANTELOPE

is in my opinion the handsomest buck we have in Nyassaland; some may fancy the more rare Kudu, but there are so few here and only usually individual bucks to be found, that I should think they are emigrants from the large river or lake region. Upon having a look round next morning, I discovered spoor of Zebra, Hartbeest and other game, so I decided to make a stay at my present camp. During a tour in the evening I suddenly rounded a corner upon about 20 zebras and bagged one with a bullet in the neck and another went off badly wounded, for I could see he was not able to keep up with the herd but forged ahead very leisurely at about 100 yards in the rear. My men gave chase and I soon followed. After tracking for about half-a-mile, one of my men pointed out the wounded beauty standing behind a rock doing a bit of an amble on all fours. It was such an amusing performance that I hesitated about firing till my feelings got the better of me, so I put him out of pain with a bullet in the neck. I found he was shot before through the stomach. It always seems to me a shame to shoot such pretty harmless, and might be useful creatures; but the skins make a handsome trophy when set up in a museum. This was my sole reason for shooting the two which fell to my rifle on this occasion. I am sure the zebra could be easily kraaled, and tamed to be a useful and docile beast of burden to mankind. They are to be found in large herds all over Nyassaland.

The following two days were occupied tracking a herd of buffaloes and four elephants which passed through the country: the latter I was very anxious to get a shot at, but I could not come up on them; they seemed to travel at a great rate and evidently on the march to some other part of the country. After a trudge of some 10 to 15 miles I returned dead beat.

Next day I had better luck and managed to knock over

A WART HOG

—not by any means common game in these parts. The other pig is common enough and a very destructive brute in native gardens, but neither is so numerous in Africa, as the wild pig of Ceylon is in the lowcountry about the tanks, being only found in pairs or at the most in herds of three and four. I have never seen more than four together.

The following two or three days I had no luck although I saw and fired at some hartbeests, so I decided to return, meantime dispatching a man for my Machella and men to meet me at the Ruu.

On my way home I shot a Bush-buck and a Nyema; the latter was to my surprise standing by the water taking no notice of us. When examined I found that he had some severe wounds on the neck and head, doubtless clawed by a lion, whom hunger had roused to approach too near before his noble lord had finished his meat.

"SENTIMENTAL" RISES IN COFFEE.

Says the London *Grocer* of Dec. 16 :- In their circular of the 14th ultimo, Messrs. W. H. Crossman & Bro., of New York, make it appear that the recent advance, principally in Brazil coffee, has been entirely "sentimental"—that is, not based on sound and cogent reasons. They, in effect, declare that the higher prices established were engineered on the reports of bubonic plague in the Brazil which, however, was not epidemic, simply sporadic; and though it did not interfere with receipts or shipments of coffee, yet, for "sentimental" purposes, the word "plague" was deemed sufficient, in the absence of actual facts, to produce a rallying power in favour of rising markets. A further manoeuvre to foster speculation in the article was to publish reports about "Italian labourers leaving the Brazils in large numbers," which, as those know who are familiar with their ways, is no more than they usually do after "the picking of the crop" is over. It also often happens that just as many and even more labourers of the same class return to the work again when the time comes round. Again, the statement that there was a "shortage of labour" is easily disproved by the bare fact that as many as 3,600,000 bags of Santos coffee were moved and marketed this season with four months. In Mincinglane, likewise, a leading firm of brokers last month described the feeling in favour of dearer coffee as merely one of "sentiment." It must be owned that some idea of this sort has had a good deal to do with the strong upward movement that has sprung up in every branch of the coffee trade since September, when prices were at their lowest. The firm added—"We cannot forget when Brazil coffee was sold from 80s. to 90s., and that only two or three years ago 50s. was looked upon as a very low figure; 32s. 6d. for good average Santos now cannot therefore be assessed as anything but a very low price, even if it has been current under exceptional circumstances, at some few shillings lower." The phrase "some few shillings lower" refers undoubtedly to the period when a similar kind of coffee was disposed of in London for September delivery at about 25s. per cwt., a point at which the most discontented of "bears," we should think, would be satisfied to see the downward tendency cease. Since, then, however, it cannot be denied that the rise in prices has made good progress, being equal to at least 7s. per cwt., and it is not improbable that, considering the highly speculative character of the business in this class of coffee, a fresh start forward will be made ere long. Still, it should be borne in mind that there is another side to the question as to whether the value of coffee is likely to advance or decline, and of that we are reminded by Messrs. W. H. Crossman & Brother, who tells that—"The low value of coffee results from over-production. The only real help for genuine better prices for coffee is diminished production. Up to now prospects of the growing crop in Brazil are reported favourable. Not a single exporter of good standing in Brazil reports the slightest doubt of this. On the weight of supplies alone coffee values declined to the lowest point, but sentiment (say they) soon put them up, and this in the face of indications of larger supplies next September than ever known before, with the 1900-1901 crop, if anything, in excess of the present—which shows positively that over-production is in full swing. The trade must remember 'bull' sentiment does not consume coffee, but higher

prices so created stimulate production. Values finally are not decided by 'sentiment,' but entirely by supply and demand, and it is probable the present sentimental rise will bring the same experience that has attended the different attempts to lift values artificially during the past three years."

PLANTING REVIEW FOR 1899.

(Special.)

TEA.—Considerably more tea has been secured than the amount estimated by the Planters' Association in February, 1899. We have exported 5,000,100 lb. more than estimated to all parts of the world, and we have sent about 10,000,000 lb. more to United Kingdom than last year. The Planters' Association over-estimated the exports of tea to Russia by two and Australia by one and a half millions. In this they erred in good company. Messrs. Forbes & Walker made the same estimate, and there were well-known and smart Colombo merchants on the P.A. Committee who made up the estimate of exports of tea to other parts than the United Kingdom. There are two or three reasons given for the Planters' Association under-estimating the output of 1899.

Manuring.—Doubtless a large sum of money has been spent in the last eighteen months on manure; and if manure is really to do us much good, it was bound to increase the exports in the last few months of 1899, and it will be wise in the Committee of the Planters' Association to take into account a still greater increase to our exports by manuring in 1900, for a second application of manure has always a more potent effect on the bearing than the first.

1899 was, taking it all round, a wetter season than 1898, and there can be no doubt that a good rainfall exerts a very strong influence on the flushing of tea bushes.

Prices.—A terrible dead level has been noticeable in 1899—low country and medium levelling up and high country levelling down. There are only a few stand-out teas, and the outside public cannot judge if these stand-out teas result from finer plucking and lower yields, or disposing of low grades under another mark. Of this we may be certain: manure will force out more leaf where the trees naturally flush more freely, and that is where teas are low priced, being wanting in strength and flavour. I do not lose sight of the fact that manure will also help the bushes to give more leaf in months when the tea bushes do not flush freely and yield good class teas. However, all this extra flush in tea will necessitate tea estates having plenty of withering room in their factories, and also machinery. Is there much inducement planters plucking finer and sending high to grades of tea to the market? The first market wire advice received from London in 1900 was: "Prices firm and steady demand for tea except for fine broken pekoes and fine pekoes." What are the *con's* to much increase of tea shipments in 1900?

Labour.—Plumbago mining and extension of railways no doubt will shorten the supply of labour. You hear already well-known

sensible planters say:—"What is the good of manuring, if we have not the labour to secure the increased flush?"

TEA Blights.—Well, we had these *galore* in May and June of last year, but they have had no effect on the flushing; but they may eventually handicap us, and do away with the probable increase high cultivation naturally encourages us to expect. One who has passed through the *Hemileia vastatrix* experience, remembers only too well an exceptionally good coffee crop after the deadly pest had begun to undermine the strength of our trees. Often and often in the papers and visiting agents' quarterly reports, you would find: "Never saw the estate looking better. The bushes have a splendid cover of leaf and coffee blossom; spike showing up well." Three months after, what a change would come over the spirit of the dream:—"I never saw a more virulent attack of leaf disease. The spike that promised so well has left us only a few berries on leafless branches," &c., &c. However, grey and brown blights are very mild ones as compared with *Hemileia vastatrix*, and present scientific and tea farmers' opinions are that they will be kept in hand by judicious manuring and that they will only be very troublesome when seasons are abnormal.

CACAO.—The exports are decidedly higher than last year, viz. by 5,000 cwt., but that is generally attributed to a large area coming into cultivation. Great attention is paid to dealing with the fungus on its first appearance, but there is the difficulty to be faced of barking the trees so much as to ring the trees, with fatal results to the tree operated on.

CINCHONA.—Notwithstanding better prices, the exports have diminished 30 per cent. under 1898. There is no cinchona to speak of in the island. I have heard men talking of commencing to plant; but I have not seen any such planting. [Certainly, there has been some planting in 1898 and 1899.—Ed. C.O.]

CARDAMOMS.—The export is less by 40,000 lb. Clearings have been planted in 1899, and some clearings, planted two or three years ago, must be coming into bearing. It is what you may call a "pocket cultivation," and only in the hands of a favoured few.

COCONUTS.—Under all the headings, except "desiccated coconuts," there is a decrease in 1899 under 1898: why or wherefore the writer cannot say.

COFFEE has made a dying spurt in the way of exports, so far as 'plantation' and is concerned. I should think the future crops will barely satisfy the local consumption.

THE TRADE OF CEYLON IN 1899.

No. I: EXPORTS.

(By a mercantile authority.)

The export trade of 1899 has exhibited a good deal of fluctuation both as regards volume and value. But, generally speaking it may be said to have resulted in what may be termed a prosperous year.

TEA.—Our staple product has contributed largely in this direction. The excess for 1898 being about 10 million lb., three-fourths of the excess going to the United Kingdom. At the same time native products, such as produce of the coconut palm, copra, cinnamon,

coir stuffs, plumbago, &c., have all to a greater or less degree, participated.

A steady exchange has helped exporters, and this in itself has contributed to promote business in the minimising of risk which had for a long time previously hampered mercantile transactions.

CARDAMOMS.—Exports are slightly under those of last year, but there is extension of cultivation going on in a few suitable localities; the result of this, however, will not be felt for some years to come. Indian demand fell off during the latter part of the year, and prices have declined to about R1 80 for first and second qualities.

CINNAMON.—There has been a good export both of quills and chips and good prices have prevailed throughout the year. The price of ordinary assortment being now about 58 cts per lb. The novel feature in connection with this article is the large export there has been of "wild" description, as much as 195,008 lb. having been exported, chiefly to London, but the value has fallen so low, that the collection of spurious sorts is not likely to be encouraged.

CINCHONA continues to fall off in quantity. About 30 per cent less having been exported last year than in the previous year.

COCONUT OIL shows a decline of about 35,000 cwts. less than in the previous year, the demand for India and Singapore having been much curtailed. On the other hand the export to London and America has gone on briskly. The aggregate for the year is a little over 20,000 tons. The present value is R312.50 to R315 per ton f.o.b., as compared with 317.50 a year ago.

COFFEE.—The year has been a little more favourable, and plantation shows an excess of 6,400 cwt., whereas native seems to have been extinguished altogether, the export being returned as nil.

COCOA.—This has continued in good demand throughout the year, and there is a steady inquiry for bright colony sorts. The value being about 45 to 47 rupees per cwt.

DESICCATED COCONUT.—This industry continues to expand. The quantity exported during the last year being 13½ million lbs., or roughly speaking, ½ a million lb. more than in the previous year.

COIR YARN AND FIBRE continue to meet with a steady inquiry. The quantity sent away being about the same as in the previous year.

PALMYRA AND KITUL FIBRES show some falling-off, the values having declined considerably in the home markets.

PLUMBAGO.—This article has excited the greatest interest during the past year. In the early part of the year, it was supposed that there would be an over-supply and a great decline in prices, and this did take place to some extent, but, it was succeeded by a renewal of inquiry, and prices were driven up to a level beyond all previous experience. There has since been some subsidence of values, but there is still a fairly good off-take at prices which must well repay the pit-owners, if not the middle-men or contractors. The digging of plumbago has attracted all classes of natives, and many must have been reaping a rich harvest, although doubtless there has been disappointment amongst the

less lucky ones. Mining on scientific principles, and by Europeans, is now being attempted in a number of directions, and if successful, this will invest the trade with an interest it has never possessed before. The exports in 1899 were over 30,000 tons, against about 24,000 tons in the previous year.

CITRONELLA OIL shows an increase, and cinnamon oil a decrease in the quantities sent away, but the export keeps very steady from year to year.

PLANTING NOTES.

TEA CORPORATION, LIMITED.—At the annual meeting of this Ceylon Company reported in our daily and *Tropical Agriculturist*, an interesting speech was made by the Chairman (Mr. Cyril Gurney) explaining the working of the concern during the year ended 30th June last. Although so much tea was not produced as was expected still the quantity was in advance of the crop of the previous year by 100,000 lb. There had also been a great improvement in the net price realised and in the quality, and make of the tea. Favourable reference was also made to the results of manuring and a generally hopeful view taken of the prospects of the concern which is being worked as economically as possible consistently with good cultivation, and management. A good deal was said about the mining of plumbago on the Company's properties, and the directors were authorised to spend up to £500 on this work provided they were advised by a mining expert that it was advisable to undertake it. The directors have also been authorised to issue additional debenture stock for the purpose of developing the property.

INDIARUBBER.—It is hardly necessary to explain the importance of the rubber industry or the great trade in rubber which has now developed with all countries supplying the raw material, and the growing need there is for supplementing such supplies by cultivating the more suitable kinds of rubber-yielding trees, more especially in the West Indies, some parts of Africa, Ceylon, Southern India and the Straits Settlements. Readers of *Commercial Intelligence*, however, will keenly appreciate the value of a work dealing fully and authoritatively with the whole question, and that is just what we have in "All about Rubber and Gutta-Purca," a manual compiled by Mr. J. Ferguson, editor of the *Ceylon Observer and Tropical Agriculturist*. The first compilation of an India-rubber Planters' Manual was prepared sixteen years ago, a second edition considerably enlarged appeared in 1887, and in response to numerous enquiries Mr. Ferguson has now published a third edition. In it the author has brought together all the available information in the latest authorities on rubber. [Then follow extracts from the book.] Space does not permit of our dealing at greater length with this admirable work. In upwards of 350 closely printed pages everything of interest in the industry is fully dealt with, and the author has taken great pains to present to his readers just the things they want to know, and in the most lucid and practical manner. Certainly no one interested in rubber should be without a copy of the book.—*Commercial Intelligence*, Dec. 21.

Correspondence.

To the Editor.

PLANTING IN PERU.

Peru, S. A.

DEAR SIR,—By chance I became possessed of your valuable "Coffee Planter's Manual, 1898", and I prize it much. There cannot be a place so destitute of conveniences, of information on any subject and especially on the cultivation of coffee, as Peru. This industry, so to speak, has lived and died here several times, but the introduction of pulpers three years ago, more especially last year, (but mark the majority are wooden pulpers) has revived the interest in coffee cultivation, as the collee can now be exported (although there is a six days' journey on mule back to the nearest railway station). I am ignorant on such subjects as the different kinds of weeds, so detrimental—Hulantala, Spanish needle, Mana grass, Lau-la, etc. We have many weeds here, and I only know them in Spanish, as also bad moths by the thousand. Beetles are not so numerous, and are very highly coloured. I should like to know of any book with coloured plates of the coffee plant in its various stages of growth, also of the weeds and insects (cockchafters) we may have here, but I would require to see their form to distinguish them. Unfortunately planting here has been in the old style, seven and eight feet apart; there is, therefore, necessity to fill up gaps by some other plant that will pay to cultivate. We are somewhere about 4,000 feet or higher, with a fine climate, except when it rains heavily in the months of Dec., Jan., Feb., March; it may rain lightly throughout the other months, and *no winds* to contend with. I would like to receive "The *Tropical Agriculturist*" which, I think, may just furnish the information we most require here and especially in my individual case.—Yours respectfully,
P. H. M.

"INDIAN GARDENING."

Calcutta, Jan. 4, 1900.

DEAR SIR,—I beg to draw your attention to the current issue (today's date) of "Indian Gardening," which enters upon a new phase of its existence, by the addition of a Planting and Agricultural Section.—Yours faithfully,

THE EDITOR.

["Indian Gardening" continues steadily to improve: the new section leads off with a sensible article on the Imperial tea duty, showing that 2d reduction is preferable to abolition; but in a time of war like the present, the less said on the subject the better.—ED. T.A.]

RUBBER IN BORNEO.—A correspondent of the *China Overland Trade Report*, writing from Sandakan, December 18th, reports that Mr. De Nije, a rubber planter on the Labuk River, has discovered a rubber tree which he believes has been entirely unknown to botanists hitherto, and which is, moreover, indigenous to this country. Its colour is whitish, but the rubber darkens on exposure to the atmosphere, ultimately going perfectly black. Its quality is very good, and the Chinese here are willing to pay \$100 per picul for as much of it as they can get. Samples have been sent to Singapore and Colombo Botanical Gardens for classification, and it is hoped the discovery will prove a valuable one.

EXPORT OF PALM PRODUCE
IN 1899:
FROM 350 TO 400 MILLION COCONUTS
REPRESENTED IN THE EXPORTS.

WE follow the practice of the last few years in drawing special attention to the total annual exports of the products of the coconut palm, in which an increasing number of colonists are becoming interested, in addition to the thousands of Ceylonese of all classes who are embarked in the enterprise. The European merchant as manufacturer and buyer of coconut oil, has since early days of British rule, been connected with the coconut industry. —the first cargo of coconut oil from Ceylon is said to have been taken to England by Capt. Boyd in 1820,—but European planters of the palm have been comparatively few and far between, until of recent years. Unfortunately, too, the earlier investors chiefly affected districts in the Northern and Eastern Provinces—probably because on the seaboard of these coconuts had long flourished—the distance of which from the capital added to the cost of transport to an extent which reduced profits disastrously. Freights have latterly have cheapened, and experience has taught during the past three or four decades, that proximity to the sea is not essential to the successful and profitable cultivation of the palm; and we have European planters now interested in the product in all parts of the Island, from Point Pedro to Dondra Head, from Batticaloa and Trincomalee to Chilaw and Puttalam. A Ceylonese proprietor advertising in our columns, has made us acquainted with the fact that he had sold seed nuts for inland districts like Yatiyantota, Kurunegala, Kadugannawa, Gampola, Matale, Pallegama, Kandy, Wattigama, &c.; while some of the seed-nuts have travelled as far as Lemesuriyagama in the Nuwara Eliya district! In most cases, these coconuts were to be planted with tea; and European planters express themselves very hopefully in regard to this (to them) new product, as a safe second or third string to their agricultural bow.

While last year saw a continuance of palm extensions, the out-turn of crop for 1899 has not been particularly satisfactory. We expressed our fears for the year's crop after the severe drought of the first quarter; and when a second drought was experienced in June-July, we ventured to indicate our conviction that the year's out-turn would be short of that for 1898. So far as the Chamber of Commerce Export Tables are a test, that forecast has unhappily been justified. In Oil there has been a falling-off from 435,935 cwt. in 1898 and 409,600 in 1897 to 400,979; of Copra 325,401 cwt. were exported, against 506,277 in 1898: in Desiccated Coconut, in which there has been steady progression since the trade started in 1891 with 1,416,330 lb., there has been a slight increase from 13 million lb. to 13½ million lb.; Poonac shows a falling off, in sympathy with Oil of which it is a bye-product, from 216,620 cwt. to 174,786 cwt.; and so with coconuts in the shell, a decrease is shown from 12,027,714 nuts (and that figure has been exceeded at least twice) to 11,723,392. There has thus been a falling back in every product

of the Coconut palm, save in the Desiccated kernel, the increase in which, however, has not kept pace with that recorded in previous years. It is fair to say that this comparatively new industry of ten years' standing, has probably come to the end of its tether, and that no appreciable increase on the figures just quoted can be reasonably expected. Desiccated coconut is mainly used for confectionery; and as a luxury the demand for it, is incapable of indefinite expansion. Another point to be borne in mind in connection with the palm industry is that it differs from others like tea, coffee, cacao, cinnamon, &c., of which practically the whole crop is exported. The local consumption of coconuts is immense; and in a prosperous year like the last, cannot fall far short of the number represented by the exports. The exports of the products of the Coconut palm, therefore, represent the total outturn of crop in a far less degree than the exports of our other agricultural products; and to a great extent the exports are regulated by the demand and by prices. Thus both the manufacture and the exportation of Oil, which is the chief product, are regulated by the ruling prices in London and America and the profits realisable from business.

Dealing with the figures for 1898, which were about the largest on record as a whole, we calculated that the exports represented about 400 million nuts as follows:—

	Nuts.
435,933 cwt. Oil represent	.. 217,966,500
596,277 cwt. Copra	... 121,506,480
13,040,534 lb. Desiccated	... 39,121,602
Coconuts in shell	... 12,027,714

Total... 390,622,296

The figures for last year, on the same system of computation, taking 500 nuts as averaging 1 cwt. Oil, 240 nuts a cwt. of Copra and 2 nuts a lb. of Desiccated Kernel, the total works out as follows:—

	Nuts,
400,979 cwt. Oil	.. 200,489,500
325,401 cwt. Copra	... 78,096,240
13,571,084 lb. Desiccated	... 40,713,252
Coconuts in shell	... 11,723,392

Total... 331,022,384

The difference in exports between the two years is thus represented by about 59 million nuts of the value, at R30 a thousand, of R1,770,000. We have omitted reference in the above tables to Poonac, as it is the refuse after the extraction of the oil from the kernel, and we have credited oil with full 500 nuts. The poonac weighs half the oil; and on that reckoning all the poonac obtained from the extraction of the oil sent away was not shipped—there being a deficit of about 25,000 cwt. That is not matter for regret, as our stock and soil will be all the better for the retention in the island of all the poonac produced. The quantities of coir shipped were much the same as in 1898; but, of course, manufacture and shipments are guided by the demand. We might ship ten times the quantity we do, if only prices were more attractive. The Distribution of Coconut Products is also of interest, and we may have something to say of this in another issue.

COFFEE AND TEA.

It is always a pleasure to see Mr. Fairhurst, of Shanghai, on one of his periodical visits to Ceylon, where he has held estate property for many years. It was in 1877—when “coffee” in Dimbula was supposed to be at the height of its prosperity—that Mr. Fairhurst became proprietor of Ferham plantation with over 240 acres of coffee. Proprietors at that time reckoned their wealth—by counting young coffee in bearing as worth from £60 to £80 per acre in the favourite districts—at many thousands of pounds sterling, but only a few years later, many found themselves ruined. Mr. Fairhurst was fortunate enough to have in Ferham an exceptionally good place where coffee continued to give crops longer than on most places; but still the change in 20 years may be represented by 1,350 cwt. of a coffee crop dwindling down year by year until now it is but 50 bushels! Still, tea more than makes up the deficiency, and Mr. Fairhurst sees no reason to dread “blights” so long as cultivation is carefully and liberally attended to. Low-country tea has been scoring for prices lately—just as in the case of China tea, 6d a lb. is given by the large blenders and dealers for tea intrinsically worth 4d, while really good teas do not fetch within 3d of their actual value—but in the long run, Mr. Fairhurst has faith in tea from the higher elevations. He recalls the time when it was said that Ceylon teas at a lower average than 1s or 10d a lb. would never pay, and here we are with more tea than ever at less than eight pence average! The first effect of an advance in the imperial tea duty—say from 4d to 6d a lb.—must inevitably be to check consumption as well as to bother the blending dealers: whether that would give a good chance for independent retailers to cut in, it is difficult to say. Undoubtedly, it was urged during the extra Parliamentary Session that the cost of the war should be provided as soon as possible, and this can only mean a rise in income-tax as well as in tea duty; but it would only be temporary, and allowing for the amount to be levied in South Africa itself, if, as most people expect, the war is over by April or May next, the outlay should speedily be covered.

Mr. Fairhurst leaves for Europe by the Japanese steamer “Awa Maru” on or about Tuesday next.

CEYLON AND INDIAN TEA SHARES—THE MARKET FOR 1899.

The unfavourable features which characterised the year 1898, so far as tea property was concerned, became intensified at the close of that year, and with restricted business in the shares, values—with some few exceptions—dropped and closed at about the lowest point. With the opening of the New Year, 1899, a reaction took place. A belief that the 1898-99 crop would prove short of requirements, owing to the large deficiency, especially in Cachar and Sylhet, caused a smart rise in values of all common teas during the spring, and this resulted in a rebound, upward, in most of the shares. When, however, accounts came to be balanced up it was found that, in many cases, results were much less favourable than

had been expected. A few of the larger Assam companies did as well as, or better than 1897-98; but the Assam Company and others panned out much worse. The Dooars district gave satisfactory results; but the Cachar and Sylhet concerns, notwithstanding the help they got from the rise in price at the end of the season, made, for the most part, a very disappointing showing, and the Darjeeling gardens likewise. Owing, however, to certain economies which had been effected, and to a considerable curtailment in extension programmes, the overhead results were not so very much behind those of 1897-98, though very little surplus was carried to reserve. As a consequence, values of shares, from the middle of the year onwards, had a dull and drooping tendency, and the market for them was restricted. In the late autumn a more cheerful feeling supervened, helped by a fairly good market for the produce, and by a smart recovery in the output from the Cachar and Sylhet districts—the stricken field of the past two years!

A feature of the year was the dispute between buyers and sellers in July last regarding the conditions of sale, full particulars of which have appeared in our columns. Though the smooth working of the trade has been interfered with, it is believed that benefit will eventually result to all concerned by the ventilation of abuses, and that means may ultimately be found to abolish some of the evils connected both with the warehousing and Customs systems.

The opening up of new fields of consumption of Indian and Ceylon tea progresses slowly, but steadily, Russia and the European continent generally now, at last, showing an advance in this respect in addition to the Australasian, American, and African continents.

The Indian rupee question has, in great measure, ceased to trouble the minds of tea planters, and the decision of the Indian Government to adopt a gold standard has been tacitly acquiesced in. There are indications that the tea industry will be able to adapt itself to the altered currency conditions.

There has been no further flotation of new companies, but some minor additions to already existing capitals. The Consolidated Tea and Lands Company, besides making an issue in August of £550,000 of 4 per cent. Debentures, called £2 per share from its shareholders, amounting to £120,000, and the Amalgamated Company obtained £95,000 by a similar call on its ordinary capital. The Ceylon Land and Produce Company made a call of 10s. per preference part paid share, amounting to £3,200, and also issued £10,750 of new fully-paid 6 per cent preference capital, while the New Dimhula Company reconstructed its old complicated £86,000 of capital by an issue of £79,000 of new £1 shares (a slight reduction!).

A marked feature in the Share Market has been the disfavour into which the issues of the two large Glasgow companies have fallen, owing to the fresh issues and calls (above alluded to) being made at an inopportune moment, when shareholders did not wish to increase their commitments in tea.

Another feature has been the great restriction in dealings in the shares of a large number of the Ceylon companies, other than the bare dozen of leading ones.

Closing prices of shares show, for the most part, a moderate rise from the lowest point, though, as compared with a year ago, they show some irregularity. The financially strong companies and the Sylhet concerns show the most recovery.

PRODUCE AND PLANTING.

THIBETAN TRADE.—The report for the past year of the Commissioner of Chinese Customs at Yatung, in the Chumbi Valley, the town opened to Indian trade with Thibet, shows the growth of trade at the place for the four years it has been opened, no duties of any kind being levied during that period. The Commissioner doubts whether, when the duty is imposed, the trade will be able to bear it, and whether it will not take some other route.

DEVELOPMENTS IN TRANS-CAUCASIA.—In addition to the cultivation of tea, the Russian Imperial authorities have introduced viticulture. Last year the area under the vine in all Trans-Caucasia was 250,675 acres, from which over 17 millions of gallons of wine were obtained, besides grapes sold in the local markets and used for distillation, the total of which amounts to about 108,000 tons. Most of the wine is consumed locally, and is of inferior quality, for the growers are poor, and cannot afford to keep it in stock to mature. Cotton of good quality is growing in great abundance both in Trans-Caucasia and Central Asia, and finds its way to the Russian markets. The silk industry, also, is growing, but it is affected by the poverty of those engaged in rearing the worms, so that last year more than half the latter had to be destroyed in the second and third stages of their growth, as their owners were unable to buy leaves for their food. The cultivation of liquorice, which was an important industry in certain districts, is giving place to cotton and rice, so that the factory-owners last year had to pay higher prices.

CHINA AND THE PARIS EXHIBITION.—The Chinese section of the Paris Exhibition is under the control of Sir Robert Hart and the Maritime Customs, there being only one private exhibitor, a well known curio dealer from Pekin. Special efforts will be made to make the section especially interesting, and the tea industry will be to the fore. An officer of the Customs, M. Vapereau, has been in Paris for some months past getting the section into order. The position is not a central one, for it is in the gardens near the end of the eastern wing of the Trocadero, but the slope of the ground and the large trees afford an opportunity for effect. There will be a four-storeyed pavilion, sixty feet high, covering about 400 square yards, and with a lake in front. One of the floors of the pavilion will contain a Chinese theatre and restaurant, while the exhibits will take up two of the floors. There are to be three smaller pavilions, and a row of Chinese shops with men at work.

CHANGES IN MAURITIUS.—The report of Sir Graham Bower, Colonial Secretary of Mauritius, which has recently been issued, draws attention to "a steady but absolutely sure change" that is taking place in the population of the island, which is likely to have important social, political, and economic results. Thirty years ago Port Louis, the capital, was a European town to all intents and purposes: now the greater part of it has passed into the hands of either Indians or Chinese. The change does not stop with the town, for a process of morcellement is going on in the sugar estates, many of the old French sugar planters parting with their lands to Indians, who last year, in spite of the general financial depression of the colony, purchased nearly 15,000 acres for over two millions of rupees. The purchasers numbered 1,427, of whom 485 were originally immigrants, introduced at the expense of the colony. During the last four years East Indians spent over seven millions of rupees in purchasing land, and it is estimated that about a third of the total sugar crop is grown by these small proprietors. The economic effects of this change, say Sir Graham Bower, have yet to be ascertained; a peasant proprietor is, as a rule, less able to bear the vicissitudes incidental to agriculture than a capitalist proprietor employing labourers at fixed wages. When disaster comes, it is

more widespread with peasant proprietors, and disaster is always possible in a country so frequently visited by hurricanes. Besides the financial supporters of a peasant proprietary are usually a small and unscrupulous money-lender class. "But, whatever the economical problem may be, the political and social consequences are apparent."

COFFEE & TOBACCO CULTIVATION IN QUEENSLAND.—In the Treasury annual report it is mentioned that the laying down of plantations is gradually increasing, with a tendency to develop rather within the tropics than in the semi-tropical regions. The products that have been sent home, though from first crops and dressed with, in many cases, makeshift appliances, have met with encouraging encomiums from merchants in London. An instructor in coffee culture has been appointed, and with his advice and assistance it is thought that before long Queensland-grown coffee will have a place in the London markets. According to the Registrar-General's statistics there were under coffee in 1896, 138 acres; 1897, 311 acres; 1898, 432 acres. The actual area planted has been ascertained to be considerably larger, but of the area under crop 199 acres only were in full bearing, the production from which was 50,552 lb. Our imports of raw and roasted coffee totalled 179,681 lb., of the value of £7,304, so that there is yet a considerable margin for local wants to be supplied before the export trade can be commercially reached. The appointment of an instructor in the art of cultivating tobacco has been well justified by the renewed attention that has been paid to this crop during the year; and it is intended—should this harvest be a favourable one—to test the London market upon a scale that will command the attention of the European merchants.—*H. and C. Mail*, Dec. 29.

WYNAAD PLANTING NOTES.

NILGIRI-WYNAAD, Jan. 8.—The past two months, with the exception of a slight drizzle in December, have been quite rainless. Water is said to be getting scarce in some parts, and springs and rivers are all very low. It is safe to say that no one can remember them having been lower.

The picking of coffee crops will soon be almost over. What the quality will turn out to be, we do not yet know, but the bean runs larger, whatever its actual weight may turn out. With abnormal seasons it seems scarcely reasonable to expect a uniform good average quality, although some estates, as was so conspicuously the case last season, may be quite up to standard. Estimates will mostly be reached, and in some cases exceeded, especially in the Ouchterlony Valley, where a few estates are picking up to 35 and 50 per cent. of their big crops of last year.

The proposal of the Director of the Government Cinchona Plantations, to fell a large block of forest at the head of the Ouchterlony Valley, owing to the appeal of the proprietors of property in the valley to His Excellency the Governor strongly protesting against it, is not likely to be carried out. It is understood that His Excellency will give the matter his sympathetic consideration, and it is rumoured that the proposal has been dropped.

I believe there are now five European miners resident in Devala and Pundalur—a beginning at least of a revival of gold mining. The whole of the District is without any hospital accommodation for Europeans.—*Madras Mail*, Jan. 12.

THE VANILLA CROPS.

Mr. J. S. Simon, of Paris, has issued his annual report on the vanilla-crops for 1898-99, and, as foreseen by him, the returns have been—

	Kilos
Seychelles	24,500
Madagascar, &c.	13,000
Bourbon	77,500
<hr/>	
Total	115,000

In 1897-98 the crops amounted to 180,000 kilos, (including 125,000 from Bourbon), so that there has been a shortage of 6,500 kilos. As to the 1899-1900 crop, competent judges are not agreed, and it is difficult to say anything with regard to Bourbon before the end of the year. The persistent drought of last year has had a bad effect upon the vanilla plantations, and the cyclone in March has much modified the expected production after the dropping and death of the trees. Some planters say that the production will not exceed that of last year; others fore see a crop of from 90,000 to 110,000 kilos., but an average figure would be 100,000 kilos. The Seychelles Islands are estimated to produce 5,000 kilos. less than last year. On the other hand, Comores is expected to yield a better return. In admitting 100,000 kilos from Bourbon, there will be an increase of only 2,000 kilos. on the total production. In Mexico the crop has been good, but quality is not satisfactory. In Europe, Mexican beans are of little account, first quality being quoted from 150f. to 200f. per kilo., according to quality. The last crop from Tahiti has been very large, and prices have declined owing to the special flavour that can be used only by a limited number of buyers. The actual stocks in Paris and Bordeaux of Bourbon beans are 20,000 kilos. against 45,000 kilos. at the same time last year. The selection offered is not complete, and the cheap, short, common, and split sorts are not to be had. Hamburg has an insignificant stock, and London has very little. Prices have been advancing throughout the year from 55f. to 75f. net per kilo. for first quality, middle length 17 cm. The first lots prepared were sold at 60f. for Bourbon, and a few days since 62.50f. was paid, representing the parity of the net quotations in Europe. Seychelles vanilla is inquired for more than ever, and has reached hitherto unknown prices. The present stocks are not sufficient to last until the end of the year, and the first arrivals of the new crop will be quickly dealt with. At the London auctions prices have been constantly advancing and the demand has been good. Concluding, present quotations are likely to be well maintained, the prospects for the second part of the season depending on the amount of the Bourbon crop, prospects on the future crop, and, lastly, the general demand for consumption. The flowering of Seychelles vanilla is very short, and as already stated, the next crop will be a small one.—*Planting Opinion.*

COFFEE-GROWING ON THE CLARENCE.

Mr. John Bale, of the Chatsworth experimental station, Clarence River, has supplied me with some interesting notes on coffee-growing. Mr. Bale says;—"I was very much interested in the notes on coffee in Queensland which appeared in the special number of the 'Mail,' October 21. I have taken some interest in the subject for some 15 years past. Coffee was grown on the Clarence in 1843, but very little was planted prior to 1894. Some was manufactured in 1898, and sold at 1s 6d per lb. In that year we collected 5,500 lb. of berries, and made 900 lb. of coffee. This season we have to date 310,080 lb., and the dried berries are very good as compared with those of last season, doubtless because both rain and sun have been in our favour. The roasted coffee is now first-class. The output will be treated at the farm, and will all be disposed of on the Clarence, in fact, a much larger

quantity could be sold locally. I observe that the cost of picking the berries in Queensland is very different to that usually ruling on the Clarence. A boy 12 years of age, can pick 100 lb to 120 lb. of berries in a day. Take the average to be 110 lb. This should give 23 lb. of coffee-beans, or about 138 lb. coffee-beans for a week's work at a cost of 12s per week, or 1d per lb. A boy and a girl will pick all my present crop of two acres, and the picking will last into next month. We do all the pulping with a wooden roller turned in a trough on an incline, so that the berries keep a peel by rolling under the roller as it revolves. The coffee is dried, and the parchment work is completed with a U.S.A. No. 750 bean mill, which cost £1 10s. The revolving roaster was made on the farm from a large oil drum. A Coffee mill which costs £2 will grind 2 lb. per minute. With regard to the question as to whether the industry will pay, a great deal depends on whether the State is prepared to assist the small growers so that the capitalist shall not have too large a share of the profits. Coffee at 1s per lb. should pay well, provided the growers obtained their fair proportion of the proceeds, but the exactions of the middleman retard development in this as in all other industries which have to grow from very small beginnings."—*Sydney Mail.*

THE LONDON COCOA MARKET.

[BY HAROLD HAMEL SMITH.]

Noticing several piles of Trinidads of late were being sold from "redrawn samples," as well as the original ones taken by the docks when the cocoa was first landed, I made enquiries to try and find out why the second samples had been drawn and were being shown together with the original samples on the counter. The reason given was that this year, owing to the spell of heat we had from the beginning of June to the end of August some of the Trinidad cocoa showed signs of becoming "wormy"; a very unusual thing with this growth; and so buyers wishing to bid for a pile that had lain at the Docks since May, that is during the hot weather, asked for redrawn samples so as to be able to judge whether the cocoa showed signs of becoming wormy or not. This precaution it seems is not only taken by the buyers, but by the sellers and manufacturers as well, all being anxious to ascertain from time to time how the weather has affected their stock.

I was unable to make out what is the real cause of this "worminess." The actual cause is "eggs." But then where do the eggs come from, and are they always there, or only during the hot spells of weather. Some seem to think they come over in the Cocoa, and only hatch out with very warm weather. Another very reliable authority believes it to be due to insufficient air, or other causes, on the voyage; and gave as a proof that a pile of a well-known brand of Trinidad cocoa was shipped in two lots, and though on landing, the Cocoa to all appearances was identically the same, the first lot soon showed signs of becoming "wormy," whilst the last lot received remained sound to the end. Another reason given was that perhaps the beans not being as well washed and free of mucilage as they might be, owing to the heat fermentation set in, and attracted the insect that lays the eggs, and it is for this reason that Gnayaquil, which always has a good deal of dried mucilage attached to the skins, is very liable to become wormy, more so in fact than any other growth, whilst Grenadas are almost, if not entirely free from the nuisance. On the other hand, dealers in Ceylon tell you that they have known the same thing happen with Ceylon Cocoa, which is the driest and cleanest of all Coconos, so that the cause of the mischief has yet to be discovered, and the sooner this is done the better, for it causes the grower to lose money, and the merchant or buyer much anxiety to know how the cocoa is being affected by the weather; and I am told the Government will

have nothing to do with any Cocoa that shows the least sign of becoming "wormy," and not to alienate such a good customer is in itself worthy of all the attention that can be given to the matter.

The Government not being buyers this week, and the trade still being reluctant to buy publicly, no Cocoa Sales were held to-day; however, from all reports this has been by no means an idle fortnight, over 7,000 bags are reported as having changed hands, besides "several hundred" bags, particulars of which were not published. The following figures will show the rate at which Cocoa is going into consumption during October—1899-1898.

Imported ... 1,163 tons ... 1,273 tons.
 Delivered ... 2,127 " ... 1,806 tons.
 So that this year the deliveries during October alone exceeded the Imports by 964 tons, against only 503 tons last year.

On seeing the rate of increase in the consumption of Europe one is not surprised at the rapidity with which cocoa is being taken up; here are the figures showing the increase in the consumption during the last five years.

England consumed 15,530 tons in 1898-99, against 10,445 tons in 1894-95, increase about 50 %; France consumed 17,230 tons in 1898-99, against 14,630 tons in 1894-95, increase about 20 %; Germany consumed 18,656 tons in 1898-99, against 9,447 tons in 1894-97, increase about 100 %; Holland consumed in 1898-99; 15,132 tons, against 8,664 tons in 1894-95, increase about 80 %; and even Spain, hard up as she is, consumed 6,424 tons this year, against 4,481 tons in 1897-98.

Mr. Edward Kynaston sums up the position very accurately when he says:—"The home consumption of Cocoa as indicated by the Board of Trade returns, continues to show a steady expansion. On the Continent also the consumption is known to be extending, and the large production everywhere has met with a ready outlet, and has not entailed any undue accumulation of stocks. We shall commence next year with reasonable stocks, and if it is quite possible, crops do not turn out phenomenally large, as they have done this season, present prices, satisfactory as they are, may well become subject to a further increase. A cold winter following two mild ones will make a great difference in the consumption of Cocoa as a beverage, and estate owners may look forward with confidence to the coming season.

The following are the stocks at the undermentioned ports:—

1898.	1899.
London 108,313 bags ..	97,618 bags
Liverpool 1,735 " ..	2,733 "
Havre 95,729 " ..	123,209 "

The Havre stock includes 23,107 bags of Trinidads.—*Port of Spain Gazette.*

PLANTING NOTES.

THE EARTH ONION.—Both the *Geographical Journal* and the *Scottish Geographical Magazine* for October publish Sir John Murray's presidential address on Oceanography, delivered to the Geographical section of the British Association, says the *Review of Reviews*. From the results it appears that considerably more than half of the sea-floor lies at a depth exceeding 2,000 fathoms or over two geographical miles. A good deal of geology is packed up in the following paragraph and its homely comparisons:—

When we regard our globe with the mind's eye, it appears at the present time to be formed of concentric spheres, very like, and still very unlike, the successive coats of an onion. Within is situated the vast nucleus or *centrosphere*; surrounding this is what may be called the *tektosphere*, a shell of materials in a state bordering on fusion, upon which rests and creeps the *lithosphere*. Then follow *hydrosphere* and *atmosphere*, with the included *biosphere*. To the interaction of these six geospheres, through energy derived from internal and external sources, may be referred all the existing superficial phenomena of the planet.

TEA PLANTING IN THE MATALE VALLEY—has long been known to be very profitable and several favoured estates have, in some years, run the far-famed Gampola Valley premier plantation very close in respect of yield. Mr. H. Storey, of Warakamure, has in this way placed on record in our "Handbook and Directory" that he has got up 993lb. and 1,066 lb. per acre of made tea, without manure—a wonderful result. In answer to an appeal, Mr. Storey has now supplied our contemporary with a full return for 8 years—curiously enough since manuring set in, the yield has fallen, owing to unfavourable seasons with droughts:—

Year.	Plucking Average.	Yield per Acre.	Rainfall.	Remarks.
1892	80	688	76.90	
1893	194	695	59.78	
1894	194	702	60.89	
1895	194½	812	87.24	No manure.
1896	198	99	104.06	
1897	204½	1066	98.95	
1898	206	720	64.31	manured 60 ac.
1899	213	907	88.31	" other 60 acres.

The very serious droughts of 1898 did a great deal of damage to crop and to the tea also, and it has taken the whole of the last year, with very careful treatment, to bring the tea round again. I am glad to be able to say, however, that now I have never seen the tea looking better. A very unusual drought during the height of the S. W. monsoon last year, and a very unsatisfactory December, affected my yield considerably as I had confidently expected 1,000 lb. per acre. Two of my neighbours run me very close in yield, and I believe several other estates, north of Matale, can show very fine yield returns.

No. 8.

“PIONEERS OF THE PLANTING ENTERPRISE IN CEYLON.”

(Third Series.)

THE LATE SIR JAMES D. ELPHINSTONE, BART.

AND

SIR GRÆME H. D. ELPHINSTONE, BART.

One acquainted with the history of Coconut, Coffee, Cinchona and Tea Planting in Ceylon, can for a moment deny the right of the two gentlemen at the head of our column—the late and the living Baronets—to be in-

cluded in the list of PLANTING PIONEERS OF CEYLON. Sir James Elphinstone was connected with Ceylon from 1837 till his death in 1886—close on 50 years. He was one of the first Europeans to go in for Coconut planting in the Jaffna peninsula. He became a Ceylon Coffee Estate proprietor at the very beginning of the enterprise in the early “forties.” He was at the time Commander of an “East Indiaman,” and, visiting the island, he traversed the hill-country when there was no road beyond Gampola, and, penetrating into the Kotmale Valley, selected the Baharundrah block, having for his neighbours Capt. Forbes and Capt. Payne-Gallwey.

Much might be said of general interest about nearly-related and distinguished members of the families of Elphinstone and Dalrymple; but such records would unduly swell our memoir, and we

must content ourselves with “one leaf out of the past,” referring to the notable lady who was mother of Sir James, and grandmother of Sir Graeme,—after whom indeed he was called “DAME GRÆME DALRYMPLE HORN ELPHINSTONE,”—born May 10th, 1782, died, aged 88, on January 28th, 1870; and we give the following reference published at the time of her death:—

THE LATE DOWAGER LADY DALRYMPLE
HORN ELPHINSTONE.

(From the “Aberdeen Journal,” February 9, 1870.)

Our obituaries of the past week have chronicled the death of a venerated lady, of the last century, one of a generation now fast passing away, and in her instance claiming something more than an ordinary notification.

The Dowager Lady Dalrymple Horn Elphinstone entered on the duties of the House she has so much dignified and adorned for the last threescore and ten years in the first of the century, then a yonny bride of eighteen, and a wide circle of relatives and a very wide one of friends in all ranks of life now mourn for “one removed” of no ordinary dignity of character and personal bearing; endeared to, and revered by all around her far beyond the happy lot of most who die. Of her, indeed, it might almost be said, “to see her was to love her.” Those who knew her will readily echo this.

Her character was of the most engaging kind. To the writer of these lines—whose happy recollection of this, his elevated, earliest, *beau idéal* of a lady reaches beyond half a century back—she seemed to

embody what the poet has so finely, if quaintly, pictured of

That sweet attractive kind of grace,
A full assurance given in looks,
Continual comfort of a face
The lineament of gospel-books;
For sure that countenance cannot lie,
Whose mind is written in the eye.

She must have appeared in some sort thus to all who were privileged to know her. Those who knew her more intimately found in Lady Elphinstone a humble, earnest Christian, exhibiting a life remarkable for its consistency—marked by unostentatious benevolence and kindness—with a liberality as considerate as it was untiring; and the warmth of her heart, her affection and friendship towards persons of all classes, endured with her life. Single-mindedness; utter scorn of meanness; an almost fiery indignation at the sight of wrong or injustice—withal a grand simplicity, a noble pureness of nature that was manifested even in her outward appearance, inspired those who came under her influence with an affection and reverence not easy to describe. With her everything was in earnest; all around her felt it. Her rule of life was "Duty." She might, herself, have written the pregnant words, "But my guiding-star was, and will be, 'Duty,' and pleasure and desire of the heart must wait, even for ever, if necessary, when Duty calls."

Her personal appearance was very striking. To the refined beauty of countenance and expression (which marked her even in old age), and the sweet graceful dignity of figure and bearing which distinguished her in youth, were added, as years increased, a certain stateliness of demeanour, which, tempered as it was by warm-hearted kindness, impressed themselves on all who approached her. Her mental and personal qualities combined, in truth, to form a personage of no ordinary stamp. She was, all in all, one the like of whom we but rarely meet with in the pilgrimage of life. In some of her characteristics, indeed, she belonged to a class of which few representatives remain; such as are embalmed in the pages of the "Lives of the Lindsays"—the highest form of Scottish character: bright examples of what a Scottish training could be in our fathers' days.

Græme Hepburn, who became "Our Lady Dalrymple Horn Elphinstone," was born on the 10th of May, 1782. Her father, Colonel David Hepburn, was descended in the male line from the ancient family of Congalton of Congalton, or "of that ilk," in East Lothian, which held considerable possessions in that country as early as the 13th century. (See Chalmers's "Caledonia," and Douglass's "Baronage of Scotland.") In the reign of Charles II., William Congalton of that ilk, through his marriage with the niece and eventual heiress of Sir Robert Hepburn of Keith-Marischal, assumed the name of that family, a branch of the Hepburns of Hailes, ancestors of the Earls Bothwell (Douglass's "Peerage of Scotland.") His son, Robert Congalton Hepburn, succeeded him, who, with his three sons, joined the insurrection of 1715. (Some interesting facts connected with the family during that "affair" are given by Sir Walter Scott in "The Talisman of a Grandfather," 3rd series). Robert Hepburn's youngest son, James, eventually succeeded him. He went "out" a second time in 1745, being the first gentleman who tendered his allegiance to Prince Charles Edward at Holyrood. James Hepburn was a man of most amiable qualities and varied powers and accomplishments. He is described by John Home in his "History of the Rebellion" as a model of ancient manliness, simplicity, and honour, who sacrificed himself to a visionary idea of the independence of his country. Dr. Carlyle, in his Memoirs, also highly eulogises his character. Mr. Hepburn married Katherine Rickart, heiress of Rickartoun, in Kincardineshire, and assumed her surname additionally. By her, besides one daughter,

Katherine, wife of General Græme of Braco (private Secretary to Queen Charlotte, and Equerry to King George III.) by whom she had an only child, Katherine, Vicountess Hampden, he left two sons: 1st, Colonel Robert Rickart-Hepburn, long M.P. for Kincardineshire, father of Colonel William R. Hepburn, of Rickartoun, whose son, William R. Hepburn, now possesses the estate; and, 2nd, Colonel David Hepburn, who married Betbia Graham, descended of the family Inchbraikie, a branch of the House of Montrose, and left, besides one surviving daughter, Græme, the subject of this memoir, two sons; James, who married Louise, daughter of the Count de la Martilliere (both deceased without surviving issue); and Francis, Colonel, 3rd Foot Guards, Major-General and C.B., a distinguished Peninsular and Waterloo officer, who, by his wife Henrietta, eldest daughter and co-heiress of Sir Henry Poole, Bart. of Poole Hall, Cheshire, and The Hooke, Sussex, left issue, Colonel Henry Pool Hepburn, C.B., now commanding the 1st Battalion, Scots Fusilier Guards, Francis Robert, Rector of Chailey, Sussex, and one daughter, Charlotte Frances Anne Hepburn.

Miss Græme Hepburn married in 1800, at the age of 18, Robert Dalrymple Horn Elphinstone of Horn and Logie-Elphinstone, Lieut.-Colonel 3rd Foot Guards, son of General Robert Dalrymple Horn of Horn and Westhall, by his wife Mary, daughter and heiress of Sir James Elphinstone, Bart. of Logie-Elphinstone; and who had lately succeeded to the family estates by the death of his elder brother without issue. By him, who was created a Baronet in 1828, in consideration of his being, through his mother, the representative of the Elphinstone family and who died in 1848, aged 82, she had issue fifteen children, ten sons and five daughters, of whom eight remain, the eldest surviving son being Sir James Dalrymple Horn Elphinstone, Bart. of Logie-Elphinstone, M.P.

Although instances of more advanced age not infrequently occur, this venerable lady formed an interesting link with a bygone time. Belonging to a family that cherished the traditions of still earlier days, she passed much of her youth in Edinburgh, and, besides the information she had inherited from a former generation, her own recollections of Scottish society, seventy years ago, were very picturesque and striking. She spoke from personal knowledge of many whose names have now passed into the regions of history; men who had fought at Prestonpans and Culloden; ladies who danced at the balls at Holyrood during Charles Stuart's six weeks' reign; veterans who had served at Fontenoy and Dettingen and Minden; men of letters, of whom Scotland could then boast a brilliant circle; of the emigrant French noblesse, who clustered round their exiled Princes, then resident, at Holyrood. Of all these, and of the leaders of Scottish society at the close of the last century, her anecdotes were full of character and interest, even in the latest years of her life, which were mercifully and blessedly free from any clouding of the spirit or mind.

But, though she cheerfully drew from her memory reminiscences like the above, it was not in such things that her heart rested. She was continually looking above and beyond this world, which she felt was not her abiding place. She lived from day to day, awaiting the summons of her Lord, and shedding to the last a grace on those around her. She has left a bright example and a blessed memory, never to be forgotten by those who knew her.

Another very notable member of the family was General John Hamilton Elphinstone Dalrymple, C.B., a brother of Sir James Elphinstone, and who greatly distinguished himself in the Crimea as Lieut.-Colonel in the Scots Fusilier Guards. We now come to the generations and personalities

immediately under notice, and we are fortunate enough to have a graphic account from a gentleman who was intimately acquainted with "Logie" and its inmates in its early days. The following speaks for itself:—

MONEO ET MUNIO.*

(Notes by Old Colonist.)

"TWO BOYS" was the brief news brought to Captain——not yet Sir James—as he patrolled the lawn in front of West Hall house one fine morning in 1841.

The bearer of the news was Lady Elphinstone, his mother, and the brusque Captain laconically replied "Two!"—adding *sotto voce*, "One too many for a poor man."

The Elphinstone family have a tremendous long pedigree, deservedly honoured in the Garioch for the past two-and-a-half centuries. Albeit a fruitful race, Lady Elphinstone herself—one of the noblest and most beautiful of her sex—contributing 15, of whom James was the eldest alive, somehow the acres did not multiply in proportion to the members of the family. Yet Logie and West Hall were amongst the most valuable properties in the "Granary of Aberdeenshire" and might with care have sustained a very large retinue.

West Hall, the loveliest in the locality, a beautiful brae-side with grand old ivy-clad house picturesquely situated amongst its old umbrageous trees. Logie, more home-like, stands on sheltered terrace within sound of the ripple of the river Gadie, where in a wooded nook it meets the Ury—as if by tryst. The house—an ideal "*Auld House*"—was built about 180 years ago and has undergone but few alterations. In front of both stands Benachie, around the foot of which wimples the Gadie of sweetest song.

There are few more hallowed spots in Scotland than the banks of the Gadie, none to which exiles look back with greater affection, or sing its praises with more pathos. A poor little rivulet—a mere burn, in which two can scarcely paddle abreast and yet, says a traveller, while lying on the banks of the greatest river in the world, surrounded by threatening savages, my inmost thoughts found expression in:—

"O! gin I were whaur Gadie rins
At the foot o' Benachie."

There are at least a dozen versions of this very pathetic song, but always with the same refrain. I well remember accompanying the eminent antiquarian, Chas. Dalrymple, on an expedition through the district, the object of which was partly to open up some ancient mounds and partly to collect from the oldest residents, such words of the local song as they could recollect. It was amusing to hear an old crone with cracked voice singing:—

"I never had but ae richt lad,
But ae richt lad, but ae richt lad,
The teen was killed at Lourin fair,
The tither was drowned i' the Dee"

Or more pathetically the old widower's:—

"O! gin I were whaur Gadie rins,
Whaur Gadie rins, whaur Gadie rins
Or she that dwalt where Gadie rins,
O! gin she were wi' me!

It's no the hill, though it be brave
It's no the sowp o' Gadie's wave—
But she that bloomed o'er a' the lave
And gae her heart to me.

Tho' few to welcom me remain
Tho' a I lo'ed be deid and gane,
Ill back tho' I should live alane,
To the foot o' Benachie."

Many are the associations connected with Logie, the most hospitable of houses. The family was Jacobite in its sympathies, as indicated by the frequency of the name *James*, but not being over-demonstrative partisans, they escaped notice, and were able to render hospitality to the less fortunate, whose lands were confiscated. A story is told of the attainted Lord Pitsligo occasionally leaving his hiding-place on Benachie to spend a jolly night with the Elphinstones. Lady Elphinstone commented upon the *hard* drinking into which the friends would fall on a safe night, but was answered by the humorous refugee that "if she was sitten upon a cauld bare stane up on Benachie, we naething but burn water, she nicht ca *that* hard drinking."

The neighbouring townships of Inverurie and Port Elphinstone were much indebted to the Elphinstone family—the latter indeed for its name and the 16-mile canal which connected it with Aberdeen; while the North of Scotland Railway may be said to have been initiated and carried through by the public spirit of the late Sir James. In reading up the old records of Inverurie I find, by the way, that the Clan Ferguson is very largely represented, the name being the most common in the annals of the village and in a solitary Tytler—"the last of the portioners"—I trace the father of our own R.B.T.

The grandfather of the late Sir James, General Robt. Dalrymple, was an officer of long and distinguished service which began actively in the expedition to Carthage as aide-de-camp to his relative, Lord Cathcart. The celebrated Tobias Smollet was a surgeon in this expedition and describes it in "*Rodrick Random*." The first Sir James Elphinstone of Logie acquired the lands in 1670. He was a Writer to the Signet and unfortunately subscribed largely to the disastrous Darien Scheme by which so many of the Scottish gentry were severely bitten. Probably the next tropical investment was in Ceylon. When the late Sir James was Commander of an East Indian, he visited the island and, as he told us at the Kadienlena dinner, explored the valley of Kotmalie in the early forties, reached the patana on the opposite side of the oya and looking towards the S.W., saw a ridge to shelter him from the monsoon and then resolved to anchor.

It is now high time to return to our boys of whom the ever-cheery father soon got very fond and proud; named one after his grandfather Robert; the other after the *grandmother, Grace*. The boys grew and flourished; early developing their individual idiosyncrasies, showing in a marked manner how the child "is father of the man." Bob,

* The motto of the family "I warn and guard."

the eldest by 15 minutes, was perhaps the greatest favourite in the nursery. Græme, open, guileless and unsophisticated, ever fond of a yarn, would repeat everything he heard; while Bob showed a diplomacy which better suited the aims of the servant maids. At the same time the old nurse predicted that 'Græme would make money and Bob would spend it.' The very fact of their being in some things so much unlike, seemed to draw them closer together: as boys they were inseparable, and ever the most affectionate of brothers. When the time came for schooling they were sent to England—Harrow, I believe; and Logie saw little of them for some years. When they did ultimately return the boys had grown into stalwart youths, the peculiar characteristics however being unaltered: Bob, the sportsman and lady's-man; Græme, the plodding working-man, he too was an adept at sport; shooting, fishing, cricket and football came natural enough to him, but his tastes lay chiefly in putting his hand and shoulder to some useful industry.

The old gardener had a peculiar penchant for attending all the funerals far and near. Master Græme, nothing loth, would take his place in the garden. One day the two youths went out after lunch. Bob seized his fishing-rod and sauntered down the Gadie, while Græme, seeing the gravel in front of the house required doing up, threw off his coat, went to the tool-house for a rake and started work as if to the manner born. Presently up drives Lord Kintore with a bevy of ladies, who, seeing the young gardener in shirt sleeves, called out, "Are the young gentlemen at home?" "Yes," said Græme, touching his straw hat, "there is one down there fishing." So Bob, to his chagrin, was called up, while Græme slipped away raking along the shady walks and was lost for the afternoon.

The time was now approaching when a future career must be chosen and Græme, whose greatest ambition was to be a bread-winner, turned his thoughts towards Baharundrah in Ceylon. The estate had hitherto been always a disappointment, leaving year after year only a further loss. Yet other coffee estates were doing well—Poengalla, for instance, the property of his relative, Patrick Boyle, returning a handsome profit—and peradventure he thought Baharundrah with careful, energetic and judicious management might show equally good results. So, to Ceylon he went and as everybody knows literally put his shoulder to the wheel. First impressions were not encouraging. After walking once over the estate he returned to the bungalow almost in despair, and had thoughts of leaving the island at once, to try his luck farther East. On second thought he however resolved to try the effects of manure and careful cultivation. With what excellent results we now all know. For fifteen years there was no more active or prosperous man in Ceylon than "Logie." A planter amongst planters, a chief amongst men, and no one ever better deserved a continuance of prosperity. But *Hemileia* was a leveller, the blow fell upon the just and unjust alike; the carefully cultivated estate and garden of the sluggard alike suffered. The transition from coffee to tea had to be faced, and

no one faced it more bravely than Logie, who indeed was amongst the first to show the way; and had his good friends at home been but well enough advised to continue their support through this critical period, Sir Græme Hepburn Dalrymple Elphinstone would unquestionably have been amongst the wealthiest men in Ceylon or the Garivels today.

To the above graphic narrative we can only add, in the first place, a statistical record, noting the connection with Ceylon and the rapid extension of interests, until the present Baronet, then universally known as "Logie," became one of the biggest "lairds" among the planting community of Ceylon. We find that, so far back as the "forties," Sir James Elphinstone owned, in Kotmale district, Baharundrah and Reillagalla estates; while in 1853, they are entered in an official list as belonging to "Sir James Dalrymple"—his original name before "Elphinstone was added to it." In the same year four Coconut plantations in the Northern Province are given as follows:—

Name of Estate.	Proprietors.
Victoria	G. E. Dalrymple
Klaly.. .. .	H. E. Dalrymple
Nungavil	Sir J. D. Elphinstone
Tattoenkotty.. ..	Heirs of Sir E. D. Elphinstone

—all members of the same family.

In our Directory for 1859, we find no change; but in the issue for 1864-65, the name of the son "Mr. G. D. Elphinstone" appears for the first time as Manager of the Kotmale estates. Then in 1869 we get the area in coffee on Baharundrah and Westhall as 900 acres; while Donside (a new estate owned by Mr. G. Elphinstone and Mr. MacLeod) had 200 acres coffee; and for the first time "Logie" and "Belgravia" appear in Lower Dimbula with 450 acres of coffee between them, Mr. Elphinstone having a half-share in each. We may now go on a decade, during which our old staple "coffee" continued to flourish and rise in estimation, notwithstanding that an "insidious defunction" was at work, in the leaf fungus all this time. In the Directory for 1876-78 —when coffee had reached its maximum of prosperity—the names of Sir James Elphinstone and his son, as whole or part owners, were found opposite 32 properties in the districts of Ambagamuwa, Dimbula, Dolosbage, Kotmale, Matale East, Nuwara Eliya, Sabaragamuwa, Walapane Lower, and Yakdessa. The total acreage included was 14,468, while the planted portion covered 8,639 acres. This must have represented a money value of nearly half-a-million sterling at the time! By 1883-84, the return made a total of 12,124 acres; planted 7,714 acres. But by 1887-88, it had fallen to less than a dozen properties, aggregating total 8,010 acres; planted 3,665 acres; and in our volume for 1898-99, the name of Sir G. H. D.

Sir James Elphinstone amongst the Planters.

Elphinstone, Bart., occurs opposite the Westhall Group of three estates, 2,587 acres, of which 1,170 are cultivated, all in tea; and of Lady Elphinstone for Logie, Dimbula, 300 acres, with 282 in tea.

Sir James Elphinstone re-visited Ceylon in 1869-70 when his son was in full flow as Manager of the old properties, besides opening estates of his own. From the *Observer* of January, 1870, we quote a graphic description (also by "Old Colonist"), which carries its own story:—

THE GREAT HARVEST HOME BANQUET AT KADIANLENA.

One afternoon some eight years ago a knot of burly farmers might have been seen gathering around the quiet country inn of Pitcahle in Aberdeenshire, their object being to meet and bid farewell to the son of a distinguished neighbour, who was about to proceed to and push his fortune in a foreign country. G. Dalrymple Elphinstone was, we believe, without one dissentient voice, the acknowledged favourite of the parish, his "weel faart" face ever beaming with fun and kindness as familiar in the panper's cot as in the Ha' and while always adding to the scanty stores of the auld widow wives, he never failed to increase his own stores of racy anecdote with which he has ever since been brimful. Great were the lamentations when it became known that "Graemie," as he was familiarly called, had made up his mind to go to Ceylon, and many a lonely auld wifie at the "fit o' Bennochie" felt that she was losing her best friend. The farmers in Aberdeenshire are by no means very demonstrative in the respect they show for their "betters," but even they were not blind to the worth of young Graemie, and determined, before allowing him to leave, to invite him to a dinner at the inn—many a hearty shake did his hand get and many a sage advice did he receive. The chairman, we remember, waxed eloquent, and told him that.

"The rank was but the guinea stamp" not to rely anything on the mere stamp, but on his own energy and the blessing of Heaven.

Five weeks after this our athletic young friend found himself in the Central Province of Ceylon, his buoyant spirits somewhat damped by the first impressions. Coffee Estates, even in those latter days, were very differently worked from what they are now. Agents, like attorneys in the West, had not yet begun to discover that the interests of their constituents were identical with their own, and consequently it too often happened, as in this case, that valuable Estates, instead of being a source of profit to the owner, were only a source of annoyance and loss.

Mr. Elphinstone was not long to be discouraged, he saw the cause and discovered the remedy. Figuratively and *practically* he put his shoulder to the wheel, and the result we now see to-day in old Baharundrah, which has tripled in value and productiveness, while by mere dint of hard work, prudence and economy he has added field to field and estate to estate till he is now one of the largest and most prosperous proprietors in the country. The coffee on "West Hall" now shows as deep green as the sombre ivy on the turreted old castle of its namesake—"Logie" as much the centre of a highly prolific district as the family mansion in the centre of the Aberdeen Granary, while "Donside" smiles sweetly amongst the beautiful river-side patnas. These promising young properties have this year given their bumper crop, which having been successfully stored, the event has been celebrated in a manner never before attempted in the jungles of Ceylon.

THE DINNER.

It was only on New Year's day that it occurred to the worthy proprietors of Logie and Donside, Messrs.

Elphinstone and McLeod, to celebrate the successful storing of a good crop by a Harvest Home after the good old Scottish style, and no sooner did it occur than it was settled for the 7th and set about with their characteristic energy. 100 invitations were set afloat, and the services of that veteran purveyor, Mr. Hudson, enlisted, as well as the king of apoons, old Francis of Kandy—both of whom did their respective duties in the most creditable manner. The dinner was laid in the Upper Flat of the Kadianlena Store, richly decorated for the occasion by the ingenuity and taste of Mr. Allan, surveyor. "Wellcome all" in large capitals was capitally painted over the entrance, while such mottoes as "We are a hand of brothers," "Let Kotmalie & Dimboola flourish," "Lanka for ever!" &c. &c. adorned the walls. At eight o'clock, some seventy gentlemen sat down to dinner, the chair being occupied by Sir James Elphinstone, on a visit to his son. Amongst those present we observed the whole of Kotmalie and Dimboola; Mr. Dawson, O. B. C. Kandy; Mr. Sinclair; Mr. H. L. Forbes; Mr. Charles Grant, &c. &c., and amongst the clans represented in the Highland costume we observed conspicuous the "Forbes" and McLellan." The hosts sat at either end of the table: to those who know *Kotmalie*, the hospitality of Messrs. McLeod and Elphinstone and what the Ceylon Hotels company *can* do, it is needless to speak of the entertainment. The table literally groaned with a superabundance of the good things of this life, while "Mum's" flowed as freely as if drawn from yonder sparkling waterfall.

Before the covers or viands were removed, the CHAIRMAN, in accordance with the good old custom, proposed the usual loyal toasts, followed by "God save the Queen," "God bless the Prince of Wales" and "Rule Britannia," which were rendered with such spirit and effectiveness as we have never before heard equalled in Ceylon. The following toasts were then proposed and most enthusiastically responded to:—

"Sir Hercules Robinson" by the CHAIRMAN.

"The Army and Navy" by the CHAIRMAN. Captain OLDFIELD replied.

"The Coffee Enterprise in Kotmalie and Dimboola," by Mr. McLEOD. Excellent original song by Mr. Allan, Mr. HOOD replied.

"Our Joint Host" Mr. McLEOD by Mr. SMITH.

"Our Joint Host" Mr. Elphinstone, by Mr. MORRISON.

"The Mercantile Interest" by the CHAIRMAN. Mr. Dawson replied.

"The Chairman" by Mr. TYNDALL.

"The Ladies" by Mr. McLEOD. Mr. ANDERSON replied.

We regret much not being able to give the speeches in detail, all of which were above mediocrity. In Sir James we of course had a great acquisition;—looking the very picture of health and soul of happiness himself he threw a geniality over the whole company which was reflected on every countenance. He gave a very graphic and interesting account of his first acquaintance with central Ceylon, now 24 years ago: how he wended his way up from Colombo, got as far as Passhagey, how he met a bluff looking European whom he accosted with the hope of getting some information regarding the locality of his land, "I don't know where the d—l your land may be," was the reply, "but if you go up yonder hill you'll find an Elephant track—keep along it over the hill and down the other side you'll be somewhere near it." "Following these very definite directions," continued Sir James, "I plodded on, arrived at the ridge of the mountain and had just got into the Elephant track I remember when, out shot an Elk (here Craigy Lea became intensely interested). I scrambled down through the Forest and arrived at the patna knoll below us. There I looked back and saw I had got a good ridge to shelter me from the S. W. So I set to work there and then and built me a hut. I lived chiefly on jaggers and fungi and I did not relish or long remain in Kotmalie then, simply because I could

not get enough to eat, and had any one told me them that 24 years hence I would see some 70 intelligent-looking gentlemen sit down to dinner in this spot I would have simply said, "You're a fool!" In reply to the tremendous enthusiasm with which his health was drunk, Sir James delivered a most eloquent speech, in which he pictured a bright future for Ceylon, he repeated his views on the Galle Harbour question and urged that the cosmopolitan spirit be carried out. "Why," he says, "we are not a colony of paupers, let us pay our way as gentlemen and demand that we be treated as such." As to the Coffee Enterprise, he was delighted to see it was now in so good hands; he admired the energy, the prudence, the honourable feeling which prevailed, exhorted all present to continue in the same well-directed course—when the result could be no other than honour and independence. As for himself, he said, he was now becoming an old fellow, in all human probability within a few years of the end; he could not hope to revisit Ceylon again, but so long as he did live he would retain a lively interest in the country and those whom he had met here.

Mr. McLeod made a long and excellent speech, giving his experience during the last 20 years, which was highly applauded, while Mr. Smith quite excelled himself in his oration in praise of our worthy, joint Host, for whom he entertained the highest possible respect as a planter, as a gentleman and above all as a great hunter.

Mr. MORRISON, in a neat speech, remarked that it must be very gratifying to Sir James to find his son here in the splendid position he had raised himself to in so very short a time. No man ever more deserved to succeed—he had shown us all an example in energy and judicious estate management. Not only figuratively but practically he had put his shoulder to the wheel and had achieved a success which had seldom been equalled in Ceylon in so short a time; he looked upon him as a great acquisition and honour to Kotmale.

Mr. ELPHINSTONE'S reply was a very humorous one, he said "Although I can yarn to any extent in private I am an exceedingly bad hand at a public speech. I cannot but thank you, however, for the very enthusiastic manner in which you have drunk my health, although Mr. Morrison has said far too much in my praise (cries of No, no) and made too much of the little success I have attained in Ceylon, the largest share of which ought to be awarded to those who have so well assisted me in all my undertakings. I have indeed been exceedingly fortunate in my friends. Ever since I set my foot in this country I have met with nothing but kindness. I am delighted and proud to see so many of you here to-night, and as I have just been remarking to my friend on the left I do not remember in the course of my life ever having seen so many intelligent looking faces at one table and I feel proud to think, gentlemen, as I look around that you are not merely acquaintances *but friends*. I feel that I entertain the sincerest friendship for you all individually (cheers.) Mr. Morrison has made allusion to my putting my shoulder to the wheel. I am constantly hearing of this in the newspapers and elsewhere. Well, I *did* put my shoulder to the wheel, and I'll say this much, I'll back myself against any planter in Ceylon to drive a bullock cart. (cheers!)

THE BALL.

Shortly after 12 o'clock, on receiving a hint from the Chair, the company rose from the table and in five minutes the whole debris was cleared away. Mr. McLeod "blew up his chanter" and played a Highland reel with great spirit and taste. Sir James opened the Ball by dancing a reel in which he showed such agility as would be creditable to one half his years and led us to hope we would yet see him back in Ceylon after many years hence. Some half dozen excellent amateur violinists now screwed up their strings and struck up "The Reel o' Tulloch. The company became electrified and the result was something to be remem-

bered. Seventy stalwartmen rose *en masse* and danced with such tremendous vigour that not only did

"Roof and rafters dirl"

but Mr. McLeod cast many a wistful look at his beams, pricked up his ears, and seemed to think the company

"Had nae other thocht than how to kill"

themselves in the shortest possible time. Gradually matters subsided a little. Still the only difference seemed to be that the company had resolved to kill themselves more orderly. Reel followed reel for three hours, varied only by a country dance and a half-hearted polka, some excellent singing then took place in which Messrs. Elphinstone, Allan and Martin particularly distinguished themselves. Mr. Martin's "*Spinning Wheel*" was capitally rendered and brought down thundering applause. At half past three the company adjourned to supper which was done ample justice to, and followed up by some beautiful sentimental songs by Messrs. Grant, Smith and others. The "*Bonnie Woods o' Craigie Lea*" was a great success. But all were impatient to return to the dance and dance they *did* with unabated vigour till —tell it not in Gath—*gray daylight*. The band which disconcerted such excellent music was conducted by Mr. Grant who was occasionally very ably assisted by Messrs. Smith and Martin. The whole passed off most harmoniously, every body seemed delighted with himself and everybody else, and all seemed to agree that such merry making, when prudently conducted as this had been throughout, was more conducive to unanimity and good fellowship in a district than all the meetings ever held in connection with the P. A. We had almost omitted to notice the splendid fireworks, which seemed to be a source of much amusement and wonder to the natives. These went on, or rather went off, at intervals during the night, but the grand display was reserved for morning's just before dawn.

Our first recollection of "Logie" was in 1869 when travelling round the planting districts, collecting, for the first time, the *planted* acreage of estates. We were visiting the late Mr. John Forbes MacLeod on Kadienlena estate and meeting all the men in the district; we were made specially welcome on Baharundrah where we had evidence of the untiring industry and spirited enterprise of the young Manager. Mr. Elphinstone was then the bear-ideal of a handsome young Scot: he had had a business training in the Oriental Bank before coming to Ceylon; but it was agricultural experience at home and fondness for work that stood him in good stead. To be able to check the native cartmen—usually considered at the time to be great rogues in over-charging and also in stealing or mixing coffee *en route* to Colombo—Logie made a whole trip himself as bullock-cart driver from Kotmale to Colombo *via* the Kelani Valley, living very much as the cartmen did, roughing it right through, and so got to know more than any other man in the island about the real cost and risks of cart transport. A riding party was quickly formed during our visit, by Logie and MacLeod to visit "Dimbula Felix," Wm. Smith and Craigie Lea and "the Colonel" (Mr. Hood) on Talawakele. Logie estate was then considered the *ultima thule* of the district, there being no cart road beyond Mount Vernon; unbroken forest between Forest Creek and Dikoya, and Louisa

and Nuwara Eliya; while Wm. Smith declared all beyond the Lindula palanas and towards the Agras—where now are found some of the richest plantations in Ceylon—as only fit for hunting purposes! We need not say how large a part Sir, or as he was then Mr., Græme Elphinstone had to do in “pioneering” beyond Smith’s limits, or how ready he ever was to give a helping hand to a poor neighbour, or even to become partner with a friend trying to get on the ladder of proprietorship.

The career of the worthy Baronet as planter here, is but an epitome of many a similar experience in Ceylon connected with the “rise and fall” of the Coffee enterprise. The hard hing in connection with Sir Græme Elphinstone is that, while he was one of the first to foresee what was coming and to pioneer with “tea,” he was not allowed to reap the reward of his foresight; and properties were taken away, even after being planted with the new product which, if they had been left in his hands, would have cleared all burdens, and become splendidly remunerative estates for the man who first planted tea.

Still it may be said of Sir Græme Elphinstone that in Ceylon he did better than achieve success—he most fully deserved it. No man ever more so: a planter among a thousand—hard-working, never idle indeed, cheery and generous and a chief among good men.

When the end of the Ceylon career came, and Sir Græme had to return to England, he, for some time, interested himself in making Ceylon tea known and in the establishment of a London distributing business. In 1894 he was elected Ceylon Planters’ delegate for tea in America and was much pleased at the confidence placed in him—sending us a letter conveying his thanks to brother planters and fellow-colonists; but other business in London and the country at the time prevented his actually going to America. After a period of rest in Cheshire, the old longing for a useful and therefore planter’s life in the tropics overcame “Logie” and we have a letter before us dated “Straits of Malacca, ss. ‘Khedive’, 11th Dec., 1895,” in which he stated the possibility of his settling down on Waterloo estate, Perak, of which he was part-proprietor. He had travelled out via Canada, Vancouver and Japan and the immediate purpose of his writing—characteristic of the man—was to enlist our sympathy on behalf of a young ship’s officer who had fractured his leg and of whom “Logie” had heard as lying in Colombo Hospital (although he had left for home before we got the letter and called). We do not think Sir Græme has been home since 1895, so that he has now had

another spell of well-nigh five years of tropical work and when last we heard from him he was going in for the cultivation of a variety of new products, sending for all our Planting Manuals in order to refresh his recollections of what had been done in Ceylon. Here again, we may not be able to chronicle a brilliant success for Logie, but that he has done his part well, there can be no doubt:—

’Tis not in mortals to command success;

But we’ll do more, Sempronius; we’ll deserve it.

It only remains now to notice the portraits presented with our present issue. That of Sir Græme Elphinstone is good and characteristic and will give pleasure to his numerous friends. In the other we have a veritable “leaf from the past,” for Sir James Elphinstone in the centre, in contrast with two of the youngest members, one on each side, is surrounded by the company assembled at the Kadienlena Harvest Home of Jan., 1870, reported above. The group may be said to be historic including many District pioneers like J. F. MacLeod, Wm. Smith, Humphrey Humphreys, John Tyndall, John Martin, “Colonel” Hood, “scientific” and genial Heelis, “Cheetah” Morrison, Jas. Wight, John Stronach, Hugh or Wm. and James Bisset, Wm. Allan (Surveyor), F. Hudson (Purveyor),—while “Logie” and Arthur Sinclair kept in the background. This is one of the best photographs ever taken by Humphreys (who is among the few survivors, now a hearty British farmer) and well reproduced by an Aberdonian Firm. But of the great majority what can we say, alas! save in poor Charles Lamb’s lines:—

The old familiar faces—

How some they have died, and some they have left us,
And some are taken from us; all are departed;
All, all are gone, the old familiar faces.

JADOO.

(To the Editor, “Tropical Agriculturist.”)

EXETER, 18th Jan., 1900.

DEAR SIR,—Our attention has been called to a reply that appeared in your issue of December 1st to a letter from a correspondent at Kandy, with reference to the use of Jadoo Fibre for strawberries. Will you kindly permit us to say that it has been proved practically impossible to “wash out” the properties of Jadoo Fibre even when exposed to tropical rain. As to its use for strawberries it is being taken up on a large scale for use with them in the open ground in Cornwall this year. And if your correspondent will apply to Mr. Batho of d’Hautier Gardens, St. Saviour’s, Jersey, he will, we know, tell him that an enormous increase in crop has gained by him last year by using Jadoo for strawberries besides getting a much better price for the fruit in the Covent Garden Market than he did for what was NOT grown in Jadoo.

With regard to what you say about Jadoo having proved a failure for use in nursery beds for Tea and Coffee, you will perhaps allow us,

to say you are entirely mistaken. We have never heard of one single instance where it has failed in being a complete success for *nursery* purposes; in fact, its root-forming properties are invaluable for that purpose. Unfortunately planters in very many cases, overlooked the fact that its use was being recommended for *nursery purposes only*, and because it was too expensive for use with old trees, condemned it and others hearing this jumped to the conclusion that it was a failure for seed beds also.

We hope hereafter to be able to reduce the cost so as to bring it into use for manuring old trees, but at the present price it is quite within the reach of every planter for nursery purposes as the freight has been greatly reduced owing to improvement in mode of packing Jadoo for export.

—Yours faithfully,

C. HALFORD THOMPSON,
Chairman, Jadoo Limited.

[Our information was entirely from practical men.—ED. T.A.]

PULVERISING THE SOIL,

The value of pulverising the soil repeatedly is not generally understood by farmers who cultivate large areas of land, but the market gardener, who has only a small space on which to make a living, shows by his methods that he realises the importance of this work. Incidentally, pulverising the soil means good culture of plants, but plants can be cultivated and the soil may not be pulverised. The finer we pulverise the soil around plants the better is the mechanical condition of the soil for making the plants grow and resisting dry weather. When we study the subject from a scientific point of view, we can understand better the effects of what is good culture. Everybody in this age understands the theory of the evaporation of water from the soil; how the water rises from the subsoil or underground springs by capillary attraction, and, if not taken up by the plants, passes off into the air. This evaporation begins on the surface, and extends gradually downward. If the soil is too thick and compact the moisture has difficulty in drying up, and the top layers dry very slowly. Such land is usually wet and muddy in ordinary rainy weather, and it is unfit for crops. In order to facilitate capillary attraction, the soil must be so pulverised that the air spaces in the soil are small. This enables the soil to rise gradually and continuously. By good cultivation on the surface the plants are kept well supplied with moisture all of the time, and every fresh stirring of the top soil starts up new reservoirs of water from the subsoil.

Gardeners have what they call a dust mulch, which is simply another name for good, thorough surface cultivation. They stir the soil around the plants every week or few days, and the soil becomes so thoroughly pulverised that capillary attraction is in rapid progress all the time. It has been demonstrated that, on the right kind of soil, garden plants can in this way be brought through the driest weather imaginable, and without a drop of water artificially supplied. The dust mulch is better for the plants than an artificial one of leaves and litter, although the latter are not to be neglected where it is impossible to give the thorough pulverisation required. This stirring of the surface soil is more important when the plants are young than when they get half grown. Then they shade the ground around the roots, and form a protective moisture holder that helps them through the hot weather. After all, it is the young immature plants that we have to care for and tend, and, if we succeed in getting them started aright, the crops are pretty well assured.—A. B. BARRETT, Minnesota.—*Agricultural Gazette*.

PRESERVATION OF STABLE MANURE.

In a paper read before the last annual convention of the Cheese and Butter Association of Western Ontario, Mr. Frank T. Shutt, M.A., Chemist of the Dominion Experimental Farms, Canada, took up a subject which is of the greatest importance to farmers who wish to get the best results from their stores of farm-yard manure. After showing how necessary it is that farmers should make themselves acquainted with the nature and composition of manures produced by the different classes of live stock, and the conditions and influences that increase or decrease the fertilising value of it, Mr. Shutt detailed certain experiments recently carried out at the Experimental Farm at Ottawa in connection with the rotting of manure. In this experiment or investigation the principal object was to learn what losses took place in nitrogen, phosphoric acid, and potash during the rotting of manure under two conditions—(a) manure completely protected from the weather, and (b) manure rotted in an open bin, using all ordinary precaution against undue leaching. Secondly, to learn the result of fermentation upon the availability of the plant-food in the manure. This is an important question, for it is quite possible to have the soil loaded or saturated with the elements of plant-food, nitrogen, phosphoric acid, and potash, but so combined that they are of comparatively little value to growing crops, that is to say, are not soluble in water. We are all aware that the nourishment crops take through their roots must be in solution. Plant-food to be available must either be in solution or soluble in the slightly acid sap which roots exude. Plant-food in other forms than these is not available for our growing crops. For instance, in various parts of Canada phosphate of lime or apatite is mined. This mineral phosphate, no matter how finely it is ground out, is useless (because insoluble) to growing crops. It had been tried and that conclusion had been reached after several years of experimenting. But treat this mineral phosphate with sulphuric acid, and it is converted into super-phosphate, a most valuable, because soluble, source of phosphoric acid for crops. It was desired to learn therefore whether fermentation under the conditions named affected in any way the availability of the plant-food in the manure.

EUCALYPTUS LEAVES.—A farmer in New South Wales claims (say the *Australasian*) to have discovered a new use for eucalyptus leaves. The discovery is certainly a valuable one if it be found as effective in practice as it is stated to be. The gentleman referred to asserts that if fruit trees are mulched in the season of rest with eucalyptus leaves they will be entirely free of blight or fungi of any kind the following season. His own practice is to gather all the gum-tree leaves within reach, and if necessary, cut down eucalyptus branches, and spread them over the orchard. If this plan is regularly followed, he states that the fruit trees will be completely protected against scale of fungi of any sort. I have not seen the trees which the owner declares to be thoroughly free from the pests mentioned, while others close by, and not so treated, are almost worthless, but I have every confidence in recommending others to give the remedy a trial. The discoverer is a practical fruit-grower, and knows what he is talking about. He further advises that all orchards should be sheltered with eucalyptus instead of other deciduous trees, which act as a breeding ground and harbour for the insect pests which so annoy fruit-growers. There seems to be a good deal of reason in these suggestions. The eucalyptus trees, it has often been observed, are remarkably free of disease of any kind, and the pungent oil in their leaves very probably does contain some property that is repulsive or fatal to the insects and fungi which infest our fruit trees with such disastrous results.—*Journal of the Jamaica Agricultural Society*.

NEW AND OLD PRODUCTS IN ZANZIBAR.

(Concluded from page 448.)

Approximate yield per tree.—The number of clove trees at Marseilles was stated to be 5,000, but on re-counting we found there were 7,500 bearing trees at Marseilles and 1,000 at Kitumba—together 8,500. On December 31st we had gathered, approximately, 1,300 frassas, and might, I think, safely count upon another 300, making a total of 1,600 frassas. This gives an average yield of over 6½ lbs. per tree. A good proportion, about one quarter, was left upon the trees ungathered through lack of labour. With sufficient labour we should, I think, easily have reached 2,000 frassas; the approximate yield per tree is therefore brought up to over 8 lbs. The trees at Dunga were just as heavily laden with buds, but they never ripened properly; at least half the crop failed. We reached about 350 frassas, which from 3,000 trees gives an average of 4 lbs. per tree.

Returns.—Our actual sales at the end of December amounted to 873 frassas which realized 5,535 rupees, while we had on hand at the custom house unsold and in the plantation godown an estimated quantity of 424 frassas which, valued at the current rate of 5½ rupees a frassa, was worth 2,332 rupees. Our gross returns up to December 31st may therefore be taken as R7,867. Our expenditure to that date was 1,725 rupees, or about 22 per cent of the gross returns, and our net profit is shewn as R6,142.

ACCOUNT STATEMENT TO DECEMBER 31st.

	R.
873 frassas sold	.. 5,535
424 „ (approx.) on hand	.. 2,332
<hr/>	
1,297 frassas	Total ..R7,867
<hr/>	
Expenditure to December 31st	.. 1,725
Net returns	.. 6,142
<hr/>	
	Total ..R7,867
<hr/>	
	Net returns ..R6,142

This is equal to a net profit of 4 rupees 11 annas per frassa.

The amount 1,725 rupees as the actual cost of gathering 1,297 frassas works out to 1 rupee 22 pice per frassa and differs slightly from my first estimate of 1 rupee 13 pice. This discrepancy may be accounted for by the alteration in the rating, which was at first per 300 pishi: I wanted the headmen etc. to receive a fair but not an excessive wage; but as the season advanced I found that I had underestimated the daily pick, which was about 400 instead 300 pishi, so I altered the rating accordingly. The spreaders were allowed 3 pice each per day, but at Kitumba where the quantity of cloves to handle was proportionally much less, the spreaders were paid at a higher rate. This would introduce another slight error into the first calculation. The whole of the Kitumba staff of headmen etc. should in reality have been rated differently, but this would have led to confusion in the accounts which were kept by an Arab who, admirably as he did his work, was not familiar with European methods of book-keeping. For the same reason I abandoned at Machui the idea of paying the pickers at the rate of 4 pice for every pishi picked after the first six. Where supervision is difficult as it is in clove picking, this system would most certainly have led to imposture by the people. It would, for instance, have been easy for two or three to have united their day's gatherings in order to make up the required quantity for the extra pice. At Dunga, which was I believe the only place where the system was adopted, we had not a sufficient amount of cloves to judge of its efficacy.

The net returns to December 31st are then shewn to be R6,142. Allowing now for the estimated 300 frassas still to pick and valuing them at 5 rupees a frassa, the price to which cloves subsequently dropped, the total net returns are increased to R7,245.

ACCOUNT STATEMENT FOR THE SEASON (APPROX.)

	R.

Rupees 7,245 from 8,500 trees is equal to an income of 13½ annas per tree.

The waste upon the trees which I have estimated at one quarter of the crop would, if collected, have sufficed to pay for the entire expenditure. My object here however is to compare our actual expenditure and receipts and to arrive at a fair estimate of what a clove plantation may be expected to yield. The unpicked surplus is, therefore, better left out of account. Treated thus it will help to neutralise the effect of basing our calculation upon an abnormally large crop.

Our cloves were not subjected to the usual 25 per cent export duty.

This reduces the income per tree to 9½ annas; or R54 (£3 12s.) per acre: 90 trees to the acre.

Cost of Working a Clove Plantation.—Beyond purchasing drying mats and paying the harvesting expenses, the Arab spends little or nothing upon his clove trees. He employs his available labour, for the most part, in growing manioc, sweet potatoes and bananas for food and for sale. Thus the resident Arab in charge of Marseilles, when we took over in May, was expected to make 34 rupees a month by the sale of fruit and annuals, and was in consequence compelled to keep his men cultivating the open spaces and to leave the trees alone. This is a fair sample of Arab practice; it is a policy of looking after the pence and neglecting the pounds. The weeds on this shamba were half way up the trees, in some cases climbing completely over them; many were dying and 1000 had been killed outright. It cost us R5 per acre to clear the land reckoning 90 trees to the acre. We let out contracts giving four pice of each space between four trees. When the land has been once or twice thoroughly weeded over, the cost of cultivation will be much reduced. In addition to cleaning the land we hope this year to dig round each tree at a contract price of probably 1 or 2 pice per tree. At Dunga we are now doing this work with two mules and a plough. Drying mats cost 30 rupees per 100 and baskets 3 rupees per score; 800 of the former and 100 of the latter were purchased for use at Machui, but at least half of these will be available for use again next year. There are no other outgoings to note beyond the overseer's wages, the purchase of a few dozen hoes, and items such as thatching and repair of houses and sheds always incidental to the management of an estate.

It seems to me indeed that clove planting as an industry has been somewhat unworthily discredited. Over-production and the labour crisis have brought about the stagnation of all enterprise, but I believe that clove planting in Zanzibar would respond to European management and proper cultivation. The production of cloves must decrease as years go on, as no young plantations are being made to supply the waste among the old trees. Such a year as this must exact a heavy toll; the enormous yield, coming as it has done in a year of drought, will exhaust the trees, while the drought itself will have killed off many thousands. It will always be to the interest of Zanzibar, if not to overproduce, at least to keep the markets well stocked in order to keep out opposition and preserve the monopoly. As long as the monopoly is maintained the clove industry will never hopelessly degenerate in the way, for instance, that sugar planting has.

Mistreatment of the trees.—The rough handling which the trees receive during picking is a very serious

evil and one difficult to check. The shamha people are as bad as, if not worse than, the outsiders and seem to have been trained upon careless and destructive principles. To be too strict in the matter is to run the risk of your wageni pickers deserting to other shamhas where they will not be molested. It is the buds upon the tops and the lateral extremities of the boughs that are so difficult to reach, and at Machni we were compelled to leave those. At Dunga where we had sufficient labour to keep half a dozen ladders going we did not succeed in thoroughly clearing the trees. Three men working one ladder will bring in 6 pishi a day; it would therefore have been unprofitable to have diverted the labour, where it was scarce as at Machni, from the accessible buds to the ladders where three men could only pick the equivalent of one.

Another fruitful source of trouble is the ravages of the *maji moto* ants, which weave their nests in the branches and are sometimes so bad that pickers cannot climb the trees till they have first smoked them out by lighting a fire underneath. When this takes place the lower branches of the trees are frequently singed and the trees sometimes fired altogether. The ravages of *maji moto* ants can be kept under by weeding. Well-weeded shamhas are seldom troubled much with ants.

Experimental drying of the Cloves at Dunga.—Both Mr. Robertson and myself have given a good deal of attention to clove drying. We studied the Arab methods and found that they almost invariably heaped up their green cloves in the godown the first night after they are picked. If the weather is showery, preventing drying, the heaps remain for several days, growing larger with each day's picking. Fermentation is in this way set up, the cloves emerging a rich brown colour. It occurred to us that as this colour approached the rich tan colour so desirable in the dried clove that a properly controlled system of fermentation might be beneficial. But our experiments showed this idea to be erroneous; cloves should be spread out immediately upon being measured in; heated cloves turn black. We trained one people to separate the burst from the good buds while staking. It can be done at this time with little trouble and with no extra cost, but the invariable custom is to let good and bad all go in together. Before finally sending to market we passed the cloves through a riddle to remove the small immature buds. By these means, which is only the old story of attention to detail, we produced what, for Zanzibar, was a fairly good sample, though falling short in the size of the buds. This was a defect which we could not remedy most of the cloves this year have been small.

Practically no difference is made in the local market between good and ordinary, so I was induced to send a small trial lot of 140 frassals to be sold separately in London, to test the value of our work. Early in the year I had sent home to Messrs. Gray, Dawes & Co. an experimental sample of cloves that had been dried last season, and Mr. Hugh Garden of that firm reported on them as follows:—

"As regards the cloves this is of course the finest sample of Zanzibar ever shown, and buyers who saw it valued it at seven-pence to eight-pence. There is still a considerable difference between this and Penang which, somehow, appear to retain their reddish brown colour. A very fine sample was bought in at auction at eleven-pence or eleven-pence half-penny, and was being held for one shilling. The market apparently makes the same difference between Penang and your sample—in value—as between your sample and ordinary fair Zanzibar, but this too you must understand is only for very limited quantities."

These cloves were dried under glass after having been specially picked. More depends upon the picking than upon the drying. It is impossible for us here to pick the buds singly because of the quantity to handle; they must be picked in bunches, as they grow; and the small and over-ripe buds sorted out afterwards.

In order to test the efficacy of glass we erected small house 30 feet long and 14 feet wide with galvanised iron walls and a glass roof. The heat of the sun was in this way increased 25° beyond what it was in the open air. This increased temperature did not hasten the drying process so much as we expected unless the cloves were first raised upon shelves. The heated air was then able to act from below and above, and cloves could be dried in two days in cloudy weather with only short intervals of sunshine. All our cloves were finished off in the glass house. I don't think that the elevated temperature to which they were exposed contributed so much to the improvement in quality as the sorting and riddling. We shall try and arrange next year a system of shelves to increase the drying area of the clove house. Our experiments have, however, shown that cloves must be exposed to the direct heat and light of the sun; if dried in the shade they turn black.

The glass house has been the means of saving labour as the cloves, once spread out in it, could be left to dry. Much time is lost, at a time when every available man is required for picking, under the present system of taking the mats in and out morning and evening and in showery weather. At Marseilles this became most serious as we had between four and five hundred mats to handle each time.

The Clove Crop generally.—The magnitude of the clove crop may be judged by the returns for November and December. In those months Pemba sent in more cloves than in any previous month of the years tabulated, while the total for the two islands for December, namely 121,858 fras. exceeds all previous returns. The Zanzibar crop was late, hence the total of 60,365 fras. for the year is the lowest since 1890, though the ports for December, namely 32,399 fras., is the highest on record for Zanzibar in one month. Still a heavy loss has taken place upon the trees. The dry weather of December, the rainfall for which was the lowest on record, following upon an unusually dry year, caused the trees, especially in the districts where the crop was very late—Dunga, Kitumba and the north end of the island—to shed starved and immature buds, and labour was diverted from picking to sweeping up the fallen cloves under the trees. A quantity has been gathered in this way though a far greater quantity has been lost. Picking in these districts never really got into full swing.

In the Machui district the crop was abundant and well forward, but the labour was totally inadequate to cope with it. The trees look as heavily laden now with ripening mother of cloves as they did in the beginning of the season with buds, and the proportion picked must be quite insignificant to that which is left. In the South Mvera country the crop was earlier and lighter and was comparatively well gathered. Pemba seems to have suffered less from the effects of the drought than Zanzibar. The soil of Pemba, having more clay than ours, is more retentive of moisture, and therefore better able to resist the effects of drought. The Pemba trees, too, are older and their roots will consequently have reached deeper levels for their food supply.

III. COCONUTS.

The Dunga trees yield about 30 nuts per year, and the Machni, which are older, 40 nuts. Gathering has cost with us about 4 rupees per thousand nuts, and the nuts can be sold on the spot for from 20 to 22 rupees per 1,000; there is therefore a profit of say £17 per 1,000. Now a thousand nuts are the product of 33 trees, at 30 nuts per tree. Trees are planted 35 feet apart which is 35 trees to the acre. Roughly then we may take it that 1,000 nuts are the produce of an acre of land and give a net return of £17 (£1.2.8) per acre of half a rupee per tree. There are no other outgoings to be charged to coconuts as the trees are not cultivated in Zanzibar. Mr. Last has more than trebled the yield of his trees at Mangapwani, which he attributes to having dug the ground round them. We find at Dunga that digging and mulching with grass can be done for about 3

price per tree; the margin of profit, therefore, as shown by Mr. Last's figures is enormous. In addition to digging and mulching with grass we scatter a little Latham island guano or lime around each tree.

The coconut industry stands well with the European markets and seems, like rubber, to have an assured future. Coconuts form a staple article of food and common utility; their cultivation must be confined to the tropical littoral, and cannot, like tea, coffee and cocoa be extended to the interiors of Africa and South America as these become opened up. I believe that the planting energies of this Island, seeking an outlet, could not be better directed than to the cultivation of this tree which is simple and inexpensive, while the profits are assured.

We have not as yet been able to make any definite experiments in copra drying. In consequence of the crude methods in vogue we have found it more profitable to sell the nuts on the spot than to make copra. We intend this year to utilise the new glass-roofed house for copra drying in the intervals of clove picking.

CHILLIES.

The small clearing on the coral of about 3 acres, which we planted two years ago, has gone through a second period of drought, and crops have been exceedingly light. All attempts to supply the gaps caused by deaths have been unsuccessful. We thought of abandoning the plantation as having shown conclusively that the cultivation of chillies will not pay here, but must be left to the Wahadimu; but in consequence of the abnormal seasons being scarcely a fair trial, we decided to keep the clearing on another year.

In August we submitted to Messrs. Gray Dawes & Co. some samples of chillies for report, and Mr. Hugh Garden wrote of them as follows:—

"I have received your letter of the 2nd inst. together with samples of chillies.....Such a sample for Zanzibar has never been shown in this market, and if coming in small parcels I think they will realize ten to fifteen shillings per cwt. over ordinary Zanzibar fair. You must not forget, however, that it is only for a limited quantity that this premium would be obtainable. Japan chillies, for instance, were fetching, I imagine, twenty to twenty-five shillings per cwt. more than Zanzibar at the time you were in London (1896). Last week Japans were sold as low as thirty-one shillings and sixpence, or practically the same price as the value of Zanzibar "fair," on account of increasing imports."

These chillies were dried in the ordinary way upon mats in the sun, but they were stalked and kept clean. Any native who chose to take the trouble could do as well. Chillies are often shed from the trees before being gathered, in which case they will have been weathering upon the ground and lost colour. The stalks are left on, and, in drying, the chillies get mixed up with soil and leaves, and often come in for a drenching on their way to market. The inference drawn from Mr. Hugh Garden's report is that if Zanzibar chillies received the ordinary care and attention that any white man would give them as a matter of course, they would command the highest price in the London market, instead of the lowest as at present.

BANDA NUTMEGS AND MACE:

By O. KAMERLINGH ONNES.

(Concluded from page 491.)

III. TRADE.

WAREHOUSING AND AUCTIONS.

When the nutmegs and mace reach the *Amsterdam* and *Rotterdam* markets by the steamers of the Dutch Steamship companies plying between Holland and the Indies, they are all warehoused in Bond, where they are gradually sorted by the worn Spicebrokers.

Every case of nutmegs is opened, the worm-eaten nuts, if any, are thrown aside, whilst the contents are classified according to quality in Nutmegs: Nos. 1, 2, 3, 4 and "Separate."

Each case of mace is equally opened, the various qualities being designed Mace: *E.*, *F.*, *G.*, "Separate" and "Broken."

Sales.—Every three months public sales are held in Amsterdam and Rotterdam, the first days of these sales alternating between the two markets.

Samples.—Samples may be inspected in the bonded warehouses daily during 4 or 5 days before sale.

Conditions.—The conditions of sale are: bids to be made in cents (Dutch) per $\frac{1}{2}$ Kg., delivery within a fortnight discount $1\frac{1}{2}$ pct., or within three months without any discount. Bids are only accepted through the medium of sworn brokers, who are bound to state name of buyer.

The large importers have lately sold their produce in public sale by auction, whilst a few others still adhere to the old system of selling under cover.

For each parcel of nutmegs or mace a dock-warrant is handed to the owner of the goods, which entitles him to remove the parcel at once or to leave it in Bond on the condition of 15 cents (Dutch) per 100 Kg. rent for warehousing, insurance included.

All banks will advance money on these dock-warrants.

IN THE FINANCIAL MARKET.

As nutmeg and mace, well stored, are not subject to deterioration they lend themselves easily to speculation when prices are low.

DELIVERY.

The buyer has a right to have each parcel weighed over again, but he seldom avails himself of this right. He is also entitled to have each case opened to inspect the contents, but it is customary to take the broker's description for granted.

Every buyer packs the goods in his own style and according to their destination.

TRANSIT FREE.

On leaving the bonded warehouses goods in transit are free of duty, but on parcels for home consumption duty is payable.

DUTY OFF!

With regard to the latter it has been proposed to take off the duty, which would be advisable as the amount of duty received is relatively small, and as it would conduce to an easier movement of the market if the goods could be warehoused free anywhere.

ADULTERATIONS OF BANDA AND NUTMEGS AND MACE.

Caution against Frauds.—The bad habit of our days of adulterating different articles of food, even when prices are low, has crept into the trade in nutmeg and mace far more than would be thought possible. *Fraudulent Mixtures.*—From the moment that the article was placed before the public in a ground state, under the pretext of

offering greater facilities and economy in the kitchen, unscrupulous caterers have not hesitated to mix the article with all sort of rubbish, which in many cases is decidedly injurious to the public health. *Detection of Fraud.*—Connoisseurs might detect the fraud either by the colour of the ground substance, showing a deviation in the shade, which ought to be a light brown, or by a pungent disagreeable taste instead of a pleasing aromatic flavour.

Caution against ground Substitutes.—In order to be always on the safe side the public should decidedly refuse the ground article and ask for the superior Banda nutmeg, which should be firm and more particularly round, whereas the inferior article such as the wild nutmeg and the New-Guinea and Borneo or similar lower class produce is of a long, oblong shape and entirely wanting in the exquisite flavour for which the real article is estimated so highly.

Other Frauds.—The deception practised upon the public does not even stop here, and lately *artificially moulded* nutmegs have come under our notice. The swindle of this kind may be detected by breaking the sham nut which does not show the characteristic graining of the real article, whilst the mark of the moulding always leaves some traces on the artificial nut.

Caution against other Frauds.—Repeatedly the nut has been robbed of its oil by Distillation (*sweating*), whilst the holes caused thereby have been filled up with sassafras. Buyers should beware of such fraud which may be easily detected by the light weight of the nut.

Swindle with Mace.—Lower class mace and other indifferent substitutes which are mixed with the genuine Banda, have been forced upon the public. Buyers should refuse inferior mace and flavourless dust.

SCIENCE *versus* FRAUDS.

Microscopic and Chemical Tests.—Besides the various tests mentioned, Science disposes of several means to detect frauds, and we are glad to say the sham article gets less chance every day to pass undetected.

Price of Nutmegs in former years:

1840—1855 highest (in 1845) 286 cents (Dutch) per ½ kg., lowest (in 1843) 120 cents.
1855—1863 prices falling; lowest (in 1863) 60 cents (Dutch) per ½ kg.
1863—1872 prices going up; (1872) 203 cents (Dutch per ½ kg.

* As a rule mace appears earlier in the market being sooner ready for shipment than nutmegs.

† 1890—1898 according to Brokers' circular, published by Mr. W. F. Westermann, Amsterdam.

* 1890—1898 according to Brokers' circular, published by Mr. W. F. Westermann, Amsterdam.

1872—1885 prices falling; 118½ cents (Dutch) per ½ kg.

1885—1890 prices going up; 165 cents (Dutch) per ½ kg.

IV.—USE.

The old German and the old Flemish songs almost identical in their opening lines, singing the praises "of the two little trees standing in my love's garden," are an instance of the secret poetical charm which things oriental have always exercised on the western mind. As Camoëns sang in the *Lusiad*, Heine in his *Lieder* on the Ganges, enriching literature with the glowing picture of oriental beauty, so in a more matter of fact way the most famous cookery books of olden days are redolent with the scent of the spices of the Indies.

This predilection for spices has not left the Flemish women yet, and their excellent kitchen recipes still do credit to the numerous piquant qualities of both Banda nutmeg and mace.

In fact we could hardly suppose a list of Flemish or Dutch *Wedding Presents* to be complete without a *nutmeg box* and *grater*, and for years a special present on the 6¼ anniversary of the wedding day called "*the Pewter-Wedding*" in Holland, has been a pewter spice-box. Fashion during many years too much under foreign influence, has made this typical present recede into the background, but wherever a young housewife considers herself the natural mistress of the kitchen, it is still an indispensable item of her wedding-wishes.

Of late the desire of being the personal attendant to her husband's comfort as well as his spiritual companion has drawn the Dutch woman's attention especially to the kitchen-department, and this good principle has been strengthened since, by the decided success of the *Dutch Cookery Schools*.

Although the days of mediæval opulence are irretrievably past, the necessity of good feeding is becoming more evident in these days of mental and bodily strain. Had children always being fed as ours are, many of the complaints of the generation which now peoples watering places and seaside resorts, would never have arisen, so we may consider it a boon that such institutions as our *Housekeeping and Cookery Schools* accustom the female mind to the ancient truism that "a sound mind can only live in a sound body."

Though perhaps Feuerbach goes too far in saying: "Der Mensch ist was er isst," and we should consider it rather an insult to man that "the way to his heart lies through his stomach;" yet a great truth underlies these exaggerated sayings, the truth that energy depends in the first place on health, one of its principal factors being good palatable food.

Among the many institutions of the kind in Holland the Amsterdam Cookery School (*Amsterdamsche Huishoudschool*) under the management of Miss S. G. F. Meyboom is one of the best.

We have much pleasure in quoting the following recipes which we owe to the kindness of this lady, whilst the photos which appear in our text were taken in the classes under her direction. One represents the object lesson in spices, whilst the other shows the practical application of the recipes we give below.

CULINARY USE OF BANDA NUTMEG AND MACE.

Brawn.—1 calf's head; 4½ lb. veal; 1½ oz. salt and pepper; some gherkins; 1 grated nutmeg; 20 cloves, pounded; ½ pint vinegar; 1 leaf of gelatine to each ½ pint of liquid.

Boil head 5 hrs; meat 3 hrs. Remove bones and chop all. Mix with spices and some broth. Put mixture into mould, place paper with a slit cut in it, on the top; add vinegar and leave 8—10 days.

Meat-Chopped.—1 lb. chopped meat; 2 oz. soaked bread; ½ oz. salt; some pepper; ¼ nutmeg, 2½ oz. butter; 1 egg.

Soak bread in egg; work it into meat and spices; flour it and bake in oven with butter 30 mins.

Crème in clear Soup.—½ pint bovril; 2 eggs; nutmeg, pepper, salt; chopped parsley. Beat up eggs 10 mins; add the rest whilst stirring; leave 20—30 mins. in oven or bain marie till quite stiff. Cut it up into small squares and serve in clear soup.

Potato-purée in Scallop Shells.—1 lb. mashed potatoes; ½ pint milk; 2 or 3 yolks of eggs; 1 oz. butter; 5 oz. ham; some nutmeg.

Mix washed potatoes with spice, yolks, melted butter and chopped ham. Fill shells, flour them; small balls of butter on it; bake in oven, brown.

Mashed Potatoes.—1 lb. boiled potatoes; 1 pint milk; 1 oz. (not quite) flour; 2 oz. butter; some nutmeg.

Mix milk, butter and flour; slice potatoes into it; leave some time in oven and grate nutmeg over it.

Asparagus.—Clean them and cut off hard points; tie 6—8 together and boil in water or steam. Add melted butter, hard boiled eggs, and grated nutmeg.

Nutmeg may be grated over various vegetables: boiled lettuce; endives, French beans, cauliflower, savoy, white cabbage, turnips, purslain, etc.

Gelantine.—½ lb. veal; ½ lb. pork; 1½ oz. smoked ox-tongue; 1 oz. fresh bacon; ¼ grated nutmeg; 1 egg; ½ oz. salt and pepper; 1½ oz. soaked bread; 1 glass Madeira; 4 truffles; 3½ oz. tripe.

Cut up meat raw; mince with tongue and bacon; mix it with the rest, and make it into a ball; roll tight in tripe; tie cloth round it and boil 1¼ hr. Press 24 hrs. between two dishes under weight; serve with aspic and lemon, sliced.

Indian Cake.—3 oz. flour; 6 oz. butter; 6 oz. sugar; 5 eggs; 1 grated nutmeg; ½ stick vanilla; 2 teaspoonfuls cinnamon; 25 cloves, pounded.

Whip butter into cream; add yolks of eggs, sugar, flour, spices and white of eggs beaten up stiff. Make thin layer in mould, previously rubbed with butter; allow layer to go brown; rub with butter; place second layer on it; etc.

Spice-Cake.—4½ oz. butter; 4½ oz. flour; 4½ oz. moist sugar; 4½ oz. currants; 4½ oz. raisins; 3 eggs; ½ nutmeg; 1 teaspoonful cloves, pounded; 1 teaspoonful cinnamon.

Mix butter and flour; stir yolk with sugar; add currants, raisins and spices; beat up white of eggs stiff. Then lay stiff white on yolks; mixed butter and flour on top; stir all gently.

Nutmeg-Cake.—9 oz. flour; 5½ oz. sugar; 7 oz. butter; 6 eggs; 1 nutmeg; 1 teaspoonful baking powder; ½ pint water.

Work butter into flour; stir yolks with sugar; add water and baking-powder. Beat up white of eggs stiff; stir it all gently; bake cake in mould, rubbed with butter, well floured and sugared.

Frankfort-tablets.—5 oz. flour; 2½ oz. potato-flour; 3½ oz. sugar; 3 oz. butter; 3 eggs; ½ nutmeg, grated; 8 cloves, pounded.

Stir butter and sugar 10 mins.; and yolks, one by one; spices, stiff white of eggs add flour. Roll out paste thin on oven-tin; sprinkle some chopped lemon-peel and bake it light brown-cut up in bars.

Tapioca-dish.—1¼ pint milk; 4½ oz. tapioca; 2 eggs; 2 oz. sugar; 1½ oz. butter; some grated nutmeg.

Boil milk; add tapioca and stir well till done. Add sugar, butter and nutmeg. Let it cool down; add beaten yolks, and last of all white of eggs, beaten up stiff. Bake brown in baking-dish in oven.

Sausage-rolls.—4 (small) rolls; 3½ oz. chopped beef; 4½ oz. chopped pork; some chopped onions; 3 teaspoonfuls milk; pepper, salt, nutmeg to taste; chopped parsley.

Cut tops off rolls and hollow them out; rub inside with butter; fill with meat, dressed with other ingredients. Put on tops again, rub outside with butter; bake in oven till crisp.

Rissoles.—12 oz. meat, fish or shrimps; 2 oz. butter; 1 oz. flour; ½ pint bovril; salt and nutmeg; 1 egg; chopped parsley.

Mix butter and flour well; add warm bovril; boil a few minutes; add egg, chopped meat and spices. Let mixture cool down; divide into balls or cones; roll well in flour; fry in hot fat till brown. Serve with sprigs of parsley, slightly fried.

Gelantine.—1 lb. scraps of meat; nutmeg and pepper to taste; 1 onion, chopped fine; parsley chopped; lemon juice; ¼ pint water; ½ oz. gelatine.

Chop meat fine, mix with spices and put in mould; pour water over it in which gelatine has been dissolved; boil all 1¼ hr. in bain marie. Gelatine may be rolled in tripe and cloth, boil 1½ hr. and press 24 hrs. between two dishes under weight. Serve with aspic.

Chopped Meat in Tripe (Old Dutch Recipe).—5 lb. beef; 2½ lb. pork; 1 oz. salt; 2½ nutmegs, grated; 35 cloves, pounded; ½ oz. pepper. Wash meat and cut up into thin pieces; mince and season with spices; leave it one night. Soak pieces of tripe well in tepid water, clean well both sides, and fill with meat, not too stiff. Sew them up and boil 2 hrs. well with salt; prick with fork from time to time. Hang them up 1 hr. and store in earthen pots with 3 parts vinegar and 1 part water. Skim off fat after cooling and keep this for frying.

Shut pots with damp vegetable-parchment covers.

To this list we may add the following summary of the qualities of the nutmeg:—

Banda Nutmeg is indispensable in a palatable and wholesome preparation of divers vegetables, cauliflower, spinach, onions, endive, turnips, etc.

Banda Nutmeg is indispensable in all sorts of minced and chopped meats.

Banda Nutmeg is indispensable in various piquant sauces.

Banda Nutmeg is indispensable in the yolk of eggs beaten up with brandy or cognac (egg-nog, a piqueur in great favour in Holland).

Banda Nutmeg and Mace are indispensable in all soups (the mace to be boiled quickly in a little cotton bag).

Banda Nutmeg is indispensable in several articles of pastry, as English "*plum pudding*," Dutch "*Speculaas*," etc.

Banda Nutmeg is indispensable in the egg-sauce with asparagus and in mashed and stewed potatoes.

Banda Nutmeg is an excellent ingredient in the kitchen, and may be appropriately used to season vegetables, made dishes and flour-puddings.

Banda Nutmeg is invaluable in seasoning every description of preserved meats, sausages and brawn.

Banda Nutmeg gives an additional relish to the dishes.

Banda Nutmeg-Tincture.—Grate three ounces of nutmeg, put the powder into a quart bottle and fill it up with good brandy or spirits of wine, cork it, and shake it well every day for a fortnight, then pour off the liquid, leaving the sediment behind. Put the tincture into small bottles, cork these closely and store for use. Probable cost, according to the quality of the spirit. Sufficient, three drops to flavour half a pint of liquid.

Nutmeg-skin Preserve and Truffles.—The fleshy outer skin of the fruit are generally left in the gardens, they may however be used to prepare an excellent home-made jam (*maniesan pala*). Stored in shallow pits they will also produce a fine edible truffle (*djamoer pala*).

MEDICINAL PROPERTIES OF NUTMEG AND MACE.

Besides the instance of the use of this nut for its medicinal qualities, mentioned in one of the first columns, showing that it was used in Persia about 906, Paulini quoted more than 138 cases of disease in which the *myristica fragrans* Houtt. may be applied, and there exists a voluminous literature on the subject. In the Moluccan Archipelago it has of old been used in case of dysentery, headaches and other nervous disorders. With the characteristic love of Eastern nations for stimulants, they were also the first to discover that it contained pronounced aphrodisiac qualities.

For skin and hair-ointment used as an embrocation in cases of cold, against sores and eruptions but especially against stomach-colics and hemorrhoids.

Even carrying nuts about one has been found beneficial in many cases and especially against rheumatism.

We quote the following recipes:—

Banda-Nutmeg. A spoonful of it grated with brandy and sugar is a pleasant, warming and inexpensive anodyne against sudden cramps and stomach-colics.

Banda Nutmeg, pounded fine and mixed with oil, fat or ointment is an excellent embrocation against rheumatic complaints.

Banda Nutmeg, used as a condiment in the preparation of vegetables, meats and other food, promotes the digestion, and acts as a preventive against spasms and other disagreeable sensations after a meal.

Banda Nutmeg acts gently stimulating on the organs secreting saliva, bile and gastric juices,

thus causing an increased secretion of these juices in the esophagus and greatly improving the digestion.

Banda Nutmeg has a most beneficial effect on the circulation of the blood, imperatively necessary for a good digestion, thus fitting the frame for a perfect absorption in the blood of the nutritious substances in the food.

Nutmeg-paste.—Inferior nuts damaged and broken are carefully excluded from export. Stamped, steamed and pressed on the estate, they produce a solid fat, which is cut in bars and sold as nutmeg paste, which makes a delicious ointment in the pharmacopœia.

AN ENGLISH STATION FOR BOTANICAL RESEARCH IN THE TROPICS (CEYLON).

The Royal Botanic Gardens of Ceylon, under the direction of Thwaites and Trimmen, to go no further back, have long been known as one of the most important centres of scientific work in systematic and economic botany. Thanks to the British Association for the Advancement of Science, a small room next to the director's office was fitted up as a laboratory, in which have worked many botanists, chiefly English. Among those who have worked in Ceylon during the last decade may be mentioned Profs. Bower, Farmer, Goebel and Potter, and Messrs. Freeman, Keeble, Pearson, Parkin, and others. During the last two years the laboratory has been very much overcrowded, being used by the staff of the gardens as well as by visiting botanists. With the commencement this year of a new research laboratory, now being erected by the Department of Public Works, and to be completed probably before the end of the year, this difficulty will be overcome, and there will be ample room for several workers from abroad in addition to the members of the staff. This being so, it may not be amiss to give at this time an account of the facilities now available in Ceylon for research in the tropics. While the laboratory is primarily intended for botanical research, there is no intention of excluding workers in other lines so long as there is room for them, though of course money cannot be spent in providing special apparatus for their work.

The Royal Botanic Gardens form a department of the public service in Ceylon, under a director. The headquarters of the department are at Peradeniya, near Kandy, where the principal garden was established in 1821 by Moon. There are now smaller branch gardens in four other places in different climatic regions of the island. A brief account of these may be of interest.

The original Peradeniya garden lies within the Municipality of Kandy, about four miles from the centre of the town. It may be reached by driving in a carriage or rickshaw, or by trains which run at intervals to a station near the garden. The roads here, as almost everywhere in the island, are excellent for cycling. The garden has an area of about 150 acres, and lies in a very beautiful situation, in a loop of the Mahaweli river, and in very mountainous country. Its elevation above sea is about 1,550 feet, so that it has a much more pleasant climate than the low country. During the day the difference is but little, but the nights are very much colder than in Colombo, so that refreshing sleep can always be had; indeed, during most of the year a blanket is necessary. The mean annual temperature is 76° F., that of the hottest months (March and April) being 79°, that of the coldest (January and June) 74-75°. The highest shade temperatures ever reached are not excessive, rarely exceeding 90°, and in the present laboratory the highest in the last two years has been 82°, the lowest 65°. Work can thus be carried on with as little discomfort as in any European laboratory. The annual rainfall is about 90 inches, but owing to the

great violence of tropical rain the number of rainy hours or days is very much less than in England. The number of days with rain averages 170 per annum, and it rarely rains more than four hours on any one day. Rain in the morning is also rare. The weather of the year depends on the mousoons. In the end of May the south-west monsoon begins to blow, and there is much wind and rain, the weather gradually becoming finer through the months of June and July. August and September and the first half of October are delightful months. In October the north-east monsoon begins, and until Christmas it is very wet. In January begins the "dry season," and during the next two or three months there is less rain than at any other time of year, and the weather becomes gradually very hot, though until April the nights are cold. March and April are the only really unpleasantly warm months in the year. The best time on the whole to visit Peradeniya is from October to March, but from July onwards is very nice, the objection to travelling at this time from Europe being the heat in the Red Sea, which, however, is much less formidable than is usually supposed in these days of swift boats and ice chambers.

The garden contains a splendid collection of tropical plants, and, being arranged like an English park, with wide spaces of lawn, the specimens are easily seen and photographed. In the centre lie the buildings of the museum, library, herbarium and laboratory, close together. The museum is chiefly devoted to the economic products of Ceylon, and contains a very good and interesting collection. The herbarium consists primarily of Ceylon plants; but there is also a general tropical herbarium, and a herbarium of the plants contained in the gardens. In the same building is the library, which contains about two thousand books and papers. There is an excellent collection of books relating to economic and systematic botany, and recently a large number of works on the other branches of botany have been added; a considerable number of journals is also received regularly, including such periodicals as the *Annals of Botany*, *Botanical Gazette*, *Botanische Zeitung*, *Flora*, &c.

The laboratory lies a few yards to the north of the herbarium. It consists of a one story bungalow of brick on a stone foundation, and with cement floor and tiled roof. The length of the building runs approximately east and west, and on the north and south sides there are no verandahs. At the east end is a verandah 8 feet wide, the ends of which are built up so as to form one a lavatory, the other a dark room for photographic work, fitted with sink, &c. At the west end is also a verandah of the same size, not built up in any way.

The building has six entrances, provided with French windows, two at each end and two on the south side. The other windows stand above the ground, and open outwards. There are doors leading from each room into all the adjacent rooms, so that free ventilation can be obtained, and at the same time any room can be completely shut up if required to prevent draughts without interference with the accessibility of the others.

The principal room, the general microscopic and morphological laboratory, lies to the north-west, and is 36 feet long 18 feet wide. It has four working windows facing north, each with table, shelves, sink, &c., and two other windows facing into the west verandah, which can also be used as microscoping windows if required. The central part of the room will contain larger tables for microtome and other apparatus, and writing table.

To the east of this room is the smaller room devoted to physiological and pharmacological investigations. Leading out of this room is a French window, which gives access to the little eastern verandah, which may be used for cultivation experiments, &c. This room has two good working windows facing north, besides the French window. It is provided with three sinks and an annual temperature of 61° F. Frost never occurs, though it is

frequent at slightly higher elevations, such as Nuwara Eliya (6,200 feet). There is, unfortunately, no accommodation for visitors at present nearer than Nuwara Eliya, six miles away; but it is hoped to erect a small laboratory in the garden, with a small living room attached, where workers may live and sleep.

A fourth garden is kept up at Badulla, the capital of the Uva province, at an elevation of 2,200 feet, on the eastern side of the mountains. The chief botanical interest of this district lies in its somewhat drier climate, so that it has much more patana land than the western side of the mountains, and in the fact that its dry season comes, not in the north-east but in the south-west monsoon, so that the periodicity of the vegetation is different. Fruit, which at Peradeniya ripens in March and April, ripens at Badulla in August, and so on.

Yet another garden is maintained at the ancient capital of the island, the famous "buried city" of Anuradhapura, the capital of the North-Central province. This lies in the middle of the dry country, which makes up about three-fifths of the island, and has an Indian climate, with rain almost confined to the last three months of the year, and drought during the remainder, including the south-west monsoon. The flora of this district is therefore, as might be expected, very different from that of the rainy south-western and central provinces.

The island can show, within an area of rather less than that of Ireland, a most remarkable range of climate and flora, rendering it very interesting to the traveller and naturalist; in this respect it is unrivalled in the tropics. The working botanist or student has, further, the great advantage of having at his hand the excellent flora prepared by Dr. Trimen, and finished after his death by Sir Joseph Hooker. There are doubtless many new species still to be found in the eastern and south-western districts, as well as many unrecorded species; but the student who does not desire to specialise in this department of botany will be grateful for the useful flora, which renders the identification of his collections, or of the plants he may be experimenting with, a matter of comparative ease. The vascular cryptogams and many of the mosses have been identified, but there is much to be done at the lower forms of vegetation.

Peradeniya is easily reached from any part of the world, Colombo being one of the greatest ports of call. Direct lines of steamers run to Europe, China, Japan, Java, Queensland, Adelaide, Melbourne and Sydney, Mauritius, South Africa, and all Indian ports. Madras may be reached in thirty-eight hours by boat and rail. To England there is a very large choice of steamers. The favourite lines with Ceylon people are perhaps the Bibby and the Norddeutscher Lloyd, but the P. and O., the Orient, Messageries Maritimes, British India, and many others, are much used. The first-named is the cheapest of the large English lines, but is first-class only. First-class returns to Colombo, available for six months, are from 70*l.* to 90*l.* Second-class, which is very comfortable on the largest lines, is from 50*l.* to 60*l.* A few pounds are necessary on the voyage for tips, sports, trips on shore, &c. Banking accounts may be opened in Kandy, and money easily remitted to and from Europe. The value of the rupee is now 1*s.* 4*d.*, and seems likely to remain at that figure.

Very little is necessary in the way of outfit. Drill and khaki clothes can be bought here for less than half their price in England; also topees (sun hats). At Kandy the usual dress is similar to that worn in England in summer; at Nuwara Eliya it is colder, and tweed suits are often worn. All articles of clothing can be bought here, and usually as cheaply as, or more so than, in Europe.

The usual division of the day is as follows: Rising at daylight, a light early tea of eggs and toast is taken about 6-15, after which a walk in the garden is pleasant, commencing laboratory work at 7-30, and continuing till 11, which is the breakfast hour. After breakfast follows a rest indoors, but not sleep, and work may be resumed at about 1-30 for a couple of hours or so. After tea the remaining two hours of

light are given to [tennis, cycling, and other forms of exercise, followed by a bath, and dinner at 7 or 7-30. The evening is devoted to amusement.

Travelling in Ceylon is easy in all but the most out-of-the-way or sparsely populated parts. Railways and good roads intersect the greater part of the island, and there are coach services to a great number of places not served by the railways. Rest-houses or Government inns are found in all towns that have no hotels, and at intervals of 14 miles along all main roads. The average cost of living while on tour may be put down as about R7 or 8 per diem exclusive of fares by rail or coach. Steamers run round the island, calling at all the chief ports.

There is at present no rest-house or hotel at Peradeniya itself, and visitors must live in Kandy, where arrangements have been made with some of the hotels to board persons working in the laboratory at from R5 to R7 per day. There is a convenient service of trains, but the most satisfactory way is to cycle in and out. The road is in excellent order, and the distance from the furthest hotel under five miles. It is hoped that accommodation may be provided at Peradeniya itself before long.

Assuming that six months are spent, from starting to date of arrival back in Europe, the cost of the trip should not much exceed 185*l.*, made up thus:

Fare (First return)	..	£85
Twenty weeks' board	..	66
Travelling	..	20
Sundry	..	12 to 20
		£191

This might be much reduced by economy, and by travelling second-class from Europe, and the proportionate cost would of course be less if the visit were of longer duration. If much travelling is to be done in the island the amount shown above will have to be increased, the 20*l.* being allowed for four weeks only. By very close economy and reduction of travelling, and by travelling second-class, the total might be reduced to perhaps 140*l.*

Trustworthy information about Ceylon may be obtained in various books. The most interesting are Sir E. Tennent's "Ceylon," which is now out of print; and to a botanist, Trimen's paper "On the Flora of Ceylon as affected by Climate," in the *Journal of Botany* for 1886. Ferguson's Handbook and Directory contains a vast mass of information and statistics, and his "Ceylon in 1893" is also of interest.

Intending visitors should communicate some time in advance with the Director, mentioning what line of work they propose to take up, and any special facilities they may require.

—*Nature*.

SUGAR IN TIRHUT.—A correspondent of the *Englishman* writes:—I hear from several sources that on account of the disturbed state of the indigo market many men are talking of starting sugar, and that several men have commenced growing cane with the idea of testing the produce of crude sugar likely to be got per acre of cane.

My advice to such is to have nothing to do with growing cane themselves. Let the ryots do this and make crude stuff called goor and *raub*. This planters could buy from the ryots and refine. There are at all indigo factories engines used for indigo work which will be quite powerful enough to drive the turbines now used in the manufacture of sugar. When sugar was an industry in these districts in the early forties what brought it to grief was that factories grew their own cane, and sugar-cane, it was found, exhausted the soil, and though the cane grew the yield fell from over 40 maunds of sugar per acre to less than 2½.—*Pioneer*.

THE TRADE OF CEYLON IN 1899.

(By a Merchant.)
(Continued from page 499.)

No. II.—IMPORTS.

EXCHANGE has been steady throughout the year and this has contributed to foster regular shipments of Imports to Ceylon. Prices although steady during the earlier part of the year have been against importers during the later stages. The year closes with bills being discounted locally at eight per cent, as against seven per cent at the close of 1898.

Money in India has been easy during the greater part of the year, but a tightness is now beginning to be felt and we shall probably have higher rates of discount quoted in the near future.

COTTON GOODS.—Since the beginning of the year raw cotton has steadily increased in value, the present prices being fully 45 per cent higher than those ruling at the end of 1898. There is a diversity of opinion with regard to the American Cotton Crop as to whether it will exceed or fall short of 10,000,000 bales and this is not without its influence on the market.

There has been a great falling-off in the importation of grey cotton goods; whilst on the other hand prints and coloured goods shew a considerable increase. The quantity of white goods imported is about the same as in 1898. The prices of cotton goods in Europe have advanced since the 1st January, 1898 :—

Grey Shirtings ..	18 per cent
Do Drills, America ..	26 do
White Shirtings ...	15 do

Prices locally, although on the upward grade, have not yet risen to the same extent as in Europe, but it is obvious that much higher rates will be quoted later on, when stocks are depleted, unless a great reaction sets in, in Europe.

Many manufacturers are well engaged, some having their looms filled for the next six months.

The following figures shew the importation for the first 10 months of 1899 and 1898 :—

	1899.	1898.
Grey cottons, bales and cases	2,375	4,341
White do do	2,032	2,058
Printed do do	996	626
Dyed do do	91	89
Coloured Woven do	8,775	6,945
Sundry	65	90
Yarns, Plain	1	11
Do Dyed	164	178
	<hr/>	<hr/>
	14,499	14,338

WOOLLEN GOODS.—During the past nine months the value of raw wool in Europe has advanced over 50 per cent. Manufacturers are consequently asking much higher prices for made-up cloth, and we are sure to see higher rates quoted locally ere long.

METALS.—A good business has been done in iron and other metals. Prices after remaining steady for the first three months of the year, suddenly took an upward tendency, and the difference between prices in

Europe at the beginning of the year and now are :—

Scotch Iron	37 per cent	higher
Belgian	50	do
Swedish Iron	33	do
Galvanised Iron		
Sheets	31	do
Hoop Iron	38	do
Tin Plates	40	do
Copper	25	do
Nails	25	do
Tea Lead	25	do

All other articles of which metal constitutes a part, have risen very considerably in value. The present situation in the iron markets of the world is, we believe, without parallel in the history of the industry. In every manufacturing country of importance the demand for pig iron has not only outrun the supply, but has so far outrun it as to make it unlikely that any country will be able to produce a surplus for export, after satisfying its own demands, for fully a year to come. The outlook then is decidedly in the direction of a continuance of the present strong demand for iron and steel, and consequently, of the present prices.

MATCHES have advanced some 12 per cent in value.

WINDOW GLASS has advanced some 18 per cent in value.

CEMENT—a fair quantity has been imported. Prices have been firm, but have not advanced much.

SPIRITS.—The following figures shew the importation of spirits, &c., for the first 10 months of the years 1898 and 1899, and it will be seen from these figures that the quantities of gin and whisky entered for consumption in 1899 shew a decided increase over those of 1898; brandy on the other hand shews a decrease :—

	in 1898.	in 1899.
Malt Liquor, in wood, hhds.	1,367	1,615
Do glass, cases & casks	538	545
Brandy cases ..	3,336	1,875
Gin do ..	2,676	6,623
Whisky do ...	6,168	5,167
Entered for consumption	in 1898.	in 1899.
Malt Liquor, in wood, hhds.	1,506	1,692
Do glass, cases	565	155
Brandy cases ...	2,260	1,657
Gin do ...	2,439	5,471
Whisky do ...	4,683	5,131

RICE.—The crops in Bengal are turning out well and Soolai Rice can be purchased locally at R3-10 to R3-20, against R3-55 ruling 12 months ago. Owing to the drought in Southern and Western India Calunda rice is rising in value.

COALS.—The importation of Indian coal is still increasing; this coal being used largely by the Railway Locomotive Department and a number of Steamship Companies. Cardiff coal continues to be brought in smaller volume each year.

THE NILGIRI RAILWAY AND LEASES OF COFFEE TREES.

On representations made by owners of coffee estates along the Nilgiri Railway, asking for a reconsideration of the Board of Revenue's refusal to permit the leasing of coffee trees on lands acquired for the Railway, the Madras Government has passed the following order :—His Excellency the Governor in Council is pleased to

direct that the coffee trees on lands taken up for the Nilgiri Railway may be leased to the adjoining landholders, subject to the following conditions:—(1) That the lease shall be for the season only; (2) that Government reserves the right of entering on such land at any time and without notice; (3) that if the Railway authorities have occasion to cut the trees during the period of such lease a proportionate amount of the rent shall be refunded.—*Madras Mail*.

THE HATFIELD CURE FOR RED SPIDER.

Relative to the note on the above subject, which was published on the 16th instant, and the footnote appended, on the utility of sulphur as an effective antidote for this insidious pest, the following quotation from E G Lohlemau's (instructor on Horticulture in the Cornell University) book on *The Spraying of Plants* may have a fitness, along with the practical experience of Mr. Norman. "Sulphur is valuable both as an insecticide and as a fungicide. Its use for the first purpose is practically confined to green-houses and conservatories, and even there only few insects are affected by it. It is most rapidly applied by evaporating in a sand bath over an oil stove, but extreme care must be given that it does not take fire, as then it will instantly destroy all the plants. Red spider and related insects are said to be destroyed by the fumes, and treatment should be made as soon as they are discovered, or even before. Sulphur may also be evaporated successfully by placing it upon the heating pipes; it is well to mix it with an equal amount of lime, and then add water to form a thick paint, with which the pipes may be covered. When applied in a dry form directly to the plants, it possesses little value as an insecticide. A moist atmosphere in the house probably renders the fumes more effective (this latter suggestion should form a valuable adjunct to the sulphur treatment, as observation tends to show that a dry atmosphere is favourable to its development; whilst the converse, namely, moisture is a deterrent, and spraying with water has always been advocated as a specific)." Sulphur is one of the most valuable fungicides for the treatment of surface mildews, and it has long been used for this purpose. Previous to 1880, it was almost the only fungicide used in Europe, and it did excellent service in controlling the European mildews which attacked the Vine and many other plants whether grown under glass or in the open. Out of doors it was commonly applied in a dry condition being blown upon the plants by means of hand bellows. Under glass it was used in three ways; in the form of powder, when mixed with water, and when evaporated from the heating surfaces. The first method was executed in the same manner as out doors. When mixed with water both the sulphur and the water assist in destroying many pests, and it is a common practice to make such applications. The proportion of the two varies greatly. It has been recommended to use 1 ounce of sulphur to 5 gallons of water, and also as much as 1 pound to 1 gallon. The more dilute mixtures are more easily applied and if the work is thoroughly done, are on the whole, equally valuable. The fumes of sulphur for treating mildews are obtained as described above. When the powder is used out-of-doors, the value of the remedy undoubtedly rests in the fact that the sulphur gradually gives off fumes on account of the heat of the sun, and the mildews yield for the same reason that they do when the powder is evaporated under glass. One of the most valuable preparations of sulphur is known as "Grison's Liquid." Although this latter insecticide is fairly old, to give the formula may be of service to some growers. Take the following:

Flowers of sulphur	500 grams or 17 oz (avoird.)
Freshly-slacked lime	500 grams or 17 oz do
Water	3 litres or 5½ pints.

Boil the above ingredients for ten minutes, let the mixture then settle, and draw off the clear liquid after which the liquid must be bottled to use, 100 parts of water to 1 part of liquid, and apply with a syringe (still lately the quantities of sulphur and lime have been reduced respectively to one-half). This prescription was always advocated as an excellent cure for surface mildews, and about three applications were sufficient to preserve the foliage. It seems feasible to suggest that instead of syringing, heating the intending wash might prove more effectual in the houses. A. O'Neill.—*Gardener's Chronicle*.

PRODUCE AND PLANTING.

CHINA TEA IN 1899.—In the planting of the past year's tea trade, the *Grocer* says of China tea, "This branch of the trade has now become almost a negligible quantity. Of late years it has only been used by the trade to reduce the cost of the low-priced blends when Indian and Ceylon leaf was high, while a certain amount of good and fine Moning will always be used by people of weak digestion or connoisseurs who drink tea as they would a glass of fine wine. Of late years the bulk of the better teas have been re-exported to Russia and the Continent when their stocks have run short, but unluckily exporters have not come to our aid the whole of this year, partly because they have imported more direct, and also on account of their using more Ceylon tea, hence the disastrous losses made between January and June on the remainder of last season's fine teas that were left.

CEYLON TEA.—Ceylon tea has been rather disappointing, more especially for the first half of the year, when Indian tea was carrying everything before it, and supplies from Ceylon were falling off in comparison with the previous year. However, it is a noteworthy fact that deliveries always improve and keep pace with each monthly increase. For the first six months of the year supplies and deliveries both showed a decrease of three million lb. Since then imports have been heavy, or, say, an increase of four million lb. for the last half of the year, thus making the total imports for the year 97 million lb., against 94½ million lb. in 1898. Deliveries have increased at the same rate for the last half of this year, the decrease for the first half being not only wiped out, but leaving a small balance in favour for 1899, or nearly 94 million lb., against 93½ million lb. in 1898. Stock, however, has increased, and we shall commence the new year with 20 million lb. against 17 million lb. We notice by the Board of Trade returns that the re-exports of Indian and Ceylon teas show only a very small increase for the year, whereas last year they added largely to our increased total deliveries. The reason, however, is not far to seek, as the Continent and Russia are taking so much more direct, and we are fast losing these valuable outlets for our increasing supplies. The year opened with low prices, viz., 5½d to 5½d for leaf, but as Indian tea improved, Ceylon leaf was carried with it, and prices rose rapidly until Easter, when good leaf teas were bringing 8d per lb, and rough, ugly, red leaf kinds about 7½d per lb, with dusts in proportion. Better teas, however, showed only small improvements, and ordinary Broken Pekoes have offered capital value all through the year. Finest liquoring and tippy Broken and Pekoes suitable for exports have been scarce, and have always commanded long prices, especially in the spring and autumn, when quality is at its best. For instance, there is often a difference of 6d per lb in the same well-known garden Broken Orange Pekoes, according to the time of year, when quality is good or poor. Fair ordinary to good Broken Pekoes, however, do not vary much in price all through the year, and are relatively cheaper than any other class, owing to their oversupply and limited demand, as export only takes leaf teas. After Easter leaf teas took a downward turn, and followed the trend of the Indian market, while the quality offering in medium grades in May was particularly good, with capital value

to buyers. In July and August, when quality was poor, the quotation ran down from 6½d to 5½d, with a very weak market; but quality and prices in September began to improve. Rates for fine teas were extreme, and Broken Orange Pekoes realised 1s 3d to 1s 8d for the favourite garden marks. A good business, with improving prices, ruled up to November. Then quality fell off, and up to the end of the year there were small ups and downs in leaf teas for price, with steady trade and good deliveries. By Ceylon circulars we find that the year's crop shows an increase of over 7 million lb. America and Russia each take 1 million more, and Australia ½ million more, the surplus balance being shipped to the United Kingdom, but probably nearly a million will go overside for transhipment. The last sale of the year closes with a very strong tone for price tea, the quotation being 6½d, against 5½d last year for either Pekoe Souchong or Pekoes. Good liquoring Pekoes and Orange Pekoes, however, are, if anything, rather lower than last year, say at 7d to 8d, and Broken Pekoes look about on a par. Dusts and fanings are a good 1d, dearer, thus showing what a run there is on "price" tea.

COFFEE IN 1899.—The total receipts of coffee in the United Kingdom during the first eleven months of the year now closed were 974,070 cwt, in comparison with 900,650 cwt in 1898 and 720,600 cwt in 1897, and the only instances where a decrease occurred were furnished by Brazil and Central America. Although very little Brazil coffee reaches this country, most of it going to other European ports and the United States, it none the less exercises the greatest influence on the world's markets, when the crops in Rio and Santos come to be considered; and the strongest movements, which are speculative, are regulated entirely by what happens in connection with the production of coffee in the Brazils. This, in 1898, proved to be the largest on record, embracing 11,332,000 bags, as contrasted with 8,942,000 bags in 1897 and 5,969,000 bags in 1896. The effect of this enormously big crop has been to overwhelm the coffee market everywhere, and almost throughout 1899 a downward tendency has existed.

MOCHA COFFEE.—In a recent report the American Consul at Aden discusses a statement which is frequently made, and which has been repeated quite recently, that no genuine Mocha coffee reaches the European or American markets from the Arabian ports. The Consul says this statement is quite erroneous, for the books of his own Consulate at Aden and of the Consular Agency at Hodeida show that over 5,000,000 lb of Mocha coffee were invoiced from these places to the United States last year not to speak of the quantity sent to Europe. But it is said that though nominally shipped from Arabia ports, it is really coffee grown elsewhere, and then shipped to Aden to be reshipped as Mocha. This suggestion is also erroneous, as appears from a letter from the British authorities at Aden on the subject. It is true that parcels of coffee from Java, Singapore, and other places landed in Aden, but according to the official communication above mentioned, these parcels are bonded in the warehouses of the owners at Maalla, and the key lodged in the trade registration department. "When the owner desires to export, a peon of the department is sent with the key to count the bags and bring them to the wharf. As the merchant or owner can have no access to his goods unless accompanied by the peon of the department, the transfer of the inferior bean to Aden for mixing with that of Mocha or Harrar is hardly possible." The Consul adds that an examination of the Customs authorities' reports show that foreign coffees are promptly re-exported to other ports, being landed at Aden for transhipment only; while the precautions in Turkish Arabia to prevent mixing are equally stringent. No doubt Mocha coffee is mixed with inferior beans in Europe and sold as genuine Mocha, but it is hardly

possible that an importer buying in an Arabian port could get anything but genuine Mocha or Harrar coffee.—*H. J. C. Mail*, Jan. 5.

CEYLON PLANTERS' ASSOCIATION.

ESTIMATE OF TEA CROP 1900.

At the last meeting of the Planters' Association Committee, a large amount of business was got through, but it is not necessary here to do more than indicate the main points. The tea crop for the current year is estimated at 138,000,000 lb, of which 108 millions will go to the United Kingdom and the rest to Russia, Australia, America and other countries. A suggestion was made by the Chamber of Commerce that the grant to America should be reduced and greater attention paid to the continent, but the allocation having been already made and intimated to our Commissioner no action can be taken in this direction at present. We thoroughly agree with the Chamber that there is very large scope for our energies on the continent and we are confident that much good will result from the labours of Mr. Renton there as well as from the Paris Exhibition where Government is to incur expenditure amounting to £3,477 on account of the tea industry. We hope Government will see its way to adopt the suggestion as to adorning the first-class railway carriages with photographs depicting the tea industry. As was to be expected a hearty vote of thanks was passed to H.E. the Governor for securing the appointment of a mycologist, and we hope that when they next meet they may have the pleasure of passing a similar compliment upon the appointment of Mr. Kelway Bamber as agricultural chemist for the Colony. Mr. Wilkinson—has been in communication with the Committee on the subject of Labour Supply and he has been informed that there is work available on estates for no fewer than 50,000 coolies. The present is considered a favourable time for recruiting from the Coast and we have no doubt employers of labour will make a note of the fact and act upon the hint. The Committee are prepared to substantiate the allegations which have been made regarding short delivery of goods on the railway. If the General Manager meets them in conference as requested, a better understanding may be arrived at and steps taken to avoid future annoyance in this respect. Other subjects considered were fire insurance rates, the prevention of cattle disease, the inadequacy of the batta allowed to witnesses attending the Supreme Court Sessions (to consider which a sub-Committee has been appointed); a proposal by Mr. Borette (deferred at present) that an ordinance should be drafted for the purpose of checking abuses that at present prevail in connection with promissory notes; the duties and powers of hospital visitors; and the opening of the Victoria Commemoration Buildings which His Excellency the Governor has been asked to perform on the 17th February. The objects of the Society for the Prevention of Cruelty to Animals have been approved, and the Ceylon Nurses'

Association commended to the support of the Planting Community and Europeans generally. The establishing of Rural Police in the Northern districts seems to have been attended with good results, the experience of the honorary secretary being that thefts of cocoa in the field had stopped since then.

SUGAR-PLANTING IN PENANG, ON ZAMBESI AND IN CEYLON.

We have had a couple of very interesting interviews lately. First, our friend Mr. Turner, of Penang (who, with Mrs. Turner and family, arrived by the "Oceana" on the 23rd ult. to give a fortnight in Ceylon) is here, as promised, to enquire about land suitable

for sugar in the Northern or Eastern divisions of the island. We have been collecting information for Mr. Turner who was likely to visit Anuradhapura last week his further movements being determined by what he may see and learn.—Then the "Clan Sinclair" to Galle brought from Beira, East Africa, Mr. Hornung, of Zambesi, and two Rhodesian friends, unable to get away via Delagoa Bay: they had to travel northwards to Beira and take this Clan boat. Mr. Hornung has a Sugar Estate on the Zambesi, but is interested in Rubber and other products, and has had our *Tropical Agriculturist* for the past 12 years. He went home by the Orient steamer last week: and visited Heneratgoda and Peradeniya in the interval.

CEYLON PRODUCE IN LONDON.

(From *Wilson, Smithett & Co.'s Circular*, January 5th.)

COCOA.—The market has remained closed as regards auctions since December 19th, and although a firm tone has existed throughout the interval, the volume of business on the spot is small consequent on the paucity of supplies, while forward business is limited by advancing quotations, although some transactions were effected at higher rates. The arrivals of new crop Ceylon are increasing and this growth is likely to form an important item at the opening sales on Tuesday next, but in the meantime business is confined to 200 bags, low at 61s to 62s, fair to good at 70s to 80s per cwt.

CINCHONA BARK.—The first auctions of the year in London are fixed for January 16th. Those in Holland for the 11th instant, when a total of 7,540 packages is advertised. This total compares with 7,087 packages analysing 5.14 per cent at the last sales, and 8,090 packages averaging 5.29 per cent. at the first series of 1899. The shipments from Java in December are telegraphed as only 626,000 lb. (Dutch), being as much as 400,000 lb. below last year: the total for the year, given below, is only a quarter of a million pounds over 1898. During the past year the fluctuations in the market value have been very wide, the net result at the close of the year being to leave prices higher by 50 per cent than at the commencement. The year opened at the first sales with the unit value 1d, but on the shipments from Java in January and February shewing an important falling off, prices rapidly advanced, culminating at the end of March in a unit of 2½d, which was the highest price touched during the year; from this date onwards, under the influence of the larger shipments from Java, which the rise in value induced planters to make, the market gradually reacted until at the October sale the unit had fallen again to 1 1-16d to 1½d. In the remaining two months of the year, stimulated by an active world's demand for the manufactured product and by the fact that notwithstanding the great pecuniary inducements held out to Java planters during the year, their shipments had only exceeded the previous year's by a little more than half a million pounds, tending to confirm the view held in many quarters that the normal harvest was being somewhat inflated, prices again rapidly advanced until 1½d the unit was paid at the December sales. The market is thus shown to be exceedingly sensitive, any slight curtailment of supplies having at once an apparently abnormal effect; should the supplies in the current year be no larger than in 1899, a further enhancement in values may be expected, and stocks in London and Amsterdam

be further depleted. Now, as for several years past, the future rests with the Java planters, British possessions being unable to furnish any important quantity. At an established unit of 23 and upwards, a certain quantity of cultivated Calisaya could be imported, but it would require 3d the unit to encourage any shipments from the old districts in South America, whence the market was originally supplied.

The following are the Java shipments for December, with the totals for the past four years; the shortness of the shipments last month, and the fact that the total for the year has only exceeded the previous year by 250,000 lb. has created a great impression and strengthened the belief that the maximum output from that island has been seen:—

Java Shipments, December.

	1899.	1898	1897.	1896.
	pounds.	pounds.	pounds.	pounds.
Amsterdam	626,000	1,018,000	731,000	890,000

Java Shipments, January-December.

Amsterdam	11,990,800	11,133,000	8,511,000	10,079,000
-----------	------------	------------	-----------	------------

From the table below of the movements in London during the past year, it will be seen that the Stocks in this port have been decreased by 4,000 packages, and are now at the lowest point touched during modern memory; the deliveries during the year have been exceptionally heavy, while the imports are considerably below 1898.

SULPHATE OF QUININE.—The market has developed strength since the bark shipments for December became known, and a further advance of ½d to ¾d per oz. has taken place, spot having sold up to 1s 3½d, March up to 1s 4d, and May up to 1s 4½d per oz. Following the fluctuations of the bark market this article has experienced during the past year some sensational movements, the value rising and falling in a manner which has not been seen for many years. The volume of business has been enormous, and largely in excess of any previous year, due in great part to the attention which it has attracted as a medium for speculation. Like the raw material the price at the commencement of this year is about 50 per cent higher than at the same time last year, and unless speculation again carries the value high than the parity in bark, its future movements must be governed by the fluctuations in that article. Commencing the year with a spot value for "second-hand" German of 10½d, the price was rapidly driven up to 1s 9d at the end of March, future months being proportionately dearer, 1s 10½d being about that time paid for October delivery; with many fluctuations the value gradually fell from this point, until the lowest point was touched at the beginning of October, viz., 10½d. A brisk rise then followed, under the initiative of manufacturers, who raised their price successively from 11½d to 1s 3½d, and the year closed with a value for "spot" in second-hands of 1s 2½d per oz.

A feature in the history of this article will be the commencement in February of periodical public auctions in Java of Quinine manufactured in the factories there.

The landings during December exceeded the deliveries by nearly 160,000 oz., a good deal of new manufacture being imported from the factories, against an increase in December, 1898, of 70,000 oz. The stocks in London are now returned as 2,793,956 oz., against 1,795,984 oz., 1,539,264 oz., 1,407,264 oz. and 1,972,432 oz. in the four preceding years. The excess in the stock is thus one million ounces, or equal to one month's estimated world's consumption.

The total imports into London last year were 1,973,000 oz., against 1,032,372 in 1898, 640,000 oz. in 1897, and 233,000 oz. in 1896 while the total deliveries were 976,050 oz., against 775,660 oz., 508,000 oz., and 798,000 oz. in the three previous years.

PLANTING NOTES.

THE AGRICULTURAL COMMISSIONER'S recommendations have, to a considerable extent, already been dealt with by the Governor. The Scientific Staff, for instance, is now well-filled, the last requirement being secured by Mr. Carruthers' appointment as Deputy-Director and Mycologist; and we learn that a Departmental Committee—of the Director of Public Instruction, Conservator of Forests, Director of Botanic Gardens and Government Agent—is now looking into the feasibility of the proposed transfer of the Agricultural School to the neighbourhood of Kandy. There remains the question of appointing a Director of Agriculture or an Agricultural Board, and we believe the latter is the more likely Executive decision as the outcome of the Commission's labours.

VISITORS FROM MADAGASCAR.—Dr. Lacaze, from Madagascar, had an interview lately with His Excellency the Governor. The object of the present visit to the East of himself and colleagues—one being an administrative, and the other an agricultural officer—is to collect information in Ceylon, the Straits and Java that may be of service in the administration and development of the big island-colony now entirely under French rule. Dr. Lacaze and Messrs. Guyon and Prudhomme have been securing a large number of our island and planting publications; and they mean to visit different parts of the island, more especially the Botanic Gardens and certain select plantations of the different staple products, before going on to Java. We bespeak all possible attention to our French visitors who will be found exceptionally intelligent with a fair command of our language and who are anxious to profit by local experience.

CEYLON TEA IN AMERICA.—We are indebted to Mr. W. Mackenzie for copies of several newspapers showing what the Americans are doing in the way of pushing the allies of Ceylon tea. The *Toronto Globe* devotes almost an entire page with illustrations to a description of the work done by, and the premises of, the Blue Ribbon Tea Company which was formed in 1896 for the purpose of putting up, in the now well-known package form, the produce of the finest tea gardens in Ceylon; and "The Weekly Common-wealth" published in Covington, N.Y., has a column principally eulogising Lipton's teas; while in others "Salada" tea is prominently advertised in English and French, a good word being put in for Ceylon greens. In one of the illustrations, typical representatives of Ceylon and Japan are shown lying prostrate: the verdict of the medical man, who has his finger on the pulse of Japan, being "beyond human help." Ceylon tea is held aloft by a figure of victory and there is the inscription: "Barbarous methods disappear before civilization."

CACAO IN TRINIDAD.—There is a curious statement in the letter of Mr. Hamel-Smith dealing with Cacao (see elsewhere). It is stated that the members of the Legislative Council of Trinidad "refused to sanction" this year's estimate of the crop, on the ground that the deficiency will be 30 (and not 25) per cent as estimated by experts! Trinidad has had a dreadful drought.

TEA IN TRAVANCORE.—The Travancore correspondent of the *Madras Mail* writes:—"A whisper reaches me that the tea planting on the Higher Ranges is not likely to be quite the success that was at first expected it would be. But I shall make further enquiries. There are all kinds of difficulties, the greatest of which are a want of sufficient rain during certain months and too much frost during others, thus minimising seasonable and profitable flushes."

INDIA-RUBBER TREES.—Large tracts of forest with abundance of rubber trees are said to exist in the unexplored interior of the State of Bahia (Brazil); but, unfortunately, owing to the difficulties of transport through a country without roads, and to the fact that the forests are inhabited by different tribes of Indians, some of whom are cannibals, it is said to be unavailable. The quantity of rubber produced in the State during 1898, however, increased materially, the high prices realised inducing collectors to proceed further a field for supplies.—*British and Colonial Druggist*.

INDIGO: A THREATENED INDUSTRY AND SUGAR AS A SUBSTITUTE.—A long communication to the *London Times* of Dec. 26th on Indigo, winds up as follows:—

Such careful selection of land as has been indicated will of necessity leave at the factories a larger area available for the cultivation of other crops. If we were to assume even that indigo-growing were absolutely killed by chemical discoveries and were to cease to exist at some future date, then, obviously, those now engaged in that industry would be called upon to grow other crops on their land, and would be obliged to find out what crops would pay them best. In this connexion their attention may well be directed to articles which appeared in *The Times* of September 2, 8, 12, 19 and 21 on the subject of growing sugar canes, and which are full of valuable information. Canes are already produced in nearly all parts of India, and in the aggregate the production must be very large. A new kind of cane is mentioned as growing in some of the West India Islands, which yields 23 per cent of saccharose, and modern machinery is said to extract 90 per cent thereof. From such cane sugar should cost less than £5 per ton. By way of concluding these remarks a final suggestion is made to Indian indigo planters. Experiment at your factories on growing sugar canes, for the product from which there is an ample market at your own doors. Remember that the conditions of India in these days in respect of communications and otherwise are very much more favourable to the successful working of such an industry than in the days when sugar was largely exported from the country; also that modern sugar machinery is more efficacious in treating the canes; and if it can be clearly demonstrated that canes of the best kind can be grown successfully in Behar, and that a formerly existing industry can be established and extended, taking the place of indigo in that quarter if the worst should befall it, then assuredly the necessary modern factory will not fail to be established to deal with the canes.

CASUARINA.—Though the Casuarinas is not of much value as a timber tree, it runs up quick enough to be a most valuable rain attractor and might with advantage be laid down on the bare humed slopes of the Assam midrange, wherever the rainfall does not exceed sixty inches. When the Madras Railway was first aligned the villagers along the route were induced to plant casuarina which supplied the line with fuel for many years. Presumption as it may seem to parade such an idea, floods can be controlled by reforesting denuded tracts, and now that the Assam railway is entertaining the project of throwing out feeder lines in all directions, the necessity of protecting the earthworks from breeching as much as possible is imperatively called for.—*The Planter*, Jan. 13.

COFFEE IN BRAZIL.—From the *Rio News* of December 5th we note the committee of coffee merchants estimate at 2,250,000 bags the Rio coffee crop for 1900-1901. The committee says that coffee in elevated and cool localities has suffered very little from drouth.—We see by the report of the last half-yearly meeting of the Recife and Sao Francisco Co. that coffee planting in the state of Pernambuco has been receiving considerable attention and that the product, though small as yet, is steadily increasing.—The governor of Rio de Janeiro has sanctioned the assembly resolution of the first inst. which concedes next year 0-02 of the proceeds the export duty of coffee to be applied to the expenses of a propaganda abroad in favor of Brazilian coffee. The same resolution also concedes exemption from export duties on all coffee sent abroad for propaganda purposes.—The *Sao Paulo Diario Popular* of the 27th ultimo is informed that a practical and credible planter expresses the opinion that the abundant rains lately experienced will develop the coffee produced from the extemporaneous blossoming of June last so that it will ripen in January, or in February at the latest. As it will be impossible, in the present state of the industry, to find labor for a partial gathering of the crop, he thinks that this part will be wholly lost, thus greatly reducing the reason's crop.

TEA DISTRIBUTION THE "THIRTY COMMITTEE."—Several of the subjects discussed at the last meeting had been previously considered by the Planters' Association Committee, such as the proposal to reduce the grant for America, and are referred to in our note dealing with the proceedings of that body. The amount voted to Mr. Mackenzie is £10,000 and a similar sum will be expended by Mr. Renton in pursuing his work on the Continent of Europe where it is considered that there are larger markets to be gained than in America. An interesting report was submitted on the manufacture of green tea on Brunswick estate and it should be a guide to those who are desirous of taking to this to supply the demand from America. Another very important matter that was discussed was a scheme for the protection of Ceylon tea in packets at home and abroad, and we look forward with interest to the result of the conference to take place between the Principal Collector of Customs and the Sub-Committee on the subject. We trust that steps will be taken to obviate the complaints that have been formulated by the Russian, and other tea buyers in the local market regarding slack packing and inaccuracy in the nett and irregularity in the tare weights.

THE DISTRIBUTION OF COCONUT PRODUCTS IN 1899.

RAPID RISE IN THE "DESICCATED" TRADE.

A careful study of the Chamber of Commerce Export Table which we issue as a supplement, discloses many items of great interest; and not the least interesting particulars relate to the distribution of the products of the Coconut Palm. Without any special organisation to push them into foreign markets, such as the enterprise and pluck of the Tea Planter have devised for his great staple, the range of their distribution is steadily extending, partly through their inherent excellence, and partly through the continuance of old-fashioned mercantile methods which are by no means ineffective. Other nations have undoubtedly been taking great commercial strides—it would be strange if they did not benefit by the example of British enterprise wherever they turned; and in some respects they have, perhaps, outstripped us by their greater pliancy and readiness to adapt themselves to circumstances; but that there is any falling-off in the commercial interests and alertness of the British race, is only what the tendency of the race to be their own severest critics suggest. When we look at the Chamber of Commerce Tables we find that our palm products find their way into almost every land on the face of the earth, and into not a few which are themselves producers. Just as our Teas have been shipped to our two great rivals, China and India, so Coconut Oil, Copra, Coconuts in the shell, find a place among the imports of the Straits, India and Africa, which grow their own palms! The process of development and expansion is particularly noticeable with regard to the Desiccated Coconut which, finding a place in our tables for the first time in 1891 with less than 1½ million lb., has mounted up in eight years to more than 13½ million lb.; while the taste for it has spread from the United Kingdom until, already, 12 out of 19 countries named in our commercial table are reckoned among the consumers. Though it would be too much to expect the demand for it to continue at the rate indicated by the growth of export during the past nine years—indeed the proportional advance during the second four years is far short of that shown in the first five years—there is no reason to fear that there will not be a steady, if slow, growth, as the new markets enlarge their orders; and thus one element in the maintenance of fair prices for nuts will continue to be present.

But after all, it is the price of Oil, and the demand for it, which is the chief controlling influence in the price of coconuts; and for the simple reason that Oil manufacture takes up as many nuts, as all other processes combined. In our recent review, we showed that in 1898 Oil represented 217 million nuts out of a total export of 390 million; and last year the figures were 200 million out of 331. The destination of the Oil and the demand for it is therefore of peculiar interest. In 1897 there was a sudden and serious falling-off in the demand from

the United Kingdom, which ran down from 91,710 cwt. to 72,004 cwt., and which caused some anxiety which was, however, allayed by the good offices of a customer nearer home. India nearly doubled her orders from 86,796 cwt. in 1896 to 166,238 cwt. in 1897, and placed herself at once *facile princeps* among our customers, America coming second with 88,060 cwt., and Singapore a good fourth with 64,058 cwt. The revolution that was expected in the trade from these figures did not come off; for in 1898, the United Kingdom advanced her demand to 123,316 cwt., though still leaving India with its 125,687 cwt. at the top of the list; while Singapore put in a claim for 91,893 cwt. and America contented herself with 65,800 cwt. These were the principal figures which went to make up the total of 435,933 cwt. in 1898, which, though higher than the figures for the three previous years, were exceeded in 1894 by over 50,000 cwt., and in 1892 by 115,000 cwt. The exports of Oil last year have upset all the calculations based on those of the previous two years; for Singapore's demands dwindled off to 23,336 cwt. or about one-fourth what it took off in 1898, and India was content with 66,728 cwt. or less than half the previous year's consumption. On the other hand, the United Kingdom took a mighty stride to 185,205 cwt. or not much less than half the total exports; while America took total second place with 102,767 cwt. What is the explanation of these violent fluctuations? The demand for Europe and America, we know, is greatly controlled by the abundance or scarcity of animal tallow; but we should be glad of information bearing on the immense variations in the figures for India and the Straits.

In Copra, there was a falling-off as compared with 1898 during which an unprecedented demand sprang up—506,277 cwt. having been sent off, or about four times the previous highest record. As we noted last year, the principal customer was Russia which had to be credited with 143,688 cwt., or considerably more than the total that had been sent away in any previous year. In 1899, too, she heads the list, but with only 104,968 cwt., little Belgium coming next, as in the previous year with 76,631, and France next with 41,232; while Germany was content with 26,451. The demand of each of these countries were much heavier in 1898, and more than double in two instances while the Mother Country, so far from coming to our rescue was content with 37,106 cwt., or about 15,000 cwt. less than in 1898. To what is this falling-off all along the line due? Was it scarcity of freight? or were the previous year's purchases pushed on through competition beyond all reasonable requirements? That is not improbable, having regard to the enormous quantities that were sent away. The fact that the quantity exported last year, though only two-thirds of that claimed for 1898, is yet far ahead of any previous year, and more than double, if not quite treble, of the best, gives hopes that the demand will continue, and that Russia will prove our best customer in the future as in the immediate past.

In the demand for Desiccated Coconut, the Mother Country takes the lead, having absorbed nearly 9½ out of the 13½ million lb. we ex-

ported, or about eight times as much as either Germany or America who were our two best customers with figures over a million. Australia comes dutifully next with 814,266 lb., the other customers being Austria, Belgium, France, Holland, Spain, Turkey, India, Africa and China. If all these countries take kindly to the new product, the demand may yet surprise and please the producer; meanwhile, we may be sure the United Kingdom does not consume all she imports, and that the secret of the profitable uses she puts the stuff to, will leak out, leading to direct brisk business with us. In Coconuts, too, the Mother Country heads the list, having imported more than 10 million nuts of the 11½ we sent away, Africa and Germany among next with 693,385 and 652,480 respectively. Belgium and Germany continue to be the two largest of our few customers for Poonac—the former having taken nearly half our exports, and the latter 14,000—cwt. less. Coir, in the forms of rope, yarn and fibre, found their way to the old markets, the United Kingdom taking none of the first-mentioned 6-7ths of the second and over one-half of the last. Singapore absorb almosts all our rope—China, Africa, India and Australia taking small supplies. It is too early to venture on a forecast of the current year, but we fear the two droughts of last year will tell on the outturn of the current year as well; so that, if the demand for Oil and Copra from all the countries which we now supply continues, prices are likely to rule high.

BLEEDING OF WOODY PLANTS.

Professor H. Molisch has made a variety of observations on the flow of sap from woody plants when wounded. In the case of palms, cocos and arenga, the bleeding, when the inflorescence is amputated, is not due to root-pressure. No sap escapes from borings at the base of the stem, though it pours out abundantly at higher parts, even at a height of 19·28 metres, when the tree is in full leaf. The spadix continues to bleed for one or two days after being amputated. The origin of the osmotic pressure appears, therefore, to be not in the root, but in the axis of the inflorescence in cocos, and in the upper part of the stem in arenga. In three woody plants, natives of Java, *Conoccephalus azureus* (Moraceæ), *Laportea crcnulata* (Urticaceæ) and *Bambusa sp.* there is an abundant bleeding from the stem, with very considerable pressure, up to two atmospheres, even at the time when the plant is in full leaf. The temperature during (our) winter months is very high day and night, with a constantly cloudy sky and daily rains. From incisions in the stem of climbing plants there is a copious flow of sap, both in the tropics and in European species. The sap flows from the vessels, thus explaining their unusual size in climbing plants. The flow is a purely physical result of the exposure of the vessels on both sides, and shows that capillarity cannot play the part either of a water-retaining or of a water-raising force to any considerable extent. The phenomenon takes place in *Vitis* and *Climatis*, in the height of summer even in dry weather and intense heat.—*Journl. Royal Micro. Society.*

COCHIN MARKET REPORT.

COCHIN, 20th Jan.

C. N. OIL.—With a large supply of copra as usual in this part of the season coupled with the steady rise in exchange prices do not shew any improvement. Business done this week in the bazaar for ordinary white oil both for prompt and forward deliveries is at R86¼ to R86⅘ per candy. Good white oil is quoted at R85⅘ nett. The "Obra" which has been substituted for the "Goolpara" calls here for Rangoon probably tomorrow and removes a few hundred casks. The "Inchmona" for New York due early next month has also booked a large quantity of oil in that direction.

COIR YARN.—Supplies have fallen off considerably and the quality of yarn now arriving as usual at this season is also very poor. Prices however keep steady.

RICE.—Chittagong boiled R6⅞ to R7 per bag. Rangoon white R6⅓ to R6⅔.—*Cochin Argus*, January 20th.

INDIAN AZALEAS.—In some of the Ghent establishments as many as 100,000 plants are grafted each year. As soon as union is effected the plants are placed in frames in the open air. In the middle of May they are lifted from the frame and planted in dried leaves. Leaf-mould is not so advantageous. Weak liquid-manure judiciously used is beneficial. An illustration in the January number of the *Revue de l'Horticulture Belge* shows a plantation of Indian Azaleas in the open air in the nurseries of M. Ed. Pynaert.—*Gardener's Chronicle.*

TEA-GROWING IN THE CAUCASUS.—Though the day is very far distant when Russian experiments in tea-growing near home can injuriously affect the demand for Ceylon tea in the Russian market, it is of interest to note what a St. Petersburg correspondent writes in the *Grocers' Journal* of Dec. 23rd He says:—

"The tea plantations in the Caucasus are becoming of greater significance every day, and the time may not be far distant when the Caucasian tea will play an important part upon the Russian market. The Government is paying special attention to, and energetically assists, the experiment. For the first time this year Caucasian tea has been placed upon the market, and two important Moscow tea merchants have offered to buy the whole produce for some years to come, but up to the present no agreement has been come to, owing to the difference in the price. It is hoped that one pound of Caucasian tea will be sold at 1·40 rouble similar to the quality of Chinese tea usually sold at 2 roubles. A special commission sent to Tschakwa has reported favourably upon the results already achieved, and it has been decided to pay still greater attention to the plantations. The Minister of Agriculture, however, instructed a high official to proceed to the Caucasus with the view of instituting a thorough inquiry, and to make suggestions accordingly. In his report he proposes the extension of the plantations beyond Batoum, and in order to induce small landed proprietors and peasants to take up this industry Crown lands are to be let in allotments. Further pamphlets dealing with the question are to be sent broadcast amongst the country people. All machines and tools required are to be admitted free of duty, and special credit advantages are also to be extended to those willing to engage in tea planting."

RUBBER CULTIVATION IN SOUTH INDIA.

(BY A PLANTER.)

IN VIEW OF THE EXISTING DEPRESSION IN THE COFFEE industry, and the uncertainty attending the future of the staple, as well as of tea, it would be wise policy for the planting community in Southern India to study the potential attractions of rubber cultivation. Twenty years ago, considerable attention was aroused in South India as to the possibilities of the Ceara, or Manicoba rubber (*Manihot glaziovii*) proving profitable, and this tree was grown, mainly from cuttings, on many properties in the planting districts, while it was even tried in the vicinity of Mettappolium, at the foot of the Nilgiris. But from circumstances, which it seems unnecessary to recapitulate, interest in Ceara, despite its robust and rapid growth, gradually languished, and the trees have been generally uprooted, while the venture never travelled beyond the experimental stage. Some, if not the majority, of the planting localities in Southern India are reputed to possess a more fertile and productive soil than Ceylon, though the climate of various Provinces in the island has a greater degree of continuous humidity than the general average of the Hill plateau in the Madras Presidency, Coorg, Mysore and other notable tracts; but as Para and Castilloa are said to thrive in comparatively moist and dry climates, respectively, it follows that if conditions in Ceylon have been shown to be suited to the successful growth of the Hevea (or Para) and the Mexican (or Castilloa), that South India offers a varied field for kindred enterprise.

THE WHOLE QUESTION OF RUBBER CULTIVATION has recently assumed a new aspect in consequence of the discoveries of Mr. Biffen, of Cambridge University, a qualified botanist, who investigated the method of preparation in Tropical America with much care, and such success that the loss of rubber from the latex in the manufacture has been reduced from 10, 15 and even 40, to 1 per cent. The milky fluid, or latex, which exudes from various plants where ahaded, is altogether distinct from the sap, as it is stored in special receptacles, which run longitudinally within the other tissues and generally form a connected and closed system. This lactiferous tissue, though not altogether absent in the vegetation of temperate regions, is specially characteristic of tropical flora, and the latest and most approved methods of collection and treatment of the latex is a powerful factor in revolutionising the result heretofore obtained in this profitable industry. By the aid of Mr. Biffen's machine, which is on the principle of the cream separator, he can, in a few minutes, extract the pure caoutchouc from the milk of any species of rubber tree, and the product thus obtained is practically identical whether evolved from the Para, Ceara, or Castilloa species, though the most satisfactory results accrue from the latex of the *Castilloa elastica*, which can be grown in the drier parts of hill tracts, whereas Para, in its native habitat, revels in moist lands, the borders of rivers, and inundated areas, thriving rapidly from the sea level up to 3,000 feet and over in any such soil. The rubber-extracting machine is something on the principle of a churn, composed of galvanised iron, and standing between 18" and 24" in height. A quart of the rubber milk is poured into the upper compartment and diluted with water. These form a species of cream, and by revolving a handle at the side the composition is driven through an extremely fine gauze sieve, which effectively isolates the rubber from all impurities. The rubber then descends into the lower and larger partition in the vessel, (where it is further diluted with water, introduced through an orifice in this lower receptacle) washing it free of what was mingled with it, and gradually rising as the compartment is filled, when the rubber, which has risen to the surface, is easily extracted through another aperture for the purpose. The water is then drawn off by a tap, and the procedure repeated indefinitely. The rubber extract is perfectly flat and thin, totally dissimilar to the rough balls produced by the native

processes, while it is practically capable of any degree of distention. The sieve in the machine is moveable, and is retained *in situ* by a firm boss of metal, so that the whole apparatus can be easily taken to pieces and cleaned. The only further treatment of the rubber consists in spreading it out for a time to dry, when any slight moisture that may be retained is dissipated.

CEARA TREES may be propagated either by seed or through the medium of cuttings. The seed coat being of remarkable thickness, its natural germination may be prolonged for months; but this result can be more speedily insured by sowing the seed in a shallow box, or brandy case, into which about three inches of fresh stable manure has been smoothly spread, the straws having been carefully removed. The seed should be thickly laid on the smoothed surface of the manure, and then covered with a similar coating to the same depth. The whole should be kept damp, and nothing more is requisite till the germination takes place, in from seven to ten days, shortly after which the plant shows above the manure, when transplanting into a nursery or seed baskets must be effected. Para seeds, which are as large as nutmegs, can be put down in a nursery, shaded and watered, and here they germinate within eight weeks. The seeds can also be planted at stake in showery weather. For inundated tracts, old plants of two years and upward are stumped and planted out two feet deep, as seed or small plants are liable to be scoured away. When planted out, they should be suitably shaded until established in the soil. Under favourable conditions, new roots are developed within a fortnight. Castilloa seed should be grown in an ordinary shaded nursery, laid out on rich soil, the seeds being put in six inches apart and one inch deep. A watering in the evening once a week suffices, under which system the seed germinates in five weeks. When the plants are half a foot high they should be removed to seed baskets, filled with the richest soil available. Subsequently, and when thoroughly established in the baskets, the latter should be placed in pits two feet square and three feet deep, cut 14 feet apart.

In considering how far the Districts in Southern India are likely to lend themselves to the profitable cultivation of PARA and CASTILLOA rubber trees, the circumstance should be noted that the yield of the latex, or rubber, extracted from species grown in Ceylon is considerably below that accruing from the same varieties in their natural habitat. But Ceylon contains no indigenous rubber-producing trees of any value, and even the milk of the jak, breadfruit and other introduced trees, which elsewhere contain caoutchouc, when grown there have none. Whether Southern India shares this peculiarity can only be determined by special tests; but, so far as experiments in the yield of the latex from these species have proceeded in Ceylon, the results should prove interesting and instructive to South Indian planters. Mr. J Willis, Director of the Royal Botanical Gardens, Ceylon, reports of the Para:—

"It succeeds best on flat, wet, alluvial soil, at very low elevations, but in sheltered positions will thrive at elevations of over 3,000 feet though the growth is of course slower. Best results have been obtained by planting eight or ten feet apart each way; the trees thus form their own shade, and keep down the weeds, a process of natural selection goes on, and the more weakly and dwarfed trees may be thinned out in subsequent years. Another advantage of close planting is that the trees grow up straight without forming many branches low down, and this greatly facilitates tapping. Para is a surface-feeding tree; probably the best thing would be to plant out the tree among tea or other products, at considerable distances apart, the tree will then grow to a large size in less time than if kept in plantations of rubber only, and their rubber will form a useful minor product."

After being grown for several years amongst tea fields in Ceylon, the Managers of various properties report that Para rubber, approximately two years old,

some of the trees being 18 feet high, is apparently "not injurious to the tea," and that "all our Para and Castilloa rubber, from six to two years old, is growing through the tea, with no damage to tea at present—trees 30 feet high and 27 inches girth at three feet from the ground." The statistics available as to the yield of rubber from Castilloa and Para trees in Ceylon are so far incomplete. It is, however, known that the yield of rubber in the Straits Settlements is in excess of the best returns in Ceylon, and this is mentioned in connection with Mr. Derry's Report on Government Gardens in the Straits for 1897, from which I quote the following:—

"How for this industry is deserving of attention may be inferred from the following moderate estimate. Para trees planted 14 by 14 feet equal to 225 to the acre:—

Age.	Yield per tree.	Yield per acre <i>c.t.</i> 1 tree by 225.	Gross value per acre estimated		
			lb.	£	s. d.
6	10	140½	14	10	0
7	18	250	25	0	0
8	26	365	36	15	0
9	34	478	47	13	0
10	42	590½	59	10	0

The importance of close planting is not generally realised. Planted at 14 by 14 feet, against 25 by 25 feet, would possibly result in a difference of one year in six, in favour of close planting. I am of opinion that planted 14 by 14 the trees could be tapped in the fifth year, if not earlier. Para rubber is a remarkably adaptable tree, growing in swampy land, or dry high ground, without, so far as I have tested, any difference in the yield of rubber."

Ere long I shall probably have more complete figures as to the yield of rubber from Para and Castilloa in Ceylon, but I have heard enough to show that the cultivation of these rubber trees promises to be a very profitable venture in that island, and I believe that excellent results await the enterprise in South India. Castilloa seed appears to be difficult to procure, but fresh Para seed is now available on application to Messrs. William Bros., Henaratgoda, Ceylon, at Rs per 1,000.—*Madras Mail*, Dec. 30.

CEYLON TEA EXPORTS:

ESTIMATES (1900) AND RESULTS (1899).

WE have brought together below some figures which present in comparative form the estimates of our tea exports to the chief countries served, for 1899 and 1900, together with the quantities actually sent away during the past year. The estimate for Russia in 1899, it will be seen, was 50 per cent too high; but seeing how greatly the Colombo market has been cultivated by the Russians during the past twelve months, we are not surprised to see the official figure is 6 million lb. again this year. The requirements of Australia also were over-estimated, but not excessively, and the estimate this year is, therefore, reduced by a million, merely—that is, put at 400,000 lb. ahead of the quantity sent southward last year. As for America, it is no doubt a little surprising to see the estimate for this year nearly doubling the exports of last; but—and it is a point to which we have already drawn some attention—we are convinced that what is put down in the Chamber of Commerce list for 1899 as exported to China, *i.e.* 1,384,490 lb., is really (or at least the large bulk of it) intended for transshipment *via* Hongkong to San Francisco or Vancouver, for California, British Columbia and Western America, generally. Thus the exports to America in 1899 would then amount,

roughly, to 4,464,492 lb. instead of 3,080,002 lb. as given in the table. Hence, perhaps, comes the justification for the extraordinary reduction of the 1900 estimate for other countries as compared with 1899, by one-half, or by 800,000 lb. on the total quantity exported last year—in the latter case the exports to China being more properly counted in with the estimate for America. The total estimate for all countries other than the United Kingdom is four millions ahead of what was sent to them last year—a fairly accurate calculation, we believe it will prove—and two millions behind the estimate for 1899. The United Kingdom, however, took 10 millions more than was expected last year, so the estimate is increased by 15,000,000—or five millions ahead of the exports in 1899. Finally, the total estimate for 1900—namely 138 millions—appears to us a rather liberal one. We have hitherto experienced that the yearly increases are alternately large and small. The increases since 1891 are roughly as follows:—

1891	...	21,300,000
1892	...	2,900,000
1893	...	13,300,000
1894	...	100,000
1895	...	13,400,000
1896	...	10,200,000
1897	...	7,900,000
1898	...	3,700,000
1899	...	10,100,000

Up to 1895 it is evident that the theory of alternation held good. In 1896 the fall is smaller owing to the quantity of fresh estates coming into bearing and to the fame that Ceylon tea was beginning to win for itself throughout the world; the figures of 1897, where we should have expected an increase, in reality balanced the smaller drop of the previous year, and in 1898 and 1899 the theory again holds good. Thus it appears to us, judging by the last 10 years, that the 1900 estimate is rather too high and that January 1901 may find us with nearer 135,000,000 lbs. exported for the last year in the century than 138,000,000. However, this remains to be seen, and with so much depending on weather, labour and even prices, it is impossible to dogmatise. Meanwhile the following from last Sunday's *Pioneer* is curiously inaccurate:—

THE EXPORTS OF INDIAN TEA during the calendar year 1899 amounted to over 151½ million pounds against 136 millions in 1898. The exports of tea from Ceylon rose to nearly 121 million pounds as compared with less than 111½ millions. "121" should be 130, while "111½" should be "119." We should need to go back to 1896 to find one year's exports below 110 millions.

The following are the figures for Ceylon commented on above:—

	Estimate, 1899.	Result, 1899.	Estimate, 1900.
Russia	... 6,000,000	3,949,740	6,000,000
Australia	... 17,000,000	15,606,833	16,000,000
America	... 4,000,000	3,080,002	5,500,000
Other Countries	... 5,000,000	3,309,457	2,500,000
	32,000,000	25,946,032	30,000,000
United Kingdom	... 93,000,000	103,948,124	108,000,000
Total	125,000,000	129,894,156	138,000,000

THE UTILISATION OF SEWAGE.

THE improvement of agriculture, through the aid of sewage is, of course, by no means a new question; but it is of particular interest to us at the present time, when Colombo is considering a scheme for the disposal of its sewage, and the rate-payer is threatened with a burden which may prove intolerable. Nor does the fact that the Nagpur Experimental Farm lies within British territory, on the adjacent continent, lessen our interest in its experiences. On the contrary it should stimulate the desire of our Municipal authorities to make enquiries with a view to ascertain how far those experiences can be reproduced here. The matter is one affecting both sanitation and finance, with an important bearing on agriculture, which, too, has lately demanded special attention locally. *The Friend of India* writes:—

Progress in the difficult task of elucidating the complex ways of Indian agriculture continues to be slowly made at the Nagpur Experimental Farm. The report for last year shows that a complication has been introduced by what seems to be some insidious form of plant disease which affects alike wheat, *tur*, and linseed. The experiments have been persevered with steadily, however, and in more than one direction encouraging results have been obtained notably in the success which has attended the application of fresh sewage manure, on the plan devised by Lieutenant Meagher of Allahabad. The Commissioner of Settlements state that the yield of *juar* which this method gave last season on the farm was phenomenal—nearly three thousand pounds of grain to the acre; while bumper cotton crops were picked on fields that had been thus treated. He thinks that, if extended to all municipal areas, it should enable large crops to be grown in their vicinity and give Municipal Committees some income from the disposal of sewage. The same experiment, it seems, had been tried with success at Deoli, in Wardha, and steps are now to be taken, through the Central Provinces Government, to try it elsewhere also. The system is described as simplicity itself, the sewage being merely deposited in very shallow furrows and covered up lightly with earth. Another successful experiment made last year was that of treating *juar* seed with cupric sulphate before sowing, as a preventive against smut. Valuable results were also obtained with an improved variety of wheat which is being introduced through the agency of the Farm. Special attention, we learn, is now to be directed to the last-mentioned branch of the operations, the introduction of varieties superior to those already in the hands of the cultivator being one of the most promising of the means of utility open to an institution like the Nagpur Farm. The Report does not say much about experiments in the direction of the selection of seed. Such extraordinary results, however, have been obtained in Europe by this means, in the case of all sorts and descriptions of agricultural plants, that it will be of the greatest interest to see it taken up more widely in India.

VANILLA DUTY REDUCED IN FRANCE.

With the idea of fostering the vanilla trade, the French Government have resolved to reduce the present duty on the importations from Tahiti and its dependencies into France by fifty per cent. This applies to the extent of the first 10,000 kilos.—*Chemist and Druggist*, Jan. 6.

THE BALLAD OF THE RAILWAY SLEEPERS.

How do the sleepers go down to the plains?

I went to discover this once on a time:
And blessed with some leisure, I'll tell you in rhyme.

Up on the mountains so blue and so far
They are felling the cedars and stout deodar.

For yearly in Delhi the Managing Staff
Demand good sleepers, a lakh and a half,
For their metre gauge railway which via Ajmere,
Bears back the exile toward England dear.

The sawyers have shaped them with axe and saw
Six feet of length without knot or flaw,
And the coolies have borne them a mile or so
Down the steep home of the buck and doe.

Another mile round the mountain side
On a man-pushed tramway the sleepers ride.

Hence to the plain how shall they go?
For it's still six thousand feet below.

Here down the steep is a sledge-car road
Fifteen sleepers make a load.

Give them a push and away they fly
A hundred feet in the twink of an eye.

Or if you prefer it on wire of steel
They can cross a valley with even keel,

For twenty seconds flying there
Through twice seven hundred feet of air.

Now they meet an aqueduct
Neatly against the mountain tucked;

Breadth ten inches, joining strong,
Downwards ever it leads along.

So let water do its part.
Throw them in and give them a start

Sometimes swift, and sometimes slow
With the water, along they go.

Here at length, they reach the shoot.
A thousand feet from top to foot.

See the water leap and gush
Startled out by their downward rush;

Once again on a gentler grade
On they speed through the forest shade

Now they're nearing the valley bed
Stream of the Kulni watershed

Over the stage like boys at school
In they plunge to a limpid pool

Now beware of an awkward block,
Full six miles, of shallow and rock.

Line the sides with built-up sleepers
And make the channel narrow, but deeper.

Then when the rest of the Army's gone
Pull down the sentries and pass them on

Yet twice the moon must wax and wane
E're the stream assumes its wont again

And the last of the fifteen myriad hoard
Launches forth on the river Broad.

So from Kulni to Tons and Gons to Jumna
Sails the mountain's late alumna:

Past the Siwaliks and through the plains,
Till the Delhi ramparts at length it gains.

Now take it over you Railway lot;
Let the sleeper sleep in its ballast cot.

Lay it to rest, (it has travelled far)
In the permanent way of the R. M. R.

—*Indian Forester*.

E. F. E. W.

COCOA BUTTER was discussed at the Society of Chemical Industry on June 5th. Dr. J Lewkowitzsch pointed out that all text books stated that it could not go rancid, which was distinctly wrong, and he said that the error had arisen from confounding acidity with rancidity, while as a matter of fact they were not synonymous.—*British and Colonial Druggist*, Dec. 29.

COCOA BUTTER DEARER IN AMERICA.

Values in cocoa butter for both bulk and cake are still advancing in a manner that occasions considerable surprise to not a few. At the most recent sales in both London and Amsterdam the prices obtained were on a higher level than those of the last previous auctions. At the time of sale in the latter city our correspondent informed us by cable that the offerings were disposed of at an average price of ninety-four Dutch cents per half-kilogram, which compares well with the price of ninety-one cents at the previous auction, in November, and even more favorably with the average price recorded at the October auction, which amounted to eighty-eight Dutch cents. With largely depleted stocks in this country, the consuming demand has grown to be of considerable proportions, while the purchasers to supply the large current requirements have mainly been of a hand-to-mouth character. Importers in this and other American markets are, generally speaking, in no position at present to supply cocoa butter in considerable quantities, and with the demand being what it is, the recent stiffening of values is not to be wondered at. A factor, however, has lately entered into the situation that is becoming of increasing importance. As prices have commenced to assume the high level recently prevailing, a large part of the manufacturing and consuming trade have in consequence had recourse to the purchase of what is now offered by several dealers as a substitute for cocoa butter, for confectioners' uses. The prices prevailing for this article are less than one-half of what is quoted for the regular goods, and it is reported that the demand for it has lately become quite large. It is, of course, doubtful to what extent this can figure as a future factor in the situation, but it is unquestionable that the business in the article is already large and growing. Although trade sentiment is somewhat at variance regarding future values in the real butter, and the holders' views are expressed only with the greatest diffidence, the prevailing sentiment seems inclined to the view that prices, although not likely to be seriously checked for the near future, have reached the level where any further large appreciation is not thought probable.—*Oil Paint and Drug Report.*

A NEW TEXTILE PLANT.

Some years ago, an explorer in Asia discovered a plant of silken fibre, used by the Turkomans for the manufacture of wibes and cord, and by the Canaques, for woven goods. This plant, known as *Apocynum venetum*, is a sort of bush with slender cylindrical branches, sometimes 6 feet high. It grows in Europe, Siberia, Asia Minor, the north of India, Manchuria and Japan but is not cultivated, and, up to the present has been used only in the natural state. The branches die yearly, and in the spring new shoots start horizontally from the roots. It flourishes best where the land is under water during a part of the year, notably in the neighbourhood of rivers that overflow at stated periods. Under favourable conditions the *Apocynum* develops quickly, and in a short time the branches form a thick growth, almost like a miniature wood. The best fibre is obtained by cutting the branches in midsummer, when the plant has obtained its full growth. The attention of the Russian Government was called to this plant in 1891. It is there known as the *Apocynum sibericum*, because it was first seen in Siberia. It grows luxuriantly on the banks of the Amu-Darya, and the Il, and the natives of the regions have used the fibre for many years for cord and fish nets. They value it not only for its great strength, but also because no care is required in its cultivation. In 1895 the Russian Government began to use it in the manufacture of bank notes, and since then the plant has been cultivated at Poltava. The results obtained thus far are considered excellent, and the time is doubtless near when the *Apocynum venetum* will take an important place in the textile market.—*Commercial Intelligence.*

MINOR PRODUCTS REPORT.

LONDON, January 4.

CINCHONA.—The Nederlandsche Veen cinchona bark department at Amsterdam report that the shipments from Java to Europe were as follows:—

Amsterdam lb., December—						
1899	1895	1897	1896	1895		
626,000	1,018,000	731,000	890,000	634,000		
January—December—						
1899	1898	1897	1896	1895		
11,409,800	11,150,000	8,437,000	10,079,000	8,827,700		

The exports from Ceylon for the week ending December 12th were 1,137 pounds only.

CITRONELLA OIL.—At the close of last week business was done ton-lots at 10½d to 11d per pound, c. i. f., and at 10½d landed terms, in large drums.

QUININE has improved to the extent of half pence per ounce in second-hand in consequence of small bark shipments from Java during December. With the exception of sales on Tuesday, when about 150,000 ounces changed hands at 1s 3½d to 1s 3¼d spot and 1s 3½d to 1s 4d for March, the market has been quiet, and on Wednesday prices were a shade weaker. Today a good business has been done at 1s 3½d to 1s 4d for March delivery.

There were no exports of Java quinine from Batavia during October; from July 1st to October 31st, 1899, the shipments have been 562 cases against 499 cases.—*Chemist and Druggist, Jan. 6.*

USES OF THE EUCALYPTUS.

Mr. L. F. Woolrych, of Cooma writes:—It has struck me that a few notes on some of the uses to which different parts of the various eucalyptus trees are put would be of interest. The eucalyptus family is truly to the Australian what the palm is to the Eastern peoples, spread as it is all over the continent and always within reach. In Europe it is a common belief that the trees of our forests throw no shade, but for shade and shelter purposes many of them are invaluable, as well as for their beneficial effect in connection with miasma arising from swampy ground. In New Caledonia the ti-tree (*Melaleuca*) is planted for the latter purpose. Then the young leaves may be used for poonies, or as sticking-plaster, which will only wear off. One variety (*E. obliqua*) called here stringybark, will provide the selector's fence, gates, slabs for house, and bark for the roof, as well as firewood. The fluffy part of the bark is splendid for kindling purposes, and the inner bark makes excellent ropes, ties and make-shift harness. The bark will also make good pipes for carrying water. The gum is often used as a medicine for sick fowls, and is also a good bush remedy for dysentery, as old bushmen have told me frequently; and it makes a good varnish when dissolved in spirits of wine. The honey from the eucalyptus, if used in quantity, said to be a violent purgative, but if consumed in the ordinary way is a mild aperient. In fact one might go on for a long time before the list of uses to which these valuable trees can be put would be exhausted.—*From the Agricultural Gazette, of New South Wales.*

CINCHONA.—In a specially translated article by Dr. L. P. Lotsji, Dutch Government botanist in Java, published in our issue of January 6th, on the localisation of alkaloid in cinchona plant, the conclusion was arrived at that the alkaloid was not contained in the sieve vessels but in the parenchyma; in the younger parts, in solution in the cell sap; and in the older parts in an amorphous solid condition.—*British and Colonial Druggist, Dec. 29.*

TROUT OVA FOR NUWARA ELIYA.

The N.D.L. ss. "Bayern," which arrived from Europe on January 26th, brought out a consignment of 10,000 trout ova for the Ceylon Fishing Club. Like the previous consignment, the present one is from the well-known trout farm of Messrs. Andrews and Andrews, Guilford, and is to be put into the hatchery at Nuwara Eliya. Another consignment of 10,000 brown trout ova, is expected by the middle of this month; while the third and last batch, of 10,000 rainbow trout ova, is expected in March.

The above reminds us that Mr. Fraser, of Abbotsford, attempted on his present voyage to convey a consignment of perch. They were duly shipped on the P. & O. ss. "Oceana" in the Thames with full instructions, as Mr. Fraser was to join at Marseilles. When he did do so, he found the perch dead, owing, it is supposed, to the effect of rough weather in the Channel and Bay of Biscay. The Commander (Capt. Crawford—one of the most obliging of P. & O. Captains) when he heard of the experience, however, and the purpose for which the perch were being taken out, offered to arrange for another consignment and to give the same the greatest possible attention so as to secure delivery in good condition. This will be on the next outward voyage of the "Oceana," and we trust the experiment will be crowned with success.

TOMATO DISEASE IN N.S.W.

Several tomato growers about Sydney have been puzzled to notice fine healthy plants suddenly collapsing and dying as if struck all of a heap by the bubonic. This week, reports the *Sydney Telegraph* by last mail, the peculiar disease has appeared on a large scale in the Gosford district. Specimens sent to the Agricultural department have been examined, and found to be infested with the "sleeping disease of tomato, a fungoid known as "Fusarium lycopersici." The entomologist states that this is a very common disease in England, where it causes great losses to market gardeners growing tomatoes. It is likely to spread, as if the plants are attacked when in full fruit, as is often the case, the fruit may ripen, and appear, even under the microscope, to be perfectly sound, yet the seeds from such tomatoes, if planted, will produce diseased plants. As the fungus first attacks the roots, and then comes up the stem, where it discolors the tissue and causes the sudden death of the plant, there is no remedy. Plants should be destroyed, and the soil treated with quicklime to exterminate the spores and keep the disease from spreading. The disease has probably been introduced through seed.

PLANTING NOTES.

RUBBER SUBSTITUTES.—Dealing with the three elastic gums which have been suggested as substitutes for rubber, Hooper does not consider that either of them are suitable for the purpose. He gives their characteristics. The first, obtained from the stem of *Ficus bengalensis*, dissolves, without previously swelling, in ether, chloroform and carbon bisulphide; the second, from *Calotropis gigantea* and *C. procera*, contains but little caoutchouc; and the third, which is the coagulum of the milky juice of *Excoecaria azallocha*, possesses irritating properties, and contains alcohol soluble resins—*British and Colonial Druggist*.

RUBBER TREES.—The U. S. Department of Agriculture has recently issued some valuable information on the subject of rubber-trees. Experiments in India with certain species were not successful, owing to the fact that the trees did not develop the characteristic laticiferous ducts. In the light of the work of the department's experts this was due to error in selecting the variety. Unless care be taken in this direction, failure will result in securing rubber, even though the trees may apparently grow well. There are four varieties of rubber-trees, which must be utilised according to the soil and climate of the place of cultivation:—

(1) *Castilloa elastica* grows well and produces rubber in places where the climate is hot, humid, and the soil drained.

(2) *Hevea brasiliensis*, in the climate be hot, humid, and the soil swampy or covered with water.

(3) *Manihot Glaziovii*, the Ceara plant, if the climate is hot and the soil dry, sandy, or stony.

(4) *Sapium biglandulosum*, in temperate or cold climates such as Florida, Louisiana, &c.

The last variety is especially suitable for growing on coffee plantations.

COFFEE IN NEW SOUTH WALES.—A farmer on the Lower Clarence, New South Wales, who is trying coffee growing, has just harvested 5,000 lb. of beans, which will produce about 900 lb. of ground coffee. The sample is admitted by experts to be equal to the best Ceylon in strength and flavor.—*Melbourne Leader*, Jan. 6.

STATISTICS OF CINCHONA CULTIVATION in India are published by Mr. J. E. O'Connor, under date Calcutta, Jan. 15. We quote:—

At the end of the official year 1898-99 there were 7,591 acres of land under cinchona cultivation, of which nearly 82 per cent was situated in Southern India, the remainder (18 per cent) being in Bengal. The area in Bengal, comprising 1,373 acres, lies in and near Darjeeling. Most of the area in Southern India is in the Nilgiris (4,531 acres). There are also 1,173 acres in Travancore, and smaller areas in Mysore, Malabar, and Coorg. In Bengal the cinchona plantations, which are the property of the State, cover 1,303 acres. In the Madras Presidency, on the other hand, the industry is mainly in private hands, the State Plantations covering only 874 acres. During the thirteen years ending with 1898-99 the area under cinchona has fallen from 14,491 acres to 7,591 acres. There has been a substantial decline in Bengal as well as in Madras, and in Coorg the cultivation has been almost entirely abandoned. The number of plants in permanent plantations has fallen in the same period from 28½ millions to about six millions. In 1898-99, a little over four millions were classed as mature and nearly two millions as immature plants. The general reason for the decline is the fall in the price of quinine. The price fluctuates, and when a temporary rise occurs it is followed by the exportation of all the bark that can be collected from plantations owned otherwise than by the State. But the manifest general tendency of the price-level for many years has been downwards.

The quantity of bark collected fluctuates with prices. Bark collected (lb. Madras 1898-99 745,472. Bengal 251,529. Total 997,001. Exports (lb.) Madras 1,361,539. Total 1,361,539.

In Bengal most of the bark collected is manufactured by Government for issue to the State medical stores and to hospitals. In 1898-99 the Government cinchona factory produced 10,335 lb. of quinine sulphate and 3,321 lb. of cinchona febrifuge. The industry generally, apart from the Government operations in the Darjeeling district, has dwindled to unimportant proportions.

CEYLON CINNAMON EXPORTS AND DISTRIBUTION IN 1899.

If our apprehensions with regard to a short out-turn of coconut products for export, as a result of the two droughts which made themselves felt last year in the lowcountry, have unhappily been justified by the event, we cannot, unfortunately, claim to have been true prophets in our forecast touching Cinnamon. We say unfortunately, not from concern for our reputation as prophets, but because a redundant cinnamon crop is a very doubtful blessing; and in the present instance the exports have been swelled by nefarious means. The supply of spices can very easily outstrip demand, and no island industry has suffered so long and so severely from over-production as the Cinnamon industry. The prices ran down from two to three shillings a lb. in the "seventies" to less than a shilling in the "eighties," involving Proprietors in much embarrassment, if not positive loss; and the slight recovery during the past decade was a very welcome relief. The advantage gained is again threatened by over-production—the explanation being that prices which barely leave a margin of profit to cultivated estates, satisfy small native holders who neglect cultivation and attend to the preparation of the bark themselves. There has always been more or less adulteration in garden, as distinguished from estate, spice; but last year, under the stimulus of high prices and small crops in the earlier months, a new industry developed, in the shape of "Wild Cinnamon!" We have already expressed our belief that before the Collector of Customs and the Chamber of Commerce united to demand a separate classification for wild cinnamon, some of it had already been shipped as plantation spice, and hence it is that quilled bark showed last year a falling-off of only 19,025 lb. as compared with 1898, while chips disclosed an increase of 415,000 lb. The deficiency of peelable bark is naturally made up by scraping chips from coarse sticks; but the 1898 production of 1,414,165 lb. of chips had never been approached within 400,000 lb. and an increase on that large out-turn of 400,000 lb. marks a stride which cannot be due to natural causes. In 1890 the export of chips was only 441,447 lb.—a large outturn as compared with previous years; and the development since then has been steady until a little over a million lb. was shipped in 1897, since when the growth has been phenomenal. The combined outturn of quilled bark and chips last year, amounting as it did to over $4\frac{1}{2}$ million lb. beats all previous records, and does not disclose a healthy state of things. The figures for wild cinnamon, which began to be compiled only during the last few weeks of the year, were 195,008 lb. quills and 628,418 lb. chips. We reiterate our hope that the reception which this stuff met with at the November auctions in London will put an end to the trade, and that the shipments which have continued to go forward since then will only add to the losses of those who are engaged in the doubtful business. Their destination was the United Kingdom and Germany, and both countries should be warned by what Messrs. Darley, Butler & Co. have already written on the subject.

Turning to the Distribution of Cinnamon which has not been described as wild, the United Kingdom heads the list, having taken 1,121,128 lb. quills and 680,638 lb. chips, a quantity which is about 290,000 lb. more than in 1898 under each head. The next largest customer is Germany with 639,039 and 650,637 lb. respectively, which is less than she took in quilled cinnamon the previous year, the falling-off being, perhaps, due to the trial she is giving wild cinnamon? In chips, however, there is an increase which brings the total up to that of 1898. No other country approaches these figures—the third, in order, being Spain with 262,100 lb. quills and 65,900 chips; but this is a great advance on her requirements of the previous year. We welcome the improvement, not only as a contribution to the island's prosperity, but also as evidence of recuperation in the commercial position of Spun. We had already noted this, in connection with her renewed orders on the London market, which have helped up the prices for our best estate marks for which she has always shown a partiality; and this is further proof that she is shaking off the effects of her disastrous contest with America. Curiously enough, America shows a corresponding falling-off in the quantities she has taken—her figures having been 146,600 lb. and 23,000 lb. for 1899, which are about the same as Spain's for 1898. Spain is thus having her revenge in commerce for military and naval disasters! Our other principal customers for cinnamon were Italy, Belgium, France and China, whose takings ranged from 117,200 lb. and 144,220 lb. of the two sorts, to 45,000 lb. of the first alone. Turkey, India, Australia and Africa took small quantities, and they complete the list.

PLANTING IN ST. HELENA:

COFFEE AND TEA.

A paper by H.E. Governor Sterndale in the "Asiatic Quarterly Review" on "St. Helena in the Present Time," gives some interesting information. The people are very inoffensive, says the Governor:—During twelve criminal sessions, over which I have presided as Chief Justice, on all except two occasions have I received white gloves. Civil litigation is common enough. They are kindly disposed one to another, showing much sympathy in sickness and trouble, and are courteous to strangers, who are generally much struck by this, and by the comparative purity of the English spoken by them. Their faults are lack of energy in overcoming difficulties, and their proneness to accept a failure as a finality—take, for instance, vine culture. I remember in years gone by

SPLENDID GRAPES IN ST. HELENA

but the vine disease was introduced and the vines perished, never to be replanted. The same thing happened in Madeira, but the people there took heart and tried again, and with success. It is a common story in St. Helena, "Oh yes, I remember such and such things when I was young, but they died out long ago." That lemons were common in the island is proved by the many places, such as Lemon Valley, Lemon-tree Gut, etc., being called after this fruit, which is now extinct and has to be imported from abroad. And with peaches, the same story of the good old days—no finer peaches to be seen anywhere, but now from ungrafted,

unpruned, in every way neglected trees, miserable, worm-infested crops of worthless fruit are gathered. Providence has been kind to the coffee-tree, which still flourishes and bears abundant crops of excellent coffee of the old Mocha stock, but for all the care that man takes, it might have gone the way of the grape and the peach. I, who have seen the care, the pruning, manuring and hoeing of

COFFEE PLANTATIONS

in India, have never ceased to wonder at the generosity of the St. Helena tree, which often bears its white starry blossoms whilst the pickers are gathering the ripe fruit. There is much land now devoted to pasturage which would yield a better return under coffee cultivation, but there is the drawback of scarce and dear labour; however, this might be overcome. I have shown that the tree does not require so much attention as in India, and the picking can be done by girls at sixpence a day, supervised by women who get a shilling. Ordinary labourers' wages have now gone up from two shillings to half a crown a day, owing to military and other works in hand. I had an idea that tea would grow well, not so much for export as for island consumption. Some years ago, whilst inspecting the Lawrence Asylum at Ootacamund, I found that the boys were drinking tea which they had grown on the estate, and had made up at a neighbouring factory for a few annas a pound (I think two annas). I saw no reason why the poor of St. Helena should not be able to buy tea at sixpence a pound, grown in the island and made up at a small central factory.

THAT TEA WILL GROW

is proved by the existence of some China plants which were introduced in the time of the East India Company. In 1896 I tried the experiment, having taken out with me a native of India who had been for nine years an overseer on a tea estate in Assam. I got some tea seed and reared a number of plants, but in the meantime I had to return to England, and whilst there to recall my tea-planter, and on my return I found that the rabbits had devoured my young tea seedlings, and so ended an experiment, which cost me nearly a hundred pounds. But still I feel inclined to try again under my personal supervision. But whatever experiments are tried in the starting of any industry, they should be tried by those who will devote the whole of their time, labour, and money to it, as a tea or coffee planter does, when he goes out to India. Land is not dear here—the average price of estates lately sold has been from £10 to £15 per acre—but as the culturable area is limited, it does not often come into the market. As I said before, much valuable land is now kept solely for pasturage, which would, if highly cultivated with coffee, yield a much better return. That island coffee is now in demand is proved by the fact that, having sent away last month a barrel of coffee from the Government House plantation as a sample to Messrs. Lewis and Peat, coffee brokers, of Mincing Lane, with a view to ascertaining its quality, I discovered that I could not purchase any island coffee from other sources, as the whole stock had been bought up by the contractors for the troops, Messrs. Solomon and Co., who kindly let me have a little for my own consumption. It was only the other day I was pointing out to some friends, who had lately arrived, some coffee-trees on an estate, which had been allowed to run up from 12 to 15 feet in height; they looked the picture of health, and were bearing freely, but ought to

have been pruned down at about 4 or 5 feet. In 1869 the Government attempted to introduce

CINCHONA,

but without much success. A nursery was farmed under the supervision of a skilled gardener sent out from Kew, who raised about 10,000 plants from seed, of which about one half were put out on the slopes of Diana's Peak; but the experiment was discontinued in 1870, by Admiral Patey, who came out as Governor with instructions to reduce expenditure, and in the retrenchments which ensued, the gardener from Kew was struck off. From that time the cinchona-trees were left to shift for themselves, and now there are probably not more than 150, some of them fine ones and fairly healthy. At the present time, the cultivation on such a limited scale as could be carried out here would not be commercially profitable, as the large cinchona plantations in India, Java, and other places have brought down the price of the bark. Still, the trial has shown the wonderful capabilities of this little island, where in an area of 47 square miles, plants from all parts of the globe have been grown with success; and one remarkable feature of this adaptability of soil and climate has been the struggle between the indigenous and the imported

FLORA,

which has resulted in the former being driven back to the central mountain range, the northern edge of the vast crater, which existed in the volcanic period, the southern portion of which is now under the sea. There you will still find the ferns of the place, from the stately tree-fern and the huge *Diplazium*, with its seven-feet fronds, down to the tiny filmy fern (*Hymenophyllum capillare*). Here too, the foliage strikes you as being of an old-world character. The trees have a weird, unfamiliar look, such as one would associate with the megatherium and the mylodon. Sir Joseph Hooker, in his lecture on Insular Floras, refers to that of St. Helena as being "most interesting; it resembles none other in the peculiarity of its indigenous vegetation." In another part he says, speaking of the indigenous species: "Forty of them are absolutely confined to the island. These forty are absolutely peculiar to St. Helena, and, with scarcely an exception, cannot be regarded as very close specific allies of any other plants at all." It is to be regretted that some of the most interesting species have become extinct, among them the beautiful ebony-tree (*Melania melanoxylon*), of which no traces remain, save a few crooked bits of wood, occasionally disinterred from the soil in places where it grew, and even these are becoming very scarce. Yet this was one of the most abundant trees, probably one of those which in Juan de Nova's time clad the rocks with verdure down to the cliffs overhanging the sea. It was so abundant that it was cut down to burn the lime used in the building of the fortifications. The destruction of the forests and extinction of many of the indigenous plants were due to the ravages made by goats, which in the sixteenth and seventeenth centuries existed in thousands, laying waste the country.

AN OLD ORANGE-TREE.

The oldest orange-tree in France has just died this is an item recently found in the "Press Miscellany." If true, it is interesting as showing the very great age to which an orange-tree may attain under favourable conditions. The details as published are as follow:—

It was brought to France with several others in 1421, by Queen Leonore of Castile, the wife of

Charles III. of Navarre, and in 1684 Louise XIV. ordered that it be transplanted to the orange grove in Versailles, and there it has remained ever since. During the last two centuries the tree has been known as the "Grand Bourbon," and for many years every possible care has been taken to preserve it from decay. Now it has passed away at the great age of 478 years, and many Parisians who knew it well are sorry that they will never again see this stately ornament of the Versailles Gardens.—*Queensland Agricultural Journal.*

STUDY THE TEA BUYER: BIG BREAKS WANTED.

(To the Editor of the Home and Colonial Mail)

Sir,—I wish to draw attention to what is becoming a very serious question for tea buyers in the London market, namely, the dividing up of a break of tea into three or four divisions and offering them all in the same week, or even on the same day. I have just been looking over this present week's catalogues and find from Salonal, three Pekoes, three Pekoe Souchongs; Dinjan, four Pekoes; Khobong, three Pekoes; Debrapar, four Pekoes and four Pekoe Souchongs; Sokerating, four Pekoes; Amo, three Pekoes No. 1 and 7 Pekoes No. 2; Carron, three Pekoes and three Pekoe Souchongs; Hapjan, three Pekoes; Greenwood, two Pekoes and three Pekoe Souchongs; Etah, two Pekoes No. 1, two Pekoes No. 2; and so on, if your space would admit of the needless multiplication of examples. Now all these gardens are presumably managed by good men of business, and yet here is plain evidence of defying the oft-expressed opinion of the market as set forth in the annual circulars of all the best informed brokers, who ever and anon have recommended the increasing size of the breaks. Some of the breaks above referred to do not average more than twenty-four chests; the quality of each of the three or four twenty-four chest lots is so close that few experts would find $\frac{1}{4}$ per lb. between them; yet instead of bulking the three together so as to save time, buyers must taste three samples and microscopically endeavour to detect a shade of difference, thus wasting much valuable time and exasperating them besides. It is perhaps too much to hope that the pointing out of this flagrant condition of things will effect any alteration, nevertheless, in the best interests of the Indian tea industry, I think attention should be directed to it. When will sellers learn that in studying the buyer is the surest way to increase business, and in the long run get the best price? And when will they perceive the fact that the man who has accurately valued one sample will bid higher for it than the man who has hurriedly and uncertainly looked at four samples and cannot for the life of him make up his mind which is the best?—I am &c.,
D F SHILLINGTON.

THE INDIAN TEA ASSOCIATION (LONDON.)

The following is an abstract of the proceedings of a meeting of the general committee held on Tuesday, 9th Jan. Present: Mr. D Cruickshank, Messrs. Robert Lyell, F A Roberts, A G Stanton, (chairman), J N Stuart, W H Verner, C W Wallace, and S A Went.

The Late General HENRY HOPKINSON, C S I.—The following resolution was unanimously passed by the committee before proceeding to the business of the day: "This Association regrets to learn the decease of General Henry Hop-

kinson, C S I, who was for many years associated with the Indian Tea Association as its chairman, and begs to express its sympathy with his family."

The minutes of the last meeting of the committee, held on Tuesday, December 19, 1899, were read by the secretary and confirmed.

Correspondence with Calcutta, which had been previously circulated to members, was laid upon the table.

SCIENTIFIC OFFICER FOR THE TEA DISTRICTS.—A letter on this subject from Dr. Voelcker, addressed to Mr. Cruickshank, was read by the secretary, and at the request of the committee Mr. Cruickshank arranged to see Dr. Voelcker again and settle with him as to the engagement of a suitable man with the requisite qualifications to proceed to India and take up the appointment.

WAREHOUSE CHARGES.—Mr. Geo. W Christison's letter of October 27th last was considered and discussed by the committee, and also the minutes of the meeting of the Calcutta committee of December 5th, 1899.

TRAVANCORE STATISTICS.—After some discussion it was decided that in future it was advisable that estimates of the Travancore crop should, if procurable, be given separately by the Calcutta Association when framing their forecast of the Indian tea crop.

WORK IN AMERICA.—The secretary reported interview with Mr. Mackenzie on 8th inst. Letter from Mr. Mackenzie dated 8th idem was read, and secretary was instructed to reply confirming arrangements made.

ILB DRAFT.—Correspondence with Mr. J A Brown, Secretary Tea Buyers' Association, was read by the Secretary, and meeting of Joint Committee arranged for Thursday, 11th instant, at Ceylon office.

PARIS EXHIBITION, 1900.—It was noted that four photos of Darjeeling had been received from this exhibition from the Calcutta Association. The photos were exhibited to the committee.

PROPOSED DOCK TRUST FOR THE PORT OF LONDON.—Letter from Mr J A Brown, Secretary Tea Buyers' Association, was read, intimating that Mr. John Lacky had been appointed as their representative for the special committee of the London Chamber of Commerce. Mr F A Roberts was requested, and agreed, to act as the representative of the Indian Tea Association, ERNEST TYE, SECRETARY.—*Home and Colonial Mail*, Jan. 12.

SUGAR.—*Capital*, writing on the sugar-cane crop in Bengal, says:—The season was rather favourable to the crop at the beginning, but subsequently heavy rain adversely affected its prospects, and in some places the crop suffered from want of rain and damage by insects. The total area under sugar-cane is returned at 860,200 acres, against 861,100 acres in the previous year. Only three districts report a crop which is above the normal, and nine districts an average one; the remaining thirty-three districts expect an outturn below the normal. The forecast of the crop was a normal outturn, but it is now probably that only 84 per cent of a normal crop will be obtained. On this basis the outturn of raw sugar may be expected to be 15,896,500 cwt. against 17,428,700 cwt. in the previous year.

ON THE DETERMINATION OF THE FUNGI WHICH ATTACK FOREST TREES IN INDIA.

The study of the fungi which are found in the forests of India, either as parasites on the leaves or as causing decay of the wood, or again as saprophytic plants on the ground in the forests, is one which so far has made but little progress. Most forest officers, however, know how exceedingly important the subject is, and many of them have had opportunities of seeing what has been done in Europe to work it up, and most especially in Germany. The real pioneer in the study of forest-tree pathology was undoubtedly Prof. Robert Hartig of Munich, whose text book of the "Diseases of Trees," which is available to English students in the excellent translation of Dr. W. Somerville, revised and edited by Prof. Marshall Ward, F.R.S. (Macmillan & Co. 1894) is one of the most interesting works which a forest officer who observes the processes which are going on in the forests, inimical to forest tree-growth and development, can study. There is an excellent, if somewhat brief, account of the principal European tree fungoid diseases, by Mr. W. R. Fisher, in the 4th Volume of Dr. Schlich's Manual of Forestry, and another in Prof. Marshall Ward's 'Timber and some of its diseases' (Macmillan & Co. 1889). But the most important and most astonishing book on the subject is the monumental work of Dr. Karl Freiherr von Tubeuf, which has been translated into English by Dr. W. G. Smith of Edinburgh as 'Diseases of Plants, induced by Cryptogamic Parasites' (Longmans, Green & Co. 1897) a work which is practically a dictionary of all that is known on the subject and refers not merely to European plants, but to the plants of the world and those

OF THEIR FUNGOID DISEASES

which have been so far discovered. A mere cursory examination of Dr. von Tubeuf's great work is sufficient to open the eyes of even the most conservative and sceptical of Foresters to the importance of the subject and to the amount of information which still remains to be obtained regarding it. It is clear that there is hardly a plant among the higher order that is not affected by some, indeed often by many, parasitic and epiphytic fungi; and the wonder is that with so many foes, plants cultivated and wild and forest trees are able to maintain successfully their powers of growth and reproduction. So far as they were known at the time he wrote, Dr. von Tubeuf made mention of the Indian species.

It is fortunate that, so far as observations have yet gone, the chief forest trees of the hotter parts of India have not been found to be affected by injurious fungi to the same extent as are the forest trees of Europe and their allies of the Himalaya, but in the Himalaya the fungi are often very much in evidence and even in the plains there are some of considerable importance, a few examples of which may be given.

In January 1891, I visited the

CHANGA MANGA PLANTATION

with the Forest School students who were on tour there under the supervision of the Deputy Director, Mr. Fernandez. Not far from the Forest and Canal Bungalows, in a low-lying rather damp area, many dead and dying trees were met with. On being cut into, the stems of these trees were found to be permeated in every direction by the white mycelium of a fungus. At first, we thought that possibly the fungus might be one of those species which attack only dead wood, but the presence of the mycelium in still living trees was against this, and after a considerable search, the sporophores of a large species were found, with every indication that they belonged to the mycelium in the wood. The sporophores consisted of a large, dark, red-brown, bracket, fixed to the tree at one side close to the root; the upper surface measured perhaps a foot to a foot-and-a-half in length and 6 inches or more in breadth, and showed several rings indicating its gradual growth. The spores were in tubes on the

under surface in the manner characteristic of the *Polyporeæ*, and the fungus, on being sent to Kew for identification, proved to be a new species and was described by Mr. G. Masees as *Polystictus egregius*. By some authors *Polystictus* is regarded as a section of *Polyporus*, that large genus of Hymenomycetous fungi which possesses so many members destructive to forest trees and timber in Europe, among which perhaps the most noticeable is *P. sulphureus*, which has sporophores very closely resembling those of the Changa Manga plant. Again, when on tour in 1889 in the Casuarina plantations of Nellore in the Madras Presidency, a similar case of dying and dead trees was observed, and the only specimen (a very young and imperfect one) which was obtained of the sporophore, was found to be very similar to the Changa Manga one and may very likely have belonged to the same species. In both cases, I remember to have very strongly urged the local officers to follow up the subject, and specially to study means for getting rid of the pest, but I have never since heard if anything store was done, and fear that *Polystictus egregius* is mill at work trying to ruin the beautiful plantations of Sissoo in the Punjab, and the Casuarina groves of the Madras coast. Of other *Polypori* the most noticeable perhaps is *Polyporus (Fomes) fomentarius*, which is everywhere conspicuous in the North-west Himalaya especially on the 'ban' oak (*Quercus incana*) and the birch (*Betula alnoides*), the sporophores consisting of a huge, hard, grey, reversed bracket. This fungus, which thrives both on living and on dead trees, perhaps more frequently on the latter, is also common in Europe, where up to quite recently, and indeed still to some extent, the dried sporophores are used for tinder. Many of us can still remember the 'amadou' matches which used to be sold in the cities of Europe for lighting cigars, and which were made of the dried felt of the sporophores of this species.

For many years, the parties who have visited the
DEODAR FORESTS OF JAUNSAH

yearly for the instruction of the students of the Forest School, have been interested and puzzled by the groups of young dead deodar to be met with here and there, the cause of death being not at once apparent. Often have we dug up specimens, only to find what might have been expected, that the roots and the lower parts of the stems were fully permeated by the mycelium of some fungus, but what kind of plant it was and what could be done to stop if we had no means of telling. Last autumn, however, (1893), spring searchings having invariably failed, I was in Jaunsar and took every opportunity of hunting for the sporophores and at last was successful in finding a rather poor specimen which was unmistakably the cause of the death of a fine young deodar near the Jako pass. It was sent to Kew and proved to be *Polyporus (Fomes) annosus*, Fries, better known by the older name of *Trametes radiciperda*, Hartig, and described by Hartig as "undoubtedly the most dangerous of all the parasites met with in coniferous woods, not only because it produces the worst kind of red-rot, but also on account of its being the most common cause of gaps in both young and old plantations." It is impossible to exaggerate the importance of this sad discovery. The Forest Department is very properly yearly spending on the reproduction of deodar large sums of money and so far the success has on the whole been considerable, better perhaps with natural than with artificial reproduction but still good in both cases. In Jaunsar and in the neighbouring leased forests of Tehri-Garhwal, the disease is, so far as my own observations go, on the increase, and it is now time to take strong measures to stop it before it goes too far. It is propagated, as is well known and as is described by all the writers on the subject, Hartig, Marshall Ward, Fisher, von Tubeuf, chiefly by the contact, in the soil, of the roots of adjoining trees and the remedy proposed, and for long adopted in Germany, is to isolate affected trees or patches of trees by digging trenches around them sufficiently deep to prevent their roots passing beyond and communicating

the disease to neighbouring trees. Further details must, of course, be worked out on the spot, but I strongly advise early action or the spread of the enemy may be too quick and we may lose some of our finest and most promising areas of reproduction.

These few examples ought to show sufficiently clearly how very important the subject is, and if we are to utilize to the full the information obtained in, and the experience of, Europe, we must begin by searching for and finding the sporophores and obtaining their identification. The identity of the fungus which attacks the stems of the Kharshu (*Quercus semicarpifolia*) trees at Deoban in Jaunsar, requires to be investigated. From the fact that it is apparent both in the mycelial form of white threads disintegrating the wood, and in the form of lough black stout rhizomorphs it is most probably the well-known *Agaricus melleus* or an allied species, but the discovery of the sporophores is necessary in order to settle the question.

In the case of Hymenomycetous fungi like those already mentioned, it is not always easy to find the sporophore and identify the enemy; but in other cases, and especially in the case of

THE LEAF-DISEASES,

it is not so difficult. Most of those who have worked in the sub-Himalayan sal forests have noticed that in some years the leaves of the trees, often over considerable areas, appear as if covered with soot. A very little examination of the effected leaves shows that the black appearance is due to a fungus, but although the spores of the fungus were readily found, its nature remained for some time in doubt. Specimens collected by myself in Dehra Dun and by Pandit Keshavanand in the forests of Oudh were sent to Dr. D. D. Cunningham, F.A.S., of Calcutta, and his report was that the blight was a Meliolaceous Pyrenomyceetenot parasitic but merely epiphytic and that where they do any injury to the host, it is purely due to their interfering with assimilation and respiration from the dense surface-coating which they ultimately tend to form." A note on the subject appeared in the "Indian Forester" Vol. XX, p. 156 and further specimens were sent to Kew where they were identified as *Meliola amphitricha*, Fries. Thus two investigations were satisfactory and showed that after all, unless the fungus was very bad indeed, it was not to be expected that it would cause greater injury to the sal forests than a slight retardation of growth. So is it also, generally, with the well-known conspicuous orange-coloured uredineous fungi which occur on the leaves of Himalayan conifers and which were the chief subject of the paper in the "Indian Forester," Vol. XXI, p. 126, by Mr. J. Nisbet, with pictures from photographs taken by Mr. C. G. Rogers. The chief of these was the yellow tassel-like fungus on the young leaves of *Picea Morinda* called by Mr. Nisbet *Æcidium Thompsoni* and identified at Kew as *Peridermium incarceerans*, Cke. and by Barclay as *P. piceæ* Barcl. This bright-looking fungus is, as Mr. Nisbet pointed out, closely allied to the *P. coruscans*, Fries, which attacks the spruce tree of Europe and is occasionally eaten by the peasants in the north, and I believe it is itself occasionally used as an article of food in the Himalaya. The damage done by it is not very great unless it happens to attack the principal leading shoot of the tree. Then there were also the Peridermia of the pines, *Pinus longifolia*, and *P. excelsa*, identified at Kew as *Peridermium orientale*, Cke. These appear as small orange-coloured sacs of spores on the needles of the trees here and there, but do little harm unless they occur, as Mr. Nisbet points out, on the branches in the form of the var. *corticola*. They have been described, in more detail, in Mr. Nisbet's paper already referred to, as well as in Dr. Cooke's paper in the "Indian Forester." Vol. III, p. 88. The *Peridermium pinæ* of Europe, which is found on the Scots pine, is known to be in its leaf-attacking variety the æcidial form of *Coleosporium senecionis*, a fungus which attacks the groundsel, but the corresponding alternate plant of the *P. orientale* has not yet been discovered and here there is some scope for the investigator. As regards the

alternate form of the var. *corticola*, Hartig says.— 'It is to be regretted that so far the plants have not been determined on which the teleutospores are produced.' Until we discover the teleuto form, preventive measures must be confined to felling pines that are attacked." Dr. Barclay thought that the form on *Pinus longifolia* and *Pinus excelsa* were distinct, and named them, respectively, *Æcidium complanatum*, Barcl. and *Æ. brevius*, Barcl. (see Jour. As. Soc. Beng. lxx. ii. 101-102). He thought at one time, that the latter might possibly be the æcidial form of *Chrysomyxa himalayensis*, a bright orange-coloured fungus very common on the petioles of the leaves of Rhododendron trees in the hill forests, but afterwards changed his mind and considered that the alternate host of the latter would more probably be *Picea Morinda* and the fungus *Æcidium piceæ* (see Scientific Memoir of Medical Officers of the Army of India, Part VI, 1891, p. 71.)

An interesting example of alternate generations in fungi is given by Dr. Barclay in the same Scientific Memoir, Part V 1890, p. 71, where he shows that the *Gymnosporangium Cunninghamianum* which grows on *Cypressus torulosa*, Don, has its æcidial form on the wild pear *Pyrus Pashia*. The cypress fungus is that one which may be seen in abundance about Bodyar in Jaunsar, having, in wet weather, the form of gelatinous yellow masses. Nisbet in the 'Indian Forester,' XXI, 132, speaks of these as a *Nostoc* or *alga*, but this is not mentioned by Barclay.

Another example, perhaps the best known example, is that of the,

'RUSTS' OF WHEAT,

and other cereal crops and grasses. A very full account of these rusts was published in 1897 by Dr. Prain of the Royal Botanic Gardens, Calcutta, in 'Agricultural Ledger' No. 16 in which he explains how, among others, the 'Black rust' (*Puccinia graminis*) which attacks wheat, oats, barley and rye, as well as other grasses, has its æcidial stage on species of barberry (*Berberis*); the 'Brown rust' (*P. dispersa*) which attacks wheat and rye and other grasses has its æcidial stage in various species of the 'Borage' family; and the 'Crown rust' (*P. coronata*) which attacks chiefly oats and other grasses has its æcidial stage on various Buckthorns (*Rhamnus Berchemia*, etc). Dr. Prain explains how it is not yet known exactly whether the common rusts of India have their æcidial stages on other plants, and if so, what plants these are, but we do know that æcidia of a fungus which has at Kew been identified as *Puccinia graminis* has been found on *Berberis aristata*, that *Puccinia coronata* has been identified as attacking *Rhamnus purpureus* and *virgatus* and that a fungus described by Mr. Barclay as *Uredo elreticæ* has been found in the Himalaya attacking the Boraginous tree *Elretia serrata*, and may be possibly identical with *Puccinia dispersa*; so that there is every reason to think that, at any rate in the neighbourhood of the north-west Himalaya the principal rusts of the cereal crops are traceable to the leaf-fungi of Himalayan forest trees and shrubs.

The pages of the 'Indian Forester' contain several articles of interest on the subject of Indian parasitic fungi, and more especially can we draw attention to Dr. M. C. Cooke's admirable papers in Vol. II, p. 350, and Vol. III, p. 14. Dr. Cooke was also good enough to name for me some specimens collected by myself and others, and these are mentioned in Vol. IV, page 90 and page 197.

The chief workers in the field of the Indian fungoid diseases of plants have been Dr. D. D. Cunningham, F. R. S., who has lately retired from service in broken health after many years of hard work in Calcutta; and Dr. A. Barclay who died in 1891 at Simla of typhoid fever at the early age of 39, to the great regret of his many friends and correspondents, and to the great loss of Indian scientific work. A notice about him and his work will be found in the "Indian Forester," Vol. XVII, page 303.

It may be well here to mention,

A FEW OF THE SPECIES,

which attack forest trees, which were described by Dr. Barclay, chiefly in the Journal of the Bengal Asiatic Society.

1 on *Berberis aristata* the rust *Puccinia graminis* Pers.

2 on *Hypericum cernuum* the yellow *Melampsora Sanctis Johannis*, Barcl.

3 on *Rhamnus dahuricus* the rust *Puccinia coronata*, Corda.

4 on *Vitis himalayana* *Uredo cronartiiformis*, Barcl.

5 on *Acacia eburnea* *Æcidium esculentum* Barclay.

The attacked twigs are eaten in the Poona District, as reported by Mr. R. C. Wroughton—see Pro. Bomb. Nat. Hist. Sec., Vol. 2.

6 on *Rosa moschophylla* *Puccinia Rosa*, Barcl.

7 on do *moschata* *Phragmium subcorticium*, Schrad.

8 on *Rubus lasiocarpus* *Phragmium Rabi*, Pers.

9 on do *biflorus* do *quinquelocularis*, Barcl.

10 on *Rubus paniculatus* do *incomplete*, Barcl.

11 on *Pyrus variolosus* *Gymnosporangium clavariiforme*, Jacq.

the alternate form of this probably comes on Juniper.

12 on *Pyrus Pashia* *Gymnosporangium Cunninghamianum*, Barcl.

alternate form on cypress, see above.

13 on *Cotoneaster bacillaris* *Gymnosporangium Cunninghamianum*.

14 on *Astilbe rivularis* *Xenodochus Clarkianus*, Barcl.

very common—spores bright yellow on the leaves,

15 on *Deutzia corymbosa* *Uredo Deutziae*, Barcl.

16 on *Rhododendron arboreum* *Chrysomyxa himalayensis*, Rhod.

17 on do *lepidotum* *Uredo* sp.

18 on do *campanulatum* *Æcidium* sp.

It is supposed that these latter may all be connected in some way, but the question still requires solution. But it seems more probable that the first has its alternate stage on *Picea Morinda*.

19 on *Jasminum humile* *Æcidium Jasmini*, Barcl.

20 on do *grandiflorum* *Uromyces Cunninghamianus*, Barcl.

21 on *Ichnocarpus frutescens* *Uredo ichnocarpi*, Barcl.

22 on *Ehretia serrata* *Uredo ehretiae*, Barcl.

On this see also "Indian Forester" XVIII. 21 and above.

23 on *Colebrookia oppositifolia* *Uredo Colebrookiae*, Barcl.

24 on *Ficus Palmata* *Æcidium Mori*, Barcl.

25 on *Morus serrata* *Cœoma Mori*, Barcl.

26 on *Populus ciliata* *Melampsora ciliata*, Barcl.

This is a light yellow fungus found on the leaves, the white one which makes the leaves look as if powdered with lime being *Ucinula salicis*

27 on *Populus alba* *Melampsora occidoides*, Barcl.

28 on *Pinus longifolia* *Æcidium complanatum*, Barcl.

29 on *Pinus excelsa* *Æcidium brevius*, Barcl.

Both these species are now united as *Æcidium orientale* as already described.

30 on *Picea Morinda* *Æcidium Thompsoni*, Barcl.

31 on do *Æcidium picce*, Barcl.

on these, see previous remarks.

32 on *Cedrus Deodara* *Æcidium Cedri*, Barcl.

This forms small yellow spots, and the leaves turn yellow, bend down and fall off, but the damage done is not great.

Since Dr. Barclay's work, little or no original work has been done in India on the fungi which attack forest trees, but many specimens have been collected and sent to Kew for naming and the first instalment of these was published in the Kew Bulletin for June 1898. The chief of these which are parasitic on forest trees are:—(1) *Gambitcola cornuta*, Masee, which occurs as black tufts on the leaves of *Berberis*

nepalensis and is very common about Chakrata, and (2) *Melampsora cpilea* Thüni, which is found as yellow masses on the under surface of leaves of *Salix elegans*. Others have also been named and will doubtless appear described in future numbers of the Bulletin; among them may be mentioned: *Exobasidium cinnamomi* Masee, the remarkable growth on the branchlets of *Cinnamomum Tamala* referred to in Mr. Nisbet's paper ("Indian Forester," Vol. XXI. p. 133) as *Exoascus* and producing a large bushy kind of witches' broom, seriously deforming the branches of the trees. It was found near Thadyar in the Tons valley, (2) *Stereum lobatum*, Kunze, a large hard fungus found on oaks (*Quercus dilatata*) in Jaunpur; (3) *Rosellinia spadicea*, Cesati, a black fungus found on the lower part of the old culms of *Arundinaria spathiflora*; and (4) *Trichosporium aterrimum*, Masee, a curious black species which apparently does considerable damage to mulberry trees in Changa Manga. It was discovered by Mr. F. Gladow.

Besides the parasitic species, there are many interesting.

FUNGI ATTACKING DEAD WOOD.

One of the most noticeable of these is the scarlet *Polystictus sanguineus*, Fries, so common in the sál-forests; the prettily-shaded *Polystictus versicolor*, Fries, is also abundant in sál forests on dead bark; *Hymenochaete Mongeotii*, Cooke, is a dard red fungus, occurring in large patches on the outer bark of *Betula alnoides* in the Himalaya *Lentinus omphalotomorphus*, Mont and *Daedalea Schomburgkii*, Berk are white fungi conspicuous on sál logs. *Hydnium Gladovii*, Masee, is a beautiful sponge-like fungus of similar situations.

It has only been possible to mention a few of the many kinds which have been discovered of recent years. Specimens of most of them are deposited in the Museum and Herbarium at Dehra Dun, but there is much more yet to be done, and the chief object of this paper is to urge Forest Officers to collect specimens and send them for identification through the Director of the Forest School, where duplicates should always be kept, allowing the originals to be retained at Kew. I feel sure that the Director of Kew will be very glad to assist in obtaining names, and that Mr. G. Masee will be delighted to continue to publish such new species as he may find among the collections sent. The information obtained cannot fail to have an important bearing on forest management especially on that of the forests of conifers of the N.-W. Himalaya, and by degrees materials can thus be collected towards a Handbook such as it is obviously desirable that we should possess. Leaf fungi can be collected and dried like ordinary Herbarium specimens, larger species can be merely dried loose and packed in paper. It is of the utmost importance to give full information and notes, and above all, to give the name of the plant upon which the fungus is found.

—Indian Forester

J. S. GAMBLE.

TEA CULTURE AND MANUFACTURE.—Mr. Kelway Bamber has been giving good advice and some useful practical hints to his neighbours in Dikoya and Bogawantalawa, which, as embodied in two Sub-Committee's Reports, will be found given on page 550. What is stated about all planters simultaneously dealing with grey blight, burning and burying prunings, plucking off diseased leaves from the next flush, &c., reads rather like "a counsel of perfection," and yet there can be no question that the nearer it is approached in practice, the better it will be for that particular district. As to manuring, manufacture and shade trees, Mr. Bamber is very much to the point; but in recommending a leguminous catch crop to dig in, we fear he is going beyond what is practicable in Ceylon, save in a few special cases,

A VISIT TO PERADENIYA GARDENS, CEYLON.

(By a Newcomer.)

At the entrance to the Gardens the drive on the left is bounded by a wall of rich, green foliage studded with large mauve flowers. This is the Burmese creeper, *Thunbergia laurifolia*, which hangs from the tall tree tops in massive sheets, a sight which strikes the newcomer from temperate climes where creepers are not nearly so luxuriant.

Driving round to the right, the visitor comes to the great "banyan tree," which from age and size is a worthy landmark in this garden of about 150 acres. Near by is another tree, *Brownia grandiceps*, of smaller dimension, with very handsome large red flowers, each flower-head being composed of a great many flowers and when fully open is as large as a plate.

Behind this, there is in course of construction a Merophyte House, in which a new system of glazing designed by the Curator is to be tried. Here will be accommodated the numerous cacti which are always fascinating on account of their bizarre appearance, and which resent the moist tropical climate of Ceylon. I was shown here some flowering plants which have retained through their evolution a close resemblance to ferns in the leaves so much so that even botanists may at first readily believe them to be ferns.

In the pond in front of the banyan tree, some odd examples of the adaptability of plants are seen. Thriving equally with plants of a true aquatic nature, are plants which in their native habitat are only found in dry rocky places, such as species of the pine-apple family. Here also is the *Cyperus papyrus*, of which the ancient Egyptians made their papyrus parchment by slitting the stem which is of a pithy texture, into thin slices. These they laid overlapping each other, smeared with the sticky clay of the Nile, and then pressed with great weights for a long time till they offered an even surface on which to write. Close by is a very interesting looking tree (*Pandanus larum*) with a smooth even circular stem for about ten feet. At that height it divides into three diverging branches, each again dividing exactly into three before the nine crowns of leaves are reached. At the base, to complete the extraordinary appearance of this tree, the aerial roots seem to tumble out of the stem about four feet from the ground, quite thick, smooth and perfectly cylindrical. This is the "bread-fruit tree" of the Nicobar Island.

In another part of the Garden it was interesting to find numerous experimental plots of economic plants, which, however, are necessarily small in extent. It seems a pity that there should not be some larger area devoted to such a purpose close to the Gardens and under the supervision of the Director.

Incidentally as regards the complaint made by a recent correspondent in the *Observer*, about the labels, I can vouch for the system of labelling the plants here now being very satisfactory, and considering its difficulties in a tropical climate, reflects credit on those responsible for it.

The Curator has lately devised labels of a material and caste different to those hitherto in use, and, being now employed for over a year, there can be no question as to their utility, both as regards legibility and lasting qualities.

In walking over these extensive grounds, with entrancing (?) views of towering peaks in the neighbourhood, majestic avenues of palms, gigantic bamboos gracefully arching over the "Great Sandy River" (Mahaweliganga), which nearly surrounds the Garden, and trees and flowers galore to admire—one can understand why this is so often considered "the finest garden in the world." The views from both the memorials erected to Drs. Gardner and Thwaites are particularly charming, and especially so as they can be admired whilst one sits in the cool and shade of these welcome retreats. The thought naturally occurs "Where is the Trimen Monument?" Alas! there is none. But a more lasting monument than a structure of wood, stone and mortar is left by Dr. Trimen himself in his works, which, I suppose, are too advanced and scientific to require a public acknowledgment similar to that which has been afforded to the less important labours of his predecessors.

The palm avenues and giant-bamboos always strike the stranger as perhaps the chief feature of the Gardens. Possibly the handsomest of the former is the talipot avenue planted in 1881 by Dr. Trimen. A new avenue of cabbage palm (*Oreodoxa regia*) has been planted lately, which in time will have a magnificent effect—Nature's Corinthian pillars—as one is pleased to think of them—which are built of a grey stone, but not with a plumb line swelling here or there as they will and ending at the top in a frieze(?) of green leaves and supporting the vaulting of the sky.

I have no doubt numerous other trees *et hoc genus omne* are worth mentioning; but time and space forbid. One of special interest, and especially at this moment, is the wonderful cannon-ball tree, which at present bears a number of large dark-brown globular fruits extremely suggestive of their popular name. As my guide suggested, the use of these might well be considered in such emergencies as are sometimes experienced in warfare. Let the Contingent, when they get to Pretoria, remember this as a useful solution of that last nut which the authorities have to crack, viz. the fate (or head) of Kruger.

Lastly let me mention four enormous Rain Trees (*Pithecolobium saman*) of South America, which were pointed out to me as the parents of all the trees of that species in the island. They are grand old progenitors with their mighty limbs and an appearance which bespeaks age and venerableness.

In conclusion let me say how well the Gardens are maintained and gradually improving as far as the votes for them allow; and how well they repay the visitor, especially if he go early or late, when the temperature and his temper are cool.

LARGE TREES.

The largest tree in the world is to be seen at Mascali, near the foot of Mount Etna, and it is called "the Chestnut-tree of a Hundred Horses." Its name rose from the report that Queen Jane of Aragon, with her principal nobility, took refuge from a violent storm under its branches. The trunk is 204 feet in circumference. The largest tree in the United States, it is said, stands near Bear Creek, on the north fork of the Tule River, in California. It measures 140 feet in circumference. The giant redwood-tree in Nevada is 119 feet in circumference.—*Ladies' Home Journal*.

CEYLON TEA MARKET REVIEW FOR 1889.

Messrs. Stenning, Inskipp and Co., in their annual report, says :—

THE COURSE OF THE MARKET.—The market opened with prices about on a par with those ruling at the close of the year, but as the month advanced quotations began to stiffen, common grades realising 6½d to 6½d; during February and March these grades went dearer, very little selling under 7d per lb. A further improvement took place during April, but a giving way was noticeable towards the end of the month. In May and June the demand was strong, but the quality generally being indifferent, common sorts market rather easier prices. During July the market was disorganised in consequence of the draft dispute, and very little tea was offered. In August sales were heavy owing to accumulations, and a lower range of prices ruled, common Pekoe Souchong selling at 5½d; fine invoices, however, realised full value. During September the demand improved, and the quantity brought forward being moderate, prices began to harden. Very little common leaf was to be had under 6½d. From October to the end of the year prices were steady, except for medium Broken Pekoes, which showed some irregularity. All good liquoring invoices brought full value. The year closed with a brisk demand.

QUALITY on the whole has been fairly up to average; some of the high grown teas have had distinctive character and realised satisfactory prices, and we are glad to note that the quantity of undesirable tea has not been so large as in former years. Teas with flavour always command attention, but when this cannot be obtained, a deep coloured liquor should be aimed at, as pale liquoring teas without flavour meet with but little inquiry.

SMALL BREAKS.—The limit remains the same as before, viz, anything under 18 chests, 24 half-chests and 40 boxes. The large number of small breaks offering in auction every week is not only a source of trouble to all branches of the trade, but it is hardly possible for the buyers to give them proper attention; business would be greatly facilitated if larger lots especially of the lower grades, could be sent forward.

FOREIGN TRADE.—It is satisfactory to note that the export from this country continues to increase.

OTHER MARKETS :—

The New Regulations regarding the weighing of tea, which were to have come into force on October 2nd last, but are still in abeyance, are as follows :—

1. If the package weighs the even pound, it is to be entered as such.
2. If it weighs the even half-pound or over, it is to be entered as the next pound above.
3. If it weighs below the half-pound, it is to be entered as the pound below.

Loss in Weight.—As this occasionally gives rise to much dissatisfaction we offer the following suggestions : That the gross weight of the package should be a few ounces, say four or five, above an even number of pounds, and that the empty package, complete with lead, nails, bands, &c., be to a like extent below an even number of pounds. In weighing here the gross weight is reduced to the even number of pounds, whilst the tare is increased to an even number of pounds,

With regard to garden bulked teas, it is imperatively necessary to put an equal quantity into each package of the break, and this quantity should be four or five ounces over the desired weight of contents, viz., if the packages are invoiced to contain 100lb tea each, not less than 100lb 4oz should be weighed in; test packages, weighing here a fraction under 100lb, are reckoned as 99lb only, or a loss of 1lb on each chest of the break.

Careful observance of the foregoing precautions will prevent loss and disappointment.

DRAFT of 1lb per package on all packages grossing 29lb and upwards is allowed to the buyer.

WEIGHT OF PACKAGES.—When a gross weight of 129lb is exceed, there is an additional charge of 5d per package up to 159lb. The following scale of charges fully explains this and deserves attention :—

Dock and Warehouse management rates, subject to an uniform discount of 10 percent., on packages grossing as under are :—

160 to 199 lb. 2s 9d; 130 to 159 lb. 2s 3d; 90 to 129 lb. 1s 10d; 80 to 89 lb. 1s 8d; 60 to 79 lb. 1s 5d; 45 to 59 lb. 1s 2d; 35 to 44 lb. 1s; 17 to 34 lb. 7d.

MARKS ON CHEST.—Nothing is wanted or is of any service here beyond (1st) garden mark; (2) description of tea; (3) garden numbers. Gross tare, and net are not of the least use, and should be discontinued.

METAL AND VENESTA PACKAGES.—There is practically no objection to these.

PACKING SMALL BROKENS AND DUSTS.—Special care should be taken to pack broken descriptions, which are so liable to lose in weight, in strongly made wooden packages. Dust should be placed in half chests, either of metal or of strong iron-hooped packages. Canvas coverings should in no case be used, as they disguise injury done to the packages by rough handling, and any tea retained in the canvas becomes of no value.

[Particulars are also given of the imports, deliveries, and stocks of the past six years; home consumption of India, Ceylon, and China teas for the past fifteen years; the number of packages from the various districts sold on garden account since 1893, and the average prices; Calcutta and London markets from May to December.]—*Home and Colonial Mail*. Jan. 12.

A NEW GERM-DESTROYER.—A new germicide has been discovered. Ozone when passed into water is found to kill the micro-organisms. This discovery has been made in Lille, where the water is notoriously bad, by two French gentlemen. They are taking steps to purify the water-supply of that town. Ozone is another form of oxygen which is common in the air after an electrical discharge of lightning and it is manufactured by a current of electricity being passed through air. It has been already found that heat alone up to the boiling point has not been an efficient germ-destroyer, so that this discovery will be welcomed by the medical profession. The boon to the traveller in France, who has no taste occasionally for wines or who may be a teetotaler, will be great. This discovery besides is one step nearer to that landmark of civilisation to which Pasteur called attention. "The first step is civilisation man made when he drove the wild animals from his cities, the next will be when he has banished all germs."—*Cor.*

TEA IN RUSSIA.

A large Moscow firm erected a large factory on its plantations last year, and the authorities on the estate belonging to the Imperial Domains at Chakva have followed this example, and have this year set up a tea-making establishment of considerable dimensions. The yield of the tea crop has been good and, comparatively speaking, fairly abundant. The flavour and quality of the tea does not, however, compare favourably with Chinese, Indian and Ceylon qualities, and the prices at which the small quantities obtained are being sold do not suggest that, for the present at any rate, any alarm should be felt by the tea-growers of the East in respect to the competition which Russian grown tea is likely to afford in the markets of the Empire.—*British Consul in Caucasia.*

SUGAR CROPS OF THE WORLD.

Though for easily comprehended reasons a statement in figures of the cane sugar crop of 1899/1900 at the present moment cannot be an exact one, still for the sake of clearness we give below a compilation of the momentary, but still uncertain export estimates of the new crop for the period between September 1st, and August 31st, in the principal cane districts.

U. States	370,000	275,000	358,150
Peru	130,000	125,000	105,463
Egypt	90,000	90,822	80,178
Sandwich I.	250,000	240,000	229,414

Total.. 2,700,000 2,851,134 2,560,677

"In the same way, though they cannot be taken as final estimates either, we give the following figures of the European beet sugar production, comparing them with the preceding campaigns as follows:—

	1899-00.	1898-99.	1897-98.	1896-97.
Germany	1,800,000	1,721,718	1,852,857	1,836,536
Austria	1,070,000	1,051,290	831,667	934,007
France	915,000	850,132	821,235	752,081
Russia	870,000	790,000	738,715	728,667
Belgium	250,000	235,000	265,397	288,009
Holland	175,000	149,763	125,658	174,206
Other countries	220,000	170,000	196,245	202,990

Total 5,300,000 4,947,903 4,831,774 4,916,586

"Thus the campaign of 1899/00 is now giving prospects of a surplus of about 352,000 tons, against the predecessor; but we remark again that exact figures for 1899/1900 cannot yet be given."—*Mr. F. O. Licht of Magdeburg.*

THE JAMAICA-ENGLAND FRUIT TRADE.

Sir Augustus Hemming, Governor of the Island of Jamaica, has made his annual report to the Colonial Office, and from it we gather the not pleasant news that there is still a deficit of general revenue amounting to over £153,000. Referring to this fact a correspondent writes:

The fruit trade with England does not so far appear to have made much progress, notwithstanding the subsidy to a fast steamboat service, of which we heard last year. It is very questionable whether such a policy will be advantageous to growers, as the distance is much greater and the freights so much higher than to the United States. The price which the American will give for his tropical fruits would never suit the English consumer. Consequently we are cut out by our American cousins in this particular trade. Fruit coming from the Mediterranean, Spain, the Western Isles, and the Canaries also enters into competition with West Indian produce, against which the latter will certainly not be able to compete under existing prices and freights. From a knowledge of the island it seems incomprehensible to me how this subsidy could ever have been granted, as the people of the island do not believe in any fruit trade with the home country being a success, and the people at Pudding-lane and Covent Garden will advise anyone inquiring not to embark in such an enterprise.

"Perhaps," the correspondent adds, "the Colonial Secretary thinks he knows better, but time will tell."—*Westminster Gazette*, Jan. 8.

PLANTING NOTES:

RUBBER CULTIVATION IN SOUTHERN INDIA is the subject of a long article in the *Madras Mail*, which we reproduce on page 553. It does not contain much that is new to us in Ceylon, but it is well to note how far our neighbours have got on, or are prepared to go, with a new product.

PADDY IN BURMA.—The estimated area under paddy cultivation in the fourteen principal rice-growing Districts of Burma is reported to be 6,055,937 acres, being an increase of 44,264 acres over the area reported last month. It is now estimated that there will be available for export 2,020,881 tons of cargo rice, equivalent to 34,252,220 cwt. of cleaned rice.—*Madras Mail.*

CACAO CULTURE.—We do not know that the planter who writes on this subject (see page 543) carries us much further in information than did Mr. Carruther's final Report, a copy of which (through the *Tropical Agriculturist* or otherwise) is no doubt handy for reference with each cacao planter in the country. Still, there are certain items of experience narrated which are worth noticing and which may lead to further interesting correspondence.

COAL IN SIKKIM.—Mr W P Mason of Darjeeling has been fortunate enough to discover coal in Sikkim in apparently large quantities and of good quality. The Political Officer of Sikkim, Mr. J Claud White, has had 20 mannds extracted and sent away to be analysed. Should the coal be of good quality, in an easily accessible spot, and in workable quantities it will prove of the greatest benefit to the station of Darjeeling and to the neighbouring tea planters. Firewood is already dear in Darjeeling, and as the forests are getting out down more and more every year, the advent of coal to take the place of wood will be most advantageous.—*Englishman.*

Correspondence.

To the Editor.

THE COCOA MARKET.

(Special report.)

London, E.C., Dec. 29th, 1899.

DEAR SIR,—This being Christmas week, and the end of the year and no business having been transacted down Mincing Lane, the usual Tea and other Circulars have not been issued. The next Cocoa sale will take place on Tuesday, 9th January, when it is hoped and expected that the Government will be buyers, if sufficient cocoa suitable for their requirements is offered.

Although nothing has been done with cocoa in London, the market is very strong, and prices are looked upon as being higher all round. The Liverpool market, which is almost entirely confined to Africans, is very firm, 33 bags having been sold this week at 63s. The present stock of cocoa in Liverpool on the 23rd December was 4,255 bags of all growths against 1,766 bags in 1898. On the same date the stock of Ceylon cocoa in London was 5,708 bags, and of all growths 83,641 bags, or 11,713 bags less than the same time last year when it was 95,354 bags.—The continental markets are very firm.—Yours very truly,

HAROLD HAMEL SMITH,

figures) 82,000 bags against 98,000 in 1898. The stock at Havre is 100,593 bags, against 72,101 bags in 1898, but in October the Havre stock was 140,000 bags, so it has considerably diminished in the last two months.

My correspondent in Trinidad writes me as follows:—"Last mail I calculated that the cocoa crop next year would be 25 per cent short, I see now the members of the Legislative Council have refused to sanction next year's estimate on the grounds that the cocoa crop will be 30 per cent. short, as estimated by experts. The drought has been something awful, the peasants will have a hard time of it next year, for their ground provisions (vegetables) started in September, got no rain and suffered terribly."—Yours truly,

HAROLD HAMEL SMITH.

THE LONDON COCOA MARKET.

SIR,—According to Mr. Ed. Kynaston's West Indian Circular, the following are the cocoa statistics of London for the past four years:—

	1899	1898	1897	1896
	bags	bags	bags	bags
Imports	202,000	236,000	198,000	204,000
Home consumption	143,000	169,000	146,000	133,000
Stock	82,000	98,000	93,000	140,000

"The apparent falling-off in Home Consumption in London is misleading, and is attributable to the increasing imports of Bahias, and Africans which pass direct to our large provincial manufacturers—chiefly through Liverpool." The deliveries of Liverpool were 90,067 bags in 1899, against 31,446 bags in 1898 and 16,380 bags in 1897: this would make the combined total deliveries, for Home Consumption, of London and Liverpool to be 233,000 bags in 1899, against 201,000 bags in 1898, and 163,000 bags in 1897 which confirms what Mr. Kynaston says:

The sale last Tuesday went off with good competition especially for fine Ceylon which was 5s to 7s dearer, some Warriapola mark selling at 95s 6d, against a previous record of 87s 6d last month—and present prices show Ceylons to be worth 63s for mixed native, good red 75s, fine red 88s to 95s 6d. The sales include 125 bags Yattewatte at 85s 6d, 28 bags Asgeria 82s, 10 bags Allagala A1 76s, 16 bags Bandarapola at 79s 6d, 13 bags New Peradeniya 1 at 83s, 80 bags North Matale at 90s, 90 bags Warriapola at 88s and 89s and 45 bags of the same mark at 95s 6d cwt.

Generally speaking all cocoa was up 2s 6d to 3s. Trinidads selling up to 82s 6d, Grenadas to 72s 6d, Dominicas to 70s 6d. For the time of year the sale was a very small one, only 3,200 bags being offered against 11,849 bags on 10th January last year. Since the sale the firmness and high rates have been maintained, anything approaching good red in Trinidad fetching 1879 and 1880. With Ceylons all the fine red has been sold, but prices for lower grades, although not in such active demand as the finer qualities, are very firm.

About 25 tons cocoa shells were offered and sold at slightly easier rates. Cocoa butter of which 65 tons was offered and sold, also went about 1d a lb. easier, selling at 1s 5d to 1s 6½d per lb., or on an average of 1s 5 9-16d against 1s 6½d in December. The average price of this article at the Dutch sales, which took place on the same day (9th) was 1s 5½d.

The stock of cocoa of all growths is nearly 20,000 bags less than in 1899, being 80,256 bags, against 100,270 bags in 1899. The stock of Ceylon and Java on 6th January was 6,770 bags.

THE WEST INDIES AND COCOA.

London, Jan. 5.

DEAR SIR,—It will be interesting to watch the results of the appointment of Mr. Sydney Olivier, C.M.G., as Colonial Secretary of Jamaica, for as the author of the essay on "The moral aspect of the basis of Socialism" published by the Fabian Society in 1890, he may perhaps instil some new ideas into the monotony of Colonial official ways. The essay is divided into three parts, (a) the evolution of morality, (b) property and morals, (c) the Re-integration of Society; and is provisionally described as an attempt to justify socialist ideals by the appeal to canons of moral judgment accepted generally, and supported by the results of positive ethical science. Mr. Olivier, who is a B.A. of Oxford, is best known as having been the Secretary to the West Indian Commission for 1896.

This has virtually been a holiday week for Cocoa, though several lots have changed hands privately, and the demand is very strong. It is not yet definitely known whether the Government will be in the market next week. So far as I can find out about 600 bags of Ceylon will be offered, and it is expected, will bring good prices, as the trade are bidding 60s for common stuff for which they would not give 58s for last sale. The stock of Ceylon on 30th December was 6,924 bags of which about 8 to 900 bags are available for offering. Today's quotation for dull to good red is 69s to 80s, fine bold has sold to 87s, but there is none offering now. Cadbury's are offering 65 tons of their cocoa butter for sale next Tuesday (9th)

Although 495 500 quintals of cocoa was received at Guayaquil during 1899, against 420,000 qts. in 1898, and the receipts of African at Lisbon were 223,000 bags against 166,000 bags last year, the stock of all growths in London is some 16,000 bags less than at the end of 1898, being (in round

Per sample post I send you samples of San Pedro D'Abadie 119 bags Trinidad cocoa imported May 1898. L. R. C. 94 bags imported March 1898. [These can be seen at our office.—ED. T.A.]

The L R C mark sold after the sale at 79/ and the San Pedro are held for 80/. These cocoas have thus been here nearly two years, and I send them to show how well good strong cocoa will keep, when well cured and prepared. Last year it seems was a very trying one with the three months bout of tropical heat that we had.

I also send an article on "cocoa" I am publishing this week in the "Confectioner's Union," the trade Journal of chocolate makers and confectioners.

HAROLD HAMEL SMITH.
London, E. C. Jan. 12th.

ON CACAO—AND THE DISEASE.

Jan. 25

SIR,—As there has been so much written lately in the columns of the daily papers, on subjects that are scarcely of any value to planters, such as "Do Tealsettle on Trees," &c., I think it strange that more important subjects, such as the *cacao disease*, was left severely alone. During the time Mr. Carruthers was with us, we heard pretty often, but lately there has been absolute silence. It is because we are all so busy fighting the disease that we have no time to argue, or what? I for one am working hard to eradicate the disease which has affected my charge, and would be glad to hear what my fellow-planters have to say on the subject. It would do us all and the country at large a vast amount of good, to thus ventilate the subject through the medium of the press, who I have no doubt would help us to the last.

Some cacao estate superintendents are shaving off the diseased parts and cutting into the wood, till the black threads are taken out, and then left bare; others apply coal tar, margosa oil, lime, carbolic mixtures, &c., both on the diseased part, and on the shaved part. And again some places (which I think is the wisest plan) are cutting all trees in the least affected, right out, level with the ground, and burning them immediately. The disease seems to be very infectious, for I find it nearly always bad near pits where the cacao husk has been buried, although they have been well dusted with lime before being covered with earth.

Trees should be examined, round the stem first, for if the disease has affected the bark *right round*, there is no use, *I say*, of letting that tree remain. Whereas if you were to shave *all the diseased part* off seeing that the tree looks healthy (like some are doing), in the hope that it will recover, I am *quite* certain their hopes will never be realised. I say this from some experience, in marking the trees so treated, for I nearly always found that they were quite dead within four to six weeks from the time they were last seen to. The above is only a means of further spreading the disease. Some planters are trying the latter course and I am sure it is only penny-wise but pound-foolish; in trying to save a few trees they are only giving it time to spread much worse. There is no doubt about it, that many of our best tea estates suffering very severely from the

disease, although we hear so little about it I know of one place where 250 acres of cacao have been quite wiped out. And from our experience we now know that it affects only the red variety; and on very rare occasions does it affect the Forastero. You can see trees side by side, yet the red is diseased badly, and the Forastero looking quite healthy.

A few years ago, some of our *best* cacao men went in for only the red variety, and would not hear of having the Forastero, the argument being that the red-fetched better prices. They never, for one moment, thought of the hardness of the growth and other prospects at the time. I fancy they are pretty sick now that they ever planted it.

For obvious reasons, it would not do for me to sign my name, but I enclose my card. I would be glad of correspondence from men similarly placed, as it would be of the utmost value to have such an important subject, at the present moment, discussed. —Yours, etc., CACAO PLANTER.

THE PROSPECTS OF TEA PLANTERS.—Says the *Investors' Guardian*, Jan. 6: When the sun rose on January 1st, 1899, he found the Indian tea trade in an unhappy condition, 1893 had closed with little or no business being done in shares, and prices were sympathetically low. In the early part of 1899, however, it was widely believed that the crop would prove short of the demand, and, in consequence, the prices of common teas rose sharply, with a corresponding effect upon the value of shares. But these favourable reports had a somewhat unsubstantial foundation; the results were certainly not very much behind those of 1897-8, even in Cachar and Sylhet concerns, whose very poor results were barely compensated for by the strictest economy and cessation of all attempts at development. A few companies were as successful in 1898-9 as in 1897-8, but for the majority the former was the worse year, and, as a result, share-values drooped from the middle of the year, with few transactions. In the late autumn when the market in tea was fairly brisk, and when the output in Cachar and Sylhet recovered considerably, the market revived somewhat. Such being the condition of affairs, it is not surprising that no new companies were floated during the year. There have, however, been a few additions to the capital of old companies. In the home trade the year has been a notable one on account of the attempts which were made to abolish the pound draft and to reform the system of weighing. Harmony has now been restored, and no harm will come to the ventilation of these vexed questions. The teas of India and Ceylon continue to open up for themselves markets all over the world. It is slow work, necessarily, but even the continent of Europe is now showing unmistakable signs of yielding to the fascination of "the cup that cheers," and especially is this the case in Russia. In fact, only the other day, a meeting was held in Colombo, at the instance of Russian tea buyers, to consider the development of the Colombo market, where Russian firms found it difficult to obtain as much tea as they required. There is no need for planters to despair; far from it. Tea shares do not lend themselves to speculation just now, it is true, but the industry is a sound one, and for investment as opposed to speculation, is worthy of consideration.

TO ALL PARTS OF ASIA, AFRICA, AMERICA AND OCEANIA.

Seeds & Plants of Commercial Products.

Castilloa Elastica Cervantes.—Orders being booked for the coming crop of seeds available in March and April, selected seed from very old trees. R. N. Lyne, Esq., Director of Agriculture, Zanzibar, writes under date 24th August, 1899:—"Please send me 200 seeds of Castilloa Elastica for further trial; the seeds of Castilloa you sent me last August germinated very well." Price and particulars in our Circular No. 32; special quotations for large orders according to quantity; immediate booking necessary to avoid disappointment.

Hybridised Maragogipe Coffee.—A large-beaned superior variety of Coffee in demand; orders booked for the coming crop of seeds, February and March delivery. Price according to quantity on application.

Hevea Brasiliensis (Para Rubber).—Orders being booked for the coming crop available in August and September, 1900. This is the only crop of seeds in the year. All orders should reach us before the end of July to avoid disappointment, as we have to make arrangements in time; guaranteed to arrive in good order at destination. We have already booked a large number of orders. A Sumatra Planter writes, dated 9th March, 1899:—"I consent to the price of £——per thousand. I herewith order 50,000 upon condition that you guarantee at least 33 % seeds germinating." Plants can be forwarded all the year round in Wardian cases. Price and particulars as per our Circular No. 30. A Borneo planter writes dated, Sandakan, 17th August, 1899:—"The last lot of Para seeds turned out very well."

Ficus Elastica (Assam and Java Rubber).—Seeds supplied by the pound with instructions; price according to quantity. This tree grows equally well in high and low land, in forest and grass land, its cultivation being extended largely by the Indian Government. For price of seeds with particulars as per our Circular No. 33.

Manihot Glaziovii (Ceara or Maniocaba Rubber).—Fresh seeds available all the year round; price as per our Circular No. 31. It is superior to Mangabeira rubber and second to Para rubber.

Urceola Esculentia (Burma Rubber) and Landolphia Kirkii (Mozambique Rubber).—Seeds and plants, both are creepers.

Cinchona Seeds.—Different varieties.

Sterculia Acuminata.—(Kolanut). Superior quality, seeds and plants; price on application, packed to stand the weather for several months, a hardy tree, cultivation easy.

Erythrina Lithosperma.—Thornless variety, new crops of seeds ready in December, May and June. Price according to quantity on application.

Seeds and Plants of Cinnamon, Nutmeg, Clove, Sandlewood, Pepper, Cardamom, Vanilla, Arabian, Liberian and Maragogipe Coffee, Cacao, Tea, Coca, Fibre, Medicinal and Fruit Trees, Shade and Timber Trees, Eucalyptus various varieties, also Palms, Bulbs, Orchids, &c.

Our enlarged Descriptive Price List of Tropical Seeds and Plants of Commercial Products for Foreign Countries for 1899-1900 are now being forwarded to applicants in different parts of the world. Also Descriptive Price Lists of Seeds and Plants of Fruit Trees, Bulbs, Tubers and Yams, and Orchids.

"**SOUTH AFRICA.**"—The great authority on South African affairs of 25th March, 1899, says:—"An interesting Catalogue reaches us from the East. It is issued by William Brothers, Tropical Seed Merchants, of Henaratgoda, Ceylon, and schedules all the useful and beautiful plants which will thrive in tropical and semi-tropical regions. We fancy Messrs. Williams should do good business, for now that the great Powers have grabbed all the waste places of the earth, they must turn to and prove that they were worth the grabbing. We recommend the great Powers and Concessionaries under them to go to William Brothers."

A leading Planter writes from *New Hebrides* under date 17th January, 1899:—"I shall like a few more of your Catalogues to distribute through these Islands, as I feel sure many would place themselves in communication with you, did they know where to write for Seeds and Plants."

Our New Descriptive Price Lists of Seeds of Shade Trees for Coffee, Cacao, Tea, Cardamoms, &c., Timber Trees, Trees for Avenues, Hedges Wind and Shelter Belts, Ornamental Trees, Shrubs and Climbing Plants; and Seeds and Plants of Palms, Calamus, Pandanus, Cycads, Tree and other Ferns, Crotons and Dracinas, now being prepared and will be ready shortly.

Agents in London:—MESSRS. P. W. WOOLLEY & Co., 33, Basinghall Street.

Agent in Colombo, Ceylon:—E. B. CREAMY, Esq.

TEA CULTIVATION: MANURING, &c.

DIKOYA PLANTERS' ASSOCIATION AND MR.
KELWAY BAMBER.

REPORT OF THE BOGAWANTALAWA SUB-COMMITTEE APPOINTED TO MEET MR. KELWAY BAMBER.

MR. BAMBER has been up to Campion twice; on the second occasion, 22nd July, 1899, he was met by the Sub-Committee. Those present were Messrs. A. C. Bonner, Fred. Hadden, W. P. Barber, and H. B. Roberts. In the morning Mr. Bamber went down early to the Factory and took one or two notes of Temperature, Moisture in the air, etc. At 9 a.m. Mr. Bamber went out to the field being manured with the mixture advised by him. During the walk he was able to give some useful hints on blights, manuring, etc., and amongst other things that quick lime dusted over the bushes after pruning, not only kills all moss and lichen, but is likewise beneficial to the tea in many ways, as nearly all Ceylon soils are deficient in lime, but this must be applied while the bushes are moist from either rain or dew. Fresh wood ashes used in the same way are also very good for the above purpose.

MANURING.—Mr. Bamber pointed out that he thought manure such as the mixture now being applied on Campion, was better forked in round the trees, than put into semi-circular holes, except on steep land where holes might be necessary.

FORCING MANURES.—With a view to getting a largely increased yield, beyond what the soil is capable of doing, he thinks somewhat dangerous.

BLIGHTS.—These Mr. Bamber considers are much on the increase, and in some districts are getting serious, especially grey blight, and that where this is the case, it is advisable to burn the prunings green if possible, and also to sweep up and burn all leaves on the ground. Also when the tea comes into leaf again, as soon as any blight appears, the diseased leaves should be pulled off and burnt, and that this should be done not by one estate but by all. Unless prunings are universally burnt and done thoroughly, burning is useless.

BURYING PRUNINGS.—Prunings if buried should be limed at the same time and then covered with soil, and this although not destroying the blight *in toto*, would certainly destroy a large proportion. Grey blight is easily identified by the black specks on the diseased part. Mr. Bamber looks upon grey blight as the most serious we have and considers it should be taken in hand at once by all estates.

GREVILLEAS he thinks beneficial rather than otherwise to tea. Mr. Bamber believes that some leguminous crop might be found which would be beneficial, if grown between the rows of trees to be afterwards buried green.

MANUFACTURE.—In the afternoon Mr. Bamber made analyses of the leaf in different stages of manufacture and found that the pungency and strength lost in the process of manufacturing was less than on most estates. This shows that longer fermentation at a low temperature can be done without losing these qualities, and therefore with advantage to the teas.—(Sgd.) A. C. Bonner, Fred. Hadden, A. L. Hine-Haycock, Hugh B. Roberts, William P. Barber.

REPORT OF THE DIKOYA SUB-COMMITTEE APPOINTED TO CONFER WITH MR. KELWAY BAMBER.

MR. BAMBER has several times visited Darrawella Estate. On the last occasion, 3rd August, 1899, he was met by the Sub-Committee, those present being Messrs. H. B. Roberts, Keith Rollo, F. G. A. Lane, W. R. Tatham, R. H. Eliot, J. Anderson, and W. P. Barber.

MANURING.—The Sub-Committee learn from Mr. Bamber that the main object should be to apply such manures as will keep the bushes in health and maintain the yield, and he would deprecate forcing manures being used so as to ensure an increase of yield only. Manuring judiciously done after analyses of soils, would lead to the liberating of plant food

at present in the soil which now lies insoluble. Mr. Bamber recommends manuring being done immediately, before or after pruning, and being forked in wherever practicable.

MANUFACTURE.—The analyses of teas in this and higher districts point to the fact that the best and most valuable qualities in the tea, are maintained by keeping a temperature as much below 75 as possible in manufacture up to the time of firing. Mr. Bamber suggests more care should be taken to prevent the made tea absorbing moisture when lying in the Factory, as this would assist in maintaining the keeping qualities of the tea.

SHADE TREES.—In reply to enquiries as to shade trees, Mr. Bamber recommends Grevilleas, Albizzias, and Dadaps planted at distances which would not make the shade too dense, and stated that the beneficial effects of these trees were:—

- (1) To encourage the tea roots to feed lower.
- (2) To bring up plant food to the surface.
- (3) To save wash.
- (4) To equalise the temperature of the soil.
- (5) To tend to help the rain water to filter through the soil and draw air to the lower depths.

Also he recommends the growth of a leguminous plant such as "*Crotalaria Striata*," and cutting down and digging it in at the time of flowering. This plant grows wild in Paddy fields in Badulla and elsewhere at 2,000 to 3,000 feet elevation.

TEA BLIGHTS.—The Sub-Committee desires to urge most strongly on all members to burn or bury prunings with lime so as to minimise the adverse influences of these pests, which they believe tend to largely reduce yields, and they understand from Mr. Bamber that when burying prunings they should be covered with 7 to 9 inches of soil and lime or basic slag sprinkled over the prunings before covering, the quantity being 4 to 5 cwt. per acre. When burning prunings the ashes should be sprinkled over the pruned trees.

(Sgd) Hugh B. Roberts W. R. Tatham
K. Rollo R. H. Eliot
F. G. A. Lane J. Anderson
William P. Barber.

COCHIN MARKET REPORT.

Cochin, January 27.

C. N. OIL.—With an improved demand in the market mainly for prompt deliveries, prices made a slight advance, and contracts were placed at R87 per candy.

COIR YARN.—Further contracts are reported at late prices. Regular shipments are going forward to Europe both by direct boats and via Bombay mainly against orders on c. i. f. terms.

ROPE YARN.—Ditto.

COPRAH.—Rassi R52—53 per candy.—*Cochin Argus*.

RUBBER ESTATES OF PARA, LIMITED.—The estates, consist of 284 square miles.—*India-Rubber and Gutta-Fercha Trades Journal*, Jan. 8.

RUBBER.—A recent issue of the *Hongkong Telegraph* has this note: "The Goa papers announce that Captain Moraes has discovered a plant in the wilds of the Portuguese territory of Goa, a tree which yields India-rubber in considerable quantities. The tree is described as *Randallia*, and it is stated that the Portuguese authorities are about to encourage its cultivation on a large scale."—*India Rubber World*, Jan. 1.

SISAL GRASS IN MEXICO.

Henequen, or sisal grass, has been in use among the inhabitants of Yucatan from the earliest times. The United States Consul at Progreso says that he has found it imbedded in the form of cord in the stucco figures that ornamented the façades of the mysterious ruined cities of Yucatan. There are two wild varieties of henequen called by the natives "cahum" and "chelem." The fibre of these wild plants is used to some extent by the natives in the making of cordage for domestic use, and some claim that hammocks made from the fibre of the cahum are the best. It is, however, the cultivated plant that furnishes commerce with the fibre known as sisal grass, Sisal being the old port from which the fibre was first exported. Like the wild plant, the cultivated one is divided into two varieties—the "zacci," or white hemp, and the "yaxci," or green hemp. The zacci is considered the finest and best, but the yaxci is a good fibre. It has been generally supposed that sisal grass, as an article of commerce, has been known only within the last fifty years, but this is a mistake. Between the years 1750-1780 quite a furor was created in commercial countries of the Old World by the discovery that the fibre of a plant found in Yucatan was good for ship's cordage. Spain sent over a Royal Commission to report upon the discovery, and in a few years many of Spain's commercial and war vessels were using cordage made from henequen. For some reason, probably because of the primitive method of preparing it, the use of silk fibre gradually declined, until at the commencement of this century the former trade had been forgotten. In 1847, Yucatan, until then a cattle-producing, cotton-growing, and logwood-exporting country, was in the throes of an Indian war. The Maya Indians had risen in rebellion, and had succeeded in driving the white race out of the most fertile portions of the peninsula, forcing them to rely for means of subsistence upon the products of a sterile rocky belt; too poor to sustain cattle in any numbers.

HENEQUEN.

was the only useful plant that would grow on such a soil. The first plantation was established in 1848, and the 50 acres planted were cleared by the use of the tonka, the primitive cleaner used by the native Maya. There was a good demand for the new fibre in ship rigging, and it gradually came into general use, until sisal grass was a well-known article of commerce. The tonka was a piece of hard wood, shaped something like a handsaw, having the end curved in. The leaf of the henequen was drawn through the sharp curve, and the fibre was stripped of the thick, pulpy covering. The leaf was subjected to this operation two or three times, until the fibre was left clean and free. This tedious process was not long tolerated. A machine was found to increase the output, but the demand again outgrew the supply. The machine known as the "Raspador," or the "Soles," from its inventor, came into use, and has held its own almost up to the present day. It consists of a large-toothed wheel, that scrapes the pulp and leaves the fibre. Its simplicity made it peculiarly fitted for use by the native servants. Plantations came to be known as plantations of one, two, or a dozen wheels. The constantly increasing trade necessitated still more rapid means of fibre cleaning. Many new machines were produced, each of which was said by its inventor to be far better than any of the others. The exportation of sisal grass during the ten years ended December 31st, 1898, amounted to 583,000,000 tons. It has been said that the best fibre-producing plant grows on the poorest and most rocky soil, but this does not accord with experiments recently made. One method of planting and cultivating is as follows:—The field is first carefully prepared and burnt. The burning produces a certain amount of ashes, and many planters set out seed corn at the same time they plant the henequen. The one does not interfere with the other in the least, and the corn crop helps to pay the cost of the henequen. The henequen plant is propagated not by seeds, but by scions, or suckers. The plant produces seeds,

and in a natural state propagates itself by both seeds, and scions, but the planter uses only suckers from 18 to 20 inches high. By this method he can produce a field of henequen ready to cut within five years, whereas by seed planting he would have to wait from eight to nine years. Once planted and properly tended—that is, cleared of weeds twice a year, and not under or overcut—a field will last twenty years, and instances are not wanting of fields that have lasted longer. A leaf is ready to cut when it extends at right angles to the trunk or the plant. A healthy vigorous plant in the maturity of its growth should yield from 18 to 24 leaves. One thousand leaves should produce from 50 lb. to 60 lb. of good, clean fibre. This amount is fair average. When the plants in an old field send up a flower-stalk, it is nature's signal that the crop is finished. The old plants must then be clipped of all useful leaves and cut down, to allow the young scions (which should have been already planted between the old plants) ventilation for growth. Bad cleaning, allowing rot to be produced by the acids nascent in the plant pulp, and dampness, produce red and mould-stained fibre, of less than one-half the value of the good, clean, white fibre. This is rarely exported, but is sold at home for domestic use. There are in Yucatan nearly 1,200 henequen-producing plantations of various sizes. The largest plantation, or, rather, the plantation producing the largest output, is on the line of the broad gauge railway between Merida and Progreso. It is called Ticilché, and produces about 1,000 bales, or 375,000 lb. of cleaned fibre per month.—*Journal of the Society of Arts.*

KEROSENE FOR SAN JOSE SCALE.

Some months ago a correspondent reported that, as a last hope, he had painted with kerosene direct from the tin some young trees badly infested with San José scale. He had evidently got the idea of this treatment from an article which appeared in the *Agricultural Gazette* for May, 1898. When the paragraph about the success of his experiment appeared in the *Gazette* there was much comment, but according to Bulletin 138, New Jersey Agricultural Experiment Station, Professor J. E. Smith (whose article was printed in the *Gazette*, May 1898) has during the past two years treated nearly 4,000 trees of all the ordinary orchard fruits, except cherries, with crude petroleum, either undiluted or mixed with from 60 to 75 per cent of water. The trees operated upon varied from stock just out of the nursery row to old trees in full bearing.

"Not a single case of injury to any tree treated in winter has been observed; on the contrary, in a number of cases the oil seems to have acted as a stimulant, and the sprayed trees have shown greater vigour and better foliage than those untreated. In no case has there been any injury to fruit buds, but on this point the observations are incomplete, no early winter treatments having been made in bearing orchards. Applications made after January 15th (midwinter) have in no way lessened the crop of apples and pears the year following, and applications made in March have not injured the fruit buds in peach and plum (July and September here). Crude petroleum is not suited for a summer application, either pure or diluted, because of its choking effect on foliage and its persistence. This, however, increases its value for winter work as compared with kerosene; the latter acts at once or not at all and evaporates very soon after it has been applied—in fact, to avoid injury, it must be applied in such a way as to favour rapid evaporation. Crude oil does not evaporate readily; it is penetrating, and, if applied with a brush half-way round a branch, will often soak round the branch completely; it remains as an oily or greasy surface coating for many weeks, and no scales can set on this coating within a month of the application and live; it does not ordinarily penetrate through even the surface layer of bark; under the most unfavourable circumstances, if the outer layer is penetrated, the inner layer remains healthy and

there is no progressive injury; it does not seem to interfere with bark functions, and young trees painted with the oil increased in size quite as rapidly and freely as those untreated. Crude petroleum will kill the pernicious scale in winter whenever it comes into sufficient contact with the insect. It is a contact insecticide, and will not injure what it does not touch; but, liberally applied, it will soak through masses of scale no matter how densely set, as nothing else will. A minor advantage is the fact that it gives a greasy brown colour to the bark, making it easy to see exactly how thorough the application has been."

It is scarcely likely that the indiscriminate use of either crude or refined petroleum will ever be recommended, but in a young orchard a little might be applied with a brush the moment a scale is discovered.—From the *Agricultural Gazette* of New South Wales for January.

VOGAN TEA COMPANY.

DIRECTORS' REPORT.

The Directors have pleasure in submitting their report and accounts for the year ended 31st Dec., 1899, which they trust will be considered satisfactory by the shareholders.

The total crop secured for the year was as follows:—

Vogan	..	263,241 lb.	as against	227,848 lb.	in 1898
Iddagodde	..	123,368 lb.	do	125,939 lb.	do
Bought Leaf	..	2,528 lb.	do	30,929 lb.	do
Stamford Hill and Barkindale	..	95,286 lb.	do	100,712 lb.	do

484,423 lb. 485,478 lb.

On actual estate account Vogan and Iddagodde have given 8,241 lb. and 3,368 lb. respectively over estimate, whilst Stamford Hill and Barkindale shew a shortfall of 4,714 lb.

The yields per acre have been as follows:—

Vogan (old tea) 611 lb. (including 78 acres young tea). 561 lb. Iddagodde old tea .617 lb.

Total yield old and young tea, 580 lb. per acre, Barkindale and Stamford Hill (old tea) 433 lb. per acre.

The following usual table shewing the cost and average of the Company's tea in Colombo (including bought leaf) for the past two years, will be found interesting:—

Estate.	Or with- out		Or with- out		Net Average 1898.	Net Average 1899.
	1898.	Manure	1899.	Manure		
	Cts.	Cts.	Cts.	Cts.	Cts.	Cts.
Vogan and Iddagodde	20-22	19-21	20-15	18-83	34-00	36-81
Barkindale and Stamford Hill	25-58	22-60	22-17	20-90	43-90	45-30

It must be borne in mind that the profit on manufacturing outside leaf has been deducted from the expenditure when calculating the cost of Barkindale and Stamford Hill estate teas.

Now that the young clearings on Vogan and Iddagodde estate are beginning to come into bearing, increased withering accommodation is required, and it has been decided to put up Messrs. Davidson & Co.'s patent air fans with air tight chambers at a cost of R3,000 to 4,000 instead of erecting another withering shed at an enhanced cost.

The amount spent on plumbago prospecting, namely R4,785-01, has been passed to suspense account pending the result obtained from the leasing of the Company's Mining rights to a Syndicate, in connection with which mining operations are expected to be commenced shortly, on the arrival of Machinery from England.

After paying interest on debentures, viz.: R6,195, the amount at credit of profit and loss is R76,088-41, which is equal to 10-56 per cent on the capital of

the Company as against 8-40 per cent last year. Of this amount R10,500 has been applied in redeeming and cancelling 21 debentures, a further 5,000 will be required to redeem 10 more debentures contracted for, and R200 has been absorbed in paying part of the Vogan Assistant Superintendent's passage to England. The Directors recommend that the available balance, namely R60,388-41, be apportioned as follows:—

By the payment of a dividend of 7 per cent for the year	..	R	c.
		50,400	00
By the payment of a bonus to the Vogan Superintendent	..	1,000	00
By placing to Depreciation Account	..	5,975	01
By placing to Debenture Redemption Fund	..	2,500	00
By carrying forward to the next account	..	513	40

R60,388 41

The average of the Company's properties is as follows:—

VOGAN AND IDDAGODDE.	A.	R.	P.
Tea in full bearing	..	590	3 23
Tea in partial bearing	..	78	2 30
Tea not in bearing	..	119	0 10
Stamford Hill and Barkindale	..	220	0 0

Total in Tea Acres .. 1,008 2 23

Vogan and Iddagodde Jungle, &c. .. 540 2 10

Total acreage ... 1,549 0 33

Owing to a considerable portion of the jungle having been felled for firewood it has been decided to plant up 25 acres of tea in the coming season, and to follow a similar course each year, when the result of the previous season's working warrant the outlay.

In terms of the articles of Association, Mr. W B Kingsbury retires from the Board of Directors, but, being eligible, offers himself for re-election.

The Auditor, Mr. J D Forbes, also offers his services for 1900.

INDIAN COAL.

At a time when anxiety is felt about the output of coal in the United Kingdom, through labour troubles and the enlistment of all classes of work-people for Military needs in the homeland and in South Africa, it is cheering to read of the advance which the coal trade is making in India. The Report of the Directors of the East Indian Railway for the half-year ended the 30th June last, makes us acquainted with the fact that coal contributed largely to the success of the concern, which yielded the comfortable return of 6½ per cent for the year. The amount of coal despatched from the collieries upcountry amounted to 95,000 tons, while there was exported from Calcutta by sea to Bombay, Karachi, Colombo and other ports, during the six months, more than in any previous corresponding period. For Bombay and Karachi alone as much as 200,000 tons were shipped. Here is, then, another instance of how the great Dependency of India is helpful to the Mother Country, while becoming its rival in trade in some respects.

LIBERIAN-ARABIAN HYBRID COFFEE.—The seeds received from Mr H B Winterbotham, of Mep-padi, Wynaad, have germinated successfully, and will be planted out in the Gardens in a suitable place when large enough.—*Agri Horticultural Society of Madras.*

INDIGO: A THREATENED INDUSTRY.

The kind of help which the Government might well be asked to give to indigo growers, must here be made. The real merits of the dye produced from the plant must first be set forth and made known to the public, and the following extracts from a little pamphlet bearing the name of Fox Brothers and Co. (Limited) will suffice to do all that is necessary in this connexion.

"The superiority of pure indigo over other dyes may be briefly summed up as follows:—

"1. Fastness of the dye.—Indigotin, the colouring principle of indigo, is insoluble in water, alcohol, ether, and dilute acids and alkalies, either hot or cold, hence its extreme fastness for all conditions of ordinary wear and tear. It is also quite fast to sunlight, and for an all-round dye there is nothing superior to it at present. There is no need to point out the advantage there is in a perfectly fast dye as compared with one which may be fast to light, but will not stand perspiration or washing, or *vice versa*.

"2. Strength and handle.—Cloth dyed pure indigo is stronger and tougher than the same cloth dyed in other ways, owing to the dye-bath being at a comparatively low temperature and the absence of any injurious chemicals or mordants. In almost all other dyes the cloth is first boiled in mordant and then in the dye, for some hours altogether; this always impoverishes the wool fibre and destroys much of its natural lustre and softness, whereas the indigo vat with its soft mellow liquor adds to the fulness and richness of the fabric. Indigo dyeing being a mechanical process rather than a chemical one actually feeds the cloth.

"Pure indigo tests.—There are so many ways of producing a blue very similar to pure indigo that it is of the first importance to make quite sure that what is called 'pure indigo' is pure indigo and nothing else. The following simple tests will give a fairly good indication whether the dye is a pure indigo or not. In carrying them out, the tests should always be compared with similar tests on a known pure dyed fabric of like quality:—

"Nitric acid test.—Put two or three drops of ordinary commercial nitric acid on the same spot of the fabric. A yellow spot with a green tinge quickly appears if the dye is pure indigo.

"Sulphuric acid and water.—Make a mixture (about half a pint) of sulphuric acid and water, and in it boil quickly for ten minutes a small piece of the cloth to be tested, say 1-2 in. square. The acid and water must be in the proportion of one part acid to nine parts water, and care must be taken to always gently pour the acid into the water and not the water into the acid. If the cloth which has been boiled is pure indigo, the solution will remain colourless.

"Soda and water.—Dissolve about 1 oz. of common washing soda in half a pint of water, and gently boil in it for 15 minutes a small piece of the cloth about 1-2 in. square. If the dye is pure indigo the liquid will remain colourless.

"In conclusion.—Our motive for placing this,

LITTLE SKETCH OF PURE INDIGO DYEING,

before the public is that from long experiences and countless experiments extending over many years we believe that there is nobody in the world equal to pure indigo, and our own experience is corroborated by evidence from all parts of the world. The one important point we wish to impress upon the public is that when ordering 'pure indigo' they must be sure that they get it as an immense amount of so called pure indigo is annually

placed on the market, and the term 'indigo' or, trade indigo is often applied to absolutely worthless dyes. To assist the public we have included the foregoing few simple tests, any two of which taken together, are sufficient proof as to the genuineness of the dye.

Seeing that there is no blue dye in the world equal to natural indigo, and that immense quantities of substitutes are used and sold under more or less the same name, it appears to be necessary, in the interests of (a) the Government of India, (b) the planters in that country, and (c) the public who wear clothing dyed with this material, to take measures to ensure that the real dye shall be used, or the fact that a substitute has been used made patent to everybody. The suggestion to be made then is that our Government with the concurrence of the Indian Government, should be asked to legislate, if the object in view cannot be attained short of this, stating in effect that henceforward there shall be stamped upon each piece of blue cloth words guaranteeing that the dyeing material used in its production is natural indigo—or indigo from the plant grown in India—or, if with a substitute therefore that this fact and the name of the substitute shall be so stated upon such cloths. Further, no indigo substitute should be permitted to be imported into or sold in, this country bearing the name "indigo" or other similar name. This seems to be a reasonable request to make of the Government, and clauses could no doubt be drawn to secure the prime object in view.

Some remarks have still to be made addressed to the indigo planters themselves. In the first place, as to the exchange question, they must fully recognize the existing position, for they may rest assured the Government of India will not change its policy to please them. The report of the Fowler Committee and the action taken by the Government since make that perfectly evident. They should endeavour to get the Government to carry into effect the suggestion last above made, which from all points of view seems to be not only reasonable but necessary, for the reasons already set forth.

It is known that the planters, under expert chemical advice, are experimenting to discover whether a greater quantity of dyeing material cannot be extracted from the plant, without detriment to the quality, than has heretofore, under the old system of manufacture, been possible; but up till now it is believed that no real success has attended these experiments. Whether they will be successful in the near future remains to be seen. The steps taken are certainly in the right direction.

The next point has reference to production. There are good grounds for believing that the depressed state of the industry at the present time fortunately much less marked than it was only a few months ago, owing chiefly to the fact that the current year's crop from India is to be an exceedingly short one, has been brought about more by what may be called "over-production" than anything else. In any case, over-production plus the discovery of "the new synthetic indigo," and the putting of it on the market for sale, which users of indigo have, of course, made the most of, in order to break down prices of the real article, have together brought about the depression.

Very probably,

OVER-PRODUCTION,

was due to a too large extension of cultivation, in combination, perhaps, with seasonable weather and consequent normal yield per acre. In growing indigo it must be kept in mind that a very large proportion of the season's outlay of money is incurred in preparing the lands for the reception of the seed, and that the preparation extend over months before a seed is put in the ground. Then the plant is perhaps the most troublesome to grow in India. Drought, too little rain, too much rain, rain at wrong times, all alike damage the crop, and little or nothing can be done by the planter in effecting savings in his expenditure. It is accordingly of very great importance to the planter to secure a full yield per acre, but not

otherwise. Therefore the planters themselves can well perform a part in preventing the ruin of a "threatened industry" by instructing their managers to see that only their very best lands are sown with indigo—that lands cropped for two seasons in succession are left fallow for a year—in short, that all land not capable of giving a yield per acre of 10 to 12 seers (20 to 24 lb.) under normal weather conditions is to be avoided. If this is done it is practically certain that a great step will have been taken in assuring the continuance of the industry with some profit to those engaged in it, for such indigo as is produced ought to be, on an average of years, moderate in cost, able to stand up against chemical competitors, and the market could not well be glutted by supplies.

Such careful selection of land as has been indicated will of necessity leave at the factories a larger area available for the cultivation of other crops. If we were to assume even that indigo growing were absolutely killed by chemical discoveries and were to cease to exist at some future date, then, obviously, those now engaged in that industry would be called upon to grow other crops on their land, and would be obliged to find out what crops would pay them best. In this connexion their attention may well be directed to articles which appeared in "The Times" of September 2, 8, 12, 19, 21 on the subject of growing sugar canes, and which are full of valuable information. Canes are already produced in nearly all parts of India, and in the aggregate the production must be very large.

A new kind of cane is mentioned as growing in some of the West India Islands, which yields 23 per cent of saccharose, and modern machinery is said to extract 90 per cent thereof. From such cane sugar should cost less than £5 per ton.

By way of concluding these remarks a final suggestion is made to Indian Indigo planters. Experiment at your factories on growing sugar canes, for the product from which there is an ample market at your own doors. Remember that the conditions of India in these days in respect to communications and otherwise are very much more favourable to the successful working of such an industry than in the days when sugar was largely exported from the country; also that modern sugar machinery is more efficacious in treating the canes; and if it can be clearly demonstrated that canes of the best kind can be grown successfully in Bebar, and that a formerly existing industry can be established and extended, taking the place of indigo in that quarter if the worst should befall it, then assuredly the necessary modern factory will not fail to be established to deal with the canes. —*Bombay Gazette*, Jan. 23.

TEA IN CEYLON.

AGRA OUVAH ESTATES COMPANY, LIMITED, DIRECTORS' REPORT FOR 1899.

ACREAGE, AGRA OUVAH.	
Tea in full bearing ..	302 acres.
Tea not in bearing ..	20 "
Grass and Jungle ..	9 "

Total Estate.. 331 acres.

FANKERTON.

Tea in full bearing ..	165 acres.
Timber clearing ..	10 "
Grass, Patana and Scrub ...	18 "

Total Estate.. 193 acres.

Grand total 524 acres.

The total tea crop amounted to 293,908 lb. (or 13,708 lb. in excess of the estimate) as against 271,241 lb. in 1898.

After deducting the cost of manufacturing 131,174 lb. tea for other estates, the cost of delivering the Company's tea in Colombo was 25.18 cents per lb., which included a sum of R2,581.29 expended in additions to machinery and the building of a new watercourse, to which reference was made in the Directors' last report. The average nett prize realized for the tea

was 48.90 cents per lb., against 53.82 cents per lb. in 1898. In common with other estates at the same elevation, prices in 1899 shewed a considerable fall, which was attributable to the larger demand and increased prices given for common teas. The gross income from manufacturing tea for other estates was R15,279 66.

As the amount at credit of the Depreciation Account amounted at 31st December, 1898, to over 68 per cent of the original cost of buildings and machinery, and as the cost of all alterations and additions is now charged to Working Account, the Directors have decided to pass only 2½ per cent. on original cost to the Depreciation Account for the past year.

After making this provision the amount at credit of Profit and Loss Account for the year's working is R71,536.14, equal to 19.08 per cent. on the Capital of the Company. To the above has to be added the balance brought forward from 1898 of R16,258.44, making the total balance at credit of Profit and Loss Account R87,794.58. An Interim Dividend of 7 per cent. was declared and paid on 16th August last absorbing R26,250, and the Director now recommend the payment of a final dividend of 13 per cent. making 20 per cent for the year, and that a sum of R10,000 be transferred to a Reserve Fund for the equalization of dividends and the balance R2,794.58 be carried forward to the current year's account.

The estimate for this year is 290,000 lb. Tea on an expenditure of R77,078.78, which includes an amount of R7,752 to be expended on manuring. It is also estimated that about 100,000 lb. will be manufactured for other estates, which will leave a fair profit to the Company.

During the year under review Mr. Jas. Polson was appointed by the remaining Directors to fill the vacancy caused by the retirement of Mr. J G Wardrop on his leaving the Island; the latter was re-appointed in the place of Mr. W H Figg, who resigned.

In terms of the Articles of Association Mr. J G Wardrop retires by rotation from the office of Director, but is eligible for re-election.

GLASGOW ESTATES CO., LTD.

ANNUAL REPORT.

Directors:—Messrs. G H Alston, G C Walker, J G Wardrop.

Estate Inspector:—Mr. G M Ballardie.

Estate Superintendent:—Mr. R W Kerr.

ACREAGE.

Tea in full bearing ..	550 acres.
Do. partial bearing ..	62 "
Do. not in bearing ..	38 "
Grass ...	2 "
Jungle, &c. ..	62 "

Total Estate ... 714 "

The Directors have now the pleasure to submit their Annual Report and the Accounts of the Company for the past year.

The crop secured amounted to 335,708 lb. Tea (or 20,708 lb. in excess of the estimate) which cost delivered in Colombo 23.50 cents per lb. The nett average price obtained was 47.29 cents per lb against 49.71 cents in 1898, the fall being attributable to the partial neglect of good teas owing to the strong demand at high prices for the commoner kinds.

After making ample allowance for depreciation of Buildings and Machinery, the amount at credit of Profit and Loss Account for the year's working is R68,789.86, equal to 21.17 per cent on the capital of the Company, to which must be added the balance of R1,482.16 brought forward from the previous year. There is thus an available balance of R70,272.02, which the Directors recommend should be dealt with as follows:—That a sum of R5,000 be transferred to Extension Fund, making this fund R65,000; that a sum of R5,000 be transferred to a Reserve Fund for the equalization of Dividends: that a final dividend of 13 per cent be paid for 1899, making with the interim dividend of 5 per cent paid on 16th August last, a total of 18 per cent for the

year, and that after the payment of R300 extra fees to the Directors, in terms of the Resolution passed on 18th February, 1893, the balance of R1,472.02 be carried forward to the current year's account.

The estimate for this year is 335,000 lb. Tea against an expenditure on working account of R33,545, which includes a sum of R6,883 to be expended on manuring. A sum of R3,516 is estimated on capital account for additions to Machinery and the upkeep of the 33 acres not yet in bearing.

During the year under review Messrs. Jas. Forbes and W H Figg resigned their seats on the Board, and Messrs G C Walker and G H Alston were appointed to fill the vacancies.

In terms of the Articles of Association Mr G H Alston retires from the office of Directors, but is eligible for re-election.

The appointment of an Auditor will rest with the Meeting.

A GOOD COCOA BEAN AND A JUDICIOUS BLEND.

BY HAROLD HAMEL SMITH.

[Cocoa Correspondent to the *Port of Spain Gazette*, Trinidad, W.I.; the *Ceylon Observer*, Colombo; and the *Tropical Agriculturist*, Ceylon.]

To properly be able to tell a good cocoa bean, it is necessary that one should have a slight knowledge of its place of origin, and the circumstances under which it has been produced and prepared. This is especially the case with Ceylon cocoa, from which after Caracas and Puerto Cabello cocoa the finest and most delicate flavoured chocolates are produced. Some even prefer the chocolate made only from the best Ceylon cocoa, and say that for delicacy of flavour this growth cannot be surpassed.

The reason of this is easy to understand when known, but can only be found out by reading up the history of the movements of cocoa from one country to another which will show that the finest Ceylons, with the cinnamon 'break' so much sought after by confectioners, originally came from the same kind, the 'Criollo' as the Caracas and Puerto Cabello growths, the improvement in the flavor, if there is any, being due to a higher class cultivation and more careful preparation than is carried on in Venezuela, whereas in Ceylon no expense or trouble is spared to produce the best results.

For all practical purposes a confectioner need only trouble about

TWO KINDS OF COCOA

known as 'Criollo' or indigenous, and 'Forastero,' or foreign. The light 'break' and delicate flavor of the Criollo cocoa is innate in the growth, being due to the cotyledons or kernels of the bean, when first taken out of the pod, being a milky white color shaded at the margin with faint pink, which when fermented and dried, turns a light brown or cinnamon color, whilst the flavor of the seed when chewed is of a pleasant, nutty, and only slightly bitter taste, with a distinct cocoa flavor, in marked contrast to the strong bitter taste of the Forastero bean, which seem to overpower any flavor of cocoa in the mouth. The original color of the Forastero seed is a deep purple, which the process of curing turns to a medium or very dark brown, according to the time expended on its curing.

During the last fifteen years cocoas from nearly 40 different countries or districts have been offered for sale in London. These I should classify under two heads as follows, placing them according to the strength or mildness of their flavor:—

STRONG FLAVOURED.

Africans, Surinams, Cayenne, Demarara, Bahias, St. Thome, Trinidads, St. Vincent, St. Lucia, Grenada, Tobago, Dominica, St. Domingo (Jeremie, Samana and Sanchez), Cuba and Para.

MILD FLAVOURED.

Ceylon, Java, Puerto Cabello, Caracas, Fine Summer Arriba (Guayaquil), Colombian and Cauca, Carupano, Guiria, Peruvian, Mauritius, Seychelles, Madagascar, Tunnaco, Esmeraldas, Madras, Neilgherri and Jamaica.

The first six growths, as a rule prove too strong—that is, the bitterness even when reduced to powder, is too marked to allow them to be made up alone as cocoa essence, therefore I do not recommend their use in confectionery where delicacy of flavour is the first consideration; but when it is only a matter of price that alters the case. Even then I would rather use Para, which not only is the fattest of all cocoas except Surinam, but is of such a mild flavor that it can be made up with any growth, and for this reason is, I believe, much liked on the continent, very little of it in comparison coming here.

Opinions differ so much as to which blend is most suitable to bring out the full flavour of the cocoa, that it is difficult to know which to recommend. The nicest chocolate as far as flavor is concerned that I ever tasted was made entirely of fine Ceylons, and it is in such chocolate that the advantage of the 'Criollo' cocoa is particularly noticeable, for without extracting any of the fat, which contains the essential oil, and so all the true flavour of the bean, you can make your chocolate simply by the addition of sugar, whereas with the generality of Forastero cocoa, no matter how carefully prepared, a slightly bitter taste is sure to be noticeable, if not the cocoa would be found to be of a superior variety of Forastero (called Verugoso amarillo) which approaches very near to 'Criollo' cocoa, the interior of the seeds being originally of a violet color does not become so dark in curing, it also contains a somewhat smaller proportion of essential oil, and is therefore not so strong to the taste as the other varieties of Forastero.

AN IDEAL BLEND,

according to some, is an equal mixture of fine Trinidads and fine Ceylons, by which you get the superior and stronger flavor of the one, toned down by the delicate taste of the other, and the color is pleasing to the eye, a point which I do not consider confectioners pay enough attention to, especially in cheap chocolates, but from remarks I hear dropped by purchasers, the public pay quite as much, if not more attention to the color, than they do to the flavor.

As far as flavor is concerned good blends can be obtained by mixing almost any of the strong flavoured growths of column I. with those mentioned in column II., preference being given price for price to those below the St. Thome in list I., for, as already stated, they are generally found to be milder to the taste. Cheaper qualities of chocolates can be made from the same growths as the best, but of cocoa, which, being less carefully prepared, sells at lower rates. As far as the matter of price goes, every maker of confectionery whether he grinds his beans or buys the chocolate *en bloc*, should watch the market reports in the trade journals or the daily papers, and note what changes have taken place, for prices fluctuate so tremendously that it is impossible to recommend any particular blend to be produced at a fixed price. Ceylons for instance, sold as high as 130s. per cwt. in 1893, but in 1895 the highest price was only 65s. 6d., which would put it within the reach of confectioners for 'bringing up' the color of all qualities of chocolates, which is not the case when fine Ceylon is about 80s. Fine Summer Arabia, the flavor of which is particularly mild and pleasant, even in the bean, also varies greatly in price, last year selling at 33s. to 35s. against only 56s. to 62s. in 1896.

To really find out which blends are the most suitable for one's trade, I would strongly recommend every confectioner to be constantly experimenting on his own account, no matter how excellent a recipe he may already have in his possession. Remember there are as good fish in the sea as out of it, and it would well repay the trouble if five or six pound samples of each growth and quality were ground up separately and portions blended together according to the color required, and the price at which the finished article is to be sold at. By so doing one can see exactly what are the results, and test which blend is most suitable to any particular trade; and even if some of the blends do not turn out satisfactorily, they

can always be used for 'foundations,' and so cost very little more than the trouble bestowed on them.

The characteristics of

A GOOD COCOA BEAN

varies in every growth. For instance, 'Calabacillo' cocoa, which forms the bulk of the Grenada crop is said to be unaffected by fermentation, so can never plump up like highly fermented Java. However, I am not wrong in saying good cocoa beans, no matter what the growth must be perfectly ripe and well fermented, which causes them to be more or less plump, and filled out; when broken they should be of a good even 'red' throughout; the bean should crack up easily, and the kernel and shell come apart without trouble. The ideal cocoa bean should have the shell a nice bright red, with a slight tendency to purple. Of late some of the Grenada Cocoa has wonderfully improved both in size and 'break,' so much so that if it is from the same 'Calahacillo' strain it has been improved beyond recognition by superior cultivation.

'Hardness of break' 'flintiness,' 'soapiusness,' 'grey color,' etc., seen in beans all betoken insufficiency of ripeness and curing; the nearer the bean is to the even-coloured 'red' peculiar to its growth, the better prepared, and the riper will it prove to be.

Of all cocoas Guayaquil gives the most trouble to distinguish one quality from another. This difference in the quality is due to the locality of the estate and the season of the year at which the cocoa is picked, and as localities run one into the other and seasons vary, so do the qualities of the produce, some Carraquez Guayaquil being very difficult to distinguish from some Arribas.

Beans of the purple or Forastero Cocoa, as Trinidads, Grenadas, Africans, etc., are naturally flatter in shape, and have a coarser shell than those of the Criollo kind, as Ceylon Java, etc. Columbian cocoa especially that grown in the Cauca district, runs very large in size, and is of an excellent quality and flavor, selling even higher than the finest Arribas of Guayaquil, which it somewhat resembles in shape, due no doubt to the two districts bordering one on the other.

The difference in the outside color and appearance of the various growths is due principally to the mode employed in the preparation. Some of the beans, as Ceylons, and some Jamaicas are regularly washed and all the mucilage removed, whilst in Guayaquil it is left on. With Trinidads and Grenadas it is more or less rubbed off by hand or other means, and with Venezuelan and other 'clayed' cocoas it is absorbed by the clay.—*Confectioner's Union*, Jan. 15.

INDIAN TEA ASSOCIATION.

The following is an abstract of proceedings of a meeting of the General Committee held on the 16th instant, present:—Messrs. H S Ashton (Chairman), H C Begg (Vice-Chairman), G G Anderson, W Brown, G A Ormiston, M R Quin, R R Toynbee and T Traill.

PARIS EXHIBITION.

Mr. Tye referred to the arrangements to be made in the Paris Exhibition to ensure prominence being given to the samples of Indian tea, photographs of tea estates, machinery, etc., and other exhibits sent from India. He stated that one or two octagonal kiosks would be constructed to display the exhibits to the greatest advantage. One of these kiosks would probably be placed in the centre of the Tea Court. The London Committee had also had a consultation with the architect of the Indian Pavilion, and they had sanctioned arrangements for the filling up, decoration, and completion of the Tea Courts, which it was understood were to be in readiness by the 1st March 1900. The first instalment of the grant sanctioned by the Government of India had been paid to the credit of the Indian Committee of the Royal Commission; and a further instalment was to be paid on the 1st March next.

NEW MACHINERY.

Considered letter No. 2703 of 13th January, from Mr. J H Apjohn, Vice-Chairman of the Calcutta Port Commissioners, in reference to the machine invented by him for bulking and re-packing tea. This machine, which had been viewed by the members of the General Committee in March last, had been working experimentally since that time in the Port Commissioners' Tea Warehouse. Mr. Apjohn stated in his letter that the difficulties of detail at first experienced had been overcome, and that as a bulker or blender the machine now gave mathematically accurate results. He had also made arrangements for the tea to be repacked in the chests by hydraulic packing. This had, after experiment, proved successful, enabling the tea to be re-packed in as many seconds as by any other process it would take minutes. He submitted a statement showing that up to the present over 5,000 chests had been bulked with satisfactory results. The bulker would be capable of dealing with 500 chests an hour and the tea would be immediately re-packed. Mr. Apjohn proposed to advise the Port Commissioners to charge four annas only per chest for bulking, grossing and taring. The rate would, therefore, be one quarter of that charged in London and in addition shippers would have the advantage of the certainty of their teas being shipped in good order. He was proposing to the Port Commissioners to erect one complete bulking and packing plant in the Tea Warehouse and another at the Kidderpore Docks; and he asked for an expression of opinion as to whether the bulking would be likely to meet a want of the trade.

The Committee discussed the letter and directed the Secretary to inform Mr. Apjohn in reply that in their opinion the proposals he made would if carried out, meet a want of the trade, more especially in the case of shippers who buy tea at Calcutta auctions, and despatch it to foreign markets.

TEA SEED CONTRACT FORM.

Considered file of correspondence, in reference to the Tea Seed Contract form, issued to members under cover of Circular No. 141-O. of 11th April 1899. After the publication of the contract certain differences of opinion were expressed by the Assam and Cachar Branches and members of the Association, as to the terms of clause 5. This clause provided that in the event of the seed when tested "proving to be 10 per cent or more under the guarantee" the buyer should have the option of cancelling the contract or of taking delivery on a scale of allowances appended to the contract. There appeared to be some conflict of opinion as to the percentage which should be allowed, and at their meeting held on the 5th September, the General Committee had decided to recommend to the Assam and Cachar Branches that a blank be left where the word "ten per cent" stand; thus leaving it open for the buyer and the seller in each transaction to come to a mutual arrangement on the point. This had accordingly been done, and a reply dated 13th September had been received from the Chairman of the Cachar Branch approving of the suggestion. The Committee had also received information through the Hon. Mr. Buckingham, that the Committee of the Assam Branch, after having submitted the point to their members, also supported the proposal.

In these circumstances the General Committee decided to reprint the contract form making the change in question; and to re-issue it with a covering letter to the members of the Association.—*Planter*, Jan. 27th.

THE RUBBER PLANTING INTEREST.

To the Editor of the *India Rubber World*: It may be a matter of some interest to your readers to know that an association has been formed in Chicago for the purpose of planting about 500,000 rubber trees on the isthmus of Tehuantepec, in the Ubero district. Incidentally, during the time required for the rubber trees to mature, it is expected that an income will be derived from cattle grazing and the growing of sugar cane. The new company is known as the Commonwealth Mexican Plantation Association. It has not been incorporated, and is operated purely on a commercial basis.

Mr. Riddle personally has had planted about 200,000 rubber trees on his private estate of La Pomona, on the isthmus of Tehuantepec.

R. P. PROBASCO.

Chicago, December 19, 1899.

THE RUBBER PROSPECT IN CUBA.

To the Editor of the *India Rubber World*: I have been much interested in an article in your journal on India-rubber in Cuba, and have sent a copy to my partner, in Manila, who will, I am sure, be equally interested in the possibility of growing rubber in the new American colonies. In a few months, in connection with some others, I hope to go into the business of planting rubber, and will thank you for some information. Would you advise planting Pará rubber or *Manihot Glaziovii* in Cuba? What is land suitable for rubber, worth in Cuba and Puerto Rico? Also what is labor worth in those islands; and what would be the probable cost of putting up necessary cheap buildings, etc.?

W. W. B.

San Francisco, December 15, 1899.

[There are as yet no data available regarding the subject above referred to, which can be quoted for the guidance of intending rubber planters, beyond the fact that most attempts made hitherto to introduce the Pará rubber tree beyond its natural habitat have been unsuccessful; besides the tree requires much longer to mature than the *Castilloa elastica*, of Central America, which thrives naturally under conditions of soil and climate more nearly allied to those of Cuba and the Philippines than of the Amazon valley.—THE EDITOR.]

NOTES ON PLANTING IN MEXICO.

The Missouri Coffee and Rubber Company., capitalised at \$150,000, was incorporated under the laws of Illinois, November 13, for the purpose of acquiring what is known as the "Crittenden tract," on the isthmus of Tehuantepec, containing nearly 1100 acres and said to embrace some of the best rubber and coffee land in Mexico. The transfer of the estate took place November 27, it being understood that payment for the property was made in full.—*India Rubber World*, Jan. 1.

A FRENCH SCIENTIST.

Amongst recent arrivals in Ceylon is M. Emile Deschamps, an eminent French scientist, who after an interval of nearly ten years is now travelling eastwards once more, partly in the interests of commerce and partly with a view to further scientific investigations; as Monsieur Deschamps said to us in a brief conversation with us the other day "Quand on a commencé, on ne laisse jamais la science." In 1892 M. Deschamps brought out a handsome volume, *Au Pays des Veddás*, published by the "Société d'Éditions

Scientifiques" at Paris and illustrated by 116 reproductions of photographs taken and sketches made by the author, as well as an original map showing the route taken by him in this isle. The writer went far afield and, beside making himself fully acquainted with all that most visitors see in the island, pursued special ethnological studies among the country Sinhalese, the Veddás and the Rodiyas. M. Deschamps' work bears marks of close and minute observation and no mean literary gifts. Our visitor spends a fortnight in Ceylon and then proceeds to Madras, before travelling further in India.

MANILA HEMP.—The price of Manila hemp has gone up 400 per cent. since the Spanish American War. What about the chances of growing this fibre in the Native States? There would be money in it.—*Singapore Free Press*.

PROFESSOR KOEBELE:

WHO INTRODUCED "LADY-BIRD" BEETLES TO
ERADICATE FUNGI FROM CALIFORNIAN
ORANGE TREES.

There arrived by the ss. "Friedrich der Grosse" last evening Mr. A. Koebele, a Professor of Entomology, who has lived in America, but has for the last five years been under the Government of Hawaii, studying the beneficial and injurious insects found in that country. Questioned by an interviewer the other day, Mr. Koebele stated his stay in Ceylon would be only a fortnight as he hopes to proceed to Java by the next steamer. He has no intention of studying insect life in this colony, but his visit is in another way of interest to all connected with our tea industry as he has brought from Hawaii about a dozen varieties of insects, which he hopes may counteract the evil influences of the green scale. These he is to hand over to Mr. Green. Mr. Koebele will, however, indulge in no prophesy as to the result which will attend this effort, which at present he regards in the light of an interesting experiment. Indeed at the time of speaking he could not tell whether the insects had survived the voyage and for all he knew might be now quite useless.

During his stay here Mr. Koebele hopes to visit Peradeniya Gardens to obtain some seeds or plants. Mr. Koebele gives a glowing account of the prospects of Hawaii, especially of the planting industry, which has been attended with much success by Europeans, Americans and Japanese. Coffee occupies the first place and is very fine, there being fortunately no insects to trouble the growers, while the prices obtained are good. The same remarks apply also to sugar, which is doing well. The Government of the Americans is good and the natives are rapidly becoming accustomed to western civilization.

Mr. Koebele has spent some time in Australia, collecting insects for fruit-growers in California. Asked how that country compared with Australia as regards fruit, he said the American fruit was of better quality, as the great difficulty in Australia was the lack of water.

This is not Mr. Koebele's first visit to our colony, as he had been here five years ago and he still retains pleasant recollections of what he saw and learnt on several of our tea estates.

THE TEA TRADE SECTION OF THE MINCING LANE WAR FUND.

[TO EDITOR OF THE "HOME AND COLONIAL MAIL."]

SIR, Some short time back you were kind enough to publish a list of some of the contributors to the Tea Trade Section of the Mincing Lane branch of the Mansion House Transvaal War Fund.

Shortly after the publication of that list the Mincing Lane branch of the fund was closed, but as certain companies appeared only to be awaiting the meeting of their boards before contributing, Mr. F. S. Long, Mr. John Lloyd and myself agreed to continue to receive donations, with the result as shown in the list sent herewith,

It does not now appear likely that any more subscriptions will come in from the appeal already made, and therefore we intend closing our list. There were a few companies which did not respond to our appeal, the reason given in nearly all cases being that the directors did not see their way to voting the company's funds to such a purpose. However, with the excellent example set by the forty-one limited liability tea producing companies who have already contributed, it is to be hoped that these remaining companies will respond doubly should any opportunity for so doing occur to them.

Again thanking you for the kind assistance you have given me in the past in making this matter public in quarters where it was most needed.—I am, Yours faithfully,
—H. & C. Mail, Jan. 19. W. T. WILSON.

PRODUCE AND PLANTING.

TEA AND THE REVENUE.—Tea is the only import commodity of great consequence that brings a substantial payment into the Imperial Exchequer, and for the past twelve months it was credited with £4,042,680, as contrasted with £3,923,568 and £3,856,663 in the years 1898 and 1897. The duty imposed on coffee earned £187,559, which was more than heretofore, when it averaged only £174,750; and, whilst that derived from cocoa was slightly on the wane at £189,322, the Customs impost on chicory was confined to £52,042, which was a smaller sum than that raised in either 1897 or 1898.

PRODIGIOUS.—It is interesting to note that the Mazawattee Tea Company, Limited, have paid to Her Majesty's Customs the sum of £85,862 8s. 8d., representing over 5,000,000 pounds of tea. Until some rival concern goes one better, if it can, this announcement serves as a free advertisement to the company named, as it is able to state that the sum mentioned represents the largest duty payment and clearance from bond in the history of the tea trade, &c.

MINCING LANE AND THE WAR FUND.—As will be seen from a letter from Mr. W. T. Wilson, (Messrs. Gow Wilson, and Stanton) which appears elsewhere, the Tea Trade Section of the Mincing Lane branch of the Mansion House War Fund has now been closed. In the list which we gave on December 1 last, 14 tea companies were included, the amount subscribed being £164 5s. The supplementary list which we now give on page ii. includes 27 companies, the amount subscribed being £310, thus showing a total of 41 companies and £474 5s. This response on the part of directors of tea companies is highly gratifying, but it may be hoped, as pointed out in Mr. Wilson's letter, that, should a continuance of the war necessitate a further appeal, the few companies who have not already contributed may see their way to respond doubly.

TEA AND PAPER.—At Newcastle Police Court, on Friday, judgment was given on a charge against the Bombay Tea Company, with which Messrs. Brooke, Bond and Co. have some connection, of having offended against the provisions of the Merchandise Marks Act by selling goods with a false trade description. The allegation was that although the packets of tea sold were of the weights represented when wrappers were included, the actual weight of tea was less. The chairman, Mr. W. R. Plummer, in giving judgment, said it was contended on the part of the prosecution that the mere handing over of the packets of tea to Langley, who had asked for two half pounds of tea, was a tacit admission by the seller that each packet contained a half-pound of tea, and that, as the packets in fact contained less, consequently there had been an infringement of the Act. The Court

were unable to adopt this contention, and dismissed the information. Mr. Clark applied for costs on behalf of the Bombay Tea Company. Langley, he said, was a purely nominal prosecutor. Mr. Ward on the other side, had practically admitted that the prosecution was by a rival firm. The Bench granted three guineas costs and agreed to state a case.—*H. & C. Mail*, Jan. 19.

SCIENCE AND SOIL CULTIVATION.

THE DIRECT ASSIMILATION OF CARBOHYDRATES BY PLANTS.

Up to within very recent times a firm line of demarcation in the vegetable kingdom has been drawn between the higher or green plants which contain chlorophyll, and the lower or non-chlorophyll-containing plants. By means of their chlorophyll apparatus, the higher plants absorb from the sun's rays energy which enables them to decompose water and the carbon dioxide of the atmosphere into their elements, from which a fairly simple chemical substance is first constructed; and then, by a progressive series of reactions, the highly elaborate and complex materials, such as starch, gums, oils, tannins and various sugars, which are easily identified as plant-constituents. The first product is usually held to be formic aldehyde, though it has not yet been identified in the plant itself as such. Many of the complex substances, however, have been artificially prepared from formic-aldehyde by the skill of the chemist in his laboratory, so that the indirect evidence is fairly conclusive, and the theory will probably be held good until actually disproved. The lower plants, however, being without chlorophyll, are obliged to make use of complex substances already elaborated. The fungi, for example, possess a destructive energy which enables them to break down for their own use, such substances as sugar, bread, wood, leather and other organic materials upon which they are commonly found growing. These are thoroughly established views. Thus in a recent *resumé* of the subject of plant assimilation entitled, "The origin and formation of organic matter in plants," which was republished in the *Journal of the Royal Agricultural Society* as late as June last, a careful and detailed account of this mode of carbon assimilation is set forth. Moreover, it is the only method which the writer considers it necessary to refer to, although he deals very fully with the latest work that has been done on the allied subject of the fixation and assimilation of atmospheric nitrogen by certain families of green plants.

Evidence is now gradually accumulating, however, that this is by no means the whole truth on the subject of carbon assimilation. Since the year 1886, when the work of Hellriegel and Willfarth and others demonstrated the extremely important part played by micro-organisms in the metabolism of leguminous plants, lines of investigation have been opened up that have shed much light on the formation of carbonaceous compounds. The final result towards which these experiments point is the possibility of green plants being able to assimilate, directly through their roots food materials that already contain complex carbon-compounds. It is only possible here to indicate the links in the chain of argument.

Winogradsky noticed that a certain lower plant, *Clostridium Pasteurianum*, was able to fix nitrogen in direct proportion to the amount of sugar applied to it in the nutrient media. This was

also found to be partly true of some common moulds, such as *Aspergillus niger* and *Penicillium Glaucum*. Mazé found that micro-organisms from a leguminous root-nodule, grown on nutritive material prepared from an infusion of haricot bean, are able to fix nitrogen when 2 per cent of sugar is added. Bouilhac has found that *Nostoc*, a green alga, in the presence of soil bacteria, fixes nitrogen in the absence of organic matter; it is true, but the yield is increased four-fold when a dilute solution of glucose is supplied, and under these conditions the organism can even grow in the dark, and form chlorophyll. Up to this point it would seem that the fixation of nitrogen is clearly connected with the presence of a carbohydrate, either specially added or present in the tissues of an associated plant, or else, to remove the cause a step further, with the presence of organisms capable of manufacturing suitable carbohydrates. Acting on the suggestion that the vigorous assimilation of nitrogen by the bacteria of leguminous root-nodules, may be due to the carbohydrates present in the legume itself, Golding has carried out pot-experiments on the effect of supplying glucose to bean, lucerne, and clover plants, and finds that a marked increase in growth is produced thereby. Further, Laurent has shown that seedling plants, such as maize, can grow, increase in weight, and form starch in the sterile solutions and in the absence of carbonic anhydride when glucose is supplied to their roots. Finally, Mazé again working with sterile water cultures, shows that vetches can be grown in the dark, at the expense only of glucose supplied to their roots. It is true that the green plants employed in these experiments belong to botanical orders that most clearly exhibit the phenomenon of nitrogen fixation through the agency of associated bacteria. Whether plants not distinguished by this property can be made to assimilate carbohydrates directly is the subject of further experiments at the present time. Should this prove possible, then a practical issue, quite apart from the extreme theoretical value of the result, may be foreseen. Sugar and other carbohydrates, though prohibited by their cost for manurial purposes on an agricultural scale, might be valuable agents for a special purpose, such as, for instance, the production of fruit, flowers and vegetables under glass and with a minimum of sunlight, at periods when they are usually obtained only with extreme difficulty.

There is also evidence in another direction that the chlorophyll theory does not explain all the facts of carbon assimilation and plant-energy. Thus, Green has published experiments from which he draws the conclusion that there exists in plants a power of absorbing and utilizing the radiant energy of light, sometimes to a considerable extent without the presence of a chlorophyll apparatus.—*Imperial Institute Journal*.

PLUMBAGO LEASES.—The new system of leasing Crown lands with plumbago seems to be working well so far as the natives are concerned. They are keen to compete for such land; and at public auction, the lease for ten years of land holding plumbago is often sold now-a-days as high as R1,000 per acre per annum! The purchaser has at once to deposit the first year's rent; but there is this proviso in his favour: that he may throw up the lease at any time, provided he has paid that particular year's rent.

CEYLON TEA IN AMERICA.

(Communicated.)

I am glad to see some American botanists have recently been on a visit to Ceylon, and have no doubt they will have seen much that was interesting and instructive, particularly in the matter of tea, for there can be no doubt they sadly stand in need of such information. Notwithstanding, the £57,000 or so Ceylon has spent in trying to teach our cousins it must be acknowledged our Yankee campaign has not been a success. The tunny advertisements, after the style of Mother Seigel or Warner, have not been taken seriously to heart. Indeed, I understand, they have done more harm than good, and I hope Ceylon with so many real claims upon it, will soon see the wisdom of discontinuing this costly and worse than useless fad and waste. If the intrinsic merits of the article are not sufficient to recommend it and push it, as they ultimately did in Australia and elsewhere, no amount of blatant advertising will do it. Of the need of more solid information on the subject, I have been forcibly reminded by perusing a paper in one of their scientific journals by a leading savant, in which paper he tells us that the world's yearly consumption of tea is 3,000,000,000,000 lb. which means say 2,000 lb. per head for every man, woman and child in the wide world! Whereas the editor of the *Tropical Agriculturist* has evidently been under the impression that the world's yield of tea was little more than 1,100 millions annually, and the consumption from a few ounces to 10 lb. per caput.

Again, I had no conception of the dangerous nature of the article till I read this:—"In a pound of tea there are 224 grains of poison, or enough to kill 45 rabbits." What puzzles me is the recollection that I used to feed my rabbits on tea leaves—theine, tannin, and all. The rabbits got fat on the leaves, my children got fat on the rabbits, and no one was a bit the worse! Altogether, this Yankee "information for the people" seems so extraordinary and incredible, that I cut out the article and send it to you as a curiosity, worthy of a place in your Museum, or say your "T.A." as a warning to others.

TEA AND COFFEE AND THEIR EFFECTS UPON THE BODY, BY W. H. RILEY, M.D.

Tea is one of the great articles of commerce, the estimated annual consumption being three billion pounds. It is a shrub native to China, but is now grown in India and other tropical countries. The tea-shrub, in a wild state, grows to a height of twenty to thirty feet, but is limited in cultivation to five or six feet, with numerous branches, and evergreen leaves, in the axils of which are to be seen the large, white, fragrant flowers. The leaves, though evergreen, are picked only at certain seasons. The first tender leaves of early spring are gathered for the finest young hyson. The later leaves give so-called inferior qualities of tea. After gathering, the leaves are first roasted in such a way as to produce variety in flavor and odor, and then treated to give different colors. For green tea, the leaves are roasted immediately after gathering, rolled with the hands, then re-roasted. For black tea, the leaves are first exposed to the atmosphere for a few hours, then roasted a few minutes, rolled in the hands, exposed to the air again for a few hours and finally slowly dried over charcoal fires

until the black color is well brought out. After this preparation, the tea is ready to ship.

The use of tea as a beverage was introduced into China from Corea, about the fourth century after Christ. From thence it extended to Japan about the ninth century, finding its way into Europe in the sixteenth century, where it met with great favor, and is to-day the favorite drink in England, Russia, and Holland.

We have already noticed that the chemical analysis reveals as a principal ingredient in both tea and coffee the narcotic alkaloid thein, or caffeine. By experiments upon animals with this narcotic, it is found to be a deadly poison. Taken in a concentrated form, death speedily ensues. One seventh of a grain is sufficient to kill a frog, and five grains will kill a rabbit. In a pound of tea there are 224 grains of this poison, or enough to kill forty-five rabbits. Seven or eight grains will cause most distressing symptoms in a strong man, and a slightly larger dose causes highly dangerous symptoms. Dr. Smith, a prominent English physician, in experimenting with the effects of coffee, took, with his assistant, an infusion of two ounces of coffee; they both fell to the floor unconscious, and remained in that condition for several hours. We quote the following incident as illustrative of the effect of tea:—

"A prominent official in the British army, now doing service in Africa, recently lost his horse in a manner that is both singular and instructive. A cook left a few pounds of tea in the sack which had contained it, which was filled with corn by a Kafir groom who knew nothing of the presence of the tea. Upon serving out the corn to a group of horses, of course the last one received the larger share of the tea, which was eaten with the corn. The result is thus described:—

"The animal plunged and kicked, and ran backward, at intervals galloping madly around, finally falling into a donga, where it lay dashing its head upon the rocks, and was despatched by an assegai thrust through the heart. The post-mortem appearances indicated extreme cerebral congestion."

The action of tea and coffee as ordinarily used is not as rapid and marked in its injurious effects as seen in the above instance, as the quantity used is not so great, and the system also becomes accustomed to the narcotic; but serious derangements of the digestive and nervous system result therefrom.

"The relief obtained from tea and coffee is sudden, before the stomach has time to digest them. This shows that what the users of these stimulants call strength is only received by exciting the nerves of the stomach which convey the irritation to the brain; and this in turn is aroused to impart increased action to the heart and short-lived energy to the entire system. This is but false strength, that we are the worse off for having. They do not give a particle of natural strength." Though there is greater ease in making exertion, a greater sense of exhaustion follows than when the drink is not taken. "Under the influence of these poisons the nervous system is excited, and in some cases, for the time being, the intellect seems to be invigorated and the imagination more vivid. Because the stimulants produce for the time being, such agreeable results, many conclude that they are actually beneficial, and so continue their use. But there is always a reaction. The nervous system, having been unduly excited, borrows power for present uses from its future resources of strength. All this temporary invigoration of the system is followed by depression." The head-ache removed by a cup of tea invariably returns, and the continued use of tea serves only to aggravate and increase the difficulty, of which it is frequently the source. Those to whom tea and coffee take the place of other food are generally found with hollow cheeks and

thin faces, indicating the lack of nourishment from these beverages. And who is more tremulous than the old lady who regularly takes tea to quiet her nerves?

We see then that seeming good derived from these drinks is only the deceptive influence of this narcotic poison. We may now notice specifically the effects upon various bodily organs and functions.

First, the digestive system. One very important part in the digestion of food is the action of the saliva upon starch, converting it into a kind of sugar called maltose, whereby it is readily absorbed and assimilated. This action of the saliva upon a large per cent. of our food is prevented by tea and coffee, even in small quantities, thus producing one of the commonest forms of indigestion, viz., starch digestion. The constituent in saliva which changes starch into maltose is known as *ptyalin*. This seems to be paralyzed in its action by the presence of the poisonous thein, or caffeine. The action of the saliva is not confined to the mouth, but continues in the stomach until the contents of the stomach become acid in character by the introduction of the gastric juice. Hence, as the tea or coffee is present in the stomach, the action of the saliva is interfered with here also.

The pepsin in the gastric juice of the stomach is one of the principal factors in the digestion of albuminous substances, such as meat, boiled eggs, gluten, etc. This very important agent is precipitated by the tannin in tea and coffee, thus scrupulously interfering with the work of the stomach. In experiments made for the purpose of determining the influence of tea and coffee upon digestion, it has been found that in a case where, under ordinary conditions, there was ninety-four per cent. of albuminous digestion upon the addition of tea, the amount of digestion was only sixty-six per cent., and with coffee, sixty-one per cent. When distilled water was added instead, there was no change in the amount of digestive work done, so that it is evident that the change was not due to the simple dilution of the digestive fluids.

Then again, the use of these beverages is injurious in taking into the stomach too large a quantity of liquid food. The effect of this is to check the secretion of saliva, and to delay the action, and weaken the digestive qualities of the gastric juice. If the drink is hot, it tends to relax and weaken the stomach; if cold, it checks digestion by cooling the contents of the stomach down to a temperature at which the work of digestion cannot proceed. Hence we see that the drinking of tea and coffee is one of the causes of the dyspepsia everywhere prevalent.

Upon the nervous system a very injurious effect is had. Upon the introduction of tea or coffee into the stomach, and the absorption of the thein in the drug is at once recognized by the system as a poison, a dangerous intruder, which must be expelled at once. The whole nervous system is aroused to energetic work, stimulating the heart, lungs, and kidneys to increased activity in order to get rid of the poison. Although the nerves may have been "run down," as we say, they are now so braced up that the person supposes that he is being greatly benefited; but after this exertion, the nerves are weaker than before. It is like a man, weary with his day's labor, plodding his way homeward. He is so tired that he can hardly place one foot before the other; but as he comes in sight of his home, he sees his dwelling in flames, or a child in danger. The sense of danger causes him to forget his weariness, and he works with energy until the danger is over; but afterward comes double exhaustion. He is more tired than at first, though for a time he had no sense of fatigue. So it is when the nerves are stimulated to undue action by the presence of this poison. The relief is only temporary, while future years are sure to bring a harvest of suffering.

A SUGAR GROWING INDUSTRY FOR CEYLON.

VISIT OF MR. TURNER OF THE STRAITS SUGAR COMPANY, LIMITED.

It is possible that we may have to date a new departure in the agricultural industry of the island from the visit of Mr. J. Turner, of Penang, which has just closed. Mr. Turner was not able to do as much as he had planned in the only fortnight he could spare; because he landed suffering from the effects of an attack of influenza caught after leaving Marseilles. Still, through the courtesy of H.E. the Governor in granting him letters to several of the Provincial Agents, through calling on the Colonial Secretary—who knew and esteemed Mr. Turner's superiors during the latter's sixteen years in Demerara—through examining plans and maps with the Surveyor-General and getting the benefit of that energetic officer's acquaintance with the country, as also through having the advantage of a very instructive letter from Mr. Ievers and opinions from Mr. Fisher and others,—Mr. Turner was able to decide on a course of action before leaving our shores. A visit to Anuradhapura, even though he only gave it a limited number of hours, convinced Mr. Turner (shrewd Scottish planter and agriculturist as he is) that not in this locality, nor farther North, must he look for sugar land; but rather towards the East. Mr. Turner came to this conclusion from what he observed on the coach journey between Dambulla and the North-Central capital, so that he saw no need to linger there or to penetrate into the Northern Wanni. As a matter of fact, this opinion coincides with that offered by Mr. Ievers and Mr. F. H. Grinlinton. The best soil for sugar is to be found near the banks of the Mahaweliganga below the Minneriya tank or in the neighbourhood of the great tanks north-west of Trincomalee referred to in the Survey Reports of last year. Of course, the soil has to be practically examined and tested, the climate (with reference to monsoon floods especially) and means of transport investigated; and Mr. Turner is by no means the man to hurry to a conclusion where so much is at stake. But he saw and learned enough,—he was especially pleased to learn how mangroves flourished in the districts recommended, because it has passed into a proverb that where mangroves luxuriate, sugar-cane will succeed,—to feel justified on Saturday in sending in a letter to Government asking on what terms and conditions would his Company get a lease of 10,000 to 20,000 acres of land in one or other of two districts named, provided after further inspection, the selection proved suitable. For less than ten thousand acres, the Straits Sugar Company (which has its headquarters at 110, Cannon Street, London) would not care to come to Ceylon; and as the opening up of so large an expanse of country means a heavy local expenditure, apart from some £50,000 on a suitable factory and machinery, it is evident that the terms offered to this pioneer undertaking must be specially attractive. Of course, it will be for the Government, on the other hand, to take every precaution to guard against a merely temporary speculative enterprise, or a breach of

the conditions imposed; to ask, in fact, for such guarantees as may ensure good faith. The Ceylon Government has had a good deal of experience now of land "grants" and "leases," and must be well able to protect the Crown and the public. But, in the present instance, we confess we can see no room for suspicion or doubt. Sir John Ramsden, Bart., and his fellow-directors are known to be wealthy and enterprising capitalists, and they have ample reason to trust the judgment of their Agent and Manager, Mr. Turner, with his ten years' experience of Penang, in addition to a long spell in British Guiana. Should the answer of the Ceylon authorities to Mr. Turner's letter of enquiry be satisfactory, it is his intention to send over a competent member of his staff (they number 38 Europeans in all) during March, to traverse the Tamankaduwa and Trincomalee districts examine the soil, drainage, river—if navigable, &c., and make all other possible observations to help to a decision. Mr. Turner himself would then follow in August—the driest, hottest month of the year in the North-East—in order to see for himself how matters look at their worst. A final decision will then be arrived at, and the land be taken up, or else the scheme be abandoned.

The revival of profitable Sugar Cultivation in British Dependencies of late years is very noteworthy. Even in British Guiana, and yet there are many plantations abandoned that were once flourishing, there are others still paying their way, although the produce realizes now only £10, in place of £35, a ton. The latter marks the day when it used to be said that "a sugar estate maintained six carriages and pairs" of merchants and agents, apart from proprietor and manager! Mr. Turner passed through the days of adversity when the screw was applied all round salaries cut down, and a course of rigid economy adopted. And looking around him while in Ceylon, he told us he could not help thinking that, judging by the prevalent tone, there was still room for economy, for closer attention to supervision and to outgoings in all their detail, in regard to work on, at least, some of our tea plantations. In Penang, as we have already mentioned, it is reckoned that the return from two tons of sugar per acre is as good as from estates yielding three or four tons in Java. Of course, one great attraction to his Company, in thinking of taking up land in Ceylon, would be a cheap and abundant labour supply. We have pointed out to him, however, that our tea planters would be up in arms if their cool districts were interfered with; but that he ought to have the full support of both the Ceylon and Indian Governments, if he applied for the transfer of a large number of labourers from points adjacent to the famine districts in India, to a country and climate so like their own as that of North-East Ceylon. He and his staff would also be very glad to utilise any local labour of Sinhalese or Moormen, giving them land and advances on easy terms, in order to grow canes in

their gardens, for which there would be a ready purchase at the Central Factory. We have said enough to show that Mr. Turner and his Company are in earnest in approaching the Ceylon Government; that there is much reason for encouraging any well-considered proposal to open up unoccupied territory in North-East Ceylon; and that the addition of successful sugar-growing on a large scale to our list of agricultural industries, could not fail to benefit the native community and general revenue. Fortunately, the Governor has at this juncture an adviser in Sir Edward Walker who is very familiar with the subject of Sugar Cultivation in the West Indies and Guiana, and who will be able, therefore, to see that Mr. Turner and his Company are dealt with prudently as well as generously and with a due regard to all the interests at stake.

INDIAN COMMON TEAS.

HOW TO PUSH A SALE IN THE COUNTRY.

The field which is open to pushing our common Indian teas throughout the country is one which might engage the attention of the Tea Association. It is many years since we advocated this, and as yet no steps have been taken beyond the Indian Supply Tea Company. The progress of the Company has been hut slow, but last year's report reads as if it was coming on a bit now, and we hope it may. There are of course a great many difficulties to face, but we believe, if vigorously pushed, there is money in it. A few years ago, we suggested asking the different inland river companies to allow their staff to undertake the sale on the steamers on commission, and we have do doubt hut that they could be approached with success on the subject, and we commend the idea to the Indian Tea Supply Company. It seems rather a disgrace to our mercantile push that nothing but Lipton's Ceylon tea can be obtained to drink on board those inland steamers. Here are the tea-planters, almost the backbone of the India General Steam Navigation and River Steam Navigation Companies, being ousted in the matter of supplying tea to drink at their very doors. Who is accountable for this? In addition to this, why are not teashops opened at the gates of the large jute mills? The jute coolies is by no means above wanting his morning cup of tea, as might be seen by any one walking out in the morning in the vicinity of our very oldest jute factories; hut it is not general, although it ought to be. We suppose it is the old story, what is so many peoples' business is no one's in particular. On our great Indian railways we understand a good deal of revenue is derived from selling the right to deal in sweetmeats, *pan*, &c. Why should not tea be treated in the same way? How much better for the traveller to have a cup of tea in the hot weather to quench the thirst than water, which, to say the least, looks far from clean, and the look of which, at any rate, viewed from an European standard, is revolting. We feel certain that many an outbreak of cholera would be prevented were the system put on its trial. Water, however dirty, is looked upon as safe to drink if it has been boiled, and we think that our idea might commend itself to a Government striving after sanitation. The amount of tea that is annually stolen from factories (the amount it is difficult even to estimate) shows that the native is by no means averse to the cherry cup, and if this is the case, how much more so is it in the North-West, Tirhoot, and Behar. The writer of this in the Behar Famine of 1875, had occasion to tra-

vel through those districts, and on several occasions was obliged to fall back upon the native bazars for tea and never had any difficulty in getting it, but it was invariably Chinese, no Indian was obtainable. The snuff, for such it invariably looked like was the commonest of dust and was being retailed at about Re. 1-4 to Re. 1-8 per pound. The packages was wooden, and weighed about an ounce and was sold at from 3 to 5 pice; and we are not presuming too much, we think, when we say that judging from the Customs entries, the same trade is still being carried on increasingly, and we think we need hardly add profitably. Does any Indian tea find its way into Ceylon? We don't think so, but a good deal of Ceylon finds its way into India. Another year or two will see a heavy strain on the London market, not so much from the increasing area in Assam and the Doora, as extensions have received a big check there; but, from all we can gather, there must be a very large amount to deal with in the near future from Travancore, or, perhaps, a better term would be Southern India, and, if we could only lighten London of 6 or 7 millions of the lower class of tea during the next year or two, it would tend greatly to strengthen the market, and there is, we hold, no reason why this should not be done; but energetic measures must be introduced. Tea must be sold by the cup at a cheap rate, and small packets done up attractively must be alongside to tempt the drinker to invest. Shops should be established in the great fairs, at places such as Benares, Lucknow, Agra, and Cawnpore; and the Brahmin should be enlisted to conduct these. Without some such vigorous methods the heathen Chinese will still continue to hold his own successfully. A retail trade may not fall in with the views of our large Calcutta mercantile community, but whichever pays must rule the roost; and we have no hesitation in saying, if the native is to be taught how to drink tea, and to pay for it, vigorous measures must be adopted, and, if these are introduced, the return on capital invested would be much greater than in some more high flown speculation. The trade would be a cash one, and there would be, or rather should be, no bad debts, and no expensive establishment to keep up for accounts. In fact, everything should be paid by commission, and worked on the cheapest of lines, and if this were done there is no need to fear the result.—*Indian Planter's Gazette.*

SOIL EXHAUSTION

BY J. L. THOMSON, TRAVELLING AGRICULTURAL INSTRUCTOR.

All branches of Agriculture in Australia will have greatly advanced when the farmer shall have learned to treat the soil as he would a bank account. No one expects to draw money from a bank continually without paying in anything, for the time would come when the cashier would write across the face of a cheque "No Funds," and it would be returned to the drawer dishonoured. And yet it is just as unreasonable to expect the soil to keep on, year after year, satisfy the heavy drafts that the farmer makes upon it. There is this difference, however, between the soil and a bank. The bank gives no notice of the progressive exhaustion of the deposit. So long as a cheque or draft does not exceed the amount of the credit, the cashier pays it without a word of warning. It is not his business to caution the depositors. The soil on the other hand warns the cultivator of its exhaustion by a decline in the yield. The warning of fertility is plainly shown in the partial failure of crops. In the older wheat-growing areas this lesson is given on the lands long tilled, but still the resort to fertilising is generally postponed. This is largely because the Australian farmer rarely look upon his land as a heritage to be transmitted to his children undiminished in fertility and productiveness. The farm in many parts of Australia is not commonly regarded as a perma-

nent home for the family and its descendants, as is done in the old country, but merely as land to be worked for all that can be got out of it, leaving posterity to shift for itself.

This view may be justified from the fact that posterity has done nothing for us. It certainly does appear that Australian posterity, at least in the abstract, will be left to "hustle" so far as this problem of fertilisation is concerned. A very little calculation would show that at prevailing prices for wheat there would be little or no profit in growing it, if the fertility it takes from the soil were to be restored by manuring in any form. So little live stock is kept on our wheat farms that the purchase of commercial fertilisers would be the only means of restoring the plant-food taken away by the crops.

The cost of such fertilisers is regarded as practically prohibitory, so far as grain-raising is concerned, and so the present exhausting system continues.

The prospect, of course, is rough for the future, but the present attitude in this regard is virtually "let the future take care of itself." There are, however, many comparatively young farmers who will be compelled by the poverty or failure of crops to grapple for themselves with this question of fertilising, for it is one that cannot be put down. It is mere folly to ignore the fact of decline of fertility and pure ignorance to insist that the full productiveness of soil can be kept up without replacing the costly phosphoric acid, potash and nitrogen that are taken away by the crops. The lesson of the situation is for the farmers to turn their attention to other crops than wheat, and to practise some system of rotation. Much improvement may be brought about by dairy-farming in suitable districts with or without irrigation, but no great change is to be looked for until, in one way or another, the large farms are subdivided, and small farming become, general, rather than the exception. The subject has many aspects and is entirely too comprehensive to be discussed adequately in a short article.—*From the Agricultural Gazette of New South Wales.*

COCHIN MARKET.

C. N. OIL.—The European Houses having accepted a few contracts caused prices to harden and rates advanced to R88 to R88.4 per candy at which figures a good business has been done mainly for prompt delivery.

COIR YARN.—Continues unchanged. Advices of the first public sale in the year held in London, on 12th ultimo, were received here by the Overland Mail of the same date and we find the parcels offered changed hands at steady prices.

ROPE YARN.— Ditto.

COIR ROPE.—With larger arrivals prices have somewhat declined in London. Good Anjeigo yarn ropes fetched only £20 per ton at the last public sale.

COPRA.—Rassi R52.53 per candy.—*Cochin Argus*, Feb. 3.

COCONUT PLANTING ON N.-W. COAST.

MARAWILA, Feb. 6.

WEATHER AND CROPS.—We, in the North-Western coast of the island, were not favoured with the showers of rain that fell last week in Colombo and even as far north as Negombo. The chilly, dewy mornings and the fiercely hot days indicate a period of drought. This is likely to seriously affect coconut crops as we had a failure of the N.-E. monsoon rains. This is the season of small crops, and, as a consequence, the price of coconuts and copra is rising. The local desiccating mills, however, have not raised their rates for buying coconuts as yet. They will have to do it before long to keep their mills agoing.

FARMERS AND THE ROADS.

The following extracts from an article by a Florida farmer in one of the leading American journals seem to be worthy of consideration:—

It is easily possible for farmers to keep country-roads in a much better condition than most of them are at present. The individual can afford to do road mending on the same principle that he repairs fences and buildings: "It pays me;" and a land-owner ought to feel as much shame, even guilt, before the general public over a mud-hole that can be drained, or over a choked-up sluice along his premises, as he ought over neglected cattle or a display of filth.

It is not necessary to wait for the road-working season to come. The most profitable, common-sense work can be put in a little at a time, if at the right time. Drainage is the beginning and the ending of the whole matter, if roads are to be roads and not sloughs. Watering-troughs and hill-side springs are common causes of standing water, yet it is a very simple matter to direct the water flowing from them in the way it should go. A stone, a loose board, a chunk of soil washed down against the end of the sluice, may choke it up till it is worse than nothing. Five minutes' work would send the water rushing through its proper channel. It is not uncommon to see water following the wheel rut for rods, when a man with half an eye can also see that a mere cut through the ridge at the edge of the road would lead the water into the ditch—perhaps down a bank.

Dropping into a bad hole or soft place a few superfluous stones now and then to keep the water out would work a double headed blessing to all passing that way. Heaving out a few stubborn old stones from the track would work a detriment to the blacksmith and waggon maker perhaps, but a big saving to the farmer. If all such patching were thus well kept up, the yearly toll of public service would count more and more toward the good roads of which all are dreaming and talking. This view of the subject is no more than one feature of practical farming, intelligent economy, a mere looking out for number one, no matter how many others are also benefited.—From the *Agricultural Gazette* of New South Wales.

SALE OF RUBBER FROM THE CHARDUAR PLANTATION IN ASSAM.

The Assam Forest Department sold in London the first produce of the Charduar Rubber Plantation at R2-8-6 per lb. The cost of transport from Tezpur and agent's and sale expenses amounted to R0-3-7 per lb. We were offered in Tezpur R1-14-6 per lb. By sending it direct to the market we profited R0-6-5 per lb. The total net profit was R1-2-6 per lb., but this is of no special interest, as the cost of collection was rendered exceptionally high by inexperience and bad weather.—*Indian Forester*.

PLANTING NOTES.

RUBBER SUPPLY DWINDLING: SUBSTITUTES USED.—The rubber supply of the world is running short, and people are asking where our future tyres are to come from. Happily, there are one or two inventions before the public as a substitute for rubber. The nearest is "velvill," prepared from semi-dried linseed or castor oil. These oils are treated with nitric acid, forming what is called "nitrolinolein" or "nitroricinolein." This preparation is then mixed with nitrocellulose, of a very low degree of nitration, and the whole worked into a homogeneous mass.—*Daily Chronicle*, Dec. 13.

SOME FRUIT CROPS OF 1899 IN CALIFORNIA.—We have been informed that this Garden of America has produced 5,250,000 lb. of Figs last year, against 4,780,000 lb. in the preceding year. The "P.ck" of dried Peaches on the coast is placed at 28,300,000 lb., against 10,960,000 in 1898. The Apricot crop of last year was 7,000,000 lb. compared with 8,240,000 lb. in 1898.—*Gardeners' Chronicle*, Jan. 20.

EXPERIMENTS IN MANURING.—From a paper on the "Arrangement of Experimental Plots in Gardens," issued by the South-Eastern Agricultural College, Wye, the following are mentioned as being the requisite amounts of manure and the right proportions of their constituent parts: "The quantities required are 2 oz. per square yard of nitrate of soda sulphate of ammonia, and kaint; 4 oz. per square yard of basic slag or superphosphate; and 1 lb. per square yard of lime." Of course, many other measures will supply nitrogen and phosphoric acid, but the above are the most convenient.—*Gardeners' Chronicle*, Jan. 20.

ECONOMIC PROGRESS IN PERU.—Our Correspondent writes on December 9th last from Lima:—With the cessation of internal disturbances there is every reason to hope that Peru will make substantial economic progress in the near future. Industrial enterprise is everywhere increasing, notably so in the direction of the production of sugar, the crop of 1899 being fully 15 per cent greater than that of 1898. A larger area of land is being devoted to cane cultivation, and this means that the production for 1900 and 1901 will be considerably heavier than in the present year. Limited liability companies are now being formed to assist the development of the sugar industry in Peru, and by this means the necessary capital will be obtained for the erection of the required machinery, and the further extension of the cane fields. Small estates will no longer require separate mills in many districts, the principle of establishing central factories for the elaboration of the cane into sugar having been recently adopted in several of the most prominent sugar-producing sections of the Republic. Improved accommodation for the working men on many of the more important plantations is solving the difficult problem of a steady labour supply to a marked degree. Moreover, more energy and a closer attention to work are being shown by the planters than have been the rule in former years. The higher price of copper during the past 12 months has opened up fresh possibilities for the mineral industry of Peru, and the export of copper ore will form a valuable item in the list of Peruvian exports for 1900. The centre of the Peruvian mining industry is at Cerro de Pasco, situated only 65 miles from the Central Railway of Peru, now in the hands of the Peruvian Corporation. Railway communication once finally established between Cerro de Pasco and the seaboard, and adequate transport provided by a re-equipment of the Central Railway with freight wagons and locomotives, means an immense development in the working of copper ores. The cost of constructing the necessary 65 miles of line to open this communication is estimated by competent engineers not to exceed £500,000, and the prospects of traffic over such a railway assure satisfactory returns on the capital invested in the undertaking. Naturally, it is the Peruvian Corporation which should take the initiative in this enterprise, for the reason that the new railway will act as a feeder to the centre line. The corporation, unfortunately, however, are at loggerheads with the Peruvian Government, and make small effort to improve their own position by extending the railway system they now control.—*London Times*.

INDIGO AND SUGAR.

THE connection between the two products may not seem very apparent, especially to those who have not any practical acquaintance with either; but in India attention is being drawn to them as helpful to each other in alternate years. Our interest in the connection is neither academic, nor purely scientific. Though Indigo has never found a place among our varied industries—save for a few scattered experiments in the time of the Dutch and the beginning part of the present century—Sugar attracted considerable attention in the earlier years of British occupation: and it still flourishes on a small, but, we fear, a steadily decreasing scale. We are however, now, entertaining the hope (as shown the other day) that it will yet figure, if not as one of our greatest industries, at least as a considerable one, if the expectation prove well founded, after the promised examination of the land along the Mahaweliganga by experts in March and August next. In India, as our readers are aware, Indigo has for some time been in a bad way, chiefly through the competition of artificial dyes. As in the West Indies, so on the adjacent Continent, the opinion is gaining ground that the planters have the remedy to a great extent in their own hands. They may be helpless, without the aid of the State, to protect themselves against fraudulent imitations of Indigo, but the Government will surely help them, if they only ask it for help, against the false representation of a substitute as Indigo. The security thus gained is not all that is wanted. There will be a market for the artificial dye, even when so described, and even if it be proved inferior to the vegetable product originally known to the trade as Indigo; and so far as the competition goes, the demand for the true Indigo will be lessened. In order to check the fall in prices inevitable from over-production, a lessened output is counselled by a writer to the London Times, who advises the planters to agree among themselves to devote only the most suitable portion of their lands to Indigo. The counsel is undoubtedly easier to offer than to follow, but it is not impracticable, and when the alternative is loss, if not ruin, an earnest effort to act up to the advice will be true wisdom. And if the land thus left unoccupied can be put under sugar-cane, as is suggested, there need be no special difficulty in following the advice.

There is, of course, the prejudice against Sugar as an industry often which leaves small profits: but it was shown in recent articles how returns have been almost doubled by judicious cultivation, and the proportion of Sugar has been increased by the choice of good seed. So far as India goes, there is the further protection which legislation has secured by countervailing duties against bounty-fed competition. It is further claimed that the new seedling canes which have been recently introduced into Barbadoes, have proved that profits are realisable from Sugar even at prices considerably lower than those which have

been ruling lately. And further, Java is quoted as an illustration of the possibility of combining the cultivation of Sugar with that of Indigo. A botanical expert, reporting to the Belgian Government on the methods adopted in Java, mentions the practice of rotation with the best results by the Java planters who alternate the cane every third year with indigo and rice. It is not by rotation of crops alone that Java is deriving handsome returns from Sugar. It utilizes European science, and pays strict attention to details; and, as we are ourselves organizing an Agricultural Department, there is no reason why Ceylon should be behind any other country in securing adequate results from the soil. This is what we read of Java:—

“Instead of wringing their hands, like the West Indian planters, and crying to the mother-country for aid, the Javans, when the crisis came, set to work to apply German science to their own plantations. The sugar-growers formed themselves into an association for the purpose of the scientific study and development of their own industry. Experimental stations were established, with chemical and biological laboratories attached, and European specialists were engaged at high salaries to superintend the work of these stations. The progress of the experiments was regularly communicated to all the planters throughout the island, by means of a periodical publication, which was also used to describe the latest machinery and to deal with any other matters affecting the industry. The result is that Java has completely recovered from the temporary ruin brought about by low prices, and that her sugar industry is now going ahead by leaps and bounds. If this can be done in Java, why not in India? Java has the disadvantage of being compelled to seek a foreign market for her sugar, and in nearly every instance has to fight her way into that market across a barrier of protective duties. In India there is an immense home market waiting for the capitalist who has the intelligence to produce sugar on European methods.”

What is said of India applies, of course, to Ceylon, which imports a very considerable quantity of Sugar.

THE SHEEP OF THE WORLD.

As regards the number of sheep, the following figures showing the number possessed by each country in the latest year, for which returns have been published, are noteworthy:—

Algeria	7,485,000	India British	16,875,000
Argentina	75,000,000	Italy	6,900,000
Australasia	103,000,000	Norway	1,417,000
Austria	3,187,000	Poland	3,755,000
Belgium	236,000,000	Romania	5,002,000
Bulgaria	6,868,000	Russia Europe	44,465,000
Canada	1,690,000	Servia	3,094,000
Cape Good Hope	14,000,000	Spain	13,359,000
Denmark	1,246,000	Sweden	1,298,000
France	21,445,000	Switzerland	272,000
Germany	10,866,000	U. S. A.	37,657,000
Holland	700,000	Uruguay	16,897,000
Hungary	8,122,000		

The great sheep-breeding countries of the world, therefore, so far as these figures show, are Australasia, Argentina, Russia, and the United States. All of these possess more sheep than the United Kingdom, which in 1898 had 31,102,000. But in proportion to area the United Kingdom enormously surpasses them, the four countries mentioned having, of course, immense territories,

The figures, which are given in the Agricultural Returns, shows that the United States cover 2,292,000,000 acres; Australia, 1,974,000,000 acres; Russia in Europe 1,244,000,000 acres; and Argentine, 715,000,000 acres. The United Kingdom, on the other hand, covers only the comparatively insignificant area of 77,000,000 acres.—*Agricultural Gazette*, London.

KANAPEDIWATTIE TEA CO., LTD.

DIRECTORS' REPORT.

The Directors have pleasure in laying before the Shareholders their Report and Accounts for the year ended 31st December, 1899, which they trust will be found satisfactory. The following figures shewing the crop, cost, and average of the tea for the past three years will be found interesting:—

	1897. Crop in lbs.	Cost in Colombo.	Nett Average.
From Estate Leaf ...	122,095 }	25'88	34'18
From Bought Leaf..	22,095 }		
Total Crop..	144,190		
	1898.		
From Estate Leaf ..	142,267 }	23'11	32'71
From Bought Leaf..	30,330 }		
Total Crop..	172,597		
	1899.		
From Estate Leaf ..	151,030 }	21'92	36'16
From Bought Leaf..	38,565 }		
Total Crop..	189,595		

It may be mentioned that the estate tea alone cost cents. 19'94 lb. laid down in Colombo, which reflects great credit on the Superintendent, Mr. Geo. Christie. The crop was 3,970 lb. short of the estimate, but the yield was 543 lb. per acre which may be considered good, as no allowance has been made for cocoa, cinchona and shade trees planted here and there through the tea.

The net profits for the year amount to R44,779'51, which is equal to 13½ per cent on the paid up Capital of the Company as against 12 per cent last year.

Including the sum of R771'24 brought forward from last year, the amount available for distribution is R45,550'39, of which R13,360 has been absorbed by the payment of an interim dividend of 4 per cent for the six months ended 30th June last.

The Directors recommend that the available balance, namely R32,190'39, be apportioned as follows:—

By the payment of a Final Dividend of 6½ per cent, making 10½ per cent for the year	R21,710'00
By placing to Reserve Fund	.. 10,000'00
By carrying forward to the next account	480'39
Total..	R32,190'39

It will be noticed that the Reserve Fund will then stand at R25,000.

In terms of the Article of Association, Mr. George Christie retires from the Board of Directors, but, being eligible, offers himself for re-election.

The Auditor, Mr. J. D. Forbes, also offers his services for 1900.

YATADERIA TEA CO., OF CEYLON, LTD.

DIRECTORS' REPORT.

The directors have the pleasure to submit the Balance Sheet and Profit and Loss Account for the year ending 31st December, 1899, duly audited.

Including extraneous profit from outside manufacture the profit for the year is R38,477'70, to which must be added R9,850'87 balance from 1898. An Interim Dividend of 12½ per cent, absorbing R23,750, was paid last August, and the Directors propose that a further Dividend at the rate of 12½ per cent and a bonus of 20 per cent., absorbing R61,750, be declared and made payable on the 12th instant, leaving a balance of R12,828'57.

It will be seen that the property representing Capital stands in the Balance Sheet at approximately R197 per acre cultivated, as compared with about R200 in the previous year's accounts, and that the profit is R100'54 per acre in bearing, and 46'56 per cent on the Capital.

The total Tea crop was 572,138 lb. or 17,138 lb. more than the estimated quantity, the latter part of the year having been more favourable. The plucking area was 880 acres, in addition to which the 33 acres of 1897 tea was plucked towards the close of the year. The total quantity of Tea for disposal was 577,214 lb., including 5,076 lb. made from purchased leaf, of which 221,481 lb. were sold locally, averaging 33'68 cents per lb., and 355,733 lb. were shipped to London, of which, 99,910 lb. had still to be accounted for; but the average obtained for the 255,823 lb. as yet accounted for is 35'75 cents per lb. The cost of the tea delivered to buyers or put on board ship, including all charges, was 18'89 cents per lb., and the nett value realised from sales (a portion being estimated) was 34'77 cents per lb. (being 4'96 of a cent more than for the previous crop.)

The Company's property consisted on the 31st December, 1899, of:—

Acres	Tea Planted in	Yielded in 1899 lb. Tea per Acre.	Average yield from 880 acres, 646 lb.
172	1885	602	
298	1887	538	
100	1888	534	
42	1889	630	
6	1890	813	
52	1891	957	
120	1892	789	
68	1894	844	
37	1895	719	
75	1896	530	
33	1897	111*	
29	1898	not in bearing.	
24	1899	do do.	
966			
22	Acres Cocoa and Factory site.		
10	,, Cardamoms.		
255	,, Forest, &c.		

Total 1,253 Acres as per last report.

* Plucked latter end of season.

The estimate crop for 1900 is 580,000 lb. tea.

Mr. J H Starey retires from the Board, and the shareholders will be requested to elect a Director and also Auditor for the current year.

EXPERIMENTAL MANURING IN VICTORIA.—

During the coming season the Victorian Department of Agriculture proposes to make a thorough trial of the value of manures in different parts of the colony. Not only will the recent experiments at St. Arnauld be repeated, but experimental plots will be treated with different manures in all the principal wheat-growing districts of the colony. The Minister of Agriculture states that he proposes to have four sets of fertilising drills at work, under the supervision of Mr. A N Pearson, the Government Agricultural Chemist, and Dr. Howell, and every care will be taken to give full publicity to the experiments. A number of sites have already been secured, and in making purchases of manures now on the market for the purpose of the experiments, the Government would take every precaution to ensure the identity of the buyer being kept a secret. Dr. Howell, who has recently joined the department, is now engaged in making a complete soil survey of the colony, and he is lecturing to farmers in all parts of the colony on manures and manuring and the splendid results to be obtained from the scientific use of fertilisers.—*Sydney Mail*, Jan. 20.

Correspondence.

To the Editor.

NEW METHOD OF HARVESTING RUBBER.

[Letter addressed to the President of the Chamber of Agriculture, by M. Josselme, of Cochin China.]

SIR,—I venture to address to you this simple note after reading an article by M. Bourdarie, which appeared on April 20, 1899, in your Review under the title, "The Cultivation of Rubber Plants." I wish to reassure M. Bourdarie and those who have the same anxiety regarding the difficulties of harvesting and who consider it requires about one man per day per tree. This statement decided me to make known the simple method I have devised, and which reminds me, though it did not so strike me at first, of the simple process adopted in the "landes" of the Gironde for harvesting the resin. This method, which I showed two years ago to Drs. Yersin and Jaquet in Assam, while cutting into some stems of *Manihot Glaziovii*, saves all manipulation and allows of one single person to make at the same time the harvest of a number of trees. This is the way:—Small bags, or rather little pockets, of calico of the poorest quality and provided beforehand with two furniture brads, or any other means of fixing them, are rapidly affixed in the evening, the side next the tree being drawn tight. The next morning at dawn, or at the time of fixing the bags, a cutter following the first operator performs the incisions passing rapidly on from tree to tree. For the process I should prefer to the hatchet the large wood scissor called by the Anamites "fish's tail," driven in with one stroke to the required depth.

The sap flows into the pocket, the watery liquids are filtered through the cloth and evaporate, while the plastic substance remains in the bag and coagulates rapidly. It is easily detached from the tissue and nothing prevents one from submitting it before it hardens to any fumigations or antiseptic processes that may be necessary. True, by this process one would only obtain what might be called rubber in tears, but it would be more difficult to use fraud in this rubber.

The initial trouble in collecting would be much lessened in this way and that is a main point. Hitherto I have made only small experiments as my trees are but young. Need I say that the same pocket moved up or down will serve for many incisions on the same tree? . . .

I may add that the coarse calico lets through a milky substance as well as a clear liquid especially now while the rains are on. This varies with different trees and with the season,—Believe me, etc., etc., J. JOSSELME.

(From the *Revue des Cultures Coloniales* of Dec. 15.)

THE CACAO MARKET :

GIFTS OF CHOCOLATE AND COCOA FOR SOLDIERS.

London, E. C., Jan. 19.

DEAR SIR,—One of the signs of the great increase in the demand for cocoa and chocolate is the large share of attention it receives in the trade journals of late; in one of them alone (the "Confectioners' Union" for January) three special articles and nineteen paragraphs are devoted entirely to it, two of the paragraphs notifying

the intention of two new firms going into the business of Cocoa Manufacturers.

Whilst new buyers are springing up on every side, asking for samples from the Mincing Lane Brokers, it will be just as well for both buyers and sellers if it were brought home to them, rather more forcibly than appears to be the case at present, that samples cost money. The little paper bags used down "the Lane" for cacao samples hold about half pound each if filled, so if a dozen buyers ask for samples it means four to six pounds of cacao, at present values costing from 3s to 5s, and from all I see and hear, more than six pounds are sometimes wolved up by professing buyers to whom the broker who at present is forced by the custom of trade to give them out, although he knows the chances are against his getting any adequate return for the loss to his merchant, in the shape of orders, or spirited bidding, which so much sampling would warrant, at the sales. As the cost of samples come out of the shippers' profits, I think it is worthy of their attention, now that there is undoubtedly a much larger demand from *genuine* buyers who must be encouraged than formerly, for samples, to see that this right is not abused and that the samples they have to supply free do not go to help fill some bag which is then sold by the collector either down "the Lane" as "duty paid" cocoa, or may be included in a direct sale to a manufacturer.

This week same as the previous one has been a good one for sellers. Pine Ceylons are still much wanted, 90s being paid in the sale for by no means Ceylon's record best, and should any such quality be offered just now—I mean beans with a nice even *light* cinnamon break free from whitish or darker beans, and with a bright "silky" outside skin—I believe, the competition would cause it to realise 100s, for by the great changes in values I am of opinion, buyers have orders "to buy on" limits much more elastic than usual. Some lots this week sold at prices out of proportion, simply owing to two or three buyers competing for the same lot, with the result that whilst some lots showed only 1s to 2s rise, another went at a good 5s higher than presale valuations.

This week 1,649 bags of Ceylons were offered, of which 1,305 bags sold, smalls and common native 55s to 68s 6d, fair to good native 69s to 75s. Middling to good red estate qualities 78s 6d to 83s 6d, fine 84s 6d to 90s.

The demand for Trinidads is also very good, sale rates varying from 80s to 82s 6d for good to fine red, and now anything approaching good red seems fairly easy to sell at 80s. The stocks of this growth are very low, being only 16,657 bags.

Grenadas at the sales went firm with an occasional rise of 6d and 1s, the best selling at 73s and 73s 6d against 72s 6d last mail.

As I anticipated, the idea of the Queen making a present of Chocolate to her soldiers has already been copied, one lady having sent 3,500 ½-lb. tins of Cocoa to be distributed amongst certain regiments at the front; this cocoa was supplied by Messrs. Clarke, Nicholls, & Coombs, Ltd., a well-known confectionery house, and one of the two firms I mentioned who are going in for cocoa.

I see by the papers, the Volunteers going to the front are particularly advised to take a quantity of chocolate in case of emergency, and being short of provisions, so on all sides the usefulness of cocoa is being recognised.—Yours truly,

HAROLD HAMEL SMITH.

PLANTERS AND AUXILIARY PRODUCTS.

Upcountry, Feb. 7.

DEAR SIR,—Now that we have to face more enemies than one, connected with the Tea enterprise, is it not time that all tea planters should turn their attention to auxiliary products suited to their different altitudes, so that we may be prepared to tide over troublous times when they do begin to make themselves felt? The prices most of us are now realizing for our staple product can but only help to keep the wolf away from the door; but when we are told of gigantic organizations to wipe us dry, by depriving us even of that last drop in the bucket, it behoves each and all of us to look alive and to be up and doing.

That such another crisis as this Island experienced in the early "eighties," is looming in the not distant future (this time not from disease but from numerous other causes too voluminous to mention) does not require a prophet's eye to discern, and when it does come, how many amongst us will then be found prepared to face the inevitable with all our eggs in the one basket, as most of us at present stand? I trow few, very few!

When the coffee catastrophe swooped down on Ceylon like a thunderbolt, those of the knowing ones amongst our planters of that day, who had cinchona planted on their estates, found and got no little help from that product to keep themselves afloat: a good many of those men will own up that their cinchona went no small way to help them to develop the new industry tea. Where in Ceylon is cinchona to be found now? Except in a handful of places, this product is a thing of the past. That this commodity is in demand cannot be doubted, when we see the "sons of the prophet" on the tramp offering quite 25 cts on the spot for a pound of dry bark. I only wish I was the possessor of a few thousand pounds of bark this day: what a haul I should have made!

I will (if you will permit me) through your columns offer a small suggestion to both lowland and highland planters. To the former I would suggest that they plant up all vacancies, roadsides, above drains, boundary belts, &c., with Para rubber, nutmegs and cloves—products well adapted to their climate—and all their flats and undulating lands with coconuts at 30 or 40 feet apart: this will in no way affect their tea. To the highlanders I would say, plant all your vacancies, roadsides, above drains, boundaries, &c., with a good jat cinchona. My brethren, take this advice in a good spirit as it is given in a kindly one; and—perhaps, it may be, at the end of five years or so you may live to thank.

EXPERIENCE OF THE EARLY "EIGHTIES."

SUGAR CULTIVATION.

DEAR SIR,—Re your articles about sugar cultivation. Did not one of the Lords Elphinstone lose heavily by an experiment in this direction at a place called "Paradua" (I think, in the Kalutara district, in the "fifties"? Rumour had it that my Lord dropped some R30,000 over the business. I hope sincerely I may have been misinformed as to the loss sustained by Lord Elphinstone, but caution is required in all such ventures.

E. F. T.

[The changes that have taken place in sugar cultivation and preparation in the past twenty years are very notable and our correspondent may be quite sure that Mr. Turner and his staff will do nothing rashly.—ED. T. A.]

PLANTING NOTES:

COREAN PEARL DIVERS.—The diving for the pearl oysters found off the Korean island of Quelpart is entirely done by women. Dressed in a kind of bathing suit, with a sickle in one hand and a gourd with a bag tied to it in front of them, they swim out from the shore as far as half a mile—boats cannot be afforded—and they dive, probably a depth of forty or fifty feet, to the bottom, cut the weeds with the sickle or if they find a pearl oyster, tear it off from the stone, and then put it into the bag, which is kept floating by the gourd. They do not go back before the bag is filled, which often takes more than half an hour.—*Home paper*, Jan. 16.

FOWLS IN FRUIT CULTIVATION.—In the old days of the *Agricultural Gazette* Mr. Alderman and Sheriff Mechi used to entertain the readers with stories of his agricultural experiences, including the work done by fowls in vegetable-gardens and orchards in clearing-off insect-pests. This sort of work is being done now with approval in many parts of the world; and from abroad come encouraging reports of the value of chicken-peck. One fruit-grower writes:—"I enclosed half-a-dozen unproductive canker-worm infested Apple-trees in a chicken-yard, and as a result the insects were cleared, and the trees produced good crops of fine fruit." Another wrote:—"The hen was a golden claw; she is a professor of agriculture, too, and teaches clean culture, and lots of it, with high-feeding for a fruit-orchard." *Verb Sap.—Gardeners' Chronicle*, Jan. 20.

TEA IN ASSAM.—The heavy rain that fell in Upper Assam and the north-east tea districts generally the week before last, though it will render the first hoeing more easy and benefit general cultivation, comes rather at an inopportune time for those who commenced their pruning last month, inasmuch as it will bring out a flush tough, leathery, and sapless that will not be worth gathering for manufacture, and yet must be removed or *bangi* will be the result. We are generally prepared for (and expect) the usual Christmas showers but hardly for such an abnormal downpour as this. One or two complaints have reached us that the rain will delay clearance, but with these we have not the slightest sympathy, as there is quite enough land under tea for all likely requirements for the next two years.—*Indian Planters' Gazette*.

THE
AGRICULTURAL MAGAZINE,
COLOMBO

Added as a Supplement Monthly to the "TROPICAL AGRICULTURIST."

The following pages include the Contents of the *Agricultural Magazine* for February:—

Vol. XI.]

FEBRUARY, 1900.

[No. 7.

1900.

HE present number is the first of a new year (and indeed of a new century). While wishing that the year 1900 has the maximum of good and minimum of bad in store for our readers, and that the agriculturists in Ceylon will experience the best of seasons and reap abundant crops, we cannot but introduce a personal element into this sentiment, and hope that the School of Agriculture will enter upon a new era. During the past year there has been a good deal of conference among those best qualified to give their views on questions connected with agricultural work, including agricultural education, and it is to be earnestly hoped that the conclusion of the whole matter will be a determination to establish an Agricultural Institution—call it a Department or what you please—worthy of the colony and capable of fostering its agricultural interests.

A COMPARISON.

We read in a review of the Report on the Madras College of Agriculture that though "the farm (attached to the College) is not maintained with a special view to profit on experiment, the fact that the net cost thereof was less than Rs. 500 is creditable to the management," and that a large share of the income is obtained from the dairy herd kept on the farm.

Without in the least wishing to disparage the efforts of our sister institution in Madras, we should wish to point out that if we took credit for the income from our dairy herd in estimating the working of our school "farm" (to wit the

cultivated area attached to the School of Agriculture) the "net income" would be represented by a few thousand rupees, and this would be substantially increased if the Model Farm revenue was added.

We feel inclined to envy the Madras College for being able to take credit for the income from the dairy herd in estimating the working of the experimental grounds, and placing it against the presumably substantial expenditure allowed for maintaining the latter—another circumstance which excites our envy. How do we stand? Why our vote for the Experimental Garden is practically *nil*, while the income from the dairy herd, and the grass farms attached to the school and the Model Farm goes to the credit of Revenue.

What the Colombo School of Agriculture has to deplore is the commercial spirit in which it is worked. It would be scarcely credited by those who have had any connection with Agricultural Schools and Colleges, that no special provision whatever is made for conducting the practical operations associated with the instruction imparted in our School of Agriculture. Not many years ago there was no dairy herd and no grass farms connected with the school, and though these latter now yield a handsome revenue, the school has the same needs now as it had then. Is it not reasonable to expect that the revenues referred to would have been utilized for the improvement and elevation of the school, especially when the institutions which yield the revenues are its offshoots, and their work directed from the school? So far from this being the case, the greater part of the grounds is in a neglected condition for want of a vote for the necessary expenditure required to maintain it as a useful experimental garden, an object lesson of clean cultivation to the students, and an ornamental purlieu of the city. The wonder then is not that the school has not produced the best results, but that it has been found possible to secure any students for the classes. In India they offer scholarships and appointments to induce the study of agriculture; here the prospects, to the intending student, are most discouraging.

Greatest amount of rainfall in any 24 hours on the 26th inst. was 2·5 inches.

Recorded by Mr. J. A. G. RODRIGO.

GUINEA-GRASS.

Mr. A. A. Ramsay, F.C.S., Sugar Chemist to the Department of Agriculture, and Superintendent of the Sugar Experiment Station, Mackay, has kindly furnished the following analysis lately made by him of Guinea-grass. He says:—

Guinea-grass has been grown for some time now at the sugar experiment station, for feed purposes and also for seed.

In July we had a number of stools of over-mature grass, which the stock would not eat, while they seemed very fond of the young leaves shooting from stools cut previously. I was led, by this, to make analyses of two samples with the following result:

	Over-ripe Grass.	Young Shoots.
Moisture	70·92	69·08
Soluble Albumenoids	·88	·86
Insoluble do	·66	2·20
Digestible fibre	1·94	2·25
Woody fibre	20·11	13·92
Soluble ash	1·07	1·02
Insoluble ash	2·29	3·55
Chlorophyl amides, &c.	2·13	7·12
	100·00	100·00

Total nitrogen	·40	·71
Total albumenoid nitrogen	·25	·49
Albumenoid ratio	1:14·3	1:5·3

I would state that these analyses are of the few stools of grass that were growing here, and available for our purpose, and no special cultivation or attention has been given them. The grass was planted in rows 3 ft. 6 in. apart and 4 ft. between the stools. The average weight of the shoots analysed (of overripe grass) was nearly 8lb.

From figures published under the authority of the Royal Agricultural Society of England I give, for the purpose of comparison, the total nitrogen in average grass, meadow hay and clover (these latter are calculated to 70 per cent. water for easier comparison). There are

Clover hay	7

JADOO FIBRE.

By J. C. BRUNNICH,

Chemist to the Queensland Department of Agriculture.

Several articles have appeared in this *Journal* on Jadoo fibre, an artificial fertilising product, which, so far, has hardly received in this colony the attention it seemingly deserves.

The Department of Agriculture supplied a quantity of Jadoo fibre to the Agricultural College for experimental purposes, and the results of these experiments will be looked for with interest, although in our rich College soils the effects might not be so marked as in poorer soil.

In order to see if what the inventor claims is really true, I made a complete analysis of the product with the following result:—

I found Jadoo fibre to be a fine fibrous product, of brownish colour, which, almost like a sponge, has the power of absorbing an enormous quantity of water up to six to eight times its own weight. This fact alone will explain part of its practical value, when used for pot plants in the orchard or vineyard. This fibrous raw material is saturated with plant foods, which, according to analysis, are to a large extent soluble in water, any plant having thus a fair amount of plant foods at once available for its growth; another portion of the plant foods is like some in the soil not soluble in water, but soluble in hydrochloric acid, and these will become available gradually, by the chemical dissolving action possessed by the roots of growing plants. As a matter of fact, Jadoo fibre must be considered a highly fertile artificial peaty soil.

Analysis.

	Per cent.
Organic matters	71·40
Containing ·812 per cent. of Nitrogen=·986 percent. Ammonia, Mineral matters—	
Soluble in water (total, 4·36 per cent.)	
Phosphoric acid, P ₂ O ₅	·445
Sulphuric acid SO ₃	1·286
Nitric acid, N ₂ O ₅	·520
Alumina and Iron, Al ₂ O ₃ , Fe ₂ O ₃	·271
Lime, CaO	·303
Magnesia, MgO	·107
Potash, K ₂ O	·357
Soda, Na ₂ O	·750
Ammonia, NH ₃	·020

	Per cent.
Soluble in hydrochloric acid, 1·1 sp. gr.	
Silica, SiO ₂	·031
Sulphuric acid, SO ₃	·926
Phosphoric acid, P ₂ O ₅	·715
Alumina, Al ₂ O ₃	·765
Iron, Fe ₂ O ₃	·170
Lime, CaO	1·875
Magnesia, MgO	·163
Potash, K ₂ O	·402
Soda, Na ₂ O	·791
Insoluble in HCl	5·838
Total ash	9·85
Moisture	18·75

The inventor does not claim the product to be a manure, and in accordance with the analysis the actual value of the plant foods, phosphoric acid, potash, and nitrogen amounts to 15/ per ton of Jadoo fibre. The secret of the preparation lies in the foundation material which has the power of absorbing and retaining the fertilising ingredients, which are thoroughly incorporated with the fibre by a slow process of fermented.

THE WEST INDIAN AGRICULTURAL DEPARTMENT.

The first number of the *West Indian Bulletin*, the official organ of the new Department of Agriculture, gives the history of the movement, and an account of the department, its purposes, aims, &c. The experimental and educational work which it is instituting, its field of operations, and the problems presented to it, make the new department worthy of more extended notice.

It will be remembered that the extreme depression of the sugar industry in the West Indian Colonies, which caused many sugar plantations to be abandoned and threatened others, led the British Government to appoint a West Indian Royal Commission in December, 1896, to investigate the condition of the Island and suggest measures for relief. The Report of the Royal Commission pointed out the causes of the "critical" condition, and emphasized the need of improving and cheapening sugar production, by the introduction and improvement of varieties of cane, better methods of culture, and the prevention of excessive losses in the manufacture of sugar in some cases by using more efficient machinery. It also strongly recommended the introduction of other farm industries where possible, and the teaching of agriculture in different classes of institutions. The commission commended the work of the botanic stations already established in a number of the islands, and recommended that they be enlarged and extended and placed under a central department of agriculture, which was to be charged with the promotion of the agricultural interests of the colonies in general.

The recommendations of the commission in this and other matters have been adopted and carried into effect. The British Government appropriated £4,500 for the new department for the first year, and it is estimated that in future an annual grant of £17,500 will be required to carry out the recommendations of the commission as adopted. "The cost of the department for a period of ten years, will be provided from Imperial funds, and grants will also be made in aid of the public revenues of Trinidad and Tobago (for the benefit of the latter islands), British Guiana, Barbados, the Windward Islands, and the Leeward Islands, to provide for or to assist in the maintenance of agricultural and botanical establishments, industrial schools, or other kindred purposes."

The headquarters of the department are at Barbados. Its duties as outlined are twofold: "(1) To endeavour to restore the sugar industry to a condition in which it can be profitably carried on, and (2) to encourage the establishment of other

industries in such colonies as afford suitable conditions to supplement the staple industry."

In inaugurating its experimental work, advantage will be taken of the beginning previously made in experimenting in cane growing and the improvement of cane at a number of places, and this work will be greatly developed and extended. Four "principal" or "central" experiment stations and eight "local" stations for the improvement of the sugarcane will be established on the island of Barbados. The object of the central stations will be the growing of seedlings and improvement of varieties, and the carrying on of fertilizer experiments. The more promising varieties will be given a practical trial at the local stations to test their adaptability and value in different soils and localities, and also as a demonstration to the planters in each parish. Experiments on similar lines have been arranged for at Antigua and St. Kitts, while the work previously inaugurated at Trinidad will be largely extended and the necessary chemical assistance provided.

The botanic stations placed under the control of the department are those at Tobago, Grenada, St. Vincent, Barbados, St. Lucia, Dominica, Montserrat, Antigua, and St. Kitts-Nevis. The expense of their maintenance has been transferred to Imperial funds. The object of these stations is to test and distribute promising economic plants for the region, introduce new or little known plants for experimental cultivation, and conduct experiments on the improvement of sugarcane. In addition they distribute information, and send out lecturers for institute work.

The excessive losses in sugar manufacture on the smaller islands under the crude methods employed, is emphasized by the statements that there is "an average of over 2,000 pounds of sugar per acre left in the cane after crushing, which is burnt in the megass;" and that owing to heavy losses in boiling, "for every 100 pounds of crystallizable sugar contained in the juice, not more than an average of 75 pounds of ordinary muscovado sugar is now produced." It is said that at present about 13 tons of cane are required to produce a ton of sugar on these smaller islands, while with efficient machinery 9 tons would suffice. The remedy recommended by the Royal Commission is the establishment of central factories, equipped with the best machinery, and it is the expectation of the department to establish one or two experimental factories at an early date.

The new department will also promote agricultural education in the islands, which heretofore has received little attention. The plan of the Royal Commission to establish agricultural schools in connection with the botanic stations has been carried out by opening a school at Dominica, and others will be started at St. Vincent, St. Lucia, and St. Kitts Nevis as soon as the necessary land is obtained. Furthermore, "the department is prepared to offer grants to enable certain institutions to employ teachers in agricultural science, and possibly provide a number of scholarships for the most promising pupils;" and in co-operation with the central educational authorities in each colony, the teachers in the elementary schools will be given a course of instruction in the principles of agriculture, to enable them to give simple instruction and conduct school gardens. It is proposed

to attach an agricultural instructor to each of the botanic stations, who will travel about holding meetings and demonstrations, and imparting information on improved methods directly to the planters; and in addition instructors or experts in special lines, as budding and pruning fruit-trees, curing tobacco, bee-keeping, etc., will be employed to spend a month or two on each island.

The publications of the department will also be a means of diffusing popular information. They will include handbooks on the cultivation of special crops, bulletins and leaflets, the latter especially being in very simple, clear language. The *West Indian Bulletin*, mentioned above, will be issued by the department periodically. The first number of this journal contains as an introductory, an account of the establishment of the department, and a report of the first agricultural conference held at Barbados. The latter contains a number of papers of merit on different features of cane growing, central factories, agricultural education, etc.

It will be seen that a very liberal and comprehensive plan has been adopted for acquiring and diffusing information, and that no effort is to be spared to make the department of the greatest direct benefit to the planters and to bring the teachings of agricultural science home to them. The progress of the new department in its various branches will be a matter of much interest to people of this country, especially in view of our interest in islands adjacent to those for whose benefit it was established. The experience there will prove of value, as well as the actual contributions to agricultural science and practice.

TO TELL THE AGE OF CATTLE.

The first ring at three years, and a ring on the horn for each succeeding year, is the usual way of reckoning; but as these can be rasped off, and some breeds do not have horns, it is advisable to determine necessarily by the teeth. The unimproved long horns, and other old-fashioned breeds which are long in coming to maturity, were found to be later in the putting out of the teeth; but the following table, drawn by Professor Simonds, is reliable for Shorthorns and others which mature early. The same order is maintained as regards the front teeth or incisors in all animals—namely, the two to come through first are the central; the next pair consists of one on each side of them, and again one on each side of the laterals, the outer laterals following until the number (eight in the ox) is completed. The molars, or grinding teeth, also afford evidence to those able to distinguish them, but for all practical purposes the age is nearly enough ascertained by the number and development of the incisors. A rough-and-ready way of remembering is, first pair at one year and nine months; second pair at two years and three months; and so on, each pair being about six months later than the previous ones in breaking through the gum. As soon as the mouth is "full," or complete, the teeth begin to show wear, and gradually separate, as well as look narrower, and

have interdental spaces, which go on increasing until, in very old animals, they fall out and leave gaps.

A Writer in an American exchange says:—I have always regarded the horns of very small importance in showing the age of the cow when buying. It is true that the horns indicate the age, but not always accurately. The rings usually begin to come with the first calf. For instance, if a heifer drops her first calf at two years old, the first ring counts two; but if she does not calve until three, then the first ring counts three years. After the cow gets along in years, the most important thing on which her continuance of usefulness depends is the condition of her teeth. Generally, as long as her teeth last, she will continue to do well in the dairy; but when these fail, she will begin to go down hill. Therefore, it is never safe to buy a cow without looking at her teeth, for some fail sooner than others. For the benefit of those who are not in the habit of examining the teeth of the cow, I will describe their appearance at various stages. In determining the age of the cow, it is necessary only to examine the front teeth of the lower jaw—I say "lower" jaw, because a man came to buy a cow some time ago, and objected to taking her because she had no upper front teeth. The calf has eight small milk teeth; but when nearing two years old, the two middle ones are replaced by two permanent and much larger ones. The two next ones come at three or a little before, two more at four, and at five years old the cow has a full mouth. The two middle ones are at this time about $\frac{3}{4}$ inch long, with the others growing shorter to the outside. After this the teeth grow shorter every year, and at seven years we may expect to find the teeth not much over $\frac{1}{2}$ inch. They keep on wearing off until at 9 or 10 years they are very much shorter and seem narrower, also barely touching each other. The gums also begin to shrink away, until sometimes a tooth or two may get knocked out by biting some hing hard.

By looking at the teeth of cows of which one knows the age, he may soon become well acquainted with their appearance. While it is impossible to tell exactly the age of a cow when over five years old, still one may judge near enough for all practical purposes. If a cow's mouth presents an 8-year-old appearance, it does not make much difference if she is nine or ten. She will, in all probability, last as long as the average 8-year-old cow. Dealers will often insist that a 10-year-old mouth belongs to a 7-year-old cow; but that is no reason why the buyer should be deceived. He can easily learn for himself.

SHOULD EGGS BE WASHED?

The *Rural New Yorker* sent out this question to a number of poultry experts, and, as usual, views differ.

The *New York Produce Review* may take its eggs dirty if it likes, but I shall continue to ship mine clean. I have been producing about 1,000 dozen a month for years, and every egg goes into a pan of lukewarm water as soon as it has been gathered out of the nest. All dirt is easily removed after the eggs have been allowed to lie in warm water a few minutes, and the heat imparted to the egg by the warm water causes it to dry quickly, and gives it that fresh appearance peculiar to a new-laid egg. If the water hurts their keeping quality, I have never heard of it. This testimony probably has little value, as my eggs get into consumers' hands before they have time to spoil. A few years ago I filled a few glass fruit cans with eggs, and then filled the cans with sterilised water at a temperature of 155 degrees sealing immediately. Eggs thus treated in December were in perfect condition after four months. The most expert chandler that I could find in the city said that they would pass anywhere for new-laid eggs, and Dr. W. E. Douglass, of Middleton, to whom I sent some, had them poached for his dinner-table, and said that no one at his table could tell them from new-laid eggs. The shells were in perfect condition so far as we could see, and the air cells smaller, if anything, than in a new-laid egg. I also tried some in the same way during the summer, but the water and eggs soon became tainted. From this I concluded that, although stated in the *New York Produce Review*, "wet eggs soon decay in wet weather," the cause is found in "warm weather," and not in "wet eggs."

Keep Eggs Dry.—The *New York Produce Review* is right. Eggs certainly are injured by washing. They will not keep so well or hatch so well as unwashed eggs. At least such has been my experience. The best that can be done for a soiled egg is to wipe it with a dry cloth; and, if the matter is important, carefully rasp the thickest of the dirt off with coarse sandpaper. If an egg is washed in either cold or warm water, it will be noticed at once that the "bloom" has disappeared, and a careful egg-buyer would at once pronounce it a stale egg. If only the fourth part of the shell is unsoiled, that part will show that the egg is fresh, because the "bloom" will be there. If you want eggs to keep well or hatch well, I would advise you to keep them out of water. Don't even rub them with a damp cloth. Keep them dry.

FIBRES.

THEIR CHEMICAL EXAMINATION.

(Dr. Dodge.)

In presenting this phase of the study of fibres, I can but refer to the valuable work that has been accomplished in England in the field of chemical research by Messrs. Cross, Bevan, and King, and I

will refer particularly to the Report on Indian Fibres and the work on Cellulose, the latter being a recent publication. The methods adopted in the chemical study of fibres and the processes essential to proper determinations are as follows:—

Moisture.—All the celluloses hold in their ordinary state a certain proportion of moisture, which, within the limits of variation (one-half of one per cent) due to atmospheric changes, is definite and characteristic of each fibre. It is noteworthy that the proportion of hygroscopic moisture is an index of susceptibility of attack by hydrolytic agents; it is certainly true that the textile fibres of the highest class are distinguished by their relatively low moisture. It is scarcely necessary to say that the moisture is determined by drying a weighed quantity of the fibre. It is necessary to raise the temperature to 110° to drive off the whole of the water; at 100° a fibre will often retain one per cent of its weight. Owing to the variations in this constituent, it is expedient to express all the results of analysis as percentages of the dry fibre.

Mineral Constituents.—The ash left on incinerating the fibre is determined in the usual way. The proportion is low in the ligno-celluloses, higher in the pecto-celluloses, especially when the proportion of non-celluloses is high. Cellular tissue further contains a higher proportion of mineral constituents than the fibres, and an admixture of the former therefore raises the percentage.

Hydrolysis.—There are two classes of reagents which intensify that resolving action of water upon organic bodies known as hydrolysis; they are the acids and alkalis. The destructive action of acids has not been included in the scheme of analysis. The action of boiling dilute alkalis, however, effecting a simpler resolution and involving very important points in the practical applications of the fibres, give results which form a necessary part of their diagnosis.

Example of Treatment.—The fibre is boiled (a) for five minutes in a solution of caustic soda (1 per cent Na₂O), washed, dried, and weighed, the loss of weight presents the proportion of the fibre which yields to the solvent action of the alkali; (b) in a second portion the boiling is continued for one hour—the loss of weight is an indication of the "degrading" action of the alkali. In many of the pecto-celluloses the hydrolytic action of the prolonged boiling is such that the non-cellulose is almost completely dissolved away. The power of resistance of a fibre to the action of bleaching processes, as well as the resisting of "wear" of the manufactured fabric in subsequent washings (laundering), where strong alkaline soaps or even chemicals are used, is shown.

Cellulose.—Celluloses, although similar in external characteristics, are of widely different chemical constitution, and vary considerably in their power of resisting the further action of oxidizing and hydrolytic action. A determination of the value and composition of cellulose is made

as follows:—A fresh specimen having been boiled in the dilute alkali (1 per cent Na₂O), is well washed and exposed for one hour, at the ordinary temperature, to an atmosphere of chlorine gas. It is then removed, washed, and treated with a solution of sodium sulphite, which is slowly raised to the boiling point. After two or three minutes' boiling it is washed on a filter when necessary, though in most cases it may be so placed in a funnel as to act as its own filter. Lastly, it is treated with dilute acetic acid, washed, dried, and weighed. The percentage yield on the raw fibre is the most important criterion of its composition and value.

Mercerizing.—This refers to the action of concentrated solutions of the alkalis upon vegetable fibres, particularly the compound fibres or those which are made up of a number of fibrils aggregated into a bundle, the larger portion of fibre consisting of such bundles. The action of the alkali often causes a very profound change in structure, not only dissecting the bundles, but altering the contour of the fibrils. The treatment takes its name from Mercer, whose original studies were for the determination of the structural modification which cotton undergoes when treated with strong alkalis.

Nitration.—When a fibre is exposed for one hour to a nitrating acid, such as a mixture of equal volumes of concentrated nitric and sulphuric acids, one of the most important results which follow is an increase in weight. An external characteristic which should also be noted is colour. A great deal of information regarding the constitution of a fibre is ascertained by this process.

Carbon percentages from Combustion.—This process consists in burning the substance with chromic anhydride in presence of sulphuric acid and leading over the gaseous products (CO and CO₂) into an apparatus in which their volume can be exactly measured. The two oxides of carbon having the same volume, the quantity of carbon in unit volume is independent of the composition of the gas, which therefore only requires to be measured. The carbon in the typical (cotton) cellulose is 44.4 per cent; the compound celluloses, on the other hand, range themselves for the most part into two groups (1) of lower carbon percentage (40-43), (2) of higher (45-50), in the former the pecto-celluloses are included, the ligno-celluloses in the latter. This is considered a prominent chemical constant of the fibre substance.

Acid Purification.—The object of this treatment is to clean the fibre and remove accidental impurities, while occasioning the minimum loss of weight and therefore alteration in composition. For this purpose acetic acid (20 per cent) is chosen, the fibre being heated with the acid to the boiling point, then removed and washed first with alcohol, and lastly with water, dried, and weighed. The loss in weight sustained is thus determined. It is in the fibre thus purified that the carbon percentages are determined

In a report on the miscellaneous fibres in the Colonial and London Exhibition of 1886, by C. F.

Cross, the scheme of analysis is thus briefly stated in tabular form:—

Moisture.....	Hygroscopic water, or water of condition.
Ash.....	Total residue left on ignition.
Hydrolysis (a).....	Loss of weight on boiling raw fibre five minutes in one percent solution of caustic soda.
Hydrolysis (b).....	Loss of weight on continuing to boil one hour.
Cellulose.....	White or bleached residue from following treatment (1) Boil in one per cent. NaOH five minutes; (2) exposure to chlorine gas one hour; (3) boil in basic sodium sulphite.
Mercerizing.....	Loss on treating one hour with 33 per cent solution caustic potash, cold.
Nitration.....	Weight of nitrated product obtained by treatment with mixture equal volumes of nitric and sulphuric acids one hour, in the cold.
Acid Purification....	Raw fibre boiled one minute with acetic acid (20 per cent), washed with water and alcohol and dried.
Carbon percentage...	The carbon in the fibre from above, determined by combustion.

Separate portion taken for each determination. Results calculated in percentage of dry substance.

THE MICRO-CHEMICAL STUDY OF FIBRES.

The microscope is a valuable adjunct to the study of fibres, not only for the purpose of determining the dimensions of the ultimate cell, the thickness of the cell walls, the arrangement of the different kinds of cells in the plant tissue, and the relative abundance of the fibre cells, but all these taken together, with the employment also of certain chemical reagents, giving a ready means of determining the identity of the species of fibre where doubt exists as to the kind of fibre that has been employed in the particular manufacture under investigation. The methods to be pursued in this kind of fibre analysis should be fully understood by the textile student, as well as the industrialist and all others who handle fibres and fabrics commercially.

Among the text-books that may be consulted no better can be suggested than the valuable work of

M. Vetillart, of Paris, who has given many years of study to the subject. As the publication is in the French, it is not readily available to English students. An abstract of the methods pursued by M. Vetillart appears, however, in Appendix B. in the valuable paper "On the Identification of Fibres," which has been specially prepared by Prof. William H. Seaman.

The identification of fibres involves both chemical and microscopic study in many instances microscopic determination only being possible with the employment of the resources of the chemist, and the use of both systems, therefore, is essential. As the work of Professor Seaman covers the ground most thoroughly, a further consideration of the subject here is unnecessary.

PEABERRIES AND MALE COFFEE PLANTS.

Dr. D. Thomatis, commenting on a paragraph in the May number of this *Journal* (1899) on the subject of male coffee plants, writes:—

"As our Government Botanist, Mr. F. M. Bailey, states, the coffee plant is neither *diœcious* nor *monœcious*, but beyond doubt *hermaphrodite*, as clearly shown by the examination of its flower. Why should the abundance of *peaberries* fruit on a tree indicate that it is a *male*? Is not peaberry fruit all the same? And still more, a peaberry seed germinates as readily as a bi-lobed berry. The paragraph says that the cause of peaberry fruit is not definitely known. I am surprised at this statement, as it is very easy to find the cause, which is in the poverty of the soil and the dryness of the weather after the blossoming time, as through these two causes the young fruit could not be fully formed, developed, and nourished; hence only one lobe grew, and the germ of the other became abortive and atrophied, and consequently the single lobe or grain grew in a roundish form, and the fruit, being a single-grained berry, is richer in the essential aroma. If the ground be rich, season favourable, tree well trimmed and pruned, and blossoms thinned, very few peaberries will be produced."

Reporting on the question raised in the paragraph and in the above letter, Mr. Howard Newport, Instructor in Coffee Culture, says:—

In the accompanying letter on this subject, sent on to me for an expression of opinion, I fail to see where the question arises as to why the abundance of peaberries on a tree should indicate that it is a male.

On referring to the article in the May issue of the departmental *Journal* quoted by the correspondent, it would seem that the first mention of the idea was in the form of a contradiction. It is later contradicted by the Colonial Botanist, and is in itself a contradiction. The amount of peaberry on a tree has nothing whatever to do with the sex of coffee.

Peaberry is the result of the failure, for some reason or other, of its fellow-germ to fructify. There are naturally in the embryo berry two cells, and it would appear that under certain circumstances one of the cells, on coming in contact with the pollen, will fructify while the other will not.

That it is so is clear on examination of the peaberry where the atrophied germ is discernable, and its envelope of parchment skin, folded together, still in its place within the "pulp." The reason why the pistils should convey the pollen to one ovule and fail to fructify the other, is the point that is not thoroughly understood yet, and not the state of the tree in which it is most liable to this condition, as your correspondent seems to think.

The peaberry is a malformation, and generally takes place when the tree is weak or in a state of low vitality, and this condition may be brought about by unfavourable conditions of soil, climate, or cultivation. A tree overbearing will produce a larger percentage of peaberry than one with a more moderate crop, even though conditions of soil and climate are as favourable as could be desired.

The shape of the malformed growth is somewhat as your correspondent states. It was thought at one time that it was the production of a special variety of coffee-bush—at any rate, by those who had to do only with the cured article; and there are many yet that still adhere to this fallacy, due chiefly to the fact of its being graded separately.

Peaberry obtains its higher value in the market chiefly on account of the advantage of its shape in roasting. Being easier to roast uniformly, it is supposed to contain a greater percentage of caffeine or aromatic properties, but this is exceedingly doubtful. Its presence on the tree is of doubtful advantage also. A large percentage of "P.B." grade—indicating, as it does, impaired vitality—although its price is enhanced, is yet a long way short of the value of the double bean in the normal growth.

As a seed for propagation, "P.B." germinates readily, but repeated experiments have been able to show no advantage in the growth, stamina, or bearing capabilities of its production over that of the bi-lobe; nor does the plant raised from a peaberry show any special tendency to produce peaberries.

"*Male*" Trees.—The coffee-tree is, as is well known, hermaphrodite; it is also well known that in such cases generally the contact of pollen from another tree or blossom obtains better results than its own pollen. It may be, therefore, that the peaberry is due, to a certain extent, to continued self-fertilising of the plant or "inbreeding."

It is supposed that the plant commonly called the "male" coffee-tree is due to this cause. However this may be among seedlings in a nursery, there is always found a small percentage of plants that appear with long narrow leaves, eyes closer together than ordinary, and a smaller and more stunted growth altogether.

In cultivating these in the field, it is found they bear very little, although they blossom freely. (I have never yet met with one that did not bear at all.) The flower is somewhat smaller than that of the ordinary tree, but would structurally appear to be identical. It is supposed that the want of fertility is due to some malformation of the stigma or ovules, since the pollen is perfectly fertile when applied to other blossoms.

This tendency to produce blossom that will not fertilise, yet will fertilise others, has earned for this long-leaved tree the sobriquet of "male" coffee. Whether the presence of such trees in an estate is Nature's own remedy for a too long-continued course of "in-breeding," and is, therefore, of advantage, is a moot point. Generally the plant is considered useless and unnecessary (since the other trees, being hermaphrodite, can do without it), and since it bears so little, is not considered "worth its keep." It is, therefore, usually picked out and thrown away as early as it shows the telltale narrow long leaf in the germinating bed or nursery.

PRESERVATION OF EGGS.

The following is a report of experiments made at the Central Experiment Farm, Ottawa, Canada, of the two methods usually considered the best of preserving eggs. The experiments were conducted by Mr. Frank T. Shutt, chemist, Dominion Experiment Farm, and Mr. A. G. Gilbert, the poultry manager. Having received numerous inquiries from farmers during the past two months respecting the merits of "water glass" as a medium in which to keep eggs, we are led to think that certain conclusions drawn from an experiment, lately brought to a close, with this and other preservatives will be of interest to your readers. The investigation was commenced last September, perfectly fresh eggs from the farm poultry house being used for the test, which consisted in immersing the eggs for varying lengths of time, from a few hours to six months in (a) limewater, and (b) 10 per cent. solution of "water glass." Those eggs which were treated for a few hours, days, or weeks, as the case might be, were subsequently placed, together with the untreated eggs to be used as a check, in a rack within a drawer in the laboratory till the close of the experiment, 30th March, 1899. All the eggs were at a temperature from 65 degrees to 72 degrees Fahr. throughout the trial. The testing consisted in breaking the eggs into a glass and noting the appearance of the "white" and yolk, whether the yolk was stuck to the shell, size of air-space, odour, &c. The eggs were then poached and again the odour, appearance, &c., noted. Without giving in detail the results of the various trials, it may suffice for the present purposes to summarise the conclusions reached, as follows:—

CONCLUSIONS.

1. In no instance, either of treated or untreated eggs, were any "bad" eggs found.
2. In all cases where the eggs were not kept covered throughout the period of the test with the preservative solution, shrinkage of the contents had taken place, as shown by the larger air-space, less globular form of the yolk, and in many instances by the adherence of the yolk to the shell. The eggs treated for seven days and less with limewater showed somewhat less shrinkage than those treated a similar length of time with silicate of soda.
3. It would appear that limewater and "water glass" used continuously are equally efficacious in preventing shrinkage. They may also be said to give practically the same results as regards both

external and internal appearances, flavour, &c., of the eggs preserved. Since "water glass" (silicate of soda) is more costly and more disagreeable to use than limewater, we could not from the present results recommend the former as the better preservative.

4. The albumen or "white" in all the preserved eggs was very faintly yellow (though not to the same degree in all the eggs), the tint becoming deeper on boiling.

5. No offensive odour was to be perceived from any of the eggs when broken, but in all instances a faint but peculiar musty or stale odour and flavour developed on poaching.

6. It is probable that no preservative will prevent the loss of flavour possessed by the fresh egg, but those which wholly exclude the air (and thus at the same time prevent shrinkage from evaporation) will be the most successful. Continual submergence is evidently better than treatment for a few days. The limewater may be made by putting 2 or 3 lb. of good fresh lime in 5 gallons of water, stirring well at intervals, for a few hours, and then allowed to settle. The clear supernatant fluid can then be poured over the eggs, which have been previously placed in a crock or water-tight barrel.

Some authorities recommend the addition of 1 lb. or so of salt to the limewater, but the writers are of the opinion that this is unnecessary, and probably leads to the imparting of a limy flavour to the eggs by inducing an interchange of the fluids within and without the egg. The all essential points to be remembered are:—(1) The eggs to be preserved shall be perfectly fresh, and (2) that they shall be covered with the preservative fluid.

GENERAL ITEMS.

The extent of mortality in Sind amongst cattle, due to the famine, may be judged from the fact that one Trading Company alone has already purchased three million hides for shipment. Up to the present time the cattle have suffered more acutely than the people. This is partly due to the promptness with which relief works have been opened, and partly to the rapidity with which grain has poured in from other Provinces by the natural operation of the law of supply and demand.

The stimulus given to the hide trade by the famine is not confined to Western India. The returns show a jump from nineteen to forty-nine lakhs of rupees in the value of hides exported from Calcutta in November, as compared with the corresponding period a year ago. The increase thus amounts to thirty lakhs in the same number of days, all classes of skins sharing in the advance.

The report of the Governor of Trinidad furnishes an agreeable contrast to the stories we have so often been told of the ruin of the West Indies. Writing in July last, Governor Knollys says: "There is no doubt that at the present moment Trinidad is more prosperous than it has ever been before."

In connection with the question of the appointment of scientific experts for the investigation

of questions connected with the cultivation and manufacture of Indian tea, the Committee of the Indian Tea Association has recommended the engagement of an experienced Agricultural Chemist, recommended by Dr. Voelcker.

The Director of Agricultural Education to the Gloucestershire County Council, Mr. Howman, has carried out a series of interesting experiments in the manuring of fields. Plots of $\frac{1}{4}$ -acre each have been annually manured under five different systems. Basic slag was used alone and in combination with nitrate of soda. Bone meal was used with mineral superphosphate in a third case, while the two remaining plots were manured with kainit and gypsum. The quantities of each manure used are not given, but the following is the cost per acre:—For slag, 15s. 8d.; for slag and nitrate, 26s. 8d.; for bone meal and superphosphate, 16s. 8d.; for kainit, 7s.; and for gypsum, 5s. 6d. The whole of the plots on two different fields were manured five years ago, and have not been manured since. In 1895 the plot receiving slag alone returned an increased value per acre of 2s. 4d.; 1896 the field was grazed; in 1897 the increased value was 59s. 4d.; in 1898, 35s. 6d.; and in 1899, 51s. 8d.; or in all £7 8s. 10d. for four years. Where slag and nitrate were employed, the increased value as compared with slag alone was slightly more in 1895 and 1897, but less in 1898 and 1899; the total increased value for the four years being £6 4s. The bone meal and superphosphate gave a total increased value of 22s. 8d., the kainit of 2s., and the gypsum of £1 18s. 8d., so that the slag proved the most useful manures.

Mr. A. N. Pearson, Government Agricultural Chemist, Victoria, writes:—Bones in country districts, where crushing mills are not available, may be reduced by means of caustic lye, quicklime, or freshly calcined wood ashes. A simple plan is to pack the bones, layer by layer, with the calcined wood ashes taken fresh from the fire, in a barrel, cover the whole with a thick layer of soil, and keep the mixture moistened for some months. Casks may be kept in constant use for this purpose on a farm, receiving every few days a fresh layer of bones and ashes, removing the layer of soil for the purpose, and freshly calcining any old ashes that may have accumulated. A quicker method is to boil the bones in an iron or copper boiler with strong caustic lye. The proportions of bones and lye are not invariable, but may be taken as about 10 lb. caustic soda or 14 lb. caustic potash, dissolved in 3 gallons of water, to 30 lb. or 40 lb. of bones. The bones boiled for two or three hours in this lye should be completely disintegrated. Even without boiling, the lye will, in a week or so, disintegrate the bones. Another method of softening bones is to mix them in heaps with quicklime and loam. A layer of bones 6 inches deep is made, and on this is placed a layer 3 inches thick of quicklime, and then a layer 4 inches deep of loam. The layers of bones, lime, and loam are repeated until the heap is of a convenient height, when it is finally covered with a thick layer of earth. Holes are then bored into the heap from the top, and water

poured in to slake the lime. The mass becomes hot, and will remain so for two or three months, after which the bones should be very friable. The whole heap may then be mixed up, and used on the ground at rate of 10 cwt. to the acre.

Watering is a question which perplexes many an amateur florist. How often shall I water my plants? How much shall I give at a time? Over and over these queries are made by correspondents. To which I can make but one reply: There is no hard and fast rule about watering plants. There can be none, because conditions under which plants are grown differ so widely that what would apply in one case would fail to do in another. But we have a general rule which is subject to such modifications as observation and intelligent study of one's plants seem to make necessary, and that rule is this: Wait until the surface of the soil in the pot looks dry, then apply water, and apply enough of it to thoroughly saturate all the soil in the pot. You can tell when this is done by the escape of some of it through the drainage hole in the bottom. Then wait again until the dry look comes on the surface before applying more. Of course Callas and other plants of a semi-aquatic nature will require more water than others like the Geranium and the Rose, and here is where study and observation must come in to enable you to care for your plants properly. To be a really successful plant grower you must understand the nature and habit of every plant in your collection, and so vary your attention as to give each plant the particular care it requires. One of the chief charms of flowers growing consists in this study of plant life. We take it up at first because we want to give our plants the attention they need in order to make a satisfactory development. In a little while we have become so interested in it that we continue it for the pleasure it affords us. It is a fascinating study. It is a study in which there is always something more to learn.

The Annual Report of the Department of Agriculture says:—Rice being a crop more especially adapted to the North, did not come under the ban that was placed upon the grain crops that are grown in the South, and was favoured with a good season. This is becoming a staple grain crop in that part of Queensland, the area for 1898 showing an increase of 418 acres over 1897, that for the former year being 863 acres, with a yield of 38,133 bushels, or an average of 44.19 bushels to the acre, as against 29.19 for 1897. Hitherto rice has been in the experimental stage, has been grown in many parts of the colony, and has fluctuated in area as success or non-success has been met with. It is, however, now settling down to be the property of the Northern district, and it is to that part that the future supply may be looked for, for it behoves the farmers to be careful to grow the variety to suit the market, for of all grains rice is most subject to prejudice and favouritism. It is the grain that in the largest quantities comes into the hands of the consumer in the form that is most nearly allied to the original state, and so is dependent upon the fancies of the consumer for the variety that shall command

the highest price. From the figures of the Registrar-General, Queensland at present produces 14 per cent. of its annual consumption, the statistics being—Production (estimated at the rate of 162 lb. of paddy to the 100 lb. of clean rice), 1,318,176 lb. of clean rice; and the imports, 8,235,564 lb., of a value of £49,456. The principal district for rice is that of Cairns, which produced 82 per cent. of the total yield, 708 acres being cropped for 33,540 bushels, or an average of 47·30 bushels to the acre.

There are many so-called remedies for warts on animals which are more or less non-effective. The latest we have heard of appears to have proved successful in the case of dogs. A gentleman in England had a beagle puppy whose mouth, tongue, lips, and face were covered with white warts closely packed together. Several so-called remedies were tried without result, and the dog died, choked. A year or two after he had a cob with warts over the shoulder, neck, and face, when, either in print or from hearsay, he learned that warm bullock's blood would remove them. This was tried, on the principle that if it did no good it could do no harm; result, after two or three dressings the warts disappeared, and did not come any more. Another case. Five years ago he had six greyhound saplings, whose mouths, tongue, and lips, outside and in, were covered with warts. It was two days after discovery before he was able get to the butcher when killing. By this time a fine crop of warts had developed. The method was this: As soon as the bullock was knocked down and stuck, the dogs' heads were dipped in a bowl of the live blood, and all the parts affected were well rubbed with it while warm (after it begins to clot or solidify it is no use). The day after the first dressing the warts turned brown. Two days after they were dressed again. The following day they (the warts) began to get soft, and looked rotten, many of them falling out on being handled. After two days, dressed again, when they all disappeared, leaving small marks such as small-pox leaves. After a time nothing could be detected at all. He gives this as his experience. At all events, it is harmless and painless, and the price of a pint or two to the butcher is not costly. This remedy might be tried in the case of fowls.

Warts on chickens may, however, be absolutely cured by dipping the fowls' heads in urine. After a few applications of this remedy the warts disappear. We cured nine valuable Cochiti chickens in this manner, whose heads were a mass of warts.

The *Pacific Rural Press* describes as follows the system of propagating trees from cuttings with the aid of nurse roots. It is of especial interest in the relation it bears to the important discovery claimed by Secretary Lelong, of the California State Board of Horticulture, as to propagation by aid of "mother roots":—If you take a cutting of almost any kind and make a side cut upwards a little above its base, and insert in this cut a piece of the root of the same kind of a plant cut with a wedge shape at the top so as to fit closely in the cut in the cutting, this root will quickly callus itself to the cutting, send sap into it and start its growth. If the cutting were planted without this "starter" root, all the moisture might evaporate from its tissues (which is death to a cutting) before it can establish roots of its own to supply it with sap. Thus this root piece becomes a nurse to the cutting until it is able to take its own nourishment, as it soon will by means of roots emitted from its own tissue. There is no recent discovery about this. It has been known for generations and has been employed in the propagation of all sorts of plants. It is simply one of the many forms of root grafting. If it is desired that the cutting grow upon its own roots alone, it is taken up at the end of the first season's growth and the nurse root is cleanly cut out and the well-rooted cutting is replanted. If it does not matter whether it grows upon its own roots and the enlargement of the nurse root (which is generally the case) it is allowed simply to go ahead as it likes. All roots on root grafts are nurse roots, more or less, because in almost any underground grafting you will have roots from the scion unless you take pains to replant with the whole of the scion or cutting above ground. This work can be done with cuttings of greater or less maturity. If you take last year's wood from a bearing tree you will, of course, get fruit in a year probably. If you take a cutting from a tree not yet in bearing you will have to wait longer. The speed of fruiting will be conditioned upon the age of the tree, and its habit of bearing upon wood of one or two years' maturity.

* The TROPICAL AGRICULTURIST *

◇ MONTHLY. ◇

Vol. XIX.

COLOMBO, MARCH 1ST, 1900.

No. 9.

RINDERPEST.*

BY G. W. STURGESS, M.R.C.V.S.,
GOVERNMENT VETERINARY SURGEON, CEYLON.

SI am constantly being asked for information as to what should be done with the view of guarding against an attack of this disease and its suppression after it has broken out, I propose in a few notes upon the subject to state as simply and clearly as possible the position at the present time, and the precautions which owners of cattle can adopt.

* CATTLE DISEASE.

Kandy, Feb. 23.

The Editor, Tropical Agriculturist, Colombo.

SIR,—With reference to the annexed copy of minute and resolution passed at a recent meeting of the Committee of the Planters' Association, I write to ask you whether the accompanying paper on Rinderpest would be acceptable to you for reproduction in the *Tropical Agriculturist*.—I am, sir, yours faithfully,

A. PHILIP,

Secretary to the Planters' Association of Ceylon.

MINUTE AND RESOLUTION REFERRED TO.

Read letter from the Government Veterinary Surgeon, Colombo, transmitting his paper on Rinderpest and adding that he was leaving the island for South Africa, and that owners of cattle should report any case of Rinderpest to the Government Agent without delay who would inform the Veterinary Department; trained inoculators are kept in readiness and would be sent when required. Resolved:—"That the thanks of the Association conveyed to Mr. G. W. Sturgess, M.R.C., v.s. Government Veterinary Surgeon, Ceylon, be confirmed and that his paper be published."

[Dr. Sturgess's paper, which we now publish, will be of interest and value to all stockholders—European and Native.—ED. T.A.]

QUARANTINE.—The question of the subjection to quarantine of all cattle imported into this country I have recently raised, and it is under the consideration of Government. Apart from that, I would advise that all fresh cattle purchased should be kept apart from the remainder of the estate cattle for a clear week as a precaution not only against rinderpest but several other less serious diseases. A cadjan shed can without much cost be provided for this purpose whenever cattle are purchased. If after this period the cattle exhibit the usual signs of health and have a normal temperature they may be regarded as perfectly safe.

TEMPERATURE.—The average temperature of cattle in health is 102 F. As a maximum 103 F. and as a minimum 101 F. may be taken. Any animal with a temperature over 103 F. should be regarded with suspicion. The temperature is taken at the rectum by means of a clinical thermometer.

RINDERPEST.—It is a highly contagious and infectious disease. It principally attacks cattle, but during a bad outbreak the smaller animals such as sheep, deer, goats may also be attacked, yet do not suffer so severely as cattle. It is communicated from one animal to another mainly by cohabitation; it may be carried short distances by the air. It may be spread by animal agency and by discharges from sick animals for long distances. The period of incubation is from five to ten days, and cattle recover or die in about the same time. The vitality of the virus in the nasal and other discharges is probably about a fortnight when exposed to the air, especially to the tropical sun; in buried carcasses it is probably several months.

SYMPTOMS.—There is elevation of temperature some days before the more marked symptoms appear, and animals may be ill and capable of communicating the disease before the more severe symptoms are exhibited. One of the earliest in many cases is puffing of the stomach resembling

ordinary indigestion. After a time the animal appears dull and dejected and loses its appetite. There may be twitching of the muscles of some part of the body. Usually at the outset there is constipation, soon followed by diarrhoea with blood in the discharges, which becomes worse as times goes on and has an offensive odour, the term "rice water diarrhoea being applied." Membranous casts resembling strings of flesh may be passed. The posterior bowel is intensely red and inflamed, and in the last stages protrudes from the anus.

There is a discharge from the eyes and nose which is irritant and often causes sores around the nostrils. The lining of the mouth becomes red and inflamed, and ulcers may be found inside the lips,* red patches may be seen inside the thighs of males and in females around the udder and vulva and inside the vagina. In the later stages the animal has a miserable appearance and may give low moans, emaciation goes on rapidly, the eyes sink and there is utter collapse and death.

PRECAUTIONS TO BE OBSERVED WHEN AN OUTBREAK OCCURS OR IS SUSPECTED.—When an animal falls ill in a herd exhibiting the symptoms of the disease it should be at once isolated in a shed as far away as possible from other cattle. As fever is one of the earliest symptoms, the temperatures of the remainder should be taken every day, and any showing high fever over 103 F. should be removed and isolated. In this way an animal can be picked out before it spreads the infection to its neighbours. It is as well to have two sheds, one for animals having a high temperature suspected to be developing the disease, and the other where those that develop the disease can be taken. Sacks soaked in creosote and water ($\frac{1}{2}$ teacupful to a bucket of water) or carbolic acid and water should be hung up in all the sheds for disinfection. The walls and floors should be sprinkled with the same solution or Jeye's fluid and water. The cattle should not be allowed to drink all from one vessel.

As an aid to prevention *all* the animals may be given ten drops of Jeye's fluid daily in their food. After three or four days' use it should be discontinued for a couple of days and then given again.

It is obvious that an owner should prevent his cattle coming into contact with other cattle as much as possible during an outbreak in a district and should not allow outside cattle to come on the estate, or cart manure from an infected village to the estate.

TREATMENT OF SICK ANIMALS.—Very little can be done in the way of treatment, but the following I have found most useful:—

Quinine	1 dram
Arrack	$\frac{1}{4}$ bottle
Rice Congee	4 bottles
(Mixed.)	

To be given once or twice a day for a week or longer if necessary.

Ten drops of Jeye's fluid may also be given daily.

* They differ from the blisters of Foot-and-Mouth disease, being *cracks* in the skin, while the superficial layer of the skin is raised in the form of a blister in Foot-and-Mouth disease, and in the latter disease the feet are sore as well.

AS FOOD.—Rice congee, scalded bran, or bovinia and water. No hard food such as straw or grass should on any account be given until convalescence is well established, and then very gradually.

If there is violent diarrhoea a few doses of the following powder will be found beneficial:—

Prepared chalk	2 ounces
Powdered catechu	$\frac{1}{2}$ ounce
Powdered Gentian	$1\frac{1}{2}$ ounces
(Mixed.)	

To be given in a quart of congee.

INOCULATION.—When Rinderpest made its appearance in South Africa and became so widespread, scientific experts were got out to endeavour by experiment to find out a method of protective inoculation. After some time Professor Koch pointed out that the contents of the gall-bladder, the "bile" possessed protective properties when taken from an animal dead from rinderpest under certain conditions. This is the "*bile method*." Later it was found that the blood of an animal that had recovered from the disease had protective properties in a mild degree. By injecting such an animal with gradually increasing doses of virulent rinderpest blood it was capable after a time of giving a blood serum of high protective value. This is the "*serum method*" and all the others are modifications of the two.

The bile method is simple and can be carried out without much difficulty. The material is always at hand whenever the disease breaks out. The serum method requires a properly equipped rinderpest station and laboratory in order to produce the serum.

The bile method affords protection for three or four months and repetition is necessary; the serum method also only gives temporary protection to healthy cattle, but it has been demonstrated that if cattle are inoculated with serum when developing the disease *as soon as* the temperature rises more or less permanent protection is given. A mild attack is contracted and a great many animals recover, but some losses occur.

The following are the details of the bile method which I published in 1898 (*vide* Ceylon Sessional Papers), and as far as I have gone with it—some one hundred cases—the results have been satisfactory. When properly and clearly carried out the cattle have not suffered any inconvenience and have returned to their work in about ten days.

THE BILE.—In a good percentage of fatal cases of rinderpest the bile will be found good for the purpose of inoculation. It should be dark-green in colour, perfectly fluid, free from shreds of the lining membrane of the gall-bladder, and from any odour of decomposition. A good number of instances occur where the bile is unfit for use, being yellow or dark-brown in colour, ropy in consistency, and containing shreds of the mucous lining of the gall-bladder. Such bile is poisonous and useless. The best bile is that obtained from an animal that has suffered severely from rinderpest for some days, or better if it has succumbed to the disease. It must be taken before decomposition of the body commences. In instances where it has been good I have noticed it was very abundant in most cases, a half to one pint being easily obtained.

METHOD OF TAKING THE BILE.—Great care must be taken in removing the bile in order to avoid contamination by blood, or contents of the

intestines, or by fluid of any kind in the abdominal cavity.

N.B.—The carcass should be placed on the left side and the abdominal cavity opened by cutting along the middle line from the breast-bone to the pubis and behind the last rib down to the back-bone. An assistant can then raise the flap, and the liver and gall-bladder lying underneath the ribs are well exposed.

The gall-bladder should be slightly raised with the hand, and if dirty washed with a weak solution of bichloride of mercury (corrosive sublimate) in water (1 in 1,000 or 10 grains to the pint). An assistant holds a glass jar against it (taking care not to allow any blood or extraneous matter to enter), and it is then punctured with a sharp knife and the bile allowed to flow into the jar. A glass cover should be placed over the jar when the operation is finished. The hands, jar and instruments should be well washed and rinsed with the bichloride of mercury solution and dried. If several good samples of bile are obtained they should be mixed together and left for several hours before using. The bile should keep good for at least 24 hours if kept cool and in a covered vessel.

METHOD OF INOCULATION.—The animals should be cast and the legs tied. Ten cubic centimetres (about three drams) of bile is then gently injected under the loose skin in front of the chest (dewlap) by means of a 10 cubic centimetre hypodermic syringe and needle. As the needle of the syringe is withdrawn the skin should be pinched between the finger and thumb at the point of insertion, to prevent any of the bile coming out again and to close the wound. The part should be gently squeezed to insure distribution of the bile in the subcutaneous tissue. Protection is given in 10 days.

After inoculation cattle should not be worked for ten days. A swelling forms at the seat of inoculation and gradually subsides. There may be a little fever. The method is only of service when the cattle are free from the disease; if they have contracted it before inoculation it is of little service as protection is only afforded after *ten days* from date of inoculation.

Probably in some cases the bile may not contain the protective property to a sufficient degree, and some inoculated animals may develop the disease after inoculation and die, but this does not detract from the general usefulness of the method.

The disease in Ceylon is usually confined to areas and appears at intervals—sometimes long intervals—and as the “serum” method of inoculation on healthy cattle only confers temporary protection similarly to the “bile” unless applied when the animals are developing the disease, which would necessitate “salted” animals being kept at a high degree of immunity so as to be capable of yielding the proper serum from their blood at once whenever the disease broke out. It takes several months to bring cattle to this stage by injecting increasing doses of virulent blood from an animal suffering from the disease. The preparation of the animals and serum could only be done at a properly isolated rinderpest station.

While favouring the permanent protection by serum, applied when the animals are past developing the disease (it is very plain to anyone I think how difficult it would be to apply this in this country). I think the bile method will answer our purpose combined with proper care in carrying out the simple rules of isolation and disinfection

as applied to any contagious or infectious disease, at least until further investigation has perhaps shown a more useful and permanent method.

In South Africa evidence tends to show that it is possible for pure rinderpest bile to communicate the disease when injected into an animal.

Bile can be kept for some time by mixing it with glycerine, one part of glycerine to two parts of bile. It should be kept 48 hours before using.

This is quite safe (due to the action of the glycerine) and it is said to be of service as a curative applied to sick animals. From fifteen to thirty cubic centimetres can be injected either under the skin in front of the chest, or into the jugular vein when it exerts its action at once.

I do not advise indiscriminate inoculation. When disease breaks out in a district I would use *pure* bile amongst the *infected* herd, in doses of 10 c.c. (for very big animals 15 c.c. may be used), and for *clean* herds in the immediate vicinity an injection of 20 c.c. of *glycerinated bile*, and 10 days afterwards and injection of 10 c.c. or 15 c.c. of *pure* bile taken from an animal that has died from rinderpest, which will confer a fairly strong protection.

G. W. STURGES, M.R.C.V.S.,
Eng. Govt. Vety. Surgeon, Ceylon.

THE GEOGRAPHY OF TEA.

Having acquired, by travel in several of the principal places of production and in most of the important countries of consumption, a personal knowledge of the geographical distribution of the Tea plant in growth and of its product in consumption, I put together the results of my experience as a contribution, to the sum of commercial geography. This subject is not one of general importance to an International Congress, the areas of production and distribution being so comparatively limited, but it presents certain aspects of interest to the student of geography, and those I propose briefly to deal with.

It is doubtful if we ever shall be able to trace at what period in history an infusion made from the leaves of the Tea plant was first introduced as a beverage for domestic consumption, or how it was discovered that those leaves yielded a palatable drink when treated in the now familiar manner. Nor are we ever likely to know definitely when or how the regular cultivation of Tea shrubs was adopted in China as an agricultural industry, but it is probable that as our knowledge of China and its history increases, by reason of the developments now taking place there, we may gradually learn more of the past and we may possibly find authentic books dealing with the subject. At present we have little more than myth to go upon, and most of it is not worth treating seriously.

It is claimed that reference can be traced to the use of Tea in the writings of a Chinese author of about 2,700 B.C., but the earliest date that the article may be said to be of interest in connection with commercial geography is when it began to be exported. Even that period is difficult to fix, but during the 8th century A.D. it had become an article of taxable value, and probably soon after that the growing of it was commenced in Japan, although the cultivation of it there as an agricultural product does not seem to have begun till the 13th century.

The special points relative to the commercial geography of Tea, to which I wish to direct attention, may be grouped under three headings—

1. The principal localities of growth.
2. The principal areas of consumption.
3. The principal trade routes for transit.

(1) THE PRINCIPAL LOCALITIES OF GROWTH.

In the popular mind China still stands as the great producer, and, although reliable statistics of internal production and consumption are difficult to obtain, it is probable, having in view the immense population of that vast empire, and the very general use there of Tea, that the Chinese production is in respect to total quantity much the most important. But China is no longer regarded as the home of the Tea plant. Investigations have fairly and reasonably proved that Tea is indigenous to the valleys of Upper Assam, and, proceeding upon the theory that a plant will thrive and develop best in what is its place of origin, the conclusion has been formed that the Tea plant of China is merely a debased variety of the indigenous Indian growth.

Probably Manipur was the birthplace of the Tea plant, as the variety of Tea known by the name of that native state has been the most successful and the most continually in favour with the planters. This state, lying just outside the tropics—an extensive valley with numerous hill ranges around it, densely clothed with jungle and large timber—seems to have developed those striking characteristics of the *Thea Assamica* which differentiate it so markedly from *Thea Sinensis*. In a climate where there is an abundant and fairly well regulated rainfall and a moist, steamy atmosphere with a cold, dry season to rest and ripen after growth, the Tea plant attained its highest development. Its existence in India and the native states bordering there-upon was unknown or at least unacknowledged till 1834; but as the Province of Assam was gradually explored and became developed by the constantly increasing Tea industry, there were found scattered through it and the adjacent districts many tracts of indigenous Tea. (See Note at end.)

Those considerations have given a fairly reasonable basis for the theory that the Tea plant made its way gradually eastwards along the lower slopes of the mountainous range lying just north of the Tropic of Cancer for some 30 degrees of longitude from the Brahmapootra Valley eastwards. At various points of the intervening distance can be found connecting links—say in Upper Burmah—until Tea is found in cultivation in Yunnan, the westernmost province of China. But the Tea, which in the jungles of Assam is often a tree 9 metres and upwards in height, has become merely a bush and so different in its general appearance that the hotanists to whom the early discovered specimens of *Thea Assamica* were submitted may be pardoned for deciding that the latter was not Tea at all. The climate and soil of China, though suited to maintain life in the plant, do not induce the rank, quick, vigorous growth which an Indian plantation exhibits during fully half of each year, and in China the recovery of the bushes after plucking is much slower. The individual leaves are smaller and the flavour of the infusion made from these is so absolutely different from the other that even an untrained palate can recognise the contrast.

Minor differences however in that respect exist between the Teas grown in different districts of the same country, and even between plantations on opposite sides of the same valley or the same hill; situation, soil, elevation, climate and temporary climatic or weather conditions, all having a material influence upon both the appearance and the flavour of the manufactured article, and altering more or less its characteristics.

From Yunnan the cultivation of Tea doubtless spread eastwards and northwards, crossing ultimately from the mainland to the Island of Formosa and later to Japan.

Until well on in this century no effort appears to have been made to remove from Mongolian hands the monopoly of the Tea production, but when the Honourable East India Company lost in 1833 their monopoly of the China Tea Trade, the Directors set themselves to ascertain whether or not it was possible to secure for their own territories the sup-

plying of a portion of what had become to them a very material business.

Vigorous but ill-advised efforts were made to introduce the cultivation of Tea into India, and seeds and plants of the debased China variety were imported. With those came Chinamen and Chinese methods of planting, cultivation and manufacture—much to the detriment of the industry, the following 40 or 50 years being occupied in getting away from everything Chinese, and through the costly experience of mistaken and misdirected effort, the poor planter and investor acquired the excellent methods upon which the Indian Tea production is now worked—worked so excellently indeed as to have practically destroyed the export trade for certain classes of the Tea produce of China. Clearances of jungle were made, including tracts of the indigenous Assam variety not then recognised, and the extensive province of Assam with its magnificent waterway was gradually opened up, the greater part of its area being carefully explored in the light of Tea possibilities with a thoroughness that might gratify any geographical society.

Following the success in Assam, Tea was planted in various parts of Bengal and other provinces of India, with more or less success until in 1897 the area was officially stated to be equal to 200,000 hectares. The greatest success has been along the line just north of the Tropic of Cancer, in the latitude where the principal part of the Chinese cultivation lay.

So far, reference has been made merely to Tea grown either in its natural habitat or in territories to which it may be said to have extended naturally, or by assistance, in a lateral direction.

But the two largest developments of production outside of India, China and Japan, have been on the Islands of Ceylon and Java,* both lying as to longitude in or near what might be termed the Tea belt, and about equidistant from the Equator, one to the north and the other to the south. In those the existence of high mountains, heavy rainfalls and climates forcing continuous growth have made the production of Tea commercially successful, although on lines materially differing from those followed in both China and India.

Other minor cultivations of Tea, have been attempted in Natal, Mauritius, the Straits Settlements, the Caucasus, Fiji, Johore, Brazil and many other places, including South Carolina, (U.S.A.), but none of them can be regarded as commercially successful on a Free Trade basis.†

(2) THE PRINCIPAL AREAS OF CONSUMPTION.

If it is a curious and interesting fact that almost the entire production for the world, of Tea, is raised within an area confined by 40 degrees of latitude and 60 degrees of longitude, it is equally curious that the consumption shows itself to have strictly geographical limitations. Outside of the domestic consumption of China and Japan, regarding with no reliable statistics can be obtained, the principal Tea drinkers are the people of Great Britain, Ireland, and of the British Colonies, the people of Russia and those of the United States of America.

Excluding the requirements of those Mongolian peoples, the world's consumption of Tea may be taken roughly at 230,000,000 kilogrammes of Tea per annum, a quantity which, including cost of transportation to the countries of consumption, but excluding revenue duties and distributive profits, may be valued at about £17,000,000. The huge volume of this will be better appreciated when it is stated that the large

* Java is far behind Ceylon in the production of tea.—ED. T.A.

† In the discussion upon the paper Captain Vasconcellos, Secretary of the Geographical Society of Lisbon, of the Portuguese Colonial Office, added to this list, the Azores, where, on the Island of San Miguel, Tea has been produced in sufficient quantity to allow of exportation to Portugal of an excess beyond local requirements.

passenger liner, the "Kaiser Wilhelm der Grosse," would have her cargo space entirely filled 232 times over were she engaged transporting it. To put it another way, the quantity of dry Tea leaves is sufficient to make an infusion of 28,000,000,000 litres of liquid Tea, or 100,000,000,000 ordinary tea-cups, being one for each day of the year for every five persons of the present estimated population of the entire world.

The Southern Hemisphere ranks lightly in the matter of population, and its Tea consumers live south of the tropic of Capricorn in South Africa and Australia; but if they are few relatively they consume heavily, the average consumption per head in Australia being nearly 4 kilogrammes per annum.

In the Northern Hemisphere (again excluding the races who consume their own produce) the material consumption of Tea is in regions lying 40 degrees north and above it, but here there is an interesting sub-division to be made. In the United States and Canada, in some portions of Europe and of Asia, and along the north of Africa there is a free use made of green or unfermented Teas with pale pungent infusions. The demand for such, as a general rule, lies principally in lower latitudes, while the further north the consumer lives he seems to require more of the black or fermented Tea of India, Ceylon or China, with the dark, thick, heavy liquor its infusion produces.

Great Britain and Ireland take much the largest total of imports, the quantity in 1898 being 107,000,000 kilogrammes, but per head this only amounts to 2.65 kilogrammes per annum of the population, or a good deal less than is taken by the British Colonies in Australasia.

Next to Great Britain comes Russia as a consumer of 42,000,000 kilogrammes, but that only represents about .34 kilogramme for each of the population, the poverty and not the will of the people probably accounting for the small figure, as they are really great users of Tea, but take it exceedingly weak, and draw the spent leaves until no colouring matter is left in them.

The United States is a large consumer in point of total—31,000,000 kilogrammes, but this is only .41 kilogramme per annum for each of the population, although the United States people are great coffee drinkers, taking 5 kilogrammes per head per annum of coffee. Besides, the population is of such a composite character that it includes many people not by descent Tea drinkers.

Except Canada, which follows the customs of its mother country and sister colonies by consuming about 2 kilogrammes per head per annum, and Holland, which takes roughly $\frac{1}{2}$ kilogramme per head there is no other country whose consumption, either in total or per head calls for special notice.

(3) THE PRINCIPAL TRADE ROUTES FOR TRANSIT

is perhaps for geographers the most interesting section of this subject.

In the absence of authentic knowledge as to the early history of Tea cultivation, and of the origin and extension of the tea-drinking habit, we may take it there was little or no foreign trade in the article until the Dutch carried small quantities of it to Europe.

Probably some left the North of China in caravans as it does to this day, and there may have been some trade done with Mongolia and possibly Siberia, but there is no record of it ever having been brought to Wisby in Gothland, the great mart for Oriental produce during the 11th and 12th centuries. There is also no reference made to Tea commerce or to Tea drinking in the travels of Marco Polo, so he probably either did not observe the habit, or if he did it did not strike him as worthy of notice.

Starting with the introduction above referred to in the 16th century, the use of Tea in England made slow progress, but a public Teahouse was opened in London in 1657, and in 1678 the import to the Honourable East India Company was 2,138 kilogrammes.

A century later it reached 2,600,000 kilogrammes per annum, and early in this century the figure was 10 $\frac{1}{2}$ millions, but that represented the supply of many countries besides England, as London was then, and until recently, the common warehouse and market for the world, and England the common carrier.

Throughout the century, fairly steady and rapid progress has been shown—especially in its earlier periods—in the trade from China, which reached its maximum in 1879. And it is here that some of the romance of commerce comes in.

As the trade grew in importance, the advantages of rapid transit for the Tea of New Season's production began to be appreciated, and the slow and stately progress of the old East Indiaman grew out of date. A type of vessel specially designed for the rapid carrying of Tea from China to England *via* the Cape of Good Hope, was introduced, known as the "China Clipper," and the competition was always keen as to which ship should make the most rapid passage. This culminated in the year 1866, when nine ships sailed almost simultaneously from Foochow, three of them crossing the bar in company. Those three were all built by the same builders in Greenock, and came in ahead of all the others, making the long voyage of fully 16,000 miles in 99 days. They each docked in a separated dock in London upon the same day, and all within two hours of each other. The two leading ships had not seen each other for 70 days and met off the lizard, from which point they ran a neck and neck race before a strong westerly wind, with every rag of canvas set.

The opening of the Suez Canal in 1869 soon changed the course of all trade with the East, and in a few years the sending of Tea per sailing ship round the Cape of Good Hope, was a thing of the past. Romance was no more, although there was extreme competition in building steamers with great power and speed to land their cargoes rapidly by the new route. This culminated in 1882, when the S.S. "Stirling Castle" made the phenomenal run for those times, of 28 days from Woosung to London.

But England, which formerly supplied almost everything to her own colonies and to many foreign countries besides, has under the modified conditions of abundant steam tonnage everywhere, become less and less of a distributive country. Consequently, direct shipments are made now from the countries of production to those of consumption. America gets its Tea largely through its western sea-board from China, Japan, Ceylon and India, while not a little is reaching it of recent years by steamers running direct from those countries *via* the Suez Canal to New York. The Australian demand is fed by steamers from Chinese ports, from Calcutta and Colombo.

The extensive Russian trade is still done in its major part by overland transit, by caravan and partly by river and railroad, and this, next to the transit to London, represents much the largest volume of Tea traffic passing in one channel. For the purpose of this trade, the greater portion of the Tea supply is compressed into what is termed Brick Tea, the Bricks being flat tablets weighing about one kilogramme each. The supplies are packed and prepared at various Tea ports in China, and concentrated at Tientsin, from where they are despatched. An enormous traffic with Siberia takes place in these, and the baskets into which they are made up are sent by camel caravans out of the Kalgan Gate of the Great Wall through Manchuria or Mongolia to Kiakhta, and thence distributed through Siberia. In some cases the shipments are made by sea to Nikolaevsk, and thence by water up the Amur River.

One of the most interesting developments of modern trade—in which Tea is an important factor—is the opening up of traffic through the Kara Sea into the Obi and Yenisei Rivers, with which the name of Captain Wiggins has been associated. By this route for several years past considerable quantities of Brick Tea have been conveyed entirely by water from Chinese ports with transshipment in London to steamers proceeding up the Gulf of Obi to Tiemen

for sale at the fair which is held annually in February at Irbit. This Journey, although about 7 times as long in point of mileage as the old direct caravan route, can be done in about 4 months as against eighteen by the other way, and it is of course much less expensive. The partial opening of the Siberian Railway has affected the trade route, and when there is through transit across Siberia from Vladivostock and possibly Port Arthur to Europe, the Russian Tea trade will probably be subjected to further rearrangement of routes.

Another recent development in connection with the Russian Tea trade has been that of the great Russian Volunteer Fleet in calling at Chinese ports and Ceylon, and carrying from them large quantities of Tea to Odessa for distribution to Moscow, Nijni Novgorod, and other points.

Other most interesting trade routes are those for the supply of Persia, Turkestan and Afghanistan, partly through the Persian Gulf on to Meshed, and partly through the Black Sea to Trebizond and Tabreez.

NOTE.—In the discussion following the paper, Professor Andreas Krassnow, from Kharkoff (Russia), expressed the opinion that the Tea plant must be indigenous, not to Assam only, but to the whole monsoon region of Eastern Asia, where it grows wild as far north as the islands of Southern Japan. Dr. Krassnow collected in many parts of the island of Shikoku in Japan, and in the environs of the town of Kochi, wild growing plants. They occur in the dense forests on the slopes of mountains, which have never been cultivated in the province of Japan, and are even now not thickly populated. Like the English in Assam, the Japanese are cutting down and felling the forests, but they are leaving the Tea plants to grow in the form of plantations of wild Tea, from the leaves of which they produce different kinds of Tea of inferior quality. Not only common Japanese Green Tea is prepared, but two or three inferior sorts, whose qualities resemble much the material from which the Chinese make their Brick Tea.

The wild tea grows to a height from 3 to 5 feet, and the flowers are a little smaller than those of the cultivated form, but the leaves are not re-curved on the edges. In some forests the plant is very numerous, in others it occurs more rarely, and is found amongst other evergreen shrubs, growing in the shadow of *Quercus glabra*, and similar trees, which largely make up the evergreen forests of Southern Japan.

Dr. Krassnow believes that the Tea plant existed in China and Japan long before it was introduced in cultivated form, and that the peculiar properties of the China plant were produced, not by cultivation in a colder climate or on exhausted soil, but by the changes of climate which have taken place in Eastern Asia since the Tertiary Epoch. The period of cultivation of tea has been too short to produce the differences which exist between the Chinese and Assam plants, and many botanists consider them to be different species. It is well known that the Assam plant is frozen by temperatures which the China plant bears very well, and that the hybrids which are cultivated in hot climates, approach more to the Indian, and those in colder climates to the Chinese plant. The hybrids suffer from the cold winters in Batoum, which the Chinese plants never do. On the other hand, China plants cultivated in hot climates never become so tall and never have such large leaves as the Indian. All these facts are stated by Professor Krassnow with more details in his book "On the Tea-producing Districts of Asia," bringing out the conclusion that the Tea plant since the remotest times formed two varieties—Assam and Chinese—the first growing wild in India, and the other occurring still wild in Southern Japan (and perhaps in Formosa) where they were discovered by aborigines after the introduction of the cultivated form from the south-west.

PLANTING COFFEE, BANANAS AND ORANGES.

I send a diagram showing how I am planting out ten acres of Coffee, Bananas and Oranges. If I am on the wrong tract I want those who have a better way to show wherein I am wrong. The way to make this "Journal" more interesting is for those who engaged in Agriculture to write up what they are doing, and how they are doing it, and what success they are having. "In the multitude of consellers there is safety," you will find in Proverbs. So come on a "multitude" of you and let us help the Editors all we can. I am planting coffee six feet apart, bananas 12 feet, and oranges 24 feet. I have two men measuring and staking coffee for which I pay sixpence per 100, or six shillings per acre. Coffee at six feet square will take just 1,210 plants per acre. I have the coffee pits dug, and coffee planted by the day—as I do not care to have this part of the work rushed or carelessly done. But I do not feel satisfied unless I can get 300 holes dug and that number of coffee plants put in for a shilling. Planters know of course that coffee just now is very low in the markets of the world, and one must therefore have more work done for the same pay. The bananas I am planting at two shillings per 100. The labourer digs 100 holes, he then gets 100 good large roots cut off the stalk close to the roots, and leaves the root-stump near the hole. My head man then inspects both the holes and roots, and if satisfactory he tells the men to go ahead and cover up. So I am planting bananas at less than a farthing a hill. Now comes my orange plants, sour stock, one year old from a nursery where they were planted one foot apart. The ground before planting the seed was dug—or forked 15 inches deep, and from this I got as fine plants as any one could wish. These I am planting out 24 feet apart. The following diagram will explain, the o is coffee, x bananas, and * oranges. As the orange trees grow and shade the coffee it is my intention to cut out the banana trees, slice them up and dig them into the soil.

It will be seen above that bananas are planted between every other row of coffee—each square of four coffee plants having a banana tree for shade—and at every fourth coffee tree there is an orange tree in the line. I have decided on this way of planting after a great amount of planing and figuring. If any of our readers have a better way by all means let us have it in the next "Journal." Many will say what's the use of bothering with coffee now, it is so cheap. In reply I will say that I have seen coffee just where it is now three times since 1861, and between times I have sold at 136s. per cwt. Take my advice, plant Coffee, Bananas and Oranges, but plant coffee plants, not suple jack coffee

suckers. Plant good thick stout banana roots, and orange plants grown in a nursery, not miserable things yanked out of cow pastures.—*Journal of the Jamaica Agricultural Society.*

Williamsfield.

J. DOIDGE.

PRESERVATION OF STABLE MANURE.

(Continued from page 516.)

"Equal weights of horse and cow manure, 4 ton of each, were intimately mixed. A sample of this mixed manure was taken and analysed. This gave the composition of the manure at the beginning of the experiment. Then the 8 tons were divided into two equal parts, and 4 tons were placed in a small building that was weather-proof, and compressed by pounding; the other 4 tons were placed in an open bin. In this bin the manure was exposed to every rain that fell, but the sides and floors being constructed of double boarding, all due precaution against the leaching was taken. From month to month, for a whole year, both these manures were weighed and sampled. The samples were then submitted to careful analysis, and from the figures obtained the losses which might have occurred were calculated, both in the 'protected' and 'exposed' manures. From these figures it is possible to say whether the plant-food in either of the manures had become more available. The following chart will show clearly the results arrived at:—

WEIGHTS OF FERTILISING CONSTITUENTS IN "PROTECTED" AND "EXPOSED" MANURES.	Fresh.		At the end of 3 months.		At the end of 6 months.		At the end of 9 months.		At the end of 12 months.	
	Protected.	Exposed.	Protected.	Exposed.	Protected.	Exposed.	Protected.	Exposed.	Protected.	Exposed.
Weight of manure	8,000	8,000	2,980	3,903	2,308	4,124	2,224	4,189	2,185	3,888
Organic matter ..	1,938	1,938	880	791	803	652	760	648	770	607
Total nitrogen ..	48	48	40	34	39	33	37	29	37	31
*Total phosphoric acid ..	25	25	20	23	26	22	25	21	24	21
†Available phosphoric acid ..	15	15	20	15	19	15	21	17	19	16
*Total potash ..	62	62	65	48	59	44	60	41	60	40
†Available potash ..	54	54	62	45	52	42	56	38	55	35

* Soluble in strong hydrochloric acid. † Soluble in dilute citric acid.

Further, in addition to determining the total amounts of those elements enumerated, the amounts of such

as were converted into compounds more available plant absorption, were estimated month by month. This is an important matter, as these constituents are of practically but little value to crops until they have been so converted.

Mr. Shutt adds:—"In considering the charts, I wish, first, to call attention to the richness of the fresh manure as produced on the Experimental Farm, Ottawa, compared with manures ordinarily found in the barnyards throughout the country.

	Average on Farms	
	lb. per ton.	C. E. F. lb. per ton.
Nitrogen	7.8	12.0
Phosphoric Acid	3.6	6.1
Potash	9.0	15.3

"You will notice that there is a very great difference in favour of the C. E. F. manure. I attribute it chiefly to the greater care of the liquid manure on the Experimental Farm. We know that the liquid manure is by far the richer in nitrogen and potash, and I cannot impress upon you too strongly the desirability of using sufficient absorbent litter to hold all the urine. This is a matter in which tons of most valuable plant-food are annually lost by farmers.

"By referring to chart No. 1, you will notice there was a continuous loss in weight, both in the 'protected' and 'exposed' manures, throughout the period of the experiment. This loss was largely due to the destruction of the organic matter by fermentation. This is made clear by comparing the amounts of organic matter present, month by month. During the first three months the 'protected' manure lost 1,053 lb., and the 'exposed' manure 1,147 lb. organic matter. At the end of the year the organic matter in the former had been reduced to 770 lb., in the latter to 607 lb.

"Secondly, there is a similar (though not so great) loss of nitrogen. From 48 lb. in the 'protected' the nitrogen was reduced to 40 lb. in three months; in the 'exposed' the nitrogen fell from 48 lb. to 34 lb. in the same period. Again we notice, then, the greater loss in the manure fermented without protection.

"Thirdly, as regards phosphoric acid, it is to be observed that practically there is no loss in the protected manure; in the exposed manure 4 lb. of the 25 lb. originally present were lost by drainage.

"Considering the effect of fermentation upon the availability of the phosphoric acid it will be seen that in the protected manure the amount of such available phosphoric acid increased. This I deem a matter of considerable moment.

"Fourthly, in speaking of potash we have again to record the fact that practically there was no loss in the protected manure. The case, however, is very different in the exposed manure. Although precautions were taken against undue leaching, by providing the bin with double flooring, yet nevertheless there was a great loss of this element by soakage. It must be remembered that the potash of manure exists for the greater part in the urine, and consequently is present in solution. This exposed manure lost 22 lb. out of 62 lb. originally present—more than one-third. It seems to me that from a consideration of this experiment we may conclude that there will always be some loss on keeping manure unless it is preserved on a cement floor. In thinking over these results I would like every farmer to ask himself if the conditions under which he rots manure are as good as those of the exposed bin of this experiment. If not, his loss of potash will be greater than that we sustained.

"In the following chart we have given the percentages of the fertilising constituents lost under the two systems of rotting, and also stated the loss

in value per ton that these manures sustained. This table is a most instructive one, and worthy of careful study.

LOSS OF FERTILISING CONSTITUENTS IN THE ROTTING OF MANURE.

	At end of 3 months.	At end of 6 months.	At end of 9 months.	At end of 12 months.
Protected.	Exposed.	Protected.	Exposed.	Protected.
p. c.	p. c.	p. c.	p. c.	p. c.
55	60	58	65	60
17	29	19	30	23
none	8	none	12	4
none	22	3	29	3
20c.	64c.	27c.	80c.	36c.
36c.	95c.	36c.	90c.	36c.

Value of fresh manure, \$2.61 (10s. 10½d.) per ton.

Loss of organic matter
 " Nitrogen
 " Phosphoric acid
 " Potash
 Loss in value per ton of original manure.

CONCLUSIONS.

1. Fermentation causes loss. In both instances there was loss by destruction of organic matter and nitrogen, though the loss of these constituents was much greater in the exposed than in the protected manure. By rotting we must allow that the organic matter is converted into compounds that more readily form humus in the soil, and this is certainly an advantage. It is an offset against the loss we have mentioned.
2. There was no loss of phosphoric acid in the protected manure, but the exposed manure suffered loss in this element. Rotting had a useful effect in rendering the phosphoric acid more available.
3. Though practically no potash was lost from the protected manure, more than one-third the amount of this value element was lost by drainage in the exposed manure.
4. Rotting does not affect the availability of the potash; in other words, the potash of fresh manure is just as valuable as plant-food as that in rotted manure.
5. There appears to be no object in rotting manure for a longer period than three months.
6. The best conditions for rotting necessitate (1) protection from rain, sun, and wind, (2) a water-tight cement floor, and (3) that the mass of manure be kept moist and compact.
7. Weight for weight, well rotted manure is much richer in plant-food than fresh manure.
8. Rotting manure destroys weed-seeds that may be present.

In answer to a question as to whether it would not be better for the farmer to use manure in the green state, unless he has foul seed in it, and he should then ferment it to destroy the seed, Mr. Shutt said:—"Not necessarily. For certain crops and certain soils it is better to have rotted manure, though it may not be possible to rot the manure without some loss; but if he is not prepared to have such arrangements whereby the manure is protected and

preserved from leaching, and if he is not prepared to keep the manure moist and compact, then it is better for him to get that manure into the ground as soon as possible. It seems to be the opinion of most practical men that heavy clay loams are those which benefit most by fresh manure. There is no doubt that the soil is a storehouse which prevents loss of the fertilising material of the manure. Clay loams are very much improved in their mechanical condition by the application of fresh manure. On the other hand, for light and sandy soils, rotted manures are probably the best. In working light and leachy soils it seems to be the greater economy to feed the crop rather than to try to improve the soil; in other words, to apply the manure annually in the rotted condition. For such soils there is nothing better than leguminous crop turned under. This is the cheapest way of permanently improving such soils."—*Agricultural Gazette*.

BORDEAUX MIXTURE FOR PEACH FRECKLE.

A correspondent writes, that in his experiments with Bordeaux mixture (very carefully prepared) for peach freckle, the fruit and leaves of some of the trees were destroyed. The fruit expert, Mr. Allen, reports that in using Bordeaux mixture on tender foliage, unless the climatic conditions are absolutely favourable, it is well to always be on the safe side and dilute the 40 gallon mixture up to 45 or even 50 gallons of water. Mr. Allen also wishes fruit-growers intending to fumigate while trees are making new growth to note that not more cyanide than 1 oz. to 200 cubic feet ten-space should be used.—*Agricultural Gazette*.

BANANA FOOD FOR INVALIDS.—After a long experience with typhoid patients, Dr. Ussery, of St. Lois, maintains that the best food for them is the banana. He explains by stating that in this disease the living membrane of the small intestines becomes intensely inflamed and engorged, eventually beginning to slough away in spots, leaving well-defined ulcers, at which places the intestinal walls become dangerously thin. Now, a solid food, if taken into the stomach, is likely to produce perforation of the intestines, dire results naturally following; and this being the case, solid foods, or those containing a large amount of innutritious substances, are to be avoided as dangerous. But this banana, though it may be classed as a solid food, containing as it does some ninety-five per cent. nutrition, does not possess sufficient waste to irritate the sore spots; nearly the whole amount taken into the stomach is absorbed, giving the patient more strength than can be obtained from other food.—*Journal of the Jamaica Agricultural Society*.

NETTLE FIBRE IN GERMANY.—Nettle fibre has of late come greatly into favour in the manufacture of fine yarns and tissues in Germany. In that country, according to the United States Consul at Glauchau, there are factories which use these fibres, both in spinning and also for ulterior purposes. In nettle spinning alone, over 10,000 spindles and some hundred workmen are employed. The raw material is imported almost exclusively from China, whence from 660,000 to 800,000 lbs. are annually sent to Germany. Nettle fibre produces one of the finest tissues obtainable from any known kind of vegetable fibre. In view of the importance with this seems likely to attain in connection with the weaving industries, it is intended to introduce the cultivation of nettles, if possible, into the Cameroons. The idea is to prepare the products of this experimental culture at the place where they are obtained, and test them in German factories. Should favourable results follow from these experiments, it is intended to organise nettle-growing enterprises on an extensive scale.—*Journal of the Society of Arts*.

COOLY IMMIGRATION FROM THE INDIAN FAMINE DISTRICTS.

HERE is an answer to our enquiry as to coolies from the famine districts, written by the Rev. H. G. de St. Dalmas who has had long experience as Missionary in Central India and also knows Ceylon well:—"Yours of 1st February has reached me here (Poona) today—only five days from Colombo! Some of the famine people would certainly be glad to go to Ceylon and some are actually going to Assam (Sylhet) and tea planters come to Rutlam to select coolies. Many were disappointed at not being passed by the doctor. I wrote to the Rutlam Missionary, the Rev. J. Fraser Campbell, D.D., Canadian Mission, Rutlam, C.I., to invite the planter to come to Sehore, but I got no reply—this was only a few days before we left Sehore. I have also heard that Government is sending Marwaris back to their own country, Jodhpur, Rajputana, and that 1,600 were sent away from Indore.

"There has been a great emigration and some, who are ready to perish, would be glad to go anywhere. Some well organized effort by Government or by a Syndicate might succeed in getting some hundreds of familie to emigrate. I doubt if this could be success fully accomplished without the presence of an agent from Ceylon who had time and money to go about to the various centres and collect suitable families and arrange for their transport. If such an agent were known to be coming, the Missionaries in Central India could get lists of volunteers from whom suitable ones could be selected. At Sehore we have relieved thousands, helping many to go to the other Provinces to look for work, and I think the most successful hunting ground might be the relief works in the Central Provinces. The new Chief Commissioner, A. H. L. Fraser, Esq., C.S.I., Nagpur, is a good Christian man (son of old Dr. Fraser, formerly of Poona.) If a large number could be taken, how would it be to write to Mr. Fraser, the C.C., and get Government help to hunt up coolies and families at the chief relief centres in the C.P.? My successor at Sehore, Mr. A. Taylor I fear could not help much, but would get lists prepared—if the Marwaris, &c., are not in the meantime sent away. Mr. Fraser Campbell, editor *Gyan Patrika*, Rutlam, C.I., could put a para in his paper about coolies for Ceylon and Mr. Evans, now at Dhar, C.I., care of the Rev. F.H. Russell (his son-in-law) has been writing about these famine wanderers in Central India and might take an interest in the scheme."

Mr. St. Dalmas himself is about to leave for England. His information ought to be useful to Government and the new Railway Contractors and later on, perhaps to Sugar growers here.

TEA LAND IN JAVA.

An advertisement in the *Ceylon Observer* shows that two fine blocks of land, suited for tea, are for sale in Java at what seems not too high a rate. We do not like in Ceylon to hear of more tea being planted; but the redeeming features in this case are found in the fact that there is a large local demand for Java tea, and that the exports are more and more taking the place of coffee in Holland and Western Germany,

CASTLEREAGH TEA COMPANY OF CEYLON, LIMITED.

ANNUAL REPORT.

The Directors submit herewith the balance sheet and profit and loss account for the year ending 31st December, 1899, duly audited.

The balance of profit (including R2,407.89 brought forward, and after providing for depreciation of buildings and machinery as shown in the accounts) is R31,157.25. Of this sum R9,600 has been absorbed in paying an interim dividend at the rate of 4 per cent. The directors propose, after placing R718.73 to reserve fund, being 2½ per cent. on the profits, as resolved on in general meeting, to declare a further dividend at the rate of 8 per cent. payable on the 13th February, absorbing R19,200 and after paying a bonus of 5 per cent. on the profits divided, including reserve fund, for the year to the superintendent, in terms of a promise made to him, absorbing R1,475.93 to carry forward to 1900 account R162.59.

The total tea crop was 175,755 lb. against the estimate of 195,000 lb., the season having been unfavourable, in the earlier months. The cost of the tea delivered to buyers was 24.82 cents per lb., or 22.82 cents exclusive of provision for depreciation on buildings and machinery. The tea was sold locally, realising 42.51 cents per lb, leaving balance of gain 17.69 cents. Cost in 1898 was 24.68 cents, and value 39 cents per lb.

The Company's Property consists of:—

476 acres tea under leaf. Yield in 1899=369lb, tea per acre.

4 " planted in 1897.

4 " " 1898.

42 " forest.

Total .526 acres.

The estimated crop for 1900 is 185,000 lb. tea, or 389 lb. per acre.

It will be seen that the property representing capital stands in the balance sheet at approximately R495 per acre cultivated, and that the profit per acre is over R60 as compared with R39 in 1898 and R23 in 1897, the profit upon capital being R11.97 per cent, or including the sum reserved against depreciation R13.44 per cent.

Mr. J.H. Starey retires from the Board.

The shareholders will be requested to elect a director and also an auditor for the current year.

THE KELANI VALLEY PLANTERS' ASSOCIATION.

FIFTEENTH ANNUAL REPORT OF THE ASSOCIATION.

Your Committee have pleasure in submitting their 15th Annual Report.

MEETINGS.—Five Committee and four General Meetings have been held during the year.

FINANCE.—The balance in hand is R567.80 against R600.75 at credit last year.

SCHEDULE.—The schedules of the Association shows 78 estates, one private and one honorary member, against 75 estates, one private and one honorary member last year, two new estates having joined the Association during the year.

CROP.—The estimate for 1900 is 15,303,800 lb. The acreage, of tea in bearing is 31,228 acres; there are 4,631 acres not in bearing total 35,919 acres, the average yield per acre is 490 lb. The large increase over last year both in acreage and crop, is accounted for by the more accurate collection of returns.

TEA PRICES.—The price of low-country teas has, your Committee is glad to note, been very satisfactory during the year, being from ½d to ¾d better than in 1898, the prices during the first six months were especially good. In August after the conclusion of the 1 lb. draft dispute the average price of Ceylon tea fell to the lowest point, and since then, though there has been a recovery, prices have been much below the corresponding rates of last year. Your Committee regret to note that the concession as to

the taring of packages on which the draft dispute was settled, has not yet been introduced, owing to the objection of some of the importers to clause G of the new regulations. There seems at present no prospect of a settlement being arrived at, and if this concession be lost, the draft dispute with its resultant disorganization of prices will have been fruitless.

KELANI VALLEY RAILWAY.

Your Committee regret that they cannot as yet report that the construction of the line has been begun. The Engineer in charge has been engaged during the year, in surveying portions of the line, according to the recommendations of the Consulting Engineers. The survey was finished in August, and the report is now, we believe, under consideration by the latter. The survey of the private lands required for the construction of the line is now proceeding; this and the proceedings in connection with the purchase of the lands will take some time. On the whole, your Committee cannot but feel disappointed with the slow progress made in commencing this railway, which has been an urgent want of the district for many years. H. E. the Governor visited the district in January and fully explained the reasons for the delay, and your Committee feel assured that the work will now be pushed on with all despatch. Your Committee regret that Mr. Mackintosh, the late Chief Resident Engineer of Railway Extension, was obliged to resign his post owing to ill-health, and wish to record their thanks to him for his services in connection with the survey of the railway. Mr. Oliver has been appointed in his place, and your Committee have every confidence in this appointment, Mr. Oliver having already had many years experience in railway construction in the island. Your Committee take this opportunity of offering the Hon. W. W. Mitchell a hearty vote of thanks for the able and painstaking way in which he has always advocated the construction of the railway and learn with much regret of his retirement from the Legislative Council of Ceylon.

MEDICAL.—The health of the coolies has been fair during the year. The extension of the Avisawella hospital was sanctioned in December, 1898; the first step in connection with the purchase of the necessary land were taken in June last and the land has since been acquired, and the foundations of the new wards are now being cut. Your Committee regret the long delay in connection with this most necessary work, as the accommodation at this hospital is, and has been for some years totally inadequate to the needs of the district served by it. During the year the hospital visitor drew your attention to the insufficient supply of clothing and nursing attendance in this hospital. The matter was brought to the notice of the P.C.M.O., and is now the subject of correspondence. Your Committee hope that the deficiencies pointed out, will be rectified. In this connection, your Committee would draw your attention to the unwarranted attack made, in his report for 1898, by Mr. Arunachalam, the Registrar-General, on the lowcountry planter. After quoting figures to show that, while the ratio of mortality amongst labourers on upcountry estates is less than that amongst the upcountry Sinhalese, on the other hand, the ratio of mortality amongst the labourers on lowcountry estates, greatly exceeds that of the lowcountry Sinhalese. Mr. Arunachalam proceeds as follows:—"The conclusion seems to be almost irresistible that in the newly developed estates of the lowcountry districts, the labourers' health is not looked after by his employer in the same manner as in the upcountry districts with their long traditions of excellent relations between employer and employed, and that it is necessary to resume the system of Government medical supervision abandoned some years ago."

While Mr. Arunachalam is, no doubt, an eminent authority on statistics, he cannot be said to be an authority on medical or sanitary matters, and an attack from such a quarter might well be passed over in silence. Nevertheless your Committee think

it best to put the following reply on record. The question of hospital accommodation and medical attendance is one which has occupied attention at almost every meeting of the Association since its foundation, and we have continually kept before Government the necessity for extending hospital accommodation in accordance with the increase of the acreage in cultivation and of the estate population. In addition to this, the majority of estates have established at a considerable cost to private dispensaries (for which the Government supply medicines free) for the early treatment of disease. While your Committee regret the large ratio of mortality, they are convinced that there is no such evasion of duties as is imputed, but that the causes thereof lie beyond your control. Malarial fever and the diseases connected therewith are the principal source of illness amongst the lowcountry estate population. As is well-known, these diseases are always prevalent in lowcountry districts such as the Kelani Valley, and until medical science is more advanced it will not be possible to control them.

TELEGRAPHS.—During the year, the telegraph wire has been extended to Ruanwella. Your Committee regret to have to report that the Post-master General still refuses to open a Telegraph Office at Dehiowita, though the wire passes the door of the Post Office. Your Committee hope that the P.M.G. will see his way to concede this small boon at an early date.

ROADS.—The state of the roads in the district has again been a source of much trouble and complaint. The Planting Member, at your request endeavoured to obtain a larger vote for upkeep during the year but without success. The vote for upkeep being indeed reduced. The dry weather during the last six months has been against repairs being executed, but the roads will never be in a satisfactory state until a large amount has been spent in putting them into thorough repair, the present vote being quite insufficient for that purpose. In this connection, your Committee would impress upon the Director of Public Works the vital importance of keeping the district communications in a thorough state of repair, until the completion of the Railway. Your Committee regret very much that the Government has not decided to construct a bridge over the Algoda River, so as to bring the Panawala Korale in direct road communication with the Railway station at Dehiowita. They regard the construction of a causeway, with approaches at a gradient of 1 in 14, as altogether unsound. Moreover, they think it is an engineering mistake and will be liable to be washed away in heavy floods.

A causeway was built on the Ritigaha Oya River some years ago, but a bridge had later to be substituted as the causeway was found unsuitable.

LABOUR.—The supply has been fair during the year but your Committee regret to note that the number of emigrant coolies has largely exceeded the number of immigrants during the past 12 months. The construction of the railways now sanctioned, will require the services of some thousands of coolies. The subject of recruiting this labour has been before the Parent Association, who appointed a sub-committee to consider the matter. This Sub-Committee has drafted a report containing suggestions and recommendations, which has been forwarded to Government.

The Government have practically agreed to recruit labour required in India, and to appoint a Commission to consider the question. Your Committee have read with lively satisfaction the speech of the Colonial Secretary in Council, on this subject.

K. V. LABOUR FEDERATION.—The K. V. Labour Federation has continued to work satisfactorily during the year. In August the Dolosbagie and Yakkessa Association affiliated itself with the K. V. Labour Federation, and a scheme has been adopted for the settlement of disputes between the members of each district.

BLIGHTS have attracted considerable attention during the year, throughout the Planting districts,

but your Committee are glad to report that the Kelani Valley is fairly free from them.

MR. KELWAY BAMBER; GOVERNMENT MYCOLOGIST, &c. Your Committee await with eagerness Mr. Kelway Bamber's Report on the cultivation and manufacture of tea. They are glad to note the appointment of Mr. Carruthers as Government Mycologist in addition to the appointment of Mr. E. E. Green as Government Entomologist, and they hail with approval this inauguration of an Agricultural Department, which has been too long delayed.

COACH SERVICES.—Numerous complaints as to the state of the coaches, and the cruelty practised on the horses have again been received during the year. The matter was brought to the notice of the Colonial Secretary, who has replied that complaints should be forwarded to the Government Agent Western Province, who will take action thereon. Your Committee hope that members will act on this recommendation, and report all cases of cruelty that come under their notice.

OBITUARY.—Your Committee regret to record the death in England of Mr. Chas. Ogilvie, a resident proprietary Planter of long standing in the district, and that of Mr. F. Drummond, both late members of your Association.

MATURATA AND HEWAHETA PLANTERS' ASSOCIATION.

FOURTH ANNUAL REPORT.

Your Committee beg to submit the fourth annual report, 1899.

OFFICE-BEARERS.—Messrs. A. C. Kingsford, Chairman; R. B. Roberts, Hon. Secretary.

COMMITTEE.—Messrs. G. H. Bennett, H. E. Power, G. F. Deane, D. H. Williams, J. St. G. Carey, E. Turner, T. N. Orchard, and H. V. Bagot.

KANDY REPRESENTATIVES.—The Chairman and Hon. Secretary, Messrs. E. Turner and L. St. G. Casey.

MEETINGS.—During the year, three general and four Committee meetings have been held. The roll of membership is 39. The balance in hand is Rs 156-09 as compared with Rs 53-39 in 1898.

The tea crop was generally satisfactory, and in many instances estimates were exceeded.

The estimates for 1900 show a slight increase—

	Total acreage in tea	In bearing.	Crop	Yield per acre.
				lb.
Maturata	6,733	5,746	2,154,875	381
Upper Hewaheta	4,146	3,580	1,653,000	461
Lower Hewaheta	6,756	6,207	2,317,350	373

ROADS.—The Grant-in-aid Road from Padiapallela to Ellamalle has been completed.

Your Committee would again urge upon Government the desirability of continuing the cart road from Loolecondera to Rahatungoda, more especially in view of the increasing traffic thrown on the Hangrunkette Road. Further they would urge on Government the necessity of improving the zigzags between the 10th and 12th mile post on the Hangrunkette Road.

BRIDLE PATHS.—The bridle paths have been kept in a fair rate of efficiency. Grants have been received from the D. R. C., Nuwara Eliya, for Rahatungoda-Denika Road R/0, Gonavy-Rahatungoda Road R/230 and considerable sums in the Maturata District.

Your Committee regret that the amounts received from the D. R. C. Kandy were quite inadequate, and in view of the amounts collected in Road Taxes from this part of the District, and number of natives using the roads, should ask for a more satisfactory vote for 1900. The Committee is glad to report that the bridle path from Upper Hewaheta via Ramboda to Nuwara Eliya, asked for by your Association is now in course of construction, and will be of great convenience when opened.

HOSPITALS.—Your Committee is now able to report that foundations for the Maturata hospital are

being cut, and the Director of Public Works hopes to spend during the year the amount provided for in this year's Supply Bill, viz Rs 35,000. Your Committee fail to understand the lengthy delay in commencing this work, considering that this hospital was sanctioned, and a vote on account in the Supply Bill, Rs 20,000 was taken in November 1897. Your Committee are of opinion that a smaller and less expensive building, constructed with less delay, would have been of greater benefit. Mr. Roberts was nominated by your Association, visitor to the Deltotta hospital in November, 1898, but as yet the appointment has not been confirmed by Government.

TELEGRAPH.—Your Committee have for some years past urged the desirability of telegraphic extension to Deltotta and Hewaheta, and regret that the more recent offer to guarantee any loss on the working has met with little response.

CATTLE BRANDING.—This matter, originally brought into prominence by your Association, has again had the full attention of the Parent Association and the public press, and your Committee trust that the Ordinance will no longer be allowed to remain a dead letter, and that instructions will be issued to the police to take action which will minimise this cruelty.

RINDERPEST.—A serious outbreak in the early part of the year caused considerable difficulty in carting. We trust that future outbreaks will receive more prompt attention.

AGRICULTURAL CHEMIST.—Loolecondera and Galaha, the selected estates, were visited twice by Mr. Bamber during the year, and we regret that we are unable to report more fully owing to the long delay in printing the report.

BLIGHT.—Your Committee are glad to report that there has been no serious attack of Blight in the district.

PARIS EXHIBITION.—Exhibits of commercial tea, were kindly sent from Bramley estate in Maturata, Columbia estate in Upper Hewaheta, and Great Valley in Lower Hewaheta.

LABOUR.—Your Committee regret that labour is generally insufficient, and they consider this is greatly due to the closure of the North Road, and consequent enhancement of the cost of bringing over coolies, and would therefore urge on Government that the funds usually devoted (approximately Rs 100,000) to the upkeep and establishment of the Northern Route should, in the event of its being considered advisable to continue this course, be devoted towards subsidising the steamer service for immigrant labour.

LABOUR LEAGUE.—This has worked smoothly, and no complaints have been received.

RAILWAY RATES.—Your Committee feel that they cannot do better than repeat their paragraph in last annual report re railway rates, viz., "We regret that so far Government have not acceded to the request to lower the rates on tea from the 4th to the 6th class; and would wish to draw the attention of His Excellency to the great difficulties and cost of transport both from Maturata and Hewaheta estates having to carry and cart their produce over difficult roads, from 25 to 35 miles, before reaching the railway, and, in addition to paying rates for cartage, contribute annually in tolls, grant-in-aid roads and private roads Rs 20,000 towards the annual upkeep of roads. All estates have used the railway from the time of its opening, and also contributed towards the export tax, which paid for one-third of the cost of construction and should therefore now, in this time of depression, lay claim to special consideration, more especially in view of the large profits obtained from the Colombo-Kandy section of the line for many years past."

PLAGUE.—Your Committee congratulate the Government and the Planting Community on the immunity of the Island from Plague during the past year, and trust that Government will continue the present most necessary precautions.

Your Committee regret to report that nine estates in Maturata have resigned membership of the Association and that no member from Maturata has attended any meeting during the year, and would, therefore, suggest that the word Maturata be deleted and that in future this Association be called the Hewaheta Planters' Association.

R. B. ROBERTS, Hon. Secretary.

PRODUCE AND PLANTING.

THE TEA TRADE OF THE UNITED STATES.—Some statistics relative to the consumption of tea in America are sent by the New York correspondent of the "Grocer." "The fiscal year of the United States ends June 30. The net imports of tea are taken as representing consumption. Prior to the levying of the present duty tea was not left in Government warehouses as is at present the custom. In 1897 imports were unusually heavy exceeding any former year by nearly 20,000,000 lb. This was probably due to importers buying heavily in anticipation of a duty being levied. This was done by War Revenue Act of 1893, when tea was taxed 10 cents per lb. During the year ending June 30, 1898, the imports were the smallest for any year since 1879, notwithstanding the population increased 25,000,000. When the Tea Act went into force there was a heavy stock of inferior grades and trash on the market, some of which was twenty years old, and had been unsaleable at 2d. per lb. The diminished imports of 1893 and the 5d. duty enabled holders to dispose of the old stocks, which were not entirely dissipated until the summer of 1899. It is a fact that the trash offered at 2s. sold subsequently as high as 11d. The result of counting net imports as consumption causes considerable irregularity in the Government per capita estimate, as it leaves out of consideration stocks in first and second hands."

THE PROBABLE DEMAND.—"The present population of the United States," says the authority referred to, "is estimated at 74,000,000, and the requirements for 1899 should be 96,000,000 lb. The net imports for the year ending June 30, 1899, however were only 72,833,070 lb., falling nearly 16,000,000 lb. below the annual average, and can only be accounted for on the ground that old stocks were larger than estimated, or else that 1'31 lb. per capita is too high as representing consumption. The imports for eleven months ending November 30, 1899, were 77,517,366 lb. So much for the Government returns, on which my statement was based, in connection with the fact that withdrawals in November were over 8,000,000 lb. According to private estimate the average monthly withdrawals averaged, June to November 30 7,300,000 lb., or 87,600,000 lb. per annum, and for the next six months are estimated at only 7,000,000 lb. If an average of 7,375,000 lb. were used monthly for ten years ending June 30, 1898, which covers five years of trade depression, it is not fair to assume that, with prosperity never before equalled, and old stocks wiped out, the consumption should increase? In a recent interview with the New York agent of a prominent tea firm having offices in Ceylon and London, and who is a careful student of the situation, he stated that his estimate of consumption was 92,000,000 lb. for the United States, less exports to other countries than Canada, a very small quantity. Undoubtedly roasted coffee at 10 cents per lb.," says the correspondent, "is cutting into the consumption of tea. Possibly I have taken too optimistic a view of the situation, but if so it must be measured by the figures given above, viz., that monthly withdrawals for six months show an annual consumption of 88,000,000 lb."

MR. RUSKIN'S TEA-SHOP.—At one time, Mr. Ruskin, in addition to his other multifarious occupations, kept a tea-shop. "How good of you," he wrote on one occasion to a friend, "to go to the tea-shop;

and I'm so glad of your report; I must really get up my sign." But the sign, we believe, never made its appearance. "Owing," Mr. Ruskin has elsewhere explained "to that total want of imagination and invention which makes me so impartial and so accurate a writer on subjects of political economy, I could not for months determine whether the said sign should be of a Chinese character, black upon gold; or of a Japanese, blue upon white; or of pleasant English, rose colour on green; and still less how far legible scale of letters could be compatible, on a board only a foot broad, with a lengthy enough elucidation of the peculiar offices of 'Mr. Ruskin's tea-shop.'" Whether it was due to the absence of a sign or not the Ruskin tea-shop was not a success. It was established at 29, Paddington Street, W., "to supply the poor in that neighbourhood with pure tea in packets as small as they chose to buy, without making a profit on the subdivision." The result of the experiment was, says Mr. Ruskin, "my ascertaining that the poor only like to buy their tea where it is brilliantly lighted and eloquently ticketed; and as I resolutely refuse to compete with my neighbouring tradesmen either in gas or rhetoric the patient subdivision of my parcels by the two old servants of my mother's, who manage the business for me, hitherto passes little recognised as an advantage by my uncalculating public. The business, sad to relate, languished, and the rent and taxes absorbed the profits and something more. This was prior to the ascendancy of Indian and Ceylon tea.—*H. and C. Mail*, Jan. 26.

CEYLON TEA IN SOUTH GERMANY.

We are glad to welcome genial and well-informed Mr. Chas. Bohringer back, after an absence in Germany of over two years. During this time Mr. Bohringer has not been idle, more particularly in trying to introduce Ceylon tea into the States of Bavaria, Wurtemberg and Baden; and he is well satisfied with the measure of success attained. The work has been a slow one, owing very much to the opposition of the Hamburg tea merchants; but a considerable hold has now been got and Mr. Bohringer was gratified in November last to obtain a gold medal for his exhibit of Ceylon Teas at the Munich Food Products Exhibition. The "Thirty Committee" should pass a vote of thanks to Mr. Bohringer at their next meeting for the good work he has been doing for our staple. If, as he believes, the people of Southern Germany are going to take freely to good tea, how much more should we expect those in Central and Northern Germany to do so? Now that tea enters duty free into Belgium, Antwerp is becoming a chief port for imports to serve a large part of Central Europe.

SUNFLOWER-GROWING IN SOUTHERN RUSSIA.

According to a French consular report, there is in Southern Russia a growing demand for oil-bearing seed, particularly sunflower-seed. Until recently there had been in that region but few establishments for extracting this oil, and the producers, finding no market at home, sent the seeds to foreign countries. Now, however, there are mills in the south which are prepared to use considerable quantities of these products, and they offer to the cultivators better prices than they could secure in foreign markets.—*Chemist and Druggist*, Jan. 27.

THE RETENTION OF DUTY-PAID TEA IN BOND.

The following circulars have been issued by Messrs. Densham and Sons, Limited, of 49 and 51, Eastcheap, E.C.:—

“January 15, 1900.

“DEAR SIR,—You will probably notice in tomorrow's papers that we have today paid a record cheque for tea duty, amounting to £85,862 8s 8d. This cheque represents a larger amount of duty-paid tea than has ever been held by any wholesale house in the history of the tea trade. We have bought this tea, and paid duty on it, for two reasons. First, because we anticipate a very large demand for duty-paid teas during the next six weeks from all parts of the kingdom, owing to the growing belief that an alteration will be made in the tea duty, and, secondly, because, as you are well aware, during the exceptionally dull months of November and December last, good teas were of far better value than has ever been known. Our purchases were made during these two months, and we are now in a position to meet this demand from our customers, however big it may be. We need hardly say how pleased we should be to send you samples of any class of Indian or Ceylon tea that you may be tasting, and we would expressly ask you not to purchase until you have seen a selection from our stock.

“We have been informed by the Customs authorities that in future no tea will be allowed to remain in the bonded warehouses, duty paid more than a reasonable time for clearance of same, and for this reason we are making arrangements for taking the whole of this stock into our new warehouse, which have a capacity of over two million cubic feet. You can therefore leave any purchases you may make from us in these warehouses, properly insured by us, and rent free, until you require them.”

“January 20, 1900.

“DEAR SIR,—Referring to our letter of 15th inst., informing you of the payment of our record cheque for tea duty, you will probably have noticed a letter on page 134 of this week's *Grocer*, evidently intended to convey the idea that the statements made in our letter were not correct. The letter is as follows:—‘10, Philpot Lane, E. C., January 18.—SIR,—In a recent announcement of new premises, a remark occurs implying that a certain risk is incurred by owners of duty-paid tea, if the tea be permitted to remain in a bonded warehouse beyond a “reasonable” time, whatever that remarkably vague period may mean. As a matter of fact, which may interest many of your readers, there is no time limit or restriction of any kind placed by H. M. Customs as to the removal of teas upon which the duty has been paid—We are, &c., BURBRIDGE, PRITCHARD, and BARTLETT.’

“We are much indebted to Messrs. Burbridge, Pritchard, and Bartlett for giving us this opportunity of stating the exact facts, of which they do not appear to be cognisant. Being most anxious in the interest of the tea trade in general, and of our customers in particular, to find out the true position, we applied to the secretary of Her Majesty's Customs for information on the subject, and to enable you to form your own judgment we subjoin an extract from his reply dealing with the question.—We are, yours faithfully, DENSHAM AND SONS, LIMITED.”

Extract of letter from the secretary to Her Majesty's Customs:—

“I am directed to acquaint you that the Warehousing Law implies that warehoused goods which have been cleared for home consumption, and on which duty has been paid, shall be taken from the warehouse immediately. Not only does the payment of duty imply that the owners of goods require them for use, and that they will be removed with the utmost expedition, but the presence together of warehoused and unwarehoused goods in bonded premises imperils the value of security by which the warehouse is covered. This being the position, the Board feels bound to withhold assent to the retention of tea in bond after duty has been paid upon it. I am to add that you are not correct in your impression, that the rules of the department have allowed a period of twenty-one days, or any other defined time, for the removal of duty-paid stock from bonded warehouses after payment of duty.”

After seeing Messrs. Densham and Sons' first circular, given above, Mr. Prowse wrote:—

“Many thanks. The underscored part of this notice (given in italics) correctly expresses our attitude, and it is quite intended to exercise all the powers we may find ourselves to be possessed of to prevent the wholesale retention of duty-paid stock in bonded warehouses.

“(Signed) R. T. PROWSE, Secretary.

“Customs, January 23, 1900.”

—*Home and Colonial Mail*, Jan. 26.

THE PROSPECTS OF CINCHONA.

Mr. Bohringer confirms our view of the great encouragement now offering to cultivate cinchona—and especially hybrid cinchonas—in Ceylon. He points out that the bye-product, cinchonidia or cinchonina—at one time comparatively valueless—is now as much thought of as sulphate of quinine itself; and further that it is in Ceylon, rather than in Java, bark such a bye-product is chiefly found. He would therefore advise the planting up of a hardy hybrid variety and there is every prospect of prices improving rather than going back, although already they are double what they were some time ago. The United States alone with Cuba, Porto Rico and the Philippines on their hands, are bound to be very large customers; but apart from this, quinine is now utilised in so many directions that a steady and growing consumption is assured. We would strongly urge Ceylon planters in the medium and higher and especially in the Uva districts, not to neglect the planting of cinchona.

SUGAR IN MAURITIUS.

PORT-LOUIS, Jan. 30.

All the estates of the island have now finished the crop. In some factories there is still some sugar to be centrifugalled, as this work could not be done owing to the usual important operations in the fields at this time of the year.

The total yield of the crop, which we had estimated at 150,000 tons, will probably slightly exceed that figure.

The prolonged drought is doing harm to the plantations. It is to be hoped that there will soon be a good downpour all over the island.—*Mauritius Planters Gazette*.

CEYLON EXPORTS IN RELATION TO
FREIGHT AND TONNAGE:
1888-1899

TEA GIVING 4 PER CENT, AND PRODUCTS OF THE COCONUT PALM 4 PER CENT, OF EXPORT TONNAGE FROM CEYLON IN 1899.

The following figures—compiled from the Annual Returns of Exports and Shipping—give the quantities of produce exported from Ceylon and the number of vessels by which such produce was shipped. The figures for produce exported are, in this instance, reduced to “shipping tons” on the basis of the Ceylon Tonnage Scale:—

In	Vessels Cleared with cargo.	Tons cargo taken.	Average tons taken per vessel.
1888	573	120,431	210
1889	611	131,849	215
1890	698	156,159	223
1891	872	174,316	200
1892	871	200,986	230
1893	848	197,823	233
1894	808	200,489	248
1895	784	213,843	272
1896	830	216,844	261
1897	756	245,830	325
1898	773	297,211	384
1899	856	293,507	343

The decrease in shipping tons of cargo exported from Ceylon in 1899 is 3,704 as compared with 1898, but compared with 1897 the increase is 47,677 tons. The slight falling-off in 1898 is due entirely to shrinkage in exports of coconut palm products, and mainly to a reduced export of copra.

Going into detail the following figures show which products have mainly contributed to keep the total export to within a few thousand tons of last year:—

	Tons.
Tea shows an increase of	10,125
Plumbago	7,166
Coffee	360
Cocoa	409
Cinnamon	1,539

The exports of cinchona, cardamoms, sapanwood and ebony do not show sufficient variations from 1898 to call for special comment. As indicated above, exports of the products of the coconut palm for 1899 show a heavy falling-off from those of the preceding year. Grouping them together—coconut oil, copra, desiccated coconut, coconuts, poonac, coir yarn, rope and fibre—the following figures will be found of interest:—

	Shipping Tons.		Shipping Tons.
1888	61,375	1894	85,711
1889	53,780	1895	84,567
1890	72,291	1896	80,570
1891	69,879	1897	100,614
1892	94,550	1898	139,334
1893	79,935	1899	119,154

Of the total exports of the year:—

Tea gives	44%	of the shipping tons.
Products of the coconut palm give	41%	do
Other products give	15%	do

The falling-off in exports of the coconut palm showing, as they do, a shrinkage of 20,184 shipping tons for the past year, as compared with 1898, is a very serious one, and it is anticipated that, owing to the restricted rainfall last year, the exports of the coconut palm for the year 1900 will show no better results, if indeed the exports reach those of the past year.

The number of vessels which cleared with cargo in 1899 shows a considerable increase over the figures for 1898. The average quantity of cargo taken per vessel works out naturally under those for 1898. Putting aside some short temporary scarcity of space, the supply of tonnage has been ample for the requirements of shippers, and the continued increase in the carrying capacity of recently built steamers, which run on the Eastern lines, will meet any expansion in our exports.

FREIGHTS have on an average been low.

Tea has varied between 25s and 30s to London. To the Continent freights have varied considerably between 20s and 30s for rough cargo. Freights to Australian ports remain as before, viz.:—£40 per ton on tea to Adelaide, Melbourne, Sydney or Brisbane.

The following are fluctuations in freights on tea by steamers to London:—

	Maxi- mum.	Mini- mum.		Maxi- mum.	Mini- mum.
1891	45/	27/6	1896	25	7/6
1892	35/	15/	1897	35/	10/
1893	30/	12/6	1898	40/	20/
1894	35/	20/	1899	30/	25/
1895	30/	17/6			

Vessels which called for coals only, and native schooners, are not included in these returns.

COCONUT PLANTING IN THE EASTERN PROVINCE.

(From a Correspondent of “Colonia”: the Colonial College Magazine.)

“I must apologize for not having written before to thank you for the ambulance certificate. When I last wrote I was, I believe, tea planting, up country, but I have now got over my planting babyhood, and am a full-fledged superintendent of one of my brother’s estates of fourteen hundred acres. When I first came down here seven months ago it was all virgin jungle, but I have cleared about two hundred acres, which I am now planting up. I have therefore been so busy that I have hardly any time to write. The estate lies on the eastern and hottest coast of Ceylon, and stretches for about nine miles along the seashore. It is, of course, not suited for tea planting, owing to the climate, but is ideal soil for coconuts. Coconuts are one of the most paying products, if not the most paying, in Ceylon; but as they do not come into bearing for ten to twelve years after planting, it entails an immense expenditure of capital in the interim. There are certainly many minor products which may be planted. I myself am planting up Indian corn and chillies, and although both of these products take a certain amount out of the soil, I hope that judicious artificial manuring will replace the good taken out of it. I now regret very much not having attended the agricultural classes at the College, though at that time I had little or no idea of taking up planting. I am thinking of going in for my licensed surveyor’s examination, as there is a good deal of work about here; and as I shall soon have a good deal of time on my hands, I could add largely to my income in that manner.

I think perhaps it would not be amiss to warn you about the so-called ‘creeper mongering,’ it is one of the planting disgraces. A few planters, I am glad to say a very few, advertise for young men to come out here to learn tea-planting, with a promise of a billet at the end of a certain time. They have to pay a premium from £100 to £200. Everything is painted in the most roseate hues. In many cases they are not shown or taught any-

thing personally, but allowed to do what they like, and when they eventually get a billet on R88-33, which is about four pounds a month, unless they are hard workers they get the sack and add to the great army of unemployed planters to be found in Ceylon. Tea seems to be on its last legs, everywhere salaries and staff are being reduced. White men are getting sacked and native conductors are taking their places on a salary about a quarter what a European would get. It will be a case of the survival of the fittest: many estates I expect will be abandoned unless something unforeseen turns up.

This is a magnificent game country, being all virgin jungle; elephants, leopards, bears, buffaloes, pig, deer, peafowl, etc. I shot a cheetah the other night about two hundred yards from my bungalow. We live on fowls down here, as butcher's meat is not procurable, and one's gun is a very useful thing to vary the monotony of the everlasting chicken. I enclose you a cheque for 30/ for my subscription to *Colonia*. I should be very much obliged if I could get the back numbers which have been issued since I left the College."

WEIGHING TEA—AND CEYLON MYCOLOGIST.

In a London letter to the *Observer*, I saw it mentioned that the scales on some tea estates must be wrongly balanced, which would account for the difference of weight which the tea chests would turn out, in London. From my personal experience I know that spring balance scales, such as are used at railway stations, and which, I believe, are the sort used in tea factories also, are in the habit of going wrong on the slightest provocation. In weighing bags of grain, averaging about 200 lb. each, these scales generally show a difference of from 2 to 4 lb. per sack, and that would just run out about the amount of deficit on tea chests. I check my scales by having myself weighed on a beam scale, which, of course, is always right, and then trying my weight on the balance scale, allowing the difference between the two. Tea planters should try this plan. Of course, Railway companies naturally patronize a class of weighing scale which enables them to charge more on packages than they are justly entitled to.

APPOINTMENT OF A MYCOLOGIST.

I am glad to see that you are, at last, going to have justice done to your island, in this respect, for a Mycologist is really one of the most useful appointments that could be made in connection with any agricultural or horticultural community. I don't grudge you your good luck in gaining your point, although we agriculturists in Britain are never, by any chance, so fortunate as to get any concession from the powers-that-be, because the policy of our Government, be it Tory, Whig or Radical, is to encourage the foreign agriculturist and crush their own countrymen. Our Minister of Agriculture, Mr. Walter Long, has lately been visiting the Scotch agriculturist on his native heath, and has been bombarded with wild provosts, J. P.'s, kerosine lamps, addresses and other bucolic products; but all to no purpose, for he simply refuses to do anything for the greatest but most depressed industry of our native land.

COSMOPOLITE.

NEW GUINEA RUBBER.

It is encouraging to learn that a high value is placed in London on rubber from New Guinea. As much as 3s 4d per pound has been realised for the article in the home market. The reason for this is said to be that adulteration, so much practised in other rubber-producing countries, New Guinea not excepted, has been promptly checked in the Possession. With the cessation of adulteration, prices have rapidly risen for the Papuan production. Let us hope that with the encouragement of quick sales and high prices the collection of rubber will become one of the steady industries of the island.

The *Northern Miner* says on this subject:—"Messrs. McIlwraith, McEacharn, and Co. inform me (writes 'city Man,' in the *British Australasian*) that the rubber which they receive from New Guinea has been steadily advancing in value of late, owing to the improvement which is taking place in the preparation of the article. The gentle and unsophisticated nigger, in whatever part of the world he is, has a nasty knack of adulterating the rubber (which he sells to the trader, and the Papuan is not an exception to the rule. But this propensity in his case has been firmly checked lately, with the result that New Guinea rubber has been selling in London up to 3s 4d per lb."—From the *Queensland Agricultural Journal*.

A CURE AGAINST DYSENTERY.

The Colonial Garden in Indo-China, through the good offices of Senator Pauliat, has received some seeds called "Ko-Sau" by the Chinese and employed by them as a preventive against dysentery. Dr. Mongeot, of Saigon, had the happy idea of utilising these seeds according to the Chinese methods, and the results have been very satisfactory. Out of 879 cases experimented upon, he met with only eight unsuccessful results. Experiments made at the Colonial Garden have shown that the seeds had a powerful physiological action. New experiments will, no doubt, enable the causes to be traced, and the effects of the action determined. If, as everything seems to point to it, the utility of this Ko-Sau seed is confirmed, the plant will be spread all throughout the French Colonies.—*London and China Express*, Jan. 26.

THE INDIAN TEA ASSOCIATION (LONDON).

SCIENTIFIC OFFICER FOR THE TEA DISTRICTS.—A letter on this subject from Dr. Voelcker, addressed to Mr. Cruickshank, was read by the Secretary, and at the request of the Committee Mr. Cruickshank arranged to see Dr. Voelcker again and settle with him as to the engagement of a suitable man with the requisite qualifications to proceed to India and take up the appointment.

TRAVANCORE STATISTICS.—After some discussion it was decided that in future it was advisable that estimates of Travancore crop, should, if procurable, be given separately by the Calcutta Association when framing their forecast of the Indian tea crop.—*Indian Planters' Gazette*.

LIQUID MANURE.

A simple and cleanly way of applying liquid manure to pot plants, is first of all to make a strong liquid manure, and into this put dry charcoal. When the charcoal is thoroughly soaked, take it out and dry it. When potting plants put a little of it into the bottom of the pot. When the roots of the plant reach it, the effect is soon visible. By this means there is no smell as in using the manure in a liquid state.—*Queensland Agricultural Journal*.

PLANTING NOTES.

MICA.—As a correspondent some time ago remarked in an Akyab paper the resources of Upper Burma are plentiful in regard to mineral wealth, but search is required. We now hear that mica mines have been found in the Ruby mines district and also plumbago. Working up is the only thing necessary.—*Mandalay Herald*, February 3.

SEED DISTRIBUTION IN AMERICA.—The Department of Agriculture began its distribution of seeds a little earlier this year than last, forwarding them south at the beginning of January. This year the seeds for distribution to all parts of the country will consist of 13,000,000 packets of vegetable seeds, 1,560,000 of flower seeds, besides field and lawn grass seeds.—(“Washington Post.”)—*Home Paper*.

SIBERIAN FORESTS.—The Russian Ministry of Agriculture has assigned the sum of 50,000 roubles to be expended in the forests in the Governments of Tobolsk and Omsk, in accordance with the methods usually practised in the arrangements of forests in European Russia. The object in view is to prevent the increasing destruction of Siberian forests.—From *Journal of the Society of Arts* for January 19th.

COFFEE IN THE STRAITS SETTLEMENTS.—A correspondent writes with reference to the remark of our Sumatra correspondent:—“\$21 per picul Liberian coffee won't make the Liberian coffee estate proprietor fat, since it costs him \$18 per picul *f.o.b.* when his estate is in full bearing. \$40 per picul was the price going when the rush into Liberian coffee was made four years ago in the Malaya Peninsula.”

TEA DRYING.—The whole philosophy (says an Indian contemporary) of rapid, economical and thorough drying or firing of tea may well be summed up in the three following points:—(1) The tea should be kept in gentle, but effectual, movement, so as to separate every leaf from every other leaf and allow the dry air to get at *both* sides. (2) The application of as much air as can be introduced without blowing the charge out of the machine. (3) The skillful adjustment of the temperature of that air, so as to obtain the highest drying power without injury to the product; in other words, firing without burning.

BUDDING OF MANGOES.—The following interesting remarks which were culled by Mr Gollan, of Saharanpur, from a quotation made by the Queensland Agricultural Journal from the Bulletin of the Jamaica Botanical Department on the propagation of the mango tree by budding instead of the present laborious and slow process of grafting, are here reproduced for information:—“Budding the mango has been generally considered an impossibility but this is a mistake, because it is done by experts in Florida, and it can be done by others when understood. The secret lies in taking the buds from about the middle of the growing shoot where they are well developed, and yet not too tender where the colour of the bark is just turning from green to purple, and at a time just prior to a vigorous stage of growth in the tree to be budded. The shield method has been used, but the ring or plate would be better.”—*Agric-Horticultural Society, Madras*.

MANURING TEA.—Can it be true that Mr. Joseph Fraser estimates the increased crop from “judicious manuring”—such as he recommends—at 200lb per acre. Take half our area as amenable to such treatment and Mr. Fraser will have to face 37 million pounds additional of Ceylon tea! But where is the labour to pluck 148 million pounds additional of leaf? Mr. Fraser must be interviewed by a Deputation of poor tea-estate proprietors!

LAGOS PALM OIL.—The exports of palm oil from 1894-98 were as follows:—1894, £187,297; 1895, £205,553; 1896, 159,150; 1897, 97,590; 1898, £97,337. From these figures it appears that the palm-oil trade is less than half what it was in 1894 and 1895. The falling-off is attributed to rubber having become, since 1894, such a large article of export from the colony, but owing to the injury inflicted on the trees (says the Governor of Lagos) from the reckless way in which it has been collected, it appears certain that within, say, five or six years this industry will fall off entirely. The export of palm-kernels during the past five year remains about stationary, the value in 1898 being £362,539.—*Chemist and Druggist*, Jan. 27.

TEA FACTORIES AND FIRE INSURANCE.—There was some reason for the Maskeliya planters specially interesting themselves in this subject; for of the 18 fires reported by their Committee, two had occurred in their district, against two in Dimbula; one only in Dikoya; two in Madulsima; two in Pussellawa; and no fewer than four in the Kelani Valley, where we should have thought the temperature was too high to encourage fires. We repeat the interesting table with the districts given opposite the estates:—

Fires in Ceylon Estate Factories during a period of eight years.

NAME OF FACTORY.	DISTRICT.	DATE.
Heatherley Factory	Pussellawa	March 1891
Suduganga do	Matale East	May 1891
Bloomfield do	Maskeliya	Feb. 1894
New Peradeniya Factory	Hantane	Jan. 1894
Alton Factory	Maskeliya	June 1894
Lynsted do	Dikoya	Jan. 1895
Kinnuagoda Factory	Madulsima	March 1896
Great Western do	Dimbula	Jan. 1898
Dunedin do	Kelani Valley	1898
Tembiligalla do	Pussellawa	1899
Knavesmire do	Kelani Valley	1899
Sirisanda do	do	1897
Knavesmire Sirocco	do	Jan. 1899
Ferham Factory	Dimbula	1898
Battawatte Withering Shed	Madulsima	1898
Dunsinane Brit.		
Drier	Pundaluoya	1897
Lower Haloya Sirocco	Nilambe	1897
Culloden Factory	Kalutara	May 1896

Total amount paid Rs.85,767.

A merchant, who has paid some attention to the question, writes, after reading the Report:—

“I do not quite understand the paragraph in their report in which they estimate the annual premium value at Rs.187,500. But if that is a fair estimate, the losses amount to 25.72 per cent of the premium insured; whereas the experience of 43 British Fire Offices in 1898 as shewn in Mr. Horsfall's circular of 7th July, 1899, was 56.12 per cent.”

THE RICE TRADE OF CEYLON:

IMPORTS FROM BENGAL, S. INDIA, BURMA, &c.

The largest import trade carried on through Colombo, is, as may well be guessed by all who have any knowledge of the local requirements of the article, the import trade in Rice. While the exported quantity of Tea—the largest item in the export trade—last year was close on 130,000,000 lb.; for the same period we notice (see tables on next page) that the imports of rice must weigh about 500 million pounds or not far short of four times the weight of the exports in tea. The trade in rice with this island being of such dimensions as we have indicated, it is worth while to consider its present condition and the changes that have recently taken place therein.

In the first place, referring to the tables which appear on next page, it will be seen that the imports *in bags*, during 1868 are given as 2,790,638 while for 1899 they are 3,031,975 showing an increase of 241,337 bags. From this one would gather that the quantity of imported rice had increased last year as it has done for several years past. On examination of the smaller table, however, it will be found that there has in fact been a *decrease* in the total quantity imported by 14,616 bushels. The explanation of this is not difficult: but to make it plain with all the figures before us, is somewhat less easy. The point is that Rangoon rice is measured in bags taking 3 bushels and not 2½ bushels, as is the case with Calcutta bags; these are the usual measures, but not even these remain continuously the same. Moreover in the cases of nearly every other port the quantity per bag is different: and as the larger table, mentions no less than 18 sources from which our rice was drawn last year it will be seen that an increase or decrease in bags is not a true criterion of the actual amount of rice imported. The decrease in the importations of rice last year is nothing abnormal and may almost entirely be explained by the smaller quantity of estate labour then available in Ceylon.

Now as to the sources of our rice supply, Calcutta, in spite of "plague," still stands easily first. Southern India coming next; these two will, we believe, continue to remain our chief sources of supply. Rangoon comes next; but from Rangoon we are again receiving only the broken rice or chips which have been imported for many years past. The trade in Rangoon rice all over the world is something enormous and the surplus crop alone in this year is estimated at about 2 million tons, a good deal of which it is expected that Bombay will take. But rice in Rangoon is differently prepared from the Calcutta and South India rice; in the latter places it is scalded and when used for cooking with curry has a better consistency and is more liked by coolies. From Rangoon there are three kinds of rice, so-called, imported; (1) Cargo Rice—the raw article; (2) Chips, or broken rice, obtained from the mills, and (3) Rice meal, the finer grindings which are used mainly in the manufacture of dog-biscuits. Looking at the

imports of Rangoon rice into Ceylon between 1887 and 1897, it will be seen that they vary between 108,000 and 174,000 bags; this all refers to the broken rice or chips, given as (2) above, which is locally imported solely for the making of hoppers and sweetmeats—while in Europe and elsewhere it is taken largely for the manufacture of starch. In 1897, when there was a scare of plague in Calcutta and it was thought that our rice supply from that quarter might be hampered, it was decided to send Commissioners from Ceylon to Burma to select some quality of raw rice which would be suitable for our coolies and could take the place of the Calcutta article; the result of this was that over 250,000 bags of Rangoon rice were imported in 1898 as against 136,709 in 1897. But circumstances were entirely against the new plan and several local firms who took up the matter found the business unprofitable and went back to former ways. First, the cooly was not used to the Rangoon rice; special instructions were issued as to cooking, but were not followed (who ever heard of a cooly forsaking the old culinary methods with his daily food?); chetties, annoyed by the Rangoon imports, kept the coolies up to these complaints, and they had to be listened to; but—most cogent argument of all—the "plague" in Calcutta was a mere scare as far as the rice trade was concerned, and with a huge crop, prices came tumbling down and the old favourite from the Indian capital thus became cheaper than the new stuff, as well as being better liked. And so, in 1899, a normal condition of things has been resumed, the imports have dropped one-half; and these, we learn from special enquiries, are only of the broken rice, used for consumption with other than the pure rice form.

The rice trade with Calcutta has for some time past been largely in the hands of Chetties; but in June, 1898, a representative of the well-known firm of Grunberg Bros. of Calcutta and Singapore came to Colombo to see what could be done here in the matter of underselling the Chetties, who by their ring had kept the prices above the normal. In October 1898 a branch of the firm was established here and the result was that by competition the prices of rice, as largely fixed by the Chetty community, have been brought gradually down. We learn further that of recent years, or rather month, the Chetties have found that the old profits cannot be made in this trade and the profession of local rice-dealers is passing more into the hands of Moors and Bombay Parsees; while the old lords of the rice market are having greater recourse to the pastime of money-lending, for which the special colonial mania for running into debt offers such terrible facilities in the matter of victims, both young and old, in the East.

In conclusion we may express the opinion that only a rise of price in Calcutta is likely to cause a return to Rangoon raw rice, the trade in which at this port has partially ceased for 18 months, and even then it is doubtful if a slight rise would make very much difference. Burma, it is true, has an immense extra crop to get rid of this year; but from recent Rangoon circulars

it is not thought there will be much difficulty in disposing of it. Strangely enough, in spite of the famine that stalks through the length and breadth of India today, Rangoon finds it a hard matter to send any of its surplus to the nearest chief port. The jealousy is great at Calcutta, of the grand supplies from Burma and almost unconquerable; and there is still less possibility of Rangoon rice ever being brought to Calcutta, and re-exported as the Calcutta article:

experts would detect the difference at once. From all appearances then it seems that direct from the city on the Hooghly Ceylon will continue to draw its largest supplies of rice, the nearer portion of the Indian continent sending about half the quantity that comes from Bengal. Of other sources Penang alone attracts attention, but the trade from that port is scarcely capable of any marked development in the near, or even distant future.

IMPORTATION OF RICE INTO CEYLON IN 1899:

A NORMAL YEAR.

Since the revision of the Customs Tariff, rice is reckoned in cwt. and not bushels as before, 2½ bushels being calculated at 164 lb.; but we put all in bushels. The importation last year showed a slight decrease on 1898, but an increase on 1897.

SCIENCE AND BUSINESS IN FORESTRY.

We are getting more practical every day; and high time we did, looking at the way other nations are catching us up, and even stalking ahead of us in some matters. And there are few things more hopeful and encouraging than the combination of Science with Agriculture. Some of our correspondents, looking far ahead, had insisted many years ago, that the Royal Botanic Gardens at Peradeniya should become self supporting! A dairy established on the rich grassy banks of the Mahaweliganga, would probably have secured this end; but such a notion might even now cause good Dr. Thwaites to turn in his grave! Dr. Trimen was scarcely less conservative as to the scientific character of his charge, though he discussed weather and crops, new products and old, with courage and wisdom in his eminently readable annual Administration Reports. The present Director of the Botanic Gardens has certainly gone farther in a practical direction, than any of his distinguished predecessors; and we may, by-and-bye, find Mr. Willis blossoming forth as the Head of the Agricultural Department, while as a first step, he is likely to take the School of Agriculture under his wing. Then his hands are already greatly strengthened by having as his assistants or allies, men of the experience and attainments of Messrs. E. E. Green, Carruthers and Kelway Bamber, and there should be a good time coming for agriculture in the island with these dauntless scientists ready to take the field against any enemy of plants and crops that may show itself from the animal or vegetable kingdom.

We have, from time to time placed before our readers or commented on, information from India bearing on the same subject. There is, however, another matter on which we have much in common with India, and that is Forests; and we have had for some years a very capable specialist at work among us from the adjoining Continent. But India, too in parts at least—is still groping for light, and its experiences and efforts have still their practical uses for us in Ceylon. The Bengal Forest Department is evidently not as far ahead as its sister establishments—only 45 per cent of Government Forests in Bengal having working plans, against 88 per cent in the North-West Provinces and Oudh, and as much as 97 per cent in the Central Provinces. Bengal has, therefore, been called on to move forward—to prepare working plans and find markets for the produce of its forests. So long as the Government has not full information of the potential supply, it cannot control the market in any way; and the Lieut.-Governor rejects the excuse that the lack of information is due to paucity of officers. If that were so, officers should not have been lent for miscellaneous services elsewhere; and now all such transfers must cease until Bengal is abreast of other Provinces in working plans! To facilitate progress, the working plans are to be less minute and elaborate, so that they may be susceptible of alterations and additions from year to year; and the following

dictum is one that all specialists would do well to keep in view:—

“Forest Officers must realize more than they do, that they are the agents of a great commercial undertaking, and that as such, they are not merely the scientific protectors of an important property, but active exploiters, whose business it is to seek and develop markets for the produce that is ready for use.”

As a beginning, a central depôt is to be established in Calcutta “to foster the exploitation of miscellaneous forest produce in remote portions of the province,” and, among others, the mica industry is to have special attention paid to it. Altogether, Sir John Woodburn seems intent on making matters “hum” in the Forest Administration of Bengal; and it is quite possible that Ceylon too may benefit from a similar stimulus?

 CEYLON COOLY IMMIGRATION AND THE NORTH ROAD—MANURING TEA.

A proprietary planter in a high district, writes after the following rather “wild,” fashion:—

Now is the time when coolies come down the North Road, and people who have nothing cannot afford a matter of ten rupees. As to advances, money sent is always retained by the kanganis who return saying they cannot get coolies and casually say put the amount against me. That's the sole reason advances are not now given out. The law gives us no redress, but only says recover your money by civil suit. We cannot get money sent to the Coast to those who would use it in coming over. Our immigration agency is a farce; it is absolutely of no use whatsoever. Give us an agency where money can be sent for *bona fide* coolies and get estates some protection, then there will be lots of money forthcoming. The wily kangani, as you call him will keep the money whether he comes by Tuticorin or the North Road. What we want is a free inlet for people to come on their own account. When need drives them, they would soon utilize it and knowing it come again. In my opinion it is the kanganis who are keeping coolies out of the country for their own ends. In days gone by coolies would have flocked down the North Road in thousands on their own account during their famine, but now this is denied. [But has our correspondent not seen that for years, fewer and fewer coolies have been coming by the North Road and that the enormous immigration of 1897-98 came through “advances” by steamers?—ED. T.A.]

But, on the other hand, an even more experienced planter says:—

Cooly Immigration—I fancy the great cutting down of coast advances after the too liberal giving out of same has a great deal to do with the sudden decrease in immigration. There is now a tendency to go in for the old style of modified coast advances. It is no use manuring, if you have not the labour to pluck the leaf, and I fancy Mr. Joseph Fraser, our Manuring expert, is too shrewd a man to recommend the application of manure to give 200 lb. tea extra per acre, unless he is satisfied that his constituents have plenty of labour available.

COCONUT PLANTING would seem to be going ahead in the Fiji islands, to judge by a letter on page 604; but then there is the liability to have young and even old clearings swept away by periodical hurricanes, from which Ceylon is so wonderfully free,

TEA AND COLONISATION.

Our Southern contemporary, *Planting Opinion*, in quoting our leader in a recent issue on "Famine Colonisation and Tea," says "*Indian Gardening*," appears to lean towards a great scheme of State colonisation, remarking that if this were established, and planters assured of a regular supply of labour, it would be possible to pass a regular stream of agriculturalists through the tea gardens to the land. We need scarcely point out, however, that success would depend largely, if not mainly, upon the regulations enforced, and with the Assam Emigration Bill in mind, we are disposed to hesitate before arriving at the conclusion that a State scheme is desirable. Certainly, 'there is no reason to doubt that effect could be given to such a scheme if the Government would take it in hand, abandoning its present merely restrictive attitude and adopting instead a spirit of hearty co-operation.' But is there not grave reason to doubt whether such co-operation can be expected from a Government that endeavours to control the scale of pay as between employer and employed, when it does not itself figure as one of the employers? The answer to this question should come from the North. We need only remark that to us it appears an anomaly and a scandal that the Government of India should so persistently manifest a desire to interfere between the planter, employer, and his employes, when it does not even pretend to have any concern for the relations of employer and employe in other industries—such, for instance, as the enormous mill industry that has been developed in India, or the still more important agricultural industry, which affords examples with which the planting industry cannot vie, of what might strike impartial economic scientists as an abuse by the employer of the helplessness of the employed. Again when labour is required for the construction of State or State-aided railways, what restrictions are imposed on the migration of labourers? We are not suggesting that Government should be consistent, for we value too highly what little reputation for sanity we possess. Our sole aim is to hint that inconsistency and eccentricity might be kept within bounds even where the administrative measures of the Government of India are concerned." Our contemporary is evidently afflicted with the historic doubt, whether anything good can come out of Nazareth. We have already had occasion to complain that the Government's Intelligence Department on these questions is not very efficiently worked, but beyond this we do not see reason to go. With full information before it, we believe the Government will give a large measure of justice in time to our industries; and it is the province of the press to see that the deficiencies of official intelligence departments are supplied. At the same time, perhaps, it might be as well for the press to set a good example to Government in dealing fairly and temperately with the questions at issue, and in avoidance of imputations of bad faith.—*Indian Gardening*, Feb. 8.

TEA BULKING AT THE PORT COMMISSIONERS' WAREHOUSE, CALCUTTA.

We have much pleasure in giving publicity to the following from Mr. Apjohn, Chief Engineer in the Port Trust, which explains itself. The views to the Calcutta Tea Traders' Association on this subject will be found in another column:—

To THE EDITOR, "INDIAN GARDENING."

Dear Sir,—Your leader in this week's *Indian Gardening* expresses approval of the introduction of local tea bulking, but gives vent to doubts as to whether the bulking can be accommodated in the Port Commissioners' Tea Warehouse unless it be extended, and you deprecate the bulking being conducted at the Kidderpore Docks. It is proposed to have bulking plant at the Kidderpore Docks in the new tea-shed being provided for the reception of

garden teas sent for direct shipment, and it is for such teas that the Commissioners were asked to provide local hulking, and the Kidderpore Docks is the proper place to conduct it.

For sale teas the bulking must, of course, be in the Tea Warehouse, where plant will also be provided, and it will not be found that this plant will take up a large portion of the floor space which, as you rightly state, is at present in much demand. One of the great advantages of my system of bulking is that but little space is required for its accommodation. Teas to be bulked are brought to the machine from where stacked in the Warehouse, the chests are then opened and their contents poured into the bulker, the empties sent down by a slide to the ground-floor where they are fed to the power packer and delivered ready for closing. All the floor space occupied by the bulker and the operations connected with it allowing ample room for temporarily stacking teas brought for bulking. Opening the chests and closing again on the ground floor does not exceed 6 per cent of the floor area of the Warehouse. The bulker and power packers would be quite capable of dealing in a week with the largest number of chests ever sold at the weekly sale.

Several tea experts who have considered the matter agree with me that the provision of bulking facilities will in time tend to economy of space, when it is recognised that bulking can be effected much more quickly than the present laying down to draw samples, and in time it will become largely the custom to have teas bulked on arrival in the Warehouse before sale, which will not only save time, but afford better samples than are now obtained by laying down each chest and drawing a sample from it. Teas laid down for the drawing of samples occupy for each chest an area of 6 square feet for an average time of 24 hours, whereas stacked to the usual height each chest requires only one square foot of floor space. If the laying down of teas was abandoned for bulking, the Tea Warehouse could accommodate quite three times as many chests as at present.

The business of the Warehouse is rapidly growing, and it is desirable that its accommodation should be increased, but the installation of bulking plant will tend to reduce, and not to increase the pressure on its resources.—Yours faithfully,
J H APJOHN.

Calcutta, 2nd Feb. 1900.—*Indian Gardening* Feb. 8

MINOR PRODUCTS REPORT.

CITRONELLA OIL.—Ten lots have been sold recently at 11d per lb, c.i.f.

COCOA BUTTER.—The auctions to be held in Amsterdam on February 6th will consist of seventy tons VanHouten's, twelve tons Helm, and four tons De Jong; while on the same date in London 110 tons Cadbury's brand will be offered.—*Chemist and Druggist*, Jan. 27.

"THE INDIAN FORESTER."—We have received the January number, the contents are as follows:—Original Articles and Translations—The Production of Sandalwood by C D M'Carthy; Natural Coppice, by Sir Dietrich Brandis, F.R.S., K.C.I.E.; The Forests of Cochin China; Correspondence—The Treatment of Bamboos, Letter from C P Fisher; Is Poinciana Elata a wild tree in India? Letters from F Gleadow and Jalkrisna Inderji; A destructive Fungus on *Xylia dolabriformis*. Letters from R S Troup; Official Papers and Intelligence—The Treatment of Rubber with Alum in Penang; Reviews—Forest Administration in the N.-W. P. and Oudh, during 1898-99; A list of the Trees and Shrubs of Pilibhit, Northern Oudh and Gorakpur; Extracts, Notes and Queries; Timber and Produce Trade; Extracts from Official Gazettes; Appendix Series.

Correspondence.

To the Editor.

PARADUA AND SUGAR IN CEYLON

SIR,—Your correspondent in Saturday's paper is surely mistaken in referring to Paradua as in the Kalutara District. Is it not in the Matara District? And did not good old J W Home acquire the mills there and himself bury a lot of money there? But as you say, the failure of sugar in the past does not necessarily mean its unsuitability for parts of the island in which it had never been tried, especially with improved methods of cultivation and new appliances for manufacture. What a man Home might have been had he not a yearning for great things, for ventures beyond his means? But he was a man of great grit. OLD HAND.

[His career in Ceylon was a romance.—ED. T.A.]

LONDON COCOA MARKET: PRICES LIKELY TO RISE.

London, E.C., Jan. 26,

DEAR SIR,—Thanks for your *Observer* of 5th January. In the paragraph on Cow Tail Hair, you print "in bales of 3,400 lb." It should be "in bales of 300 to 400 lb."

I read Mr. E O Darley's letter on "Cocoa" in Mexico with great interest, but I cannot make out his calculations. He speaks of planting his trees 15 feet apart=200 trees (about) to an acre. He then estimates 50 pods to the tree which gives (treckon) 4 lb. dried cocoa, not more. This would make 800 lb. dry cocoa per acre or 2,000 lb. per hectare, against the 4,500 or 5,000 lb. he speaks of. How does he arrive at his calculation?

Messrs. C M and C Woodhouse in their annual report on cocoa say: "The market opened with a generally quiet tone, but by the end of Feb. there was a moderate advance in value of all British Possessions kinds, which did not extend to those of foreign growth, and then, when the larger arrivals began to press upon the market, there was a steady decline for all descriptions, which prevailed till the middle of July. Subsequently the demand for West India and Ceylon decidedly improved, and this continued with occasional periods of flatness, to the end of the year, by which time prices showed a considerable advance for Trinidad and fine Ceylon."

These gentlemen give the following figures as the consumption in the different countries from which we have been able to obtain reliable information:—

	1899.	1898.	1994.
mths.	lb.	lb.	lb.
