

PRIZES

IN CONNECTION WITH THE

“Tropical Agriculturist” 1903-4.

At the end of the current Twelve Months, three Prizes will be offered by the Proprietors of the “**Tropical Agriculturist**” for the **THREE BEST ESSAYS** summarising and embodying the information given in the *T.A.* volume for the current year (July, 1903 to June, 1904) respecting

NEW PRODUCTS

that is, Products apart from the staples Tea, Coffee, Cacao, Cardamoms, Cinnamon, the Palms, Sugar, and Rice;—and adding such additional and illustrative information as the writers may consider wise.

First Prize	...	Rs. 300
Second „	...	Rs. 200
Third „	...	Rs. 100

 Essays must be sent in within four weeks after the issue of the June number of the *T.A.* for 1904.

A. M. & J. FERGUSON.

1903.

TROPICAL AGRICULTURIST

29 AUG. 1903

TO OUR READERS.

In closing the Twenty-second Volume of the "**Tropical Agriculturist**," we would as usual direct attention to the large amount of useful information afforded and to the great variety of topics treated in the several numbers. From month to month, we have endeavoured to embody in these pages the latest results of practical experience and scientific teaching in all that concerns tropical agriculture; and our ambition has been to make this periodical not only indispensable to the planter, but of service to business-men and capitalists, never forgetting that agriculture trenches upon every department of human knowledge, beside being the basis of personal and communal wealth.

While directing our attention chiefly to the products prominently mentioned on our title-page, we have always taken care to notice minor industries likely to fit in with sub-tropical conditions; and our readers have an ample guarantee in the index pages before them, that, in the future, no pains will be spared to bring together all available information both from the West and East, the same being examined in the light of the teachings of common sense as well as of prolonged tropical experience in this, the leading Crown and Planting Colony of the British Empire.

Special attention has, for a few years back, been given to the introduction and extension in Ceylon, the Straits, Burmah, &c., of an industry in rubber-yielding trees (more especially in the planting of Para and Castilloa trees), and much literature on the subject will be found throughout our pages; also on cacao in Central America and the West Indies as well as in Ceylon; to "Spices" of various kinds (nutmegs, camphor, &c.); to palms, especially "coconuts" in different districts; to coffee and allied products in Brazil, Mexico, Costa Rica, East Java, Nyassaland, British Central Africa; Liberian Coffee in Sumatra, Java, the Straits Settlements; and to other new developments in palms and tobacco planting, &c, in the Malayan Peninsula, Sumatra and North Borneo, as well as in this Island.

The Tea-planting Industry has sprung into so much importance in India (South as well as North) and Ceylon, as also in Java, that a considerable amount of space is naturally given to this great staple; and with reference to all Companies' Reports, to Sales and Prices, as well as to hints for economising, we think it will be admitted by impartial judges that the *Tropical Agriculturist* should be filed, for the convenience of planters, in every Tea Factory in this Island, in India and in Java.

A full and accurate Index affords the means of ready reference to every subject treated in this, the Twenty-second Volume, which we now place in our subscribers' hands, in the full confidence that it will be received with an amount of approval, at least equal to that which has been so kindly extended to its predecessors.

To show how fully other Products besides Tea are treated in this volume, we may mention the number of entries under several headings as follows:—Coffee (including Liberian) 35; Cacao 40; Indiarubber 160; many besides to Gutta Percha; to Coconuts and other Palms, Rice and other Grain, Cinchona, Camphor, Cloves, Fibres, Tobacco, Fruits and Miscellaneous Products over 1,000. In the 22 volumes, the references to Rubber, Cacao and Coffee number many thousands, as also to Coconuts and other Palms.

A "Topical Index" to the twenty-two volumes is now in active course of preparation, and we trust to publish it before the close of the present year.

We are convinced that no more suitable or useful addition can be made to a Planting Company's Library or gift to a tropical planter or agriculturist, whether he be about to enter on his career, or with many years of experience behind him, than the twenty-two volumes of our periodical which we have now made available. They are full of information bearing on every department and relating to nearly every product within the scope of sub-tropical industries.

In conclusion, we have to tender our thanks to readers and contributors, and our wish that all friends many continue to write instructively and to read with approval; for then, indeed, must the "**Tropical Agriculturist**" continue to do well.

NOTICE.

THE interest and responsibility of Mr. DONALD WILLIAM FERGUSON of 20, Beech House Road, Croydon, in the "*Ceylon Observer*" and connected publications, and in our firm, ceased on the 30th June last.

A. M. & J. FERGUSON.

Colombo, 11th July, 1903.

MR. RONALD HADDON FERGUSON, B.A., has been admitted a Partner in our Firm as from the 1st instant.

A. M. & J. FERGUSON.

Colombo, 11th July, 1903.

[With reference to the above notice, we may mention that Mr. IVOR ETHERINGTON, with experience gained as Assistant Editor on "*The Farmer and Gardener*" in England, will henceforward take charge of the *Tropical Agriculturist*, and many improvements are contemplated during the coming year. One of Mr. Etherington's first duties will be to prepare the much-required "Topical Index" to the series of 22 volumes, so that the really valuable information in each set, can be made readily accessible. The Prizes offered for Essays based on the matter in the current volume, will, we trust, quicken interest in the "*T. A.*" and increase the number of its readers; and Advertisers should make a note of this.—A. M. & J. F.]

☞ All Planters of New Products or Pioneers in new lands should not fail to order this periodical as their best instructor. —Every Tea Factory, Coconuts or Cacao Store ought to have a file of TROPICAL AGRICULTURIST, which contains a vast amount of information about these products, and a Record of the Tea and other Produce Sales.

The Portraits and Biographies of some more OLD COLONISTS AND PLANTING PIONEERS are likely to appear in the Volume for 1903-04. In August's Number:—JOHN LEWIS GORDON.

ORDER FOR THE
"TROPICAL AGRICULTURIST."

.....
.....1903.

Sirs,

Please forward the above publication from the beginning of Vol. XXIII, 1st July, 1903.

Please send also (lettered as for.....Estate)
Vols. I, II, III, IV, V, VI, VII, VIII, IX, X, XI, XII, XIII, XIV, XV, XVI, XVII, XVIII, XIX, XX, XXI, ^{AND}_{OR} XXII, for 1881-2, 1882-3, 1883-4, 1884-5, 1885-6, 1886-7, 1887-8, 1888-9, 1889-90, 1890-91, 1891-2, 1892-3, 1893-4, 1894-5, 1895-6, 1896-7, 1897-8, 1898-9, 1899-1900, 1900-1901, 1901-1902, ^{AND}_{OR} 1902-1903,

I am, Sirs,

Yours faithfully,

.....
To the MANAGER,
"CEYLON OBSERVER" OFFICE,
COLOMBO, CEYLON.

SUBSCRIBERS TO THE

* "TROPICAL AGRICULTURIST" *

are reminded that with the June Number, already received by them, and the Index and Title-page now issued, the TWENTY-SECOND VOLUME (1902-1903) is closed.

SUBSCRIPTIONS are due payable in advance for 1903-1904, at the following rates:—

For Ceylon	{	Yearly	Rs. 12		For Europe, &c.	{	Yearly	£1 6.
and India		Half-yearly	Rs. 7		Half-yearly		15s.	

N.B.—Subscribers to the *Ceylon Observer* or *Overland Ceylon Observer* Rs. 4 (6s.) LESS per annum.

Single copies, Rs. 1; back copies, Rs. 1½.

Per Bound Volume, Rs. 16; or £1 6s.

Those who have not settled for past subscriptions are requested to do so by return of Post, and to send Cheque, Post Office Order, or Bank Draft in favour of A. M. & J. FERGUSON, Colombo.

Covers for binding the Twenty-second Volume, July 1902 to June 1903 (873 pages) can be obtained for Rs. 1.50. Cost of binding and cover Rs. 2.50.

WHAT IS THOUGHT OF

THE "TROPICAL AGRICULTURIST."

For cultivators of New Products, it is invaluable, telling us so much that is doing in other countries with the results of their work in Rubber, Fibres, Tobacco, Cotton, Camphor and other Spices, &c.—"Planter."

A gentleman resident in the Central Province, who has as good opportunities of knowing what is of benefit to Planters as anyone we know, sent us the following explicit testimony to the value of the "T.A."—

"Since its commencement, I have regularly seen and perused the *Tropical Agriculturist*. There can be but one opinion that its scope and object are highly important, and that it supplies a distinct desideratum, which it is to the interest of every estate proprietor, to have available in the bungalow for the use of his *locum tenens*, or superintendent. As a magazine it provides varied and instructive fresh literature at intervals; deprived, as most in Ceylon are, of easy access to libraries; and as years go by it will growingly become 'The Ceylon Encyclopædia' with reference to agricultural operations. Viewing estate property as practically a permanent investment to any proprietor, the trifling charge of R12 per annum—a rupee a month—is certainly of no account, provided the separate numbers are kept and bound together yearly as a book of reference for the benefit of the manager and his successors. In that light, as the property of an estate to be handed over just as much as its office furniture, few proprietors would probably refuse to authorise its being taken and filed regularly (if the periodical was brought under their notice), more especially as on looking over the most recent volume one cannot fail to see how much valuable information on 'Tea' has been collated. In the belief that 'Tea' has restored prosperity to Ceylon, and that plantation property is a good investment for capitalists, such should not omit the office and connected equipment so advisable on all 'puoka' estates, a part of which should be the *Tropical Agriculturist*. I find I have gone on writing, but, as I am getting the numbers for the past year ready to be bound, the volume is before me."

THE VALUE OF THE "T.A." TO CEYLON ESTATE OWNERS.—A planting correspondent wrote some time ago:—"I think proprietors should supply every tea estate with the *T.A.* The information in it with regard to everything in connection with tea, &c. is invaluable; it would pay its value over and over again. Owners of estates should not leave it to bard-up superintendents to take it in."

A CORRESPONDENT WRITES:—"I venture to say the volumes of the *Tropical Agriculturist* will be at a premium a few years hence; it is a book which is bound to rise in value as time rolls on, and subscribers will probably, if they so choose, be able to sell at a handsome profit, besides having had the benefit of using the information in the meantime."

FROM A PROPRIETOR:—"I wonder how many planters know what they lose in not subscribing to your wonderful publication? The cost is absolutely nothing, compared to the convenience of having in a bound book all that is interesting and necessary in the literature of their calling. Information culled from a thousand sources, price lists of all produce sold locally, and home advertisements not seen elsewhere, and a hundred other things necessary for them to see and to know. The *T.A.* is, in fact, a convenient file of useful information daily arising and permanently preserved."

SIR W. T. THISLETON DYER, F.R.S., F.L.S., C.M.G., OF KEW GARDENS:—"Sir Joseph Hooker and myself always look out for the successive numbers of the *T.A.* with eagerness, and I keep a file in my office for reference. It is impossible to speak too highly of the utility of such a publication and of the way it is managed."

SIR GEORGE KING, LATE OF THE CALCUTTA GOVERNMENT MUSEUM: "I know your *Tropical Agriculturist* well, having carefully secured every number since the beginning. You have succeeded in making it a wonderfully useful magazine of information for planters."

SURGEON-MAJOR BIDIE, F.L.S., OF THE GOVERNMENT CENTRAL MUSEUM, MADRAS:—"I find the *Tropical Agriculturist* a most interesting and useful publication. It finds a place on the table of our Public Library and is much prized."

* The TROPICAL AGRICULTURIST *

COLOMBO, JULY 1ST, 1902.

No. 1.

FURTHER OBSERVATIONS ON HELOPELTIS.

*Circular and Agricultural Journal of the
Royal Botanic Gardens, Ceylon, June, 1902.*

At the request of the Kelani Valley Branch of the Ceylon Planters' Association, I visited that district in March last and spent nearly a fortnight on an estate in Yatiyantota, where I had a favourable opportunity of studying the habits of the *Helopeltis* insect and its effect upon the tea plant.

My investigations on this occasion has shown me that much more work is necessary before an adequate knowledge of the pest can be acquired. I find that the breeding habits of the insect vary at different times of the year, and will necessitate different modes of treatment. Before a complete scheme of treatment can be offered, it will be necessary to have more accurate observations of the insect throughout the year, and from different elevations and localities. At the end of the present paper I have suggested a few ways in which those interested in the matter could materially assist my work.

I now append the results of my investigations and experiments.

Having previously, on several occasions seen the pest at the height of its activity, I endeavoured to time my present visit to enable me to study the insect at the period of its least activity.

There has been a general idea that *Helopeltis* completely disappears at certain periods. Opinion of local observers varies on this point. Some Superintendents insist that the disappearance is complete; while others maintain that living specimens of the insect may be found, by careful searching, at any time. My own observations lead me to favour the latter supposition. There is no doubt,

however, that there are usually two periods of comparative inactivity: the first, from the middle of March to the middle of June; the second during the months of September, October, and November. These periods vary both in duration and intensity. In 1901 reports from an estate near Dehiowita showed very little decrease of activity during the above-mentioned periods. In other years affected fields have apparently enjoyed periods of complete freedom; though it is almost certain that some of the insects must remain upon the bushes, possibly in a partially dormant condition. The conditions (climatic or other) that govern the periodicity of attack have not yet been properly determined. Rainfall does not appear to be an important factor, as the two periods of greatest activity coincide, the one with a season of comparative drought (January, March), the other with a time of heavy rains (July, August). Wind has been suggested as a cause for the decrease of the pest, but I find that strong wind prevails only at one of these periods.

At the time of my present visit the pest was evidently on the decline, *pro tem*, but the fields showed signs of recent severe attack.

My first experiment was to try the effect of a powerful acetylene gas light. An apparatus supplied by Mr. E. B. Creasy, fitted with a burner of 50 candle power, was used for the purpose. The lamp was set up in a hollow where there was ample evidence of recent attack, and where specimens of the insects were being daily captured by hand. A dark still night was chosen, and all conditions were in favour of the experiment. The burner of the lamp projected from the centre of a basin filled with kerosine and water. Insects attracted by the light fell into the basin and were held and killed by the floating film of oil. The lamp was lit at 6.30 p.m., about half an hour after sunset, and remained burning until daylight next morning, when the surface of the liquid was found to be covered with a floating mass of miscellaneous insects. The work of sorting out and examining the catch occupied the whole of the

next day. There were representatives of nearly every family of insects:—Moths (*Lepidoptera*); Caddisflies (*Trichoptera*); Beetles (*Coleoptera*); Earwigs (*Forficularia*); Flies (*Diptera*); Parasitic Wasps (*Hymenoptera*); Termites (*Neuroptera*); Bugs (*Hemiptera*), both aquatic and terrestrial, including many species of *Capsidae*, a group to which the *Helopeltis* insect belongs, but not a single example of *Helopeltis* proper. I had not been sanguine of complete success, but the failure to capture even a single specimen of the enemy was a surprise and a disappointment. It seems evident that the *Helopeltis* insect is not responsive to attraction by light, though another trial must be made at a time when the pest is in full activity.

I am reserving experiments with a different kind of trap, something on the plan of the hopper-dozers used in America, for trial when the pest is in full activity. I have hopes that by the use of such an apparatus the insects may be captured much more effectually and economically than by hand.

As mentioned above, at the time of my visit the pest had been declining in activity for some weeks. The bushes bore evidence of an earlier severe attack on the mature leaves; but young flush was beginning to come up freely, with only occasional signs of recent injury. An exhaustive examination of many bushes was made to ascertain whether eggs were still being deposited, and in what positions. For this purpose marked bushes were cut across, as in light pruning, and the prunings brought to the bungalow and examined—shoot by shoot, leaf by leaf, and bud by bud—in such a manner that not a single egg could escape detection. The result proved that very few eggs were being deposited at the time, and that a large proportion of those eggs have been deposited in such a position that they could have been untouched by plucking to the initial leaf. Some of the bushes examined had been so badly attacked (previously) that the shoots were small and brush-like, but others had a sufficient amount of new growth to form a possible nidus for the eggs. The larger number of the eggs found were empty. In the following figures only such eggs are reckoned as were judged (by their positions) to have been deposited within the previous month. The average works out at 7.66 groups (the eggs are laid in groups of two or three) per bush examined. Of these, 42 per cent. were above the initial leaf, while the remaining 58 per cent. were in such situations that close plucking would not have touched them. Besides the normal position in the succulent shoots, eggs were found embedded at the base of the unopened axillary leaf bud, and in the thickened base of the midrib of the leaf itself. The flower buds were carefully examined, but no eggs found in them.

The paucity of recently deposited eggs was the more remarkable when it was found that the insects that were being captured at the same time, by the "poochie podians," contained in their bodies a large number of fully-formed eggs than I had previously found in insects examined during the period of greater activity. The day's catch of one of these podians was critically examined. It contained twenty-one female *Helopeltis* insects and twenty-six males. Dissection of the males showed eggs ranging in number from seven to twenty, and giving an average of 12.25 per insect. My previous record had been eight eggs per insect.

Ten gravid females were confined in glass vessels and supplied with fresh tea shoots. They fed freely, but died on the second day. Examinations of the shoots showed that only one insect had deposited a single group of eggs during the period of captivity.

I can only surmise, from these facts, that this period of inactivity is marked by the retention of the eggs in the bodies of the female insects, to be deposited at some future time when conditions may be more favourable for breeding. How long they may be retained in this manner will be a subject for further investigation.

To test the vitality of eggs in prunings left on the ground, young shoots containing recently deposited eggs were placed in a cardboard box and allowed to dry up. None of these eggs hatched out. On another occasion, some eggs in which the embryo was more fully developed, produced larvæ after the shoot had become dry. I am of opinion, however, that little danger need be apprehended from the hatching of eggs from pruned branches. Such larvæ would find no young shoots upon which to feed, and would die of starvation.

The practical immunity of the indigenous varieties of tea remains established. A few cases of partial attack have been reported, but in all such cases it appears that it has been "shuck" trees, or patches of trees on poor soil, that have been affected. This might be expected, for an indigenous plant, growing under unfavourable conditions, would lose its characteristic free growth and free flow of sap, which is believed to account for its immunity. At the same time it is quite conceivable that the pest may gradually adapt itself to the conditions found in indigenous tea, if allowed the opportunity. *Helopeltis* insects, confined with shoots of indigenous tea only, will feed freely on them, but such unnatural conditions do not afford any sure guide to the probable conduct of the insects in the field. (When speaking of "Indigenous Tea," I refer both to the Indian varieties and to Singlo-indigenous, *i.e.*, the direct progeny of Indian plants grown in Ceylon.)

Although *Helopeltis* does not usually attack recently pruned tea, I have records of the return of the pest, in force, after the third tipping.

Search was made for other host-plants of the pest. I was informed that a certain shrub (afterwards found to be *Mussanda frondosa*), growing amongst the tea, was sometimes punctured, but I did not see any such punctured plants myself. Examination of the jungle, on the edge of affected fields, failed to produce any reliable signs of the pest. Some spotted leaves of *Dalbergia championii* were observed, but these spots proved to be due to a fungous disease. I have since received leaves of a species of *Dillenia* (native name "Decapura") that have undoubtedly been punctured by some sucking insect, and the symptoms are very much those of *Helopeltis* attack. No eggs of the insects were, however, found in the specimens.

Helopeltis is extending its range in Ceylon. It formerly confined its ravages (as regards the tea plant) to estates situated in the low-country, *e.g.*, Kelani Valley, Kalutara, Udagama, Morawak Korale. I have recently investigated an undoubted case in the neighbourhood of Nawalapitiya, at an elevation of about 2,000 feet, and I hear of other affected estates in the same district. The pest promises to be as virulent here as at lower elevations. The same conditions were observed here as obtained in the Kelani Valley at the same season, *viz.*, a marked paucity of egg-laying, with an exceptionally large number of eggs in the bodies of the female insects. Nine females were dissected, resulting in an average of 13.22 eggs per insect. There was no difficulty in finding recent signs of attack, and insects could be captured in considerable numbers, but I was informed that the pest had been on the decline since the commencement of March.

I have received the following particulars of the habits of *Helopeltis* in the Morawak Korale district. January to March is usually very dry and hot. *Helopeltis* has been very severe during those months. Heavy plumps of rain commence in the middle of March, when the flush outgrow the attack and shows little or no signs of injury. Another bad attack commences in June and lasts into August, when strong south-west winds appear to check the pest. I am informed that on one estate *Helopeltis* was very severe last year, but had not re-appeared in 1902. No reason could be suggested for this disappearance. It is noticeable here, as in the Kelani Valley, that the first period of activity occurs in the dry hot season; while the recrudescence is coincident with continuous S. W. rains.

In the R. B. G. Circular No. 21 (on *Helopeltis*) I stated that we were without data of the number of moults undergone by the insect during its development, or of the time required for it to reach maturity. I have not yet been able to determine these points for our Ceylonese *Helopeltis* (*H. antonii*) on tea. But Dr. L. Zehntner of Java has supplied particulars for the insect that feeds on cacao in that country. Dr. Zehntner speaks of it as *H. antonii*, but the Java insect has usually been described as a distinct species (*H. bradyi*). The duration of the different stages is given as six days for the egg stage, followed by five moults at intervals of two days each. The number of moults may prove to be the same in the case of our Ceylonese insect, but the duration of the several stages will probably be affected by different climate and food. For instance, I have repeatedly found that the egg stage of our tea *Helopeltis* occupies just ten days.

CONCLUSIONS AND SUGGESTIONS.

My recent investigations show me that, at this spring period of inactivity, the formerly advocated system of plucking to the initial leaf will have little or no effect in checking the pest. A similar condition may possibly obtain during the autumn period. It is most important that the egg-laying habit of the insect (*i.e.*, the quantity of eggs being laid, and the position in which they are deposited) should be accurately determined for every month in the year. It may then be possible to formulate some logical scheme of plucking to suit the varying habits of the insect. For the present, I must recommend the abandonment of close plucking. There is no doubt that that system tends to produce a brush-like formation of small shoots particularly suited to the tastes of the *Helopeltis*. A free succulent growth should be encouraged. Just as anything that tends to reduce the vitality of the "Indigenous" variety lays it open to attack, so any extra vitality in the hybrid or China "jats," producing a character approaching that of the indigenous plant, will incline to make them distasteful to the pest.

At the same time nothing should be allowed to interfere with the campaign against the insects themselves. The more carefully and thoroughly this work is carried on, the less will be the loss of crop. The average loss through *Helopeltis* has been estimated at 200 lb. per acre. Putting the profit on that tea at 12 cents a lb., this means a loss of Rs. 24 per acre. This figure would cover, several times over, the cost of systematically catching the insects. The collection of the insects is even more important during the period of partial inactivity, for, as I have shown above, at such times the females contain the maximum number of eggs.

The more I see of the habits of *Helopeltis* on our tea estates, the more convinced I am that the work of checking this and other insect pests would be very greatly facilitated by breaking up the area into blocks of from 10 to 20 acres, divided from each other by narrow but compact belts of other trees. The insect does not fly high; its flight is weak, and, when on the wing, it is carried from place to place more by the wind than by its own wing power. I have frequently noticed the effect of an ordinary wind-belt in limiting the spread of the pest. It would be possible to fight the pest in such isolated blocks one by one, with some assurance that they would not be immediately re-infected from neighbouring fields. Such a screen would almost certainly prevent the incursion of the pest into fields of indigenous tea. It would be necessary that there should be some thick undergrowth to complete the screen. In districts suitable for them, economic trees and plants might be employed for the belts. For the larger trees, Para rubber, Coconut, Nutmeg, or Kola-nut suggest themselves. For the undergrowth, Croton Oil, Annatto, Castor Oil, or Tapioca might be used. Or the screens might consist of trees and plants, the clippings of which would be suitable for green manure, such as *Albizia moluccana*, or "Dadap" (*Erythrina*), with *Crotalaria* as an undergrowth. The tea plant itself, allowed to run up, would form a good undergrowth, and might be used for seed production. Tea, grown in this manner, is little—if at all—affected by *Helopeltis*, which is dependent upon the constant supply of flush, occurring only on pruned bushes. But some other plant would be preferable.

To enable me to complete my investigations on the breeding seasons of the insect, and the position in which the eggs are laid at different times of the year, fresh (if possible, living) specimens of the insects, and the tops of a certain number of bushes, from selected estates, should be sent to me at regular intervals—say on the 15th of each month—for examination. I would suggest that four estates should be selected from different localities, and that the prunings of two bushes from each of these estates should be sent in regularly on the specified dates. Bushes that show the most recent signs of injury should be chosen. If the pest appears to have gone into retirement, bushes from the most lately attacked fields should be selected. The whole top of the bush should be cut off, as in pruning to a level, the prunings from each bush collected and tied up separately in sacking or jute hessian (slightly damped), and despatched by first train to "The Entomologist," R. B. Gardens, Peradeniya. It is important that the specimens should arrive in as fresh condition as possible. At the same time living specimens of the insects (about fifty from each estate), packed in tea sample boxes, should be posted to the same address.

E. ERNEST GREEN,
Government Entomologist.

Peradeniya, May 20, 1902.

DESICCATED COCONUT—AND OIL.

SEYCHELLES, 9TH JUNE, 1902.

(The Editor, "Tropical Agriculturist," Colombo.)

SIR,—I am writing to ask if you, or any of your readers can give me information as to the process of desiccated coconut manufacture? What machinery is necessary and its probable cost? What would be the lowest number of coconuts dealt with per day to make it a paying concern at prices now ruling in

Ceylon? Can the manufacture of oil be carried on at the same time and in the same building as the desiccating process? I should be much obliged if you could give answers to the above questions.

I am, yours truly,

VANILLA.

[We would advise "Vanilla" to address one of our Machinery houses, say Messrs. Walker, Sons & Co., Ltd., The Colombo Commercial Co., Ltd., Colombo, as for the requisites in machinery required for desiccated coconut and the oil.—ED. T. A.]

FRUIT, SUGAR, TOBACCO, &c. IN JAMAICA.

From a paper read before the Society of arts by Mr. H. T. THOMAS, twenty-five years resident in Jamaica, we quote:—

The products of Jamaica are as numerous and varied as are its climate and degrees of temperature at various altitudes. Its soil is, in most districts, of wonderful fertility; and of it one may truly say that it has only to be tickled with a hoe to make it laugh with a harvest. A great number of those products now rot uselessly on the ground, and still await the touch of capital and enterprise to convert them into sources of wealth. *Oranges*, golden and luscious, grow wild. Only within the last six or seven years, since their value as an article of export has begun to be more and more realised, has any attempt been made at systematic cultivation, and improvement by budding and other processes. The sour *Seville oranges*, of whose rind the most delicious marmalade is made, literally wither on the trees or rot on the ground by millions year by year. The same is true in an even higher degree of the *guava*, the fruit from which the well-known luscious jelly is prepared. In some districts the tree is positively a noxious weed, and has to be cut down and cleared away by the acres to make room for cultivation of other products.

As a matter of fact, in spite of these circumstances, orange marmalade, manufactured in England or Scotland, and imported into Jamaica, can be purchased at a less price than the manufacture of the home-made article costs; and the same would no doubt be the case with guava jelly, if the latter fruit could be procured at home, as oranges are, from other sources. The cause of this apparent anomaly lies in free trade, which has the effect of making the sugar necessary for these manufactures a more expensive article in Jamaica, where the sugar itself is made, than it is at home. And this brings us by a natural process to the discussion of *sugar* itself, and its concomitant, *rum*, which were once the staple of the island, but have now fallen on such evil times, owing entirely to the operations of the free trade principle, as to constitute jointly only 18 per cent of the total value of the exports. The decay of this industry cannot, I think, be more forcibly illustrated than by the statement that, whereas at the beginning of the 19th century there were upwards of 800 sugar estates in cultivation, there are to-day no more than 121. The famous rum of Jamaica, which is a household word, has been so largely superseded, even in the island itself, by whiskey, that it is now little more than a recollection and a name. There is, however, a particular description of rum which is only manufactured on certain estates in one district of the island, and which, although utterly unfit for human consumption in its natural condition, is much prized in the German market, and is eagerly bought up at prices which appear enor-

mous when compared with those given for the ordinary kinds.

The place once occupied by sugar in the trade of Jamaica has now been completely usurped by fruit: first the *banana*, and then, a long way after, the *orange* and the *pineapple*. In the year 1875 the first load of bananas was taken away from Jamaica to the United States in a small schooner by a Yankee skipper. In 1879 the total value of the fruit exported from Jamaica was estimated at £40,000, while in the returns for 1899-1900 it is set down at £314,000. These bare figures describe the growth of the fruit trade more eloquently than any words possibly can do. And this trade is entirely the offspring of American enterprise. The Yankee skipper above-mentioned is now the head of the Jamaica branch of the gigantic concern known as the United Fruit Company, whose headquarters are at Boston, Mass., with offices in New York, Philadelphia, Baltimore, and numerous other places in the States, in Central America, and in the West Indies; notably, since the termination of the Spanish-American War, in Cuba and Porto Rico. They own hundreds of thousands of acres of land in Jamaica, employ thousands of labourers, and use thousands of head of horses, mules, and cattle. They contribute thousands of pounds to the Inland Revenue and the Customs of Jamaica, over and above what they spend in wages, &c. Besides shipping their own fruit, they purchase millions of bunches from other growers, and in the busy season, which last from April to July, they despatch from twelve to fourteen steamers a week laden with fruit. They have laid down tramways, and strung telephone wires round half the island. They have converted the town of Port Antonio from a fishing village into a thriving, bustling, business centre. They have built a fine hotel there, on one of the loveliest spots in the whole island, and they fill it every winter with hundreds of tourists brought down from the States in their own steamers, whose money circulates in the island to the common benefit. They have prevented the eastern and north-eastern districts of the island, where the sugar industry fell into decay more rapidly than in any other part of it, from relapsing into the condition of a primeval African wilderness. In short, if there is one man in the world to whom the grateful inhabitants of Jamaica should erect an imperishable monument, that man is the Yankee skipper who took away that load of bananas in 1875.

The Americans are more a nation of fruit-eaters than the English; and it is to this fact, and to their recognition of the actual food value of the banana, that the continued increase of the demand for it is due. It is becoming a common article of diet among the working classes; and we hope to see the day before long when its value in this respect will be equally recognised in the mother country.

In this direction a determined and laudable effort was begun last year by a man who has been aptly described as a "Napoleon of commerce." He is now Sir Alfred Lewis Jones, K.C.M.G., the head of the firm of Elder Dempster & Co. He has built a small fleet of four steamers which ply direct between the port of Bristol and Kingston, Jamaica, making the voyage in twelve to thirteen days. By the terms of his contract, he is bound for a period of five years, to purchase in the land a minimum of 20,000 bunches of bananas every fortnight for sale in the United Kingdom. I well remember the interest and anxiety with which the

arrival of the "Post Morant," the pioneer vessel of the fleet, was awaited throughout the island in February last, and the crowds which thronged the wharves to watch her progress up the harbour when her approach was signalled. It was felt that the links which bound the ancient British colony to the mother country, neglected and almost rusted through, were now being forged afresh, and that a new era was about to dawn. And I remember how eagerly the telegram was longed for which should announce the arrival of the ship at Bristol, and the condition of her cargo; and what a wave of relief and rejoicing swept through the island when news of the best was flashed across the wires. Since then the venture has made steady progress, and the fruit trade between Jamaica and England may be regarded as being established on a firm basis. Experience and resolution have corrected the faults and overcome the drawbacks inseparable from the initial stages of such an experiment, and the tide is steadily flowing, never again, let us hope, to ebb.

Not content with exploiting the fruit trade, Sir Alfred Jones has insisted on the advantages of Jamaica as a health and a winter resort—with which I shall deal later on—and has leased from the Government the two principal hotels of the island, placing them under such management that the tourists and invalids whom he conveys thither in his steamers may enjoy to as great a degree as possible the comforts to which they are accustomed at home.

The first-class return fare is only £32, and the voyage—in itself a pleasure and a substantial benefit to those in weak health—lasts but from twelve to thirteen days each way.

The principal disadvantage attending the cultivation of the banana is the danger of destruction by gales of wind that would not affect any other description of cultivation. Added to this is the careful handling which the fruit requires to prevent its being rejected by the buyers on account of bruises. On the other hand the profits are enormous and may be calculated at not less than from £9 to £10 per acre per annum. Thus damages by storm or flood can always be amply recouped within twelve months, the period which elapses between the planting of the sucker and the reaping of the mature fruit.

An excellent, nutritious, and easily digestible flour is made from the green fruit; and the development of this branch of the industry only awaits the discovery of some process by which it will be possible to produce the flour so cheaply as to enable it to compete with wheat flour. When that shall have become an accomplished fact, millions of bushels which are now unmarketable and are thrown away, or given as food for pigs and other stock, will be turned to use and profit.

Pineapples are now receiving great attention in Jamaica. Certain kinds of them bear transport better than any other description of fruit with which I am acquainted. Some fellow-passengers of mine brought over several in May last, simply stowed underneath the berths in the cabin, and on our arrival at Bristol, they looked as if they had been gathered the previous day.

The Jamaica orange is second to none in flavour and juiciness, especially the kind which grows—practically quite wild—in the parish of Manchester. Readers of Mr. Froude's "Bow of Ulysses," will remember his almost rapturous description of the Mandeville orange. The great bulk of this fruit is now shipped to the United States; and as already

stated, it is being systematically cultivated. Experts who have been driven out of the state of Florida—Jamaica's chief rival in the American orange market—by repeated frosts, have migrated to Jamaica and turned their attention to the cultivation and packing of the fruit there. This product is also receiving its due share of attention at the hands of Sir Alfred Jones; and I have been greatly gratified by seeing in the fruiterers' shops in Bedford, Jamaica oranges which in appearance and flavour leave nothing whatever to be desired.

The cultivation of *cocoa* has very largely increased of late years. It is now planted, almost as a matter of course, in all the banana fields, where the bananas afford the young plants the shade which is indispensable to them for the first year of their existence. The same soil suits both, and the one cultivation does not interfere with the other in the slightest degree. At the same time the art of curing the *cocoa* is much better understood than was previously the case, and the Jamaica product is now steadily bridging the great gulf in price that not long since lay between it and the celebrated Trinidad *cocoa*.

Coffee has shared the fate of most other products, and suffered disastrously in competition with other producing centres of vast extent which are being opened up year by year; but the delicate Blue Mountain coffee, which is grown at high altitudes among the mountains, still maintains its reputation for unrivalled flavour, and has not been affected by competition in the same manner as the lower grades.

I am unable to assign any reason for the fact that the excellence of the Jamaica *tobacco* is not more widely known in the United Kingdom. It is a fact that as good a cigar, of local manufacture, can be purchased in Jamaica for twopence, as would cost at least sixpence in London. The manufactures of the island supply it entirely with cigars, and to a great extent, with cigarettes, manufactured almost exclusively from native-grown tobacco, only the outer leaf or "wrapper" being imported; but it does not appear that any attempt has been made to establish export trade on a large scale. The tobacco trade has hitherto been exclusively in the hands of Cubans, who, driven from their own country by constant rebellions and Spanish oppression, have settled in Jamaica, in considerable numbers, most of them becoming naturalised as British subjects. But this industry is now receiving the attention it deserves at the hands of a gentleman who brings to bear upon it not only wealth, but position and influence. He is the Hon. Evelyn Ellis, uncle of the present Lord Howard de Walden, and a large land owner in the western part of the island. He has there established a tobacco plantation which is already the largest, under the control of any one man, in the world. Factories have been erected on the spot, and cigars and cigarettes are being turned out in large quantities. There is also a chemical laboratory in which highly skilled experts experiment with numerous other products that now run to waste. There is not the least doubt that Mr. Ellis's exertions will be of incalculable benefit to the island, especially if he takes up the matter of an export trade in cigars to the mother country. He it was who entirely revolutionised the breeding of cattle for draft purposes in the island by importing stock from India to his magnificent properties of Jamaica, which, crossed with the native breed, make the most ideal draft oxen that can be desired. His herds now practically supply the

whole island, and his annual sale is a great event among the sugar planters in the western districts.

Another industry which has only very recently sprung into existence, and in the future of which I have great faith, is the cultivation of *rice*. Rice is very largely in use as an article of food among the negroes, and there are thousands of acres of swampy land, utterly useless for any other purpose, which might be profitably turned into ricefields. I myself witnessed the first experiment which was made in the vicinity of the town of Falmouth, on the north side of the island, and can testify both to its success as a commercial venture, and the improvement to the town effected by it from a sanitary and an aesthetic point of view.

CASSAVA POISONING.

Amongst the important food plants cultivated in the West Indies is the 'Cassava' or 'Manioc' *Manihot utilisima*, a member of the 'Spurge Order, or *Euphorbiaceae*', grown for the sake of the store of starch contained in its long, thick roots. Two kinds of cassava are commonly recognised, the 'bitter' and the 'sweet,' and sometimes considered to be two distinct species of plants. Bitter and sweet cassava are put to separate uses. From the bitter variety, after grating and careful expression of the milky juice, a flour is obtained from which thin cassava cakes are made. It is also the source of 'farine' and the tapioca of commerce. The raw juice cooked and concentrated is known as casareep. The sweet cassava is more commonly eaten, as a vegetable, after boiling or roasting. Bitter cassava in the fresh condition is well known to be harmful and experiments have been made which prove the extremely poisonous character of its milky juice. The poisonous constituent of the raw juice is prussic acid, or hydrocyanic acid, easily recognizable by what is known as the 'smell of bitter almonds. Prussic acid is fortunately a poison which it is comparatively easy to get rid of completely. It is only necessary to ensure that the substance containing it shall be thoroughly heated, and all the prussic acid present is destroyed and the substance rendered perfectly harmless.

As already said, bitter cassava is universally regarded as a poisonous substance. With regard to sweet cassava, on the other hand, opinions vary and even in a standard book of reference on Chemistry it is stated that 'the milky juice in the sweet variety is innocuous, whilst that in the bitter is highly poisonous.'

Deaths from eating improperly prepared sweet cassava occur from time to time in the West Indies, principally amongst badly-fed or neglected children. In order to prevent, if possible, the recurrence of such accidents, it is desirable that the actual facts should be published and made widely known in the hope that teachers and others may be able to put children on their guard against the danger of eating sweet cassava unless care has been taken in its preparation.

As long ago as 1877, Professor Francis, then Government Chemist at Trinidad, stated, as the results of experiments that sweet cassava root contained considerable quantities of prussic acid. His work has recently been repeated and extended by his successor Professor P. Carmody (*Annual Report of the Government Analyst, Trinidad, 1901, p. 15*). From their investigations it appears that sweet cassava not only contains the poisonous prussic acid, but contains nearly as much as bitter cassava, and that by mere chemical analysis it would be impossible to distinguish between the two. Professor Carmody was able to show that whilst in bitter cassava the prussic acid is distributed more or less uniformly throughout the tissues of the root, in the sweet cassava it is located chiefly in the skin and outer portion of the rind. It follows that in order to prepare sweet cassava

so that it may be a safe food for human beings the following precautions should be taken:—

(1) Carefully scrape off the skin and outer portion of the rind, whereby the greater portion of the poison will be removed.

(2) Thoroughly heat the remainder by boiling or otherwise, so as to destroy and drive off any remaining prussic acid.

Thus prepared sweet cassava is a thoroughly wholesome article of food, as the experience of many who eat it regularly is sufficient to prove.

One other word of warning is necessary. Professor Carmody has indicated that although all the prussic acid originally present in the root may be got rid of, it is possible that a small further quantity may be formed later by changes dependent on the addition of water. Cassava which has been cooked and then kept for some time may still be a dangerous substance, and should not be eaten. The rules to be followed in preparing and eating sweet cassava are thus:—

(1) Scrape the root. (2) Cook it well, so as to heat it throughout. (3) Eat cassava only after it has been freshly cooked.—*West Indies Agricultural News*

COMPOSITION OF THE BREAD FRUIT.

The following analysis of the bread fruit is recorded in the *Experiment Station Record, Vol. xii, p. 1076*:—

Water	46.21	per cent.
Protein	2.34	" "
Fat	0.40	" "
Starch	41.42	" "
Crude Fibre...	4.20	" "
Ash	1.78	" "
Undetermined	3.65	" "

In comparison with the sweet potato and yam (which agree very closely with one another in their chemical composition) the bread fruit contains 25 to 30 per cent. less water, about 25 per cent. more starch and a distinctly higher proportion of protein or nitrogenous matter. Expressed in other words, whilst one pound weight of sweet potato or yam contains about twelve ounces of water and two ounces of starch, one pound of bread fruit contains about six and a half ounces of starch and only seven of water. Although superior as a food stuff so far as actual chemical composition is concerned, the presence of over four per cent. of fibrous matter in the bread fruit is a point in which it compares unfavourably with the sweet potato and yam.—*Agricultural News.*

RUBBER OUTPUT OF THE AMAZON VALLEY.—The United States Consul at Para reports that at the close of 1901, the receipts of rubber at Para were nearly 30 per cent. greater than ever before at that season. Business was good in 1900, exchange low, and credits easy. The labourers and middlemen indulged in many luxuries. The end of the season found the crisis at hand, exchange rising rapidly, the gatherers deeply in debt, and the price of rubber reduced 20 per cent. Now they are making a desperate effort to pay off this indebtedness and make a fresh start. They are getting a large proportion off their food from the streams and forests by hunting and fishing; they are purchasing only absolute necessities; and are working overtime to increase the crop and liquidate their bills. It was reported in December that there were on the way down the river, from the upper tributaries of the Amazon, about 700 tons more rubber than had ever before been shipped from that section in one season, and that there were at least 200 tons more to follow. About 30 small steamers and launches left Para and Manaus for the Acre, Juruá, Purus, and Beni rivers, and were due to return to Para in February. Altogether, adds the Consul, there is reason to believe that this season's rubber crop will exceed that of last year by a very considerable margin.—*Imperial Institute Journal,*

THE PURCHASE OF ARTIFICIAL MANURE.

The following is the first portion of a paper which appeared in the *Journal of the Board of Agriculture* for March 1902:—

There are three substances, and only three, that are valued in artificial manures, namely, nitrogen, phosphates, and potash. According, therefore, to the greater or less quantity of one or other of these substances the value of the manure will rise or fall. Some manures contain only one of these substances—for instance, nitrate of soda and sulphate of ammonia contain only nitrogen; super-phosphate, precipitated phosphate, and basic slag contain only phosphate; and kainit, sulphate of potash, and muriate of potash contain only potash—while other manures hold two substances of value, as in the case of bones, which furnish both nitrogen and phosphates, or saltpetre (very seldom used, however, as a manure), which supplies both nitrogen and potash. Only one class of so-called artificial manure, namely, Peruvian or other similar guano, contains an important amount of all three substances.

NITROGEN.

In price lists nitrogen is frequently expressed as ammonia. The relationship between the two substances is, however, a very simple one, and need occasion no difficulty or uncertainty: 17 lb. of ammonia always contain exactly 14 lb. of nitrogen, or what is the same thing from the farmers's point of view, 14 lb. of nitrogen are the equivalent of 17 lb. of ammonia. If, therefore, a sample of, say 'corn manure' is offered as containing 4.5 per cent. of ammonia, this is the same as saying that it contains 3.7 per cent. of nitrogen. Sometimes, though not often, the figure is made to look more attractive by being stated as sulphate of ammonia; but this also need cause no difficulty, if it be remembered that 66 lb. of this substance are equivalent to no more than 14 lb. of nitrogen and 17 lb. of ammonia. If, therefore, we take the above example, the figures mean one and the same thing, whether they are stated as 3.7 per cent. of nitrogen, or 4.5 per cent. of ammonia, or 17.4 per cent. of sulphate of ammonia. But a manure merchant who failed to effect many sales for a fertilizer of ever so high-sounding a name on a statement of 1 per cent. of nitrogen 1.2 per cent. of ammonia might be more successful with a certain class of buyer if he entered the nitrogen as equal to 4.7 per cent. of sulphate of ammonia, and yet the figures all represent the same fact. Under the fertilizers and Feeding Stuffs Act, 1893, the invoice must contain the minimum guarantee of nitrogen, stated as such.

PHOSPHATES.

Phosphates or phosphate of lime may also be entered in an analysis or price list in several ways, but as a rule this ingredient is either stated as above or as phosphoric acid. In an invoice, however, the statement must be made as soluble or insoluble phosphates, as the case may be.

The relationship between phosphates or phosphate of lime, whether soluble or insoluble, and phosphoric acid is quite as simple as that between nitrogen and ammonia: 142 lb. of phosphoric acid always form 310 lb. of phosphate of lime, so that to convert the former into the latter one may multiply by 2.2 which, though giving an answer slightly above the truth, is quite accurate enough for all ordinary purposes.

If, therefore, the analysis of a manure is returned as 12 per cent. of phosphoric acid, it is equivalent to saying that it contains fully 26 per cent. of phosphates. Similarly 30 per cent. of phosphates is equal to nearly 14 per cent. of phosphoric acid.

POTASH.

Potash usually exists in manures in the two forms of sulphate of potash and muriate or chloride of potash. It takes 94.2 lb. of pure potash to form 174.2

lb. of sulphate of potash, whereas the same amount of potash will form only 119.2 lb. of the muriate or chloride. In the former case, therefore, to convert potash into terms of sulphate of potash we multiply by 1.85, whereas in the latter case we multiply by 1.58. If, therefore, an analysis of, say, kainit is stated as 12.5 per cent. potash, that is equivalent to say that it holds over 23 per cent. of sulphate of potash; while muriate of potash guaranteed to contain 58.8 per cent. of potash is of about 90 per cent. purity.

Just as a buyer may sometimes be led into purchasing a manure through its nitrogen being expressed as sulphate of ammonia, so may the contents of potash be made to look more attractive by being stated as sulphate of potash. In an invoice, however, the potash must be stated as such.

The rules for approximately converting the various terms into their equivalents may be thus summarised:—

To convert Nitrogen into terms of Ammonia multiply by 1.2.

To convert Nitrogen into terms of Sulphate of Ammonia multiply by 4.7.

To convert Phosphoric Acid into terms of Phosphates multiply by 2.2.

To convert Potash into terms of Sulphate of Potash multiply by 1.85.

To convert Potash into terms of Muriate of Potash multiply by 1.58.

Nitrogen and phosphates, and, to a less extent, potash, vary in effectiveness, and therefore, in value, according to their source or origin. Nitrogen is never so effective as when in the form of nitrate of soda. [See 'Note added' Ed.] It is not quite so active, and for some purposes not so valuable, when in the form of sulphate of ammonia, though under certain circumstances this somewhat slower action may be regarded as an advantage. Nitrogen in what is called the organic form is in its least active condition, though here again the rapidity and effectiveness of action vary greatly. Nitrogen is in the organic form in blood meal, fish meal, bones, shoddy, etc., and yet, as a source of plant food, blood meal is more active than these other substances. It is claimed as an advantage for slow-acting manures that they last longer, which is true; but one applies manures not to last, but to act. It is only where it is convenient to apply manure at somewhat long intervals, as in the treatment of orchards, that the more inert manures are worthy of much consideration.

As regards phosphatic manures, it may be said that while soluble phosphates are all alike active, there is considerable difference in the value of insoluble phosphates. The insoluble phosphate of bone meal, for instance, is less effective, and for most purposes less valuable, than the insoluble phosphate of basic slag, precipitated phosphate, or even dissolved bones. Some of the insoluble phosphate of the last manure has once been soluble, and has 'reverted,' and such phosphate is not much less effective than soluble phosphate. But raw bones as a manure have been longer known to British farmers than other forms of phosphate, and for this reason their price has kept relatively high.

[NOTE ADDED.]

With regard to the statements above relative to the superiority of nitrate of soda, as a source of nitrogen, to sulphate of ammonia, it must be remembered that the conditions which obtain in temperate regions are referred to. Experiments in Barbados have shown that sulphate of ammonia produces better results in sugar-cane cultivation than nitrate of soda. Sulphate of ammonia is changed by nitrification in the soil, into nitrate of calcium. Nitrification is very active in tropical soils, and this fact, together with the liability to loss by leaching in the case of nitrate of soda, may explain the superiority of sulphate of ammonia in certain tropical lands.—*Agricultural News.*

"THRIPS" ON CACAO IN GUADELOUPE.

Through the courtesy of Mr. Louis H. Ayme, United States Consul at Guadeloupe, a copy has been received of a translation of a report by M. Aug. Elot on the occurrence of 'thrips' on cacao in that island. This pest was the subject of an article, with figures of the young and mature insect, in the *West Indian Bulletin*, Vol. II, pp. 175-190, where its occurrence in Grenada, St. Vincent, St. Lucia and Dominica was noted, with a comprehensive description of its habits and distribution in Grenada.

M. Elot's report deals evidently with the same insect and, whilst showing that it has extended its range to Guadeloupe, describes an attack closely similar to that observed in some parts of Grenada during 1900. In his summary, M. Elot says that the pest is pretty widely distributed among the cacao plantations of Guadeloupe; that the damage is sometimes insignificant, sometimes very great, according to the environment; that the best way of protection against the disease is found in seeking favourable conditions for the culture and in giving the plantations every care compatible with such culture, and then if, in spite of these, damage is caused by the insects the remedy is to be sought in spraying the trees affected with kerosene emulsion.

The attacks of 'thrips' in Guadeloupe are similar to those elsewhere, the amount of the damage being large or small according to circumstances. Evidently M. Elot's experience fully confirms the view that whilst careful treatment of the trees will do much to lessen or avert the attacks of the pest, the ultimate reliance must be placed in spraying. The question of spraying was very fully dealt with in the article on thrips referred to above, and whilst kerosene emulsion was recommended especially for spraying pods, rosin and other washes were suggested for general treatment. The insect can probably be regarded as a pest of cacao, always ready to become troublesome and cause damage whenever the conditions are favourable, either from drought or from neglect and wrong treatment of the trees.

Whether the pest will eventually become so destructive as to need extensive treatment on a large scale is doubtful, but cacao planters in Grenada, St. Vincent, St. Lucia, Dominica and Guadeloupe will need to be on their guard for signs of injury and use the spraying machine to check the increase of the insect whenever it becomes destructively abundant.

M. Elot's report states that the insect had been sent by him to Prof. Giard at Paris, who has named it *Phytopus rubrocincta*. It was previously regarded here as belonging to the genus *Heliothrips*. Mr. Pergande of the U. S. Department of Agriculture, to whom the insect was referred for determination, was of opinion that it constituted a new genus allied to *Heliothrips*.

Specimens of the insect were also sent to Mr. E. E. Green, who had previously recorded the occurrence of a thrips on cacao in Ceylon. In a letter of September 16, 1901, he states:—"I beg to acknowledge receipt of your specimens of the 'Grenada thrips.' This insect appears to be closely allied to the thrips affecting cacao in Ceylon. The larva and nymph of our Ceylonese insect are also distinguished by a transverse crimson band, which appears to be a striking feature in the early stages of the Grenada thrips."

The geographical distribution, as known at present, is Grenada, St. Vincent, St. Lucia, Dominica, Guadeloupe and possibly Ceylon. It is not improbable that the insect will be found to occur in other parts of the West Indies and South America.—*West Indian Bulletin*.

FORESTRY IN INDIA.

[Yearly Forest Report, Madras, 1899-1900.]

SEVERE CRITICISM: WANTING TO KNOW ABOUT
EUCALYPTS.

I have searched in this report, amidst the dreary waste of undiscussed and undigested figures, for information regarding the interesting growth of Australian trees on the Nilgiris. *Eucalyptus* I find referred to as if it were one tree, not a class of trees. Your readers are probably aware that there are about 150 species of *Eucalypts* with climatic requirements ranging from the tropics to that of the temperate zone. There are two or three species which flourish in Java; and Roxburgh refers to a *Eucalyptus* Moluccana, which was cultivated for some years in the Calcutta Botanic Gardens. These species flourish under the equator. Going polewards we find the last of this most remarkable genus of timber trees in a climate hardly differing from Devonshire in England—a little more snow in winter, and a little higher insolation. Nine tenths of the species of *Eucalypts* are worthless for timber purposes. A few, such as the W. Australian Jarrah and Karrie, the S. Australian sugar gum and Leucosylon gum, and the E. Australian iron-barks, tallow-wood, and E. resinifera, together with E. rostrata of the dry interior, afford some of the most useful timber trees for out-door use and whenever great strength is required. As I remember the Nilgiris (Now alas! nineteen years ago) only the least valuable kinds were grown there, but these were marvellous as regards celerity and vigour of growth. Since then a railway has been made to the Nilgiris, and this White-man's oasis thoroughly opened up. In Ceylon and many other countries the steel sleepers (which should never have been put down) are being replaced by hard wood, *Eucalypt* sleepers from Australia. One naturally, therefore, turns to the Madras report to see what is being done to grow these valuable *Eucalypt* timbers in the temperate climate of the Nilgiri plateau which is seemingly so well suited to them! The information afforded in the Madras Forest Report is miserably meagre. Thus we read that some *Eucalypts* have been planted in the plains of the North Arcot district which had failed, as might be expected. Some seedlings in nurseries on the Shevaroyys were 2 inches high. "The trees of the different species of *Eucalyptus* in the Nilgiris were, on the whole, doing well." Surely the Madras Forest Department might do more, or tell us more of what was doing than this. Is it that its work is paralysed by the unfortunate system of dual control and divided responsibility?

The Madras Board of Revenue describe this meagre report "as a full and interesting one." No doubt it is full to the brim of figures. One is tempted to enquire what purpose is gained by printing 50 pages of figures and bald statements. Would it not be better to place these in the archives of the Board of Revenue, and furnish to the Government of India, and to the public, an intelligible digest, thus following the course pursued in other large industrial concerns run on a business footing?—(D. E. H.) Cape Town, 6th September, 1901.—*Indian Forester*.

CULTIVATION OF TOBACCO UNDER TENTS.—We are informed that the cultivation of tobacco under tents is now being experimented with in Connecticut. The experiments were made originally at the State Agricultural Station, as well as by private individuals, in the effect to raise wrapper-leaf tobacco of the Sumatran type in fields completely covered and o'osed in all round with thin cheesecloth. The result is declared to be perfectly satisfactory. If memory serves us aright, the experiment was tried some thirty-five years since at a place called Broxbourne, on the G. E. R., but only on a small scale, and was attended with a fair amount of success; netting of sm. ll mesh was used as a covering to the "pens"—*Gardens' Chronicle*.

ANNUAL REVIEW OF THE RUBBER MARKET FOR THE YEAR 1901.

KRAMRISCH AND COMPANY., LIVERPOOL AND LONDON.

During 1901 the Rubber Market has not been characterized by heavy or exceptional fluctuations; it was again not a particularly satisfactory one for holders and importers of the leading grades, and although trade remained exceedingly active throughout the year, the values of all grades of Rubber at the close are less than a year ago, and Fine Para shows a further recession of 3d per lb, and other grades in proportion. The bulk of the stocks of Mediums has gradually been exhausted, although it must be admitted that the prices realised were exceptionally low and showed an enormous loss to the importers or holders; and even the more recent imports were disposed of at prices which, not alone showed no profit, but in most instances the prices realised show a considerable loss. The imports of important Medium grades have fallen off considerably, and as the enquiry has increased for same we do not anticipate a further appreciable decline in values, as one ought certainly to advocate the encouragement of a substantial increase in the imports.

As regards the quality of Para Rubber, considerable grievance was again caused by the want of care in the proper selection of these grades, especially from the Island districts, and this has led to numerous disputes amongst contracting parties. Trade in Great Britain and with leading Continental Rubber works was fairly good and the stocks of raw material at the factories is not large, and in spite of the fact that deliveries have been exceptionally heavy the reported consumption of Fine Para exceeds that of previous years. The American market showed the position there not to be so strong except for the first few months, but generally speaking the Rubber trade has been busy and the only important speculative stocks are held by one leading American house, whose position at the close of the year was considered very precarious. Visible supply now of Para and Peruvian is 4,618 tons against 4,100 tons last year. This includes America with a stock of 2,005 tons against 1,200 tons last year.

Should the demand for Para Rubber continue good, the statistical position at the end of 1901 is certainly a very healthy one. The total for the year's crop (from July 1st to December 31st) amount to 13,680 tons, this means an increase of 2,400 tons, while against this the total increase of the visible supply gives us only about 480 tons, thus about 1,920 more tons have gone into consumption, this despite the fact that it is well known that the "invisible" supply is exceptionally small. Although grave financial difficulties were experienced by many holders of Rubber, the position of the Rubber market is fairly sound, and with constantly increasing consumption, Rubber must be considered very reasonable at present quotations.

PARA KINDS.—At the beginning of the year we had to record a brisk enquiry to Para grades, and business on a large scale resulted, but, owing to continued "bear" operations, prices quickly exhibited an important recession, and while Hard Fine Para was quoted at the beginning of January at 3s 10³/₄d, Soft at 3s 9d, NEGROHEADS, Scrappy at 2s 9¹/₂d, ISLAND at 2s 1¹/₂d, CAMETAS at 2s 4d, PERUVIAN Ball at 2s 7¹/₂d, and Slab at 2s 2d, prices declined rapidly during the latter portion of the first month, and sales for forward delivery at a market decline were done on a large scale, with the result that prices for PARA grades receded about 3d per lb. by the end of the first three months. In America, Fine PARA was then sold as low as 3s 6d, Scrapies 2s 6¹/₂d, ISLAND 1s 11d, Ball 2s 4d, and Slab 1s 11d per lb. We then began to receive the first advices from Para of probable shorts receipts, and some important buyers partly relying upon these reports bought large quantities, thereby causing considerable brisk-

ness; this improvement was actively maintained for a few weeks, and as high as 3s 10d to 3s 11d was paid for Fine during the middle of April. Other sorts were 2d to 3d per lb. dearer. Soon afterwards, however, the market again showed signs of weakness, the demand being somewhat dragging, and in July Hard Fine was quoted at 3s 8d, Soft 3s 6d, but a temporary reaction in August resulted in quotations again reaching 3s 10¹/₂d to 3s 9d. We have then had irregular declines of 2d per lb, and in November Hard Fino was as low as 3s 5³/₄d, Soft 3s 3³/₄d, the lowest of the year. Additional cable advices from Para of probable shorts receipts during the end of the year and the early months of 1902 brought about some recovery on less pressure to sell, and with very large deliveries and moderate receipts we close the year firmly with quotations of Hard Fine at 3s 6³/₄d and Soft at 3s 5³/₄d. NEGROHEADS continue to remain very scarce, Scrappy being quoted at 2s 9d, ISLAND (of which the greater portion is being shipped to America) 2s 1¹/₂d, CAMETAS 2s 2d, Ball 2s 6d and Slab 2s 0¹/₂d. The total amount of Rubber imported from Brazil shows a further increase of 3,200 tons and the total quantity exported from the State of Amazonas, including PERUVIAN via Iquitos and Manaos, is 4,000 tons against 3,100 tons. The PERUVIAN Fine imported has we think been better as a whole, but owing to the Rubber having arrived in most cases uncut and unselected before shipment new rules had to be adopted in order to provide for this altered mode of shipping this Rubber. The PERUVIAN Ball imported has not been up to the expected quality, and at the end of the year the standard of fair average quality was considered lower, although some nice clean Hard Balls when received did realise fairly good, and in some cases exceptional prices. The Slab continues to be of good serviceable quality, and the consumption of it is certainly spreading. BOLIVIAN kinds have been very fair, but the imports were not as large as last year. MOLLENDO again showed a remarkable improvement in quality, and consequently sold exceedingly well. From VENEZUELA via Orinoco the supply was less than last year and the quality not very attractive.

Imports of OCEANA Scrap are smaller, but of these grades only the best qualities could be sold easily, others are dragging. Of MANICORA kinds we received less, but quality was good, and prices realised were satisfactory. PERAMBICO and ASSAREE qualities have somewhat improved, but owing to the general decline of the Rubber market, the values of these classes receded considerably. There were not very important arrivals of good MANGABERIA, and although the stocks are considerably going down and available supplies very small, the prices realised for ordinary quality show an enormous falling off in price. The imports of MATROGROSSO, in sympathy with PARA, showed similar fluctuations, although transactions were only spasmodic. CENTRAL AMERICA has again been conspicuous by a further considerable decline in its export of Rubber, probably owing to the continued political unrest existing in those parts, and the only Rubber reaching us comes from the COLUMBIA districts, but the quantities were very insignificant. The EQUATOR and GUAYAQUIL kinds sold readily, and the prices at the end of the year are only about a 1d lower than they were a year ago. Of course this refers to good qualities only. Inferiors and mixed kinds are much cheaper. The imports from HONDURAS, MEXICO and PANAMA were likewise very small.

AFRICANS.—As expected at the close of the previous year, the increase in imports of these descriptions was not only not maintained but showed a considerable and serious falling off, and we estimate the difference of imports from Africa to be about 2,000 tons below that of last year.

With the exception of slight spurts in April and again in August (in sympathy with Fine PARA) the year 1901 has been characterised by an uninterrupted decline in AFRICAN Rubber, the only exception being

First SIERRA LEONE Niggers which are actually rather dearer than a year ago, while all other descriptions show a decline varying from 1d to as much as 6d per lb.

From ANGOLO we received 250 tons less, made up in shipments from BENGUELA of 1,250 tons, as against 1,500 tons in 1900. LOANDA 730 tons, against 678 tons (besides 200 Thimbles). Quality has been hardly so good. The Congo has slightly increased, but the quality has seriously declined; about 5,300 tons, against 5,000 tons in 1900. The average price shows a very considerable fall because so much was of poor quality. The supply from SIERRA LEONE and FRENCH GUINEA has again fallen off, partly owing to the prohibition by the French authority of the exportation of dirty, wet, and inferior Rubber from CONAKRY. The quality being thus reliable has caused consumers to look on this kind with favor, and their appreciation is reflected in the price which is unusually high compared with other Rubbers, both AFRICAN and BRAZILIAN.

Quite an extraordinary decline in supply of GOLD COAST, ACCRA, LAGOS, &c. and only moderate from CAMEROONS, SIERRA LEONE, GABOON, &c. and small of SENEGAL. Prices of nice Hard only about 2d lower, but Soft common and Lagos fully 4d decline for the year. We no longer quote STRIPS and BISCUITS, the pressing of LUMP Rubbers being practically abandoned. Liverpool imports of WEST AFRICAN, 4,200 tons, against 5,140 tons in 1900 and 5,600 tons in 1899.

The CONGO FREE STATE has again increased its exports to Antwerp, but other kinds of African have gone there in reduced quantities, so that the total Antwerp imports show little change.

During January, AFRICAN Rubber met with a disappointing demand at rather easier prices. February and March were very dull and prices declined for most sorts, closing with lower values all round. In April, fairly good trade was done at rather better prices, closing however somewhat quieter. A moderately large business was done in May at irregular prices. Good SIERRA LEONE sorts were then well in demand, showing however little, if any, change in price, whilst Lump descriptions were 3d to 1d per lb lower. During June and July, African Rubbers met with a moderate to poor demand at generally lower rates, and only a comparatively small trade was done at barely steady prices. The demand was better in August, especially for parcels of good quality which arrived from Sierra Leone. This position of the market was not maintained, and we see a constant falling off in the demand, which remained disappointing with only small business passing at generally lower rates, until the end of November, when quite a steady trade was done at generally unaltered and in some instances slightly increased prices. The demand continued to improve during December for all the better grades, and rather higher rates were paid all round.

EAST COAST OF AFRICA, (ZANZIBAR, &c.).—The supplies of these descriptions have continued to gradually fall off, and to this must be ascribed the fact that at the close Red hard Rubber is only 1d per lb lower, but White and Common Ball Rubber declined about 4d per lb. LAMU BALL (MURASSA): The arrivals were not important although the quality was fair and good clean Rubber sold fairly well, prices, however, showing a decline of 21 for the year. NYASSALAND sent us some very good Rubber, but the consignments were small, and when they reached the market were brought up readily at fair to full prices. MADAGASCAR supplies were again on the decrease, and have only been about half of what they were last year, and values were consequently well maintained.

Imports from CEYLON were again insignificant, but whatever small quantity reached this market it proved very attractive, as the quality and condition continued to be excellent, and many buyers were anxious to secure even the small arrivals, owing to the specially clean condition of this Rubber. We confidently expect that if larger imports could be arranged a great

circle of consumers would come in and pay full prices for these grades, especially if the quality be kept up. It would be advisable to encourage the planters and others interested in this product in giving particular attention to this most valuable Rubber. High prices were realised, and 3s 9d was recently paid for Fine and 2s 4d for the Negroheads. It is, of course, known that this Rubber should practically be of the same kind as the one coming from the State of Amazonas, being grown from Para seed.

RANGOON and PENANG has also been in much reduced supply. Of the later description we practically received no further shipments this year, but in spite of this, all the old stocks held were most difficult of sale, and what was disposed of showed an enormous decline, and thus Rubber that was quoted at 3s 21 a little more than a year ago sold at about 2s 2d to 2s 5d per lb. according to quality. If good quality of these descriptions could be imported to sell at present rates, it is certainly worth encouraging, as with scarceness of good red Mozambique Ball, the demand for these Red Penang kinds would again grow gradually.

Small quantities of ASSAM were shipped, but the quality was very poor and sandy, and consequently did not meet with any requirement or interest.

BORNEO.—Of this Rubber the supplies have not been excessive, but in sympathy with the general tendency of the market prices declined. These grades are still held for higher prices, and with a continuance of the lower quotations all round we must also look for much reduced values in these grades before one will be able to effect larger sales. PONTIANAK: Supplies were about the same as those of last year and sold readily, prices showing very little change at the close of the year.

Rubber from the FRENCH COCHIN CHINA and from LOWER CHINA have continued to sell well, the quality and condition of nearly all arrivals were satisfactory, and the small trade done must have been profitable to the importers.

JAVA Rubber and NEW GUINEA have been very scarce, but generally speaking these qualities were not in great demand, and quotations were only nominal.

BALATA.—We had reduced arrivals of these descriptions, and all the imports of these grades have met with a good demand, although at one time Block BALATA was as low as 1s 7d. The year closes with buyers at 2s and sellers at 2s 1d. Nearly the whole of the stock in first and second hand has been cleared off and gone into consumption, and all new arrivals are selling very readily at full prices. SHEET BALATA.—Owing to the increased consumption the prices have also gradually gone up, and the market closes with buyers at 2s 7d, showing 4d per lb advance for the year.

GUTTA-PERCHA.—The year opened with a very poor demand, and the market continued weak throughout almost the whole of the year. It was only during November that, owing to larger contracts for cables being placed, extensive buying orders appeared on the market, thus increasing values of GUTTA-PERCHA, and since then a fairly large business has been done. There seems to be every prospect of a continued good market, with fair prices being paid for good and desirable qualities of GUTTA-PERCHA.

THE "TAPPING OF RUBBER TREES."

The "Journal d'Agriculture Tropicale" (II, 1902, 99) contains an interesting contribution from the pen of M. Henri Lecomte to the question of the tapping of the rubber trees.

As I have repeatedly pointed out in these pages this important operation is at present carried out much in the same happy-go-lucky style so characteristic of the crude rubber industry. But it is quite obvious that the manner in which the incisions are applied to the trunk of the rubber tree must be of

considerable importance as regards the yield of rubber milk obtained. In other words, the application of the incisions should be based upon a knowledge of the anatomical structures, at least of the laticiferous tissue of the various trees.

On the example of *Landolphia Hendlotti*, M. Lecomte illustrated this point. This is a creeper which furnishes the bulk of the rubber of the tropical regions of French North Africa. On producing a cross section through one of the branches of this plant, it may at once be seen that the laticiferous tissue is situated in that part of the bark which is nearest to the wood. It is therefore quite necessary to penetrate into the wood with the incisions.

The laticiferous vessels of this *Landolphia* run in comparatively straight vertical lines along the bark, and they are, to a moderate degree, only ramified and anastomosed (inter-communicating). From this it follows at once, that longitudinal incisions, however extensive, must prove very ineffective, the number of vessels thereby opened being very small indeed. On the other hand, it will easily be recognised that horizontal incisions lay open the maximum number of vessels which may be reached by any single incision, and thus must produce the greatest possible yield of latex. Of course, there is the objection to horizontal incisions that they do not lend themselves so readily to the collection of the latex by the simplest means. This difficulty is, however, easily avoided by producing these incisions at an obliquity just sufficient to induce the flow of the exuding latex towards a channel common to a number of such incisions.

There is another important advantage in these transversal incisions which is worth calling attention to. In consequence of the constant increase in bulk of the ligneous core which is surrounded by the bark, the latter is under very considerable tension, and exerts a corresponding pressure upon the whole of the tissues. This tension of the bark, which exists in every tree, can easily be demonstrated by cutting an annular band from the bark of some tree, and then trying to place it again into position, when it will be found impossible to make the ends of this band meet.

It is exactly this tension which causes the flow of the latex from the laticiferous vessels in which it is held by capillary action. Now it is perfectly clear that vertical incisions, apart from laying open very few laticiferous vessels, must in a large degree have the effect of relieving that tension with the result that capillary attraction maintains the upper hand, and we obtain only a feeble flow of latex. From these various points we arrive thus at the conclusion that horizontal, or transversal incisions are the most rational. Nevertheless, it should be borne in mind that by making such incisions indiscriminately all over the trunk of a tree the latter would very soon become worthless for tapping purposes. Each transversal incision severs of course the connection between a large number of laticiferous vessels, which, when the incision has again healed up remain separated, so that if these incisions are made in an unsystematic manner they very rapidly result in dividing the whole of the laticiferous area of the bark into a number of disconnected sections, each of which is capable of a very restricted yield of latex only.—*India-Rubber and Gutta-Percha Trades' Journal*.

preparing crude or commercial papain has been contributed by the Hon'ble Francis Watts, F.I.C., F.C.S. :—

The preparation of crude papain is a comparatively easy matter, provided that attention is paid to certain matters of detail.

COLLECTING THE MILK.

The juice, or milk, which forms the starting-point is procured by making a scratch or shallow incision in the skin of the fruit of the papaw while in a green condition. It is desirable to employ a bone or wooden knife, like a paper-knife, for the purpose.

The milky fluid rapidly exudes and may be caught in a cup held beneath the fruit. After a time the flow diminishes and the liquid coagulates in the neighbourhood of the incision, this is carefully removed by means of the bone or wooden knife and placed in the cup with the milk already collected.

The fruit is not removed from the tree and is may be subjected to the operation of tapping several times at intervals of two or three days. It is essential that no iron knife, or iron utensils, should be brought into contact with the milk. Wood or bone should be employed, and the milk should be collected in earthenware basins or cups, or in glass vessels, and not in tins, which are sure to blacken it.

After collecting the juice soon becomes coagulated and then should be in the form of a snow-white curd, possessing a somewhat pungent, but not putrid smell. It speedily decomposes if not rapidly dried, and, when decomposing, emits a most unpleasant odour. It is necessary then that drying should be effected as speedily as possible. When considerable quantities are being prepared, the collection of the juice or milk should be undertaken in the early morning and the drying should begin before mid-day. This ensures that by evening the material is in a sufficiently dry condition to keep without deterioration until the following morning when the drying can be completed.

DRYING THE MILK.

The drying may be effected in several ways. In dry, hot weather the coagulated milk may be placed in thin layers on sheets of glass and exposed to the sun. This, however, is rarely satisfactory on a large scale, and it is best to adopt some form of drying apparatus. Drying is well effected by spreading the coagulated milk on drying frames made by stretching brown linen on light wooden frames, somewhat like those used for framing school slates; these may be of any suitable size to fit the drying apparatus employed.

FIG. 1. Elevation.

A small American fruit drier will answer very well, or a drying-stove (Fig. 1) may be constructed by building, in brick, a chamber about 3ft. high, 3ft wide and 6ft. long, these dimensions can be changed in accordance with the amount of material to be dealt

PREPARATION OF COMMERCIAL PAPAIN.

It is well known that the milk obtainable especially from the fruit, of the papaw tree (*Carica Papaya*), possesses the property of rendering meat tender and in fact of partially digesting it. In recent years this property has been utilized by evaporating the milk into a dry powder known as 'papain.' There is a moderate demand for this substance and where the papaw tree is abundant it might be advantageous to prepare it. The following account of

FIG. 2. Section along the line x. x. of Fig. 1. FIGS. 1 AND 2. DRYING STOVE, FOR THE PREPARATION OF PAPAINE.

(A), Opening, across which the drying trays are supported. (B), Iron plate. (C), Fire Grate. (D), Chimney, with. This is open at the top. About a foot from the top the chamber is divided horizontally into two compartments by a sheet of iron. (B.) and below this division a small fire grate (C), is constructed; at the opposite end from the grate a chimney (D), is placed to lead the smoke from the lower compartment. (Fig. 2.) In order to obtain an even heat in the upper compartment it is well to spread a layer of sand, one or two inches thick, over the iron plates. The frames carrying the coagulated milk are placed on the top of the chamber, so as to form a lid or cover to the opening (A.) when heat from the iron plate drives off the moisture at a low temperature.

It is important that the temperature at which drying is effected shall be as low as possible. Any over-heating destroys the active principle, so that a carelessly prepared product may be useless. In practice, the temperature is kept as low as is consistent with getting the substance dried before decomposition sets in; if this can be done without the temperature of the tray being raised above 100 deg. Fahrenheit so much the better.

As the substance becomes dry it shrinks considerably in bulk. The contents of several trays may now be emptied into one and the drying continued. The trays emptied are ready to receive another day's supply of fresh material.

Drying must be continued until the substance is crisp and in such a condition that it can be reduced to a fine powder without any difficulty being experienced from stickiness. The dried material should be ground to a fine powder when the resulting product should be a white or cream coloured powder with a characteristic, but not putrid, smell. The powder should be packed in tins or bottles, and carefully preserved from contact with the air. Grinding is easily effected in a mill of the type commonly employed for grinding coffee: when grinding it is desirable to have the papain slightly warmed

CULTIVATION OF PEPPER IN THE BOMBAY PRESIDENCY.

A further account of Manures used in Spice Gardens.

By J. MOLLISON, Esq., M.R.A.C. DEPUTY DIRECTOR OF AGRICULTURE, POONA.

[The Survey Commissioner and Director, Land Records and Agriculture, Bombay, having furnished this office with a copy of Mr. Mollison's report No. 547, dated the 7th October, 1900, (on the above-mentioned subject) the following extract from it is given as a

supplement to the *Agricultural Ledger* No. 3 of 1900. The additional information will be found to include enumeration of those trees, the leaves of which are commonly used for leaf manure, as well as the chemical analysis of the different kinds of leaves, manures, and soils by Dr. Leather, Assistant Agricultural Chemist to the Government of India. The information thus furnished may be found of interest as a contribution to the large question of GREEN MANURING.] *Ed.*

The more common trees in *beta* lands and in protected forest, which are specially useful to the cultivators, for manure purposes, are referred to in short detail below:—

*Kaval or Kavla (K.)** (*Careya arborea, Roxb.*)—Leaves big, fleshy, soon rot as green manure, and considered specially good for leaf-mould. Trees abundant in *beta* lands.

Honne (K.) (*Pterocarpus Marsupium, Roxb.*)—Leaves are rather small and are not considered particularly good for leaf-mould.

Jambe (K.) (*Xylia dolabriformis, Benth.*) Used more as a covering for the leaf-mould manure as light branch wood than for leaf-mould. They do not decay quickly.

Nirda (M.), Alale (K.) (*Terminalia Chebula, Retz.*)—The best leaves of all for green leaf-mould, and are supposed to kill insects and grubs. Leaves small and do not rot very quickly. They are eaten as fodder by cattle.

Kanagal (K.) (*Dillenia pentagyna, Roxb.*)—Leaves are good for leaf-mould. They are very large and fleshy and decay very quickly. Flowers, buds and fruit eaten. Berries eaten greedily by deer and other animals.

Honal (K.) (*Terminalia paniculata, Roth.*)—Considered nearly as good as *matti* for leaf-mould. Leaves not large and do not decay particularly quickly.

Matti (K.) (*Terminalia tomentosa, Bedd.*)—Leaves and branches considered excellent for leaf-mould, the former large and easily collected. Leaves used as cattle fodder.

Nerlu (K.) or Jambul (M.) (*Eugenia Jambolana, Linn.*)—Used to a considerable extent for a leaf-mould or for branch wood, used as a covering over leaf-manure.

Bute (K.) (*Dalbergia latifolia, Roxb.*)—Blackwood. Reserved as a valuable timber tree.

Nelli (K.) (*Phyllanthus Emblica, Linn.*)—Branches also used as protective covering for young cardamom seedlings. Fruit and leaves good fodder.

Surhone (K.) (*Calophyllum tomentosum, Wight.*)—Sirpoon tree. Evergreen. Found in *Kans*, not in *beta* lands or protected forest.

Kari Mittala (K.) (*Ougeinia dalbergioides, Benth.*)—Leaves used for fodder.

2. It will be noticed that the unreserved trees which are reported to give the most useful leaves and branches for garden requirements have no great value as timber trees.

3. A Kanara gardener requires that the leaves for green manure shall be within his reach so he pollards and lops. Afterwards the foliage (it is cut every second year) is within easy reach and for a number of years a large amount of both foliage and light-branchwood is produced. In course of time the tree dies prematurely by exhaustion or ill-health induced by bad usage. The pollarding practised unquestionably shortens the life of trees. It will also diminish their full value when dead, because they have spent their substance in producing by unnatural treatment leaves and small branches instead of natural growth. But the result justifies the means because small branches and leaves are specially required by the gardeners. And if young trees of suitable varieties are so protected that they replace old decayed trees, and if pollarding is prohibited until young trees attain certain dimensions as proposed by the Committee in the draft rules, then I think the interests of Government will be fully safeguarded, and the requirements of the gardens fully maintained. I saw numerous instances of well-managed *beta* lands.

* (K) indicates that the name is Kanarese, (M) that it is Malayalam.

It is difficult to understand the deficiency of potash in the 4th sample. The nitrogen and phosphoric acid are probably about average for this kind of manure. Samples No. 1 and 2 were originally of similar class to sample No. 4. They were, I imagine, superior in quality originally to No. 4. No. 1 sample (taken in handfuls from many trees) is by no means exhausted 14 months after application, and it may be inferred from this that the gardeners' methods of application and of protecting the manure from surface wash and heavy rainfall by a covering of branch-wood and leaves are successful in practice. From personal observation, I can say that the branch-wood, a full year after being first put on, is sufficient to break the force of heavy downpours of rain, and when first put on or afterwards allows the rainfall to percolate through the manure to feed the plants. It is suggested in the papers by one officer that the gardeners should use the leaf-sheaths of the *supari* palm (*Aroca Catechu*, *Linna.*) leaves as a protection for the manure instead of the branch-wood now used. The leaf-sheaths are all required for another purpose in the garden (economy, and in any case the manure does not as Mr. Davidson points out) need a water-proof. It needs protection and needs also to soak up the rainfall, as it falls in a fair and reasonable way.

9. No. 2 sample was taken in the same way as No. 1 in handfuls from above the roots of many trees. The samples were taken two months after application. No. 2 contains less sand than No. 1 for obvious reasons, and probably its original manurial elements had been since application utilized to considerable extent, as the trees and plants were in active growth. The garden soil and the manure were quite moist, and there had been rather abnormal heavy rainfall some little time before the samples were taken. These are conditions which would help the plants to utilize the manurial ingredients quickly. The sample No. 3 from dry leaves used as litter under cattle is quite as good as might be expected. It has about half the manurial value of good cattle dung manure. The owner considered it was poor stuff. The high percentage of sand is noticeable.

10. There is no doubt that the present system of manuring in the Kanara Gardens is successful in practice, provided the gardeners are allowed to use in sufficient quantity the kinds of forest produce which they prefer. The system of manuring is expensive, even though the materials are got free, and the destruction caused to forest growth is enormous. Under the circumstances, it would, I think, be most advisable to test by experiment whether available concentrated manures, such as castor cake or safflower cake, could take the place of a portion of the manure now used. These cakes can be imported from Dharwar at reasonable rates into the district. Castor cake is less valuable manurially than safflower cake, and is dearer. In the Gardens of Bassein, with heavy rainfall in light soil, castor cake is successfully used. It is obnoxious to insect life, and if used in the Kanara gardens there would probably be less damage done by grubs and borers, which certainly do considerable damage to the garden plants and trees now.

11. I append hereto analyses by Dr. Leather of samples of four descriptions of soils which are sufficiently described in the appended tabular statement;—

Lime (CaO) total	.11	.09	.15	.19
Magnesia (MgO) total	.30	.30	.29	.38
Alkalies total	1.07	.31	.	.
Potash total	.154	.071	.110	.27
Potash (K ₂ O) available	.003	.008	.004	.005
Phosphoric acid (P ₂ O ₅) total	.086	.04	.073	.074
Phosphoric acid available	.001	.0017	.0005	.0015
Nitrogen total	.014	.20	.09	.18
Nitric acid (as Nitrates)	.0009	<i>Nil.</i>	<i>Nil.</i>	.003

Kagadali earth, e.e., the earth excavated from embankments and carried in head-loads to renew the garden soil of old-established garden when renewal is required.

Earth from rice beds near a thriving spice garden and similarly situated to the garden and presumably capable of being converted into garden.

Soil from old-established gardens.

Soil from new extension of an old garden.

12. Dr. Leather says the samples are all deficient in lime phosphoric acid and more or less so in available potash. I should, as a matter of fact, class them as agriculturally poor, but in my extended notes regarding the garden cultivation I remarked that it does not matter much whether the garden soil is naturally fertile or not, because the yield of the crops is mostly affected by the quality and quantity of manure given. As regards the soil it must be of such consistence that it withstands the denuding effect of flood water and be so retentive of moisture that little or no irrigation is required in the fair season; All the samples submitted to Dr. Leather possessed these desirable qualities. It has already been shown that the leaves and twigs used by the cultivators are rich in potash and also in nitrogen, in which the soils are decidedly deficient. It has also been shown that the trampling of the leaves under cattle and the absorption of the excreta particularly, if the cattle are partially fed on cake, improves the resultant manure in phosphates. Dr. Leather has not separately estimated the amount of lime in the manures, but he shows that the soils are deficient in this important ingredient. I have already stated that the *matti* tree when burnt leaves and ash rich in lime, or, according to local opinion, it yields *chunam*. The cultivators are specially anxious to be allowed to take the leaves and twigs of this tree. If the manure applied to the trees in the Kanara gardens was mixed, as in common Agricultural practice, freely with the soil, then the soil in old-established gardens would probably be richer in manurial ingredients than new soil.

13. I conclude from a study of Dr. Leather's analysis that the system of manuring, as practised in the gardens of Kanara, is as right in theory and practice as it well can be, provided the manure as it accumulates in the pits is subjected in the least possible degree to the wasteful wash of the heavy Kanara rainfall,—*Agricultural Ledger*.

PLANT BREEDING.

We learn from the March number of the *Journal of the Board of Agriculture* that the United States Department of Agriculture have recently issued a Bulletin, by Professor W. M. Hays, on plant-breeding, which contains a good account of the *technique* of the subject, and some stimulating suggestions. "Many look to the production of improved varieties

of cultivated plants as a sure way of increasing the yield and quality, and already results have been achieved sufficiently remarkable to encourage much hope for the future. One of the most striking instances is furnished by the Sugar-Beet, which in Germany, in 1836, contained only five per cent. of sugar, and now furnishes not much less than fifteen per cent. During the same time the gross yield of roots per acre has increased by about fifty per cent., so that the output of sugar per acre is now over four times as great as seventy years ago, a result for which careful breeding is chiefly accountable.

In this and other countries much has been accomplished in the matter of plant improvement, but much undoubtedly remains to be done. It is work that makes no exceptional demands on capital or skill, as is proved by the fact that many of our best varieties of plants, especially vegetables, flowers, and fruits, have been raised by amateurs, in not a few cases by cottagers. It is, however, work that requires much perseverance, and at certain seasons much attention; though the demands that it makes on time necessarily depends upon the extent to which it is carried on. For its successful performance it requires intelligent observation, a knowledge of the gardener's or farmer's requirements, delicate manipulation, and accurate recording, rather than strenuous exertions.

Two main lines are usually pursued to produce a new and improved variety of crop-plant. One method of producer, which has been successfully adopted by some of the best known workers, is to make a careful examination of the individual plants in crops cultivated in the ordinary way, and from these to make a selection of those that are distinguished by superior merits. Such superiority may take the form of yield, capacity to tiller, a high percentage of starch as in Barley and Potatoes, or of sugar as in the case of Turnips, Swedes, and Mangolds), capacity to ripen early, to resist disease, &c. But whatever may be the object selected, it must be kept steadily in view, and all individual in the progeny that fall short of the character that may have been set up must be carefully eliminated. By intelligently pursuing such a system of selection during a series of years, a distinct type or variety will be produced.

The other method commonly pursued begins by artificially crossing two individuals whose superior qualities it may be desirable to unite in a single variety. The seeds that result from such a cross are shown, and it is generally found that the resultant plants are extremely mixed in character. Many are inferior to either of the parents, others occupy an intermediate position, while a few may be superior to both. It is the latter only that are reserved for subsequent cultivation, and from their progeny also many individuals must be eliminated. In the course of time, however, the percentage of inferior individuals becomes smaller and smaller, until, at last, the variety comes true to type.

In the main, these two systems of improvement are the same. The plants selected in the first case may be natural crosses, while in the second they are artificial crosses, but the improvement is, in both cases, completed by selection. The larger the number of plants selected or of crosses effected, the greater are the chances of a really valuable new variety being found and for this reason it is desirable to work with large numbers, though, of course, one may be fortunate in producing a valuable variety even when the work is being carried on but on a very small scale.

In sowing pedigree seeds, the soil should as a rule be of good quality, so that the resulting plants may have the opportunity to produce the maximum yield. But it is of even greater importance to arrange matters so that each individual plant is placed in possession of precisely the same conditions of growth. Only in this way can we be sure that the appearance of superior qualities in the progeny is due to some-

thing inherent in the plant itself, and not to the specially favourable character of the situation where it has been grown.

Farmers have generally given more attention to the breeding of animals than of plants, but just because less has been done in the latter field, more probably remains to be accomplished. It is surprising how quickly a single plant multiplies, if the conditions be made as favourable as possible. The Late Mr. Shirreff gives an instance from his own experience. In the spring of 1819 he found a specially vigorous wheat plant in a field on his farm in East Lothian, and he resolved to propagate it. He therefore removed the plants in its neighbourhood, and gave it a dressing of manure, the result being that, notwithstanding some damage by hares, he harvested from this single plant 63 ears, containing 2,473 grains. In the following autumn these grains were dibbled in wide rows in a suitable piece of ground, and in the two succeeding seasons the produce was sown broadcast. The result was that the fourth harvest from the original plant yielded 42 quarters of seed, which was subsequently placed on the market under the name of Mungoswells Wheat."—*Gardeners' Chronicle*.

CENTRAL AMERICAN RUBBER.

It is generally considered that Central American rubber is the product of *Castilloa elastica* Cervantes, described and figured in the *West Indian Bulletin*, Vol. II, pp. 191-3. The tree has a variety of local names the most important of which are 'Hule' or 'Ule' and 'Caucho.' Distinct from this plant is *Castilloa Tunn*, Hemsley (*Hooker's Icones Plantarum*, plate 2561), a tree also found in Central America and sometimes confused with the true Central American rubber tree which it closely resembles in general appearance. In an article which appeared in the *Beihfte zum Tropenpflanzer* for July 1901, Mr. Th. F. Koschny, a planter of long experience in Cost a Rica, distinguishes the following varieties of 'Hule' trees:

<i>Castilloa elastica</i> :	
'Hule blanco'	White rubber tree.
'Hule negro'	Black rubber tree.
'Hule colorado'	Red rubber tree.
<i>Castilloa Tunn</i> :	
'Hule tunn'	'Gutta percha.'

The names of the three so-called varieties are given from the colour of the bark of the tree. 'Hul-Blanco' is described as the only one worth cultivation, giving thick and abundant latex. The tree is not shade loving, being seldom found in forests, and not easily injured by tapping. 'Hule negro' gives a watery latex, and that of 'Hule colorado' whilst good, is scanty.

Mr. Koschny suggests that 'Hule colorado' may have been introduced into Java and Ceylon, and be the reason for the comparatively small returns given by Central American rubber trees in those islands. This point was touched upon by Dr. Morris in his Cantor Lectures on the 'Plants yielding Commercial India Rubber' to the Society of Arts in 1898. 'The plants distributed from Kew and now under cultivation in various tropical Colonies would be more correctly termed, according to their place of origin, Darien "Castilloa" or Darien "Caucho" trees. This would distinguish them from the Ule trees of Mexico, British Honduras, and Nicaragua, and indicate their history. It is Possible that there is no great difference, if any, in the quality of the rubber yielded by these trees, but so far no one has undertaken a comparative investigation of the produce.'

The Ceylon plant has been considered as possibly belonging to the species *Castilloa Markhamiana*, Markham, (Circular No 11, Botanic Gardens Ceylon). On the other hand in the *Kew Bulletin*, for Sept, 1901, Mr. W. B. Hemsley states that *Castilloa Markhamiana* is not distinguishable from *Castilloa elastica*. Careful comparison at Kew between typical specimens of the rubber tree from British Honduras,

Mexico, and Darien, so far, has failed to reveal any differences sufficient to warrant the recognition of definite varieties. Mr. Koschny's varieties have not yet been established botanically. Specimens have been sent by him to Prof. Warburg of Berlin, an authority on this group of plants, and their determination will be awaited with interest.

It is important meanwhile to draw attention to the fact that probably more than one variety may be cultivated under the name of 'Central American rubber tree,' and intending growers should be careful to secure seeds or plants from reliable sources.—*West Indian Bulletin.*

THE PRINCIPAL VEGETABLE PRODUCTS OF THE HAWAIIAN ISLANDS.

As everyone in the horticultural world knows, Sugar is the staple industry, and is largely cultivated throughout the Islands. It was cultivated in very small quantities before 1876, when a treaty of commercial reciprocity with the United States came into effect. Under the provisions of this treaty an era of unexpected prosperity set in, and the production of Sugar, as well as Rice, increased more than was ever anticipated. Large barren tracts of land were brought into cultivation by extensive irrigation, some of the ditches being 40 miles in length, carried through dense woods, tunnelled through rock, and spanning wide canons. The Ewa Plantation, near Honolulu, is one of the largest and finest in the Islands. About 90,000 acres are taken up with the various plantations, with a yearly yield of about 225,000 tons of sugar. It requires an average of eighteen months for a crop to mature, the ordinary yield being $3\frac{1}{2}$ tons to the acre; yet on specially rich alluvial soil, it is sometimes as great as 9 tons to the acre.

Next in importance comes Rice. Its culture is principally carried on by the Chinese, and in the San Francisco market it grades with the best coming from China. The ground is ploughed and well harrowed, the field is then submerged, the water being allowed to stand until the crop ripens, when it is drawn off. The method of cultivating is crude and primitive. The Chinaman sows the seed thickly in a small field; when the plants are about 6 inches high, they are pulled up and taken to the field for planting, where they are set out in the mud by hand in rows about 8 inches apart. When matured the water is drawn off to allow the straw to ripen. The crop is then cut with the sickle. No threshing machines are used by the Chinese Rice grower, but the grain is separated from the chaff by being beaten out with the hoofs of horses or Chinese cattle, as in ancient times.

Coffee is cultivated, but not to a large extent, although Hawaiian, or Kona, Coffee takes a high place among the best Coffees of the world; the trees are grown anywhere, from the sea-level up to 3,800 feet above the sea. One of the greatest difficulties to contend with is insect blight, which is greatly kept in check by peculiar parasites, and ladybirds that have been introduced for each kind of insect. The cultivation of Tea is carried on with good results, the best quality of leaf being obtained on the higher elevations. The high price of labour prevents its more extensive cultivation.

Hemp has been experimented with, and pronounced by experts to be of a good, strong description. The expense of cultivation is trifling, and the yield per acre is about 13 tons. Ramic, or vegetable silk, grows luxuriantly, but the industry is not developed, owing to the want of suitable machinery.

The soil and climate of Hawaii cannot be excelled for the production of tropical and sub-tropical fruits, and their introduction has added largely to the prosperity of the islands, especially so in the case of semi-tropical fruits, such as the Alligator-pear Banana, Lime (*Citrus Limetta*), Orange, and Lemon. The Alligator-pear grows to a large size, and the fruit is of a superior quality. The flesh is of butter consistency, with a nutty flavour, and it makes a delicious dressing for salads; the largest of these heads is

about 6 inches long, and weighs upwards of 3 lb. The Mango grows in great profusion, and several varieties are used for making chutney, the best varieties having been imported from India and Jamaica. It is an evergreen with small, glossy leaves; and a gum which exudes from the trunk of the tree is used in medicine. It bears fruit several months of the year, and it is not unusual to find trees with fruits on one side and blossoms on the other.

Cocoanuts grow all along the sea-shore, or any spot where nothing else will grow; but they are now very little cultivated. The Sapodilla, Sourson, Pomelo, Cherimoya, Custard-Apple, Papaw, Citron, Water-Melon, Granadilla, Pomegranate, and Tamarind are some of the desirable exotic fruits that do well in the islands. Vegetables of all descriptions are raised throughout the year, and Water and Cantaloupe Melons are superior to those grown in most countries. Pineapples grow wild on all the islands; there are some twenty-five varieties taking their names from the localities whence they are obtained. Near Pearl City, some eight miles from Honolulu, a plantation of an excellent variety exists. The average weight of the fruits is 8 lb., although the fruits of some varieties have been known to reach a weight of 17 lb. The Pineapple season is from the middle of the month of May to the middle of August.

Bananas are raised in great quantities and shipped to the west coast of the United States, the cost of cultivation being very small. Along the mountain ranges are trees and Vines in luxuriant growth, forests of a magnificent species of tree, whose wood has beautiful markings, and capable of taking a high polish, equalling the finest walnut and mahogany; this is the Koa-tree. The islands at one time were very rich in Sandal-wood, but when the natives found it would be a great source of income to them, they cut down the old trees in a very short space of time, and sold them to dealers in the United States, and neglected to plant young trees for a future supply.

Next the least important vegetable product is Taro. It consists of two kinds—the upland, which grows on the hillsides in dry ground, and the lowland, or more important staple, which is propagated like Rice, under water. Long irrigating ditches are required in preparing the bed. The ground is levelled off and enclosed by a wall impervious to water. The floor of the patch is made as rich as possible, and the top is cut from the ripe roots and set out in hillocks placed several feet apart. The water is let in, and allowed to remain until the crop is mature, i.e., in about twelve months, the only labour required being to keep the soil clear of weeds, and provide a depth of about 6 ins. of running water. Taro can be planted at any season, and a ripe crop obtained. The root is oblong, the largest being about 1 ft in length, and from 3 to 4 inches in diameter. The root is baked by the natives, who make from it what they call *poi*, the baked root being pounded till it forms a paste, which is thinned by adding water, and afterwards allowed to ferment. As a food it is most nutritious.

Another important plant much used by the natives is the Ti; it has also a large, oblong root, and the leaves are of a shining green tint. The Ti-leaves were at one time woven together, and formed a short cloak, which the natives sometimes wore. The root, after baking, is sweet and pleasant to the taste. It is also used to make an intoxicating drink, by bruising the roots with a stone, and steeping in water until it ferments.

Besides the plants mentioned, there are many beautiful flowering and foliage plants, among which *Cudmanms* (*Crotons*) are worthy of special mention. All the varieties grow in great luxuriance, and show exceedingly rich leaf-colouring. Round the College grounds, in the suburbs of Honolulu is a hedge of a night-blooming *Cereus* (*Cereus nuycticalus*), which is a magnificent sight when in flower, the blossoms ranging from 2 to 3 feet in circumference, *Donald McIntyre Moanalua, Honolulu.—Gardeners' Chronicle,*

POINTS FOR PRACTICAL PATRIOTS
[IN JAMAICA: HOW MANY
APPLY TO CEYLON?]

If you want to help on the finances of the island in a practical manner, adopt the following hints; and if everybody did so a few years would see the circulation of perhaps double the amount of cash among the people, for there would be a half less sent out of the country for things we can and do produce easily ourselves.

Use country corn, when available, even if it is a 6d. a bushel dearer than imported corn; it would soon get cheaper.

Use Jamaica "red peas" and black-eye peas even though they are 6d. a quart, and the American can be got at 4½d.; our own are fresher and sweeter.

Use Coconut Oil in all cases where you use Cotton Seed or any other salad oils at present.

Use Cassava Starch and stop buying imported corn or potato starch.

When you go to buy Arrowroot, be sure to ask if it is Jamaica-grown,—you will soon get the home product if you want it.

Make your own Preserves and use less sugar, as they usually are too cloying; or buy the Jamaica Preserves when you can. If they are often asked for they will get cheaper.

Use Jamaica-made Soaps which are again available; the factories employ local labour, pay taxes, and buy coconuts and other local products to make the soap of.

Patronise the local dairy when you want milk—it is better than condensed milk and the more that is asked for the cheaper it will ultimately be got for,—quick returns encourage small profits.

Fresh pork and beef are in all ways better than the barrelled salt-junk which may be horse or dog for all you know.

Use more honey, it is the most healthful of all sweet stuffs, and can be employed in the household in a score of ways more than at present.

50 ACRES OF LAND AT 1s. PER ANNUM.
IN THE NEW HEBRIDES.

The 100,000 acres at the New Hebrides which Messrs. Burns, Philp, and Co. have placed at the disposal of the Commonwealth Government for the purpose of encouraging British settlement is to be leased to intending settlers at 1s. per annum for each 50 acres or part thereof, with a provision for sale to the occupants under conditions prescribed by the Commonwealth Department of External Affairs. Between 50 and 60 men, representing with their families between 200 and 300 souls, are expected to go down by the "Mambare" from Sydney on June 1.—*Sydney Mail*, April 12.

COLOMBIAN CASSAVA.

A FAMINE PLANT.

Under the above heading we several months ago offered some observations on an interesting series of letters that had passed between the India Office and Mr Robert Thomson on a subject of great importance to Jamaica and her sister West India colonies. The primary object of the correspondence, however, on the part of Mr Thomson, was to suggest to the Government of India the introduction into that country of some of the more important varieties of cassava under cultivation in Colombia and other South American countries with a view to mitigating the calamitous effects of the ever-recurring famines that inflict such severe suffering and distress on extensive provinces of our Indian

Empire. One of the distinguishing and—so far as their introduction into India is concerned—most valuable properties of the Colombian varieties of cassava is what may be termed their constitutional flexibility—their independence of climatic and other vicissitudes. Rice, the principal article of food in India, requires for its cultivation a rainfall of at least 76 inches, and an Indian province requires an average fall of at least 50 or 60 inches to grow rice as a staple crop.

We are glad to know that Mr Thomson's correspondence has borne fruit and that the Director of Land Records and Agriculture, Bombay, has decided to commence the cultivation of Colombian cassava on the Government farms. Mr Thomson has just received a letter from the Director acknowledging, with many thanks, the receipt of a case containing some twenty-three varieties of cassava from Colombia, and mentioning that the stems or cuttings had arrived in good condition. This information furnishes pleasing verification of what we said months ago to the effect that the stems, if carefully handled, would retain their remarkable vitality for several months after being cut. The cuttings, we may mention, were brought from Colombia—having been obtained from sections of the country a thousand miles apart—by Mr Thomson's son—Mr Kay Thomson—who in consequence of the insurrection then in progress took several weeks to reach the coast from the mountainous interior. Notwithstanding this delay and the time taken in conveying the cuttings from Jamaica to Bombay, the Colombian varieties reached their destination in good condition and the Director of Land Records and Agriculture promises to let Mr Thomson know the result of their propagation in due course.

Our readers will be pleased to learn that the nursery, formed in August last with the cuttings brought from Colombia by his son, has proved a signal success, and that thousands upon thousands of cuttings are now available. In addition to the several acres of the ordinary varieties of cassava which have been planted at May Field on the Hope Road in the neighbourhood of King's House, Mr Thomson purposes planting the new varieties on an experimental scale with a view to determine the relative merit of the several varieties. From Mr Thomson's interesting report on his visit to Florida we gather that Cassava cultivation promises to be the staple industry of that enterprising peninsula. It is a noteworthy circumstance that Florida is indebted to Jamaica for this important industry. About three years ago an American tourist in Jamaica, Mr Perkins, was struck with the value of cassava as a starch-yielding plant. On his return to Florida he organised a company and erected a great factory which Mr Thomson visited at the end of June. We learn from his report that a thousand acres of cassava are planted in the vicinity, hundreds of acres being cultivated by gentlemen connected with the factory. Within sixty miles of the factory the managers purchase the tubers delivered at railway stations at five dollars per ton, and the culture is extending rapidly. Not only is cassava the cheapest known source of starch, but it is said to be the cheapest and best ration for feeding and fattening farm stock. From the report of the Professor at the Florida Agricultural Experiment Station, Mr Thomson makes the following extract:—

"With all the facts procurable, and with the experience not only of myself, but many practical farmers to support the opinion, I have reached the conclusion that, all things considered, cassava comes nearer furnishing the Florida farmer with a more universally profitable crop than any other which he can grow on equally large areas. It can be utilized in more ways, can be sold in more different forms, can be more cheaply converted into staple and finished products and can be produced for a smaller part of its selling price, than any other crop."

In a future issue we shall show how practicable as well as desirable it is to establish a great cassava in-

dustry in Jamaica. Some of the Colombian varieties are doubtless well adapted to the soil and climate of Jamaica, and the establishment of a new industry is a matter of no small importance to Jamaica and the sister West India colonies. But, as we remarked on a former occasion, the introduction into India of a new, adaptable article of food is of vital importance to the inhabitants of the Eastern Indies, inasmuch as it marks the initiation of an enterprise which will, we trust, be pregnant with benefit and blessings to millions of our fellow-subjects in the East Indies.—*Jamaica Daily Telegraph*.

EXPERIMENTING IN GREEN TEA MANUFACTURE.

[BY AN OLD PLANTER.]

The great reduction in the cost of equipment, and construction of cold storage chambers that has recently taken place, and the certainty of still further cheapening down, should enable those planters who have a desire for manufacturing teas resembling the Japan greens to turn them out with some chance of succeeding in the competition, though it must be remembered that Japans are roasted by direct heat, not baked as ours are, and though we have been found fault with for recommending a return to something approaching the old-fashioned firing, in vogue before introduction of the sirocco, we still hold to the idea that our engineers could, if they devoted attention to the subject, devise an apparatus for roasting, in which economy in fuel with retention of the aromatic properties in the leaf could be combined. On many estates this promises to be a season of experiments, but we earnestly trust that these will be limited to dealing with small quantities, as, though we have been assured that unfermented tea (as it is called) is stated to have been successfully manufactured in both hill and low country in Ceylon—an assertion, however, since rather discounted by Mr Galt—it would be most unwise to plump for a thoroughly radical change in dealing with the whole crop, there being four instances of the disastrous effects of so doing between 1862, the era of the sand tables, and 1880, when the sirocco first commenced to replace the *pucca dholes*. We entered fully into the effects of keeping rolled leaf in a state of suspended animation (if that term is permissible) a year ago, pointing out that the cooling down of rolled leaf permitted the evaporation of tannin, while, though teas so treated were lacking in strength to a very infinitesimal degree, the flavor was improved, and now that the object is to force Indian tea into consumption on its own merits alone, the "retention" of tannin, hitherto needed for salting weak China, is no longer requisite. Reliable information published last year from our Consuls in Russia showed that large as the importations of Indian and Ceylon teas were, they were quite unfitted alone for the *Samovar*, and though we know nothing definite as to the importation overland of Chinas into Russia we may infer that our teas are merely used for blending with the weaker Congons through the large and increasing quantities taken would lead to the idea that our weaker teas were gradually coming into vogue for the stewing process, unmixed. Hagenback, who has so recently made the great haul of Ukraine horses in S.E. Russia, states that, in one of the inns the first water poured on the tea in the *samovar* after stewing for an hour, was drawn off, deanted into jars

and set aside to fortify the second brew as it weakened. Such a proceeding, from what other travellers tell us, would produce a liquor suited to the Russian taste, and account for the growing demand, but our opinion is that this demand would greatly expand did we supply a tea that could be used without resort to the practice, and such a one can be turned out by cooling down and slow firing. Both operations, moreover, would give whiter tips which Continental dealers desire; in fact, we should, aim at turning out a more delicate liquoring leaf, though at the expense of strength. That such will entail considerable alteration in the present methods of manufacture must be admitted, but in this, as in all other cases, the public are dictators, and obey them we must. Toning down the raspiness of our teas should occupy first attention, which, as we have shown, can easily be accomplished by evaporating the surplus tannin in the cooling chambers. Adoption of the "basket" firing, as practised in Japan and China, presents, we admit, some difficulty in the way of lighting upon some fuel as inodorous as charcoal; but, as we have now a qualified chemist at command, there ought not to be much difficulty in that, and until he has settled the point, one must adhere to the Sirocco for drying off: surely our engineers can hit upon a furnace that would radiate heat, at the same time securing the leaf from contamination by the fumes. The cooling chamber, according to our experiments, should be kept at a temperature of 40° as, if allowed to go below this, the tannin, volatile as it is, would cease to evaporate, while above 40° there would be the risk of fermentation setting in. The method of obtaining the gray color and white tips is by alternately cooling and heating. That the manufacture of what the American market demands will entail the outlay of money goes without saying, and although the Canadian and Northern States dealers pass eulogiums on Ceylon "greens," it seems to us that the price they are willing to give hardly justifies the entertainment of their recommendations. [?] Should we succeed in ousting Japan and China, securing the 70 million pounds, the uphill fight to do so will be a long and costly one, hardly justifying our entering on it at even the top price for the best greens, *viz.*, 42 cents per lb. While urging the manufacture of green or gray tea, on the experimental scale, we must not ignore that we are still really overproducing, and that our 30 million pounds of reduction of output has dwindled to something less than a third of that; whether from disloyalty or miscalculation, it is needless to enquire. We still earnestly advise further restriction in output, for though the latest news from the districts is a doleful record of ripped flushes from hail, these early violent north-westers are invariably followed by favorable meteorological conditions, and if abstinence is not observed, we may again be tempted to glut the markets, just as we were hounded on to do by the London riggers in 1900. We can always increase our output in normal seasons after the rains have set in, and as the stocks in London warehouses are some 15 millions in excess of last year, and in Melbourne half a million with an unknown quantity locked up on the Continent, it would be as well if some arrangements could be come to by which output could be restricted to 140 millions at the outside. Unfortunately we

notice that a large number of concerns have estimated for an increase over last year's production, which, if attained, cannot but lead to lower prices, while what Ceylon contemplates doing we have not the least reliable information about.—*Indian Planters' Gazette*, May 3.

THE CULTIVATION OF COCOA IN AFRICA.

At present the little Portuguese Island of St. Thomé is the great source of production of African Cocoa, but from maps of the Island showing the area under cultivation, as well as from reports, the area suitable for cultivation is pretty well taken up, and anyone wishing to buy an estate cannot but be struck at the very high prices asked; but in Fernando Po to the North of St. Thomé and the little Ile du Prince between the two, Cocoa is receiving great attention, and shows signs of becoming an important industry, the climate being suitable, and though at present, owing to the absence of means of transit in the centre, the cultivations are mostly along the coast, it is hoped, especially in Fernando Po, that the interior will soon be opened up, and offer facilities for the carriage of produce down to the coast.

Taking the Islands off the East Coast next, the Seychelles islands are slowly but surely pushing ahead, though the quantity they supply is never likely to be very important; in the French Island of "La Réunion" the cultivation has gone back, for whilst in 1884 the total crop amounted to 4,000 kilos, in 1889-1900 it was evidently too small to attract the attention of statisticians, and local chocolate makers complained that they were unable to obtain sufficient Raw Cocoa to satisfy their trade. As Cocoa was well-known in the Island in 1827 it cannot be that the climate is unsuitable.

Cocoa from time to time is also received from Mauritius, but up to now it seems that the cultivation of sugar has engrossed the attention of cultivators, and so Cocoa has had to take a seat in the rear.

It is Madagascar that may in the future become a very large source of supply, (and together with the German Cameroons deserves careful attention) and if it had not been for the (Madagascar) War there is little doubt that it would have been a much more important centre than it is at present. Originally the seeds came from La Réunion, and in 1883 it was calculated that about 6,000 trees were planted, all near the coast, and then came the war so that 1888 (five years later) still found them with only 15,000 trees; but since then I have heard that more than 20 estates have been planted. The climate of this island, however, shows some signs of confining the area suitable for cultivation, the rainfall being too uncertain in the North and South, and too small on the Western side (the one nearest to the Continent of Africa), so that it seems as though the East Coast and the centre are alone suitable for Cocoa; but then the Island is very large, so there should be plenty of room in the centre.

The district round Tamatave seems to be the best district, all the year round.

To go now to the mainland, Cocoa is being planted in French Guinea, the Gold Coast, the Ivory Coast and round Calabar but it is badly prepared and at present, I believe, is in the hands of natives who sell it to Europeans to properly dry, if not to cure as well. Reports agree that all these places are suitable for the growing of Cocoa, and considering the absence of skill, attention, &c., the results up to now have been satisfactory.

In the *Belgian Congo* where Cocoa was not introduced until 1884 and not really planted until 1887-88, it was estimated by Mons. Wauters that in 1898 there were 125,000 trees in cultivation. The natives seem to be also growing it under the direction of their chiefs. In the *French Congo*, although it was not started until 1887, Cocoa seems to have made more progress than in the Belgian centre, and is reported to be now in general cultivation throughout the Colony, and has given on the whole satisfactory results. The total shipments from the Colony in 1898 are put down to be 3,800 bags, of which about one-third went to France, and the balance, the estate belonging to a Dutch firm, to Holland.

Now we come to the German Colony of the Cameroons whose cocoa, I believe, is shipped entirely to Hamburg; if so the following receipts of this growth in Hamburg will give some idea of the extent to which the industry has grown since 1892:—

In 1892 the Cameroon returns say	the Colony shipped	...	900 bags
In 1895 the Cameroon returns say	the Colony shipped	...	2 640 "
In 1807	1893	1899	1900
5,400	6,745	9,047	9,833

—bags were received in Hamburg from the Colony. And to the end of February, the figures compared as follows:—

1898	1899	1900	1901
2,046	1,842	2,053	4,041

bags received in Hamburg from the Colony, showing a regular and substantial increase.

After St. Thomé therefore the Cameroons are expected to be the most important supplier although the very optimistic idea as to returns, when the district was first planted between 1886 and 1890, were rudely disappointed. Before 1886 only a few trees were in existence, and those had been planted by the natives. The cocoa has come from a good stock originally, the seeds having been brought at great cost from Trinidad, Venezuela, Ceylon and St. Thomé. At present most of the plantations are near the coast, or along the river banks in the Western and South Western districts, and there is an abundance of land equally suitable for cultivation, once the trouble of transit has been overcome.

The Germans, it seems, pay great attention to the outward appearance of the bean, and the "break" has been sacrificed for the appearance outside; excessive fermentation, which all African cocoa seems to require, rather spoils the shell, as well as the rounded appearance, but owing to the complaints

from German cocoa manufacturers, it is hoped, buyers will attend more to the "break" than the appearance, and by paying a higher price for a good breaking sample wean the planters from spoiling the inside for the outside. At one time it was maintained that it was impossible to rid the St. Thomé bean of its bitterness, but the experts I sent samples to in the West Indies all said that, given about twice as much sweating, the cocoa would come all right, and certainly of late we have had some piles showing a marked improvement in the break.

H. HAMEL SMITH.

CEYLON TEA IN RUSSIA

AND WHAT A REDUCTION IN THE DUTY WOULD MEAN.

With reference to the tea deputation in London to Prince Stcherbatchoff, presenting the importance of bringing about a reduction in the Russian tea duty, which received some prominence in our issue of last evening, we thought the opinions of local Russian firms on the subject would be of exceptional interest. We have, therefore, made enquiries, with the following results:—One firm which does not desire its name mentioned, says:— "We have read the articles in your paper on Ceylon and Indian tea, and tea duties in Russia. Our opinion is that, should the duty be reduced, the consumption of tea in Russia would be very largely increased. Cheapest kinds of tea are sold in European Russia at about the equivalent of R1 70 per Russian lb. (36 English pounds=40 Russian), and a substantial reduction in the duty would mean that these kinds of tea would find their way even to the poorest classes in Russia, who cannot now afford to indulge in the luxury of tea-drinking, and the present consumers of tea would probably buy more tea at the cheaper prices, or would take the same quantity as before but of a better class of tea.

"As regards the paragraph about a deputation to Prince Stcherbatchoff, we do not think it will have much influence on our Government, as they must have their own important reasons for not having reduced the duty on tea before this."

Mr. W. P. Ampenoff today favours us with the following statement:—"I am inclined to think that a reduction of Duty in Tea will probably lead to a increased consumption of Tea in Russia, but I doubt the Duty will be reduced by the Russian Government as it is not quite evident whether the increase of import will be in proportion to the loss to Government in Duty, if reduced."

TROPICAL PRODUCTS IN THE FEDERATED MALAY STATES.

From the report by Mr. A. Berrington, Commissioner of Lands and Mines, F.M.S., on the lands, mines and surveys of the Federated Malay States for the year 1901, which has just been issued as a supplement to the Negri Sembilan Government Gazette,

we quote the following review of their agriculture for the year:—

The reports of the Collectors only refer to the progress of agriculture incidentally, in connection with the alienation of new land, and no doubt it is more a matter for Administration reports than for Land Office reports. Still, I may notice a few matters of interest in this connection.

PADI.—In Krian, where the cultivation of sugar and padi has been long established on a considerable scale, there has been a disastrous failure of the padi crop, though happily it does not seem to have affected the rent collections. Owing, as the Collector says, to the supineness of the penghulus, in neglecting to see that the transplanting was done at the proper time, the first nurseries were almost entirely ruined, and by the time that second nurseries were ready, and their contents transplanted, heavy rains came to retard the development of the young plants, which were then attacked by a wire worm and the greater part of the crop was spoilt. As a result, the export of padi from Krian, which in 1900 was valued at \$538,404, was in 1901 worth no more than \$190,533. In several other districts, however, the padi crop has been a fine one. In Kuala Kangsar, where it has been particularly good, I have heard the result attributed mainly to the influence of the penghulus, who understood what ought to be done, and took care that it was carried out.

SUGAR.—Sugar cultivation in Krian produced an export of the value of \$1,480,163, as against \$1,315,974 in 1900. At the large estate at Sungei Gelong in the Matang district, where over 1,100 persons are employed, the crop is estimated to produce 55,300 pikuls of sugar.

PINANGS.—From Selama it is reported that 10,630 pikuls of pinangs were exported in the course of the year.

COCONUTS.—In Lower Perak, Kuala Selangor and Kuala Langat there has been a considerable demand for land for coconut plantations, but there are also many complaints of the damage done by beetles and by rats. Mr. Hale, the Collector and Registrar of Titles in Kuala Lumpur, thinks that unless rigorous measures are taken it will soon be hopeless to attempt to grow coconuts within five miles of the centre of Kuala Lumpur, owing to the number of heaps of stable and other refuse in which the beetle (*Oryctes rhinoceros*) is allowed to breed undisturbed.

TAPIOCA.—In Negri Sembilan, where tapioca has been largely grown for years, a considerable area of fresh land was alienated during 1901 for that cultivation, with a condition requiring the planter to introduce some "permanent" form of cultivation (e.g., getah rambong or coconuts) *pari passu* with the planting of the tapioca.

GAMBIER AND PEPPER.—The price of both gambier and pepper has risen, and some fresh land has been alienated for their cultivation.

COFFEE AND RUBBER.—The prospects of coffee have, unhappily, not improved materially, and a great deal of land planted with that product has been abandoned. Many estates, however, have been kept going, and may be expected to do well in the future with the help of the para rubber which is now growing up between the rows of coffee.

TOBACCO.—In Ulu Langat tobacco is grown on small scale by Javanese settlers.

CEYLON TEA ON THE CONTINENT OF EUROPE.

In our opinion, no fuller nor more satisfactory Report has as yet been published from a Ceylon Tea Agent—or Planters' Commissioner—than that supplied for 1901, regarding the Continent of Europe, by Mr. J. H. Renton, and which we publish on page 25. It discloses a wonderful amount and variety of work, and, considering the small sum allotted to the Commissioner, we think he has done wonders. He certainly has not spared himself, nor adopted any one rough and ready course of getting rid of the Ceylon grant with a minimum of trouble to himself; but in encouraging "demonstrations" and a variety of modes of advertising, and of making known the virtues of Ceylon tea, Mr. Renton has been very wise and active in his campaign. In respect of Russia, the Report was framed before the disappointment respecting the St. Petersburg Exhibition was known, and it is very curious to see the suggestion that, as the regular course of trade should not be interfered with, a bonus should be offered (from the Cess money, we suppose) to all importers (or exporters) of Ceylon tea. We do not know if this will be approved of by Russian tea merchants, even if the "Thirty Committee" had the money available to make a grant or bonus worthy of acceptance. But it will certainly be a striking fact in the history of our tea trade development if the export of our staple to Russia should run up, year by year, within a comparatively brief period, to 32 million-lbs. without any further call on the Cess Fund.

IN THE WORLD'S IVORY MART.

Billiards are impossible without billiard balls and billiard balls, we may inform him, are equally impossible without the ivory sales. Ivory is one of those commodities that are most intimately bound up with the "romance of trade." There lies the ivory on the merchant's counter, but who shall say how it was originally acquired—what dark dealings went on in the swamps and silences of Africa before it found its way to the trader's possession? About two years ago saw the most curious as well as abundant shipment of ivory from Africa that has been known for many years. It was the time of the Benin expedition, and the natives ransacked the country for ivory with which to seize this unique opportunity of trading. Even the heathen temples yielded up their treasures, for some of the ivory shipped was in the form of idols. And on several of the tusks there was the mark of human blood. The shipments reach the London docks at all times of the year but they are stored up carefully until the time of the sales, which occur four times yearly. Then they are sorted out and arranged in lots on the floor of one of the extensive warehouses attached to the docks. The actual sales occur

AT THE COMMERCIAL SALE ROOMS IN
MINCING-LANE,

but for several previous days the ivory is on view to the trade; the scene during these inspection days is not unlike an Academy private view. Dotted about the warehouses stand the representatives of various firms, notebook and catalogue in hand, marking

off the most attractive lots and discussing the merits of the display.—This week's sales are considered small as ivory sales go: but, nevertheless, the sale value of the stock is roughly estimated at £40,000. The best ivory is what is known as the "soft teeth," which comes chiefly from East Africa, and particularly from Zanzibar, the West Coast supplying the bulk of the other kind—the "hard teeth." Good Zanzibar ivory is very valuable, and in proof thereof it may be mentioned that the record price recently fetched by a tusk of this ivory was £350. The specimen thus purchased was acquired by the British Museum.

MAMMOTH IVORY.

Very little is imported nowadays from India and Ceylon; but a fair supply comes from Siberia. The latter kind is thousands of years old, being the tusks of the ancient mammoths dug up out of the ice. Their size is often tremendous. Our illustration represents two mammoth tusks on view this year, worth probably about £150; they are the finest ever seen at the dock. Mammoth ivory is of inferior quality, however, deteriorating sometimes to £2 per hundred-weight.

160-LB TOOTH.

The best ivory—that from which billiard balls are made—is priced at about £89 per hundred-weight, "Bangle ivory" is also quite a recognised trade term, for the teeth used to make the bangles worn by Indian high-caste women. The average weight of the "teeth" is 80 lb, but of course specimens vary tremendously. An enormous "tooth," weighing no less than 160 lb, has been on view at the dock. A curious thing in this connection is the evidence of disease—corresponding almost with our own toothache—sometimes discovered in the tusks, which are frequently hollowed out far beyond the average extent by these ravages. When we consider what agonies of pain a small human tooth is capable of inflicting, we ought not to grudge the ready tear for the elephant afflicted with several yards of toothache. The cure for neuralgia must be in great request in the elephant world. And it would probably not soothe the sufferer to know that his diseased tusk is worth some £16 per hundred-weight less than that of the animal whose molars are in good condition.—*Morning Leader*, April 21.

RUBBER FOREST IN THE SOUDAN.

Lord Cromer, in a recent report to the Foreign Office, states that considerable quantities of rubber trees are reported in many of the districts of the province of Bahr-el-Ghazal. Mr. Broun, the Director of Woods and Forests, has been despatched to report on the possibilities of re-opening the india-rubber trade of the Bahr-el-Ghazal, which in former days was one of the principal sources of revenue in that district. It is also hoped, in the near future, to develop the rubber forests in South-western Kordofan, which, from all accounts, are of great importance.—*Globe*, April 25,

MORE ABOUT PEARLS AND PEARL OYSTERS.

THE MANUFACTURE OF PEARLS.

(From "SCIENCE JOTTINGS.") BY DR. ANDREW WILSON in THE "ILLUSTRATED LONDON NEWS," April 19.)

Among the curiosities of natural history science may be regarded the manufacture of pearls. In contradistinction to the case of the diamond, pearls appear before us as the work of living animals. The diamond is the product of cosmical heat, and possibly

dates from the days when the earth was young, and when its carbon became crystallised under the action of fervent heat. For, as most of my readers may know, the diamond simply represents crystalline carbon. It has near relations, chemically speaking, in blacklead and charcoal. Chemical science, recognising this fact, has attempted to produce diamonds from a carbon basis. In this imitation of nature I believe they have proved successful; only the diamonds, built up as it were from their carbon parentage, are so small that, commercially speaking, they are of no account. Till chemistry can imitate on a bigger scale than is possible today the work of the inner fires of the globe, it is hardly possible to conceive of the diamond being successfully imitated by the laboratory product.

The ruby and the sapphire also represent mineral products which possess a geological significance. But it is entirely different in the case of the pearl. There we have to deal with the manufacture of an animal form, which of course belongs to the molluscan or shellfish type of life. If we examine an oyster-shell we find it to be lined with a beautifully delicate layer known as nacre or mother-of-pearl. In the well-known "ear-shells" this layer assumes great thickness and by refracting the light from its ridges gives us a typical play of colour and of iridescent hues. Every mollusc in fact shows mother-of-pearl as the lining layer of the shell, although as may well be understood there are infinite variations in respect of the quality, delicacy, and therefore commercial value of this substance. In many shells it is coarse, as to others it is of fine texture and special colour. It is in the latter case that it gives origin to the pearls of great price.

The typical pearl-producing mollusc is, of course, the pearl oyster concerning the welfare of which an English Commission is at present busily inquiring in Ceylon. The Scottish pearl mussel was also celebrated in its day. I use the past tense here because the goose that laid the golden eggs was daily killed in this case as in so many others through the mussels being fished to extinction in the rivers of the North. These shellfish, as the typical pearl-producers, present us therefore with an illustration of the animal manufacture of a precious product. Certain interesting circumstances connected with pearl-production have of late been ventilated by Dr H L Jameson in the course of a paper read by him before the Zoological Society of London. What Dr Jameson has to tell us of the manner in which pearls are produced in a certain species of mussel serves to throw light on the possible manner in which they are manufactured by other shellfish.

Each oyster or other shellfish is enclosed in a kind of skin to which naturalists give the name of the "mantle." It is this membrane which at once envelops and encloses the body of the animal and of course lines the shell. The mantle is the source of the mother-of-pearl which is deposited by it in the shell and naturally it is to the mantle that we also look for formation of pearls. Long ago it was known that each pearl was formed round some solid particle or other which had gained admittance to the shell. It was as if the irritation of the particle induced the mantle to secrete around it layers of the mother-of-pearl substance by way of rendering the foreign body harmless. In the case of the pearl-producing molluscs the real jewel was thus formed while in others the "Pearls" were of course valueless. The Chinese have been accustomed to introduce into the shells of big molluscs little metal images, which become coated over with the pearl secretion and are thus rendered presumably more attractive. So that scientists assert that the pearl is really in one sense an abnormal thing, in that it represents the physiological resentment of the shellfish against a particle which has no business to be where it is.

Dr Jameson's discovery in this light is of a singularly interesting nature. For he tells us that the nucleus or particle, around which a pearl is formed in most cases, is the larva or young form of a certain parasite

which has found its way into the shell. The parasite is a fluke, and is therefore allied in its nature to the animals of that name which we find familiarly infesting the liver of the sheep and the ox. The flukes whose youthful forms gain access to the shells of the molluscs are found as unbidden guests in the eider duck and in the Scoter duck. The life history of the parasites, as far as we know it, shows us that on escaping from the egg the young forms seek the water. Then they require to pass into the body of another animal than that in which they become mature in order to undergo the preliminary stages of their development. In the case of the sheep-fluke, we know that it passes the days of its youth in the body of the water-snail; and so in the case of the flukes Dr Jameson describes we may suppose their young select the mussels as their temporary hosts.

It is when the young fluke in the shell comes to grief, and its body degenerates into a limy speck, that it forms the nucleus of the pearl; but occasionally it will bore its way out of the pearl and thus leave the latter presumably imperfect. Dr Jameson has succeeded in infecting mussels artificially by keeping them in an aquarium. He also suggests that the real pearls of the oyster similarly originate from the young of the parasites which lodge within the shellfish. If infection of the pearl oyster could be rendered possible and swarms of parasites could be liberated in an oyster-bed doubtless the artificial production of the precious stones would become a feature of commerce. But it seems to me that, just as the diamond is only carbon after all, so our beautiful pearls parallel its case by owing their origin to the work of a low form of parasitic life.

THE TEA TRADE WITH PERSIA.

In your issue of the 1st instant, under the above heading, appears an extract from an official communication from Meshed, suggesting that the Indian Tea Association should, for a time, turn their attention towards the Bombay Agents of Persian firms, who might be won over to the advantage of buying tea at some place nearer the producing tea gardens than Bombay, and of the land route as against the sea route. As an old resident of Teheran, I have watched with interest the various proposals made and the action taken by the Indian Tea Association in the matter. The Nushki-Seistan route is being boomed to an extent which it certainly does not deserve, for what reason I am at a loss to understand. Those interested in the tea trade with Persia, should, in my opinion, use their utmost endeavours to popularise Indian tea in such parts of Persia as are already to an extent supplied with Indian tea, and where British influence is in the ascendant; they should not commence operations in such parts of the country as are solely under Russia's influence, and where necessarily the markets have already been captured by Russia to a certain extent. First assault and capture the outer works, before trying to take the enemy's stronghold. It is not much use trying to win over the Bombay Agents of Persian firms, where, no doubt, vested interests would be at stake. The best plan by far would be to send out an agent with a supply of tea to travel through the country to be exploited, and to cultivate the already established taste for such teas. When this is accomplished, the Bombay Agents would of necessity be obliged to buy such teas to meet the demand which would arise.

The towns in Persia I would advocate an agent visiting are Bushire, Shiraz, Kerman, Ispahan, Yezd, Teheran, Kermanshah and Hamadan—all great commercial centres. The less said the better about

such a fatuous idea as the land route being so much superior in every respect to the sea route. During my stay in Persia this matter was never once referred to by my Persian friends and acquaintances, some of whom were keenly interested in the tea trade; this supposed superiority must be put down as one of the ingenious but fallacious arguments of the boomers of the Nushki-Seistan route. In the official communication already referred to, mention is made of every man considering his cup of tea a necessity rather than a luxury. This is not literally correct, as the Persians do not drink tea in the same manner as we do. At many street corners of every town in Persia, there are restaurants or shops for the sale of drinks, where a customer can also obtain a smoke from the *kalian*. Usually music of a sort is also provided, the musician being only too glad to perform in return for a drink and a smoke. In each of these restaurants there are one or more brass samovars (Russian *urus*) continually on the bubble. A small quantity of tea is placed in a China teapot, which is filled with boiling water from the samovar, and then placed aside to brew. On a customer calling for tea, it is poured out from the teapot in a small vase-shaped glass, which holds about 20oz, a piece of loaf sugar is added, and the glass and a small spoon are placed on a china saucer and handed to the customer. Persians do not add milk. To show special honor to a customer, the lump of loaf sugar should project out of the tea like an iceberg. The Persian likes his tea sweet.

Should any enterprising individual or firm be contemplating a campaign with the object of establishing a tea business in Persia, I should be only too happy to place my knowledge and services at their disposal, as the country and people are to me most interesting.—TEHERANI, Sambalpur, C. P., in the *Statesman*.—*Indian Gardening and Planting*, May 8.

THE LIFE-HISTORY OF HELOPELTIS THEIVORA.

NOTE ON A DISPUTED POINT.

(By Harold H. Mann B. Sc.)

As is well-known, *Helopeltis theivora*, the "Tea Bug of Assam" as it was called by Mr Wood-Mason, the "Mosquito Blight" as it is generally termed—is the most alarming pest which has yet appeared on tea cultivated in India. It causes the more disquietude as it tends to increase as years go by,—fluctuating according to season, but generally increasing, and invading new areas. During 1901 which was a particularly bad year in almost all districts subject to the pest, a very moderate estimate gives seven lakhs of rupees as the nett loss to the Indian Tea Industry from this cause alone.

Though we have a knowledge, thanks to Peal, Wood Mason, Dudgeon, Watt, and Green, of the general life-history of the insect from the egg to the adult stage yet there remain several points which have been very obscure. Of these the most important is the question as to what becomes of the insect during the time when it apparently disappears from the tea bush. So complete is this disappearance, as a rule, that most planters living in affected districts in North-East India have hardly ever seen a single insect during January, February and March. Mr Dudgeon has suggested that it hibernates in the ground but offers no evidence for his position, and declares frankly that he had not been able to verify his conjecture. It has also been supposed that hibernation takes place in water and swamps, but again, not a scrap of evidence in favor of the view exists, and the

same may be said of the very general idea among tea planters that in the cold weather the *Helopeltis* goes on to various jungle trees.

With a view of acquiring information on this point I have spent considerable time in January, February and March of the present year in two of the districts most affected by the pest—the Darjeeling Terai and Cachar—at a period, that is when the insect was supposed to be hibernating. As a result I have come to conclusions of which the following is a summary:—

The *Helopeltis theivora* can be found on the tea bush in every stage of development during every period of the year. The cold weather kills off the bulk of the mature insects and practically all the larvæ, but at all times sufficient remain to carry on the pest to the next season, and in addition the bushes are full of eggs. These latter were found not only in the usual position on the young shoots but also at a much lower part of the bush than has previously been noticed, embedded in the usual fashion in the midrib of the large mature leaves. The larvæ were found on 11th January in small numbers on unpruned and sheltered bushes, then forming about 2½ per cent of the total number of insects caught. By 12th February, however, a very different proportion of adults and larvæ was obtained, and now instead of 2½ per cent the larvæ formed 80 per cent of the total catch. This proportion was approximately kept up during several weeks from that date. The difficulty in obtaining evidence of their presence at this time is due to their attacking almost entirely the slightly shaded young leaves, the surface growth being rarely attacked in the early part of the year.

The insect could, further, not be found on any jungle plant at this time. Though jungle of very miscellaneous character was systematically searched both by myself and by the children who are regularly catching the insect, not a single one was discovered in any form.

It appears, therefore, evident that there is, from present knowledge, no need to assume a hibernating stage at all for *Helopeltis theivora*, and that the insects remain and can be found in every stage of growth, from the egg to the mature female full of eggs, at all times of the year. Whether the egg found low down in the bush, as described above, can be considered as a special hibernating egg, I can hardly say, but there certainly was no difference in structure or in method of deposition from that usual during the regular season. Inasmuch, then, as there is absolutely no evidence of the cold weather being passed by the insect in the soil, in water, or on other trees, and furthermore, as careful observation can always detect the insects and their eggs on tea bushes in affected districts, there is no need to imagine any hibernation stage at all in India, and beyond a certain retardation in development, due to the reduced temperature, the reproduction of the insect may be considered to take place in a similar manner throughout the year, and to be carried out on the tea bush itself during the whole period.

These observations have a very practical interest, and may lead to a sound method of attempting to deal with the pest, and experiments in this direction are now in progress. HAROLD H. MANN.

—*Indian Gardening and Planting*, May 8.

VANILLA CULTURE IN BENGAL.

We have in previous issues referred to the experimental cultivation of the *Vanilla planifolia* in the gardens of the Agri-Horticultural Society of India. It may interest our readers to know that the Vanilla plants are making most vigorous growth, and have fully established themselves on the stakes. The manner of growing the plant on a commercial basis was fully described by us just

a year ago (*vide* issue of 9th May 1901, page 330). All the older vines are laden with pods of fine size and substance, many of the pods being over nine inches long already, and have another four months yet to grow in.—*Indian Gardening and Planting*, May 8.

THE RUSSIAN TEA MARKET DESCRIBED.

BY A RUSSIAN TEA MERCHANT.

Mr. T. C. Tchokoff, the Acting Russian Vice-Consul's address to the "Thirty Committee" last week, was to the following effect, Mr Tchokoff clearly setting forth his views under three heads:—

- 1 The favourable condition just now for buying tea on the Chinese market.
- 2 The under-fermenting of Ceylon teas intended for the Russian market.
- 3 The demand at present in Russia for low-grown tea.
- 4 The necessity of the one-pound draft to be allowed as done in London.
- 5 The improving of tea chests for shipment.
- 6 The means of advertising Ceylon tea in Russia.

MOMENT FAVOURABLE FOR BUYING IN RUSSIA.

Let me now look into the above-mentioned questions.

1 Talking of the favourable condition just now for buying tea in China, the tea market for Russia, you are, of course, Gentlemen, all of you aware, that at the present moment the cost of silver is about 20 per cent lower than it was a year ago. Take the average price of China tea paid by Russian buyers last year—it was about 20 taels per picul, which at the present low exchange would be 30 cents per pound on the local market.

Now I have information by wire from Hankow that they expect a very large crop this year and I don't see any reason why the average price in China should be higher this year than last year. The average I paid here last year for Ceylon tea was 42 cts. per pound and, reckoning with the present condition of the local market, I don't think that my average will be lower this year; thus I shall have to pay twopence more for Ceylon tea than for China tea, always considering the exchange and the lower price of silver. If I mention this, Gentlemen, I do it to show you how keen I expect the competition to be in Russia between China and Ceylon teas this year, and how every effort must be made to maintain the Ceylon tea at the place it has already attained on the Russian market.

CEASE UNDER-FERMENTATION OF CEYLON TEA FOR RUSSIA.

2. One of the measures to this effect I should think would be to stop the under-fermenting of Ceylon tea intended for the Russian market. We want the Ceylon tea for blending with China tea and therefore we require all its primitive vigour, especially so as teas in China are, owing to the low prices, manufactured very weak. Adapting Ceylon tea to so-called Russian taste by making it, through underfermenting, more like China tea is, in my opinion a decided mistake, as pure Ceylon tea is, up to the present date, sold in Russia in very small quantities.

RUSSIAN DEMAND FOR LOW-GROWN TEAS.

3. At the present moment the demand in Russia is mostly for cheap grades and, therefore, the low-grown teas if well fermented, when they are very appropriate for blending, ought to be more energetically pushed on the local market than has been done.

NECESSITY OF THE ONE-POUND DRAFT.

4. In my opinion it will have to be done sooner or later, that a draft of one pound per package should be allowed, which I am quite sure will be greatly ap-

preciated in Russia. We must all of us not forget that every buyer in London has not only this privilege but also a three months' credit, which considerably facilitates business.

IMPROVED CHESTS WANTED.

5. Don't you think, Gentlemen, that the chests, in which the tea is packed and shipped, might be improved upon? I often do not buy tea from estates, where the packing, to my knowledge, is unsatisfactory. As to the means of advertising Ceylon tea on our Russian market, I don't think that any special activity on the part of the agents would be of any great use.

THE TEA BUSINESS IN RUSSIA

is practically in the hands of a few leading firms in Moscow and St. Petersburg who have a full insight into the qualities of Ceylon tea and who at present buy it on the London and local markets, selling it themselves to smaller firms. To try to enter into direct communication with these smaller, would-be buyers, through agents or with consumers even, by establishing tea kiosks etcetera, is not only, in my opinion, a perfectly useless and hopeless spending of money, but is sure to lead to displeasure on the part of the principal firms, the buyers of Ceylon tea, and in that case they are sure to look for other markets to get their tea from, for instance from India.

THE LEAF.

One more point, Gentlemen, I should like to draw your attention to, and that is the leaf; a small, carefully rolled up leaf is especially appreciated on the Russian market.

PLANTING NOTES

GREEN TEA.—Our contemporary's omniscience as to the best green teas for the American market, although no reports of the prices fetched by the new makes have been announced yet, is vastly amusing. We shall be interested to note the attitude it will take up when and if substantial eye-openers come to hand. Meanwhile green tea producers in Ceylon, who we were very glad to see had made nearly 750,000 lb. in four months this year, will doubtless better appreciate the *I.P.G.'s* most practical article by an "old planter" (reproduced elsewhere) better than half a column or a column of semi-second-hand editorials, such as appear in the local "Times" of last night.

THE HEMP TRADE.—A circular has been issued to the members of this trade drawing their attention to an act recently passed in the United States, entitled "Act temporarily to provide Revenue for the Philippines and other purposes." Under this Act (Section 11) the present export duty of \$7.50 gold per ton is abolished in the case of hemp shipped direct to the United States, the effect being tantamount to the imposition of a discriminating tax on all hemp shipped from the Philippines to the United Kingdom and other parts of the world. The circular points out that "the grave importance of this matter to the rope-making industry of the country will be obvious. The fact of our manufacturers having to pay about 30s per ton more for hemp than their competitors in the United States constitutes a serious menace to the trade, especially as there would appear to be nothing to prevent the present export duty being doubled or trebled, should the United States Government think fit." It is suggested that it is in the interests of the trade that a memorandum on the subject should be submitted to the Foreign Office.—*London Times*, April 7,

THE CEYLON COMMISSIONER FOR EUROPE

REPORT FOR 1901.

I do not suppose it will be considered necessary that I should recount in my report for last year the impressions I have received, the information I have obtained, and the details of the methods adopted in the various countries which I have visited, to introduce and push Ceylon tea. All these details have been given in the numerous letters I have written from time to time to the Chairman of the Committee. I shall therefore give only as brief a summary as possible of the work done.

Travelling.—In the early part of the year I visited the West and South of Germany, Austria-Hungary, Northern Italy, South and West of France, and Paris. In the Spring I went to Saxony, and Central Germany; in the Summer to Northern Germany, Sweden, Norway, and Denmark; in the Autumn Switzerland, Paris, and a few towns in the North of France, and in the Winter to St. Petersburg and Moscow.

Mode of Operations.—I have presumed that the object of my mission is (1) to make Ceylon Tea known on the Continent, that is, to let the Public on the Continent know that Ceylon produces tea in large quantities, that Ceylon Tea is superior in every way to China, and any other tea; (2) to get the Public to taste the tea, and to show the Public how the tea should be prepared. With these ends in view I have confined my work entirely to the Trade. I have not been successful in France and Germany in inducing the oldest and largest first-hand Importing Houses to interest themselves sufficiently in Ceylon Tea to push it with their retail clients, or make a speciality of it. However, one Bremen Commission House has interested itself very considerably in the article. The reason of the abstinence of the large firms is obvious. They have an established trade in China Tea, and see no reason why they should act as missionaries in introducing a new article to their clients, especially when the profits on the new article are smaller than on the old. However, all the tea-importing firms in France, Germany, and Scandinavia import our Tea now, and I know of only two exceptions, one firm in France and one in Sweden, which refuse to have anything to do with it. I have worked mainly with the smaller importing firms, the dealers in the inland towns, the agents of London firms, and of Continental firms established in Ceylon. I have acquiesced in these firms carrying on the propaganda in the way in which they consider they will be most successful. No retail firm has received any support with the exception of one in Vienna, one in Florence, one in Naples, but these firms have for some years drawn their supplies of tea direct from Colombo. I have paid for no general advertising, and none has been done.

Germany.—Work in Germany has been carried on by three more or less different methods:

(1) By the help of a Bremen importing firm, which has endeavoured through their clients to establish depôts for the retail sale of Ceylon Tea.

(2) By subsidies to other dealers in the inland towns, who in their turn have carried on the campaign by newspaper advertisements on behalf of their clients, or by distribution of advertising material, post cards, circulars, leaflets, etc., and free samples of tea.

(3) By distribution of the pamphlet "Tea Cultivation in Ceylon" and other circulars to all the Trade and numerous Hotels.

As regards the first method, the firm in question has tried to induce its clients in Germany, Austria, and Scandinavia to take up and push our tea. So far they have established only three agencies in Germany, one with its centre in the Rhine Provinces, one in Breslau, one in Holstein. The first-named is a large coffee-distributing firm with 700 branches all over Germany; it possesses therefore special facilities for distributing the article. But in addition to these special agencies, this Bremen firm has induced several of their clients in Cologne, Baden, Strasburg, Leipsic, and Frankfurt—who had never hitherto imported Ceylon Tea—to pass orders for and stock it. It has imported in 1901, 120,000 lbs. Ceylon Tea against 20,000 lbs. in 1900, but part of this increased import has been for Austria and Scandinavia.

From their appendixes A. C. D. & C. it will be seen that their clients had up to the end of the year (1901) established in Germany 756, in Austria 600, in Denmark 189, and in Switzerland 20 depôts for the sale of Ceylon Tea. The expenditure by these agencies in Germany has been confined entirely to illustrated circulars, and window placards. This scheme was discussed and formulated early in 1901, but it was only in the last three months of the year that the bulk of the circulars and placards were issued. I hope for good results but they will not be apparent for months yet. As I write, I hear that several new agencies have been started, and it is anticipated that at the end of 1902 all the Provinces in Germany will be assigned to agents.

2. In addition to these I have continued grants to the three firms who, induced by their Ceylon connections, have already been at work for some years pushing our tea. One of these is in the neighbourhood of Frankfurt, and draws its supplies of tea from the only estates which are owned by Germans in Ceylon; the second is in Stuttgart, and the third in Munich. They have all carried on a very active Propaganda, the Frankfurt people mainly, on the lines of distributing their circulars as a supplement of various special monthlies and weeklies. The papers they have chosen are some illustrated papers, and special papers for the Army, Navy, doctors, clergymen, railway employees, etc. In this way they have distributed 600,000 of their special circulars, and 100,000 of various other publications, and they have advertised in some 24 different newspapers. Their denunciation of China tea in their leading pamphlet is perhaps a little too forcible. Our object is not to make tea drinkers disgusted with tea generally.

Our Stuttgart and Munich friends have worked by means of newspaper advertisements, circulars, leaflets, photos, calendars, with views of Ceylon, and advertisements in special Ladies' Magazines and periodicals. They have also inserted one or two leading articles in a couple of newspapers. Stuttgart is able to report an increase of sales in 1901 over 1900 of 12,300 lbs., Munich of 800.

In addition to these three firms I have been successful in getting other three firms, one in Frankfurt, one in Berlin, and one in Königsberg, to interest themselves in our tea. The Frankfurt and Berlin people have advertised it freely, and have brought out special labels for pure Ceylon tea in packets. The Königsberg people have increased the proportion of Ceylon largely in their blends, none of which is now without a mixture of Cey-

on. All the three houses quote it at various prices on their Circulars and Price Lists. The Frankfurt House, which is one of the oldest tea Houses in Germany, will, I am glad to think, push Ceylon tea vigorously. Their import in 1901 exceeded that of 1900 by 10,600 lbs.

The third method of work in Germany has been the distribution of the Illustrated Pamphlets "Tea Cultivated in Ceylon." In 1900 the principal tea firm in Bremen advised me that, in their opinion, the very best way to introduce Ceylon tea was to get a series of articles published in the German Press, and that these articles should appear in all the Ladies' and Girls' papers, and in the Medical and Scientific journals, and be written from a semi-scientific point of view. I have had many interviews with this firm and some correspondence, but have not yet found someone to write an article of this description. In the meantime another gentleman has used the information I supplied him with, and published the pamphlet known as "Tea Cultivation in Ceylon." Up to date it has been distributed in Germany to 1,422 Hotels, 931 tea and colonial produce dealers 112 Sanatoriums, and 1,100 newspapers. I have seen notices of the brochure by 48 of these newspapers; some have devoted an article to it, others only a notice of a dozen lines. Four illustrated papers, with a circulation of half a million, have reproduced the pamphlet in its entirety, giving some of the illustrations. All these notices in the daily papers, and the reproductions in the illustrated papers, have been given gratis, and have therefore cost us nothing.

In Germany I have so far not been able to do anything by way of demonstration. I still have to find the proper parties to undertake this work. I am convinced we must get a wholesale or importing firm to interest itself in the undertaking before making a commencement. I am sorry the arrangements made for Stuttgart fell through at the last moment. I am in hopes we shall in a short time see Ceylon tea rooms in half a dozen of the principal German towns.

The Colombo export returns show an excess in 1901 of direct exports to Germany of 183,387 lbs. over 1900. Part of the exports to Germany is no doubt for transit to Scandinavia and Switzerland. The Colombo returns also give an excess of exports to Holland and Belgium of 11,868 lbs. The bulk of the imports into Holland and Belgium are for Southern Germany and Switzerland, the water transit by canal from Rotterdam and Antwerp being the cheapest way for goods to Basel, Baden, Wurtemberg and Hessen.

The German Custom Returns for 1901 give an increased import in Ceylon Tea over 1900 of 89,300 kilos, say 196,460 lbs., in Indian Tea of 43,200 kilos, say 95,040 lbs., and from Great Britain of 124,300 kilos. I think we may safely assume that quite one-third of the supply drawn from Great Britain is Ceylon tea, so the increase in Germany of Ceylon tea for 1901 may be calculated at close on 270,000 lbs.

Appendix "A", prepared for the information of the Committee, shows that the total expenditure in Germany by the various agencies engaged in pushing Ceylon tea has amounted to 39,261 Marks, 94 Pfennige, to which I have contributed 14,779 Marks, 90 Pfennige, and out of this latter sum 1,500 Marks have been paid in consideration of expenditure undertaken in 1899 and 1900. The actual contribution for 1901 is 13,279 Marks, 90 pfennige.

France. Work in France in 1901—may be divided into two classes: (1) General advertising and trade propaganda. (2) Demonstration.

The former has been carried on by six different firms, and the bulk of the Propaganda has been done by the two houses which interested themselves so largely in 1900, in Ceylon tea, both during and after the Exposition. These two agencies have conducted a vigorous campaign in Paris, and have advertised largely in the newspapers and magazines such as the *Mode Pratique*, *Lectures pour tous*, *Le Matin*, *Figaro*, *Echo de Paris*, *Femina*, *Le Journal*, *Bottin*, *Revue de Paris*, *Le Gourmet*, etc., in all some 20 papers and periodicals have been used for general advertisement. But the bulk of their expenditure on general Propaganda has been in their outlays for, and grants to, grocers, supplying them with window signs, placards, free samples, etc., and in Menu Cards to Hotels and Restaurants. The third firm, which runs a large tea room in Paris, has issued cards, circulars, and leaflets, and continues to see only Ceylon tea in cup in their Tea Rooms. The fourth house confines itself entirely to grocers in Paris, and has given them leaflets and small presents of perfumery and other articles in return for all orders for Ceylon tea. The fifth agency, a Paris importing house, has confined its work entirely to the provinces and has issued special circulars to all its clients, has distributed 2,000 placards to grocers, and given 500 kilos in free samples of tea. This firm has also canvassed all the regiments in France by circulars. The sixth, a small firm in Marseilles, has confined itself to distribution of leaflets and copies of Mr. Bamber's pamphlet in France.

But in addition to the above very important work carried on by the trade through the trade mainly, another, *demonstration*, viz., the presentations to the public of Ceylon tea in cup properly made, has formed a special feature of last year's work. One firm opened in April a first-class tea room, beautifully furnished and well equipped, and went to the expense of obtaining Sinhalese boys from Ceylon as waiters. This room in the Rue Caumartin has been crowded during the autumn and winter months, and is one of the best advertisements we could possibly have. The same firm had a very large room nicely decorated and furnished at the Exhibition of L'Enfance a travers les ages, held at the Petit Palais in the spring. This room was well attended. This firm also had a bar and show at the Tuilleries Exhibition for one week. Another firm has been instrumental in starting a small and unpretentious, but useful little tea room on the south side of the Seine. We have therefore now four tea rooms in Paris selling only pure Ceylon Tea in cup. In addition to the Paris work, the last-named firm has started a demonstration round in the Provinces. We recognise that it would hardly pay as yet to run tea rooms in the Provincial towns, but with a view to let the inhabitants taste tea, properly made tea in cup has been distributed free of charge in the afternoons in those grocers' premises, who were willing to give space for this purpose. Twenty-two towns have been visited by the demonstrator, and up to the end of last year demonstrations have been given in 16 of those towns for 78 days, 16,483 cups of tea have been served, 9,200 visitors have bought dry tea, and the Paris firm has secured 56 new grocers as clients for their teas. The demonstrations have been well advertised in the local papers of each town, large posters have been displayed in the grocers' windows, and 529,350 copies of printed matter and leaflets have been distributed. This work has been very

hard and arduous, and I wish the demonstrator could have had more help. We ought in fact to have had two men, not one. This work is now being continued in the East of France. The opinion of the grocers in whose establishments the demonstrations have been held, is that no better advertisement of Ceylon tea could have been given, and although they admit that the sale of tea is very small, they all seem now prepared to push Ceylon tea in their sales in preference to China. A very great deal of money has been spent by our friends in France on the campaign last year, though my contribution has been proportionately much less than in the other countries. A sum of 84,409 francs and 02 centimes have been spent on general Propaganda and demonstration, to which I have contributed 21,896 francs 11 centimes. On the installation and equipment of three tea rooms 64,926 francs 05 centimes has been spent, to which I have contributed 5,500 francs for advertising purposes. In France those who have taken up Ceylon tea have certainly shown their interest in the article by the way in which they have found funds for advertising the tea. With the exception of 3,510 francs, no travelling expenses have been included in the sum of 84,409.02 francs. All the six houses actively engaged in the Propaganda report an increase in their sales varying from 5 to 40%. Returns of 7½% in tea on amount of tea imported, has been made to fifteen firms, who have imported Ceylon tea into France during 1901. I fear the withdrawal of any return in 1902 will check the imports of Ceylon tea in France for the current year. Many of the above Firms, though unwilling to push Ceylon tea, have no doubt been tempted to take it up on account of the return, and use it for mixing purposes. I should have liked to have given a 3 or 4% return this year.

The only figures as yet available for 1901 are those for the direct exports from Colombo to France, and these show a falling-off of 8,934 lbs. and I fear that the imports from London for 1901 will show a larger reduction, as there can be no doubt that towards the close of 1900 heavy importations were made in order to obtain the full benefit of the large return made in that year.

The French returns for 1901 will not be available till the autumn, but those for 1900 are disappointing. They are as follows:—

Country of Export	1899	1900
England	168146 kilos.	197952 kilos.
Belgium	1465 "	2152 "
British India	124698 "	144002 "
China	523064 "	591001 "
Other Countries	21422 "	27288 "
Indo-China	46015 "	130275 "
Other Colonies	116 "	656 "
	884926 "	1093326 "

According to the above return the increase in all tea from England was 29,806 kilos or say 65,573 lbs. whereas the London brokers' returns give the increase in Exports from the United Kingdom in 1900 as 49,244 lbs. for Ceylon, and as 38,537 lbs. for Indian, or an increase in export of British-grown teas alone of 87,597 lbs., the figures being:

Export to France	1889	1900
Ceylon	83867 lbs.	131111 lbs.
Indian	50537 "	88890 "

I have not got the figures for the direct exports from India, but from Ceylon they were as follows:—
 in 1899 98952 lbs. 1900 326800 lbs.
 or an increase of 227,848 lbs. The increase as per

the French figures from all British India, which I presume includes Ceylon, is only 19,904 ailos, say 43,788 lbs. Even if we deduct one-third of the increase in Export from Ceylon, say 76,000 lbs. as being in Bond, or on the water, there still should remain an increase of over 150,000 lbs. from Ceylon alone for 1900 over 1899. I therefore fear the French figures are not altogether reliable so far as country of Export is concerned. The increase in the imports from Annam is very great, over 184,000 lbs. and I believe that for 1901 the increase exceeds 250,000 lbs. I do not believe the acreage in bearing under tea in Annam is capable of giving this large Export. One of the Importers has admitted to me he has received a lot of stuff which was not tea at all, and I know that the quality has been so bad that three or four of the biggest importers vow they will import no more. I cannot help thinking, however, that teas have been brought to Tonquin from other parts of China, and exported as Annam to enable them to secure the benefit of the much lower duty on French Colonial products.

Belgium.—In Belgium very little has been done. Two dealers have begun to advertise our tea through their clients and are able to show an increase in imports of 12,100 lbs. over 1900. They have spent 2,000 francs against a subsidy of £30, say 750 francs. When the war in South Africa is over, I think Holland offers a very fair field for Ceylon tea, as its consumption of tea per head of the population is the next largest in Europe to that of Great Britain.

Austria.—Work in the Austrian Empire has been carried on through 5-agencies. Three of these firms have their centres in Vienna, one in Trieste, and one in Basle. I have granted support to four out of the five. The Trieste firm received no subsidy. This firm being a Commission House took no direct part in propaganda work or advertising, but they have interested themselves in our tea by importing and selling it, and financing the dealers when necessary. Two of the Vienna firms have been connected with Colombo for some time, the principal one being directly interested in a Colombo House. This firm commenced the importation of tea into Austria a couple of years prior to 1901.

In addition to the grant for 1901, I have given them a grant in consideration of the work and outlay incurred by them in 1899 and 1900. I have no doubt that it is mainly due to their extensive advertising that others have come forward and taken an interest in this article. The other firms, being already in the tea trade, have perhaps obtained more successes in the way of increase of imports and number of depôts for sale of the tea, and thus have reaped the benefits of the more extensive advertising done by our Colombo friends. This firm has advertised in 44 different newspapers and periodicals, has issued 20,000 special circulars, put up 2,000 posters, put up special posters in the railway stations, has a standing advertisement in the Volks Theatre, etc. It has been successful in securing four members of the Imperial family as regular clients and has distributed 25 copies of Cave's "Golden Tips" to leading and influential personages in Vienna. In addition to its general propaganda amongst the trade and public, it made a most attractive show at the Food and Agricultural Products Exhibition held at Karlsbad in August and September, and obtained the gold medal for its tea; 45 lbs. of tea in oz. packets were distributed free to the visitors.

The second firm is that of an old-established retailer, who has the sole agency for many food specialities. He has for many years drawn a very small supply from Colombo direct, and was very anxious to enter on a more vigorous campaign and push the sale of the tea. He has not only advertised in some 20 newspapers, but has issued leaflets with deliveries of his other articles, has issued Post cards with advertisements of Ceylon tea, and been successful in getting special articles on the advantages derived from drinking Ceylon tea inserted in the Press. He has also circulated Mr. Bamber's pamphlets.

The third firm, being an Austrian tea importing firm, has confined itself entirely to grocers, has advertised on behalf of these grocers in 73 papers in the Empire, has established 600 depôts for sale of Ceylon tea throughout the Empire, the tea being put up in 2 oz., 1/4 and 1/2 lb. packets, and sold under a special brand of their own, and has issued 66,300 circulars and 1,350 placards to their clients for distribution.

The fourth firm working from Basel has done little direct newspaper advertising, but has granted its clients small sums for that purpose. It has furnished the restaurants with note blocks for their bills, the back of which contains an advertisement of Ceylon tea: it has given Menu Cards to the Hotels, and has supplied the shops with signs, cards and leaflets for distribution among their customers. It has also distributed a large amount of tea free, as samples. The expenditure in Austria in 1901 has amounted to £1,703-19-8, to which I have contributed £1,032-9-2. No mention is made in the London brokers' returns of the Export from the United Kingdom to Austria. From Ceylon the figures are 50,958 lbs. in 1901 against 24,633 in 1900. The increase is so far satisfactory. The Austrian Customs returns give the figures as 52,200 kilos in 1901 from India and Ceylon as against 41,700 kilos in 1900, or an increase of 25,300 lbs. in last year. From Great Britain the total import in 1901 was 23,300 kilos as against 21,200 in 1900. I think we may assume that the bulk of what was imported from Great Britain was British-grown tea. But even assuming it was all Indian and Ceylon, the total importation from these countries is only 78,500 kilos out of a total 1,023,800 kilos. So we have in Austria some very heavy work before us, to even displace the bulk of China tea, as British grown teas do not form as yet one-tenth part of the whole import. I regret to see that total imports into Austria for 1901 show a falling-off of 41,500 kilos, as the total import for 1900 was 1,065,200 kilos. I am glad therefore to see that the reduction has not taken place in the quantity imported from Great Britain, or India and Ceylon.

There is a very fashionable tea room at the Hotel Bristol in Vienna, the proprietor drawing his supply of Ceylon tea from London. In the Spring we shall have a small demonstration at a Charity Bazaar under Imperial Patronage in Vienna, and I hear special Ceylon tea rooms may be started in Vienna and Buda-Pesth in the coming Autumn.

SCANDINAVIA.

Work in Scandinavia has been carried on in Sweden and Norway by three firms in Stockholm, who for the past two or three years have interested themselves in the article at the instance of their Ceylon friends; in Christiania by the same firm who received support from me last year, and in Denmark by a new firm who took up the article for the first

time in 1901. The oldest and largest Swedish firm have been at work for some years now, and they, with their branch House in Christiania, have advertised on the largest scale. The lines on which our friends in Sweden and Norway work are varied; while one firm has confined itself mainly to newspaper advertisements and posters, and the third (the largest) to work amongst grocers, supplying them with tins and canisters, signs and advertising material in the shape of leaflets, and pamphlets for their clients. All these agencies practically keep and sell only Ceylon tea.

In Copenhagen a new firm have taken up the pushing of pure Ceylon tea under a special brand of their own. They have advertised in 73 different papers and issued 63,600 circulars and established 180 depôts for the sale of Ceylon tea.

I notice that the direct exports to Sweden from Colombo in 1901 show a decrease of 6,196 lbs. I presume the export to Denmark is included in that under Sweden. Although the direct exports may show this falling-off, I feel certain a very much larger quantity of Ceylon Tea has been imported from London. One firm alone has drawn 10,000 lbs. from London in 1901 in excess of its 1900 supply from the same place, while another has taken nearly 10,000 lbs. more from Germany in excess of 1900.

From appendix "D" it will be seen that the total expenditure on advertising and propaganda in Scandinavia has been £944-10-1, to which I have contributed £289-3-3.

Afternoon coffee is not a Scandinavian custom, and I fear afternoon tea rooms would not be a success in these countries. But I think an effort might be made to introduce the sale of Tea in the Russian fashion per glass, as tea made very weak and sold per glass at a low rate in the winter ought to popularise the beverage amongst the masses in these Northern Countries.

Switzerland and Italy.—In Switzerland the extensive advertising and efficient work undertaken in 1900 by a Basel firm has caused all the other tea dealers to bestir themselves, and not only those who have hitherto made Ceylon tea a speciality, but also others have been compelled to take up Ceylon tea and at any rate stock it. Not less than seven firms have been willing to advertise it, and I have given assistance to six out of the seven. Our friends of 1900 have continued their work with the grocers in the smaller towns, and have given them help to advertise the teas; they have also continued the campaign with the Hotels and Restaurants. They made special demonstrations at the International Shooting Contest, "Tire Federal", held at Lucerne, and at the Cantonal Exhibitions held at Vevey and Basel, and have aided in the establishment of a Ceylon tea room at Lausanne. Another firm has made Ceylon tea a speciality for the first time by selling a pure Ceylon tea in packets under their own Brand. They have issued some 60,000 special circulars, advertised on behalf of their grocers for 6 months in the local papers, and given their clients 600 placards.

The third firm, an old established Swiss firm, has also taken up Ceylon tea as a speciality for the first time. Their work is entirely confined to grocers. They have distributed 20,000 circulars, advertised in 25 different newspapers on behalf of their clients, and established 50 depôts in 20 places.

The fourth is represented by a gentleman who has for some years sold Ceylon tea. Many years ago he

lived in Ceylon for six months, and although his business is small, he takes a great interest in the article.

The principal partner in the fifth firm is a gentleman who from his position, wealth, and influence can give us a great deal of help: As a large Export Merchant he does a large trade with Ceylon. His sale of our tea is entirely retail, and he has issued a large number of circulars and distributed a quantity of Bamber's pamphlets.

The sixth firm may be said to be the pioneer of Ceylon tea in Switzerland, their present manager having been resident in Ceylon as a planter for many years: they keep Indian and China to prevent their clients going elsewhere for those sorts, but by far the bulk of their trade is all Ceylon. In addition to their customary propaganda by circulars and price lists, the feature of their work last year was special lectures on Ceylon tea delivered by the manager in 13 towns in Switzerland. These lectures have been illustrated by magic lantern views; free samples of tea, and tea in cup have been distributed at them.

The seventh, a London firm, has established a tea room in St. Moritz. Full particulars of the undertaking and vouchers for the expenditure have not reached me as yet. In Italy, this same London firm received a small advance to commence work through a firm of colonial produce brokers in Genoa, but no particulars of the expenditure have as yet come in. At the instance of a Colombo export firm small grants were made to firms in Naples and Florence. Their expenditure has only just begun, and has been confined to a view advertisements in papers and tramcars. One of the Basel firms has entered Italy and has commenced work with the Hotels and Restaurants in Northern Italy. This house is able to report an import of 8,734 lbs. into Italy against nil in the previous year. Only four out of the seven firms working in Switzerland have furnished me with particulars of their imports for 1901. I see that their total increase over 1900 amounts to 20,963 lbs. The expenditure in Switzerland in Italy amounts to £1,054.4-2, to which I have contributed £476-1-9. But in return for this year's grant, one firm has still to spend £160 in Switzerland, and another should render accounts for £150 to be spent in Italy.

Russia. I only visited this country in order to make the necessary preparations for the Ceylon tea room at the Exhibition to be held during the summer at St. Petersburg. I took the opportunity to visit Moscow, and while there I called on all the principal importers. The unanimous opinion of the Russian houses was that our tea was doing very well in Russia, and required no outside help to stimulate the expansion of its consumption. Messrs. Rogivue & Co. think otherwise. My stay in Russia was not long enough to enable me to advise or say in what way any further propaganda on behalf of Ceylon tea should be made. That the great mass of the people know nothing about Ceylon and its tea is certain. I think special Ceylon tea rooms in Moscow, St. Petersburg and three or four of the largest towns would do good, and help to popularise our tea. But I should be very careful not to offend the susceptibilities of the trade. If, however, anything special is to be done in Russia, it will have to be on a very large scale and be continued for some years. I am inclined to think that a rebate or return of 1 or 2% to the Importers would probably have more immediate results than any other method. Tea in Russia is drunk so weak that one might almost call it hot water flavored with tea, lime juice and sugar. It is, however, a most palatable and agreeable beverage at

all times, especially in the cold winter months. Our object is not so much, as in the other countries of Europe, to get the inhabitants accustomed to the taste of our tea, but to show the Russians that in the long run it is much the cheapest, because a little of it goes further. Although Russia imports about 103 million lbs. of tea, the consumption per head of their population is only 0.82 lbs., therefore the cheaper the article can be given to the public, the greater the chance of an increase in consumption. There is not only no chance of obtaining an equalisation of the duty on sea-borne as against overland tea, but I see statements in the English newspapers to the effect that from this year, in order to bring freight to the Siberian Railway, the duty will be abolished on all teas entering Russia by the Siberian frontier. In the meantime the Russian Importers advise me they would buy more of our teas if, 1st. the net weight of the packages ran more evenly. I have great complaints on this head. They insist they are always coming to grief with their clients over the difference between the Invoice and actual weights. 2nd. If quality were always uniform. Complaints have come from the interior as to difference in quality, not only in one line of tea, but in single packages of one line. Single chests supposed to contain Pekoe, for instance, have been found to contain dust and coir yarn. 3rd. If Colombo prices were more on a par with London. They cannot understand why the London market is always cheaper than Colombo. They would buy more in Colombo if the prices were equal, as the idea of buying in London does not commend itself to some importers. I venture no opinion as to whether the London market is cheaper or dearer. I merely pass on the opinion of the Russian dealers. They are all unanimous in thinking there is a future for Ceylon tea in Russia, provided the quality be maintained. The expenditure of £270 in Russia has been solely in disbursements for the tea room at the exhibition.

Spain.—I mention this country simply to note the fact that the Colombo export returns show a falling-off of 17,480 lbs. in the export to this country in 1901 as compared with 1900. I think it will be found that the reason for this is that the bulk of the export in 1900 was for the Army and Navy Contractor in Gibraltar, and that supplies, hitherto drawn direct, have in 1901 been obtained from London, the excessive and irregular freight from Colombo to Gibraltar rendering it unprofitable to continue to obtain direct shipments.

Conclusion.—In conclusion I would like to express my opinion that with one single exception in Switzerland and Italy, I am convinced I have received very full value, both in work and money, for the grants I have made. I feel certain the funds have been well and economically spent. What the result will be it is impossible to say. I do not believe we shall ever—at least not in the time of this generation—see France, Germany and Austria tea-drinking countries to the same extent as Great Britain, but by quietly pegging away, I think we shall in course of time oust China tea in all the three countries, and in Germany and Scandinavia I hope we shall do more. My correspondents in France, Austria and Germany are most hopeful, and notwithstanding the fact that, owing to the general trade depres-

sion and the very mild winter, the tea trade in Austria and Germany was bad last year, yet they think there is a decided future for Ceylon tea, provided quality be maintained, and if possible improved. I reserve my opinion as to what should be done in Russia till after the Exhibition is over, but I do not advocate the spending of any large sum to make a "splash" either in one or in all the other countries. The expenditure should be confined to induce the trade to push the article, and to demonstrations, and we should keep steadily and quickly at the work for some years. It must not be forgotten that, owing to the enormous increase in the world's coffee production, coffee has become very cheap. Coffee growers are doing what they can to find new outlets for their produce. Brazil has sent a delegate to Europe to see what can be done to develop the trade, and special efforts are being made to induce the Russians to drink more coffee.

I want to take this opportunity to acknowledge gratefully the kindness, help, and information given to me by Mr. Bennett of the British Embassy in Vienna, by Mr. Austin Lee of the British Embassy in Paris, and by the British Consuls in Stockholm, Christiania, Copenhagen and Stettin.

(Letter from the Ceylon Commissioner
in Europe to Chairman, P. A.)

TEA IN ANNAM.

Buckeburg, 16th March, 1902.

Dear Mr. Kingsford,—Since forwarding my report I have received through the kindness of the British Embassy in Paris the following communication from the French authorities as per translation herewith.

"According to information received from the Administration in Indo-China the figures given, viz.: 71½ hectares as representing the extent of acreage under tea in Annam, must not be considered correct. It is difficult to estimate the acreage exactly, but it is for all that sufficiently large to explain the production announced in the statistics (Note:—about 450 acres). In the Province alone of Binh Binh there are 147 hectares and generally the cultivation of tea in Annam is developing rapidly. The local customs watches the exports to France with the greatest care, and grants no certificates of origin (of growth) without having obtained all information as to the exact source of the teas intended for export." My supposition that other teas from China were being exported as Annam teas is therefore wrong, but I think excusable, when according to the official figures the total acreage under tea in Annam was given as 71½ hectares. If my report is published, this letter should be published as well.—Yours sincerely,

(Signed) J. H. RENTON.

A. C. Kingsford, Esq., Rookwood.

OVER PRODUCTION.

It is wonderful in how many directions the evils of "Overproduction" are realized! We have just received the "semi-annual report," April 1902, of Messrs. Schimmel & Co. of Miltitz, near Leipsic and of London and New York, dealing with "Essential Oils," and this is what we read in regard to "Eucalyptus Oil":—"The trade in this product suffers from excessive overproduction, which, in spite of every warning, is carried on unflinchingly at the two principal sources of supply—Australia and Algiers—and which will lead to unpleasant consequences, if the production is not soon carried on in a more rational way." It cannot be very easy—however desirable—to bring producers, situated so far apart as Algeria and Australia, into line or to get them to combine to reduce their output of a product which depends so largely on epidemics of "influenza" to secure a profitable market. Still more surprising is the case of the French "wine crop" as we learn from a copy kindly sent us of a very able and interesting Report by Mr. Consul-General Hertslet on the District of Havre for 1901, and lately published. It seems that last year the yield of the French vineyards was much above the average. But so far from this being a subject for congratulation, the Consul-General declares that the excessive production has proved to be a source of disastrous losses to the wine-growers and from them has reacted with bad results on the whole trade of France. Here is the explanation as given in the Report before us:—

Consumption of wine, as a result of low prices and the removal of octroi duties, has undoubtedly increased, but it still falls far short of the immense production of the past two seasons. Stocks have accumulated, and as the poorer qualities, of which there was an unusually large production during the past year, will not stand keeping, prices have fallen to such a low figure as to yield the grower in many cases practically nothing. In view of the enormous extent of the wine industry in this country, the crisis has had far-reaching effects on the trade of the whole of France, and has contributed to a large extent to the general feeling of uneasiness and depression, even at places so far removed from the wine-growing districts as Havre and the ports of Northern France.

The tea planters of Ceylon and India have, therefore, many to sympathise with them in different countries, in their experience of the evils of over-production; for, to get a further illustration we have only to go to Mr. Hertslet's next paragraph dealing with "coffee," the trade in which with Havre had reached an unprecedented figure last year. The Brazil coffee crop of 1901 is now known, to be by far the largest on record; but nevertheless speculation became active on unfavourable reports of the prospect of the succeeding crop coming to hand, and prices advanced considerably out of such speculations. At the same time, the stock of coffee in Havre was (in January) expected very shortly to reach a total of 3 million bags,—which is by far the largest quantity ever accumulated in one port and is as

large as the stocks held in the whole of the United States! It seems that the Brazilian crop of 1900 1 equalled 10½ million bags; 1901 2 is estimated to be at least 14½ millions; but 1902-3 is expected to fall to 8½ millions. We should be inclined to doubt the latter figure; but taking the total for three years at 33 millions, and knowing that the world's consumption of Brazil coffee does not exceed 9 million bags a year—we see that there is the prospect of overproduction this year to the extent of 7 million bags, and without much chance of working this off next year except at ruinously low prices and, perhaps, an attempt to drive coffee into consumption at the expense of tea. It is clear that so long as coffee is abundant and cheap—"over-produced," in fact, more than tea—there is less hope of getting the fragrant leaf into increased consumption in "coffee countries" such as the United States, France and some parts of Germany and Austria. But there must come a great reaction in Brazil from the enormous outturn of this year. The ordinary planters there, many of them burdened by debt, cannot continue to produce coffee at a loss, and it is believed that already many are turning their attention to food products consumed in the country. The sooner the world's production of coffee is brought within the limits of consumption, the better will it be for an extended and extending demand for tea.

TEA AND COFFEE PUBLICATIONS.

We have received from Messrs. Henry T. Coates & Co., publishers of Philadelphia, three uniformly bound books written by Mr. Joseph M. Walsh, entitled respectively—"Coffee: its History, Classification and Description"; "Tea: its History and Mystery"; and "Tea Blending as a Fine Art." We know that Mr. Walsh has had some of our Ceylon books; but they cannot have been of recent date; for his information in regard to Ceylon is absurdly out of date and he is strong about "the presumption and audacity of India and Ceylon tea-growers and dealers" in regard to the superiority of their teas. The following extract condemns his little book on "tea" as quite unreliable:—

The relative positions of China, India and Ceylon teas in England at the present writing being

Kind	Consumption, Pounds.
India (estimated) ...	105,000,000
China ...	50 000,000
Ceylon ...	35,000,000
Total ...	180,000,000

The same is true of the "coffee" compilation; for, Ceylon, we are told exports about 80 millions lb. We only wish she did. Mr. Walsh has yet to learn that tea has taken the place here of coffee. No doubt in regard to Brazil, Mr. Walsh is more reliable. His work on tea-blending has a good deal of useful information; but here again is an amusing paragraph;—

"CEYLON TEAS—Are comparatively new Teas to commerce, and are known to trade as Matagalas, Mandulsumas, Rakuwanas, Kanda-loyas, Kanda-pole and Soocanduris, but as with India Teas they are chiefly converted into silver and golden Pekoe, Congous, Souchongs and Pekoe-Souchongs. Their leaf, liquor and flavour like their India prototypes varies greatly in style and quality, according to the elevation at which they are grown, their uniformity also varying from year to year as in the India districts."

THE FOREIGN TEA TRADE OF CHINA IN 1901.

REPORT BY THE STATISTICAL SECRETARY.

The report of Mr F E Taylor, the Statistical Secretary of the Chinese Imperial Maritime Customs, upon the trade of China for 1901, with an abstract of statistics, has been issued from the Statistical Department of the Customs. Mr Taylor writes on tea exports:—The tariff export duties are in most cases very light, and tea is the only staple on which the duty is unreasonable. There was again a falling off in the export of the black tea, which only amounted to 665,499 piculs, the lowest on record. The crop was short, owing to heavy rains in April, but the quality was fairly up to the average. Green tea fell to 189,430 piculs, the supply having been shorter than for many years, and the quality was, on the whole, rather below the average. Russia is taking more India and Ceylon tea each year, and Foochow teas have now lost the markets in Canada and Australia. The export duty and *likin* raise the cost of low grade teas sometimes as much as 40 per cent., and while this continues there is no hope of checking a continuous decline in the trade. There was a further decrease in the export of black brick tea to 244,565 piculs—half what it was five years ago; but it is explained that Siberia is overstocked, and the new regulation that the heavy import duty must be paid immediately on arrival has checked importations until existing stocks are exhausted. Green brick tea rose from 31,334 to 48,957 piculs.

EXPORT OF TEA

The following are the figures for the two years:—

	1901.	1900.
	<i>Hk. Tls.</i>	<i>Hk. Tls.</i>
Tea ...	1,157,993 18,512,826	1,384,324 25,444,801.

—*L. and C. Express*, May 2.

DESTRUCTION OF VALUABLE TIMBER IN SIAM.

"WHAT A FINE COUNTRY FOR TEA."

The destruction of valuable timber still continues on the mountains throughout the Northern districts. There is really no excuse for this. The mountain tribes could as well leave valuable trees standing, if they were so instructed; it would not interfere with the necessary amount of clearing to make their gardens. By the way, what a fine country for tea! There is abundance of water, and the hills are covered with splendid soil. The native tea gardens here are a success.

The annual destruction of young teak trees by forest flies is another matter worth attending to. Even the trees that live through it are injured so that their future value is decreased considerably. In fact a lot of the standing teak is worthless as timber, being crooked, hollow, short and stunted. There are large tracts of country going to waste that are exactly suited to teak growing, for this is the natural home of teak. All the valuable teak has been cut in the tracts above-mentioned. Nothing is left now but scrub stuff and other waste, with the fires every year destroying the seedlings that spring up of their own accord. No doubt the Forest Department is doing good: but it is poor policy to neglect all that territory draining into the Mekawng. Let me say here that in Mnang Pan district, I am told; there are no restrictions placed upon the cutting of teak for use in housebuilding. This is very different from the unjust regulations in some places that hinder a man from using teak sticks that he cut in the olden time, squared and dragged. These can be left to burn or be stolen but the rightful owners cannot use them.—*Bangkok Times*, April 26.

PLANTING NOTES.

THE BURMA RUBY MINES.—The ruby mines of Burma are now worked by electricity, obtained from a mountain stream some three miles off. Finds of copper fish-hooks and other implements in the ground point to the present site of the mines and civil station having been a large lake in pre-historic times.—*Statesman*.

ARTOCARPUS HIRSUTA.—This fine forest tree has been introduced into the Agri-Horticultural Society's Gardens at Madras, from seeds supplied by Mr Ferguson, Director of the State Gardens, Travancore. It is a native of the Western Ghats, where it grows up to an elevation of four thousand feet. It yields a valuable timber, the trunk of a well-grown tree sometimes reaching a height of 150 feet, straight and clear. It yields the "angili" wood of commerce; while the concentrated juice forms a tough, light-brown wax, used in cementing broken earthenware and stoneware. It bears a fruit the size of an orange, containing a pulpy substance much in favour with natives.—*Indian Gardening and Planting*, April 17.

PLANTERS—are being repeatedly advised not to place all their eggs in one basket. The following is what Andrew Carnegie has to say on the subject of concentration:—"Don't put all your eggs in one basket" is all wrong. I tell you "Put all your eggs in the one basket and then watch that basket." It is easy to watch and carry the one basket. It is trying to carry too many baskets that breaks most eggs in this country. He who carries three baskets must put one on his head, which is apt to tumble and trip him up. It took me some time to learn, but I did learn that the supremely great managers, such as you have these days, never do any work themselves worth speaking about. Their point is to make others work while they think. I applied this lesson in after life, so that business with me has never been a care. My young partners did the work and I did the laughing, and I commend to all the thought that there is very little success where there is little laughter."—*Indian Planters' Gazette*, May 81.

AGRICULTURAL EDUCATION.—The Agricultural Education now in practice (though still very limited to what it ought to be), we hope will prevent visitors of the future being "instructed" in the products of the island as is being done at present, and of which the following is a sample:—A lady, who has been in Jamaica all her days, explained to a visitor, that "this is a Nutmeg, its covering is the Mace, its stem is Cloves and the bark of the tree is Cinnamon." Truly a wonderful combination of spices.—*Jamaica Journal*.

ANTS AND ORANGE TREES.—According to the "Implement Age" of Philadelphia the orange tree has an enemy in Cuba in a large ant more than half-an inch long, having an enormous head provided before the mouth with powerful pincers, with which they despoil of leaves in one night the largest orange tree. The ants live in the sub-soil. They make large holes and very long galleries—sometimes 100 yards long. The method employed to kill them is to introduce an iron pipe, to which a large bellows is connected, into a hole made in the place where the ants enter the ground. Sulphurous smoke and gases are then blown through the pipe by means of the bellows, and the ants are destroyed.—*Globe*, May 10.

COCOA AND CACAO.—The latest illustration of the confusion arising from the use of similar spelling for the name of the palm and the fruit of the Chocolate plant, is afforded by the *German Export Review*. A recent number contains an excellent paper on "The Manufacture of Chocolate" with a series of very interesting illustrations, so far as the machinery, &c. go; but there is also the inevitable "Cocoa Plantation"; and instead of this being a grove of *Theobroma Cacao*, it is simply "a Coconut Palm Garden"! Now if all and sundry would only drop the "a" out of "Cocoanut" giving the *Cocos nucifera* palm the proper short name of "Coconut" for its fruit, we should soon find people understanding that "Cocoa" (as well as "Cacao" and "Chocolate") referred to the fruit of a different tree; and the confusion would ere long cease to exist.

THE DROUGHT IN AUSTRALIA.—Says the *Melbourne Leader*:—

As will be seen from our district correspondents letters, the present prospects are by no means as favorable as could be desired, owing to the continued spell of dry weather. The acceptable fall of rain with which the autumn opened gave hopes of a good season, but that rain wanted following up with more within a moderate interval. In the northern, as well as other districts, the grain sown has only had moisture enough to sprout it, and now the dry weather is so shrivelling the young plants that in many cases it is feared that resowing will be necessary. The drought is also much against the work of getting in the fodder crops, and those that have been sown are awaiting the rain, while the grass is also suffering. Even should rain now come the grass cannot do so well as at an earlier period, owing to the soil having parted with its summer warmth, and the time of the frosts approaching. A thorough soaking of the soil would, however, now be of the utmost value throughout Victoria, and to a greater degree all over Kiverina, where the situation is becoming particularly serious.

A MAP OF PRECIOUS STONES,

BY H. L. HOLMES.

A map of France cut from the rarest jasper, flashing with costly jewels, and resplendent in gold and other precious metals! Truly a Royal gift worthy of both giver and recipient: from the Imperial Czar of All the Russias to the great Republican nation, his friend and ally. It is doubtful if the Czar could have chosen a gift more likely to prove acceptable to France and her people. An immortal map, which moth and rust can never destroy, appears to be a symbol of a nation that will live for ever. That the Royal giver had something of the sort in his mind when he selected his present is not for a moment doubted by the appreciative people whom the Czar thus honoured. It was when feeling between the two countries was warmest and most brotherly that the Royal Nicholas presented his unique gift. During the exposition of 1900 this map of jewels and gold was the centre of attraction so far as French visitors were concerned. For foreigners it possessed features that lovers of art and of the curious could not resist. Rarely, whilst the magnificent gift was on public view, was it not surrounded by a crowd which was always full of admiration and interest, and frequently of enthusiasm. Even now adorning, as it does, a selected position in the Louvre, it still attracts a great deal of attention owing to the circumstances surrounding its presentation as well as its magnificence of design and artistic finish. Besides it is claimed that there is nothing in the wide world like it: as a map it is unique. The French nation is proud of it. Even the usually taciturn officials who guard the priceless treasures of the Louvre wax, eloquent and discursive when courteously asked for a short account concerning it. This wonderful map was not produced without infinite pains. Thousands of Russian workmen and artists had a hand in the manipulation of its varied components. It was designed with the personal approval of the Czar, by the distinguished Russian engineer, De Mostovinko, who also superintended its production and completion. It was put together at the Imperial factory of Ekaterinburg. Months were occupied in the process. It was finished with as much care and correctness as the importance of its destination demanded. So pleased was the Czar with his map of precious stones that he warmly eulogised its designer and presented him with a decoration.

Perhaps the most interesting feature about this wonderful map is that every precious stone and jewel included in its production came from the Imperial mines in the Ural Mountains. Several of the stones are only found in those mines, and are appropriated by the Czar. Some of them are never found at all in commerce.

The map measures forty inches along each side and is framed in slate-coloured jasper. The sea is represented by a pale marble, and the portions of foreign countries necessarily included—England, Germany, Italy and Spain—are in dark grey. The whole is enclosed within a magnificently designed, heavy walnut case, elaborately carved and standing about eight feet in height. The formation of the various departments (or countries), as well as the surrounding seas and countries, is as perfect as that found in Governmental maps. The whole of France is shown

entirely in polished jasper, and it will be found that each department (or county) has been cut from jasper of a different colour, the whole blending without the slightest offence to the artistic eye. The mines were ransacked in all directions for the necessary material to ensure this effect. The large number of counties thus represented will give the reader some idea of the enormous labour bestowed by the Czar's workpeople on this portion of the undertaking. The jasper used is all of the most beautifully veined that human eye has gazed upon. The polishing is perfect, the cutting of such piece must leave entailed the greatest care, so artfully are the joinings of the various departments concealed, so exquisitely do the lines meet. One hundred and six of the more important towns are given: the names in letters of pure gold, the towns represented by costly jewels. Paris is represented by a ruby of immense size and value, and it must cause commotion amongst those connoisseurs who make a pilgrimage to the Louvre for the purpose of gazing upon this magnificent collection of precious stones. Havre boasts a beautiful emerald under its golden name, Rouen is represented by a sapphire, Lille by a phenacite (a rare variety of rock-crystal), Rheims by a chrysolite, Lyons by a tourmaline, Nantes by a beryl, Bordeaux by an aquamarine, Marseilles by an emerald, Nice by a garnet, Cherbourg by an alexandrite (a variety of chrysoberyl found in the Ural Mountains, and which looks green by day and reddish-blue by lamplight), and Toulon by a chrysoberyl.

Twenty-one other towns are represented by amethysts, thirty-five by tourmalines, and thirty-eight by quartz-crystals.

It can be easily imagined that a map whose towns were represented by precious stones should have something equally fine to mark the country's rivers. And the expectations will not be vain. All the river shown in this extraordinary map are represented in platinum sunk in the jasper. To effect this the courses of the rivers had first to be cut in the stone and the platinum laid in and polished. The whole effect is very beautiful indeed.

'And a pretty penny it must have cost!' the business-like Briton mentally exclaims. That the map cost a very large amount indeed is obvious. But the exact sum which came out of the Czar's exchequer to 'pay the piper' has never, of course, been made public property; nor is it likely that the information will ever be known in a general way. Estimates by experts on this point vary very greatly, ranging from £16,000 to £80,000. A well-known Parisian jeweller has explained the reason. All the stones and jewels came from the Imperial mines, and practically the only expense was the cutting, polishing and putting together. The stones only found in those mines (and appropriated by the Czar), never being found in commerce, consequently have no quoted value.

'In fact,' said the eminent jeweller referred to, 'it is probable that the map did not cost the Czar more than £16,000, if as much; but if a millionaire came to my shop and ordered one like it, I should have to charge him three or four times as much—if, indeed, I could make it at all.'

However, no matter whether the Czar expended £10,000 or 100,000 in its production, this map of France, with its precious stones and gold, is regarded by Russia's ally as one of its most priceless treasures.—*Strand Magazine* for May.

COLOURED GREEN TEA.

THE EDITOR, "INDIAN GARDENING AND PLANTING."

SIR,—If I am correct in inferring from your article and Mr Drummond Deane's letter in your issue of the 1st instant—"Coloured and Uncoloured Green Teas"—that a *true Green tea, not only in "liquor," "infusion" and "flavour," but in actual colour of "leaf" too, is only produced by artificial means—or "facing"*—I would point out that this is a mistake, as a very handsome "blue-green leaf" can be, and is, produced by *entirely natural, i.e., not artificially coloured* means; but, as Mr. Drummond Deane suggests, at an enhanced cost in "Panning." T.

—*Indian Gardening, May 22.*

THE BOTANY OF CEYLON.

25 PER CENT NEW SPECIES IN ONE HAUL.

We learn from a good source that the expedition to Hinidoo kanda, Sabaragamuwa, made last November by Mr Herbert Wright, the Scientific Assistant, Peradeniya, has proved most valuable. As we then stated, the primary object was that of determining our indigenous gutta-percha and ebony trees, but, in addition, a representative collection of all the plants growing on this hill was made. It has since transpired that the collection of plants forwarded to Dr. Levier, the Continental Cryptogamist, have proved to contain no less than 25 per cent of species new to science. This is interesting as pointing out what still remains to be done, though such renowned botanists as Gardiner, Thwaites and Trimen previously worked in the same district. The investigation of local foras should now become more important. Two of the new species have been named after the discoverer, Mr. Herbert Wright; viz.:—(1) *Sematophyllum Wrightii* and (2) *Syrhropodon Wrightii*.

PRODUCE AND PLANTING.

Mr Ernest Tye gives some interesting figures relating to the area of

TEA UNDER CULTIVATION

in India and Ceylon at recent periods, together with the crops produced, based on official records. In 1890 there were 344,800 acres under cultivation in India and 250,000 acres in Ceylon, India producing 112 million lb of tea, and Ceylon 47 million lb, the total crop being 159 million. In 1895, with a cultivation in India of 415,700 acres and in Ceylon of 305,009 acres, the respective crops were 143 and 98 million lb, total 241 million lb. In 1900 the cultivation was in India 522,000, and in Ceylon 334,000 acres, producing 197 and 148 million lb of tea respectively, or a total of 345 million lb. The average annual increase in the Indian crop for the last ten years has been 8½ million lb, and in that of Ceylon 10 million lb. The home consumption for British-grown tea for the last calendar year—1901—was 238½ million lb; the consumption in foreign markets and ship stores 95½ million lb, making together 334½ million lb.

The crop of

FORMOSA TEA

is reported by the British Consul to have been last year of good average quality, and the foreign firms engaged in the traffic on the whole had a prosperous year. For many years Amoy was practically the sole market for the Formosa tea. This state of things has now changed, A dis-

criminating duty of 60c per picul (133 1-31 lb.), the legality of which is disputed by the British merchants, exists in favour of the Kōbē route, which is sometimes quicker for shipments by mail steamers to points on the Pacific Coast. Shipments by this route amounted this year to 70,000 half-chests, against 33,000 in 1900. But so long as freights across the Pacific are maintained at double the Suez Canal rate to New York, the bulk of the tea must go by the latter route, for which Amoy is the more convenient and better depot. In the year under review 75 per cent. of total shipments went *via* Suez. The Japanese Government are doing all in their power to divert the trade from Amoy to Kōbē, and, if they can do so without protest, will no doubt increase the differential duty above alluded to.—*H and C Mail, May 16.*

AGRICULTURE IN THE PHILIPPINES:

In a recent article on the Warfare of Commerce, we dwell on some information, forecasting American ambition in connection with the newly acquired Archipelago, as set forth in its Philippine section by the *San Francisco Bulletin*. Our cousins across the Atlantic are too shrewd a race not to appreciate fully the value of their recent acquisition; and the Commission entrusted with the task, has reported at length on every subject connected with the administration of the Islands and their social, religious and industrial development. Under the heads of religion, education, laws, municipal Government, taxation, mining, forestry, agriculture, &c., we find practical and suggestive comments and recommendations, which are bound to bear fruit; and as we glance at these, the reflection is forced on us,—How much better if the capital, enterprise and energy of their new masters be turned to these channels, which can profit the Filipinos as well as the Americans very largely, instead of being devoted to devising huge monopolies for the enrichment of those already rich at the expense of the masses even in respect of the necessaries of life. Wiser counsels, however, may soon prevail, when the attitude of the Governments of the United States, as well as of the United Kingdom, is realised, towards the Trusts and Combinations which in their grasping selfishness, threaten to involve great States in serious complications; and when the Philippine Islands are reduced to a more loyal acceptance of the change of rulers, it may be that they will attract all they need in capital and energy for their progress in prosperity. And we shall not be wholly disinterested spectators: for while our own industries may be more or less affected by the development of similar ones in the Philippines, we shall also, doubtless, be able to learn not a little from what is being attempted and accomplished there, perhaps by methods differing from those with which we have long been familiar.

In Agriculture, probably, more than in any branch of industry, will this island be touched by what goes on in the Philippines—to learn as well as to teach, to put forth fresh efforts, as well as to reap the fruits of what has been sown. Hitherto,

the chief exports of the Philippines have been sugar, valued at 2½ million sterling thirteen years ago, hemp (£1,600,000) and tobacco (£500,000). We always understood that in coconuts the islands would be formidable competitors of ours; but we have not been able to trace any special mention of the palm industry in the pages which have come into our hands. On the subject of Agriculture, we read

The Philippine Islands are fundamentally an agricultural country. So much has already been said, and said truly, as to the great productivity of the soil and the diversity of climate within the archipelago that this subject may here be passed over. The methods of cultivation at present employed are of the crudest. Modern agricultural implements are practically unknown. Artificial fertilization of the soil is almost unheard of, and, as a rule, land is not deemed worth cultivation unless it will continue to produce crops indefinitely without enrichment.

There is a wide field for the introduction of new fruits, fodder grasses, grains, rubber and gutta producing trees. Grapes, strawberries, raspberries, blackberries, figs and walnuts have already been planted in Benguet, and are growing well. Tea has also been introduced with encouraging results.

Much of the agricultural land of the Philippines is admirably adapted to cultivation by steam plows and harrows. The water buffalo, which has suffered most heavily from rinderpest, has always been at best a slow and unsatisfactory draft animal. The American mule, on the other hand, thrives here.

And again

That the agricultural resources of the Philippine Islands are immense goes without saying. A country containing a vast area of fertile and undeveloped virgin soil where for years agriculture has been neglected and retarded by the constant state of war and insurrection that has existed for many years past; where no attempt has been made by the indolent natives to produce more than was needed for immediate consumption, and where modern implements and machinery and agricultural methods have been heretofore entirely unknown, the Philippine Islands stand today ready to receive the influx of capital, the farmer, and up-to-date implements and methods with which to develop its extensive resources; and this development will surely take place just as soon as the Government will make its policy, such that the settler and homesteader will have equal chance with the capitalist and moneyed syndicate and the public lands of the islands are thrown open to settlement.

Copra, tobacco, hemp and sugar are well known exports, while the cultivation of rice has been so neglected that at the present time there is not enough of this product grown to supply the local market. Sugar, while being produced in large quantities, is grown and harvested with such lack of skill, and the syrup extracted by such antiquated methods that the output of simply the area now under cultivation could be increased 50 per cent or more by the introduction of intelligent cane culture together with modern machinery and appliances. The rubber and coffee trees and also many other minor branches of agriculture can be profitably engaged in and yield large returns.

But the Filipino is by no means inclined to work, and the labour difficulty is one that the investor must reckon with. And on this point the deliverance is more plain-spoken than encouraging:—

The greatest obstacle that confronts the investor in the Philippines is the labor question. It seems to be the general impression in the States that labor in the Philippine is "dirt cheap," a laborer being able to live on but a few cents a day and working for an extremely low wage. However, experience with the native laborer will soon destroy the illusion of cheapness. The price of an article alone does not determine cheapness—it depends upon what you get for your money. The average Filipino does not want to work; does not see the use of work, and is not going to work unless compelled to do so by pressing necessity. They can be divided into two classes; those who only work when necessity demands, and those who never work. They are much like the American Indian in the belief that women were made to work rather than men. The women are employed extensively in the cigar and cigarette factories and are good workers; they also occupy the markets in selling small products, and usually contribute the greater part of the support of the family.

The average day laborer receives a wage of from \$8 to \$12 gold per month, but a gang of twenty natives working together hardly accomplish as much as two or three good American workmen would do in a given space of time. They have no conception of the value of time or necessity. A large portion of their time is consumed in lighting and smoking cigarettes and in conversation with each other and a little work now and then just to fill in the time. Neither have they any idea of independent action, and must be told and shown every detail of what they are to do, and even then they seldom do it right the first time.

As to reliability, it is something entirely foreign to the Filipino. If he is told to do a thing he must be watched until it is completed or it will never be done. His veracity cannot be depended upon under any circumstances, as his last resort is the truth, and then only to be used in case of emergency.

Between "fiestas," church holidays and the indisposition of the "hombre" himself, twenty days' work in a month is a good average, and after each pay day or two he will have enough money on hand to tide him over for two or three weeks while he takes a vacation and visits his relatives.

Since writing the above review, the news has come to hand of President Roosevelt hinting at a restoration of independence to the Philippines later on. That prospect would be likely to discourage investment, unless such safeguards were taken as might ensure due protection for foreign capital; but in any case a guarantee of this kind must be one of the conditions.

OPENING OF THE EXPERIMENTAL STATION AT GANGAROWA, PERADENIYA.

In the article on the history of the Botanic Gardens with which this volume opened, it was

mentioned on page 12 that the chief desideratum for a complete modern organisation of the Department was the opening of an experiment station or garden, where experiments could be tried on a large scale with staple products or with new products not yet staples. This station is now opened, the Government having purchased at the beginning of this year the almost historical estate of Gangarooma, lying on the side of the river opposite to the Botanic Gardens. The estate is of 550 acres, and of approximately horse-shoe shape, forming the opposite bank of the Mahaveli-ganga up to the sky line all round the north, east, and west sides of the Botanic Gardens, while on the east side between the river and the hill there are about 200 acres of nearly level land with good soil. Visitors to the gardens will remember that many of the most beautiful views are obtained at places where the river curves, and that their beauty is due to the banks of the river itself and to the wooded hills behind. All these hills are included in the new experiment station, and are to be worked as forest reserves, so that there will be no interference with the scenic beauty of the neighbourhood. The experimental plots of economic plants will be laid out on the lower and more level land of the estate, which at present is mainly cultivated with cacao, pepper, coconuts, grass, arecas, and croton.

The estate is of historic interest in two ways. Round the bungalow enclosure may be seen the remains of the earthworks of the former Portuguese fort, the scene of a great defeat and slaughter of one of the armies which invaded Kandy. About 1824 the estate was opened in coffee, indigo, sugar, &c., by the then Governor, Sir Edward Barnes, who was one of the very first pioneers in the planting enterprise, which soon afterwards spread so rapidly over the central districts of the Island.—*Mr. Willis's Annals.*

THE NEW BRANCH GARDEN AT NUWARA ELIYA.

The Government having decided to open a small branch garden for experiments with cultivation of useful and ornamental plants in the peculiar soil of Nuwara Eliya, a small site of about 5 acres has been set apart for the purpose in the new park, and is now being brought into cultivation. It will be worked like the Badulla garden, as a branch of Hakgala. The land lies at an elevation of about 6,200 feet, and is at present mainly patana with scattered Rhododendrons and a small piece of swamp.—*Ibid.*

THE NEW RESTHOUSE AT PERADENIYA.

The building, mentioned on page 21 of the present volume as in progress, was opened to the public on 10th March, and is very convenient for visitors to, and workers in, the gardens. It lies about 200 yards from the principal entrance to the Botanic Gardens, contains dining and sitting-rooms and four large bedrooms, and is fully furnished with all necessaries. Visitors working in the Peradeniya laboratories have a prior claim to some of the rooms, for which a charge of Rs 1 per day is made. Meals are supplied according to arrangements to be made with the resthouse-keeper.—*Ibid.*

INDIA-RUBBER PLANTING.

It is becoming increasingly evident that for cultivation, at any rate in Central America and the adjacent territories, *Castilloa elastica* is much the most satisfactory tree for a variety of reasons. These are its rapid growth, its modest requirements as to

quality of soil, its early maturity, its fine, smooth and branch-free trunk, and its large yield of latex.

It is true that, regarding the latter, the evidence available is so far contradictory to a degree, the annual yield of a full-grown tree being variously stated as amounting to from one to twelve pounds or more per annum. Thus we find Dr. Morris (The Colony of British Honduras, London, 1883) stating that the yield of a large tree of *Castilloa*, two feet in diameter is about 16 lb of rubber when first cut, and that such trees at the end of eight or ten years may be reckoned to produce an annual yield of at least seven or eight pounds of rubber. But according to Senor Horta (Diplomatic and Consular Reports, No. 2,354 1899), an experienced planter, one pound per annum may be considered a fair average yield. This is in agreement with a recent statement made by the René Guerin (Journal d'Agriculture Tropical, 1902, p. 79), but all these data are opposed to Dr. Warburg's assertion (Les Plantes à Caoutchou, trans. by Vilbouchevitch, Paris, 1902) that trees grown in favourable sites will produce an annual yield of 2.4 lb.

To reconcile such widely divergent statements made on the one part by planters of undoubted experience, on the other part by equally experienced botanists, is very difficult indeed. No doubt, to some extent, the explanation of this very wide discrepancy is to be found in the fact that the above data refer to trees grown in different districts, on different soils, and at different elevations from the coast. It is well known that all rubber trees are very sensitive in this respect, and *Castilloa* not the least so. That conditions of this description exert a very important influence upon the yield is further evidenced by the fact that the conditions under which the *Castilloa* should be planted are just as differently stated. One authority strongly advocates its planting as a shade tree for cocoa and coffee, while another equally strongly deprecates this practice as utterly mistaken, insisting upon these trees themselves being grown in the shadow of other trees. Nor do we find any closer agreement between the methods adopted for tapping the trees, horizontal cuts, vertical cuts, V-cuts, or pricking being recommended. Each of these methods appears to have its adherents in different localities. The only point of agreement in this respect seems to be that circular cuts round the whole circumference of the tree unfailingly result in its destruction.

Equally diversified are the methods proposed for the coagulation of the latex when obtained. We find Biffen's centrifugal method strongly recommended, whilst others seem to consider the spontaneous coagulation of the latex on the trunk of the trees perfectly satisfactory, but the majority of writers appear to favour the coagulation of the latex by means of decoctions of various plants.

One begins to understand the causes and nature of the keen disappointments not unfrequently resulting from rubber-planting ventures in the past in running the gamut of these contradictory statements, and it is perfectly evident that, while the ultimate success of rubber planting on the large scale cannot reasonably be doubted, the whole subject is one requiring much more careful specialised study than it has so far received.—*India Rubber Trades' Journal*, May 12.

HOW TO TAKE QUININE IN MALARIA.

Major Ronald Ross, in the ninth edition of his book on "Malarial Fever" (2s 6d, Liverpool University Press), gives some useful notes on taking quinine. He explains that, as quinine is wanted in the blood, and not in the stomach, the best form is to take it dissolved by means of acid. The next best form is that of the powder shaken up in water. Quinine pills, tablet forms, or capsules takes longer before it is absorbed into the blood, and, if pills or tablets are used, they should

be previously immersed in water for a few minutes so as to disintegrate them. The bitter taste of suspended or dissolved quinine can be corrected by taking one or two mouthfuls of food immediately after the medicine. Just before meals, especially before breakfast, is the best time for quinine, and its presence in the blood should be announced by a ringing in the ears within half an hour. Details of the doses needed in malarial fever are given—for a first attack 10 gr. of quinine should be given about every twelve hours for a week, which may be increased to 15 or 20 gr. In cases of vomiting it may be necessary to reduce the dose, and it is often useful to administer a saline purgative with the first dose of quinine. If a person has once become infected with malarial fever, he must continue to take quinine regularly for at least three or four months, so as to ensure extermination of the parasites, otherwise relapses are sure to occur.—*Chemist and Druggist*, May 17.

TROUT OVA.

It will be interesting to our readers to learn that of the first consignment of 20,000 brown trout ova, which arrived a few months ago from the Wyresdale hatcheries about 12,000 were hatched out successfully. At a Committee meeting of the Fishing Club recently held, it was decided to distribute the fry out to the different streams as follows—and which has since been done:—

Belihul Oya	500
Ambewella	1,000
Horton Plains	3,000
Nuwara Eliya Streams	1,500
Barrack Plains	300
Maskeliya..	500
Mr. R Jackson, for Sita Eliya	200

The other fry are at present in the stew pond. Of the first consignment of 20,000 rainbow trout ova from the Earl of Denbigh's hatcheries only 2,500 are reported to have hatched out and within the last fortnight these have begun to die to the extent of 40 to 50 a day. Of the second consignment of 20,000 rainbow ova also from the Earl of Denbigh's hatcheries 50 fry only hatched out. There were also 5,000 brown trout ova sent out as a present. Of these only 200 are said to have hatched. The fry of this consignment and also that of the first consignment of brown trout ova are also dying daily but in smaller numbers.—*Cor.*

VACCINATING OYSTER TO PRODUCE PEARLS.

Pearls are found to be due to the presence of a larva, which is an intestinal parasite of the eider duck, and has also been found in the scoter or black duck. The larva, parasitic in the mussel, is found to arise as a tailless creature, which enters the tissues under the skin of the mussel, and becomes surrounded with a sac similar in character to the outer shell-secreting skin of the mantle. If the intruder dies in the sac, it becomes calcified and forms the nucleus of a pearl, the pearl arising, like the shell itself, from the line of the cell wall. The parasite sometimes migrates out of the sac, in which case the nucleus of the pearl is inconspicuous. The complicated life-history of the parasite,

and absence of organs of locomotion suffice, in the opinion of the *British Medical Journal*, to account for the hitherto inexplicable distribution of pearl-bearing mussels. By experiment it has been found that pearls are caused by similar parasites in some of the pearl oysters; and it is believed that artificial infection of pearl oysters could be effected in a manner similar to that which has been found successful in the case of the common mussel,—*Bombay Gazette*, June 3.

SOUTH AMERICAN RUBBER INTEREST

(From *India Rubber World*, May 1.)

Arrivals of rubber at Manaus during the first three months of 1902, from the different rivers in the state of Amazonas, were as follows:—

Purus	kilos 4,424,837
Jarua	1,840,747
Solimoes	729,446
Madeira	1,010,482
Various streams	239,290

Total	...	kilos 8,244,803
Total, same months, 1901	...	6,991,286
Total, same months, 1900	...	7,779,935

A correspondent at Manaus wrote recently that many persons there were hoping for an advance in prices, and were for that reason holding back rubber. Business was depressed, and the large houses were not disposed to sell goods except on strictly cash terms. The inspector of the treasury, Colonel Felipe Minhos, and Dr Portirio Nogueiro, secretary to the governor, had gone to the United States to try to negotiate a loan of \$1,000,000, in return for which, it was rumoured, the lender would have very desirable concessions in respect to export duties on rubber. A law had been introduced in the congress at Manaus to substitute a fixed duty of two or three milreis per kilo for the existing *ad valorem* rate of 22 per cent.

The *South American Journal* (London, April 12) contained advices from Para, stating:—"A most important move in the rubber business is about to be made by a Peruvian, named Spinoza, who arrived here a few days ago from Iquitos, bringing with him 70 workmen who understand working Caucho." The idea appears to be that, on account of the exhaustion of extensive Caucho fields in Peru, increased attention is being given to Caucho in Brazil, where the preparation of the gum is not understood, while the Peruvians are expert in it. It is reported to be probable that on the Tocantina and other large rivers in the state of Para "large quantities of Caucho will be found, and now that a commencement is about to be made, the result will probably be an immense increase in the production of Caucho in the next few years."

ESSENTIAL OILS. OF INTEREST TO CEYLON.

(From Semi-Annual Report of Schimmel & Co. (Fritzsche Brothers) Miltitz near Leipzig, London and New York.—April 1902.)

CAMPHOR OIL.

It is, of course, well-known that the production of camphor in Formosa has been monopolised

by the Japanese Government, and that the monopoly for this kind of camphor has been transferred to an English firm. But the production of camphor in Japan remained as before in the hands of private firms, and it was only natural that the value of the article could not always be kept at the level of the prices fixed by the monopolists but occasionally moved backwards.

Under these conditions the Japanese Government was compelled to consider the question of also monopolising the camphor production of Japan. A bill to that effect has been brought before Parliament but, we are informed, has not been passed.

The Formosa Government will probably sooner or later take over the whole of the Japanese camphor and work it jointly with the Formosa camphor, so that the production of both countries will be under one single control. It remains to be seen whether the further exploitation in such case will also be granted to a private firm. Only when the whole world's production of camphor is controlled by one hand will it be possible to keep up the value.

CINNAMON OIL, CEYLON.

In the course of the last few months the prices of fine Ceylon cinnamon chips have suffered a decline, which enabled us already in January to reduce our quotation of the well-known fine sweet and heavy oil. They have never before been so low as at this moment.

CITRONELLA OIL (CEYLON).

The fluctuations, which the value of this important article has undergone during the last six months, are so trifling that they may be left out of account. The sensational reports, which regularly make their appearance at certain periods, that at the low quotations the distillation no longer pays, and is slowly becoming extinct, are refuted by the fact that the export again shows an increase as compared with that of the previous year. There can be little doubt that, with a selling price of about 2/- per kilo, the manufacture of citronella oil is not very remunerative, more particularly as the present state of the knowledge of the article renders the profitable adulteration of the oil, which used to be the order of the day, an extremely difficult matter. At the same time, the unfair trading in this article has not yet been completely done away with, for samples are constantly being submitted for our opinion, which do not answer the conditions specified by us. In view of the unexampled cutting which prevails in citronella oil, the greatest care is required in purchasing.

We have obtained extraordinary results with the Java citronella oil specially distilled for us. This product shows clearly what can be obtained by rational, expert cultivation and distillation of the crude material, for the species of plant used in Java is the same as in Ceylon. And yet what a vast difference between these two oils!

It affords us great pleasure to be able to present to our readers on the next page a picture showing part of the plantation on which this oil is produced. In the foreground is seen a field planted with citronella grass. The building on the left contains the apparatus used for distilling the oil. In view of the interminable trouble and care caused by undertakings of this character in such far-off countries, it is sincerely hoped that the excellent product may constantly increase in favour, and may meet with the appreciation to which it is justly entitled, so that the manufacture may be continued on a large scale. If produced on a small scale, the expenses are proportionately too high.

We shall be pleased to supply samples.

GLOVE OIL.

According to the official reports from the German Consulate at Zanzibar, the clove harvest

extends over the whole year, commencing in the beginning of July and lasting until the end of June. This report states further:—From 1st July, 1900 to 30th June 1901, 250,000 frazilieh have been brought to the market. An average crop was formerly estimated at 375,000 frazilieh, but should now, no doubt, be taken at a lower figure, as the trees have been neglected through lack of labour. The prospects of the 1901-1902 harvest are said to be good; it is hoped that the yield will be 400,000 frazilieh, or 14,000,000 lb.

The export was:—

	lb.	Value in Rupees.
in 1898 ..	10,856,566	2,155,956
„ 1899 ..	16,593,340	2,953,487
„ 1900 ...	11,783,095	2,372,227

It was divided as follows:

	1898	1899	1900
	Quantities in lb.		
Europe ..	4,138,686	8,023,780	5,235,383
America ...	729,960	648,970	719,600
Asia ...	5,912,800	7,599,517	5,769,293
Africa ...	75,720	316,078	63,814

	Value in Rupees		
Europe ..	797,375	1,394,217	1,031,952
America ...	149,402	110,108	150,079
Asia ...	1,194,032	1,397,837	1,177,754
Africa ...	15,147	56,425	12,442

The export to America was exclusively to New York; that to Asia, to Bombay, of which perhaps a part has been re-shipped to Europe.

The export to the various European ports was made up as follows:—

	1899	1900	1899	1900
	lbs.		Rupees	
Rotterdam ..	4,473,240	2,674,160	786,212	537,810
London ..	1,432,475	1,404,963	254,852	274,520
Hamburg ..	1,249,850	715,260	204,267	122,912
Marseilles ..	292,215	217,000	51,229	49,800
To Rotterdam's share should be added	84,000 lb.			
Value 18,000 Rupees, shipped to that port via Amsterdam.				

Clove stems were exported:

	Quantities in lbs.			Value in Rupees.		
	1898	1899	1900	1898	1899	1900
To Europe:—	534,640 3,605,245 1,743,426 24,055 104,351 70,453					
To Asia:—	305,561 216,483 220,447 14,845 6,748 11,621					
To America:—	336,875 555,940 98,000 19,657 31,708 7,700					

Whilst in the previous year the export to America was more than double that to Asia, the former has now become quite unimportant. It is shipped to New York and Bombay. In Europe, Hamburg takes the first place:

	1898	1899	1900
	Quantities in lbs.		
Hamburg ..	456,890	2,980,110	1,478,226
London ...	74,900	379,335	83,160
Marseilles ..	38,850	179,900	28,000

But in clove stems also Rotterdam enters strongly into competition. The import amounted in 1900 already to 112,000 lb, to which should still be added 42,000 lb from Amsterdam.

The reports emanating from Holland are in some respects in direct contradiction to the official consular reports; in others their calculations, or rather estimates, anticipate events in such a fantastic manner as to astonish every thoughtful reader. In the statistics of one of these reports, dated January of this year, the estimates made include not only the yield of the harvest 1902 to 1903 (i.e. commencing in July 1902 and ending in June 1903), estimated at 3,000,000 kilos, but also the consumption from 1st September 1902 to 31st August

1903 (5,400,000 kilos) and even the stock in September-October 1903 (2,420,000 kilos)! And as the stocks on 1st January 1902, at all the principal markets, amounted in the aggregate to 137,000 bales or 8,220,000 kilos, the anticipated reduction of the stocks by September-October 1903, by 5,800,000 kilos, is used as an argument for an increase in the prices of cloves!

MUTILATED SEEDLINGS.

“Knowledge” has an interesting account of the behaviour of seedlings when mutilated by the removal of the plumule. “Seedlings of various plants were experimented on, including some of the garden radish. On removing the plumule soon after the plants were above the ground, it was observed first that the cotyledons assumed a much deeper green than usual; then the petioles developed extraordinarily, becoming three inches long, while the cotyledons attained a breadth of an inch and a half and nearly double the thickness of those of a normal plant. It was also observed that they were raised at an angle of about 45° instead of being approximately horizontal. A microscopic examination showed that the greater thickness of the cotyledons was due to the increased size of the cells and not to a multiplication of the layers. The roots developed to nearly the ordinary market size. In seedlings of the common sunflower, treated in the same manner, a remarkable elongation of the hypocotyl was noticed, this becoming twice as long as in the unmutilated plants.”—*Knowledge* for May.

WEST INDIAN SWEET POTATOES.

Owing to the possibility of profitable cultivation of sweet potatoes, considerable attention has been given to the potato crop by the Imperial Department of Agriculture for the West Indies, and a great deal of experimental work has been carried on. Experiments were made in Antigua with a view to determining the best varieties for cultivation. Fifteen varieties were planted and the crop from each weighed; the yield varied from 6 to 4·4 tons, the varieties ‘Eliza,’ ‘T.1,’ and ‘T.2,’ giving the largest crops. A full report of these experiments will be found in the *Report on certain Economic Experiments in connection with the Botanic station, Antigua, 1900-1901*. In Barbados alone starches, grains, and meals, which are food-stuffs similar in composition to sweet potatoes, are imported to the value of £95,000 per annum, so that, if the potato crop could be preserved for consumption during the year, it could be used instead of this imported food. Sweet potatoes will not keep without some desiccating treatment in the West Indies, the conditions for their preservation being storage in dry air at about 50 deg. to 60 deg. Fahrenheit. In Japan they are preserved by cutting them into slices and drying the latter in the sun. Many tons of potato meal were made by Mr Spooner, of Antigua, who prepared it by slicing the potatoes in a chaff-cutter, and drying the slices in the sun while spread out on wire netting, the drying being complete in about eight hours.

One ton of potatoes by this method yields 910 lb of meal, at a cost of about £4 10s 0d per ton of meal.

Dr. Voelcker, who analysed the product, found it had the following composition:—

Moisture	11 99	per cent.
Nitrogenous matter	5·12	do
Oil	1·19	do
Sugar	9·90	do
Starch and carbohydrates	67·01	do
Woody fibre	1·89	do
Mineral matter	2·90	do

As regard the keeping qualities of the meal, some of it was stored in tins for twelve months, and was then found to be perfectly good.

A large portion of the sweet potato crop is at present used for making spirit, which is shipped to Portugal and used for fortifying wines.—*Home paper*.

PLANTING NOTES.

WHITE ANTS AND COCONUTS.—Writing to us from Pemba, Zanzibar, Mr. Theodore Burt of the “Friends’ Mission” says:—“In regard to the destruction of young coconuts, by white ants, some time ago I tried watering them with sea water. This had a most beneficial effect, but, of course, it can only be done when the plants are near the shore. The ants do not trouble to eat the husks, they eat out the central shoot of the growing palm and then it dies.”

RUBBER PLANTING.—The various plantation companies organised in the United States for operations in Mexico, with rubber as the principal or an important feature, appear, says *the India Rubber World*, May 1st, on the whole to have made steady progress during the past year. No company which has once made a definite beginning has withdrawn from the field, while new companies are being organised all the while. Much preliminary development work has been done, a considerable amount of rubber has been planted, and a great number of rubber nurseries are in existence or are being planned for the coming season. The managers of the several companies appear to feel encouraged as to the results of their work thus far, and there has been developed nowhere any reason for fear that, in the end, rubber cannot be cultivated profitably under right conditions and right management, even if some of the many enterprises, under weigh should result in failure.

THE CRY OF “COARSE PLUCKING.”—We hope this cry is not going to be overdone at home, because we see in it one of the levers used by the dealers there to work a reduction in the price of tea. Favourable weather for flushing has just now made planters in many districts very busy, and from many quarters we hear of a rush of leaf. Stores, as a Pussellawa resident wrote a day or two back, are “chock-a-block,” and it is incorrect and unfair to attribute rushes of crop, which run up the poundage figures, to a return by planters to coarse plucking. Local “Times.”

FOR A NEW PRODUCT.—Application to Government for a grant of land.—We learn that a visitor, Mr. Ervert, who has been in the island some months, has applied to Government for a large block of land in the North-Central Province, on favourable terms, for the cultivation of new products, viz. aloes and hemp. The Government has asked for particulars and in the meanwhile the applicant is prospecting for a suitable block of land for the cultivation of the fibre plants. Mr. H P C Armitage, Assistant Conservator of Forests, it is said, has been asked to lend the prospector any assistance that might be required. The land applied for is in the North-West portion of the Province, which has a fine soil suitable for aloe cultivation. Nothing has yet been settled, the matter being only in an initiatory stage, and the Government has not yet received particulars from the prospector.

RUBBER IN CUBA.—Writing in *The Independent* on "The Future of Cuba," the president elect of that republic, Senor Tomas Estrada Palma, says: "As for rubber, there are some Caoutchouc trees growing in Cuba, chiefly on soil that has no other use. But in the province of Havana Cubans are already establishing nurseries of young trees, and the people are buying them extensively."—*The India Rubber World*, May 1.

TOBACCO-GROWING UNDER TENTS.—It is stated by the "Implement Age," of Philadelphia that growing tobacco under tents is now being carried on in Connecticut. Experiments were made in 1900 and 1901 by the State agricultural station and by individual growers in the effort to raise wrapper-leaf tobacco of the Sumatra type in fields completely covered and closed in on all sides with thin cheese cloth. The results were so gratifying that it seems likely the methods of tobacco culture in that State will be revolutionised.—*Globe*, May 10.

QUEENSLAND COFFEE SEED.—Mr H McLeod Playfair, of Mudigera, has received a parcel of coffee seed from Cairns, North Queensland, and appears to have avoided the risk of introducing leaf-disease. Seeds put down in January have yielded exceptionally sturdy and healthy plants, and as the seed is offered for sale a good number of coffee-planters will probably desire to make a trial of it. We have written so often about the desirability of introducing new and healthy strains that we have really nothing fresh to say on the subject. Our own belief is that, if care be exercised in the selection, the introduction of such strains provides a check upon disease instead of helping to spread it.—*Planting Opinion*, May 31.

TWO MORE TEA COMPANIES.—The Hunasgiriya Company has fallen on evil days and unless there is an improvement in prices, or a full maintenance of the better rates now being realised, it may be necessary to circumscribe the area under tea and concentrate attention on the very best fields. In the olden days, Hunasgiriya was quite a show-place under coffee; but much was taken out of the soil in those years.—The Eastern Produce and Estates Company has had a striking career since it took over the affairs of the old Ceylon Company, Limited, and the full report of the annual meeting which we publish elsewhere makes interesting reading. Commencing with a burden of no less than £193,000 in Debentures, by good careful management and the profits from tea in the early days, this debt has been reduced to £72,500 and the whole capital of the Company is now only equal to £30 a cultivated acre, without counting valuable property in mills, &c. in Colombo. The Directors thoroughly believe in fine plucking and are going to adhere to it. The Company makes a profit—apart from attention to its own estates—through its engineering and agency work; and having plantations at all elevations and in a great variety of districts, the shareholders must be content with a fair average price for its tea and not expect the prices appertaining to the high estates of a Company that has no medium nor low country properties. Mr. R. A. Cameron, Mr. Norman Grieve and the other Directors may well be satisfied with the outcome of their labours, following on the good work done by their staff in Ceylon.

THE PRODUCTION OF CACAO IN AFRICA.—A West Indian merchant writes to *The Times* to say that in a few years' time Africa seems likely to prove a formidable rival to South America and the West Indies as a producer and exporter of cacao and those interested in the West Indian possessions of the United Kingdom and anxious to see the island more prosperous will do well to watch how the cultivation of cacao is being pushed on with satisfactory results throughout the continent of Africa. This year the German colony of the Cameroons, hopes to ship three thousand bags of cacao, to be increased, it is estimated, to ten thousand bags in 1906. Our correspondent adds:—'Mr McClouie, head of the scientific department of British Central Africa, reports the successful shipments from Kew and receipts at Lomba of 210 plants which had been planted out and were doing well. Lagos is also going in for cacao, and one of her planters is now travelling in the West Indies to see how the estates are managed in Trinidad and Grenada.' He also says that the little Portuguese island of St. Thomé has greatly increased its export of cacao in ten years, the shipments in 1891 being under four thousand tons, whilst last year very nearly sixteen thousand tons of cacao were exported.—*Agricultural News*, April 25.

METALLURGY AND ENGINEERING.—The tenth "James Forrest" lecture was delivered on Wednesday-night at a special meeting of the Institution of Civil Engineers by Sir William Roberts-Austen, whose subject was the 'Relation between Metallurgy and Engineering.' As to the use of cast iron and malleable iron, he said it was admitted that the necessity for pumping water out of mines was the main factor in the evolution of the steam engine, and in turn the development of British metallurgy of iron and steel dated from the time when Watt's steam engine enabled air readily to be pumped into the blast furnace employed for the production of cast iron. More than half of last century had elapsed before the age of steel began, and towards the end of that century great attention was devoted to considerations connected with the molecular structure and properties of steel. When metallurgists gave engineers mild steel they provided a cinder-free solid solution of iron and carbon. All subsequent advance had been due to the recognition of this fact, and to the study of the properties of metallic solid solutions. Sir John Hawkshaw in his presidential address to the Institution delivered in 1862, said that if the strength of iron could be doubted the advantages might be equal to the discovery of a new metal more valuable than iron had ever been. This was exactly what metallurgists had done with regard to steel by suitable thermal treatment and by suitable additions of comparatively rare metals. The lecturer next explained the nature of solid solutions, and dwelt on the importance of allotropic modifications of iron. Some very beautiful experiments were shown in evidence of the possibility of the past molecular history of a mass of steel being traced by microscopic examination of the solid metal, which might even reveal by its structure the vibrations to which it had been subjected. Finally, in regard to the efforts metallurgists were making to study the influence of rare metals on iron and other metals, the reducing power of aluminium on metallic oxides was exhibited, very high temperatures of 3,000 deg. C and over being produced. A vote of thanks to the lecturer was proposed by the president, Mr C Hawksley, and seconded by Sir Frederick Bramwell.—*London Times*, April 25.

TAHITI VANILIA.

In the May number of *Chambers' Journal*, Mr A McFarlane of Moorea, Society Islands, contributes an interesting article on vanilla-growing in Tahiti, after reading which one is tempted to sigh for the life of a vanilla-planter. Tahiti, he says, has the finest tropical climate in the world—no hurricanes, no malaria or fevers—and a friendly race of natives to live among. A man with three or four acres of vanilla has a competence; with ten or more he is rich, and for one who likes to "potter" around among flowers there is no life more attractive, says Mr McFarlane. So much has been written about vanilla planting and curing that Mr McFarlane's article necessarily traverses old ground, but he gives several interesting facts in describing the methods employed in the South Sea Islands. Although Tahiti is one of the largest vanilla-producing countries, yielding annually nearly one hundred tons of pods, the product is the worst vanilla that reaches the European market. This is mainly due to the native planter who does not give the necessary attention to the curing, which is the most important work. There is no secret about the method of curing, although some pretend that there is. It consists in alternate exposures to the sun, always under dark-coloured blankets, and sweating in the house in light tins or boxes. The average price of Tahiti vanilla is six shillings per pound, and as Mr McFarlane, who is a cultivator and curer of vanilla, estimates that it costs two shilling per pound to grow and cure, a good margin of profit is left for the grower. Most vanilla-planters suffer from small itching blisters on the hands, resembling "prickly heat," which is brought about by the constant handling of the beans, Mr McFarlane has found a specific in his own case, and that is a mixture of equal parts of carbolic acid, glycerine and rosewater, rubbed on the hand—rather strong in carbolic, we think; perhaps he means carbolic lotion.—*Chemist and Druggist*, May 17.

INDIAN TEA ASSOCIATION,

Calcutta, 20th May 1902.

THE GREEN TEA BOUNTY, 1902.—With their letter of 2nd May, the London Committee forwarded copies of correspondence which had passed between the Baraooora (Sylhet) Tea Co. Ltd. and themselves on the subject of the Green Tea Bounty for the ensuing season. The correspondence explained the circumstances which had led the London Committee to accept the proposal of the Baraooora Company to make 200,000 lb this year and to allow from 25 to 30 per cent of the amount to be sold on the Continental markets. The correspondence had been placed before the Green Tea Sub-Committee for consideration, in connection with the preparation of the circular for issue to the members of the Association, detailing the conditions under which the bounty would be payable during the ensuing season.

Recorded letter of 14th May, from the Secretary of the Liners' Conference, Calcutta, acknowledging receipt of the Committee's letter on the subject of the establishment of communications with the

BLACK SEA

ports with the view of fostering the Indian Tea trade with Russia. It was stated that the matter was being placed before the various owners and that it was hoped that some arrangement would be arrived at whereby the Indian Tea Trade with Russia might be helped.

Considered, a Memorandum by Mr.

HAROLD MANN,

Scientific officer of the Association, reviewing the position since the institution of the Scientific Department two years ago, and suggesting for consideration in view of the fact that his agreement would expire in another twelve months, certain proposals for future procedure in the event of a continuance of his engagement being decided upon. Mr Mann drew attention to the many problems connected with tea culture and manufacture, awaiting full investigation, and dwelt upon the practical impossibility of his being able to deal with them satisfactorily, single-handed. His first suggestion, therefore, was that an Assistant should be engaged from England, who should be capable of taking up more especially the manufacturing problems and working them out under Mr Mann's supervision. Another important advantage to be kept in view was that by the engagement of such an assistant the continuance of operations would be assured, in case of a breakdown in health of either Officer. Mr Mann's proposals also embraced the establishment of a central laboratory, the engagement of a trained Babu to work out analyses of soils, etc., and the provision of a small experimental station in the Tea Districts where observations could be made of the properties and results of various fertilising agents, such as phosphates. Altogether, Mr Mann estimated the increased cost of the establishment of the complete scheme at Rs12,000 per annum. Accompanying the Memorandum was a Note by the Chairman dealing with the financial aspect of the proposals. The Association, he pointed out, was at present contributing about Rs5,000 a year towards the present expenditure, which amounted to about Rs15,000 per annum, but it could not find more without trenching on its reserves. The question thus arose as to how the extra Rs12,000 required was to be found.

The papers had been previously circulated, and a lengthy discussion now ensued as to the practicability of the scheme. The consensus of opinion was in favour of carrying on the investigations, as much good had undoubtedly resulted from Mr Mann's work hitherto. It was finally decided in the first place to publish Mr Mann's scheme with a covering circular letter to the various local Associations and to the London Committee, stating that the Committee were generally in favour of the views therein expressed, provided that funds could be found to carry out the proposals. The financial position of the Association was to be pointed out and the local Associations asked for an expression of their views, particularly as to their willingness to increase their subscriptions to the Scientific Investigation Fund. Reference to the Governments of India, Bengal and Assam, which would be necessary ultimately, was to be deferred pending an expression of opinion from the representatives of the Industry.

It was decided, after discussion, to forward a copy of the statement to Messrs Andrew Yule & Co., the Commissioners for the Indian

TEA MARKETS EXPANSION

Commission, and to inform them that the Managing Agents, Messrs. Kilburn & Co., would be ready to assist as far as possible any efforts which might be made to stop refuse tea going into consumption.

The Secretary reported that the new signatures to the Compulsory

TEA CESS

Memorial brought the area up to 412,236 acres, or approximately 79 per cent of the total area under tea cultivation. The area reported on 23rd April amounted to 409,000 acres,

THE BANANA.

A fruit that has never yet come properly into its own is the banana. Such, at least, is the opinion of vegetarians, not a few of whom justify the faith that is in them by living altogether on banana products; and even less heroic martyrs are beginning to think that the banana will prove the most persuasive weapon of conversion in the vegetarian armoury. Already there has appeared in the Midlands an enthusiast, just fresh from South America, with an unheard-of collection of banana recipes; and if all goes well with the propaganda, we may expect to be taking within a few years for breakfast plain bananas, banana pancakes, banana muffins, and banana coffee; for lunch, banana fritters, banana bread, banana biscuits, and banana cake; and for dinner, banana wafers, banana figs, and a small cup of banana coffee. Apropos of bananas, there is a costers' club in a quiet street off the Edgware-road which was formerly devoted to innocent recreation. But the spirit of utilitarianism has prevailed over the desire for social enjoyment, and the premises have now become a forcing-house for West Indian bananas. The bananas are consigned direct to the club, thus saving the middlemen's profits, and every room is filled with great bunches of the fruit, ripening under gentle heat for the public palate. The members of the club can select their own bunches and pay for them as they sell them, so that an initial capital is not required. On a good day, with a cartload of these bananas, a coster can clear a net profit of—but perhaps it will be more discreet to keep the figures dark. The coster's, like all other callings, already suffers from overcrowding.—*Daily Chronicle*, May 16.

VANILLA GROWING.

BY A M'FARLANE, OF MOOREA, SOCIETY ISLANDS.

I have been for years a cultivator and curer of vanilla.

The white planter in the tropics, after he has been for some years subjected to the enervating effects of the climate, becomes averse to anything in the shape of labour more than is absolutely necessary for conducting whatever particular avocation his may be. So that the residents of a Northern clime have to depend upon the kind services of the 'globe-trotters' for their information upon the various cultures; and, owing partly to the short time which they are enabled to devote to acquiring information, and often to misleading statements made by planters intentionally, sometimes this information is very incorrect. This stricture, however, does not refer to the article by Mr Cater, and I must compliment him upon the care which he has evidently displayed in his study of the vanilla. He has, however, made a few mistakes; and I thought it might perhaps interest your readers, were I to correct them and also describe the methods employed by us here in the South Sea Islands.

Although Tahiti is one of the largest vanilla-producing countries, ranking second or third, annually yielding nearly one hundred tons of the dried product, ours is nearly the worst vanilla that reaches the European markets, commanding only about half the price which is paid for vanilla produced in Reunion or Seychelles, or one-quarter of that paid for the best Mexican. However, to offset this advantage, we have the advantage of the finest tropical climate in the world—no hurricanes (Tahiti being outside of the 'hurricane belt,' which only reaches the Raratonga or Cook Islands, six hundred miles to the west), no malaria or fevers, no poisonous serpent, and but few noxious insects—and have a gentle, friendly race of natives to live among.

We have here in cultivation two varieties of vanilla: *V. planifolia*, grown only in very limited quantities, as, owing to the tendency of the bean to split when nearing maturity upon the vine, and afterwards during the process of curing, it does not appeal to the native grower, and the variety in common cultivation, which is that known in Mexico as *pompona*. Both varieties

were originally brought here from Mexico. *V. planifolia* produces the true vanilla, while *pompona* yields what is known in Mexico as *vanillon* and in the London market as *vanillos*. *V. pompona*, although yielding such an inferior quality of fruit, has advantages which endear it to the Tahitian. The bean does not split; it can be cured by simply exposing it to the sun, not requiring to be dipped in hot water or subjected to a process of baking, as do the others; and it always gives two and sometimes three or four crops of flowers during the year, while *planifolia* gives but one and that of short duration.

Most of the Tahiti vanilla is planted so as to climb upon the guava, which is about the worst tree that could possibly be obtained for the purpose as; the bark constantly peeling off causes the tendrils of the vanilla to lose their hold with it, and the vines have to be hung over any convenient branch to keep them from falling to the ground. The guava is an imported tree, but it has taken possession of large tracts of land; and to make a vanilla plantation requires the minimum of labour, usually only the cutting out of a few guavas where they may be growing too thickly, and the planting of vanilla-vines at the roots of the remaining ones. Upon hillsides where the *purao* (a species of *Broussonetia*) grows, the vanilla is at home. In fact, it is a mistake to plant it upon level land, as, although the vine revels in moisture, the roots are very impatient of water lying stagnant about them. The *purao* is, however, a rapid-growing tree, and considerable labour is required in pruning in order to keep it within bounds and prevent it from overshadowing the vanilla, too much shade being even worse than too little.

The best situation for a vanilla plantation is on a hillside, preferably in a valley, not too near the sea; and the best system of planting, for one who can afford to wait, is to clear off all the trees which may be growing upon it, and to plant at regular intervals young trees or posts, of varieties which will grow from cuttings. In my experience the best is a small tree known locally as *pini*, a species of *Bauhinia*, and which will grow in two years to a height of from twelve to fifteen feet. The usual distance apart for the posts is six by eight feet. When these posts are in place, the vines are planted as Mr Cater says; only that we usually use cuttings of ten or twelve feet in length. When cuttings of this length are used a crop of beans is secured nine months or a year sooner than when short lengths are planted. We reckon on a small crop of cured beans eighteen months after planting, and a full crop in two years and a half.

The flowers, which last but one day, open about 7 a.m. and close about 3 p.m.; and have to be pollinated by hand during that time—that is, all those which open upon one day must be pollinated the same day. We use small, pointed sticks for this purpose; the pollen, which is a small compact mass, being transferred more rapidly by these than by any other method that has been tried. A very expert worker can pollinate three thousand flowers in one day, but most are satisfied with from fifteen hundred to two thousand.

About nine months after the flowers appear, the beans become mature. This stage is known by their changing in colour from a dark to a light-yellowish green, or by their becoming brown at the lower or flower end, when they must be picked and taken to the house to undergo the process of curing, which should occupy about three months. They can be cured in a shorter time, but always at a sacrifice of quality. This is the most important work of the vanilla-planter and entails constant care, as a few days' neglect may spoil the whole crop. This, I think, partly explains why Tahiti vanilla has such a bad name in the markets of the world. Most of the native planters cure their own crop, but they will not give the necessary attention to this work. There is no secret about the method of curing, although some pretend that there is. It consist in alternate exposures to the sun, always un-

derdark-coloured blankets, and sweating in the house in tight tins or boxes. Experience is the only teacher as to when the bean has arrived at the proper stage of dryness.

I have to differ from Mr Carter regarding a few of his statements. For one thing, the vanilla is essentially a terrestrial orchid, and derives a large part of its sustenance from the soil. In proof of this, in any old, neglected plantations plants may be found which have been uprooted or broken off. When this happens, the part of the vine which is left at once takes on a sickly yellow hue and sends down long roots—I have seen some of these over thirty feet long—which on reaching the soil take root, and the vine at once recovers. The small tendrills do not feed upon the trees to which they cling, these being simply used as anchors for the vine. This refers to live trees; when the tendrills come upon a decayed branch, or when the tree upon which the vanilla is trained dies, they then change their character, becoming elongated and entering into the decayed places as proper roots, and evidently feed upon it.

In his estimate of the possible crop and probable profit I cannot agree with Mr Carter. First, an estimate of four beans to a vine is ridiculously small. If a vine has only one bunch of flowers, that ought to give from eight to twenty flowers—we usually have eight to ten beans to a bunch; but it is a very poor vine which does not give in the year over ten bunches of flowers. However, to be safely within the mark, let us say that each vine averages five bunches of flowers, giving six beans to the bunch, or thirty beans to the vine. This will give three thousand beans to the hundred vines. Taking these at a hundred and fifty beans to the pound, the usual average, we have twenty pounds as the crop. This at our average price of six shillings gives six pounds sterling, or at the price mentioned by him—twenty shillings—twenty pounds. Where he is wrong is in the weight. One thousand beans—and they must be the best—will weigh fifty pounds, but only when they are green; and in the process of curing they lose at least three-quarters of their weight. Figures, however, are sometimes misleading, and I cannot do better than give as an example the result from a small plantation in which I am interested. A careful account of the expenditure and receipt has been kept. At the end of three years and a half from the time of planting the vines we have paid back all that has been expended upon them, and have a small balance in hand. A man here with three or four acres of vanilla has a competence; with ten or more he is rich; and for one who likes to potter around among flowers in the temperature of a greenhouse I cannot imagine a life more attractive.

By the way, although the fruit of the vanilla is in no sense a bean, it is invariably called by that name.

Our vanilla is one of the most speculative crops, rivaling hops in that respect. I have known it to sell for two shillings a pound—that was ten years ago and it has never gone below four shillings since and again for sixteen shillings. The average price, however, is six shillings; and, as we estimate that it costs two shillings per pound to grow and cure, a fair margin of profit is left for the grower.

I will conclude with a little information for brother-planters. Vanilla possesses two irritant poisons, which, like some other vegetable poisons, act differently upon different individuals. To a few they are innocuous. The juice of the vine, or even the rain or dew from off the leaves, produces in some an itching sensation somewhat resembling 'prickly heat.' The dry or partially dry beans produce small blisters on the hands of some of those constantly handling them, and in extreme cases sores upon the arms and body, which all itoh incessantly. I have suffered slightly for years from these, and have only lately found what seems to be a cure; in my case it has proved a specific. This is carholicacid. I use a mixture of equal parts of carholic acid, glycerine, and rose-water, rubbed on upon going to bed. I have tried the same remedy upon a number of natives, and have cured them all. Was hing with Calvert's 20 per cent carholic soap, after handling the beans, act as a preventive.—*Chambers' Journal*, May 1

INDIAN TEA ASSOCIATION.

BOUNTY ON GREEN TEAS.

CALCUTTA, May 31, 1902.

The following arrangements, regarding the payment of bounty on the manufacture of Green teas, have been decided upon for the current season.

(a) That the bounty will be paid on 400,000 lb. as against 200,000 lb. last year.

(b) That the bounty will be the same as last year, viz., 1½ annas per lb.

Of the total quantity of 400,000 lb. on which the bounty will be paid the Baraora (Sylhet) Tea Company, Limited, have offered to make one-half, and this offer has been accepted by the London Committee. There remains, therefore, 200,000 lb. upon which the bounty will be paid to other gardens. The object of the London Committee in accepting the offer of the Baraora Company is to ensure that a larger quantity of green tea shall be made, as it was somewhat disappointing to find that the bounty was earned upon only 72,703 lb. last year.

2. CLASS OF TEA TO BE MANUFACTURED.—Enquiries have been made of the recipients of last year's bounty, which was given on green tea of the Gunpowder, Hyson and Young Hyson varieties, as well as upon green Pekoe and Pekoe Souchong kinds similar to the Ceylon type. The consensus of opinion is that unfaced greens of the China type are preferred, as they come into competition at once with the class of tea with which the consumer is already acquainted. But the fact that Ceylon exported to America last year upwards of one million pounds of green tea and is continuing to manufacture for America affords evidence that there is a market there for both classes, and therefore no restrictions will be placed upon the class of tea to be manufactured.

3. The bounty will be paid subject to the following rules:—

(a) The General Committee propose to leave the decision, as to what may be suitable for the American and other green tea markets, largely to the discretion of those who make the tea, and do not require that experimental samples should be submitted for their approval before the tea is made.

(b) They reserve the right, however, to defer payment of the bounty in any case where after examination of samples drawn under clause (d) they think the tea is likely to be found unsuitable, until production of a certificate showing its *bona fide* sale at a price not under the equivalent of three annas per lb. in Calcutta for any separate grade in the invoice.

(c) The Committee, while they do not require the previous submission of samples, nevertheless recommend those who intend to make tea in consideration of the bounty to submit samples to them for the examination and report of experts. The leaf to be used for the manufacture of green tea should not be coarser than that ordinarily plucked for black tea manufacture.

(d) When teas upon which the bounty is claimed have arrived at port of shipment, samples should be drawn and sent to the Committee; and on approval of these, and on proof of sale or shipment, the bounty will be paid.

(e) There is no objection to the teas being sold on the Calcutta market if the producer so desires.

(f) It is proposed to pay the bounty only to those gardens which have subscribed in 1901 to the American and Foreign Market Fund, or to the Indian Tea Markets Expansion Fund.

4 I am directed to ask those who intend to make green teas to inform me of their intention as soon as possible, stating the quantity they intend making. It will be understood, however, that such an intimation will impose no obligation either on the garden to make the tea, or on the Committee to pay the bounty, should the latter not become payable—either under clause (b) or clause (d)—before the amount now allotted has been exhausted.

THE CONSUMPTION OF TEA.

(From the second number of a Board of Trade memorandum.)

TEA.

The first thing that strikes one in glancing at these tables is the enormous extent to which the tea industry is dependent upon the United Kingdom, and in particular how vital this market is to the tea industries of India and Ceylon. The tea that John Bull and his family drinks is mostly and increasingly grown under the protection of the Union Jack. We take a smaller quantity relatively every year from China. To put the matter in a nutshell, the total consumption of tea in the United Kingdom exceeds that of all the other European countries and the United States put together. During the seventeen years from 1884 to 1900 it has risen from 175 million lb to 250 millions, an increase of 43 per cent. To go into further detail, it may be added that every person in Great Britain and Ireland, counting each centenarian and baby in arms, the upper tenth and "the submerged tenth," consumes annually over 6 lb of tea, an increase of 1 lb in sixteen years.

Of a total world's production of about 600 million lb in 1900, nearly half was taken by this country, while of the actual Indian export Great Britain absorbed seven-eighths and of the Ceylon export three-quarters, comparatively little being re-exported. This peculiarly British preference for tea as against coffee extends also to the purely British colonies, but not to the kindred nation of the United States.

The taste for tea can scarcely be said to be based upon climatic conditions, since it is prevalent in the dry, hot countries of Australasia, in Canada, with its severe cold and brief spells of heat, and in the United Kingdom with its mild and moist arrangement of weather. The Australians, in fact, consume more tea per head than any other nation in the world, the average being as high as 10 lb per capita in Western Australia for 1900, whereas in the United Kingdom it was 6.10 lb per head. That the consumption of this country not only increases with the natural growth of the population, but increases also per capita, the average having steadily advanced, with the exception of a single year, from under 5 lb per head in 1839 to 6.17 lb last year, while the total consumption in the same period has risen from 185 million lb to 255 million lb. So great has been the expansion in tea production in India and Ceylon that even this enlarging market is not sufficient to cope therewith, and it is consequently reassuring to find the demand for tea slowly developing in other countries. Russia is pre-eminently a tea drinker, but the people there are so poor that the consumption per head after years of expansion was in 1901 under 1 lb per head. Germany and France which are coffee-consuming countries, show a tea consumption of only 0.13 lb and 0.05 lb per head respectively. France makes practically no progress as a tea consumer, but in Germany the beverage appears to be slowly gaining ground, while in Holland the consumption has gradually advanced to 1.48 lb per head in 1900. The United States—an enormous potential market for tea—has so far exhibited no really satisfactory expansion. Last year the consumption per head, after a gradual advance since the drop caused by the imposition of the 10 cents duty in 1897, was only 1.14 lb per head. Still the fact that consumption has gradually advanced since the duty of 5d per lb was im-

posed, though only to the extent of 0.21 lb per head in four years, is encouraging so far as it goes, but the progress made is almost painfully slow. Unfortunately the increase in tea consumption exhibited by America and some European countries does not necessarily mean exclusively in Indian tea. Russia still satisfied herself mainly with China tea imported over the Asiatic frontier, Holland takes 50 per cent of her tea from Java, while in the United States more than half the tea consumed is from China, and of the balance about two-fifths come from Japan.

The prospect of increasing the American demand is for our Indian and Ceylon planters if they wish to secure a hold upon that great market, to adapt the preparation of their tea to the tastes of the inhabitants. The victory of Indian and Ceylon over China tea is pretty well complete so far as the market in Great Britain is concerned, but elsewhere there is much to be done, and there is plenty of scope for the propaganda in favour of British tea, which is now being very actively supported.

China, though she has sadly fallen from her high estate, is still the largest tea producer, supplying not only a percentage of what we require, but keeping her customers in Russia and in Holland—which favours Java also—and the United States. China's decline is, nevertheless remarkable, and apparently is almost entirely due to the falling-off of imports to this country.

In the period 1884-86 the amount of tea exported from China averaged 282,000,000 lb, whilst in the period 1893-1900 it averaged 202,000,000 lb, a decrease of 28 per cent.

Meanwhile the exports of tea from the three other producing countries—British India, Ceylon and Japan—have been constantly increasing of late years; in the case of British India the exports have doubled in thirteen years, whilst in the case of Ceylon the export, which is now nearly 150,000,000 lb., was in 1884 only 2,000,000 lb.

Though tea does not seem to vary much in cost to the consumer, its wholesale price is changing, and the tendency is in favour of the consumer. In 1884 the value of the tea landed in this country averaged 11½d. per lb.; in 1900 it averaged about 8½d. The landing value of the tea imported from different countries was British India in 1884, 14.12d.; in 1900, 8.71d. Ceylon, 17.26d. per lb. in 1884; in 1900, 8.59d. China in 1884 averaged 10.59d.; 1900, 7.85d. In the period 1884-1900 the export value per lb. of Indian tea has dropped 33 per cent., of Ceylon tea 50 per cent., and of China tea 29 per cent. No wonder that our planters are anxious to find fresh markets.

COFFEE.

In respect of coffee we have the converse of the position as compared with tea, for Great Britain and her colonies are the smallest consumers of the former, just as they are the largest tea-drinkers. British coffee is a terrible production and it is not popular, though it is used slightly more today than it was. How do we compare with the rest of the world in this respect? The three countries where the consumption per head is the largest are Holland (with an annual normal consumption of from 15 to 17 lb. per head), Belgium, and the United States. In Belgium the annual consumption per head may be put at about 8½ lb. and in the United States somewhat higher, probably over 9 lb. After these countries come

Germany, France, and Austria-Hungary in the order named. These all are the countries whose total consumption exceeds 50,000,000 lb. The United Kingdom falls far below this level with a consumption of only about 2.3 lb. per head of population. As regards total consumption (as distinct from consumption per capita) the United States stands pre-eminent, the quantity of coffee there consumed being nearly as great as that of all the other countries mentioned put together. In Germany the total consumption, though less than half that of the United States, is nearly twice as great as that of France, which takes the second place in Europe as a coffee consuming country.

The consumption of coffee per head is for Australia 0.58 lb and for Canada 1 lb, and the tendency towards an increased demand is very slight. As regards sources of production, it is estimated that in 1900, out of a total export by the chief producing countries of 1,813 million lb, 1,179 million lb came from Brazil, the next largest producers being, in the order named, the Dutch East Indies, Central America, and the West Indies, but the shipments of the most prolific of these secondary countries were under 150 million lb. Curiously enough the direct imports of coffee into this country from Brazil are comparatively small, notwithstanding that we re-export more of the berry than we import. "The very small quantity of coffee that comes to this country from Brazil," says the report, "is worthy, however, of special remark, and even though the greater part of the quantity that comes from the United States be Brazilian, yet the total imports from the two countries are only about one-fifth of the whole." In view of the enormous preponderance of Brazil as a producer this fact is rather remarkable. On the other hand the United States, which is by far the largest coffee market in the world, obtains three-fourths of its supplies from Brazil, and as it imports nearly as much as all the other countries put together, its influence in the coffee market is, of course, pre-eminent.—*H and C Mail*, May 23,

CEYLON TEA COMPANIES IN 1901.

("THE FINANCIAL TIMES.")

Most of the Ceylon tea companies have now published their reports for the past year, and the results shown are, as a rule, not particularly brilliant, though in view of the conditions prevailing they are no worse, and perhaps somewhat better, than might reasonably have been expected. There was, however, one favourable feature in a generally disappointing year in the shape of a small reduction in the total output, and, although this was mainly the consequence of a poorer crop, it was also in some slight measure due to intentional limitation of production, and to the increased attention paid to the finer classes of tea. The prices realised in the early part of last year were extremely low, but towards the end of the selling season a distinct improvement set in, more especially for the commoner descriptions. It may be noted that the finer kinds of tea suffered relatively more in price than the cheaper sorts, partly because the quality was not so good as before, but mainly owing to the demand being concentrated more upon the low-priced qualities. That tendency may possibly have been assisted a little by the higher duty, but the increased impost is now scarcely a factor in the situation,

and the trade has pretty well adjusted itself to the altered circumstances. It is natural that with such adverse influences to contend against the companies should, as a rule, show a diminution in profits; but we may once more point out that those concerns have emerged best from the ordeal which have strengthened their position by making substantial appropriations to reserves in good years. A bird's-eye view of the main results achieved by the leading companies may be obtained from the following table:—

Company.	Nett Profit.		Appropriations for Reserve and Depreciation.			
	1900	1901	1900	1901	1900	1901
	£	£	£	£	p.c.	p.c.
Alliance ...	4,660	4,870	1,000	1,000	7	6
Ceylon Tea Plantations...	41,010	37,199	10,000	5,000	15	15
Dimbula Valley	*11,306	13,501	*1,380	2,500	*10	8
Eastern Produce and Estates ...	15,790	16,839	†nil	†nil	3½	3
General Ceylon Tea Estates...	713	3,717	2,000	2,000	nil	nil
Nuwara Eliya..	18,263	11,893	2,963	2,000	7	6
Standard Tea...	2,148	8,960	2,800	nil	15	15
Scottish Ceylon	5,318	4,154	638	429	10	8
Yatiantota ...	6,753	5,962	1,000	1,000	4	2½

It will be observed that the Ceylon Tea Plantations has been able to maintain its dividend at the high rate of 15 per cent, but in order to do so it has been obliged to greatly reduce its appropriations to reserve. As regards this reserve, which stands in the balance-sheet at £100,000, it may be mentioned that nearly the whole of it has been invested either in the coconut plantations or in the development of the tea gardens. However, notwithstanding the smallness of the actual liquid reserve, the company may be said to be in a fairly sound financial position. It is unfortunate, however, that the coconut plantation, from which so much was expected, should still barely more than pay its way; nevertheless, the outlook in this respect is stated to be now favourable, so that in a year or two's time the company should be able to obtain a fair revenue from this source.

Another company which has maintained its dividend of 15 per cent, in spite of a considerable reduction in net profits, is the Standard Tea. It may, indeed, be doubted, in view of the lower price obtained for the company's teas, whether it was altogether sound policy to make such a large distribution this time, especially as it involved the abandonment of any appropriation for reserve or depreciation. Still, the company is reputed to possess very fine estates, which have been largely improved of recent years, and it is to be hoped that it will be able before long to get back to the higher price level of former years. The Nuwara Eliya has adopted a more prudent course, in face of a marked decline in profits, and has reduced its dividend by 1 per cent, but even to pay 6 per cent it has been obliged to draw on the balance forward. In this case also we may hope that, being a fine tea producer, with gardens at a high elevation, it may experience better luck

* Nine months' working.
† £7,500 of Debentures with bonus redeemed each year.

during the current year. The Dimbula valley, which we may note has altered its financial period so as to coincide with the calendar year, has done fairly well, and is to be congratulated upon being able to put aside a portion of its profits, although at the expense of a reduction in the dividend. This is the only company of those under review whose shares are quoted on the Stock Exchange, and consequently a little more general interest attaches to it than to the others. The Scottish Ceylon, though reducing its dividend, records fairly satisfactory results, considering the conditions obtaining, but public interest in this company's shares is comparatively small and dealings are few. The Alliance is yet another company which has been obliged to cut down its dividend, but has nevertheless got through the year fairly well. In view, however, of the considerable amount of debentures it carries, and of the fact that it has no reserve fund, it can scarcely be said to occupy as strong a financial position as some of its neighbours. The Yatiyantota is notable as being a producer of low-grade tea at a very cheap cost, but the better prices ruling for this class of tea at the end of the season hardly compensated for the very unsatisfactory quotations obtained earlier. At the current range of values the company should be able to improve its position. The General Ceylon Tea Estates has come in for much adverse criticism owing to the general feeling that it was brought out at the top of the boom. We are glad to see therefore that, thanks to drastic alterations in the management, its report shows a considerable improvement, and it seems possible that there may be some future for the preference shareholders, whatever may be thought of the prospects of the ordinary. A slight reduction in dividend is likewise shown by the Eastern Produce and Estates, but the company has still been able to find £7,875 for the usual liquidation of the debentures, whereby it every year improves its financial position. A favourable feature of this company is the fact that it possesses a remunerative agency business, the profits from which, as stated by the chairman at the last meeting, are more than sufficient to defray the entire expenses of the London administration.

It is a truism to repeat that the future prosperity of the tea industry is bound up with the establishment of rational relations between supply and demand. In respect of over-production we are afraid the best that can be said is that we are a little nearer the end of the tunnel than we were a year ago. Some slight improvement in this respect was certainly shown last year, but we have still to face the prospect of the current and the following year's production being in excess of the demand. We believe, however, we are correct in saying that the extensions of gardens have now been brought practically to a standstill; and, further, it appears to be generally admitted that there has been some very considerable abandonment of less remunerative areas, and this goes far to compensate for the opening up of new grounds. The planting community, we are credibly informed, are doing their utmost to limit the quantity in favour of the quality of production, and, although we are not amongst those who believe that very much can be attained by artificial means, the effort deserves every recognition, and is decidedly in the right direction. The bright spot on the horizon

is the opening up of fresh markets, which there is reason to expect will be prosecuted more vigorously than ever. The Ceylon Government has authorised an increase in the forced "cess" imposed on the planters to defray the expenses of the propaganda abroad, while a very influential petition is being presented to the Viceroy of India with the object of inducing the Indian Government to impose a similar "cess" on the planters there. If this movement be successful the future energetic cultivation of foreign markets will be assured. As regards the value of tea shares, the past season has naturally had the effect of greatly depressing prices, the few exceptions only serving to accentuate the general decline. It is probable, however, that in many cases the price has been forced down unduly, as the result of small sales upon a narrow market. Even now we are not prepared to advise people to rush into the market, but at the existing level as presented in the quotations supplied to us from week to week by the Indian Tea Share Exchange, it is quite worth watching. In particular some of the cheaper preference shares, which have been depressed in an undue degree as compared with the ordinary issue of the same companies, merit attention, since they hold out the hope of a considerable improvement in capital value sooner or later. We have not included any Indian tea companies' results in the present review, as, although the season in India coincides with that in Ceylon, only one or two reports owing to the greater distance to be traversed, are so far to hand. In a short time, however, sufficient information will be available to enable a fair appreciation to be made of the results of the year's operations in the great tea gardens of the Dependency.—*Home and Colonial Mail*, May 23.

THE BIGGEST IVORY MARKET IN THE WORLD.

Some day when Mr. Pierpont Morgan is less busy than he appears to be at present he may turn his attention to an "ivory trust." If he does so he will find the biggest ivory market in the world at the London Docks, where the quarterly sales of ivory average over £100,000; 70,000 elephants are slaughtered every year to keep up this supply. Eastern Siberia exports a vast quantity of fossil ivory, chiefly to the Continent, where it is more highly valued than it is in this country. African ivory commands a higher figure than any other description of ivory on the market. The biggest price ever paid for a pair of tusks was £188; they came from Uganda. The average price for ivory in this country runs from £30 to £40 per cwt. A great deal of ivory used to come here from India, but the Indian wild elephant is now getting very scarce and of late years India has actually imported ivory.—*Tatler*, May 21.

PRODUCE AND PLANTING.

The *Journal d'Agriculture Tropicale* for April gave a report by the Dutch Consul at Warsaw which dealt with particulars relating to the

COMPRESSED TEA TRADE.

According to this report more than 53,000,000 kilogs (a kilog is equal to 2·2lb) of tea are annually imported by

RUSSIA,

of which 34,400,000 kilogs consist of brick tea, 18,000,000 kilogs of black tea, 975,000 kilogs of tablets and 280,000 kilogs of green tea. A small quantity of yellow tea is also consumed, which however is too insignificant to be taken into consideration. Green tea is rarely found in Russian households and the great majority of Russians have never tasted it. Tea in tablets is manufactured with tea leaves of inferior quality. They are 130 millimetres long (a millimetre is .03937 inches), 40 wide and 20 thick, and each tablet is divided into eight sections. The tablet weighs $\frac{1}{4}$ lb (Russia) and is enclosed in paper bearing the name of the manufacturer. For packing purposes tin-lined cases, each containing 126 Russian lb, are used. The retail price at Moscow is 1 rouble 10 copecks per Russian lb (about 2s 7d per English lb). All the tablets used at Warsaw bear the name of a firm at Hankow. Brick tea is also manufactured at Hankow. There are two qualities: the first quality measuring 227 millimetres, long by 160 wide and 11 thick, and weighing $\frac{1}{2}$ kilog. each. Bricks of the second quality measure 237 by 183 by 23 millimetres, with an average weight of 1,160 kilog. These bricks are packed in wooden cases holding from 216 to 240lb (Russian). The retail price at Warsaw is 70 copecks per Russian lb (about 1s 8d per English lb) for the first quality, and 60 copecks (1s 5d) for the second quality.—*H. and C. Mail*, May 23.

CEYLON DIVIDENDS.

It is interesting to have the following full résumé of the Dividends of Ceylon Tea Companies for 1901 from the May report of Messrs. Lloyd, Matheson and Carritt of Leadenhall Street:—

- Alliance Tea Company pays a final of 3 p.c., making 6 p.c. for year.
- Augusta Tea Estates Company pays preference, but no ordinary dividend.
- Balmoral Company pays final of 6 p. c. free of tax, making 11 p.c. for year.
- Bandarapolla Company pays 6 p.c. free of income tax.
- Burnside Tea Company pays no dividend.
- Ceylon Tea Plantations pays a final of 8 p.c., making 15 p.c. for year, free of tax.
- Dimbula Valley pays a final of 4 p.c., making 8 p.c. for year.
- Eastern Produce Company pays 1 $\frac{3}{4}$ p.c. making 3 p.c. for year on ords.
- Ederapolla Company pays 5 p.c. free of tax.
- Galaha Tea Company pays 3 p.c. on ords.
- General Ceylon Tea pays no dividend.
- Highland Company pays final of 2 p.c., making 4 p.c. for year, free of tax.
- Imperial Ceylon pays 3 p.c. free of income tax.
- Kelani Valley pays no dividend.
- Lindoola Company pays a final of 1 $\frac{1}{2}$ p.c., making 4 p.o. for year, free of tax.
- Nahalma Company pays no dividend.
- Nuwara Eliya Estates Company pays a final of 3 p.c., making 6 p.c. for year, free of tax.
- Panawal Tea Company pays 3 p.c. on ords., free of tax.
- Poonagalla Company pays no dividend.
- Ragalla Company pays 4 $\frac{1}{2}$ p.c. on ords., free of tax.
- Sunnygama Company pays preference dividends of 6 p.c. up to end of 1901.
- Standard Tea Company pays 10 p.c., making 15 p.c. for year.
- South Wanarajah Company pays 5 p.c. on ords. free of tax.
- Tyspane Tea Company pays final of 4 p.c., making 6 p.c. for year, free of tax.
- Vellikellie Tea Company pays final of 2 p.c. making 5 p.c. for year, free of tax.
- Yatiyautota Tea Company pays 2 $\frac{1}{2}$ p.o. on ords., free of tax.

BRAZILIAN RUBBER TRADE.

In his report of 13th January, the U S Consul at Para says with regard to rubber shipments from the Amazon Valley for 1901:—"The shipments from Para for 1901 show a steady increase over the business of 1900, the total gain being 3,255 tons of which the increase to Europe was 500 tons and to the United States 2,755 tons. In other words Europa took 14,254 tons of rubber from the Amazon in 1900, and the United States 12,621 tons during the same time; but during 1901, Europe took but 14,755 tons and the United States took 15,376 tons. Another significant feature shown by these statistics is the enormous growth of the rubber trade at Manaos, amounting to almost 100 per cent. During the year 1900, there were shipped from Manaos a total of 8,012 tons of rubber, and 13,467 tons from Para. During the year just closed, however, Manaos shipped 15,469 tons and Para but 13,639 tons. This change was caused by the passage of a law in January, 1900, enacting that thereafter all rubber extracted in the State of Amazonas, and all other products of that State, should be shipped direct from Manaos. A large portion of this rubber had formerly been sent to Para. Another feature of these statistics is the large increase in shipments from Iquitos. During the year 1900, Iquitos shipped 920 tons of rubber direct, and in 1901, 1,391 tons, a gain of more than 50 per cent. Next year will probably witness a still greater gain and within a few years the Upper Amazon and its affluents may produce as much rubber as the lower river.

EXPORTS FROM PARA AND MANAOS IN 1901.

	Europe.	U. States.	Total.
	Tons.	Tons.	Tons.

COFFEE IN GERMAN EAST AFRICA.

The boards of the German colonial companies have clubbed together to send out an expedition to experiment with coffee planting in German East Africa.—*Planting Opinion*, June 7.

PLUMBAGO.

Messrs. Chapman, Anthony & Co., of 43, Gt. Tower Street, have furnished the following notes on the plumbago trade to our contemporary. There has been a sensational rise in the market from the low level reached a few months ago and those who had the courage of their convictions and bought in then have since reaped a golden harvest:—

The market during the past week has shown signs of considerable activity and we have put through several contracts in lump, chip and dust at current rates asked by shippers. Our sales have been fairly evenly distributed between the Continent and America. As we go to post, we make the tone of the market rather duller probably owing to the fact that buyers have supplied their immediate requirements. A considerable quantity of plumbago has changed hands on spot in London, as parcels which are being offered here now on estate account are being sold at prices which are considerably less than the Colombo market is asking today for the same quality.

For all good qualities of plumbago the demand seems to be on the increase, but for poorer kinds and for flying dust the supply is greater than the demand. There is some pressure to sell the latter, several parcels being offered at 5s delivered in London which is the equivalent of 4s 6d c.i.f.

HOW GEMS ARE SEARCHED FOR.

The following extracts from "Gold, Gems and Pearls in Ceylon and Southern India" (Messrs. A. M. and J. Ferguson) are of special interest, in connection with H.E. the Lieut.-Governor's visit to a Gempit near Ratnapura:—

There are two ways in which gems are searched for—one in beds of streams, and the other by sinking pits on land, generally on the borders of streams, in which previously search had been made and found to contain the gravel. At Weralupa both plans are now pursued—in the stream which runs through it, and on the meadow lands on its banks, the first discoverer of the deep-seated bed of gravel having been an enterprising resident of Ratnapura. A correct description of these modes of gemming in water and on land (as the phrases run) may not be wholly without interest. In water gemmings the implements and appliances used are few and simple, consisting of a few mamoties (called "Menik Udalo") stout, of an oblong square form, double the size of the ordinary ones, and concave on the handle surface, having a long pole called a *rita*, of greater or less length according to the depth of the gravel, fixed to it for a handle; a few crow-bars to break through any impediment that may be found in the way of getting at the "illan"; a long iron sounding-rod called *Illankoorā*, and a close wicker-basket called "*Menikvattia*," made of the prepared split bamboo-reed (*bata*). This wicker-basket is an admirable contrivance for the purpose it serves: it is basin-shaped but more conical and about two feet in diameter, with a strong rim of rattan. A dry season of the year being selected, generally between December and March, when the water in the streams is low and sluggish, the gem-men commence operations by putting away the sand in the spot selected, sounding with the sounding rod from time to time to see whether the gravel is at an accessible depth. In this part of the business the ordinary coolies assist, but not after the gravel has been exposed—when only

THE INITIATED GEM-MEN

work. In the way of getting at the gravel, sometimes the impediments of the trunks of trees and blocks of rocks are found, but almost invariably a sort of crust called "*catooa*," has to be got through. The illan commonly lie just under this *catooa* or crust which presents different appearances at different places, though at times it is entirely absent. It is seldom of greater thickness than a few inches, but its hardness varies from almost that of granite to sun-baked bricks. Just under this crust, which varies in colour also in different localities, is found the illan resting on a bed of clay of greater or less thickness, and of different colours, even at short distances of space called "*Malawa*." I have seen it green, blue, grey, reddish, and at Balangoda deep yellow; but the first-mentioned colours are reckoned the most promising. It is said that under the stratum of clay another bed of gravel has been found, richer than the one on the top, but of this I have no

personal knowledge. The gravel being exposed though under water, it is slowly and steadily cooped out with the mamotie above-described, its concave form facilitating this, and being brought to the feet of the man engaged, is then deposited in the "*Menik Wattia*" (wicker basket) held under water with his feet. A sufficient quantity of illan being collected, he lays by the mamotie and washes it himself, or hands it over to another to wash, and goes on with the mamotie work. The washing of the illan is the next operation to be described, and is performed on this wise. The basket being held under water by the rim, the illan in it is rotated with a quick motion, by which the clay, now dissolved, and the lighter particles of stone are thrown out at the rim. From time to time the larger stones are taken up examined and rejected if they are not gems. The whole is now reduced down to what is called the "*Nabooa*," which is the heavy, thin sand, mostly composed of particles of precious stones, jet and the gems, the objects of search, settled down by reason of their greater weight at the conical part of the basket. The basket is then brought ashore and the *nabooa* examined, when the precious stones are easily recognised and removed. The foregoing is a brief account of gemming in water.

GEMMING ON LAND

is done in the following manner:—The place being selected, also in the dry season, the operations of pitting are begun, the pit being invariably of the square shape. The earth being removed to the level of the water, it becomes soft. From this stage commence at the sounding of the pit from time to time to ascertain whether the illan is at a practicable depth, the "*illankoorā*" in the hands of the experienced seldom misleading. The illan being found, the gem-men are obliged to re-double their exertions as now they have to contend against the influx of water which they are obliged constantly to bale out, and this the more as they get nearer the above described "*crust*," over which generally lies a bed of very permeable sand of greater or less thickness. The sand being got rid of, the illan is got at either after breaking through the *catooa* or not, if it does not exist. The illan is detached from the bed of clay with the crow-bar and heaped up to be washed, but the larger stones that are found have almost all been discovered whilst breaking the illan from its situation. After collecting the gravel, its washings take place either in the pit itself, if there be sufficient water in it, or in an adjoining stream or pond, and this by the above-described basket. It ought to be mentioned that the whole of the pit is not gemmed at once: the earth of only one-half is wholly removed at first, that of the other half being partly left constructed into a flight of steps to expedite the removal of earth and the baling of water. The first being exhausted of the gravel, the earth of the remaining half is thrown into the empty space, and the illan got out, thus saving a good deal of labour. I also omitted to mention that in gemming in water the sand of the spot on which the men with the mamoties stood, which spot is called "*Hetty Katlia*," is invariably washed in order to detect any pieces of gem which might have fallen into the water in the act of transferring the illan from the mamoties to the washing basket,

CEYLON PROPRIETARY TEA ESTATES COMPANY, LTD.

Directors.—Messrs. G A Talbot (Chairman) H K Rutherford, R A Cameron, F H Wiggins, Secretary. —Sir Wm. Johnston, Bart, Manager in Ceylon.—Mr. H V Masfield. Office.—20, Eastcheap, London, E.C.

Report of the Directors to be submitted at the Fifth Annual Ordinary General Meeting of Shareholders, to be held at the Office of the Company on Tuesday, 13th May, 1902.

The Directors herewith submit the General Balance Sheet and Profit and Loss Account for the year ending 31st December, 1901, duly audited.

The nett amount at credit of Profit and Loss Account, after providing for General Expenses, Income Tax, &c., is 3,505 19 5

Debtore Interest paid to 30th Sept., 1901 (less Income Tax) amounts to £709 7 6
 Less from last Account 178 2 6
 531 5 0

Three months' Debtore Interest to 31st Dec., 1901 (less Income Tax) amounts to 211 17 6

Preference Dividends paid for 1901 (less Income Tax) amount to 1,232 17 3

It is proposed to write off for Depreciation 750 0 0

And to carry forward to next year a Balance of 779 19 8

£3,505 19 5

During the past year the Company's Estates have given a yield of 407 lb. per acre against 490 lb. in 1900.

The gross price for the Teas sold in London and Ceylon averaged 6.36d. against 6.10d. last year and the rate of exchange is 1/43d against 1/4 13-32d.

The low prices ruling for medium and low elevation teas in 1900 continued in 1901, but it is a matter for satisfaction that the prices realised for the Company's teas have been higher than during the previous year. The shorter output caused by a very unfavourable season on, and to some extent by more careful plucking, has, however, seriously reduced the profits.

The following statement shows the results of the working of the Company for the last five years:—

Year.	Acres of Tea in Bearing.	Yield per Acre.	Sale Price of Tea, d.	Tea Manufactured for others, lb.	Total Tea, lb.	Profits, £
1897	2100	413	6.90	89,307	990,816	6,277
1898	2105	407	6.94	94,370	990,251	4,834
1899	2111	439	7.11	1,681	990,848	6,790
1900	2071	490	6.10	3,331	1,119,124	3,691
1901	2165	407	6.36	..	936,485	3,124
Exchange for five years.—1897 1/3 15-32 1/4, 1898 1/4 15-64d, 1899 1/4 13-32d, 1900 1/4 13-32d, 1901 1/4 13-32d.						

* Estate Tea for five years.—1897 868,710 lb., 1898 857,351 lb., 1899 927,395 lb., 1900 1,016,412 lb., 1901 883,174 lb.

* Bought Leaf Tea for five years.—1897 32,799 lb. 1898 38,530 lb., 1899 61,772 lb., 1900 99,351 lb., 1901 53,311 lb.

Under Clause 69 of the Articles of Association, Mr R A Cameron retires from the Board on this occasion, but being eligible, offers himself for re-election.

The Auditors, Messrs. Harper Brothers, Chartered Accountants, also retire from office, and offer themselves for re-election.

By Order of the Board, Wm. Johnston, Secretary.
 London, 5th May, 1902.

OUVAH COFFEE COMPANY, LIMITED.

(Incorporated in 1896.)

CAPITAL £100,000 IN 10,000 SHARES OF £10 EACH.

DIRECTORS:—Alfred Brown (Managing Director) L Famin; J G Wardrop and P C Oswald. SECRETARY:—J Alec Roberts. Offices.—5, Dawgate Hill, London, E. C.

REPORT

to be presented to the Seventh Ordinary General Meeting of the Company, to be held at No. 5, Dawgate Hill, London, on Thursday, the 15th day of May, 1902 at 12 o'clock noon.

The following Annual Accounts are now presented to Shareholders, viz:—

Balance Sheet made up to 31st December, 1901. Profit and Loss Account for the year ended 31st December, 1901.

The receipts from the sale of produce were as under:—

	£	s.	d.
Tea from the Company's own estates	1,029,400		
Tea made from bought leaf	68,666		
Total	1,098,066	31,574	1 2
Coffee 220 cwt. 0 qr. 13 lb.		881	14 3
Cocoa 31 cwt. 0 qr. 15 lb.		218	8 1
Cinchona 2,889 lb.		46	10 9
Sundry sales in Ceylon		117	16 0
Value of Cinchona Bark and Cocoa under-estimated last year		603	6 9
Total receipts	£33,441	17	0

The total expenditure in Ceylon and London amounted to £27,053 10s 10d, and deducting this from the value of the produce a profit is shown of £6,388 6s 2d, to which has to be added the balance of £705 5s 4d brought forward from the previous year, making a total of £7,093 11s 6d at the credit of profit and loss.

From the above sum the Directors have transferred to the credit of Badulla Factory account (£50). The interim dividend of 2½ per cent, paid on 15th, November, 1901, absorbed £2,500, and Income Tax £332 2s 1d, leaving a balance of £3,761 9s 5d, out of which it is proposed to pay a further dividend of 3½ per cent, making 6 per cent for the year and to carry forward to next account the sum of £261 9s 5d.

Climatic conditions during the past season were not favourable, and this, combined with a system of finer plucking, reduced the yield of made tea to 520 lb. per acre, against 602 lb. secured during the year 1900.

The finer plucking improved the quality of the tea, which sold at an average of 6.90 per lb. against 6.10 for the previous reason, but the smaller yield enhanced the producing cost, which rose from 24.51 cents to 28.13 cents f. o. b. Colombo.

The policy of liberal cultivation has been continued, and the Company's properties are reported to be in good heart and condition throughout.

Mining on the line of the plumbago vein has been suspended, owing to the difficulty of keeping the vertical shafts ventilated and free from water at the increased depth. Work is at present confined to driving a low-level inclined tunnel, which is expected to cut the vein of plumbago, well in advance of the present workings. This tunnel will form a natural drain from the mine, and all ore bodies will be removable by means of gravitation, which should reduce the cost of working to a minimum.

The acreage of the Company's property is now as follows :—

	Acres.
Tea, over 5 years old ...	1,926
Do Planted Nov.-Dec. ..	1897 133
Do do ..	1898 23
Do do ..	1899 18
Do do ..	1900 40
Do do ..	1901 46
<hr/>	
Area under Tea ..	2,186
Area under Coffee and Cocoa ..	341
Area under Fuel ..	336
Forest, Patna and Waste ..	712
<hr/>	
Total Area ...	3,575

Mr. J G Wardrop, a member of the Board, retires on this occasion, and, being eligible, offers himself for re-election.

Messrs. Deloitte, Dever, Griffiths & Co., the Auditors, also offer themselves for re-election.—By order, J. ALEC ROBERTS, Secretary.

London, 5th May, 1902.

HUNASGERIA TEA COMPANY, LTD.

REPORT OF THE DIRECTORS.

To be presented to the seventeenth ordinary general meeting of the Company, to be held at No. 5, Dowgate Hill, London, on Thursday, the 15th day of May, 1902, at 1 o'clock p.m.

The following accounts are now presented to share holders, viz:—

Balance-sheet made up to 31st December, 1901.

Profit and loss account for the year ended 31st December, 1901.

The tea crop amounted 353,030 lb. of which 348,760 lb were sold in London for £3,873 3s 11d, giving an average selling price of 6'10d per lb. Tea was sold in Ceylon to the value of £69 3s 3d.

The expenditure in Ceylon and London, inclusive of £331 11s 7d spent on machinery, amounted to £9,901 15s 5d, showing a loss of £959 8s 3d on the year's working, and after adding to this the balance of £527 6s 3d brought forward from last year, there is a sum of £1,486 14s 6d at the debit of profit and loss account.

The area under tea remains at 763 acres, of which 31 acres are in partial bearing.

At the commencement of the year under review the price of medium quality tea stood at a level considerably under the cost of production.

In these circumstances it became necessary to make a change in the system of working, and during the past year, fine plucking has been resorted to, which reduced the crop to 353,030 lb. against 479,170 lb. secured during the previous year.

This step was taken in conjunction with the majority of tea gardens similarly situated in Ceylon and India and the desired result of curtailing supplies has to some extent been attained; a less favourable flushing season has also helped to keep supplies within moderate limits.

During the last six months of the year the estate worked to a profit, which has gone to reduce the heavy loss sustained before prices had time to respond to the effect of shorter supplies, and the new year has commenced on a better basis.

The cultivation of the property has been fully maintained, the bushes continue to crop well, and the future entirely depends upon market conditions.

Mr J G Wardrop, a member of the Board retires from office on this occasion, and, being eligible offers himself for re-election.

Messrs. J and J Sawyer & Co., the Company's Auditors, also offer themselves for re-election,

THE ANKANDE ESTATE COMPANY OF CEYLON, LIMITED.

REPORT OF THE DIRECTORS TO 31ST MARCH, 1902

DIRECTORS :—Messrs. John Aymer, Chairman ; H Creasy, W. Rae Sands. Agents and Secretaries :—Messrs. Baker and Hall.

ACREAGE.

Tea	156 acres
Cocoa and Liberian Coffee..	104 „
Cardamoms	95 „
Jungle	197 „
<hr/>	
Total ..	552 acres.

The Directors have now to present to the Shareholders their Report, Balance Sheet and Profit and Loss Account for the year ending 31st March, 1902.

Interest on the loan of £1,500 has been paid to 36th June, 1901, but it has since been in arrear, and depreciation on buildings, viz: R250'93 has been written off.

The Directors regret to say that a sum of R2,104'70 remains lying to the debit of Profit and Loss Account, owing to the poor results of the working account which is entirely due to the shortage in crop.

The Total Crop harvested during the year were as follows:—

ANKANDE.	
Tea	1b 55,415
Cocoa	Cwts. 42-7
GLENURY.	
Tea Green Leaf ..	1b 9,778
Cocoa	Cwts. 46-2-0
ALTWOOD.	
Cardamoms	1b 2,413

and a small quantity of minor products were sold.

Mr. W Rae Sands retires by rotation and is eligible for re-election.

The appointment of an Auditor for 1902 will rest with the Meeting. By order of the Directors,

BAKER & HALL,
Colombo, June 2, 1902. Agents and Secretaries.

PLANTING NOTES.

KWANGO RUBBER.—I note that according to Mr. Deghilage, who has been for some time in the Western Kwango District of Africa, that rubber can be collected and sold in the district for 80 centimes per kilogram. The transport to Matadi costs 8 francs for 35 kilos., and the rubber is sold in Europe at 4 francs to 4-50. Surely this trade is worth developing.—*India Rubber trade Journal*, May 12th.

TOBACCO AS A GERMICIDE.—The "Lancet," replying to the invitation of "The Daily Chronicle" to make some declaration concerning the influence of tobacco on microbic life, regrets its inability to say anything definite on the point. That which it makes clear by a reference to the experiments of Tassanari is that when steeped in dense tobacco smoke for many hours certain disease germs were either scotched or kil'ed. The "Lancet" remarks that the conditions of the experiments cannot of course be represented in the use of pipe or cigar. Yet it is not at all unlikely that a very considerable effect may be produced on mouth microbes (many of which are quite harmless) by the ingestion of tobacco smoke. Possibly the soil is rendered a less fertile one for microbe development; but microbes have an evil habit of breeding rapidly, and in the contest it is quite likely the tobacco makes only a feeble second after all. As yet I am afraid we who smoke cannot present the germicidal power of the weed as a strong argument for the anti-tobacco societies to tackle.—*Daily Chronicle*, May 8.

RAINBOW TROUT FOR EVERY RIVER AND STREAM IN CEYLON.

We direct attention to a very important suggestion made by "Piscator" in a letter which we publish elsewhere. We would ask the Committee of the Fishing Club at the earliest possible date to lay the subject and proposition—if they approve—before His Excellency the Lieut.-Governor. It is a matter of great importance to the whole community of Ceylon to add to the local Food Supply, and especially to make such a welcome addition as that of rainbow trout. "Piscator," who must know what he is saying, insists that they can be acclimatized to sea-level, so that every "ganga," "oya," and even "ella" in the island, may have the benefit of the introduction. We need say nothing in regard to the very welcome and enjoyable sport the fishing of such trout should afford. We put the matter at present, entirely on a utilitarian basis, and we trust the Fishing Club will induce the Government to take the needful action. If the Legislative Council were sitting, a motion could be made by one of the unofficial members. But, in any case, a matter of such general advantage and utility, must not be overlooked.

CEYLON AND ECONOMIC PRODUCTS.

At last we are to have a reliable hand-book on the Vegetable Economic Products of Ceylon, whether they be native or imported. The Supplements, which are now being issued with the "Annals of the Royal Botanic Gardens," Peradeniya, are being compiled by Messrs. J. C. Willis and Herbert Wright, and appear to contain all available information regarding the various products which are dealt with. The latest Supplement dealt with Gums and Resins, and will be followed by an account of our Caoutchoucs Guttaperchas, Oils and Fats, Dye Stuffs and Tanning Substances, Fibres, Drugs and Medicinal Products. Edible Products, Timbers, Miscellaneous Products and Useful Plants. This is a great work and if we mistake not, should form a volume which for accuracy and detail will compare favourably with that of Dr. Watt on the "Economic Products of India"—one of the most useful compilations in our library of reference.

TROUT OVA.

BROWN TROUT OVA.

Of the first consignment of Brown Trout Ova which turned out so very successfully, and of which we gave our readers a statement as to the manner in which they had been distributed in various streams and shewing 1,500 fry as being still left over in the stew ponds, some few commenced to die in twos and threes, of some disease, daily. Health having been completely restored in the hatcheries, the balance of the fry were late last week put out in the streams in and about Hortout Plains, while the remaining 683 were placed out in streams and about the town.

RAINBOW TROUT OVA.

Both consignments, owing to bad packing, as is known have proved failures. The actual result of the turnout, of two consignments, is estimated as early 1,600 fry, of which some died in larger numbers than the Brown trout fry during the 2nd

and third week in May. These fry are now healthy and are said to be doing very well. 300 of the fry have been sent to Mr G G Ross Clarke early this week. Mr John Fraser is expected to remove 200 other fry during the present week.

THE BREEDING OF RAINBOW TROUT IN

NUWARA ELIYA STREAMS.

Mr J Wickwar's letter having finally established the fact, any "doubting Thomas" who would like to satisfy his doubts would do well to visit the little tributary stream branching off in a curve from the main stream running parallel with the drive into Saint Andrew's Hotel. Here the writer who had been in quest of proof, had his attention drawn to a shoal of little fry barely $\frac{1}{4}$ inch long.—*Cor.*

THE BEGINNING OF THE INDIAN TEA SEASON, 1902-1903.

Yesterday the new tea season, 1902-1903, was fairly inaugurated. What is it to bring forth? That is the present question. The days are past when tea producers and merchants entered upon each new season with light hearts and pleasing interest. The interest is there still, but it is of a much more anxious order than formerly. No longer is it, in the majority of cases, What are we going to make? but, What are we going to save? No longer do we look forward with pleasure to a big crop, in the sure and certain hope of clearing some more China tea out of our way and making room for our produce.

At present there is no reliable indication of what the present season will bring forth in the way of quality or quantity. The first teas are of the usual non-committal order. Those that were offered yesterday were neither very good nor very bad, though on a slack market they were depreciated. Cachars were perhaps a bit bolder than last year and it may be that this mark a return to the manufacture in vogue before the movement for turning out a finer tea took hold in the Surma Valley in 1901. If the Surma planters found last year's alteration did not pay, they cannot be blamed for returning to their old style of tea making, and at all events there are none to dictate to them. Each district is entitled to adopt its best gait. Of the all-important Assam there is little opportunity at present of judging. But few invoices are on the Calcutta market and there is nothing particular in these. Terais are a bit disappointing after the one or two nice teas that came from the sub-Himalayan district and were snapped up as soon as they reached Calcutta a fortnight ago. Darjeelings are plain, but the hill teas will improve as usual with the May flush and no judgment can be passed on the first plucking.—*Indian Gardening and Planting*, May 22.

AUSTRALIAN COFFEE CULTIVATION

Among the future industrial possibilities in New South Wales is that of coffee cultivation on a remunerative basis. It has already been successfully introduced into Queensland, where it furnishes employment to about a couple of hundred workers. Nearly a quarter of a century ago encouraging experiments were made in the Clarence River district, in the northern portion of the parent State, when,

from the very outset, it was demonstrated that coffee trees would grow and yield good crops of berries. There were coffee trees growing in Grafton, the beautiful Northern Coast Metropolis, upwards of 30 years ago, which yielded good crops, and at the present time several, over 25 years old, healthy and productive, are to be met with. The cultivation and treatment of the trees have (says a recent visitor) a great deal to do with the production of a berry of good quality and flavour. Then in the transformation of the berries into the brown powder-like substance which makes the popular beverage, there are many processes, on the proper execution of which depends the preservation of the essential qualities of the coffee in a form which readily assimilates with boiling water. The leading experiments in cultivation were made on a river island having an area of about twenty acres, the coffee plant being grown with other crops. Last year there were about 580 trees in bearing. It is estimated that coffee should be planted 8 feet by 8 feet, which would give 680 trees to the acre. The average production of berries on each tree is 10 lb, from which 2 lb of manufactured coffee is made. This, at 1s per lb wholesale, would be £68. The principal cost is the picking of the berries, which is put down at £3 per acre "pulping" costs £1 10s for the product of an acre; fermenting, bleaching, and cleaning, £1 16s; roasting, £3; tinning and labelling, 15s. Total.—£13 6s for the produce of each acre. This leaves a profit of over £50 an acre, not counting cultivating expenses. These, however, are light once the trees have been planted and well grown. The ground must be kept cultivated, and the trees pruned. The work of picking the berries is light, and may be done by boys and girls, one person being able to pick from 100 lb to 150 lb per day. The next operation is that of "pulping." This is done by means of a small wooden roller, with corrugations on its surface. The object of this operation is to crack the shell, which contains two beans of a bluish-white colour. The machine used for this operation is of the grower's own construction, and with it two boys can treat 2 cwt per hour. The beans have also to undergo a process of cleaning, in which an "Enterprise" bone mill (costing £1 10s) is used. They have also to be fermented, dried and bleached, in the course of which they must be exposed to the sun on stretchers, and brought under shelter at night, and when the weather is showery. These processes cost £1 16s for the produce of an acre. The roasting process is estimated at about £3 per acre. For grinding a newly-patented American machine (costing £2) is used, which puts through 20 lb per hour. The usual addition of chicory is mixed with the coffee. Last season's coffee speedily established a reputation for its quality on the Clarence and Richmond Rivers, and has become a favourite with all who have used it, thus ensuring a ready market for all that can be raised in the future. From this it would appear that those practically acquainted with the work of Coffee cultivation would possess unlimited opportunities for turning their knowledge to profitable account in New South Wales.

Did you ever read anything more idiotic than the remarks of an Australian Journalist on Tropical products? I recollect in the Melbourne Exhibition seeing samples of coffee from some district with a descriptive pamphlet stating that the coffee was grown from the "finest pea-berry variety!"—*Old Colonist.*]

TERRIERS AND A COBRA.

Mr. C W E Cotton, I O S, Hosur, Salem writing in the *Madras Mail* of the 24th says— "James" and "Dolly," two English-bred fox-terriers which I am looking after for Mr. F Gompertz (now on furlough), killed a large cobra measuring 5 ft. 1 in., in the compound of this bungalow this morning. "Dolly" found the cobra lying up in some long grass on a high bank and proceeded to haul it down by the tail. It was not until it reached level ground that I realised she had got hold of a cobra, and, though I tried to call her off, she was too excited to pay any attention. At this point "James" joined issue and gave the cobra the *coup de grace*. It was a very smart piece of work, and simply a miracle that neither dog was bitten, as the cobra showed plenty of fight and their agility alone saved them. It was an exceedingly exciting five minutes for myself and Mr. F J Richards, I.C.S., who were the sole spectators.

ACETYLENE LAMP.

Le Phare Agricole—MEDUSE.

This lamp, for the destruction of night, butterflies and other insects, seems worth noting. The price is moderate, *i.e.*, 16 francs (12s 10d), including packing and delivery anywhere in France. Address: V. Vermores, Villefrance, Rhone, France. The lamp is simple and strong, and cannot blow out in the wind. It is easily filled and for the intense light it gives is very inexpensive, costing, in France, only about a farthing an hour. Dazzled by the light, the butterflies fall into the receptacle around it, which contains water upon which floats some kerosine, and are drowned. When butterflies are numerous they are caught by hundreds in a minute. One lamp has been known to dispose of 5,000 creatures in the night. In vineyards the lamps are placed 50 yards apart, and only lighted on calm nights; if it is cold or windy, the insects seek shelter, and are not flying about. We publish these particulars by particular request for the benefit of planters and others.

THE DETERIORATION OF RUBBER.

Mr. James D. Sargent, of the Scottish Vulcanite Company, in a letter published in our issue of March 21st, takes exception to our statement that in the last 20 years a considerable improvement has taken place respecting the loss on washing of a number of rubber qualities, and he points out that this can refer to African qualities only. But Mr. Sargent must have overlooked that this is all we desired to call attention to. From the list we appended to our remarks, it is perfectly obvious that at best the high-grade qualities, as perhaps the American qualities as a whole, have only just held their ground. Therefore, there is hardly any difference of opinion between us. Mr. Sargent goes a step further and asserts that the present loss on washing fine Para rubber is at least 18 to 19 per cent. If this is his actual experience this is difficult to contradict, but this experience is indeed not the writer's. In a considerable number of lots of fine Para, washed during the last two years and selecting only the top 7 figures, the following losses were ascertained:—16.1, 15, 15.0, 14.9, 15.9 per cent. The quantity of resinous matter in these same lots

varied from 2.2 to 2.9 per cent., average 2.5 per cent.; the amount of ash varied from 0.27 to 0.59 per cent., average 0.41 per cent. These figures, certainly do not support Mr. Sargent's contention, but they would tend to show that the quality of fine Para has remained stationary.

It is not easy to account satisfactorily for the reason of the great difference between Mr. Sargent's contention and the above-quoted figures. The difficulty in this respect is all the greater as the numerous complaints, which have recently been made regarding the serious adulteration of fine Para, must have some foundation in fact, although the writer has not succeeded so far in obtaining a specimen of such an adulterated sample. Perhaps the washing losses quoted by Mr. Sargent were obtained with such adulterated lots.

The fact that adulterated Para begins to appear in the market appears to us an ominous indication of the state of affairs in the rubber districts of the Amazon. It seems to us highly probable that as the distances which the rubber collectors have to travel, in order to find a sufficiency of trees worth bleeding, increases from year to year, at the same rate also increases the danger of the rubber being adulterated. If this is so, the determined efforts now put forth in all parts of the world to make the cultivation of rubber trees a commercial success come none too soon.—*India Rubber Trades Journal*, April 28th.

TEA IN THE UNITED STATES.

New York May 7.

The market continues favourable to sellers of both Moyune and Pingsuey greens which bring full prices. Young Hlyson firsts Moyune, 32c to 35c; Pingsuey Gunpowder firsts 31c to 33c; Blacks barely steady; Formosa superior, 26c to 27c. Japan steady. Today at noon the Montgomery Auction and Commission Company hold their regular auction sale of teas. The offering comprises 3,571 packages as follows: 62 packages Moyune, 47 half-chests Japan (basket-fired and dust), 839 half-chests and boxes Congon, 273 packages India, Java and Ceylon Pekoe, 653 half-chests Foochow, and 1,697 half-chests and boxes Formosa.—*American Grocer*.

CEYLON TEA COMPANIES IN 1901

A year ago many of those interested in the Ceylon industry had come to the conclusion that although the official scheme for reducing the output had fallen through as unworkable, much might be done in the way of improving the prospects by individual effort in the way of more careful selection of the leaf. This, however, as we pointed out at the time, was not enough in itself to bring about a recovery in price sufficient to compensate the planters for their smaller output, and the policy of reckless extension of the planted area would also have to be abandoned in favour of a more conservative plan which would regulate the increase in the acreage by the growth of the demand. Apparently this has been done to some extent during the year but the companies have had to suffer for their folly in the past, and nearly all of them show an enlargement of their plucking area. In spite of this, however, the efforts to restrict production evidently made some headway, although the heavy decrease in crops cannot be altogether ascribed to the forethought of the planters. Much of it was due to the adverse climatic conditions which prevailed at the beginning of the plucking season when the bad

weather and heavy hailstorms experienced did considerable damage to the bushes, and necessitated the exercise of even greater care than would otherwise have been the case to avoid permanent injury. Several of the companies venture to estimate their production for the current year, and these appear to have learnt little or nothing from past experience, as they are apparently preparing to increase their outturn again with little thought for the probability or otherwise of a commensurate improvement in the demand.

Prices in the first six months of the year continued poor, but in the second half there was a decided recovery, due no doubt to the market having by that time realised that supplies would be reduced by the causes mentioned above. The public, however, turned its attention chiefly to the poorer qualities and for that reason the average prices secured, although higher than those for 1900 in most instances, could not be said to be altogether satisfactory. Several of the larger companies were unable to do more than maintain the 1900 level, while others, notably the Dimbula Valley and Standard, experienced serious reductions, the first of 0.87d., and the second of 0.80d., and among the smaller companies, producing less than 500,000 lb., the Highland showed a decline of 3/4 to 7/4d. The Alliance, Eastern Produce and Estates, and General Ceylon on the other hand realised moderate gains of 0.15d to 0.40d.

These higher values were insufficient in many instances to help the undertakings to secure larger revenues, partly because they were realised on smaller quantities of tea marketed but also because working expenses were proportionately heavier. The Ceylon Tea Plantations and the Standard of Ceylon managed to maintain their dividends at 15 per cent., but in both cases it was at the expense of the allocations to reserve and depreciation, which in the first-named were reduced by half and in the latter abandoned entirely. By the same plan of reducing the depreciation allowance from £62g to £300 the Elerapola contrived to increase its distribution to the shareholders by 2 per cent. to 5 per cent. The Imperial Ceylon Company with an increase of over £700 in its net profits, again transferred £500 to depreciation account and increased its dividend by 1/2 to 3 1/2 per cent., the Bandarapola paid 6 per cent. against *nil* in 1900 and the Rangalla paid 4 per cent in each year, in addition to doubling its depreciation allowance. These, however, were the only companies to improve or even maintain their previous record and all the others were forced to ont down their return to the shareholders from 1 to 2 per cent., notwithstanding the fact that most of them at the same time devoted less to depreciation. The Nuwara Eliya was perhaps the most prominent example of this unfortunate state of affairs, and was only able to pay 6 per cent. compared with 7 per cent. a year ago, after setting aside £4,655 less, but the Portmore was still more to be pitied, as it could not afford to make even the same small provision of £207 as in 1900 in its effort to keep up the dividend, and even then had to be content with paying 12 against 13 per cent. Such a record as our tables display are not calculated to induce any great hopefulness for the future, especially as the results of the over-planting have not yet been felt to their full extent, and there is every prospect that the trade will have to face a still great excess of supply over demand unless the

efforts now being made to find new outlets for the produce of the gardens meet with a more ready response than at present seem probable or even possible. In time no doubt the new markets will be opened up, but until they are secured the industry will have a hard struggle for existence.

"SOLUBLE TEA EXTRACT."

A CEYLON PREPARATION TO BE EXPLOITED BY A LIMITED COMPANY.

"Soluble" tea is by no means a new idea. Many attempts have been made by different people for years, but without success, to produce an extract of tea, which would retain all the well-known and popular characteristics of tea in its ordinary form. The local inventors (Messrs. John Rogers and Kelway Bamber) of the new "Soluble" tea, claim that, by their patented process, they have produced an article which makes a sound wholesome cup of tea and one which has been favourably reported on by experts and others in Ceylon, England and elsewhere. This

"SOLUBLE" TEA IS ABSOLUTELY PURE

and no chemical or chemical process is employed in its manufacture. Moreover, its keeping qualities are proved by the fact that samples made two years ago are still favourably reported on. Like ordinary tea it must be kept in air-tight packages; otherwise, owing to its having a similar hygroscopic character it will in the same way lose in point and quality if exposed to a moist atmosphere. Its convenience in use is evident from the fact that the mere addition of either hot or cold water is all that is necessary, sugar and milk being added to taste. It is expected that its convenience in use will find for it new markets in countries where tea is scarcely in use at all, and in Continental armies and navies and that it will be used by travellers, the man in a hurry, and colonists, and others in out-of-the-way places. Its purity and wholesomeness will commend it to people of weak digestion, as a cup of "Soluble" will contain less tannin than a cup of ordinary leaf tea. "Soluble" tea will

SUPPLY A LONG-FELT WANT

in tea such as the wellknown essences did in coffee. It certainly will not displace tea in its ordinary use, but it will be used when it would not be convenient to infuse leaf tea in the usual way. It will doubtless displace coffee essences in some measure, and some so-called non-intoxicating drinks. "Soluble" tea can only be made from good green leaf. In fact, as in ordinary tea manufacture, the better the leaf the better the tea, and a blend of samples made from different estates in different districts has been found to give the best results. It is expected that, as for every pound of "Soluble" tea made three pounds of leaf tea will be removed from the market, the introduction of this new product will in some measure

RELIEVE THE OVER-SUPPLY OF THE MEDIUM SORTS OF TEAS

which bulk so largely in the tea-sale lists both in Colombo and London. "Soluble" tea manufacture will be carried on in the existing tea factories, but will probably require more personal supervision than ordinary leaf-tea making.

THE PLANTING ENTERPRISE OF
CEYLON.

IN JUNE 1902 :

IN TEA, CACAO, CARDAMOMS, CIN-
CHONA, RUBBER, COFFEE AND MINOR
PRODUCTS.

6,000 ACRES LESS IN TEA ; 5,000 ACRES
MORE IN RUBBER, CARDAMOMS,
CINCHONA, CACAO, ETC.

Omitting the usual elaborate analysis and review, we summarise the information sent to us in correction of our Directory and here present the results in the briefest possible form :—

	Acres.
Total area of 1,906 plantations and planting properties ..	817,933
Total area of 1,539 plantations in cultivation with 1,493 Superintendents and Assistants (apart from Conductors, &c.) ..	460,215
Total approximate extent under Tea ..	392,343a
Do do Cacao ..	24,136b
Do do Cardamoms ..	8,621
Do do Coffee (<i>Ara-</i> <i>bica</i>) ..	4,304
Do do Coffee (<i>Libe-</i> <i>rica</i>) ..	758
Do do Cinchona [8 to 9 million trees or plants] =	3,471
Do do Rubber ..	2,356c
Do do Grass (Culti- vated) ..	4,461
Do do of Camphor, Annatto, Coco, Kola, Ramie, Vanilla, Pepper, Cloves, Citronella grass, Divi-Divi, Croton, Castor-oil, Aloes, Cinnamon, Tobacco, Cotton— in our plantations' list ..	11,201

Coconuts, Arecas, Nutmegs, Fruit trees (on the cacao, tea, or coffee plantations) ..	22,696
Of Fuel, Timber, Sapan, and Kapok (on the tea, cacao or coffee plantations) ..	7,576

The most notable fact is the falling-off in the area of Tea—our total in cultivation on plantations being 4,000 acres less than a year ago, or including native gardens a decrease of 6,000 acres, making a total of 386,000 in place of 392,000 acres. This must be due to the abandonment of non-paying fields and some unprofitable gardens; for it is accompanied by an extension of the total extent in cultivation by 1,000 acres, although poor "Coffee" has gone down, being 3,200 acres less than a year ago. Cacao on the other hand is 500 acres more in planted extent; Cardamoms are greater in area by 1,800 acres; Cinchona shows an increase of 1,000 acres; and Rubber of nearly 1,000 acres—which must, however,

be rather under the actual area planted during the year, our total extent planted being about 3,400 acres. In several minor products, too—Camphor, Nutmegs, Crotons—there has been a good deal of planting; and still more have we had in the Kelani Valley and other low-country estates, a planting out of Coconut Palms among the Tea, just as Para Rubber has been put in freely on the Kalutara tea estates.

The check to Tea, and the fact that there are no clearings this year to plant, ought to strengthen the hopes of those who believe in a future for our staple, so soon as consumption overtakes production. A year ago we anticipated that there would be 400,000 acres under Tea at an early date in Ceylon; whereas now we are in reality back to 386,000 with no immediate prospect of extension.

PLANT SANITATION IN INDIA.

THE "PIONEER" ON MR. J. B. CARRUTHERS'
SUBJECT.

A striking instance of the progressive specialisation in agricultural science is to be found in the latest issue of the *Contemporary Review*, which contains an article by the well-known authority Mr. J. B. Carruthers, entitled "Plant Sanitation," and dealing with the methods adopted by advanced communities for the prevention of ordinary plant diseases. Not very long ago an agricultural experiment station was considered to be adequately equipped if it was supervised by a chemist and had a botanist on the staff; nowadays there should be at least ten experts in different branches of science; soil-physics, agricultural entomology, cryptogamic botany, bacteriology, vegetable pathology—each of these requires an expert, and the latest development is the sanitary inspector. In the United States the foundation of the whole system appears to be based on compulsory notification of disease, combined in some cases with regular inspection of nurseries.

Now there can be no doubt that India offers ample scope for plant sanitation. Mr. Carruthers quotes the well-known estimate that the annual loss to this country from wheat-rust alone amounts to ninety-one millions sterling, though by some curious error he attributes this damage not to when trust, but to the ravages of the hop-aphis! The destruction of the mango crop in wet seasons is believed to be due to an insect; the occasional entire loss of the mohwa crop may possibly have a similar cause; sugar-cane suffers enormously from grasshoppers, borers and fungoid pests, rice and poppy from caterpillars, and almost every field crop grown largely in the country has its own peculiar enemies. Of general enemies to plant life it is sufficient to mention the locust, whose ravages we have recently discussed.

What is wanted is organised and sustained research into the life-history of our pests; and we welcome the recent strengthening of the Imperial Agricultural Department by the appointment of a cryptogamic botanist and an entomologist as an important step in this direction. But where the area of research is so vast, a few experts cannot make rapid progress; they require the co-operation of trained observers all over the country. To take an instance: the intermediate host of the wheat rust in this country is still unknown;

a This is apart from perhaps 3,000 acres still cultivated in native tea gardens of small extent; so that the grand total under tea in Ceylon in June 1902 may be taken at say 386,000 acres.

b Apart from 7,000 to 8,000 acres in native gardens.

c Chiefly young, and interspersed with other products.

"intermediate host" it may be explained, is the technical term for the plant on which the fungus lives during the interval between one crop and the next, much as the malaria parasite finds a temporary rest in the body of the mosquito. The search for this intermediate host, if indeed there be one, for even that is still a matter of doubt, involves the patient examination of every shrub and weed that exists during the rains, an impossible labour for any individual, but quite within the power of an organised band of zealous students. It is the absence of the trained observer that, more than anything else, retards the progress of agricultural science in this country, and it is one of the main arguments for the establishment of agricultural colleges that they would in time tend to remove this difficulty; but in the meantime the experts must work alone.

But the question is sure to be raised: Supposing you know all about the pests and have found means of combating them, what is the good? The cultivator will take no notice of your suggestions, even if he ever happens to hear of them. This is in fact the great obstacle to improvement in the agriculture of this country, and it is too large a subject to be discussed at the close of an article. Briefly speaking, our view is that information of such matter must proceed from the experts to the wealthy landholders, and from them to their tenants; and this is the second

ARGUMENT FOR ESTABLISHING AGRICULTURAL COLLEGES,

and using all legitimate means to induce the sons of the landholding classes to attend them. Something doubtless can be done by lessons in the elementary schools, but results obtained in this way will be very limited, and not to be compared with what will follow when in every district there are a few landholders cultivating their *sir*, or home farm, in accordance with the teachings of science, and influencing their tenants to follow their practices in combating disease. In this way a natural system of sanitary inspection might gradually be evolved, for a landholder who saw his tenants allowing preventable disease to spread would probably take effective steps to protect his own interests. Paid inspectors are of course out of the question, at least for very many years to come; but it is only a natural development of the authority of the landholders that they should take the lead in influencing their tenants and neighbours for objects that will benefit all alike.—*Pioneer*, June 11.

PLANTING NOTES.

SIR FRANK SWETTENHAM has made a grant of K8,750 for the purpose of completing the publication of the "materials for a Flora of the Malay Peninsula," by Sir George King, formerly Superintendent of the Botanic Gardens near Calcutta. Its publication had been so opposed for want of funds.—*Straits Times*, May 16.

THE VALUE OF GREVILLEAS—is usefully argued in Mr. Maclure's letter to the Mycologist quoted elsewhere. At 15 years, the correspondent reckons, a grevillea is worth B3'40, and a tea-bush a small fraction of this: so where crowding occurs he would remove the tea-bush. Have other planters' experiences and estimation of the grevillea been different?

ESSENTIAL OILS.—All concerned with citronella, cinnamon, camphor and clove oils will peruse the report of Messrs. Schimmel & Co., quoted on page 37 with peculiar interest. We had no idea that Java had gone in so extensively as it has for citronella oil.

A SPECIAL MANURE TO SECURE QUALITY IN TEA—is likely to be the next improvement made available to the tea planter. The working-out of the constituents are in competent hands and careful experiments are to be made, so as to afford satisfactory tests, before the new fertiliser is brought to the notice of the planters generally.

200,000 GALLONS OF WATER A DAY.—"What is said to be the deepest artesian well in Rangoon has just been completed by Mr D D Coath at the Italian Colonial Company's mill at Dowbong. The well is 348 feet deep, and at a recent test gave water at the rate of 200,000 gallons a day. During boring a boulder was encountered about 200 feet from the surface; that tube had to be withdrawn and put down in another place."—*Times of Burma*, April 26.

PRODUCE AND STOCK IN THE NORTHERN PROVINCE.—Interesting information from the Government Agent's Report on Tobacco-Wild Beast Destruction, Cattle, and Horses breeding in the Northern Province is quoted today. In the islands devoted to the latter there has been serious mortality both in horses and cattle. On Iranativu a poisonous plant, which Mr. J. C. Willis may be called upon to investigate, is thought to be the cause: insufficiency of pasture accounts for it among cattle on Delft. General Olivier, it appears, has offered valuable suggestions.

"MACHINERY IN THE TEA INDUSTRY."—We have received from Feilden Publishing Company, Limited, a Copy of "Feilden's Magazine" for April 1902, which contains the first part of an interesting article on "Machinery in the Tea Industry" from the pen of Mr H J Kersting Green. The article is intended for readers at Home and elsewhere who have never had the opportunity of visiting a tea estate and seeing for themselves the buildings and machinery erected thereon. The article is well-illustrated, and will prove of value to planters in foreign lands (other than India), who may be thinking of going in for tea.—*Indian Planter's Gazette*, April 26th.

THE TRADE OF JAMAICA.—For the year ending March 31st, 1901, the following were among the Exports from the Island:—Ginger 26,530 cwt, value £66,324; logwood 34,006 tons, value £98,618; pimento 100,547 cwt, value £110,602. In the previous year the figures were: Ginger 21,205 cwt, value £60,615; logwood 23,871 tons, value £77,971; pimento 123,973 tons, value £173,562. The falling off in quantity of pimento was due to short crops resulting from unfavourable seasons: The price moreover, fell from 28s to 22s per cwt. Logwood shows an increase in quantity, price and total value the last by £20,647. Logwood extract was valued at £31,599, in place of £15,881 in 1899-1900. The bee-keeping industry, which is almost entirely in the hands of persons of limited means, shows remarkable improvement, honey having increased in value in five years from £1,891 to £10,739. This fact indicates the exercise of increased intelligence and industry.—*B. and C. Druggist*, May 9.

TO THE PLANTING WORLD.

Seeds & Plants of Commercial Products.

Hevea Brasiliensis.—Orders being booked for the coming crop August-September delivery 1902, booking necessary before the end of April, quantities of 100,000 and over at special low rates. Plants available all the year round, 100,000 and over at special low rates. A leading Rubber planter in Sumatra, who purchased 50,000 seeds in 1899, and 100,000 in 1900, writes us, under date 15th November, 1900:—"I received your letter of 20th October, from which I learn that you added another case of 5,000 seeds to replace the loss, &c. I am satisfied hereby, and even after this adding I am satisfied by the whole delivery of this year." Special offer, post free on application.

Castilloa Elastica.—True superior variety cultivated in Mexico, seeds from specially reserved old untapped trees. Orders booked for August-September delivery 1902, immediate booking necessary; large quantities on special terms; Plants in Wardian cases.

A foreign firm of Planters writes under date 14th October, 1901:—"We beg to enquire whether you would procure us 100,000 Castilloa seeds, in which month we might expect them, and what would be the average price." Special offer, post free on application.

Manihot Glaziovii.—Seeds and Plants available all the year round, 100,000 and over at special low rates. A Mexican planter in sending an order for this seed wrote on the 22nd August, 1900:—"If they arrive, fresh and germinate easily I may send you larger orders, as they are for high ground where the Castilloa does not thrive."

Ficus Elastica.—Seeds available in May-June; booking necessary before the end of March; also plants.

Mimusops Globosa (Balata) wood of the tree is much sought for buildings, fruits sweet like a plum and eaten, oil from seeds, said to yield as much as 45 lbs. of dry rubber per tree per annum, the milk is drunk and when diluted with water used as a cow's milk, grow from sea level up to 2,000 feet, orders being booked for seeds and plants, price on application.

Cinnamomum Zeylanicum (Cinnamon superior variety).—New crop of seed in April to June; booking necessary before the end of February; also plants.

Coffea Arabica, Liberian Hybrid and Maragogopie Hybrid.—New crop March-April; immediate booking necessary.

A foreign Agricultural Department writes dating 9th September, 1901:—"Please accept our order for 175 lbs. of Tea seed and for 2,000 Coffee beans. In regard to Coffee seed I would say that this will be the first importation made by this department, and we will leave the selection of the varieties to be sent to your judgment."

OUR DESCRIPTIVE PRICE LISTS.

The following six Descriptive Price Lists are now being forwarded with Circulars and special offer of Seeds and Plants of Rubber and other Economic Products:—

1. Tropical Seeds and Plants of Commercial Products, enlarged edition for 1902.
2. Seeds and Plants of Shade, Timber, Wind-Belts, Fuel, and Ornamental Trees, Trees for Road-sides, Parks, Open Spaces, Pasture Lands, Avenues, Hedges, and for planting among crops (Tea, Coffee, Cacao, Cardamoms, &c.)
3. Seeds and Plants of Tropical Fruit Trees including Mango grafts.
4. Bulbs, Tubers and Yams.
5. Orchids—Ceylon and Indian.
6. Seeds and Plants of Palms, Calamus, Pandanus, Cycads, Tree and other Ferns, Crotons, Roses, Dracinas, Shrubs and Creepers.

Special Arrangements made with foreign Governments, Botanical and Agricultural Departments, Planters and others for supplying seeds and plants of Commercial Products in large quantities.

"SOUTH AFRICA."—The great authority on South African affairs of 25th March, 1899, says:—"An interesting Catalogue reaches us from the East. It is issued by WILLIAM BROTHERS, Tropical Seed Merchants of Henaratgoda, Ceylon, and schedules all the useful and beautiful plants which will thrive in tropical and semi-tropical regions. We fancy Messrs. Williams should do good business, for now that the great Powers have grabbed all the waste places of the earth, they must turn to and prove that they were worth the grabbing. We recommend the great Powers and Concessionaries under them to go to William Brothers."

Agents in London:—MESSRS. P. W. WOOLLEY & Co., 90, Lower Thames Street.

Agent in Colombo, Ceylon:—E. B. CREASY, Esq.

Agent in British Central Africa:—T. H. LLOYD, Esq., Blantyre.

Telegraphic Address:

WILLIAM, HENARATGODA, CEYLON.
Liber's, A.I. and A.B.C. Codes used.

J. P. WILLIAM & BROTHERS,
Tropical Seed Merchants,
HENARATGODA, CEYLON.

Correspondence.

To the Editor.

RUBBER PLANTING IN COSTA RICA

April 25.

DEAR SIR,—As far back as January last I promised to write you an article on Rubber-planting in the San Carlos Valley, and intended at that time to have made a trip over there, and to furnish some newer information and experiences acquired personally. This I have not been able to do; when we got through with the handling of the past coffee crop about the middle of March, I was taken with acute neuralgia in the head, and from this I am still suffering. I had, therefore, to avail myself of the kindness of Mr. Alfred Long, an American, who is settled in the San Carlos Valley on quite a large scale, for most of the information that follows. Mr. Long returned a few days ago, after spending about two weeks, visiting the more settled parts of the Valley.

Mr. Theodore Koschney, well-known to you and to the readers of the *Tropical Agriculturist*, is without doubt the oldest living of foreign settlers in the San Carlos Valley, as well as the most practical of Rubber planters, his experience running back over some 25 years in the district. Strange to say that, though at all times interested in Rubber for the purposes of trade, his own plantation should consist of Rubber trees not over two years old, which he has planted and kept up in a way dictated to him by his own observations, and all his plantation is so far of very good promise.

Mr. Koschney's method of planting calls for the preparation of a seed-bed six or eight months previous to planting, and as handy as possible to the plantation, and the felling of the virgin forest to admit of a liberal amount of sunshine on the ground, leaving it under what is termed "light shade." This felling is quite a matter of judgment with the planter, and he varies it according to the kind of timber, and the dryness or humidity of the soil, these being the principal things to consider. At the time of planting the six-or-eight-month seedling is between 18 and 30 inches high; and though some have planted the seeds themselves 2 or 3 to each stake, there is nearly always a heavy loss from the small lizards or chirbalas, and replanting never ends. A cleaning is given to the young Rubber about 3 months after planting. This is not more than a rough chop-down 4 or 5 feet on each side of the

ROWS OF PLANTS

(which are set about 18 or 20 feet apart both ways) and is repeated 5 or 6 months later, and kept on pretty much in this manner once or twice a year to ensure the Rubber tree good freedom from the scrub or undergrowth, while at the same time it is being shaded overhead by the trees of the virgin forest left standing. The style of Rubber tree thus obtained is similar in growth to the forest Rubber tree, a long straight trunk with but few extending branches. In the preceding manner Mr. Koschney planted about 6 hectares (15 acres) for his neighbours, Messrs. Kotelmann and Heynsohn, about 6 years ago, and so far the plantation leaves nothing to be desired. Mr. Koschney has several rubber trees of long standing in his pastures and other cleared ground, quite sufficient to prove that, alone in the open the Rubber tree cannot flourish, a large number of lateral

branches being developed; the flow of latex is very small and of poorer quality, and the tree often dies after a few tapplings. The only known advantage of the Rubber tree grown in the open is that for production of seed it is more prolific. In past years Mr. Koschney experimented unsuccessfully by adopting another method—that of felling all the timber after scattering Rubber seed broadcast. Bananas were planted also at the same time. At first the Rubber came up like corn, every seed seemed to have sprouted, but in a few months many died, and the increasing growth of the bananas affected the balance unfavourably.

Mr. Carl Grutzmacher, a settler in Caño Negro, is a strong advocate of another system in

RUBBER PLANTING,

differing considerably from the "light shade" method, and though his experience does not cover many years, his hopes of success are very bright at the present time. It calls for the seed-bed 6 or 8 months old, but the felling of all the trees in the forest for planting, the young plants being set out in rows 18 or 20 feet apart both ways. Three months later a cleaning is done, about 4 feet on each side of the rows of plants, and so on at regular intervals of 3 months until the plantation is 1-year old, when everything is cut down again, and the rubber trees stand alone in the open, but only for a short time. In about 3 months the soft-wood or charral growth is up again almost equal to the small Rubber trees, and another cut down in the rows is given, and repeated at gradually increasing intervals, serving to give at all times an advantage in height to the Rubber tree above the charral, the latter serving as perpetual and regulated shade to the trunk of the tree, but with no large forest trees to shade its crown. The growth of the tree is also similar to that of the wild Rubber tree. A little observation is needed to see that this is a tree grown precisely under the same conditions as the forest Rubber tree, which is always found among charrals or shrub growth. There is a disadvantage in the first cost of this method, it being more expensive to fell all the virgin forest than a part of it, and at the same time leaving the ground more encumbered; and the clearings for the first 2 years are more frequent than in the "light shade" method, after which time they run about equal. Time is needed to show which of the two systems is the better: in results the "heavy shade" and "in the open" Rubber trees have both turned out failures, and are not being repeated where they have once been tried.

The only kind of Rubber planted in the Valley is the *Castilloa Elastica*, and most of it on the flats at an altitude of 400 feet and less above sea-level, though one of the newer plantations—that of Mercedes Quesada is somewhere about the 1,500 feet level.

Many of the foreign settlers are at present hanging fire to see what the U. S. Government determines on the Isthmian Canal question. Should the Nicaraguan route be voted for, hundreds of families would be down in a short time from the States; in the other case many will draw out and abandon what they have invested in.

The following is a list of settlers who have made Rubber Planting their business in San Carlos Valley:—

1—Messrs. Umfried and Schoch at the head of Tabla Grande with 40 hectares (100 acres) which they started to plant 4 years ago.

TROUT IN CEYLON.

May 19.

2—Messrs. Hoppenstadt and Gillett in Banco de la China, 3 hectares, all planted 6 years ago.

3—Mr. A. Long below the mouth of Arenal river, 37 hectares, all planted at different dates since 1897.

4—At the mouth of the river "Tres Amigos," an American family the Hogans are at present making preparations to plant Rubber on a large scale.

5—Mercedes Quesada has about 6 hectares of 6-year-old Rubber on his estate in very good condition.

6—Messrs. Kotelmann and Heynsohn have about 6 hectares of 6-year-old Rubber planted for them by Mr. Koschney in excellent condition and has had one tapping.

7—Mr. Koschney has on his estate 25 hectares of 2-year-old trees, 11 hectares of 1-year old Rubber and 16 more being planted.

8—Mr. Koschney together with other planters have planted in Caño Negro 4 hectares barely a year old, many of the trees being now 2 metres high, 100 hectares being now actually planted and preparations being made to plant 350 hectares more.

9—Mr. Long has in Caño Negro 6 hectares planted about 1-year old and is preparing to plant 30 hectares more.

10—Max Bergmann has several hundred trees planted in Caño Negro, 1 to 3 years old, all in good condition.

11—Carl Gratzmacher has about 4 hectares planted in Caño Negro, 3 years old, in very good condition.

Hoping that you will find the foregoing of sufficient interest to publish.—I remain, yours very truly,

ED. COLES.

SUNSPOTS AND EARTHQUAKES.

SIR,—Of the times and the seasons we are told we can have no exact knowledge; and though men have professed to interpret the dark sayings of scripture, most intelligent people believe that there is an impenetrable veil drawn over the time when the world will come to an end, which man cannot pierce. Still, one may reverently regard the trend of great events which convulse the world, without exhibiting any undue curiosity, and without professing the prophetic gift. The connection between sun-spots and seismic disturbances seems now well established from the scientist's point of view, but was not the connection foretold in a way in St. Luke's Gospel (XXI. 25)? "And there shall be signs in the sun and in the moon, and in the stars; and upon the earth distress of nations, with perplexity; the sea and the waves roaring; men's hearts failing them for fear, and for looking after those things which are coming on the earth." Was there ever a time when the conjunction was more marked of signs in the heavens and of convulsions (physical, moral, intellectual) on the earth?
STUDENT,

DEAR SIR,—It is a pity "A. J. M." should have gone so far afield as the "Asian" re rainbow trout breeding in Ceylon, as his doing so has prevented myself and others from criticising his remarks prior to his going to glory in South Africa.* If "A. J. M." is still within the bounds of civilization he will no doubt see this, so I beg to assure him the fry in the Ambewala stream are not trout fry. May I now publicly ask Messrs. Farr & Sparling to catch a few of those fry and little fishes they are so certain about being young trout, and to satisfy themselves that they really are trout? They might send a few to the Hon. Secretary of the Fishing Club and the Curator of the Museum, so that there may be no question as to their identification as the settling of this point, once for all, is of considerable importance to the Fishing Club and the whole community in fact. Mr. Farr says there are on native fish in the Hortons stream. I say there are. Hence my doubts now, though at the time I said I'd swallow all Mr. Farr reported—the wish, I fear, being father to the hope, but do let us have the point authoritatively settled. As to "A.J.M.'s" animadversions upon the varying sizes of the fish in my pond, I doubt if it is worth while wasting your space, but I should have liked to reason with him on the subject.

Any child born on a river bank will tell you that trout of similar age vary in size, whether they be in ponds or rivers. My pond is about the size of your bath tub. I got 197 rainbow fry from the Fishing Club in May, 1900. I repeatedly cleared out the larger fish of from 3 in. to 6 in. during the following twelve months, and in May, 1901, the remaining 25 varied from 2 in. down to the size they were when I got them, which was about 1 in. I turned these dwarfs out last month and they then ranged from 2½ lb. down to about an oz. or two, as three of them were still only about 3 in. long. And yet, in face of this, "A J.M.", whose friend caught a 4-in. trout, dogmatically informs us and all Asia that trout have been breeding in Ceylon for years! My fry were fed three times daily and food on the Hortons is not over superfluous. Do give us something definite, please.—Yours faithfully,

JOHN FRASER.

P.S.—By the way out of the 197 fry I received, I reared 127 trout. I think you will find this is not at all a bad outturn for Asia or anywhere else.
J. F.

POTASH SALTS.

Colombo, May 22.

DEAR SIR,—Enclosed we beg to hand you copy of a leaflet published by us, entitled "The Value of the Stassfurt Potash Salts," the contents of which, we trust, will be of interest to your readers.—We are, dear sir, yours faithfully,

FREUDENBERG & CO.

*"A. J. M." have gone to the Coronation.—ED., 7, 1.

[The leaflet gives an interesting account of how 15 mines near the Hartz Mountains supply rich Potash Salts which are found to be of great value in the manuring of tea and cacao, the favourite preparation being "Sulphate of Potash" with a purity of 90° to 96° equal to 50° to 52° of pure Potash. Planters of tea and cacao should apply for copies of the leaflet which gives good deal of useful information.—ED. T.A.]

USEFUL AND ORNAMENTAL TIMBERS.

Hauwella, May 31.

DEAR SIR,—Referring to your notes and comments in your paper of the 29th inst. re "The valuable timber tree," the *suriya mara*, I am surprised to hear of its being used for the construction of bullock bandies. I think, even in Ceylon, it is a rare cabinet wood, far more valuable than nedun, though similar in appearance, but heavier than nedun.

Suriya (Tulip) is the wood par excellence used in building all sorts of conveyances in the island. Its heartwood is of a dark red colour, and is very light in weight, a cubic foot being equal to about 40 lb. I may mention here that there are four kinds of *maras* found in the Western Province, viz., *Sriyamara*, *Hurimara*, *Rabalmara*, and *Madityamara*. I suppose *Aramana* or *Waya* is also one of these species. The two former are very useful trees, both for cabinet and other purposes, and the rest are only used for building. *Mora* wood, referred to in your paper of the 28th instant, is not a cabinet wood, being very heavy. A cubic foot is said to weigh 62 lb. It is largely used as firewood in cremation and also for brick and lime kilns and is of a light brown colour.

A NATIVE.

[Our authority about *Suriya-mara* (Sinhalese), "Albizzia Lebbek" (of botanists) is the late Mr. Wm. Ferguson, F.L.S., who, writing in 1863, said:—"Wood brown, used for bullock bandies." Doubtless this timber was more plentiful then. Of "*Suriya-gas*" (*Thespesia populnea*—the tulip tree) the same authority reported:—"The best-known timber tree of the island, wood a shade between the colour of walnut and English elm; a tough, excellent wood used for felloes, naves and panels of carriages and for gun stocks."—ED. T.A.]

RAINBOW TROUT FOR EVERY STREAM IN CEYLON: GOVERNMENT SHOULD AID IN THEIR INTRODUCTION.

June 3.

SIR,—Now that it is an established fact that rainbow trout are breeding in Ceylon, would it be out of place to suggest to the Government that it might very graciously subsidise the Fishing Club liberally, so that trout may be introduced to every stream and river in Ceylon?

These trout can probably be acclimatised down to sea-level, and, if properly regulated and looked after, you can hardly imagine what a splendid food supply they would prove for the Colony, not to mention the grand sport for young and old.

Them's my sentiments, What do you think, Mr. Editor?—Yours,

PISCATOR.

II.

THE FACT ESTABLISHED BEYOND QUESTION.
Ceylon Fishing Club, Nuwara Eliya, June 2.

SIR,—I am requested by the Managing Committee of the Ceylon Fishing Club to inform you that there is now no doubt that rainbow trout are breeding in Ceylon—both in the Horton Plains and in the Nuwara Eliya streams. Mr. Farr has sent two small rainbow trout for inspection, that could only have been locally bred, whilst at least one tributary to the main Nuwara Eliya stream is swarming with rainbow fry, two members of the Fishing Club having caught and examined several varying in length from 2½ inches to 3½ inches.—Yours, &c.

J. WICKWAR, Hon. Secy., C.F.C.

SOUTH AFRICA RECOMMENDED TO YOUNG MEN WITH A LITTLE CAPITAL.

June 3.

SIR,—I wrote you the other day that I heard the rustle of the wings of the Angel of Peace, and now the glorious Angel has appeared in all her smiling beauty, bearing a palm-branch in her hands. Lord Wolseley (then Sir Garnet) at the Vaal told the people that the country would remain English till the sun stood still in the heavens and the waters of the Vaal ran backwards. Now it will come true; but many dark days of blood and slaughter have come between. The struggle is ended, and all those farms and towns we saw devastated—deserted—ruined will again be peaceful happy homesteads around which the golden oranges, the soft peaches, and green fields will yield rich harvests. To show you the sad ruin war brings, I will give one instance. At Rustenberg I obtained leave to go through the town to get firewood (or anything else handy I could pick up.) I went along the street and approached the door of one of a line of pretty cottages and knocked. On the door was a paper beseeching any one who came to spare the property in the house. I knocked again. I heard heavy footsteps inside and went round to the back. There were a number of Tommies in there. They had gone through everything. It had been a comfortable, well-furnished house; but clocks, pictures, ornaments and furniture were lying on the floor, tossed about and trampled on. I went into the bed-rooms and there were all the paraphernalia of a lady's bed-room and toilet strewn on the floor. Articles of clothing, &c., &c., lying about. I went to the kitchen—in fact everywhere it was the same. One Tommy said, "There is little enough you will pick up. They have been through everything." This is only a sample of hundreds of houses we saw. One woman said they had been robbed by Boers and British by turns as they occupied the town.

And now to know that all this has ceased, that the country will begin to prosper and that there is room for thousands of British settlers to go and form happy homes in the veldt! Unlike Australia the veldt has everywhere a natural drainage and is undulating. Thus water can be tapped in the hollows; and many a grand stream of clear pure water we

saw flowing past farms which had been tapped from the hillside with comparatively little labour. I would recommend all youngmen in Ceylon, who have a little money, and who find their prospects in tea planting the reverse of promising, to go out to this country and gradually settle and participate in the coming prosperity that is near. Government will be most indulgent and liberal to all immigrants. With a powerful, wise and settled Government, and the presence of large numbers of hard-working British immigrants, the country will develop by leaps and bounds; and those who go there now will share in the coming prosperity. Though Peace has been declared, the Government will have a responsible task and large numbers of Police will have to be maintained, and regiments of soldiers in the chief towns, till matters gradually adjust themselves after the long war. Bitterness of feeling will gradually die out.

TROOPER.

MOSQUITOS AND FLIES.

Colombo, June 5.

DEAR SIR,—We have not heard much about the experiments with kerosine oil and "chuloos" against lake flies, mosquitos *et hoc genus omne*. May I draw the attention of that august body, the Municipal Council of this city, to the remarks of an American paper (The *Public Health Journal*) with reference to a simple remedy for abating the mosquito nuisance, viz., permanganate of potash (in solution known as *Condy's Fluid*) which is said to kill the insect at any stage. To quote the journal itself: "a handful of permanganate will oxidise a ten-acre swamp, kill its embryo insects, and keep it free from organic matter for thirty days at a cost of 25 cents.* With care a whole State may be kept free of insects at a small cost, [and so might a small island like Ceylon]. An efficacious method is to scatter a few crystals widely apart. A single pinch of permanganate has killed all the germs in a 1,000 gallon tank." Will the Acting Sanitary Officer, who seems zealous of the good name of his department, put the alleged marvellous properties of permanganate of potash to the test and see if some benefit could be derived from the above remarks of the *American Journal of Public Health*?

Another matter, which will no doubt interest the Health Officer just at this time, when enteric is abroad, is the following statement which occurs in an article on the Entomology of the Housefly, by the Government Entomologist at the Cape:—

"Numerous diseases, some of them most serious in character, may result from the visits of the fly to our food and our persons, for it often brings with it virulent germs from the faecal or putrid matter which it has visited. It has been demonstrated that the fly can contract plague from feeding on animals that have died of this disease, and that having contracted plague, it may live for several days and finally fall or drop dead on to food, meanwhile having been depositing excrement laden with virulent bacilli. It is firmly believed by medical men in India that cholera is very frequently transmitted by the house fly. Tuberculosis bacilli are taken up by it through feeding, as it often does, on the sputum of consumptive persons, and these germs are given off in the

excreta. The excreta of flies that had been fed on infective sputum, when injected into rabbits, has given rise to tuberculosis. But of all diseases that it may transmit, typhoid or enteric fever probably ranks first in importance. The dejections of persons infected with this disease, it has been stated on the best of authority, harbour the causal organism not only during the period of actual illness, but for some days before and for some time after apparently complete recovery. The fly becomes contaminated by alighting on dejections that have not been properly disinfected, and then may carry the germs into surrounding households. The bacilli multiply rapidly in milk, and how easily can a fly render a whole painful poisonous by falling into it or even simply sipping it! In cities and towns with good sewerage systems and well-enforced sanitary regulations, the carriage of typhoid by the fly is doubtless exceptional, but in concentration and army camps it is presumed to be very common."

Let us hope that before long we shall have in Colombo, such a Sewerage System and such Sanitary Regulations as those referred to above.—
Yours truly, SANITAS.

VOLCANIC DUST FROM BARBADOS.

MR. JOHN HUGHES' EXPERT ANALYSIS.

London, May 30.

DEAR SIR,—I enclose you a specimen and Photo-micrograph taken by my senior assistant, Mr. A Ashe, of the Volcanic dust, which, as the result of the eruption of Mount Soufrière in the island of St. Vincent, fell in such quantities in Barbados on the 6th of May and following days. The Dust is of a dark grey appearance, possessing a distinctly gritty character, though the largest particles probably do not exceed the size of a printer's full stop." When exhausted with a weak vegetable acid solution of a strength of one part Crystallised Citric Acid to 1,000 parts of cold distilled water, employing 1,000 parts of such solution to one part of the dust, and allowing 48 hours for exhaustion, there is only 2.60 per cent dissolved out and 97.40 still remains in an insoluble form as Silicates of Iron and other Mineral associated with Quartz. In the portion soluble in the above weak solution, Iron Compounds chiefly predominate, associated with small quantities of Calcium Sulphate, Potash, Salts and traces of Phosphoric Acid. Though not possessing any special fertilising value in itself, the dust by reason of its minute state of division will naturally improve the physical character of a soil such as that of Barbados, and it may reasonably be expected that the crops of sugar will under the influence of a suitable rainfall give an increased yield during the next two years at least, if not for a longer period. Under the microscope it will be seen that the dust consists of two classes of minerals, one being large and fairly uniform in size while the other consists of a very fine dust. Of the former a large proportion is black and opaque; whilst the transparent particles are partly white, such as Quartz associated with crystals tinged with green. The very fine dust appears to be composed almost entirely of Quartz. The dust when exhausted with a strong solution of Hydrochloric Acid (50 per cent Hcl) was dissolved to the extent of 14.45 per cent and contained .39 Potash probably derived from Felspar, a common ingredient in igneous rocks.—Yours faithfully,

JOHN HUGHES, F.I.C.,
Agricultural Analyst,

THE
AGRICULTURAL MAGAZINE,
COLOMBO.

Added as a Supplement Monthly to the "TROPICAL AGRICULTURIST."

The following pages include the Contents of the *Agricultural Magazine* for July :—

Vol. XIV]

JULY, 1902.

[No. 1.

OURSELVES.

THE *Agricultural Magazine* has rounded off another year of its existence, and with the present issue appears the first number of Volume XIV. Of modest aspirations the little periodical has, we venture to think, done good work, and that it is appreciated is evidenced by the many applications we have received for special numbers from those who are not regular subscribers. Through the Magazine as an exchange, we have been enabled to keep in touch with the agricultural literature of other countries, and to the Editors of foreign Journals we owe much thanks for their liberal co-operation in the cause of agricultural advancement. We have also to thank our subscribers, both local and foreign, for the support we have received during the past year.

CLOSE PLANTING.

There is little doubt that one of the unfortunate tendencies in planting, and particularly in the cultivation of perennial crops, is planting too close. The manner in which trees are crowded together in native gardens where sunlight and air are to a great extent kept away from most of the foliage, and almost altogether from the stems and roots of crops, is often spoken of with scorn and ridicule, but are we sure that we are growing our coconuts, for instance, to the best advantage when

we plant 75 trees to the acre? The advantages of reducing the number of trees per acre have before now been discussed by correspondents in our columns, and we fancy that there is a tendency—slow but sure—towards increasing the distance between the trees on coconut plantations. The idea of getting the most out of one's land by occupying it as fully as possible is difficult to get over, and there are a large number of growers who have yet to be persuaded that this is false economy, and that the liberal treatment of trees in the matter of air and light is reciprocated in a measure that leaves no doubt as to the wisdom of such treatment.

A cocoa planter of long experience lately stated to us that if he had to plant an estate again he would not place his trees less than 20 feet apart. Many will smile at the decision, and say that there is no necessity for doing so, as the cocoa tree does not develop to the space provided by such a system of planting. The truth is that it does not because it has not the opportunity. Give it the chance and it will. The extreme artificial conditions of plant life under cultivation are in a great measure answerable for the trouble that has followed the cultivator, who is generally set on making what he thinks the most of his resources with a thought only for the present and none for the future.

The latest illustration of the advantages to be gained by a more liberal system of cultivation—liberal as regards the natural environments of plant life, so as to produce the fittest individuals without the struggle for existence—is the experience with regard to coffee cultivated according to what is called the Leeming system, which

is no more than the rational system, or, as Dr. Watt is reported to have termed it, the correct scientific system. What Mr. Leeming has done is what every other grower of "fruits" might have done before him, viz., he thought out and applied to coffee growing the principles carried out by practical and scientific growers of fruit trees in various parts of the world. Large cultivators are too apt to look upon and treat their estates as a composite mass without sufficiently recognizing the claims and requirements of trees as individual living organisms. We need not here refer to the various elements that go to secure the benefits resulting from what some are pleased to call "intensive cultivation": we are only concerned with the necessity for giving room—air space and ground space—for the full development of trees, without which there must always be limits to development which the most liberal treatment in other respects cannot extend.

We read with regard to the Leeming system of coffee culture that the crops were increased enormously by the removal of more than half the bushes and proper attention given to the balance. To quote the *Indian Agriculturist*:—"Mr. Leeming has cut out his trees from 6 feet to 8 feet, and from 8 feet to 12 feet, and the further apart the trees are grown, the better he finds the yield in quality and quantity." Those who are interested in the details of cultivation should consult the proceedings of the United Planters' Association of Southern India for 1901, but we would now only point to that one important condition which, when attended to, would appear to allow not only scope for the development of the trees, but scope also for the ingenuity of the planter and for the possibilities of more successful and remunerative cultivation.

OCCASIONAL NOTES.

"Cocoa and its Adulteration" by an "Expert" will be found instructive and racy reading, and should, if printed in the form of a "Circular," appeal to the convictions of many with whom cocoa is now only a casual beverage. Before long, we have no doubt, the economical householder will discover that cocoa, unlike tea, is not merely a dilute of sweetened milk, but in itself a nutritious food. The infusion of tea leaves will do for the better-off to sip to their heart's content, but those who possess a moderate-sized purse and wish to get their money's worth of nutriment, will very soon take to buying pure cocoa where it can be had at reasonable rates.

The dressing of the horse's hoof is a matter of interest to many. We give below the views of Mr. A. Chinniah, Veterinary Surgeon, on the subject. "Covering the hoof with tar is a pernicious practice which has taken deep root in most stables in Ceylon. Tar gives a mechanical and impermeable coating, and is no doubt favoured on account of its cheapness. Tar, as we know, is used as a protective agent against the action of air on iron, &c., and thus prevents oxidation. Now the wall of the hoof is not dead tissue, and though

hard in consistency, it is thin and protects very sensitive tissue, not merely against concussion but against excessive heat and cold and other atmospheric changes. When tar is applied, it effectually keeps out air, with the ultimate result of 'brittle hoof.' All that is wanted is a good dry stable and an attentive syce. As a protective substance any bland oil may be used. When tar is recommended by some as a hoof dressing, it is no doubt intended to be applied not to the walls of the hoof but the sole surface (and that with discretion), viz., the frog, bars, cleft, &c. But this is only necessary where a number of animals are kept (as in omnibus stables) under the care of one man; it is out of place in a private stable. There are many hoof dressings on the market, but the one commonly in use in Ceylon is Stockholm tar and fish oil, which is often seen forming a thick layer over the hoof, when this 'finger nail,' as it indeed is, should appear in its natural beauty."

The Director of the Royal Botanic Gardens accompanied by the Director of Public Instruction and the Superintendent of School Gardens inspected some of the School Gardens in the Western Province on the 18th June.

We observe with much regret that there is a possibility of the company of which Mr. E. Elliott is Manager being wound up. In India, we read, agricultural farming is just being taken up by Europeans, and that a Mr. Wilde has obtained a grant of 1,000 acres of waste land in the Darrang district on a 30 years' lease, and will devote his attention to mixed farming, cultivating commercial crops, such as oil-seeds, flax, jute, alces, &c.

The following note from the *Veterinary Journal* for June will doubtless prove of interest to the authorities in control of the Harrasbedde Breeding Farm, where hitherto the lambs born have all turned out to be males!

Working on the hypothesis that sex is determined by the influence of the more vigorous parent, M. Dechambre gives the following observations. He deduced from the hypothesis that in a lambing season the influence of the male might be predominant at the beginning, and that of the female towards the end. M. Dechambre examined three flocks, and found that out of 1,069 lambs 519 were male and 546 female. Dividing the season of copulation into two portions he found:—

First half, for every 100 males 96.6 females.
Second " " 100 " 117 "

Dividing the season into three portions he found—

First third, for every 100 males 89.6 females.

Second " " 100 " 119 "

Third " " 100 " 125 "

Dividing the season into four portions he found—

First quarter, for every 100 males 81.3 females.

Second " " 100 " 107.3 "

Third " " 100 " 109.3 "

Fourth " " 100 " 146.3 "

It will thus be seen that at the beginning of the copulative period male lambs were in the majority, but the females soon made up on them, and at the end formed a distinct majority. M. Dech-

ambre does not lay too much stress on these results, and says that a great number of observations are necessary before any reliable data can be found.

The subject of castration is one concerning which we have often had enquiries, and about which there is much misconception. We have therefore taken over from the last Veterinary Journal a reliable, clear and full account of the operation, which we have no doubt will prove useful to our readers.

CLUB-ROOT.

We were sorry to find on a recent visit to the Nuwara Eliya district that the cultivation of Cabbages was being greatly checked by the prevalence of this troublesome disease, about which we append the following note for the information of our readers:—

Club-root in Turnips, Cabbages, Cauliflowers, Rape and other cruciferous crops is the name given to the malformation of the roots. When pulled the main root is found to be much dwarfed, while the side roots are often swollen into spindle-shaped masses, presenting an appearance to which the name of finger-and-toe is appropriately applied. Lumps or nodules may also be seen upon the roots. A crop thus affected ultimately perishes, owing to the decay of the roots.

This disorder—whether called club-root, finger-and-toe or "anbury"—must not be confounded with a malformation of the root which occasionally arises as a result of some peculiarity of the soil, seed or manure, and is really a case of degeneration or "reversion" to the wild type. In such cases the growth though distorted is nevertheless healthy, but in club-root it is only necessary

to cut across the root to see that it is full of decaying matter.

Nor, again, should the wart-like growths formed upon the roots by the small beetle termed the turnip-gall weevil be mistaken for clubbing. By cutting across such galls on the roots of turnips and cabbages the legless "maggots" of the insect may be found.

True Club-root is always associated with the presence of a slimy fungus known as *Plasmiodiophora Brassica*.

The spores of the organism are very minute, and they not only attack and destroy cruciferous crops, but they infest the soil to such an extent that it is unwise to grow such crops on the same land again for several years. A spore existing in the soil finds its way into a cruciferous plant through a root-hair, and at once makes a demand upon the protoplasm of the plant. The spores produce slimy masses called *plasmodia*, and these have a slight power of locomotion from cell to cell of the infested plant.

The refuse of the diseased crop should not be left on the ground or thrown about in the neighbourhood of the garden, as it is capable of serving as a new source of infection. Dressing the land with lime—and especially gas-lime—tends to destroy the spores in the soil. Therefore, burn all crop refuse and diseased plants and thoroughly cleanse the soil of spores by using gas lime, or, in its absence, caustic lime, before replanting an infected area.

SODIUM ARSENITE AS A PLANT DESTROYER.

Some time ago we published a note with reference to the efficacy of this chemical in eradicating Prickly Pear and other plant pests, and received a communication from a leading coconut planter, who is nothing if he is not up-to-date, asking us to procure for him a small quantity of the arsenite for purposes of experiment. This we have been able to do, and in order to give some idea of how the chemical has been used in other countries, we append a description of the method of mixing, applying, &c.

There is no doubt that many plants can be similarly treated, but it is questionable whether "Tiluk" (*Imperata arundinacea*), which is truly the "planter's curse" will succumb to the destructive agent, unless liberal application of the solution, so as to reach the roots, be made.

Here is an account of how it was used against Prickly Pear, the native "Katupathok."

Making the Solution.—8 lb. of the chemical was first weighed off and placed in a kerosene can or old bucket; to this was added 2 gals. water, and it was then placed on a fire and heated until the chemical was quite dissolved, the operator stirring it occasionally. The 80 gal. vat nearly filled with cold water, and the 2 gals. of solution then poured in, and more water added to make up to 80 gals. One great advantage in using sodium arsenite is that it dissolves easily, and therefore no trouble occurs from pumps or spray nozzles becoming choked, which is so often the case with many solutions used.

Method of Application.—For applying the solution a powerful "Doncaster" spray pump was used. This was mounted on an 80 gal. vat and placed in a light cart drawn by a single horse. Two lengths of hose were attached and connected with nozzles mounted on light iron pipes, so that two sprays were working at once, and by means of the pipes the spray could be got over the top of the tallest plants. It takes one man and two boys (or three boys would do) to carry out the work, *i.e.*, one to work the pump and drive the horse, and two to apply the spray. With this plant there is no difficulty in spraying an acre of thickly-infested pear land per day, and, generally, as the land is rarely thickly covered, some few acres per day could be sprayed.

Time to apply.—The experiments extended over two years, and as they were conducted at regular intervals, a good opinion could be formed as to the best time to spray. It appears that, as might be expected, the spray proved most effective when the sap was active, *i.e.*, in spring or summer after heavy rains.

Cost.—It was estimated that to spray an acre of land thickly covered would cost as follows:—

80 lb. sodium arsenite, at 3½d.	0 18 8
Application—wages for 1 man and 2 boys	0 12 0
Horse and cart for 1 day	0 6 0

As a rule, however, even on badly-infested land, I do not think that the cost of spraying would exceed 10s. or 15s. per acre, and often it could be done for less.

Sodium arsenite can be purchased in Sydney at 3½d. per lb. for large quantities.

Spray pumps suitable for the purpose can be obtained at from about £4 to £10 each, complete. Almost any ordinary spray pump will do, such as those used by the fruit-growers.

Effect of the Spray.—The action of the spray was very rapid, as within 24 hours the leaves were fading, and a strong smell of decaying vegetation was given off. By the end of the first week the foliage had all turned brown, and large numbers of the leaves had broken off and fallen to the ground. *Within from three weeks to a month the foliage had decayed, and was sufficiently dry to burn off rapidly without the aid of brushwood, &c.*

In all cases it was found that none of the chemicals destroyed the roots of the pears, and nearly all the plants made a fresh growth if left undisturbed. If, however, the decayed mass is burned off, there is very little trouble from plants shooting again; and should they show any signs of life, the few roots that do start can be easily removed, as they are only very shallow.

Danger to stock.—In using any poisonous spray for eradicating prickly pears, &c., there is a great risk of stock being killed if they are allowed to graze in the paddock where the treatment is being applied. No matter how carefully the spraying is carried out, the grass near the plants is certain to receive some of the poison, and should stock eat this they may die. If, however, the stock are kept out of the paddock for a week or so, there is little danger afterwards as the poison soon disappears.

Briars, lantana thistles, and other weeds can be treated in a similar way to the pears, and it will be found that the arsenite of soda solution is very effective in destroying them. Also it is a good remedy for eradicating couch grass from garden paths, roads, &c.

COCOA AND ITS ADULTERATION.

[BY AN EXPERT.]

Theobroma, meaning in the Greek "the food of the gods" was the name given to cocoa by the eminent botanist, Linnæus, who could find no language more fit to express the inestimable qualities and the delicious flavour of this food. In Mexico, in the untrodden mould of forests primæval, by the banks of the mighty Amazon, and hidden away under the cool shade of the heavily-timbered glens and ravines, may still be seen this rare and beautiful plant in all its wild luxuriance.

In many parts of the world it is, however, now found under cultivation.

"Historicus" writing on cocoa so lately as 1892, says that the finest qualities are grown in Central America, Trinidad and Ceylon. "The latter is of comparatively recent cultivation, but it is the most delicate in colour, flavour and aroma, and unfrequently commands the highest value in the market."

Ferguson in his Ceylon in 1884 says: "To the late R. B. Tytler belongs the credit of introducing this cultivation, and in his hands Ceylon cocoa speedily realized the highest prices in the London market, experienced brokers remarking that there must be something in the soil and climate of Ceylon peculiarly suited to cocoa." That is so. Our earliest acquaintance with cocoa as an article of diet may be dated from 1494, in connection with the discovery of the western world by Columbus; but its great value was known long before to the dwellers of the countries where the plant grew.

Prescott, in his history of the conquest of Peru, says: "The Emperor took no other beverage than the chocolate. The beverage, if so it can be called, was served in golden goblets."

So early as in the reign of Charles II. medical men recognised its excellence, and a Dr. Stubble wrote a book on it entitled the "Indian Nectar," extolling its "secret virtues" as he termed its nutritious properties.

But it was not long before unscrupulous dealers, even at so early a date in its history, recognised the great facilities it afforded for adulteration; for the elder Disraeli in his "Curiosities of Literature," tracing the cocoa to Mexico, tells us that "the Spaniards introduced it into Europe," but not in its purity, for he adds "it was a coarse mixture of ground cocoa and Indian corn with Racca."

The adulteration which began then cannot be said to have ceased yet, for some few years ago there were several prosecutions in London, and it appeared upon analysis that there was in some cases as much as 30 per cent. of pure starch added to the cocoa, and to-day can it be said that there

is no cocoa in the market which is not absolutely pure? Neither the rigour of the law nor the vigilance of officials has yet succeeded in suppressing adulteration, and indeed we have to take our cocoa on trust very much as we do our tea, though with regard to the latter article the absence of all mystery about it, and the absence of all necessity to adulterate it at the present day, has given it a consumption which is not likely to be reached by cocoa so long as the public continue to take their cocoa without a guaranteed analysis.

The fact is, the public know very little about cocoa, far less than they know about the fermentation of wine or the brewing of ale; and then as it is quite a common practice among manufacturers to add flavouring agents to cocoa and chocolate, it is by no means a simple task for the ordinary consumer to pick out a genuine brand of cocoa from a host of sophisticated lines found on the market. And so a confection made soluble through chemicals, and bearing a glorified label on an attractive packet concealing a large percentage of starch and other "wholesome" ingredients, may upon analysis appear to be a veritable whitened sepulchre. And hence the shyness of the public in approaching cocoa.

There is one test, however, which seldom misleads, and that is the test of colour. Where cocoa deteriorates and falls off in quality and brightness of colour, nothing will bring it back. There is no sophistication possible here, and you could recognise it as readily as you would an Australian aborigine.

The London brokers' highest quotations are for what is known in the trade as "bright bold," and with this brightness is invariably associated flavour, freshness, perfect curing, &c.

On every plantation there are well-cured and ill-cured samples. There are beans picked up from under the trees by the bushel—daily dropped by squirrels, and already black before they can be handled by the planter. There are also samples spoiled by rain, as well as hard unripe beans from "cankered" pods. To all these no art can give back their lost colour, although benzoin and vanilline may substitute a flavour. Yet these are sold and shipped, and what follows is all a mystery.

Ask the doctor and he will explain the reason why he recommends the cocoa "nib" to his patients, and directs them to make their own decoction. Solubility of a powdered cocoa may be secured at the cost of quality and wholesomeness, for it is well known to the initiated that with the aid of tartaric acid and carbonate of potash, coupled with the retention of a part of the butter in the cocoa, a thick, creamy and most attractive sample may be produced. But the eminent scientist, Dr. Hart, referring to such a producer, has told us that we should remember potash combined with fat is commonly called soap. And no wonder that, what between starch on the one hand and chemicals on the other, consumers are often heard to assert that they like cocoa but they get bilious over it, and have to discontinue the use of it after a while.

Ignorance regarding this most wholesome food is not confined to the general public alone. The

most educated and enlightened may be often found in the ranks of the deluded. Once an amiable but credulous physician of some distinction, speaking to the writer about cocoa in Ceylon, and the superiority of the article prepared by the Spanish and Portuguese, was relating how a Catholic priest in Ceylon had offered him such a luscious bowl of cocoa that the spoon might have been made to stand in it. The writer unguardedly interjected "Chiefly starch!" for it was that, or both starch and the fat of an indifferently cured sample that gave it the consistency. The physician and the writer have never met since, but the priest who holds to his particular gruel as he upholds the dogmas of his creed, and the doctor who is by now the guardian of that jovial monk's liver, are disseminating the gospel of their own "Societas de propaganda fide" from high places.

A well-known confectioner, who may be said to hold in his hands the four corners of Western Australia in that time, expressing his opinion on a sample of Ceylon cocoa sent to him at his request, wrote back: "Its flavour is most excellent, but it is not dark enough for this market."

It was soon explained to him that colour and flavour are correlative, and went together or disappeared together, and he is now ordering his supplies largely from Ceylon, and doubtless educating the Australian eye to the true colour, and the palate to the genuine flavour of pure cocoa. One more illustration. A Ceylon newspaper, referring last week to the "*German Export Review*" says: "A recent number contains an excellent paper on the manufacture of chocolate with a series of very interesting illustrations so far as the matter is concerned, but there is also the inevitable "cocoa plantation, and instead of this being a grove of the *Theobroma Cacao*, it is simply a coconut palm garden."

Ye gods and little fishes! What confusion is here. For when the oil of the coconut is expressed, what is left is "poouac," the favourite food in Ceylon of cart bulls and pigs, and when the fat is taken out of the other what is left is the food of the gods!

These illustrations are intended to show the public how widespread is the general ignorance which prevails all the world over with regard to this remarkable article of diet, and it is deplorable to think that its popularity in many cases is retarded one way or another by the makers themselves. The general unwillingness to partake of it as liberally as we do tea or coffee no doubt arises out of this ignorance, and the doubt and suspicion in the public mind as to the purity and genuineness of the article offered for sale.

One may, however, venture to assert that if the public were made better acquainted with the manufacture of cocoa, and the makers agreed among themselves to drop their mysterious declarations and rival claims for special preparations, and substituted instead a simple certificate of the chemical analysis of their produce, cocoa may speedily become as popular a drink at our breakfast table as is the homely Ceylon tea, about which there is no mystery, and to which nobody

sets up any exclusive claims of superiority arising out of secret methods of preparation.

The highest claim a manufacturer should make regarding cocoa is that having expressed the expressible oil, he is content to leave well alone. It were vain to attempt "to paint the lily or guild refined gold"!

SERICULTURE.

In our last issue we had something to say about the proposed introduction of Sericulture as a village industry. The *Indian Agriculturist* for June in referring to the encouragement which His Excellency the Viceroy of India is giving to industrial work, goes on to give an account of the progress made with Sericulture. Apparently the rearing of silkworms exactly suits the tastes of the Indian peasantry, to judge from the manner in which Sericulture has been taken up, not casually but on sound scientific lines; and this fact should give encouragement to those who are endeavouring to popularise silkworm culture in Ceylon. The following extract will give an idea of the progress of Sericulture in Bengal:—

The Government of Bengal, acting in conjunction with the Bengal Silk Committee, have done useful work in introducing improved methods of rearing silkworms, and the industry has now been placed on a sounder footing. The chief evil which threatened to destroy the industry was that of diseases affecting the silkworms. The principle disease is known as pebrine. It is hereditary, affecting the blood of the worm and has the effect of killing the worm attacked when just about to spin its cocoon. Impressed by the wonderful results secured on the continent by the adoption of the Pasteur system of silk rearing and disease prevention an effort was made to introduce it into Bengal. The Silk Committee consists of representatives of three European firms in Berhampur, and the Collector *ex-officio*. At the outset of the Committee's operations they were not particularly successful but persevering in their efforts to see the Pasteur system given a fair trial, they now have the satisfaction of witnessing their labours attended by more satisfactory results. The Government of Bengal contributed Rs. 3,000 annually towards the experimental work that was being carried on, and this year the grant has been increased to Rs. 6,000, on condition that the Committee raises a similar sum.

Incredible though it may sound, there is no doubt that, especially in the Malda District, where the people are more intelligent, the Pasteur system is practised with excellent results by mere peasants to whom the microscope and bacteria were but a short time ago unmeaning terms.

Starting then with the female moth that has been placed in a position to lay fertile eggs, these eggs hatch out in about a week, and the worms are carefully taken by the rearers and placed on big bamboo trays. The worms are fed on mulberry leaves for varying periods according to the

time of year, as long as forty days in the cold weather, until the expert rearer by their appearance judges they are about to spin a cocoon. At this stage the worms are placed on a spinning tray called a *chandradi*, which has running from the outer edge of the centre in spiral form little hedges of wicker-work some three inches apart. Five hundred or six hundred worms are accommodated on one of these trays, and here they soon start to work, spinning around themselves what proves in their case a shroud of silk.

On the moth hatching out and being ready to lay eggs, it is placed by the rearer inside a small circle of tin with a piece of paper underneath on which it lays its eggs. Pebrine being a hereditary disease it follows that the eggs of healthy moths only should be retained. To determine the existence of disease in the blood of the moth the microscope has to be brought into requisition and the fungoid growths are so marked that with a little preliminary training it is apparently easy to distinguish between the healthy and unhealthy moths. In the case of the latter both eggs and moths are burned or buried without loss of time, eggs of the moths free from disease alone being retained.

In addition to the microscopical examination of seed the Silk Committee have built three rearing-houses. The results have so far been most satisfactory. The produce of silk per unit of cocoons reared at Chondonpur has been 40 per cent. greater than that of native reared cocoons. One of the houses which the Committee is building will be divided into two compartments, one having ruby and the other violet coloured glass windows. The use of ruby glass excludes the actinic rays, and worms raised under this condition are said to develop more perfectly than when reared in the ordinary way. The object of the violet glass is to destroy microbes inimical to the health of the silkworms.

All this goes to show that Sericulture in India has come to be a regular "business." And why should this not be the case in Ceylon also?

CASTRATION

[BY E. WALLIS HOARE, F.R.C.V.S.]

The operation of castration appears to be regarded as one of vast importance in veterinary surgery. Nearly every practitioner fancies himself an expert on the subject, and proclaims that his method is superior to all others. Some, with an exaggerated idea of their own skill, tell us that so successful are they at the work that no colt ever dies as the result of their operation.

At one time, in the simplicity of youth, we used to regard such individuals with awe, and a touch of envy at their success and our misfortune when a case slipped through our fingers, and we got the credit of slaying the animal. But as years rolled on we gradually learned that these successful men had similar experiences to our own, with this difference, however, that in our case we attributed the cause of death to the operation, in their case it was a calamity resulting from some disease that was lurking in the system

prior to the operation. And not only this, but, *mirabile dictu* they were able to persuade the owners that such was the case, while our reputation was hanging in the balance, and we were anathematised as having caused the death of the rent-payer of the farmer or the pride of the widow. Indeed, not so long ago we saw it reported that the cause of death in one case that succumbed was the attempted swallowing of the testicle that was left in the animal's stall!!

One would imagine that some great surgical skill was required in the operation if we consult recent works on veterinary surgery. In a work recently issued we find no less than thirty-nine pages devoted to this operation, different methods being given, and plates of instruments, and some implements belonging to a former age. For such a simple operation it is surprising how much space is occupied, and what a number of barbarous methods are described. We beg to assert, however, that a student would learn everything about the operation after assisting a practitioner of modern views, and that he might read the descriptions given in the thirty-nine pages *ad nauseam*, and be totally unfit to castrate even a donkey.

Let us for a moment inquire into the essentials of the operation. In normal cases the proper securing of the spermatic artery, in order to prevent hæmorrhage, and the after-treatment, which consist in measures for the prevention of septic peritonitis and tetanus, comprise the important details.

That the operation, by whatever method employed, is a simple one, is apparent when we consider the large number of animals mutilated by empirics, and the small percentage of fatal results. As regards fatal results and untoward complications, the element of chance enters very largely. Sometimes even with the greatest care a fatal result will occur, and no one is to blame. Again, we find that, as a rule, cases do better when on grass every day than under the best hygienic surroundings and surgical care in town, of course provided the weather is suitable.

As to the method of operation, modern practitioners prefer one on surgical lines. Certainly the antiquated clam and the hot iron are not in accordance with modern surgical ideas, in spite of the dogmatic assertions of those who pin their faith on ancient methods. The method by torsion and that by ligature are both scientific and surgical, and our experience of the former leads us to state that it is perfectly safe and expeditious. We do not, however, agree with the illustrations given of this method in modern text-books, as it is essential to apply the torsion forceps as close as possible to the surface of the clamp, in order to operate in as short a time as possible, and to avoid leaving a quantity of bruised tissue behind. Some of the instruments illustrated in works on veterinary surgery are exceedingly crude for this operation.

The hot iron and the clam have a strange fascination for many practitioners. These barbarous methods are adopted by the travelling castrators, we presume, in consequence of a superstitious belief in the efficiency and in the simplicity of their manipulation. The qualified man, however, should not be influenced by such considerations.

It has been stated that the results of the hot iron are more favourable than those by other methods; but we would like to inquire how such results are arrived at, as we are not going to accept the *ipse dixit* of the individual on the matter, or draw conclusions from his results of the different methods of operating.

The devotee of antiquated surgical methods resents violently if his deductions and handiwork are criticised; but as "old customs die hard," we are not surprised at this.

Veterinary surgery is bound to progress with the times, and not lag behind to follow in the trail of human surgery. As an example, we may mention the employment of chloroform, which, although by no means as largely used in veterinary surgery as it should be, still, aided by the humane owners of animals, its use is becoming more general. We take it as a sign of the times when owners of animals insist on the employment of anæsthetics, but we do not consider it altogether to the credit of the profession that such a request should be necessary.

With regard to castration, we were told more than once during a long paper discussion that it would be impossible to carry out anæsthesia, and the most trivial excuses were put forward. What was the result? Every excuse that was mentioned was proved to be imaginary, and any one who has operated with the patient under chloroform will continue to use it. Prejudice and a want of practical knowledge of the employment of anæsthetics are the real causes for their use not being general. So long as prejudice exists, a want of knowledge is sure to continue, with its attendant train of erroneous ideas.

A long experience of the method of castration by torsion enables us to draw attention to some important details in connection with the operation. We do not claim that no unfortunate sequelæ follow this method: as we have already remarked, the element of chance enters largely into the results, no matter what method be adopted. No doubt the condition of the animal has a great deal to do with the results; if his constitution be sound and fit, he has a far better chance of doing better than under the opposite circumstances. After all it is simply a question of the healing of the end of the spermatic cord and of the operation wounds; and, just as in wounds of other regions, if the animal's constitution be unhealthy or out of condition, and if the surroundings are unfavourable, we cannot expect satisfactory results.

Aseptic castration we look upon as impossible under existing circumstances and conditions. No doubt attempts may be made to bring about such a fortunate state of affairs by those who are not engaged in the routine of daily practice; descriptions of the attempts also serve to embellish the chapter on castration in works on modern veterinary surgery.

While we can never hope to perform this operation under conditions similar to those in human surgery, and with the same results, still we must as far as possible pay attention to antisepsis and surgical cleanliness. We can at least have our instruments aseptic by taking the precaution of placing them in boiling water; we can also have

the instrument tray aseptic, and the vessel containing the antiseptic solution in a similar condition; we can to a certain extent disinfect the skin and surrounding parts of the field of operation; and, last but not least, we can render our hands aseptic.

Next comes the great difficulty and drawback to our efforts, viz., the surroundings and the attendant. Our experience has been, that provided the weather be favourable the animals are far better on grass than in the best-formed stable, also that the less handling they receive from the attendant the better. Of course no hard and fast rule can be laid down on the subject, and while some give no trouble, without any attention from the attendant, others require to be looked after. With very few exceptions do we find buildings which are fit to accommodate surgical cases, certainly not in country districts where the majority of colts are housed after the operation. Many are filthy in the extreme, and even the aid of a Hercules would not render them clean enough to satisfy our minds. Still we have to make the best of our surroundings, and endeavour to have them cleaned and disinfected as far as possible. As regards the ordinary farm attendant's hands, we imagine that even prolonged boiling would hardly sterilise them. Under such circumstances we cannot be surprised when bad results of the operation follow, a combination of dirt and rough handling being opposed to natural healing.

Taking everything into consideration, we may state that the results obtained are very satisfactory, and that the unfavourable sequelæ to which we shall shortly refer can to a great extent be minimised or prevented. Given an animal in healthy condition, and surroundings as favourable as can be expected, the next important point is with reference to casting for the operation. Of course all necessary precautions must be taken, as in casting for any operation. We may state that we prefer casting with small-sized hobbles, and performing the operation with the animal lying on the side, the uppermost hind leg being released from the hobble and secured towards the shoulder by means of a side-line. Needless to say, we administer chloroform to animals of all ages, and have no trouble, danger, or anxiety from its use. Next with reference to the instruments. We use a special-clamp, with edges that fit accurately like an artery forceps. The testicle is exposed in the ordinary way, the so-called non-vascular portion of the cord is severed by means of a pair of scissors with serrated edges. This precaution prevents hæmorrhage from the small testicular artery. The clamp is then fixed on the vascular portion of the cord as high up as possible, without dragging on the latter, and the instrument is closed as tightly as possible. The torsion forceps are then applied, and if the testicle be large it is removed a short distance from the forceps. We apply the forceps as close as possible to the surface of the clamp, and then rotate the forceps slowly and regularly, the first few turns being more rapid; by this means no bruised tissue is left behind, and the operation is more

expeditions. We never permit an assistant to hold the clamp, as we can do so ourselves, and perform torsion with facility. The important matter is to avoid any dragging on the cord.

In the case of yearlings, if we operate in the country we leave them on the grass at once, provided the weather is favourable; of course, they are housed at night for a variable period. In two-year-olds and upwards we keep the animals inside until next day, then leave them on the grass, and make certain they have at least an hour's exercise daily. The importance of daily exercise cannot be over-estimated.

The sequelæ of castration we are all unfortunately too well acquainted with.

Hæmorrhage, either primary or secondary, will sometimes occur in spite of all precautions. Although we have never known a case that terminated fatally as the result of hæmorrhage, still it is our experience that colts which bleed after the operation do not progress favourably, and frequently develop other sequelæ. The source of the hæmorrhage is not always easy to discover, but in yearlings we have often observed that the small testicular artery is very well developed, and we are of opinion that the hæmorrhage arises from this vessel. If this portion be severed by means of a serrated scissors instead of a knife, there will be practically no hæmorrhage. In weak yearlings we have found it of advantage to place the entire cord in the clamp, and sever the non-vascular portion on the surface of the instrument before applying the torsion forceps. It is rare to encounter hæmorrhage immediately after the operation; of course, some animals bleed more from the scrotal incisions than others, but this soon ceases.

It is hæmorrhage occurring from two to six hours after the operation that is likely to cause trouble. As regards its suppression, much depends on circumstances. If the bleeding be only slight, the application of cold water may help to bring about a spontaneous cessation; but if profuse, especially with evidences of arterial bleeding, we must resort to plugging the canal, and the best material is carbolised tow pushed in firmly in pledgets. This has always succeeded, but we must admit that next morning there is always enormous swelling, and a tendency for a recurrence of the hæmorrhage when the pledgets are being removed. It is astonishing the tendency to hæmorrhage possessed by some animals; we have seen intermittent hæmorrhage to last for three days, and recur in a continuous drip every time the pledgets of tow were removed. One important detail is not to allow the packing to remain in too long, as it very quickly becomes septic. At the same time care is required in removing it. One of the most troublesome cases of bleeding we ever encountered was when acting as assistant. The animal, a large yearling, was castrated the previous day by another practitioner. By chance we happened to be passing by, and found the groom in a great state of alarm; the blood could be heard gushing in a firm stream. No appliances were at hand, and not even tow or wool. We came across some alum and dissolved it in cold water, and applied

same diligently, and sent to town for the operator. When he arrived the hæmorrhage had ceased spontaneously, and the animal made a good recovery, although having lost a large amount of blood.

It is a point worthy of note that in bleeding after castration the animal generally keeps the hind legs moving and frequently disturbs the clot, and so favours a continuance of the hæmorrhage. When hæmorrhage does occur it is absurd to attach blame to the operator; in spite of every precaution it will occur in some instances, and we believe that a similar result would ensue from a wound in any other part of the body.

We are aware how profuse is the hæmorrhage in some animals after the operation of docking, and how difficult is its suppression. If asked what suggestions we would give in the prevention of this annoying sequel, we would say:—

First. Avoid exciting the animal before operation, and have him cast as quietly as possible.

Secondly. In weak animals, take especial care in twisting the spermatic artery, and in every instance see that the animal gets an opportunity of rising without knocking himself about. Do not walk him immediately after the operation, but keep him at rest so as to give the arteries a chance of being properly sealed. On no account permit an animal to be walked home the same day if it is any distance. The owners of animals usually exaggerate the extent of bleeding, and become very much alarmed at a small amount of bleeding. Our experience teaches us that in many instances the bleeding will cease spontaneously without any plugging, and the latter is certainly to be avoided if possible.

In our next article we shall consider some more sequelæ of castration.

THE COCONUT PLANTER ABROAD.

One of the greatest troubles of Coconut growers on the river has hitherto been the destruction caused by the natives, who cut step in the trees to reach the nuts. The trees never bear after this mutilation. They have, however, had it explained to them that they are "killing the goose that lays the golden eggs" by this proceeding, and further more that it is very displeasing to the white residents. They have consequently promised not to do this for the future, and will not allow their picaninies to do it, so that now there is very little danger of loss by coconut planters.

When planting the nuts, all the protection they get is three stakes driven into the ground round the spot to keep off horses. In cases where there is danger of fire, sweet potato vines are planted about the young trees, which are thus quite protected from that element. Once the trees have made wood, cattle and even goats may be allowed amongst them, as they never touch them, and trees under which cattle camp thrive better than others.

In planting coconuts, Mr. Pentreke says:—"I shall in future always plant them in an upright position with the eyes uppermost. The reason is that when a tree is sheltered, the nuts

will remain in their place till the germ pushes the nut off (unless it is forced by some extraneous cause), and if in falling it strikes the sand or soft earth, it will stand upright and grow into a straight upright tree. The nuts only turn on their side when they fall on hard ground. When the nuts stand in the natural, upright position, the gases or volatile oils float on the top of the contained liquid near the embryo, which liquid and oils serve the purpose of lubricating the kernel near the seed, and supply the germ with its first food, and continue to do so till the young plant makes its appearance on top. Crooked growing plants should be removed as they indicate the first stage in degeneration."—*Queensland Agricultural Journal.*

If the "cutting of steps" by the natives (ready to obey when told not to do it again) is the greatest trouble of the Coconut Planter in Queensland, then the Queenslander is fortunate, as also in having so effectual a means of insurance against fire in the sweet potato plant. But the scientific explanation of the advantage of planting nuts upright, viz., to bring the embryo within the influence of the "gases or volatile oils" which "float on the top of the contained liquid" is something new even for Ceylon.—*Ed. A.M.]*

GENERAL ITEMS.

The *Station, Farm and Dairy* of June 12th referring to the variability in the composition of cows' milk, says that there are many causes for variation as conclusively shown by a series of tests carried out by the Highland Agricultural Society (Scotland) where 700 analyses were made of the milk of 18 cows during a period of 21 days, each cow's yield being collected and analysed, separated both morning and evening. Samples containing less than 3 per cent, or even 2 per cent, often occurred, and a few days later tests of the milk for the same cow would give 5, 6 and 7 per cent of fat. Of course the average milk of a herd would not vary so greatly, but according to the best authorities tests might go more than 30 per cent above or below the average for the year. It was found in England that the average of a herd during drought was much lower than the same period in the previous year. Variation might be classed as due to three causes: (1) those that are natural and progressive, (2) those that are accidental and usual temporary, (3) those that are unknown.

Oxalis Crenata, the "oka" of the Peruvians, is spoken of as a vegetable worth cultivating, though not likely to take the place of the "tubers" already in cultivation, such as sweet potatoes or artichoke. Sir W. Thistleton Dyer referring to it says:—"The tubers should be planted 3 feet apart in sandy soil and treated like the potato. New tubers are formed at the end of the season, and under favourable conditions they are 3 inches long and weigh 2 oz. When lifted they should be exposed to sunlight for 2 or 3 days. To cook them boil for 20 minutes in water containing a pinch of carbonate of soda; they then turn into a

bright amber colour, and if eaten with pepper and salt they are palatable and of pleasant flavour." Another closely allied species is *O. esculenta*, the tubers of which are cooked in salt water and served with melted butter and cream.

The following appears in the *Victorian Agricultural Journal*:—Beyond acting as a support, wood is not actually necessary to the life of bark and leaves. Any cylinder of bark from which the wood has been skilfully removed will, if its sides are carefully closed against air, go on growing and deposit new layers in its inside until a centre of solid new wood is formed. This applies only to exogenous trees, or such as increase their diameter by depositing new layers on their exterior. Such are all our fruit trees, and when it is realised that the entire life of the superstructure is wrapped up in the bark, the need for careful and systematic attention to this substance is not to be over-estimated.—This statement is apt to mislead those who know no distinction between the heart wood and sap wood, for it cannot be said the sap wood is not necessary to the life of the bark and leaves. But of course the object of the above statement is intended to impress upon those, who are apt to think little of the bark of a tree, that it is not the least important part of the stem structure. The agent that is really responsible for the deposition of new layers of wood tissue is the cambium which lies between the wood and the bast, or the inner part of the bark.

Mr. A. Crawford, an authority on poultry, in reply to the question how much food should be given daily to fowls, writes to the *West Australian Journal of Agriculture*:—This is rather difficult to reply to, for so much depends upon the breed and the surroundings; in some places the fowls can pick up nearly their whole living when running about, while in others they are entirely dependent on what is given to them. Then there is the difference in the habits: some breeds are good hunters, and extremely active, always on the go in quest of what they can pick up, and will wander far afield, while others will hang round the homestead or sit in the shade waiting for food to be thrown out, and even when neglected do not seem to have the sense to try and make a living for themselves. Then again, there is the matter of size to be taken into consideration: a Leghorn or Hamburg will not eat anything like as much as an Indian Game or Cochin, but if we take ordinary fowl of moderate size, the following ration would be about an average of their requirements:—For breakfast, from $3\frac{1}{2}$ to $4\frac{1}{2}$ ounces of soft food such as pollard, bran and pollard, pea meal, bean meal, oatmeal, etc., and for the evening meal from 2 to $2\frac{1}{2}$ ounces of grain; always remembering that it is better to rather underfeed than overfeed.

The *Journal of Agriculture*, West Australia, does not approve of the application of lead paints and similar preparations for healing the wounds, but recommends vegetable oils, lard or other animal fat or grafting wax, which it thinks suffi-

cient to keep out disease germs, insects, and molds and extremes of heat and cold, so that any sap brought to the margin will remain active and form new bark. Wounds when intentionally inflicted (as in pruning) should be as smooth and clean as possible to induce quick healing.

Says the *West Indian Bulletin*:—Uncooked sweet potatoes may be sliced and then dried either in the sun or in evaporators. They are prepared for the table by soaking and baking. Dried sweet potatoes were exhibited among the products of Japan at the Columbian Exposition. Their preparation is described as follows:—"Cleanly washed potatoes are placed in a suitable basket and immersed in boiling water for a short time; when taken out of the basket they are cut into thin slices and spread over mats and exposed to the sun for two or three days. In order to make a superior quality, the skin of the potato is peeled off before slicing." As an indication of more recent developments it may be mentioned that a company has been lately started in New Jersey, America, with a capital of 1,000,000 dollars, to make flour from sweet potatoes. The early results are reported as being very successful, and it is proposed to erect mills all through the sweet potato growing region. The more important States in this region are North and South Carolina, Georgia, Texas, Alabama, Mississippi, Virginia, and New Jersey.

Mr. Clark Nuttall writing in *Longman's* about the banana, gives us some idea of the increasing trade in the fruit in the following extract from his interesting paper:—The coast of Honduras is a great centre of the export fruit trade, but in 1883 one little schooner was sufficient for all the requirements in the way of transport. Now three lines of steamers and sixteen sailing vessels barely meet the demands made upon them, the greater part of the fruit they carry consists of bananas. The cargo of a steamer may be anything between 8,000 and 15,000 banana bunches; hence it is obvious great numbers are exported yearly. The West Indies, Cuba, Costa Rica, and Central America generally tell the same tale of increasing trade. From Jamaica alone we get millions of bunches now every year.

The fruiting of the "Male" papaw tree is the subject of a special note and illustration in the *Queensland Agricultural Journal* for May. The phenomenon—if it could be called so—is familiar enough in Ceylon where the papaw is so plentiful, but the fruit, as an inferior product, is looked down on—in fact never gathered. The papaw is as a rule dioecious, but when the "Male" bears, as it sometimes does, seeded fruits, the term male tree becomes a misnomer. The fact is that the papaw which is generally dioecious exceptionally bears hermaphrodite flowers on the "Male" trees.

We read in the same Exchange of the suitability of Queensland for cinnamon, which, however, appears to have a deadly enemy in the shape of a black beetle that attacks the young plants.

Banana bread made from the flour is now available in Chicago, and is voted excellent.

No. 2.

"THE ECONOMIC RESOURCES OF THE STRAITS SETTLEMENTS AND THE MALAY PENINSULA.

By H. N. RIDLEY Esq.

MR Cecil Clementi Smith presided, on the 16th December, at an illustrated lecture given at the Imperial Institute by Mr. H. N. Ridley, Director of the Botanic Gardens, Singapore, entitled "The Economic Resources of the Straits Settlements and the

Malay Peninsula.'

Probably, said Mr. Ridley, no portion of the Empire was so little known to the English public as the Straits Settlements and the attached Federated States. It was, however, one of the most thriving of the smaller colonies, and possessed in Singapore, the most important port in Eastern Asia.

Its heavy rainfall, of over 100 inches annually, was evenly distributed throughout the year; so, unlike other tropical regions, there were no season. The trees, which were evergreen and for the most part bore flowers and fruits irregularly all the year round, grew with great rapidity; consequently it had been found more suitable to cultivate plants whose produce was derived from the vegetative portion rather than from the fructificative. The climate, though hot, was neither unpleasant nor unhealthy, and cases of sun-stroke were almost unknown. Coolie labour on the estates was supplied by Japanese and Tamils; the Chinese, though very industrious and invaluable when working for themselves in agriculture; commerce, or mining, had not been found amenable to European methods of discipline.

The greater part of the Malay Peninsula, which consisted of hills rising to about 7,000 feet altitude with more or less flat country running along the coast-line, was or until recently had been, covered with dense forests; and the characteristic view from almost any of the hill-tops at the present day was one of endless trees, of which there were several

thousand kinds, although to the casual observer they seemed very similar. These produced excellent timber, both hard and soft woods suitable for all kinds of purposes, while some of them, ebony and other ornamental woods, were suitable for cabinet work.

Among the trees of special interest Mr. Ridley mentioned the camphor, not the Japanese camphor tree from which the camphor of commerce was now obtained, but a much larger one, belonging to a different natural order, and from which camphor had originally been obtained some hundred of years before the discovery of the Japanese tree. This Malay camphor was obtained from the hollows of the trees but it was very scarce and far too expensive to come into the London market. It was sought by the Malays with quaint ceremonies, and generally used in magic and religious ceremonies by both the Malays and the Chinese.

Wood-oil was obtained from certain of the large trees by cutting a hole in the trunk about a foot across and six inches deep and lighting a fire therein. This caused the oil to flow out, which was caught in tins and used as varnish. Owing, however, to the death of the trees the supply of the oil had become so scanty that it seemed nearly to have disappeared from commerce. The sweet-scented incense gum, benzoin, was also obtained from one of the Malay forest trees, and formed the chief element in the incense used in churches.

The most important of the Malay jungle products, however, was gutta percha, without which the submarine telegraph cables could never have developed to their present importance. This tree, the *Isonandra gutta*, was confined to the Malay Peninsula, Sumatra, Borneo, and the islands of the immediate neighbourhood. It was discovered in 1843, first being noticed on account of its property of becoming soft and easily moulded in hot water. Its high insulating powers, and resistance to sea-water, were soon noticed, and it very shortly was in great demand for electrical work, surgical instruments, and many other purposes. The tree was of very slow growth, but eventually attained great size. The gutta percha

was obtained by felling the trees and cutting rings through the bark all up the trunks, when it exuded in the form of white milk, which was collected in leaves and set into blocks of different forms.

So great indeed had been the demand that every accessible tree of any size had been felled, not only by the Malays, but by the wild tribes who rambled all over the forests, and consequently in large areas no tree large enough to produce seed remained, and the plant was on the verge of extinction. The trees produced seed very seldom, and although Mr. Ridley had offered large prices for some none had been forthcoming. The Government of the Straits Settlements had consequently stepped in and taken measures for the protection of the remaining trees. The amount of gutta percha produced by felling and cutting was very small in proportion to the age and size of the trees; one upwards of a hundred years old would produce but 2 or 3 lb.

However, a Frenchman in Singapore, had, about eight or nine years ago, discovered that, by drying the leaves and twigs of the tree, and grinding them to powder and then mixing the powder with water, the gutta percha floated to the top so that it could be skimmed off and pressed into blocks. He had started a factory in Singapore, which had, at his death, passed into other hands and had been eventually transferred to France, whither the leaves and twigs were now sent to be worked. By this simple method, and by growing the plant in the form of bushes rather than trees, it was hoped that in time the Malay peninsula would be able to furnish the world with a good and regular supply of this valuable product.

The rattan was another important jungle product. It was the stem of a thorny, climbing palm which scrambled about and over trees by the aid of sharp hooks with which the leaves and flower-stems were provided. There were a great many different kinds of rattans, and Mr. Ridley gave an interesting account of the method of cutting them down and preparing them for shipment to Europe and the United States, for manufacture into chairs, baskets, etc. As the supply was hardly equal to the demand, the plant was now beginning to be cultivated, and a reasonable return might be expected with but very little expense.

Coffee was cultivated over a large area of the Peninsula, and the large seeded Liberian had been found to grow there very well indeed, and better than the more valuable Arabian variety; but, unfortunately of late, the price of Coffee had been so low that most of the planters were adding the valuable Para rubber tree to their estates. This tree, a native of the Amazon district in Brazil, had been introduced from Ceylon in 1834 to the Botanic Gardens in Singapore, where it has been found to grow with remarkable ease and rapidity, and to produce a very good yield of first-class rubber.

While coffee had been in the ascendant, however, the planters had not troubled themselves about rubber, but now, owing to the increased demand for the latter commodity, due in great measure to the rapid evolution of the bicycle and the motor car, the attention of planters all over the world had been directed to this product. A large number of plants produced rubber, of one kind or another, but that from the Para tree was by far the best. Attempts had been made to cultivate this tree in many parts of the world, but with only partial success. In the constantly damp and warm climate of the Straits Settlements, however, it has grown with astonishing rapidity. A tree raised from seed attained its full height of 60 feet in five or six years, after which it continued to increase in girth to about 4 feet, in twelve years. The expense of cultivation was very small, no manure being required, and the tree could be tapped when six years old, when it would produce about 2 lb. of rubber a year. Older trees produce more. The rubber was obtained by cutting first a narrow channel through the bark vertically,

with slanting ones leading into it all the way down the trunk of the tree, at the foot of which a little box was placed with the lid so arranged that, although the rubber-milk could get in, dirt and rain-water could not. The trees were tapped in the afternoon and the rubber collected from the boxes on the following morning. Every day for a week, at 4 o'clock, a thin slice was cut off the edges of each slit, and more milk ran out until the tree was finally exhausted. The wounds were then left to heal, which usually took about one or two months. The trees could be tapped once or twice a year according to size, and the rubber thus obtained was worth from 4s. to 4s. 6d. a pound. Even at half that price the cultivation would be the most remunerative of any in the East, and thousands of trees were being planted all over the Peninsula, as fast as the seeds could be procured.

The India rubber, *ficus elastica*, so common in pots in English houses, was being cultivated by many planters. Its appearance, however, was very different when grown into a large tree with great roots. It was a native of the Peninsula, and thrived well there, but its rubber was of less value than that of the Para.

Another paying crop, which was cultivated wherever the soil was sufficiently sandy for its growth—generally along the sea-coast, was coconut; and large areas were devoted to its cultivation in Singapore, Penang, Province Wellesley, and elsewhere. In some places the trees were severely attacked by two kinds of large beetles, which burrowed through the shoots and soon caused the death of the tree. The destruction of trees, at one time, had been enormous, until a law had been passed compelling owners to destroy badly affected trees, and also the rubbish heaps in which one of the beetles bred. This law had had very beneficial results. The nuts were sold either for food, for which there was always a large demand, or as copra—made by splitting the nuts in two and drying the halves, which were used for the manufacture of oil and stearine.

The betelnut palm was also cultivated to a considerable extent, and although betel chewing had largely gone out of fashion in the Peninsula, there was still a considerable demand for the nut in India. It was also used to a small extent in European medicine.

The most useful of the palms, however, was the sago, which was planted in a good many places in the Peninsula. Three sago plants would give more nourishment than one acre of wheat, and one acre of sago as much as 163 acres of wheat; in fact sago gave a larger amount of food per acre than any plant in the world. The plant was grown from cuttings, or seeds, in wet swampy places, forming dense thickets, with its huge leaves 20 feet in length. The main stem crept along the ground and threw up great branch stems, about 40 feet high and 1½ feet through, which eventually produced at the top great panicles of flowers and fruits. The plant took twelve years to produce its first stem, after which its growth was more rapid, and fresh stems appeared regularly, so that at most times of the year, in a big plantation, there were generally stems ready to cut. These were felled when full size, but before the appearance of the flowers, and cut into pieces about two feet long. They were then split in half, the bark and woody exterior removed, and the sago manufactured from the inside white pith, first into sago flour and then into granulated or pearl sago. A full size stem would produce as much as 600 or 700 lb. of flour, and about 30,000 tons were exported annually from Singapore.

The tapioca plant was a tall, half-shrubby plant, resembling somewhat the castor oil. It was a native of South America, but had long been cultivated all over the East, and was very largely propagated from cuttings of the stem, which we just stuck into the ground, and, in a year or eighteen months, attained a height of about six feet, forming huge thick roots under ground. When these roots were of full size, the plant was cut down and the roots dug up and taken to the

factory to be manufactured into flake or pearl tapioca. This plant was always cultivated by the Chinese. Only three crops were taken off the land. Its cultivation, often a very paying one, was said to injure the soil, and so was not one upon which the Government looked with much favour. Tapioca and sago were, of course, used for many other purposes than as food.

Gambier, cultivated entirely by the Chinese was a climbing shrub. It was always grown in the open field in the form of bushes, which was severely cut every year. The branches and leaves were then taken to the boiling sheds, and, after going through various processes, the gambier was shipped to Europe for the use of tanners. Another, a totally different plant, the mangrove, produce a tan-stuff which was now finding its way into our markets. The mangrove was a tree, growing on the edges of tidal rivers and seashores, wherever they were muddy. This particular tan-stuff was also used in combination with indigo as a dye-stuff by the Chinese. Indigo, however, was not a large or important cultivation in the Peninsula. It was only grown to meet a small local demand.

Pepper was another plant generally cultivated by the Chinese, usually by gambier planters. It was raised from cuttings and climbed up large stems or posts. Formerly it had been a highly priced article, but of late years had fallen off very much and its cultivation in the Straits had diminished. Now however, the price had risen and the Chinese and Malays had recommenced planting.

The Straits Settlements were famous both for nutmegs and cloves, which were also chiefly cultivated by the Chinese. The nutmeg, as grown in the Straits, was quite a small bushy tree with deep green leaves and fruit resembling a small peach. When ripe the husk split partly open, exposing a black seed, covered with a beautiful scarlet network. This net-work, the mace, was taken of when the fruit was ripe and dried in the sun. It was often more valuable than the nutmeg itself.

This cultivation was an old established one. In 1848 Singapore alone supplied over four million nutmegs, but in 1860 a disease was developed which entirely destroyed the cultivation in that place, and nearly did so in Penang. European planters had been ruined, and their estates and houses sold for very small sums. The Chinese then started the cultivation in Penang, and had kept it up to the present time.

Mr. Ridley, not long ago, had his attention called to what he considered the same disease, and on investigation he found it due to a minute beetle which burrowed into the bark of the tree, beneath the ground, so that its presence was not noticed until, by its burrows, the cambium, or living layer of the bark of the tree, was destroyed and the tree appeared to die suddenly. Had this discovery been made in 1860 the cultivation could easily have been saved. This was, he said, an excellent example of the importance of the entomologist to the planter.

The most important native cultivation in Singapore was the pineapple. The plants grew from cuttings, placed close together, and completely covered the ground. The fruit, when ripe, was cut and brought into the town in cartloads to the preserving factories. The industry of tinning pines was a large and very remunerative one. By far the largest number of the best preserved pines in the markets of the world came from Singapore, where the price of a pine varied from $\frac{1}{4}$ d. to a penny a piece. The plants produced fruit nearly all the year round, were very easy to cultivate, grew in the worst of soils, and its only enemies were porcupines and wild pigs.

From the leaves of the pine a very beautiful fibre was extracted. The leaves of the ordinary varieties, however, were too short to be used successfully for this purpose, the most suitable leaves being from plants in waste ground that had grown up with grass and scrub among them.

The Malay Peninsula was remarkable, according to the mineralogists, for having given samples of almost all the known elements, but these were so sparsely and generally scattered over the whole region that the expense of collecting most of them would hardly repay the cost. Tellurium, wolfram, and titanium were comparatively common. Gold, silver, lead, zinc, copper, antimony, and other metals all occurred in small quantities widely scattered over the country; but little mining had been done except for gold and tin. In former years the Peninsula produced a good quantity of gold; the yield, however, at the present time was but small.

Tin was the mineral of the country, being found there in great abundance; in fact, more than one-half the world's supply was derived from the Peninsula. The greater part of the mines were alluvial, though lodes had been found and worked. Rich beds occurred in the stream valleys at the base of the hills in Selangor and Perak, and were worked by the Chinese, who dug to no great depth, and washed the alluvium with very primitive sluices. The tin was sold to European firms, melted into ingots at Singapore, and then exported.

In conclusion, Mr. Ridley said that in the course of a single lecture it would be impossible to give more than an idea of the great wealth of resource of the colony. He had attempted to describe rather the peculiar vegetable products of the country, so as to show what had been done in the introduction and cultivation of new and exotic plants during the last half-century. When Sir Stamford Raffles planted the English flag on Singapore Island in 1819, it had been inhabited only by about 200 fishermen and pirates; now it was the most important port in Eastern Asia, with a population a thousand times as large. Then the Native States had been in a constant state of war and anarchy, and the natural wealth of the country was neglected; now, owing to the energy of the white man, aided by patient hard work of the Chinaman, the forests had been felled, mines opened up, cultivation introduced, and commerce developed. An era of justice, freedom, and peace to all had been inaugurated, and the country had become one of the most thriving of our tropical colonies.

There were still, however, large areas of country practically unexplored, and doubtless much mineral wealth untouched; and Mr. Ridley was of opinion that the colony was only really in its infancy, and that gradually and steadily the work of progress would continue year by year, and he was confident that the future of the Malay Peninsula would be one of great and increasing prosperity.

The lecture throughout was illustrated by a well-selected series of slides, many of which had been specially prepared.

The chairman, in proposing a vote of thanks "for a very attractive lecture," referred to Mr. Ridley's commendable simplicity of language, and to his avoidance of technical expressions, which had enabled all those present to carry away every single piece of information which he had been good enough to impart to them.

Sir Cecil Clementi Smith said he should like to take this opportunity of drawing attention to the work that Mr. Ridley, and the Directors of other Botanical Gardens, were doing in going out to the Colonies and devoting themselves with ardour and zeal to economic botany. They, in a quiet and unobtrusive way, were winning victories over nature of which the ordinary man in the street knew absolutely nothing. They did not get honours thrust upon them or mentioned in the newspapers, but their work was nevertheless of extreme value in forwarding our efforts of making human life more endurable and more delightful. Mr. Ridley's labours—only a small portion of which he could have referred to that evening—in experimenting on the cultivation of plants, and the similar work of the Directors of

other Botanical Gardens, were of immense benefit to the Empire. Most people in this country knew Kew as a place where they could see beautiful and attractive things grow. It was, however, much more than that. The making the gardens attractive formed but a small part of the duty of Kew. It was a mighty organisation and the centre of the botanic activity of the Empire; and Mr. Kidley would probably be the first to acknowledge the great assistance he had received in his botanical efforts from the Authorities of the Royal Botanic Gardens, Kew.—*Imperial Institute Journal*.

PHOSPHORIC ACID AND POTASH IN SOILS.

The fertility of a soil is estimated, not by the total amount of chemical constituents which it contains, but chiefly by the availability of the plant-food ingredients.

Phosphoric acid, though soluble in water, is not easily washed from the soil, either by rain falling upon it or by artificial waterings.

In some recent investigations by Dr. Bernard Dyer with soils obtained from the Experimental Station at Rothamsted, it was found that there was little risk of loss of either phosphoric acid or potash, even if larger quantities are applied at one time than what are required for the immediate use of the growing crop, but that these elements accumulate in the upper layers of the soil, where they remain until taken up by the plant. It was, however, found that these ingredients when derived from farmyard or stable-mannure were less stationary than when derived from artificial manures; considerable quantities were found to have penetrated into the subsoil even as low as 27 inches from the surface. This is doubtless due to the more open and porous texture of the soil under the influence of continuous applications of large quantities of organic and bulky manures.

When a manurial application of superphosphate, combined potash, and other mineral salts is made, a distinct influence is exerted in the retention by the soil of phosphoric acid in a less fixed and, therefore, presumably more available condition; while if, for want of nitrogen in the soil, the growing plants have been unable to utilise all the phosphoric acid thus rendered available, more of it descends to the subsoil, as a result of the soluble action of these alkali salts. The importance has for many years been fully recognised by the intelligent horticulturist of applying nitrogenous manures in combination with phosphates, and the reason for this practice is shown in the foregoing statement.

In some of the vineyards of France it was found that there was a feeble development of wood, a falling-off of blossoms, diminished yield of Grapes, diseased leaves and roots, with a consequent retrogression of fruit quality. Attempts were made to remedy this defect by the application of abundant dressing of cow-manure—a material which has long been recognised to be one of the best of fertilisers available for the purposes of viticulture; nevertheless, this treatment proved utterly incapable of arresting the gradual exhaustion of the soil. Old vineyards exhibit a continuously progressive falling-off in fertility, and require digging at intervals, which become more frequent, or even, after a short period, they frequently have to be replanted. It is readily conceivable that soil which is frequently being turned over, so that fresh portions are always brought in contact with the roots ramifying in it, must, in course of years, lose much of its pristine richness, that cannot be completely restored by cow-manure alone.

The writer is acquainted with a plantation of Black Currant bushes which had been manured year after year with heavy dressings of peat-moss manure, and yet this material utterly failed as a restorer of soil fertility; the Currant-trees blighted, lost their leaves, and the fruit was scanty and of poor quality. After

various trials it was found that to ensure perfect nutriment of the bushes, and to render possible the production of good and full yields of fruit, chemical manures providing available phosphoric acid must be resorted to. Phosphoric acid is directly connected with the increased development of fibrous feeding roots within the surface soil, that enables the plant to obtain the maximum of benefit from rainfall and bright sunshine. This is the special effect of phosphatic manures when applied to superficially rooted crops, such as Turnips, Onions, Potatoes, Carrots, &c., and it is by virtue of this development that these crops so markedly exhaust the available nitrogen within the soil, and especially of the surface soil.

In regard to the element potash, it is sometimes stated that this ingredient is of relatively less importance than either nitrogen, phosphoric acid, or lime; partly for the reason that fertile soils are naturally richer in potash, and because the generality of plants remove a smaller quantity of this element from the soils than of the other substances mentioned.

Until recent years it had not been made quite clear what function potash exactly performed in the plant, although it has been proved over and over again that no plant is able to grow satisfactorily unless potash be present in a more or less available condition within the soil.

A theory was at one time held that soda, which is not an indispensable plant ingredient, was capable of replacing potash in the plant; but this has now been shown to be false. No other substance can replace potash, which is an essential constituent of all plants.

According to investigations at Rothamsted, it is found that the presence of available potash in a soil is an important condition of the formation in plants of carbo-hydrates generally. It is always to be found in the actively growing parts of vegetation, as in the growing buds and shoots, and it exists in relatively large proportion in the seed. In the culture of Potatoes potash is a most necessary ingredient in the production of the carbo-hydrate starch; and in the culture of Turnips, Carrots, Beets, and all descriptions of fruits, the carbo-hydrate sugar is greatly dependent on a liberal available supply of potash—and the richer the soil may be in the element nitrogen, which necessarily increases the luxuriance and succulence of growing plants, the more potash will be required. In fact, the great function of potash is, that it acts as a carrier of the ingredient nitric acid to growing parts of vegetation, and assists in the maturation, colouring, and ripening of fruits.

Now, there are some Apples which are fit for table in early autumn, while there are others which only become ripe when kept over the winter. Experiments have shown that succulent fruits, such as Apples and Pears, are remarkably influenced by the different elements of manure, not only with regard to their size, but also with regard to composition and maturity of the fruit juices; thus, the substances, potash and phosphoric acid, favour early maturity, while nitrogenous manures retard ripeness. Consequently, Apples and Pears that are required for early market or consumption, may be stimulated to forwardness by dressings of superphosphate of lime, basic slag, and potash; while fruits that are grown more exclusively for winter use may be retarded by making the ingredient nitrogen of greater prominence in the manurial mixture than either potash, phosphoric acid, or lime. Further, the later crops having the whole season for their growth, greater dependence can be placed upon the natural resources of the soil.—J. J. WILLIS, Harpenden.—*Gardeners' Chronicle*.

PLECTRANTHUS AS A VEGETABLE.

In a recent issue of the *Journal de l'Agriculture Tropicale*, attention is called to a paper of M. Lemarie on the tubers of *Plectranthus* as a vegetable. These plants are Labiates, closely allied to the already known *Stachys affinis*; they produce tubers that can be used similarly. MM. Pailieux and Bois, who in-

roduced this plant (and also the *Stachys*), have failed to acclimatise it in France, owing to insufficient heat, but M. Maxime Cornu introduced it successfully into Madagascar, the Congo, Gaboon, the Soudan, and Indo-China, whence excellent reports of it have been obtained, testifying to its value in countries where Potatoes do not thrive. The tubers of *Plectranthus* even exceed in amount of starch and farinaceous properties those usually cultivated in the colonies, and those of *Stachys tuberosa* (*affinis*). There are several species of *Plectranthus*, and they are not easily identified; most of them are natives of tropical Africa, India, and Malaya. At Hauoi in 1898 four small tubers, the size of a nut, were planted in the botanic garden, and from these M. Lemarie raised gradually increasing crops of tubers, that in January, 1900, were as large each as a hen's egg, and in their entire weight attained to 208 kilos., or about twice that number of English pounds. At the same time, very similar tubers were distributed which, when cultivated, showed such differences that they were determined to be distinct species. In the flowers the tint of blue and the position of the stamens with regard to the pistil varied. M. Cornu gave the first plant here mentioned the name of *Plectranthus Coppini*. Dr. Heckel prefers the name *Coleus Coppini*. M.M. Pailieux and Bois received from Réunion tubers of yet another species, known in the Transvaal; these on trial proved to be those of *P. tuberosus* (*Coleus tuberosus*). Now it is identified with *P. ternatus*. In 1887 the late M. Pierre, Director of the Libreville Botanical Garden, introduced the new vegetable into the Congo, where it was highly valued. The *Potager d'un Curieux* mentions yet a fourth species, *Coleus tuberosus*, cultivated in Ethiopia; this has since been identified with *C. edulis*. Various other species have also been reported from tropical districts, but some of these are doubtless identical with those already mentioned, and when the vegetable receives further attention, the list of distinct species will be diminished. The properties of the varieties are practically alike. In parts of Tonkin the *Plectranthus* tubers will fill an otherwise unfruitful period between May and October, leaving the ground free for other crops the rest of the year. This remark applies to other countries also. M. Lemarie judiciously remarks that before drawing hasty conclusions or planting the new tubers on too large a scale, attention should be paid to developing those that are largest of size, and in hastening on also the period of growth as much as possible. The species mentioned as producing edible tubers are *Coleus tuberosus* (Malaya), *Coleus barbatus* (East Tropical Africa, India), *Plectranthus esculentus* (Natal), *Plectranthus floribundus* (tropical Africa).—*Gardeners' Chronicle*.

OUR PRINCIPAL TIMBERS

(By W. MAIDEN, NEW SOUTH WALES.)

IRONBARK.

We have four ironbarks:—

1. The white or grey iron bark;
2. The narrow-leaved ironbark;
3. The broad-leaved ironbark; and
4. The red ironbark, or mugga.

(No. 1) *Eucalyptus paniculata*, Sm., is confined to the coast districts, and is paler than the others, although it varies in colour to a pinkish and even pale red colour, so that in the south it is sometimes known as "red ironbark"; this is the hardest, toughest, and most esteemed of our ironbarks.

(No. 2) *Eucalyptus creba*, F. v. M., is very widely diffused. It is the principal ironbark in that enormous stretch of country between Dubbo and Pilliga, &c., and also forms a part of the ironbark country east of Dubbo. But in greater or less abundance it is found over the whole of the north-eastern fourth of

the State. It is red in colour, is known in the trade as "red ironbark," and is a valuable timber. It is a narrow-leaved, drooping species, the most graceful of the group.

(No. 3) *Eucalyptus Siderphloia*, Benth.—This is largely developed in the Clarence River Ironbark district, but it extends along the coast and for a considerable distance south of Port Jackson. Like the preceding one, it also is well developed in the interior, though not to so great an extent. It crosses the dividing range and is abundant north of Dubbo, and is more or less diffused in the *creba* country between the interior and the coast, but it is much less plentiful in most districts than *creba*. It is always known as red ironbark, and is a valuable timber though, occasionally it is too free to be classed as a best ironbark.

(No. 4) *Eucalyptus sideroxyylon* A. Cunn.—This is *par excellence* the ironbark of the interior; at the same time there are few districts of the State, even in the coastal belt, in which it is not found sparingly. It penetrates furthest into the interior of the ironbarks being found at least as far west as Nymagee and Mount Hope, is well diffused in the south-western portion of the State, where it is the only ironbark tree, and is the only ironbark that extends into Victoria. In the northern half of the State it is also found, but, as a rule, not forming dense forests. It is a less compact tree than the others, yields timber of a deep-red colour and, although the least valuable of our ironbarks, is a valuable timber, often the best in the districts in which it grows.

RED HARDWOODS.

Timbers of this colour are usually very durable, hence people who have been victimised by receiving bad pale hardwoods frequently specify only red hardwoods. But even amongst red hardwoods we may have inferior timbers, some of the white gums, for example, having redwood. Our red hardwoods include—

1. Red mahogany (*E. resinifera*, Sm.).
2. Grey gum, which includes two species (*E. punctata*, DC., and *E. propinqua*, Deane & Maiden).
3. Murray red gum (*E. rostrata*, Schlecht).
4. Forest red gum (*E. tereticornis*, Sm.).
5. Sydney blue gum (*E. saligna*, Sm.).
6. Woollybutt (*E. longifolia*, Link and Otto).

The whole of these belong to the coastal belt, with the exception of the Murray red gum, whose principal habitat has already been indicated; it also is found near watercourses in the greater part of the western half of the State.

Red mahogany is chiefly found in the north Coast districts, though it is sparingly found for many miles south of Sydney. It is of a rich-red colour, and is one of the most durable of our timbers. It has a fibrous bark, and is a handsome tree.

Grey gums have bark of a dull grey colour, and somewhat blotched. The bark is a little roughish, in contradistinction to the smooth and even shaly appearance of that of some of our gums. Grey gum is one of the most valuable timbers of New South Wales, and is one of the principal timbers to be relied upon as an ironbark substitute, and thus to arrest the depletion of our ironbark forests. The best description of it as a timber lies in the fact that it is difficult to tell it from red ironbark on appearance only; an expert usually discriminates between the two by noting the tensile strength of a fibre. It is remarkably durable timber, and the only cases in which it should not be substituted for ironbark are where the tensile strength of best ironbark is required. It is largely used and esteemed in New South Wales, and can be recommended with the utmost safety to the foreign buyer.

Murray red gum is well and favourably known partly because it is the most gregarious of New South Wales trees. As with the Western Australian jarrah, so with Murray red gum, there is no difficulty in supplying a practically unlimited demand

of a timber of one uniform quality. We have other trees yielding timber of quality equal and even superior to these two, but because they are more scattered in distribution, there is always some liability to admixture with other timbers.

The forest red gum is botanically closely related to the Murray red gum; in fact, in their extreme forms the species run into each other; but, as a general rule, while the Murray red gum frequents river banks and flats, the forest red gum generally (but by no means always) prefers dry, open forests. Its durability is superior to that of Murray red gum, many experts always selecting it in preference to the latter when both are available. This preference of forest red gum is another instance of the general truth of the observation that the best timbers grow in dry or, at least, well drained localities.

The Sydney blue gum may be so called to distinguish it from the pale-coloured blue gum (*E. globulus*, Labill.) of Tasmania and Victoria. It, however, occurs in both north and south Coast forests, preferably on rich damp land or flats. In this respect it is similar to Murray red gum. It forms magnificent straight trunks, is extensively used, being one of the best of our timbers where durability is required. It is much sought after for felloes of wheels.

Woollybutt, found in the south Coast forests, is the least known of the group. Yet, although not of the first-class on account of deficient tensile strength, it is undoubtedly a durable and generally useful timber. A good many people use it without knowing what it is, but it can stand on its merits, I think. Its bark is sub-fibrous, and its timber is not unlike red ironbark.

I have omitted a few of our *Eucalyptus* hardwoods that I might have included, but time does not permit of the inclusion of a complete list.

Turpentine and Brush Box.—Turpentine and brush box are useful hardwoods, and both occur in the coastal forests, the former from the Shoalhaven to the Tweed, and the latter in the northern forests from Port Stephens northwards, usually in brush, but often in open forests. Turpentine is botanically known as *Syncarpia laurifolia*, Ten.; and brush box is *Tristania conferta*, R. Br. Though not *Eucalypts*, they are closely related thereto. Turpentine is so called because of the peculiar oleo-resin it exudes; it forms magnificent straight trees in deep gullies, and is, perhaps, the most generally useful of our timbers resistant to marine borers, hence its very extensive use for piles in harbour works. It also has the great merit of being almost unflammable, and hence is sometimes used for beams in buildings. Brush box is a durable timber, obnoxious to white-ants; it has other merits, and in spite of its tendency to warp, it should be more largely employed than it is at present. It is one of the most beautiful of our trees, and is often seen in gardens and boulevards under the name of "Lophostemon."

Cedar, Beech and Hoop Pine.—These valuable timbers I must dismiss in a few words. They are chiefly found in the area marked blue on the map, as already indicated, though cedar is found in patches in mountain fastnesses in a latitude as far south as Sydney. Red cedar (*Cedrela australis*, F. v. M.) is one of our few deciduous trees, and is a denizen of rich brush forests. The timber takes the same place here that the West Indian mahogany does in Europe; our cedar being, however, much lighter in weight. Closely allied to it and substituted for it to some extent, are Rosewood (*Dysoxylon Fraserianum*, Benth.) and red bean (*D. Muelleri*, Benth.), valuable timbers, though less esteemed than red cedar. White beech (*Gmelina Leichhardtii*, F. v. M.) is another instance of a handsome tree yielding a valuable timber. It is of a pale colour, durable, does not shrink much, and is one of the best carving timbers we have. It is the most esteemed of a number of brush timbers of the same class, of which *flindosa* or cudgerie (*Flindersia australis*, R. Br.) is one of the most important. Hoop pine, or white pine, or Colonial pine,

or Richmond pine, are all names for the timber of *Araucaria Cunninghamii*, Ait., which occurs in brush lands at the heads of our northerly rivers. *Arancariae* form remarkable looking trees in the forest with their branches in whorls and their conical habit. They are more often planted for ornamental purposes than for timber. The hoop pine is our most abundant soft wood of the pine class, and is a useful timber, particularly in a country whose predominant vegetation is hardwood, yet it falls far short of the best soft woods of the Baltic and the Pacific Slope.

Cypress pine covers extensive tracts in the drier pastoral districts, and is chiefly confined to the western and southern plains and tablelands. It is usually more or less admixed with box of various kinds, although there are large areas entirely covered with pine. The cypress pine area has been already indicated on the map, and the pines therein consist mainly of two species, Murray or white pine (*Callitris verrucosa*, R. Br.) and red or black pine (*Callitris calcarata*, R. Br.). Other species extend to the Coast ranges and tablelands forming for example, dense forests in New England gullies, and even to the Coast, the beautiful cypress pine of Port Jackson being a case in point. Cypress pines are beautiful trees, and yield valuable timber in the arid districts in which they grow. Such timber is usually highly ornamental, even garish, in figure and colouring. Its chief merit is its resistance to white-ants, which enables it to be used for telegraph and fence-posts, in country infested with those insects and carrying but little other timber. It is also commonly used for house construction, and stands well. It is full of aromatic resin, and hence burns readily, diffusing a sweet fragrance. The attention of the forester has, during recent years, been a good deal devoted to thinning areas of cypress pine, work which will afford the State an adequate return if it be carried out under experienced direction and on business principles. Residents of the Coast districts do not readily realise what the conservation of our cypress pine forests means to the arid western districts which do not possess the abundant and comparatively accessible forests of the Coast belt. Cypress pines are small or medium-sized trees, compact and shapely in habit, and quite different in appearance to the hoop pine. They grow readily (too readily many people think) from seed, and are well worthy the attention of those who desire to cultivate the most horticulturally desirable of our native plants.

Miscellaneous.—I have only time on this occasion to mention by name brown pine (*Podocarpus elata*, R. Br.) of our northern forests; the silky oaks (*Grevillea robusta*, A. Cunn., and *Orites excelsa*, R. Br.) of our northern rivers and tablelands; the black bean (*Castanospermum australe*, A. Cunn.), from the Clarence to the Tweed; the tulip wood (*Harpullia pendula* Planch.) of the northern brush; the myall (*Acacia pendula*, A. Cunn., of our western plains); the she-oaks (*Casuarina*) distributed practically all over New South Wales. —*Indian Forester.*

A RUBBER PLANTATION IN GUATEMALA.

The large specimen of crude rubber shown at the entrance to the Guatemala pavilion at the Paris Exposition of 1900, and for which a good medal was awarded, was produced from cultivated trees (*Castilloa elastica*) on the hacienda "El Baul," in Guatemala, on the Pacific slope. This plantation was specially mentioned by Dr. Paul Preuss, in reporting on his expedition to Central and South America, under the auspices of the German colonial committee. It has more recently been referred to at length—because of its size, of the care taken in the extraction of rubber, and of the good quality produced—in the *Journal d'Agriculture Tropicale* (Paris), from which the details that follow have mainly been derived.

The plantation "El Baul," until recently the property of Joachim Asturias, is now in possession of a wholesale mercantile firm of Hamburg, who are extensively interested, like many other German houses in coffee planting in Guatemala, and its management is in the hands of Fritz Konig. He, by the way, is a brother-in-law of P. Ossaye, owner of the coffee, vanilla, and rubber plantations "Arenal" and "Seamay" in the same region. Such details are mentioned here as indicating that large and permanent planting interests exist in Guatemala, based upon outside capital, as a result of which much experience has been gained in such matters, which is shared by many persons of repute and success, whose confidence in the practicability of rubber cultivation is entitled to consideration.

According to Rene Guerin, director of the Central Laboratory of Guatemala, writing in the *Journal d'Agriculture Tropicale*, the plantation "El Baul" comprises about 50,000 rubber trees, of which 30,000 have reached a productive stage, being from 10 to 15 years old. Dr. Preuss, by the way, writing two years earlier, mentioned 20,000 trees between the ages of 15 and 20 years. The soil, very liberally watered, is divided into sandy and black-earth zones, though no difference has been observed either in the growth or the productiveness of the trees planted in the two zones. The vegetation, is continuous, but at the beginning of the dry season—March and April, when the seeds ripen—the leaves turn slightly yellow and fall.

The trees growing in the plains furnish at all seasons a latex of the same quality. The trees on the higher altitudes, and which are for this reason less well watered, yield during the rainy season a larger quantity of latex than during the dry season. However, as this latex is less rich in caoutchouc, the true yield is the same. The rubber trees which have developed in the plains, exposed to all weathers, begin yielding seed from the third year. Those growing in the woods develop much slower, and at that age have not reached a height above 3 meters. But as soon as these have attained the height of the surrounding trees, and receive the sun's rays direct, their development proceeds rapidly and they reach large dimensions and possess exceptional vigor.

In extracting the latex, incisions are made in the bark horizontally, at a distance of $1\frac{1}{4}$ inch apart, so as to not girdle the tree completely. The latex coagulates spontaneously on exposure to the air, and at the end of two or three days the rubber can be gathered from the tree in bands, which, after being washed, may be rolled together into balls. Each tree yields about 125 grams of rubber (from incisions in the trunk alone, and without the branches), and as the cuts will heal within three months, it is possible to make four extractions each year, giving a total yield of 500 grams [=1.10 pound.] The annual yield of 1000 grams [=2.15 pounds] mentioned in Dr. Preuss's report, resulted from making incisions in the branches as well as the trunks, but this involves an undesirable amount of labor.

Much thought has been given on the plantation "El Baul" to the choice of a tool for incising the rubber trees, with a view to affording a suitable outlet for the latex, without cutting into the wood, which contains no latex, and the wounding of which tends to decay. Dr. Preuss found in use in Guatemala for this purpose a sort of transformed saber, a sketch of which appears in the first of the two cuts herewith. Senor Asturias has had made to

old model. The latter comprises a blade of tempered steel—square at the end, about 3 inches long, and at the top about $1\frac{1}{2}$ inches wide—mounted in a hard wood handle $3\frac{1}{2}$ inches long. The steel blade diminishes in thickness from the handle, until at the other end it does not exceed the thickness of a playing card. The left angle of the blade is turned over so as to form a rounded gutter, about finger wide, and at 45 degrees to the axis of the tool. The left side of the blade is notched right at the gutter, so that the lower end of the gutter projects at that side. The parts that do the cutting are the two sides of the turned over angle.

M. Guerin states that Senor Asturias intends trying a new process of extraction, by the employing a vacuum, in the hope of accelerating the flow of latex, and adds: "It would be desirable if other cultivators, intelligent and progressive like M. Asturias, would display the same activity in the improvement of rubber cultivation and the rubber product." In too many cases, however, the collection of rubber is left to the native, who injure the trees unnecessarily, besides producing a poor quality of rubber by the use of soap or vegetable compounds, whereas by the spontaneous coagulation of the latex, after the complete elimination of the serum, an article of superior quality may be derived from the same trees.

It was found by Senor Asturias that trees on his plantation which presented precisely the same appearance, yet yielded different qualities of rubber. M. Guerin forwarded specimens to the museum of natural history at Paris, where Jules Poisson, of the museum staff, has discovered differences in the fructiferous receptacles of the seeds, and if further engaged in endeavoring to discover whether different species exist. While some of the trees yield caoutchouc of a superior quality, the product of others remains after coagulation sticky, glue like, and with little elasticity. There is also a perceptible difference in the color of the latex, that from both trees being white, but in one case with a tinge of yellow and the other with a grayish tinge.

The question of differences in the product of the *Castilloa elastica* is by no means new, but generally the trees not yielding the true rubber have been supposed to bear outward marks by means of which they could be avoided by persons having any experience in hunting rubber. By the way, in connection with the subject, it is interesting to quote from Dr. Preuss: "One has repeatedly asserted to me that there were, on the other hand, places where *Castilloas* exist that are rich in caoutchouc, and yet whose latex flows along the trunk, so as to be collected in liquid state in vessels, but I have never been able myself to prove the fact." Which would indicate an interesting difference between the trees on "El Baul," the latex of which, as above stated, coagulates on the trunks, and those in Mexico, for example, whose latex flows more freely and requires to be coagulated by other means.—*India Rubber World*,

THE TREATMENT OF OLIVE OIL IN FRANCE.

In an interesting report on the treatment of olive oil in France, R. P. Skinner, United States Consul-General at Marseilles, points out that the manufacture of crude olive oil in Europe has undergone comparatively little change since Scriptural times. The olive tree gives a good yield of fruit every two years, which is gathered in France in either November or December. In Italy the picking season is in either February or March. The rule is to collect the olives before their maturity, without which they fall, become bruised and give an oil green in color and sharp in taste,

order, in the United States, the tool illustrated in the second cut, which is regarded as superior to the

Gathered too long before their maturity the oil extracted has these same disagreeable quantities, and it is therefore necessary to recognize with certainty the proper moment for taking them from the trees. At first green, they become yellow, then red and finally reddish brown, at which point they have arrived at the desired state of maturity. The olives found upon the ground are placed aside, and the trees are then shaken in order that the completely ripe fruit may also fall and be put apart. The oil extracted from these olives is of inferior quality and has the flavor of the fruit itself. The olives remaining upon the tree are either picked by hand or beaten with long poles. The latter method is discountenanced, as the fruit is thereby necessarily bruised, with disastrous consequences to the oil, and the trees themselves give a less abundant yield thereafter. This system is so expeditious, however, that in a large proportion of cases the trees are beaten and the fruit falls into sheets held beneath for the purpose. An olive tree ten years old should yield about six pounds of fresh olives, and at twice that age twice that quantity and at the age fifty years from twenty-two to twenty-six pounds.

In the south of France and Italy the crop of olives is gathered in large sheets and transported to warehouses or cellars, and there laid in beds six to eight inches in thickness. They remain for from twenty-four to forty-eight hours, until they commence to wrinkle and lose a little of their water, but not sufficiently long to permit fermentation to begin. In other countries, and particularly in Spain, the habit is general to store the fruit in piles, where it remains for from twelve to fifteen days. A black water is drawn from this mass which heats and ferments. Before the fermentation proceeds too far, a point which is decided by thermometrical test, the manufacture of the oil begins. The piles should not exceed six feet six inches in height. The extraction of oil from olives thus manipulated is easier than otherwise, as the cells containing the oil are less resistant, but the oil has a strong odor and is less desirable than that of more carefully handled fruit.

The manufacture of the oil, properly speaking, begins with the crushing of the fruit, which usually takes place in an old-fashioned mill. The crushed fruit is placed in round mats, of which twenty-two are usually placed one above the other, the weight of olives ranging about 165 pounds. The first pressure being applied for the virgin oil, the oil and water drain into tubs, the proportion being 72 per cent. of water and 28 per cent. of oil. The virgin oil is set aside, and the mats, removed from the press, are bent back and forth by hand, some of the manufacturers pouring a quart of hot water upon each mat, after which the twenty-two are placed in a hand or hydraulic press and the second pressure applied. The oil and water are drained into tubs, as with the virgin oil. The pulp remaining in the mats is removed, and by a single mechanical process, which takes place in a separator, the kernels are separated from the pulp, from which latter a third and very low grade of oil is obtained by chemical process. This process is rarely carried on by the olive growers, as it requires complicated apparatus. Both pulp and stones have a regular market price, however, and are manipulated in Marseilles on a large scale. The local cultivator occupies himself with the first and second crushings of the olive only.

The oil in the tubs, as it comes from the press is carefully skimmed and placed in barrels. After all the oil of the surface has been skimmed, apparently, the water itself is poured into stone or tile cisterns, called the "enfer," where it remains three or four months. In the course of this period a considerable quantity of oil in suspension mounts to the surface and is also skimmed off and sold as "huile d'enfer." Its odor is very strong and the price is low. The oil of the first pressing, or the

virgin oil, and the oil of the second pressing are always kept separate and sold for what they are. They are decanted three or four times from one barrel to another, and finally deposited in huge earthenware jars, where they remain until spring, and are then decanted for the last time into barrels and offered for sale in the market.

The successful manufacturers and exporters of olive oil find their raw material wherever they can, having buyers who scour France, Italy, Spain and Tunis, and the success of the business hinges mainly upon the tasting capacity of the head of the house, whose work begins after the oil has been pronounced upon by chemical analysis.

The most important operation in the treatment of the crude oil is its filtration. While the various nut and seed oils are now readily freed of the manganin in suspension by subjection to a low temperature, this process cannot be successfully followed in the case of olive oil, which is a much more delicate product. Until comparatively recently the packers of olive oil filtered it through cotton, and probably the majority of packers cling to the old system mainly because of the expense of the improved paper filters. Excellent results are obtained by passing the oil through cotton, but the process is slower, and the cotton itself absorbs large quantities of the oil which cannot be expressed and used, except as an inferior product. It is now generally agreed that no more satisfactory filtering material has been found than specially prepared paper, and the oil is passed through paper either by means of force pumps, hydraulic pressure or the application of the stand-pipe principle, the pressure upon the paper depending upon the height from which the oil is injected into the apparatus.—*Bradstreet's*.

PLANTING NOTES.

EARTH-NUTS IN UGANDA, &c.—It appears that these Nuts can with ease and profit be grown in East Africa—so says the *East Africa and Uganda Mail* of a recent date. In British India 46,000 acres are under cultivation with this nut. In the native states of India over 16,000 acres are under the same culture, and this area will yield nearly 11,000 tons; and the journal noted is of opinion that after satisfying the home demand, sufficient would be left to pay for exportation to Eng'and and elsewhere.—*Gardeners' Chronicle*

MARTINIQUE.—The following extract from a private letter to one of our correspondents bears witness to the beauty of the stricken island:—"The scenery of Jamaica and Cuba cannot be compared with that of Martinique and Dominica; my pen cannot adequately describe the beauties of Martinique, rising smartly out of the sea, and its mountains towering away up into the skies! Dominica, too, is sublimely beautiful, with its deep gorges and primeval forests. Tremors have been felt in Dominica, and a lake on the top of a mountain is said to have gone dry, so that they are evidently within the seismic sphere of disturbance."—*Ibid*.

DORYANTHES AS A FOOD FOR PIGS.—According to the *Agricultural Gazette of New South Wales*, the Giant "Lily" (*Doryanthes excelsa*) has been suggested as a useful food for pigs. Analyses have been made of the bulbs of the plant (here so prized, but in the upper Mangrove district growing wild), to see if it would be valuable for fodder when other foods are scarce. It is considered that the bulbs compare very favourably as to feeding values with ordinary root crops, and that, provided they are found palatable, they should prove fairly nourishing; superior, indeed, in this respect to Parsnips, Beets, and Turnips. But New South Wales swine do not consider the Lily-Bulbs eatable when raw, but prefer them boiled and mixed with a few handfuls of ground Maize. So served "the pigs consume the mixture greedily,"—*Ibid*,

SCIENTIFIC AND TECHNICAL
DEPARTMENT OF THE IMPERIAL
INSTITUTE.

RECENT EXPERIMENTS ON THE CULTIVATION
OF TOBACCO.

The tobacco industry has become so highly specialised that it is necessary for the successful planter to become thoroughly acquainted with the scientific side of the processes involved in the cultivation and fermentation of this material. The qualities of the tobacco leaf as regards the size, shape, thickness, flavour and aroma, the grain and general appearance, are so easily influenced, and so difficult to control, that its cultivation in new localities can only be attended with success after much experimental work.

At the present time experiments are being undertaken in Ireland, on the culture of tobacco, by the Department of Agriculture. Some useful information on this subject is contained in Report No. 63 of the United States Department of Agriculture, and the following summary is compiled from this source. The report is a review of the experimental work conducted for some years past at agricultural experiment stations situated in widely separated localities, and is intended to throw light upon the various problems connected with the growth and cultivation of tobacco.

Methods of growing plants in seed beds.—At the Alabama State station various methods of starting tobacco seed were compared. Seeds were started in several beds, some open and others covered with cheese cloth. During the first year of the experiments the greater number of plants in the open beds were destroyed by a spell of cold weather, and during the second season they were injured by the flea beetle. In the covered beds the plants came up well, grew rapidly and were not subject to insect attacks. From these results it is evident that under the climatic conditions of Alabama young tobacco plants are readily affected by low temperatures, and quickly killed by frosty weather. At the Colorado station, in pursuing this work it was found that it took no longer to produce plants suitable for setting out by growing seeds in cold frames than by the use of the hotbed.

The following method of germinating the seed at the Georgia station proved very successful. The seeds were placed in wine glasses and soaked in water for half-an-hour, the water was then poured off,—the glasses placed in saucers containing water, and a tumbler inverted over each glass so as to confine the moistened seed in a damp atmosphere. In about a week, when the seed had started to germinate it was sown in a cold frame, and within a month from that time plants suitable for transplanting to the fields were obtained.

In the experiments conducted at the Central Experimental Farm, Canada, the seeds were sown in hotbeds, and some of the plants thus obtained were transplanted to cold frames before being set out in the fields. A striking difference was noticed between the plants set out from the hotbeds and those transplanted to the cold frames prior to setting out. The latter were stronger and grew more rapidly than those taken direct from the hotbeds. It was also found that if the plants were transplanted to a second hotbed before setting them out in the fields, the vigor was increased and the number lost in transplanting was materially reduced.

In the districts where fungoid diseases gave any serious trouble it was found quite possible to sterilise the soil used for the plant bed. Boiling water, hot stones, or steam under high pressure may be used for this purpose.

The size, weight, and condition of ripeness of the seed, as well as the method of planting, has been shown to have an important bearing upon the crop.

Varieties of Tobacco.—At Calhoun, the North Louisiana station—ten varieties of tobacco, namely, Conqueror, Hester, Long-leaf Gooch, Ragland Improved

Sweet Oronoko, White Burley, Comstock Spanish, Persian Rose, Improved Havana and Brazilian American, were tested. Of these Comstock Spanish, Persian Rose, Improved Havana and Brazilian American, are cigar-leaf, and the rest are described as bright-leaf varieties. The last-named, with the exception of White Burley, produced a leaf which, when cured, was of a lemon yellow colour; they were more successful than the cigar-leaf varieties which, when cured, produced leaves too bright and in but small quantity.

It was also shown that Conqueror, Long-leaf Gooch, Hester, Oronoko, and Ragland Improved, cured brighter than other bright-leaf varieties, and that Vuelta de Abajo, Havana, Seed-leaf, Imported Havana, Choice Havana, Little Dutch, and Pumpelly, produced a leaf of greater silkiness and finer texture than other cigar varieties tested.

The kind of tobacco which can be grown in any district depends partly upon the climatic conditions and also upon the character of the soil. In testing varieties, therefore, consideration should in the first place be given to the type of tobacco adapted to the locality, to the soil, and the grade which the climatic conditions and soil may reasonably be expected to produce.

Influence of distance in planting.—A study of the relation of distance of planting to yield and thickness of leaf, was made at the Wisconsin station. Plants were set 20 inches apart in rows 31 and 36 apart, and at intervals of 2½ inches in rows 42 inches apart; close planting was found to increase the yield, and the plants nearest together in the row produced a thinner leaf than those further apart; but lessening the distance between the rows did not have this effect. A distance of 31 inches between the rows was sufficient for the full development of the plants. The surface area of the cured leaves per pound from the closest planting was 42.01 square feet, and from the widest planting 40.86 square feet.

Other experiments made with a view to ascertain to what extent close planting may be advantageously practised, showed that planting 1 foot apart in the row was not too close for Wilson Hybrid, the variety grown in this experiment. From these and other experiments it was concluded that too close planting interferes with the development of the leaves, while too large spaces between plants tend to produce coarse leaves. The dimensions of the leaf, thickness, elasticity, and size of the vines may all be more or less modified by giving the plants space or increasing the number in a row.

Fertiliser Experiments.—The results of experiments at Kentucky indicated that potassium, chloride, and sulphate, gave equally good results as fertilisers for tobacco, and that sodium nitrate produced a better quality leaf than other forms of nitrogen.

Tests with complete fertiliser applications were also made. A yield of 1,460 lb. of cured leaf per acre was obtained after an application of 80 lb. of sodium nitrate, 80 lb. of dried blood, 160 lb. potassium chloride, and 140 lb. of double superphosphate per acre, whereas by doubling the quantity of fertiliser the yield of leaf was increased to 1,620 lb.

Fertilisers used on soil in a good state of fertility, were found to increase the yield of tobacco considerably, and potassium chloride proved more efficient than the carbonates of potassium and magnesium.

At Calhoun experiments were conducted on red sandy and grey sandy soils—and it was shown that potash had little or no effect on the crop, but nitrogen, either in the form of sodium nitrate, ammonium sulphate, cotton-seed meal, or dried blood, caused a marked increase in the quantity obtained. An application consisting of cotton-seed meal, acid phosphate, and sulphate of potassium produce the best quality leaf.

The effects of different fertilisers on tobacco were studied at the Virginia station. Five plots matured with complete fertilisers, all of the same cost per acre,

were compared with an unmanured plot. Dried hood gave the largest yield and the best financial returns as a source of nitrogen. The tobacco grown without fertilisers ripened ten days to two weeks later than that grown with fertilisers.

Influence of Time of Harvesting.—These experiments were undertaken at the Wisconsin Station to determine whether the tobacco leaf increased in size and thickness, and whether the loss in curing diminishes, when the plants are allowed to stand a considerable time after topping.

The results showed that when the plants were permitted to stand 32 days, as against others allowed to stand only 18 days, the thickness and dry matter of the leaf tended to increase, and the yield has a like tendency, *i.e.*, after curing, a greater weight of the leaf was obtained, but the area per pound of leaf was less.

It was thus possible to vary the commercial grade, and influence the price considerably, by harvesting the crop at different stages of maturity. This was one of the methods by which the quality of tobacco might be sensibly controlled.

Effect of Priming Tobacco Plants.—Priming, which consists in removing the leaves from the stalk of the plant as they mature, has a marked effect on the growth and chemical composition of the upper leaves. The removal of the lower leaves causes an increase of growth in the upper, and also a higher percentage of nitrogenous matter and nicotine. Priming is believed by many practical growers to be the proper method of harvesting the cigar and cigarette-types, for in this way the leaves are uniformly matured and the subsequent product is consequently of a more uniform character. The priming of tobacco is more expensive than cutting the stalk, as more labour is required, but the improvement in quality fully warrants this additional cost.

Experiments in Topping Tobacco were conducted at the Central Experimental Farm at Ottawa, Canada, in order to determine how the time of topping, and the number of leaves left on the plants, affect the yield. The plants were topped July 20th and 26th and August 2nd, and on each date one plot was cut back to nine leaves and another to eleven leaves per plant. The larger yields were obtained from the latest topping, and the greater number of leaves per plant. The time and manner of topping has a great influence upon the character of the leaf produce. As a rule the earlier a plant is topped and the lower it is cut, the heavier, richer and darker-coloured the leaves become. This is a decided advantage for some crops, but a disadvantage to others.

Disease of Tobacco.—The disease to which most attention has been given manifest themselves during the curing process, and are commonly known as "stem rot" and "pole burn" or "pole sweat." The latter makes its appearance as small dark spots on the surface of the leaf near the veins and midrib, where moisture is most abundant. The disease is supposed to be primarily due to a fungoid growth which attacks the leaf on the surface and gives access to a bacterial process of decay by disintegrating and partially destroying the leaf tissue. It has been ascertained that moisture and temperature have a marked effect on the activity of these organisms. Decreasing the amount of moisture lowered their vitality, and a temperature up to 70° F. or even 90° F. favoured their development, while a temperature of over 100° or 110° F. and below 35° or 40° F. temporarily or permanently checked their vitality.

From investigations it was concluded that under the atmospheric conditions most favourable to the development of "pole sweat" the temperature and moisture in the interior of a closed barn could be regulated by artificial heat so as to reduce to a minimum the liability of tobacco to damage from fungi or other like organisms.

"Stem rot" is a fungoid disease which frequently affects the stems of the plants in the last stage of

curing. No special experiments were made upon this disease, but as a remedial measure it was suggested that when the crop is cured all stems and refuse attacked by stem rot be burned before the fungus has matured, and the barn fumigated with sulphur immediately after curing, and again before the harvesting of the next season's crop.

Experiments in curing Tobacco.—Tobacco goes through certain processes of fermentation from the time it is cut until it is ready for the manufacturer. During this time it is said to be curing and ageing. After the harvest the leaves are speared upon laths and hung in a barn to dry. Artificial heat is often employed for this purpose. Experiments with different methods of curing tobacco have been conducted at several experimental stations. At the North Carolina station, the ordinary method of cutting down the plant and curing it with the leaves on the stalk proved less profitable than curing by the Snow process, in which the leaves are cut from the stalk as they ripen, and cured separately. A greater yield was obtained with the tobacco cured by the leaf process and the quality was better. This effect is ascribed to harvesting the leaves as they became mature, while, by the stalk process, many of the lower leaves were over-ripe, and the upper leaves still green at the time of cutting. It was found that the time and temperature required for curing leaves from different parts of the plant varied according to their ripeness, and for this reason the leaf-curing provided the most desirable method, as the leaves were all of the same degree of maturity. At Wisconsin it was found that the loss of water in curing was about 71 per cent. of the weight of green leaf.

It is stated that the changes in the colour of the leaf during the curing process were not directly due to the loss of moisture, but depended largely upon the degree of ripeness—the riper the leaf, the lighter in colour it would be when cured.

From data obtained in this work it was concluded that tobacco should be cured in as moist an atmosphere as possible, without incurring damage from "pole burn." A temperature within the curing house not exceeding 75° F., and a degree of humidity among the plants represented by a wet bulb depression of 2°, were regarded as suitable conditions. In order to maintain these requirements, the plants should be evenly distributed in the curing-house, in order to equalise the humidity of the building, and the ventilation should be under perfect control, with a provision to regulate the humidity of the air by the use of artificial heat.

Fermentation of Tobacco.—The fermentation or sweating of tobacco is carried out in several ways. To give a general idea of the method of procedure, that followed in Florida may be cited. After the tobacco is cured, the leaves are stripped from the stalk and made up into hands, *i.e.*, bundles tied together at the base. These hands are either piled on the floor or put into bins, and the fermentation allowed to proceed gradually. The temperature of the pile gradually rises, until it reaches its maximum, which is sometimes as high as 180° F. From this point the temperature gradually subsides, and finally attains the normal temperature of the room.

In connection with the changes which take place during the process of fermentation, most attention has hitherto been given to the loss in weight of the leaves and to the chemical changes which occur. At Connecticut State station the weight and chemical composition of cured and fermented leaves was compared. The loss in the fermentation of upper leaves, short seconds, and first wrappers was 9.7, 12.3 and 9.1 per cent. respectively. About three-fourths of the loss in the short seconds consisted of water, the upper leaves, lost almost the same proportion in dry matter, and in the first wrappers the loss of dry matter was a little less than that of water.

The nitric acid, ammonia, fibre and starch contents of the leaves were affected very little by the process of fermentation, and the chief loss of dry matter was found to have occurred in the nicotine, albuminoids,

and amide bodies, nitrogen, free extract and ether extract. At the Pennsylvania station it was found that the loss in fermentation was greater with tobacco fertilised with barnyard manure than with tobacco grown with other fertilisers.

When it is considered that, commercially, tobacco is divided into four classes, viz.: cigar, cigarette, snuff and export, it becomes evident that the systematic observations as briefly described are invaluable to growers, who must, of necessity, produce tobacco suitable to the requirements of the market.—*Imperial Institute Journal*.

COFFEE CULTIVATION IN INDIA. REPORT ON THE LEEMING QUESTION.

The following report on the "Leeming System" of coffee cultivation was supplied to Messrs. H. J. Gardner and Co., Loubon, by Messrs. Binny and Co., Madras:—

MESSRS. BINNY AND Co., Madras.

DEAR SIRS.—As requested by you in your letter of the 9th instant I went to the Shevatoy Hills and visited Scotforth, Mr. Leeming's estate, on the 12th and Kooderay Panjan Estate, of which he is manager, on the following day, and beg to report as follows:—

The system of cultivation carried out on these properties has, for the sake of convenience, been called the Leeming system, but Mr. Leeming does not claim to have discovered anything new. He says he has merely thought out and applied to coffee growing the principles carried out by practical and scientific growers of fruit trees in various parts of the world, and his system as it stands at present, is the result of careful observation and experiment carried on over several years. I was taken over every field in these two estates, so that I might see for myself the effect of the system on both the good and poor soils. Mr. Leeming answering all my questions without any reserve whatever.

The system may be said to have been instituted seven years ago, when he ceased to either prune or handle and allowed suckers to grow, the trees being left to nature, but he continued to cultivate and manure the soil more carefully than ever. The result was that his crops increased and his trees suffered less from leaf disease; but it was apparent that they were so crowded that they could not give nearly as good crops as they might. In 1896—only three years ago—he began cutting out in field No. 10 of Scotforth reducing the number of trees from 27,000 to 13,500, just half, and giving them a space of 12 by 12 feet in which to spread, i.e., about 600 trees per acre. 1899-1900 he picked 1,500 struck bushels of ripe cherry from this field, equal to nearly 7 cwts. per acre. Last season he picked 1,700 bushels, nearly a ton more than in the previous year, and in April, again, he thinned out the field to 10,200 trees, and the estimate for the coming crop is nearly 10 cwts. per acre. These figures I took from the estate books myself, and are unquestionable, and a better record than this can hardly be imagined. The other fields were similarly treated in 1899 and 1900, and now his object is to finally get about 300 trees per acre, and no more. In field No. 3 of Scotforth this has been done.

No sooner had the trees got root and air space than they at once began to fill out laterally, and the long branches came sweeping down to the ground, thereby increasing the bearing area enormously, and suckers grew very slowly. What suckers there are were grown before the thinning-out process began. These trees are now 10 to 12 feet higher, and the branches have a spread of over 15 feet, and I agree with Mr. Leeming in thinking it will take another five years to see them at their full development. I merely give the figures of field No. 10 because it was the first to be cut out, but those relating to the other portions are equally good. When thinning out from 600 to 700 trees per acre, he first cut off the primaries, leaving the suckers for a couple of years, thus giving air and some root space

to the trees that remain, but he is not certain that it would not pay better to take them out at once.

When going over Kooderay Panjan, he took the same trouble in order that I might see part of each field. I remember seeing this estate some eight or nine years ago, when, although it grew very fine oranges and silver oaks, the coffee was very poor indeed; now, under this system, there is a complete transformation, oranges, etc., have disappeared, and the avenue of great coffee shrubs, healthy and vigorous, with dark glossy leaves and laden with crop, have taken their place. When Mr. Leeming took charge of it, eight years ago, its crop was $\frac{1}{2}$ ton off 65 acres; last year, off the same area, with some little assistance from the young coffee, he picked 25 tons. For seven years he never pruned, and in 1899 he cut out to 600 trees per acre, and there is a good deal of it now thinned to 300 trees per acre. The coming crop is estimated at 11 tons, and, judging from the wood now making, it should easily be followed by 30 tons. The way trees that were a mass of sticks from overbearing, both here and at Scotforth, are making new wood is simply marvellous.

The new clearings on both estates are planted 7 by 7 and 8 by 8 feet apart, and beyond topping the trees that are intended to be permanent, they have never been touched with a knife. Those trees that are to be cut eventually will have their primaries cut off, and a crop or two taken from the suckers. I have never seen finer clearings, soil, climate, and deep cultivation being all in their favour.

Regarding cultivation, Mr. Leeming believes in deep drains (3 to 4 feet deep) and 40 feet apart to enable those large trees to send their feeding roots deep into the soil, a six-inch digging with a quantities once a year and $\frac{3}{4}$ lbs. bone meal, poonac, and nitrate of potash scattered over the surface and dibbled in. The supervision of applying the manure has been very greatly simplified under the new system, and each individual tree can be studied, and manured according to its needs. He is also growing a legume (a creeping pea) in the middle of the row, one to each tree, which, when growing, will cover the ground and act as a mulch in preventing wash and loss of moisture, and induce the earthworms to come up and make casts. I was shown examples of these casts as we went along. Just before flowering the legumes will be dug into the soil, and will enrich it with a cheap store of nitrogen. He very kindly gave me a supply of the beans to try in our district.

The advantages of the Leeming system, as compared with our present methods, are: Economy, in that no pruning or handling are required, and only half the quantity of manure is necessary (Mr. Leeming believes in manuring at least once a year; improved quantity of bean, as leaf disease is not nearly so virulent now that none of the leaves, which are the lungs of the tree, are sacrificed in pruning, and the crops are not only more regular, but are much better. These large trees are not nearly so easily affected by a bad blossoming season, although they will always do best in a good one. Mr. Leeming's figures speak for themselves, the results are, as Mr. Hodgson remarked at the Conference of the U.P.A.S.I. simply astounding. Whether we in Mysore are ever likely to achieve such results is doubtful, as the Shevaroyes are, generally speaking, much more favourably situated as regards soil, climate, and rainfall, but even if we only receive a third of Mr. Leeming's success, we will improve our position enormously.

The system has been objected to on the score of borer, but I find Mr. Leeming has had worse borer than we ever get, and yet he has no fears on that score. He says it is only destructive on the clearings, and that old trees are rarely attacked, as the branches are close and come down to the ground, thus protecting the stem, and this is borne out by the fact that those trees that have suffered have been brode near the top, when the damage amounts to very little. It has been alleged that if trees are neither pruned nor handled they will lose their primaries,

SOME NOTES ON RUBBER GROWING.

SOME VALUABLE POINTS.

The following notes are written by a gentleman at present in the island who from his long experience in the handling of rubber in all its forms is entitled to be considered somewhat of an authority upon the subject:—

The continued increase in the price of the raw India rubber has naturally turned the attention of both planters and manufacturers to the extension of our existing rubber supplies. The ever-increasing demand for the manufactured article, its ever-widening field of application, the new and great demand not only for rubber tyres, but also for road vehicles, and the thousand and one applications of the manufactured material for mechanical purposes, had all so increased the demand for the raw gum, that the world's supply barely met the necessities of the demand, consequently the cost of the raw material had advanced to famine prices. Para, the standard brands had advanced from its normal price, viz., 3s. per lb. to 4s. 6d., an increase that left the manufacturer poor indeed, and the producer rich beyond all telling. This increased demand not only then, but also now, promises to be permanent and to expand still more, rubber cab and cycle tyres have come to stay; the advent of the motor car has also added to the demand. The climatic conditions of Ceylon, its temperature, its heavy rainfall, the character of its soil, all pointed to this island as being an extremely good, if not an ideal, rubber-producing country, the plantations both at Henaratgoda and Edangoda, where the Hevea *Braziliensis* so successfully flourishes, proved that the merely experimental stage had been safely passed; a loamy soil, with a heavy rainfall, a country not too liable to flooding, plenty of moisture in the atmosphere not too much around the roots, at any elevation up to 1,500 ft., had already proved to yield satisfactory results. Cheap and plentiful labour held out a reasonable prospect of many coolies becoming fairly intelligent in rubber collection, if properly trained. In brief, the promise of Ceylon as a rubber-producing country to the visitor versed in rubber culture was distinctly favourable, perhaps this opinion was influenced and biased by the lovely climate, by the good nature of the people, and, perhaps too, by the beauty of the natural scenery.

THE FINEST RUBBER.

Far and away the finest rubber is derived from the Hevea *Braziliensis*, it is hardly worth while now to experiment with any other variety, the same care and attention given to the Hevea will produce a far better gum, stronger in fibre and possessing a much higher breaking strain than any other, and for this reason it will command higher prices than the products of either the *Syphonica* or *Ceara*. The seeds of trees now in the island are derived from plants sent hither from Kew in 1876, and although these still produce excellent results it is certainly worth the experiment to introduce a fresh stock direct from Manaus on the Amazon, the native home and habitat of the true Hevea *Braziliensis*. Reliable agents there are of opinion that the seeds can be safely sent to Ceylon if in proper and specially made germinating cases, and if this experiment proved successful Ceylon would be in possession of a new stock, the development of which it would be interesting to note side by side with the existing growth. The growing requires but little care. Rough weeding is quite sufficient. Upon the tapping of the trees at say eight to ten years old, and subsequent curing of the milk the success of the crop absolutely and solely depends, and upon this first crop also depends the reputation and future prosperity of the estate from which it is exported. A new brand placed upon the market immediately attracts the attention of the manufacturer. He is quick to secure a portion, and test a new rubber to discover if perchance there be "any good thing" in it. Happy is the new rubber which has no history. It is received eagerly, put upon its trial with every wish to make the best of it. If this

test is satisfactory future success promises well, if unsatisfactory the shadow of suspicion and the coolness of neglect will for a time at least hang over that estate. To secure a good result from the first collection, it would be advisable to import two or three experienced collectors from the Amazon—not a costly enterprise; and where several planters are interested and prepared to combine, the expenses may be shared, and the more intelligent of the coolies on the interested estates duly instructed in their work. This policy was adopted by the Belgian Government on the higher reaches of the Congo, and here these Amazon experts succeeded in extracting from the African indigenous Hevea, by careful extraction and curing, a rubber called *Rubi* (after an adjacent village), which is actually better than Para itself, with a lower percentage of rubber resin, and a lower percentage of foreign matter, thus offering a higher tensile strain. Naturally, this secured a better price in the European markets than Para itself, and is in great demand. This care, of course, is the ambition and goal of every grower. The same course was adopted by the Liberian Government in reference to the rubber trees near Monrovia, and at first it exported some excellent samples, truly capable of improvement; but, upon the departure of the rubber experts, the native Kraw boys, either from want of care, or pure and simple laziness, abandoned due care, and consequently, Liberian rubbers are to-day more or less under a cloud in the market. The first and greatest care necessary and even imperative,

IS ABSOLUTE CLEANLINESS IN THE EXTRACTION

of the milk; the bark of the tree to be tapped should be carefully cleansed, the knife to be used carefully cleaned, the V shaped cuts and perpendicular central channel all should be perfectly clean before the milk is allowed to run, the collecting cups and milk can also need attention in this respect. The necessity of this seemingly excessive care is clear, in view of the fact that oftentimes the smallest particle of grit present may cause endless trouble to the manufacturer, depreciating or destroying the quality of his work. The manufacturer, to start with, must have his raw rubber perfectly pure. To this end the imported gum is first of all heated, then torn and rolled between friction rollers, under a stream of water to remove the foreign matter that may have been introduced through the carelessness of the collector. This constant tearing and rolling necessarily reduces the original strength of the gum, the greater the proportion of foreign matter to be removed, the greater the percentage of the loss of tenacity of the material. For instance, the removal from firm Para rubber, of even 5 per cent. of impurity, will oftentimes occasion the loss of 20 per cent. in strength and vitality of the resulting product. It is oftentimes the one little grain of sand which does the greatest mischief. As an illustration, may we take the case of a cycle tyre inner tube. If a little grain of sand is allowed to get into the milk in collecting, these little particles are the most difficult to remove mechanically by washing, hence the grain of sand eventually finds itself embedded in the thin skin of the cycle tube. Upon inflation the grain of sand pops out leaving a point of least resistance. Subsequent inflations tend to form a bubble, in a few days the bubble bursts; the sand has done its work, and the tube requires mending. Manufacturers know this to their cost, and are therefore willing to pay highly for a perfectly clean reliable rubber, and look with suspicion of either "gritty rubber" or "barkly rubber." In the latter case the embedded fragments of bark or vegetable matter being very difficult to remove from the gum, become charred or carbonized during the process of vulcanization at a temperature of 250° F. and then simply drop from the article as so much soot. These foregoing remarks refer to what one may regard as accidental impurities due to want of cleanliness or absence of sufficient care, but which nevertheless, depreciate the value of the article from 2s. to 6d. per lb. There is, however, another form of adulteration which will in time destroy

the reputation of any brand, and effectually "boycott" from the markets the estate sending it. This is the designed admixture of inferior gums, such as *Euphorbia* gum and many others of the resin class to reduce the price and illegitimately to increase the meantime profit, but to court disaster, and discredit the market of the future. For example, some six years ago, Borneo produced a fair rubber promising with increased care and experience better things. The producers in their haste to be rich, introduced "potato gum" into the milk; and down to the present time the class of rubber is hopelessly discredited and

CONTEMPTUOUSLY SPOKEN OF AS "DEAD BORNEO."

Many other brands have met the same fate from the same cause. On the other hand, where resolute and continuous attempts have been made to improve the method of collection, such efforts have been amply rewarded. Four years ago, the poor gum of Accra, Cape Coast and Saltpond sold with difficulty at 10d. to 11d. per lb.; and now, by a process of clean collection and careful curing, the price has advanced to 2s. to 2s. 3d. per lb., at which it finds willing buyers. Perhaps the most striking illustration of this appreciation of quality is that shown by the Congo rubbers, the preparation of which is yearly steadily improving with a proportionate increase in price, moving from 1s. 3d. to 3s. 6d. per lb. The process of curing to produce the first grade rubbers also necessitates an experienced headman, so that the smoking or curing may be thorough and complete, that all the immature so may be duly coagulated into caoutchouc—here decrimination is necessary, secured by experience in order to smoke the milk thoroughly, yet not excessively. Great care in this process is necessitated by two considerations—in the first place, to be certain that all the sap is coagulated, failing which the immature juice will be lost in washing, causing perhaps the loss of 15 to 20 per cent. in weight, instead of 5 per cent., as in the case of a well-cured, clean rubber, and in the second place to secure its freedom from rubber resins. To the presence of these has been traced the cause of the rotting or hardening of vulcanized rubber, and this knowledge has led to the issue, by Sir A. M. Rendel, of a rigid specification on behalf of the Government, refusing to pass any rubber article found to contain more than 5 per cent. of rubber resins. This official specification is being rapidly adopted by the Indian Government, and by the principal engineers, and will, in a few months, become the recognized standard for a good rubber. If Ceylon rubber is to command a good place in the market, it must meet this requirement; otherwise the product will be relegated to a third class group, looked upon with suspicion and priced at "rubbish heap" rates. Recently some experiments have been made by prof. Henrique, to effect the removal of these resins by chemical treatment, with alcoholic soda. Good results are predicted, but the practical results of time, sunlight and heat upon the manufactured article must be awaited before any reliable opinion can be formed as to the value of this chemical process, and also of its cost upon a commercial scale.

IN CEYLON'S OWN HANDS.

It is proven that the soil, climate, and rainfall of Ceylon are all alike favorable to this new industry, but it now depends upon the care, the attention, the intelligence of the planter, in view of the considerations herebefore mentioned, as to whether Ceylon rubbers are to command a high place in the markets of the world, securing profit to the planter and reputation to this colony, or to become one more addition to the role of discredited and unreliable products.—Local Times.

NEWS AND VIEWS FROM MANAOS.

(To the Editor of the *India Rubber World*.)

The Brazilian nut crop now being over, the landholders are turning their attention to the rubber crop for the coming season, and already large shipments of goods

have been made from Manaos to the rivers Jurua, Purus, Japura and Madeira, and rubber is trickling in from the Eubira, Tarauaca, and other affluents of the Jurua. The past season has been very poor, as regards both quantity and price.

The production of Upriver rubber is not expected to be so large during the coming season, for many people are saying that rubber at 4\$ 500 Brazilian is not worth working. Yet the receipts are larger to date than last year at this time. The price here is equivalent to 50 and 55 cents a pound for fine, and further up it is selling at 25 to 30 cents.

As indicating the tendency to introduce modern improvements in Amazonian towns, it may interest some of the readers of the *India Rubber World* to know that an electric lighting plant has been installed at Lahrea, on the river Purus, at the point where the Itaxy joins the Purus, 692 miles from the Amazon. The plant was constructed by the C. & C. Electric Co., of New York, and is based on the Nernst lamp system. The same company will probably supply a plant for Manacapuru, in the same region. The town of Labrea is also planning to obtain a water works system.

The Indians on the river Japura have been out on the war path, burning two or three rubber stations and killing some thirty persons.

The Amazon cable is as usual broken, so that business in rubber has been done by fits and starts depending entirely on the arrival of ships bringing news of exchange rates from Para.

The greatest present need of the Amazon country is a better, quicker, and cheaper means of steamer communication with the United States.

THE CONWAY CONCESSION ON THE ACRE.

Everybody here is talking about the concession by the Bolivian government, of the Acre rubber district to the American syndicate, of which the *India Rubber World* has lately published accounts. The river Acre rises in Bolivia—in which country it is called the Aquirv—but enters Brazil before discharging into the Purus, one of the largest tributaries of the Amazon. The highest point on the Acre navigable is 1,058 miles distant from the Amazon. The chief towns (they are called "cities") are Floriano Peixoto on the Brazilian section, and Puerto Acre (or Puerto Alonzo), at the boundary, in Bolivia. At the latter place in a Bolivian custom house exists and a fort is being built; a mule road is also being opened to La Paz, the capital of Bolivia. On the Brazilian Acre are rubber stations at Aphy, Arares, Nazareth and the state revenue station at Caqueta. On the Bolivian section there are rubber stations at Flor de Ouro and at Bagaro, where Galvez, the head of the late so-called "republic of Acre," fired upon a Brazilian boat.

The dispute at one time between Bolivia and Brazil over the ownership of this territory arose from the trouble in determining the exact source of the river Javary, the division line being specified as running from that point to the mouth of the river Beni. This point having been settled, Peru now bases a claim to a portion of the Acre district, on another imaginary line, and has filed a formal protest against the validity of the concession granted to Sir Martin Conway.

That the Acre district is the richest portion of the Amazon valley, there can be no doubt, some of the *seringales* their yielding from 8 to 12 kilograms of fine rubber a day, per *estrada* of 180 trees. This is equal to 2.3 ounces per tree. Elsewhere in this paper the same writer refers to 1.5 ounces as a good average yield.—[THE EDITOR]. The Caucho has been largely worked out on the Brazilian Acre, but doubtless very much still exists on the upper waters of the river.

At present the prices of goods are very high on the Acre, owing to heavy freight rates and the fact that everything must be imported. In 1900 I paid at the rate of \$1 a pound for jerked beef, and

everything else in proportion. But a fairly active man could earn \$8 to \$12, gold, a day, at working rubber, and in sixteen days I once made \$1,400 cutting Caucho on the Xapury, a branch of the Acre. But the Cancho is gone in that region, and rubber is selling at 50 cents a pound in Manaos and 15 20 cents on the Acre.

Several steamers ply between the Acre and Manaos and Para, at least two a week leaving Manaos for that river at the height of the season. The Acre is somewhat rich in minerals, coal, gold, quartz, and tiny emeralds having been found in various parts.

S. G.

Manaos, Brazil. April 14, 1902.

CULTIVATION OF VANILLA IN GERMAN EAST AFRICA.

The current number of *Der Tropenpflanzer* (April, 1902), the organ of the German Colonial Economic Committee, contains an interesting article on this subject by Herr Blintzner, a planter who has grown vanilla in Africa, and who has had considerable experience in the preparation of this material for the European market. The object of the article is to extend the cultivation of vanilla in such German colonies as the Cameroons and Togoland, and for this purpose full information on the question of choosing suitable localities for the plantations, the artificial ripening of the pods in inclement weather and the proper packing of the commodity for export to Europe are given, and may be commended to English planters in tropical colonies where vanilla cultivation is possible.

Of the various species of plants yielding vanilla the one giving the best results is *Vanilla planifolia*, which begins to bear usually in the third year after planting and yields from 3 to 5 crops. It flowers in East Africa from August to November and bears fruit from April to July, the latter requiring about eight months to ripen in normal weather, and a further two months for drying and fermentation. For a plantation of about 10,000 plants, 15 labourers are necessary, and the wages of the latter on the East Coast of Africa are about 3½d. per day each. In forming a vanilla garden special attention should be paid to the selection of a site protected from wind shaded by trees from the direct heat of the sun, and in the neighbourhood of a stream which is not dried up in the hot weather. The importance of the latter is obvious when it is remembered that the roots of the plant only penetrate about twelve inches into the ground and, therefore, obtain water only from the easily dried surface soil. For this reason it is necessary to have a good supply of water for irrigation, in dry weather. The plants are arranged in parallel rows about five feet apart, passages being left at intervals of about 45 to 50 yards to permit of regular inspection of the plants. As supports for the orchids poles of ebony are sufficient in situations where there is sufficient natural shade, but, if the latter is deficient, then *Jatropha curcas* may be grown in the garden to afford both shade and support. It is usually best to place the young vanilla plants for about a fortnight in a well-shaded moist situation where they are kept well watered, and then to transplant them to the small pits about twelve inches deep already prepared with leaf mould for their reception in the plantation, the aerial portion of the plant being at once secured to the support by bast or banana fibre. The orchids should not be allowed to grow higher than about 5 feet, and when they reach this stage the heads should be carefully bent towards the ground. The plants require manuring with leaf mould or similar material once a year. The chief enemies of the vanilla orchid are beetles, snails and caterpillars, which eat the fleshy roots and young stems, the only remedy being the constant examination of the plants, and destruction of these insects, when they are found. The

flowering period is an important time, since the plant, outside its native habitat, is not self-fertilising, and must therefore be pollinated individually by hand. This work, although rather a delicate operation, can be readily taught to negroes. In order to secure pods of good quality it is necessary to limit the fruit production of each plant to from 20 to 25, although in special cases the maximum limit may be 35; if this number be exceeded the ripe fruits suffer in size, appearance and flavour. Ripeness of the fruits is indicated by the formation of a yellowish patch at the base, and at this point they should be gathered by breaking the attachment to the stem cautiously with the finger nail.

The operation of curing the ripe pods has an important bearing on the quality of the vanilla ultimately obtained, and great care has to be exercised in the carrying out of the drying and fermenting processes. The pods, after gathering, are sorted on the following day into about three sizes, and placed in large pots warmed to about 80° C by hot water for about 14 seconds, then packed in wool-lined boxes for a day, and finally dried with a linen cloth and placed in the sun on wool-lined trays for complete desiccation. In wet weather the exposure to the sun is dispensed with and the final drying accomplished by careful heating in ovens kept at temperatures between 80° and 100° C. The prepared pods are then stored in drying rooms and finally in large metal-lined boxes.

The preparation of the finished vanilla for the market, consists in sorting it into various qualities according to its appearance, size of pods and flavour. The pods of the same quality are then tied into bundles of about 50 to 60 each, scoured with fine twine and packed into well-closed zinc- or parchment-lined boxes, capable of holding from 10 to 12 lb. of the product.—*Imperial Institute Journal*.

WATERING YOUNG TREES AND SHRUBS.

Amateur gardeners as a rule do not understand the art of watering in dry weather. When they see that the flowers and shrubs are drooping, they attach a hose to a stand pipe and thoroughly wet the surface. They rarely think of looking to see how deep the water has penetrated, and would be astonished to find that after half-an-hour's hose play the soil is only wetted to the depth of less than a quarter of an inch. Such watering is worse than useless. Far better to mulch the soil, and trust to that for the preservation of moisture than to form a thin layer of damp soil, which only attracts the roots upwards to it that they may be par-boiled by the hot morning sun.

A good way to water shrubs is one which we adopted with perfect success in the case of some valuable coffee-trees during a very dry season. We took a number of beer bottles, and, with a tap of a pick on the bottom knob, drove the bottom neatly out. These bottles were then buried neck downwards close to the tree. Every night they were filled with water, which slowly drained away beneath the surface—1 foot below. The rootlets then sought the needful moisture downwards instead of upwards, and the plants grew luxuriantly. The surface was never watered, but by capillary attraction it was kept fairly moist.

In India, gardeners bury a porous jar like a water monkey unglazed. They are filled as soon as empty and a plug on the neck serves to keep out insects and dirt. If gardeners would try this plan they would save many a plant which would die under the ordinary hose treatment.—*Queensland Agricultural Journal*.

HONOUR FOR SIR JOSEPH D. HOOKER.—An official announcement in Berlin states that Sir Joseph Dalton Hooker, formerly Director of the Royal Gardens, Kew, has been appointed a Foreign Knight of the Order pour le Mérite for Science and Arts.—*Gardeners' Chronicle*.

GREEN TEA FOR ASIATIC MARKETS.

It is gratifying to find that my last letter on the above subject has attracted the attention of so many both in India and Ceylon. I regret however to notice that your leader criticising my remarks on the trans-frontier markets was based on more than one misconception as to my meaning. I will therefore feel much obliged if you will kindly allow me to explain and defend the position I took up regarding this once valuable trade.

You state that "so far from the making of the new style green tea being experimental in India, it is only following on the lines which proved successful in Ceylon." This may be, but why slavishly follow Ceylon at all in this matter, when India can already produce the genuine article, which proved so successful that it rapidly ousted its China rival from the great markets of Afghanistan and Central Asia? The trans-frontier markets are acknowledged to be

TOTALLY DIFFERENT FROM THE GREEN TEA MARKET OF AMERICA.

In the former we have to compete against the produce of China and in the latter that of Japan, and the mode of attack in each case must necessarily be different. It does not follow that because the Ceylon green teas suits America, which many experts still doubt, that therefore it is also the best for Afghanistan. Strange to say this is conceded in your leader, when you say, "in point of fact the American and not the Afghan market was aimed at." If this is really the case, then why is the Association trying to force the Afghan market with these new teas when the North-West can supply a tea that is already known and appreciated by all Asiatics? You further remark "that the three old districts did not make the slightest impression on the American market." But I do not believe anybody up here ever seriously tried to make any such impression, simply because there was no necessity for wasting our efforts in America, when we were receiving the highest prices in India at our very doors. The North-Western planters claim no special favours, but they do claim equitable treatment, and object to being arbitrarily brushed aside on behalf of purely Calcutta interests. The Association ostensibly exists for the benefit of the whole Indian tea industry. Why then is it promoting internal competition by artificially aiding Bengal tea against the teas of Dehra Dun, Kangra and Kumaon, the markets legitimately belonging to these districts? What would the Bengal planters say if the Association withheld its support from them in the direction of America, while it deliberately encouraged the North-West men to exploit and capture the American market? Regarding

THE ACTUAL PRODUCTION OF GREEN TEA

you say, "but we are of opinion that the expense and trouble of making green teas on the old system will always stand in the way of their being turned out in quantity." But the argument will not hold, as we have only to quote China, with its millions of pounds of green tea, every particle of which is made by hand in the old style." And nearer home, the much maligned "three old districts" also turned out between them a million or two of this very tea, and made it cheaper than the black teas of the period; and I feel assured that even now the same results could be easily produced. There is no reason why the process of "panning" should be done any longer by hand. I had not much difficulty even in the

old days, in erecting a rough but workable hand apparatus by which one man did the panning of a dozen or more. Something on similar lines, adapted to steam-power would, with a few attendants, do the work of the whole factory. So we need not fear any difficulty about the cheap mechanical production of the old style green tea. What is really causing serious anxiety is the casual and airy way the inexperienced men of Bengal have decided to discard this tea for a new hybrid green which is untried and wholly unknown to the conservative Asiatic markets. I will take this opportunity of once more reiterating that genuine green tea, of a greenish hue, can easily be made without the addition of any foreign colouring matter whatsoever. But it is very probable that our Asiatic customers will insist on having a lighter green, and this can only be produced by "facing" the natural green with certain effective and harmless ingredients which cost next to nothing.

To resume our arguments. You state that "after all a style of manufacture which died out for want of support on the great markets is scarcely worth while making special efforts to revive." But it is forgotten that it was not the "style of manufacture," that caused the loss of our markets; but on the contrary, it was the extinction of these markets by the political and fiscal actions of Russia and Afghanistan that made it unprofitable to make any more green tea. Again you say, "by all means let the old tea districts revive their green tea trade with Afghanistan, but they cannot help us in America or elsewhere." I beg leave to doubt this latter assertion, but even if we allow it to pass, why should Bengal go out of its way to foist its new imitation green teas on the Afghans, when there is already a well-known and suitable article available on the spot? What would be said of our Government if in a trans-frontier war, it entirely neglected and ignored the splendid native army of the Punjab, and deferred taking active measures, till it had raised, equipped, and trained a scratch lot of raw and untried Bengalis and Cingalese for the campaign! When India first started capturing the tea markets of the world from China we

WISELY DID OUR BEST TO CLOSELY IMITATE OUR RIVAL'S TEAS

in make, colour, and even in names. The reason we triumphed in the end was because, quality for quality, we gave our customers better tea for their money. We did not, as some still seem to imagine, manufacture an entirely new kind of tea with fancy names of our own concoction. Likewise when the North-Western planters made up their minds to oust China from the trans-frontier markets, they did not waste their time and money in trying to force a wholly unknown commodity on the suspicious and extremely conservative natives. They took the more businesslike course of first obtaining approved samples of green teas from the great China entrepôts at Kabul, Kandahar, Mashed, Bokhara, and Samarkand, and then manufactured up to these qualities. And as they were not above consulting the people and meeting their wishes, they very rapidly secured a firm foothold in the desired markets. Had the Russians and Afghans not deliberately closed these markets to us, we would—long ere this—have secured the entire monopoly of tea in that direction, and could easily have defied competition from elsewhere. We lost this lucrative trade not because our teas were unsuitable, but because of the antagonism of Russia and Afghanistan, and

the indefensible supineness of our own Government, which had not the courage or the statesmanship to maintain the "open door" for our commerce. Reasoning from the above two examples, showing how we ousted China black teas from the home market and China greens from the transfrontier markets, one is forcibly obliged to come to the conclusion that our present campaign in North America would have been greatly facilitated had we imitated and improved upon the Japan teas now supplied there, instead of placing an entirely new product before the Americans, to which they have not in any way been previously accustomed. It will

NOW BE NECESSARY FIRST TO EDUCATE THE
YANKEE

palate and inclinations: a slow process which must produce stronger competition on the other side, and consequently greater loss of time and money to India. Whereas had we given America, quality for quality, name for name, a genuine green tea but one superior to that now supplied by Japan, it is hard to believe that our cute commercial cousins across the Atlantic would not by this time have deserted the old love for the new. The decadence of England's world-trade of late years, it is well known, has been caused principally by the Englishman's perverse and thick-headed policy of always trying to force his unsuitable manufactures down the throats of people who have been accustomed to, and want, something totally different. While on the contrary our foreign rivals, with their keener insight into human nature, take the more practical course of first consulting their customers, and then supplying just what is most suitable to each particular case, regardless of whether or not the article comes up to their own personal ideas of perfection and convenience. In my humble opinion

A SIMILAR MISTAKE IS AGAIN BEING
PERPETRATED

both in America and Afghanistan with the new so-called green teas. These teas may gradually become popular on their own merits, but that is another story. As they stand, however, they are undoubtedly retarding instead of facilitating the introduction of our green teas in the above markets. I cannot help thinking that we would win over our customers more rapidly by "panning" these teas if possible, till they assumed a natural green colour: after which the same names should be used as for Japan greens in America, and China greens across the frontier, with the addition of India or Ceylon as the case may be. We have succeeded before on these lines, and there is every reason for believing we would succeed again.

If we are to make a serious attempt to revive the former green tea trade across the frontier, we must first bear in mind that there are many political issues involved, which can only be satisfactorily settled by the intervention of the Home and Indian Governments. It is therefore necessary that the Indian Tea Association, working in conjunction with the planters of the North-West, should lose no time in approaching our Government about the matter, Both Russia and Afghanistan might be persuaded to remove the difficulties in the way by a little judicious pressure on their own trade with this country. In 1888 I suggested to the Punjab Government, that if Russia would not agree to let our tea in to her territories in Central Asia on reasonable terms, the Indian Government as a set-off should put similar prohibitive duties on the import of

kerosine oil from Batoum. At the time, my suggestion was received with horrified amazement by the official worshippers of the free-trade fetish; but some years later a duty was actually imposed on imported kerosine, though not sufficient to make Russia relax her restrictions on our Indian tea. There is, however, yet time to put the screw on in this direction to India's great advantage.

WITH THE PRESENT AMIR THERE SHOULD BE NO
VERY GREAT DIFFICULTY
in arriving at some mutually satisfactory arrangement. But in both cases the initiatory steps must be more political than commercial, and the Association's business should be to persuade the Government to make an early move in this matter.

The North-West men, rightly or wrongly, think that the I.T.A. does not take a sufficiently broad view of the whole position. There is ample room in the world's tea markets for all sections of the Indian tea industry: but it is urged that each market should be dealt with on its own merits separately, and the most experienced men, and the most suitable tea should be told off for each particular situation. No one with any glimmerings of intelligence can be expected to believe that Calcutta tea and Calcutta men are the only possible means of opening every new market that appears on the horizon. Yet some such idea seems to prevail down Bengal way, as witness the manner things have been done regarding the trade in India, and in Persia, and now towards Afghanistan. Specialisation and decentralisation, that is, special men and special means, and delegation of authority, are the mainsprings of all modern progress. If the Association would only bear this in mind, there would be less irritation and dissatisfaction, and more combined and harmonious work done for it by the varied planting communities of this country.

J. B. LESLIE ROGERS.

Umballa, Punjab.
—*Indian Gardening and Planting*, June 12.

WHERE GREEN LEAF IS PREFERRED.

The following particulars may interest the Indian Tea Association and others concerned to revive the green tea trade with Afghanistan and Central Asia. Tea grown in China and Ceylon is most in demand in those countries. It finds its way by rail from Bombay to Peshawar, whence the bulk of the export trade goes by the Khyber or Mohmand country to the Districts beyond. The tea is most carefully packed by the Peshawar dealers in packages varying from two to four maunds, according to the transport animals to be used. The outside wrapper is of undressed leather, and thus the loads are fully protected against rain and snow. On reaching the Afghan frontier the Amir's officials levy 1 anna (Kabuli) per Kabul seer, which is equal to 8 seers Indian. This payment entitles him to an import certificate, which he has to produce at the place where he ultimately disposes of his tea. Upto and including Kabul this terminal charge is R5-1-6 (Kabuli) per Kabul seer. The total dues thus levied before the consumer is reached amount to about 2½ annas per pound, English. If the tea is carried through Kabul to the Oxus, for the Central Asian markets, the further charges are about the same, while the Russian fiscal duties in their Asiatic territory are practically prohibitive. The Indian planter, therefore, can scarcely hope for more than a re-entry into Afghanistan: he must consider the Central Asian khauates closer to him. We may

mention that Indian hill tea is not in favour in Kabul circles, where the upper classes are great tea-drinkers. The product of Assam and Kangra Valley are considered too heating, and the green-leaf from China is preferred. It is, by the way, a mistake to suppose that the tribesmen of Afghanistan consume great quantities of tea. They are much too poor to be able to afford the beverage. In the big towns and bazaars tea is commonly drunk by well-to-do people; while traders and caravan men also use it freely. If the Punjab and the North-West Frontier Province were properly exploited, they would offer a much better market for Indian tea than can ever be secured in Afghanistan.—*Pioneer*, June 14.

THE INDIAN RESTRICTION OF OUTPUT CIRCULAR.

The following resolutions were unanimously agreed to at a meeting held at the offices of Messrs James Finlay & Co., London, on 26th May, 1902:—

(1) That those present agree to recommend and to use their influence to stop manufacture of tea from 1st to 21st August inclusive.

2 That if sufficient support is obtained, say to the extent of 65 per cent. of the crop, or 118,000,000 lbs. of tea, the Ceylon growers shall be approached to stop manufacture for a period of three weeks; and provided growers representing 50 per cent. of the Ceylon crop—or, say a total of 72,000,000 lbs. of tea—agree, the scheme shall forthwith be given effect to.

(3) That importers signing shall not alter, in the direction of coarser plucking, their present instructions to managers.

(4) That all signatories shall submit the totals of their estimates for the present season's crop, and at the end of the season will also submit the total figures of their actual crop.

(5) That the following gentlemen be appointed as a Committee to carry out the above, and to consider other steps that may be beneficial to the combination:—W H Verner, R B Magor, J N Stuart, C C McLeod, and A Bryans.

CEYLON TEA COMPANIES REVIEWED. ADDITIONAL PARTICULARS.

We have to thank the secretaries of the under-mentioned Companies for supplying the supplementary information required to complete our statistics, and which we now print for reference purposes. The acreage in bearing of the Burnside and Highland companies in 1901 was the same as in the previous year at 1,134 and 617 acres respectively, and the Kelani Valley Company showed an increase of ten acres only to 1,222, but the Poonagalla and Portmore undertakings had 1,280 and 522 acres against 1,237 and 480 acres in 1900, and on the other hand the Ederapolla reduced its acreage by 53 acres to 1,336 acres. As regards two companies, of which the particulars of prices obtained were omitted, the Panawal should have been classed with those showing an improvement as the average rose from 5½d. in 1900 to 6d. per lb. in 1901, but the Nahalma was less fortunate than its companion, and realised only 4½d. compared with 5½d. a year ago.—*Investors' Review*, May 31st.

THE HANKOW TEA TRADE. NO DIRECT SHIPMENTS TO THE UNITED KINGDOM.

The following details in regard to the tea trade at Hankow last year, contained in the report of the British Consul at Hankow just issued, will be interesting not only to tea dealers generally

but to investors in Indian and Ceylon tea companies:—

The local supplies of Hankow teas during the season were 531,389 half chests against 698,897 half chests in 1900, and the settlements 479,587 half-chests, against 677,733 half-chests. For Kewkiang teas the settlements were 180,620 half-chests, against 210,228 last season. Shipments to Shanghai on native account amounted to 62,687 half-chests against 34,663 in 1900. There were, as in 1899 and 1900, no direct shipments to the United Kingdom. The subjoined table shows that the demand in the United Kingdom continues to fall as it does for Russia direct, while shipments to Russia *via* the northern ports only slightly recovered from the collapse of the previous year; but the supplies for Canada and America doubled last year in fear of extra taxation, show a satisfactory increase on former figures. A certain amount of tea goes up the Han River for Mongolia and Siberia. This year the supply of leaf, brick, stalk and dust totalled only 6,870,800 lb against 7,300,000 and 11,860,000 lb in 1899 and 1900; the value is returned at £160,775:—

Destination.	Quantity,		
	1901. lb.	1900. lb.	1899, lb.
Great Britain	6,324,991	8,271,788	16,141,506
Russia	24,828,088	35,447,580	25,940,112
Tientsin and North	7,517,219	6,905,756	23,889,948
America and Canada	6,794,396	10,583,182	5,264,276

The market opened on 9th May, when the most attractive parcels of Khemun tea were settled at prices ranging from 40 to 55 taels per picul (say, 10d to 1s 2d per lb). Quality turned out to be quite satisfactory, and later on lower grades were in strong demand, chiefly for Russia, and very few chops remained unsold for more than a few days. Crack chops of Ningchows found buyers up to 57 taels, but though some were excellent, the majority were not superior to last season's. Hankow teas were of a good average quality, and the two Ichang crack chops were quietly taken at 58 taels. There were again no settlements at Kewkiang. The average cost laid down in London of first crop of tea, nearly the whole of which was settled before the end of May, was 9d per lb. Second crop teas began to arrive on the 16th June. The supply was very small; the tea-men, aware that the demand would be much less than usual, have made up their minds to reduce the production. Nevertheless, but for a partially unexpected demand from America, a considerable amount would have been left on the market.—*Financial Times*.

CRUDE RUBBER.

(To the Editor of the *India-Rubber and Gutta Percha Journal*.)

Dear Sir,—There is a great deal of activity going on here in rubber planting, and the Peninsula must before long be an important rubber-producing country. The soil and climate seem to be particularly suitable for the cultivation of Para (*Hevea Brasiliensis*) and Ficus (*Ficus Elastica*) and, should the results equal the experiments which have been carried out from time to time, this country will afford a very profitable field for investment in this direction. Straits rubber has, I believe, a bad name, which is because it is more or less a heterogeneous collection of indigenous rubbers and saps collected by the natives, and, of course, we

planters do not wish to associate our cultivated product with this variety. Although my own estate is not yet in the productive stage, yet I can extract sufficient latex to make small experiments, and I read with very great interest your remarks on crude rubber. From these articles I learn that a great deal of waste occurs in the washing process in consequence of adulterants. Well, Sir, I am only anxious to turn out as pure a rubber as possible, and I am prepared to do anything in reason to accomplish this, but, being a planter, I know nothing about the manufacturing side. Since there is a process of cleaning rubber, would it not be possible to accomplish this on the estate, and so avoid paying freights on useless material, or, better still, so prepare the milk as to avoid this washing process? With scrap it is quite impossible to collect the latex in a pure state; an admixture of rubber bark and soil always results.

If you would, through the medium of your valuable paper, advise the planter what to do, you would be conferring a great benefit upon the community. I know there is a great deal of diversity in the opinions as to the best means of coagulating the latex; one is recommended alum, spirits, centrifugalisation, smoke, and various other methods—one of which is to allow coagulation to take place naturally. I was privileged last December in the company with Mr. Fox, the assistant director, Singapore Botanical Gardens, to take part in an experimental tapping of some Ficus trees (5½ years old) belonging to Mr. Tan Chay Yan, of Malana. From 3½ imperial pints of latex were obtained 2 lb. 10 oz. of dry rubber, which was coagulated by adding water while the latex was still in the fluid state, and then boiling the mixture for about 1¼ hours in an earthenware pot. This rubber has since been valued in Mincing Lane at 2s 6d per lb., and described as "good, clean, fairly elastic, and dry." It is, of course, open to question whether the value would have been higher if some other means of coagulation had been adopted, but it would be interesting to know whether this sterilising of the latex is likely to deteriorate it in any way, as otherwise it seems to be an effective and handy method of coagulating. Some information on this point would be very useful.

I trust I am not unduly intruding upon your valuable space in asking you to insert this letter, as I think a great deal of good could be accomplished if the manufacturer and planter had some means of communicating with each other to discuss this important subject.—I remain, Dear Sir, yours faithfully,

FRANCIS PEARS.

CACAO PLANTING IN SAMOA.

(From a Planter.)

Apia, Samoa, May 18.—It may interest you to hear that Cacao planting is being undertaken on a large scale here. The prospects are very promising, and this year's crop will probably fully justify past experiences and the predictions contained in reports already sent to you, particularly Mr. Moor's letter to you about a year ago. Our Cacao is a hybrid of Criollo and Forastero, the former largely predominating, and fetches a good price, 85s to 95s so far. I have seen many trees under 3½ years old full of young pods, and the older trees bear frequently 200-300 in a year. I shall have 500 acres planted by this time next year (170 so far) and there are numerous other smaller plantations being laid out.

CINNAMON IN LONDON.

The information to hand by the last mail helps to explain the private commercial telegram which we published three weeks ago, that at the quarterly sales of cinnamon held in London last month, prices had advanced as much as 2d. to 3d. per lb. Just as the fall at the February auctions was caused by an over supply, last year's exports of the quilled spice having exceeded 2¼ million lbs.—the highest quantity ever exported from the island—so the recovery of prices (and more) was due to exceptionally small offerings. The May auctions are generally not very heavy—the drought of the first quarter of the year, and the festivities of the Sinhalese New Year early in April, combining to keep down the out-turn; but 433 bales represent about the smallest quantity offered, we suppose for the last 25 years. At the corresponding sale last year, 1,088 bales, or considerably more than double the offerings of this year, were brought to the hammer. And of this small quantity, only 156 bales were "worked"; but it was not these alone which shared in the gain of 2d. to 3d. per lb. While worked Firsts ran up as high as 1s. 9d., a figure we do not remember to have heard of since the early seventies, "unworked," which is a comparatively recent innovation, born of resistance to an exorbitant charge for undoing, examining and re-doing each bale, at about four times what the whole operation of sorting and baling costs here, also shared in the advance. During the ten years or so that cinnamon has been offered in the London markets as "unworked" spice—in the face of threats of boycott!—prices for Firsts have always been short of a shilling. But then it must be remembered, that the marks which dared the London monopolists were not the better marks, but those which studied quantity rather than quality. We do not think these have suffered by offering their wares without the hall-mark "worked"; but 1s. 3d. per lb. for their cinnamon is an unprecedented figure, and must rejoice the heart of shippers. Still, it would be unsafe to calculate on such prices again. They are not likely to be repeated except under very exceptional circumstances; and our counsel against over-production remains. The market for spice, which is a luxury, is necessarily a limited one; and though the statistical position was good last month, the Cinnamon that is now being hurried into the market will turn the scales.

The following is the Report on the last Sales of the leading Firm whose views we regularly quote:—

King William Street, London, May 27.

CINNAMON.—At the quarterly sales held yesterday the exceptionally small supply of 433 bales Ceylon quill was brought forward compared with 1,311 bales in February and 1,088 bales at this period in 1901. Considering the small quantity offered, competition was not brisk, except for a few small lots of "Firsts," which brought 2d to 3d per lb. advance for "worked" and "unworked."

Only 156 bales "worked" spice were offered and all sold at firm prices, to occasionally dearer, especially 8 bales Firsts A.S.G.P. which brought 2d to 3d per lb. advance.

Of 277 bales "unworked," 235 bales were cleared chiefly at 3d to 3d per lb. better for "Thirds" to "Firsts," which "Fourth" ruled about steady. "Worked" Firsts 11d to 1s 9d; Seconds 10d to 1s 6d; Thirds 9d to 1s 5d; Fourth 7½d to 11d. "Unworked" Firsts 7½d to 1s 3d; Seconds 6½d to 1s; Thirds 3½d to 10½d and Fourth 5d to 8½d per lb.

CHIPS, &c. -1,088 bags offered and 350 bags were sold in the room, a little coarse bark at 1d to 1½d. Chips up to 2½d and quillings, &c. 5½d to 9½d per lb. No wild Cinnamon catalogued.

	1901.	1900.
Stock of Ceylon	..3,313 B against	3,442 3,644 B
" Wild	..1,979 "	2,725 2,606 "
" Chips, &c.	..2,093 "	3,705 5,333 "
" Wild bark, &c.	7,301 ;	8,242 8,100 "

The next auctions will be held 25th August.

PRODUCE AND PLANTING.

AT THE MEETING OF THE TOWER HILL COMPANY, LIMITED,

another of those large distributing companies which handles tea so profitably, Mr. T. Lough, M.P., referred to the report on tea and coffee recently issued by the Board of Trade and given in our columns. The statistics given in that official document are certainly encouraging to those connected with tea in any way, but especially so to those who distribute it. As was pointed out by Mr. Lough, out of about 600,000,000 lb. exported in 1900 from the great tea-producing countries,—China, India, Ceylon, Japan and Java,—nearly half was imported by this country, this large proportion including seven-eighths of the whole Indian export, and three-quarters of the Ceylon export of tea. Notwithstanding the increase of 50 per cent in the duty on tea, which took place in March, 1900, the consumption throughout the United Kingdom continued to increase. Five years ago, in 1897, this consumption was 5'81 per head of the population, in 1898 it became 5'86, 5'98, in 1899 6'10, in 1900 and 6'17 in 1901. A large percentage of this recent increase was due to a greatly extended use of tea in Ireland. In that country the consumption was now nearly 8 lb. per head of the inhabitants, it was difficult to say precisely. This placed the United Kingdom far ahead of all European countries. The recent increase of duty had made our tea duty stand very high in proportion to that of other nations. In Belgium tea was admitted free, in Holland the duty was 2½d per lb., in Denmark 4d, in the United States 5d, in Germany 5½d, in the United Kingdom 6d, in France 9d to 1s 5d, and in Russia from 2½d to 1s 10d per lb. Seeing that the Empire was so deeply interested as a tea producer, it was surely to be deplored that they did not follow the example of those countries that gave the most favourable treatment of this indispensable article of diet.

DR. MORRIS AND VOLCANIC DUST FROM BARBADOS.

Dr. D. Morris, Commissioner of the Imperial Department of Agriculture for the West Indies, has forwarded to the Royal Colonial Institute a sample of volcanic ash collected in Barbados on 7th and 8th May last.—*Daily News*, May 28th.

RUBBER IN BURMA.

The "Moulmein Advertiser" writes—The apparent or seeming ease with which India Rubber is extracted in the hill-forests above Bhamo in the Upper Province is responsible for some loose ideas on India rubber planting and cultivation, it being assumed that it is quite simple matter which looks after itself and only wants to be left alone. Those who have entered upon this kind of planting in the Malayan Peninsula are beginning to realise that rubber plantations entail a long wait for capital, and some very heavy work before actual planting can be begun. And there might be much in these 'handicaps' to account for the long complaint made some time ago against the local Government for its intention of opening out about 10,000 acres of land in the Mergui district for rubber cultivation as a Government enterprise. So far as the Amherst district is concerned, we have, we believe, a small rubber venture at Amherst of which the result is an uncertain, if it is not an unknown, quantity as yet. We have never been able to trace the origin, on the large tracts of hill country, inhabited by the Kachins and other tribes, of the widespread forests of the India-rubber-yielding trees. In those parts there is nothing to show that those forests were at any time artificially raised; and during a stay of several weeks in that part of Burma, enquiries about how those forests were preserved and continued were very disappointing. But it is quite a certainty now that rubber, when adopted as a special cultivation, is by no means the easy enterprise it looks when extracted from a forest which apparently has been planted and cared for by Nature. From some reports that have been printed and published of India Rubber Companies, we learn that their undertakings have swollen financially to very large proportions by the preliminary work that has to be done before planting is possible. *

Under these circumstances the action of the local Government, which unfortunately has not always led where private enterprise would follow, is most commendable in having resolved to experiment in rubber planting on such a scale as would afford a reliable precedent to private companies investing large capital in developing the rubber enterprise in such parts of Burma where the soil and atmospheric conditions are favourable. The advantage of having these plantations as near as possible to a port is obvious; it avoids the heavy expenses incurred in transit. And the Mergui district is, perhaps, the most convenient, if it is favorable, district in Burma for exporting rubber, dressed ready for use. The enterprise as we have shown is so

THE MEETING OF LIPTON'S, LIMITED,

on Tuesday was not quite harmonious. A reduced dividend is not conducive to excessive amiability on the part of shareholders. Only one gentleman, however, referred directly to Sir Thomas's yacht-racing proclivities as calculated to lessen his attention to business but his remarks found little endorsement among his fellow shareholders. Sir Thomas Lipton said he was very hopeful that the current year's trading would prove the turning point in the adverse market conditions from which they had suffered. He had not sold one single share since the formation of the company; in fact, he had increased his holding since the last meeting, and now owned nearly half of the total issue of each of the Ordinary and Preference shares and Debentures. The whole of the advertising outlay had been borne by Sir Thomas Lipton himself, in accordance with an arrangement made last year, and in consequence of the bad condition of trade, and although the actual amount of this was not disclosed it is estimated in some quarters at about £40,000.

THE BALANCE SHEET OF THE CO-OPERATIVE WHOLESALE SOCIETY

for the first thirteen weeks of the present year has just been made up. The sales totaled £4,413,708, being an increase of 9 per cent on the corresponding

period of 1901. The London branch was responsible for about three-quarters of a million, and the tea and Coffee department in Leman Street, E, for £13,000. So far as the general policy of the Wholesale Society is concerned, the most significant recent development has been the purchase of two tea estates of 364 acres in Ceylon—the outcome of a deputation of two years ago, and also of the demands of Co-operators to go direct to the origin of things.

LYONS & Co.—It is not alone the distributing companies which make large profits in connection with the sale of tea. The possibilities of profit to those who run tea shops and cater for the multitude are apparently illimitable. The directors of J. Lyons and Co. have, in accordance with expectation, issued another bonanza report, in which the gross profits are shown to have expanded by over £50,000. The net result to the shareholders is a final dividend on the increased capital of 32½ per cent., as against 30 per cent., whilst they have the satisfaction of seeing a larger balance carried forward and their reserve augmented to £400,000.

THE QUARTERLY SALES OF CINNAMON—held last week attracted more than ordinary attention. The total number of bales passing the hammer amounted to 433, as against 1,311 bales in February last, and these consisted—with the exception of a few thirds—entirely of good and fine qualities, fair plantation being conspicuous by its absence. This fact illustrated more clearly than anything else the depression from which the trade had suffered for a considerable period and which had rendered forward business almost impossible. Even a certain few operators among shippers appear to have failed in their endeavour to find buyers of usual assortment at greatly reduced prices. Offers of 8½d c.i.f., we are told, had to be returned to Colombo as being too dear for our market. Evidently some consumers have unwisely allowed their stocks to run dangerously low. The trade had to purchase and was forced to concede prices which were much in excess of those accepted privately. Fine sorts realised an advance of about 2d above last sales' rates, and good fetched about 3d more than was paid in the February auctions, whereas the few fair bales of thirds found buyers at an advance of ½d per lb. The tone in the market has since been a firm one both here and in Ceylon.—*H. and C. Mail* June 6.

CEYLON ASSOCIATION LONDON.

(Report of the Executive Committee.)

[For the year 1901-1902.—To be laid before the fourteenth annual general meeting on Monday, 16th June, 1902.]

The number of members on the roll is 154. The chief business of the Association during the year has been dealt with by the Tea and Produce Committee, and the Executive Committee has had no other important business before it. In last year's report it was stated that there was an unexpended balance—£39 8s 3d—of the money raised in 1900 for providing comforts for the Ceylon Contingent serving in South Africa. Of this balance £19 17s was contributed to the cost of the dinner given to the contingent, and the remainder, £19 11s 3d has been remitted as a donation to the Planters' Benevolent Fund. The Association is much indebted to Mr. W S Bennett for a present of lantern slides with views of Ceylon, forming a valuable addition to the collection purchased in Ceylon a few years back. The slides have been much used by members for the purpose of illustrated lectures.

THE DEATH-ROLL FOR THE YEAR

includes the names of the following members:—Mr Daniel W Blyth, Mr George Smyttan Duff, Mr Donald Noble, Mr John Mackintosh Smith

and Mr George T White. The connection of the two first-named with Ceylon dates back to the middle of the last century. Mr Smith and Mr Noble were well-known in the Colony at a later date as Planter and Banker respectively, while Mr White, as a leading London Tea Broker, has been a Member of the Tea and Produce Committee since its formation in 1889.—The report of the Tea and Produce Committee and the accounts for the year are, as usual, appended to this Report.

REPORT OF THE TEA AND PRODUCE COMMITTEE.

(For the year 1901-1902.)

The Committee has held nine meetings during the year.—The first business of the year was the appointment of a Sub-Committee consisting of the President, Messrs R A Bosanquet, A Brown and A Thomson, to consider and report upon the proposal for the formation of a Joint Indian and Ceylon Tea Growers' Association, in accordance with the resolution passed at the annual meeting of the Association on 24th June, 1901. The Sub-Committee, acting in concert with a Sub-Committee of the Indian Tea Association, submitted, in February last an interim report, after consideration of which by your Committee the matter was referred back for further inquiry.

The question of the increase of the Tea Cess in Ceylon from 20 cents to 30 cents per 100 lb has engaged much attention. In considering this important subject the Committee had the advantage of hearing addresses by Mr P C Larkin of Toronto, Canada, and by Mr J H Renton, Ceylon Tea Commissioner on the Continent of Europe. After hearing the former a resolution was passed and forwarded to the Thirty Committee in favour of devoting to the bonus on the manufacture of Green Teas a larger proportion of the funds available.

On the question of the proposed increase of the Cess much difference of opinion was at first manifested; but in response to a circular issued in December, together with a letter from Mr. E Rosling, Chairman of the Planters' Association, appealing for support for the increase, a large majority of the replies received from tea growers in this country were favourable. An ordinance to remain in force to June, 1905, has since been passed by the Legislative Council, enacting that the Cess may be at the rate of 30 cents per 100 lb of tea exported from Ceylon.

It was mentioned in the Committee's report last year that it had been agreed to give a trial to private sales of tea, under conditions to be arranged by the various sections interested in the trade. For three months, July, August and September, private sales of Ceylon tea were held every Thursday, but sellers, finding no advantage in the system, reverted to the Tuesdays' public sales.

At the beginning of the Indian tea season the Committee for the regulation of sales resumed its operations. Your Committee was prepared to assist in these, both by supplying information as to the quantities of Ceylon tea being brought forward for sale and by a vote in aid of the expenses, but the Regulation Committee, unfortunately, failed to receive adequate support from Indian sellers and again its operations came to an end.

Several suggestions have been made to your Committee during the year by the Tea Buyers' Association (1) For the marking with the letter R of all packages containing tea which has been racked into fresh packages at the Custom House; (2) For the nomination of three representatives to confer with representatives of the Indian Tea Association and of the Tea Buyers' Association on certain specified matters connected with the tea trade; (3) For the re-weighing—of the ounce—of the selected average tared tea packages by the Customs authorities. The Committee has not been able to assent to any of these proposals.

There have recently been many complaints on the part of Importers of damage to Tea, by fruit

idea, &c., shipped in the same vessel. A Sub-Committee, consisting of the President, Messrs W H Anderson, R A Cameron, J B Keitb and T C Owen, has been appointed to confer with the Shippers in connection with the numerous claims arising from the damage so incurred.

A Deputation of India and Ceylon Tea Growers waited on the Chancellor of the Exchequer on 4th February, with reference to the duty of Tea entering the United Kingdom, and met with a sympathetic reception. No change has been made in the British and French duties, while in Anstralia Tea will in future be free. In the United States also it is probable that Tea will be freed of duty at the end of the year.

Other objects that have engaged the attention of the Committee during the year are the planting by the Indian Government of a large area in Burma with rubber trees; the rules of steamships as to claims on account of "nillaged" packages, and the more careful plucking of Tea on estates.

ACCOUNT OF RECEIPTS AND EXPENDITURE 1901-1902.

RECEIPTS.—1901, May 23, To Balance with Messrs Smith, Payne & Smiths, £157 8s 9d; To Use of Ceylon Room, £1 1s; To Newspapers Sold, 8s 3d; To Subscriptions—Planters' Association, £60; Ceylon Chamber of Commerce, £50; Members—1899-1900, £2 2s; Members—1900-1901, £10 10s; Members—1901-1902, £134 8s; Members—1902-1903, £2 2s—£259 2s. Total £418.

EXPENDITURE.—£1901 By Secretary's Salary, £100; By Rent, £80; By Firing, etc., £2 13s 4d; By Room for Annual Meeting, £1 11s 6d; By Book Case, £9 10s; By Office Repairs, £11 11s; By Newspapers, Books, &c., £7 19s 7d; By Printing and Stationery, £27 4s 7d; By Ceylon Contingent Fund, £39 8s 3d; By Postages and Petties, £12 13s 3d; By Balance with Messrs Smith, Payne & Smiths, £125 8s 6d. Total £418.

Examined and found correct, W. M. ROLLO.
London, 29th May, 1902.

ANNUAL REVIEW OF TEA TRADE.

(By Messrs W J and Henry Thomson.)

38, Mincing Lane, June.

Another season's business being completed, and London figures published for the twelve months ending 31st May we take this opportunity of reviewing the events of the year and considering the future.

Attention is at once fixed upon the contrast with record of the previous season. A year ago we were confronted by

OVER-SUPPLY AND INFERIOR CROP, from India and Ceylon, expansion in China's export, and a serious decline in value. Now, we record reduction in the total output of British-grown tea, contraction in exports from China, and the beginning of recovery from depression. Amidst much that changes, two features are constant, viz: that the use of tea almost everything increases, and that British-Grown tea advances in favour wherever it once fairly gains a footing. What were the remedies proposed a year ago; how have they been applied; what has been the result? They were, in the first place to raise the standard of quality; in the second place, and as a consequence, to make less tea, and then to find new buyers. Smaller and better crops have been made, partly because weather checked growth of leaf, partly as the result of more careful plucking. The crops have contained less common tea, and the average value has risen, although, for reasons to which we will presently allude, all kinds have not shared in the improvement, but only those that were specially depressed. Directly or indirectly, our trade with Colonial and Foreign markets is maintained, and openings are lost for business which should be larger during the coming year. The attempt to place tea within the reach of native consumers in India is

watched here with interest; the business-like way in which it is being carried out, and the progress already made, augur well for ultimate success. But when expedients, schemes and policies have been contrived, discussed and given a trial, we come back to the elemental facts that what Planters need is a better price, and that the value of tea, as of other commodities, is subject to the inexorable law of supply and demand. We said a year ago—and it will bear repetition—that producers could maintain prices at the level that pays by combining to keep supply within reasonable limits; for consumers in the aggregate, outside the producing countries, are now dependent upon India and Ceylon for the greater part of their requirements, and tea has become so necessary that its use will not be stopped by such a moderate advance as would satisfy growers and could be caused by reducing supply.

The necessity of making no more than is required is particularly felt by those at home who see the balance of power passing into the hands of buyers with large means, fertile in resource, who operate in London, Calcutta or Colombo as may suit them, and are ready by acting in concert to control the market—but are only able to do this effectually when there is too much tea; where it is, or who has it, matters not. But if the law of supply and demand prevails in the long run, markets are affected by other influences which have also to be taken into account. Tea has been too long subject to the

DEPRESSING INFLUENCE OF HEAVY DUTIES,

and the theory held by some that they are wholly paid by consumers has broken down under the practical experience of those engaged in trade. Every grower abroad, every shareholder at home, pays part of the sixpence levied here; shippers of China and Japan teas have suffered from the 10 cents' war tax in the United States, and traders all the world over are hampered by duties almost everywhere imposed as though tea were a needless luxury instead of a most nutritious and, to many, a necessary article of diet. Those who think otherwise rely upon the argument that consumption is large here than when the duty was less, and ignore the fact that the average value is much lower than when duty was fornpence, notwithstanding that over-supply is arrested and crops are of good quality. They also seem hardly to realize that when more of the buyer's capital is taken for payment of tax less of it remains for purchase of tea—which must be prejudicial to the seller, for the capital employed in a trade is not capable of indefinite expansion unless business is so profitable as to attract it, which is not the case with tea. We dwell upon this because a beneficent industry of great importance to India and Ceylon is being partly crippled by high taxation, and unless there be relief some gardens will be abandoned and native labour will cease to find employment. That the fruit of British enterprise in our Eastern Possessions should have to pay an impost of nearly £6,000,000 upon a value of £7,500,000 before it can reach consumers at home, to whom it is a necessary of life seems to be without precedent. Would such a tax upon the produce of Australian or Canadian husbandry be now agreed to?

What prospect is there of relief, and where? The Australian markets are now free: they should take more from us, and tea of higher value. The American tax will be abolished next year, an impetus given to trade, and larger imports called for, as stocks are low—an encouragement to India and Ceylon to make more uncoloured or green tea than has yet been thought of. This should be tried at once and where it can be done cheaply on gardens whose black tea does not usually command a high price. An estate that can put a crop of black on the London market at a cost of 4d per lb could lay down a crop of green tea in New York at 9 or 10 cents per lb without much risk. Such a chance may not recur for years; it should not be missed and America left dependent upon Japan and China. The probable

reduction of the German duty to 1½d per lb should also do good. But helpful as all this will be, it is but little compared with the importance of getting the duty reduced here. It is admitted to be excessive, and while the highest authorities declare increased indirect-taxation to be necessary, they also see the need of broadening its basis by adding to the number of dutiable articles. Every addition brings nearer the day when taxation can be more equally distributed and relief given to those upon whom the burden has fallen most heavily.

But what are growers to do in the meantime? It is easy to say "curtail the supply"—but at whose expense and how is it to be done? A decline in the value of the finer qualities, discouraging to those who grow and import them, has been the result of heavier duties and lighter crops. Quotations always move towards an average; a short supply means higher prices for common followed by lower rates for fine tea, and the approximation in value of the different qualities will be accentuated if the crops be shortened only at the end where cheap teas are made, although the average value of the whole would be raised. The problem is a hard one, but it must be faced, and persuasion of its difficulty lead us once more to speak of

THE BENEFIT OF AMALGAMATION.

To combine in one interest estates in the same district is good; to unite those in different districts, yielding both high and lower-price tea, is better; to link together groups of estates in Ceylon or India, and thus lessen the risk to which individual growers are in turn exposed by a change in value of the particular variety they happen to make, would be best of all, and it would facilitate all-round reduction in the quantity, the shortest road to all-round recovery in price. But things being as they are, we have to consider probabilities. They seem to be that more low-priced tea will be made; that its value may recede, especially if the increase be obtained by coarse plucking, and that a recovery in rates for better qualities may follow. Those who contemplate making heavy crops should, therefore, watch what is being done in their district, and the quotation for common tea in London, lest they repeat the experience of 1900-1901. Those who usually make a large crop of medium quality should, we think, make a smaller one, concentrating attention upon its improvement; while the few who grow the finest varieties should, maintain the highest possible standard of quality. Extensions should be stopped for the present, the closest scrutiny be applied to expenditure, and labour and energy be transferred from poor acreage not giving a profit to that part of the estate which pays for cultivation. Now

AS TO FINDING FRESH OUTLETS,

progress has been slow where the most pains have been taken, *i.e.*, in the United States, and quicker where our tea has been suited to local tastes and has made way on its merits, *e.g.*, in the Colonies and Russia. What is the bearing of this upon future efforts? It teaches us that it is of little use to push black tea upon those who want something else, and that if the industry is not to stand still we must learn to make what others wish to buy. The funds raised by Cess or otherwise should, we think, first be spent in freely subsidizing the pioneers prepared to make the new kind suitable for America and foreign consumers—say to the extent of 10 million lb. this season and 15 millions next. The outlay will be recouped later on in the price of black tea, and in the extension of India's and Ceylon's trade. Then, if enough money be available, let it be used for extending the work already begun of making the merit of tea known in European countries whose vast populations are still almost strangers to its value. At our doors are 200 millions of potential tea-drinkers taking between them a mere 15 million lb per annum. Surely a wide field for enterprising traders to explore! But these are visions of the future: our present task is to reckon how much we can take here,

In 1901 nearly 300 million lb. were disposed of—256 millions at home and 43½ millions abroad—but this included the excessive clearances in the spring, and perhaps was not all used; allowing for increased consumption, we therefore assume 300 million lb to be the utmost we can sell here without lowering the price; to meet it there is in hand a stock of 82 million lb.—10 millions too much we therefore estimate that imports should not be more than 290 million lb. Apportioning this on the basis of recent deliveries, India's share would be 158 millions, Ceylon's 106 millions, China's 20 millions and Java's share 6 millions. How to keep importation within these limits and find a market for the rest elsewhere are problems to be solved.

We abstain from discussing matters of detail and conclude by saying that severe as the trial is through which many Planters are passing the position is better than it was twelve months ago. We have still to feel the full effect of extensions made in former years but it will not be quite what some seems to fear for against yield from new gardens must be set the deterioration of old ones and the abandonment of outlying and unprofitable plots which continually goes on, and the more rapidly when expenses have to be cut down and the labour staff is reduced.

WM. JAS. & HY. THOMPSON,

PLANTING NOTES.

THE CEYLON ASSOCIATION'S ANNUAL REPORT appears on page 96, and deserves careful perusal, along with that of the Tea and Produce Committee. The latter body showed over £125 balance; and the "Association £38, which was divided between the "Planters' Benevolent" and the Ceylon Continent.

RAINBOW TROUT IN NEW ZEALAND.—During the coming season the Wellington Acclimatisation Society expects to have, given even moderate success, 500,000 rainbow trout ova and fry for sale and distribution. The proportion of rainbow fry in the Masterton ponds is far larger now than the society has ever had before.—*Auckland News*. May 29.

STINGLESS BEES.—Stingless bees are not uncommon in the West Indian islands, living wild and making nests in trees. A colony is to be seen in the Dominica Botanic Station and is worth a visit. The bees are small and very active, and become very excited if the nest is disturbed. Even though one knows they are stingless, it is hard to remain near the nest when the bees become angry and fly about just as the real honey-bee does: one instinctively fears a sting, and instinct in this case proves stronger than reason. The bees belong to an undescribed species of *Melipona*, a genus which includes numerous tropical stingless bees.—*Agricultural News*, May 24.

COFFEE.—During the coming year it is expected by some authorities that the coffee crop will be small both from East India and Central America, with the exception of Mexico where a larger yield is promised. Costa Rica will also produce a much smaller crop than usual. According to "American Trade," however, the crop of coffee from the States of Salvador, South-Western Honduras, Western Nicaragua, and Costa Rica will be as large in quantity for 1901-1902 as the aggregate of the last two crops. The cost per pound to gather it for market will be more than twice that in previous years—*Tea* for June.

THE NORTHERN PROVINCE (CEYLON)

IN 1901.

(Extracts from Mr. Ievers' Administration Report.)

TOBACCO CULTIVATION.

Next to food supply, this industry ranks highest in this Province. The following is the statement of tobacco exported beyond sea and coastwise:—

		Beyond Sea.			
Quantity.		Value.			
	Cwt. qr. lb.	Rs.	c.		
1900	... 42,519 0 17	..	981,665	05	
1901	.. 28,269 2 4	..	673,061	68	
		Coastwise.			
Quantity.		Value.			
	Cwt. qr. lb.	Rs.	c.		
1900	... 25,932 2 12	..	602,070	25	
1901	... 51,220 2 12	..	583,660	60	

It is important to note that the export to Travancore has fallen, while the local trade to Colombo and other parts has more than doubled. The Travancore trade has fallen off from the successful competition of Coimbatore tobacco, and the price has fallen. It is a matter for the serious concern of the local producer to find outlets for his tobacco. This can only be done by improvement of the process of manufacture. It will, I hear, take a long time before the grower realises this, and meantime he must be content with less profit and reduction of crop. During the close of the year Jaffna was visited by Mr. MacD. Gibson, who is said to have large experience of tobacco growing in Sumatra and elsewhere, and he expressed his opinion that the locally-grown leaf is of excellent quality, and the methods of planting and irrigation are sound; but the plucking is erroneous, and the curing injurious to flavour. The leaf is actually made rotten, and hence the difficulty in keeping the cigars for any length of time. He was unsuccessful in inducing any local capitalist to take up new methods. The idea here is that, when such methods are introduced by other people's money, the local grower and manufacturer will learn the methods without expenditure. Meantime I am rather discouraged at the prospects of this important branch of trade. The great increase in export coastwise cannot be maintained without a heavy fall in prices, for the market is now glutted, and there is little or no possibility of local expansion for the class of cigar now produced.

It is possible that Government may grant a concession of land in the Vanni for experimental cultivation of tobacco under proper guidance. I think this would be useful, for, if the people see that tobacco cured in the modern methods fetches a higher price, it may induce them to follow these methods and obtain a more extensive market. But no initiative can be locally expected.

CATTLE.

The following is an account of cattle in the Jaffna division:—Buffaloes 3,552; Black cattle 163,911; Sheep 77,236; Goats 57,284.

There was no cattle disease in the Jaffna District during the year, and the condition of the cattle was on the whole good. An experiment was made, through the local Agricultural Association, with fodder seeds obtained from Queensland. I regret to say it was altogether a failure, as the seeds did not germinate.

Another attempt will be made after request for special care in selection of fresh seeds. An irrigation wheel, which can be easily made locally

and worked by a pair of bulls, was procured from Cyprus. It has not been tried experimentally, pending receipt of some information which has been asked for from Cyprus.

IMMIGRATION.

The immigration route continues to be closed from the early part of January, 1900. But during the year a relaxation of the plague regulations was made in respect of the coolies for the Giant's tank works, and 42 coolies were landed at Pesalai from South India, the number of emigrants being 15.

The whole question of immigration and the best route for coolies into Ceylon must soon be well weighed and considered. This consideration will be forced on the local Government when the South Indian Railway system has been extended from its present terminus on the mainland to the proposed harbour on Ramisseram island. It will then be a question whether the steamer lines are to run direct to Colombo, where the Ragama Camp is used, or be taken to a similar camp on the mainland of Mannar and on to Madawachchi Railway Station. A road tram line would probably afford the best means of transport from the landing-places to the camp and onwards. The camp would probably be formed somewhere near Murunkan, and between the 10th and 14 miles from Mannar, for a sufficient supply of good water for a large camp is not procurable nearer to the points of landing.

A steam ferry would probably replace the sailing ships in conveying the coolies to Vengalai and Pesalai according to the monsoon seasons. Possibly a road-tram from Dutch Bay to some convenient point on the Kurunegala-Anuradhapura section of the railway might be better. No doubt the two routes will be considered in the view of cost, convenience and time of transit. But any reversion to the old system of road travelling for coolies is to be most earnestly deprecated.

DESTRUCTION OF WILD BEASTS.

This item is more important in the Vanni and Mannar Districts. For the Jaffna District rewards were paid for the destruction of ten leopards and three bears in the mainland divisions. But since more is paid by traders for skins than can be obtained in the official reward, the figures in no way represent the actual killing of these animals.

HORSE ESTABLISHMENT, DELFT.

The following figures give the statistics of the establishment:—Revenue R1,675; Expenditure R332'97; Nett Revenue 842'3.

There were 32 births during the year, of which 9 died, chiefly of weakness caused by the mothers being old. Eight brood mares died during the year of old age, and they have been replaced by young fillies from Iranativu.

There were at Delft on the 31st December—Stallions 2; Brood mares 60; Foals 33; and at Iranativu under three years old 26.

From the commencement of the experiment in 1898 the total expenditure has been R5,140'36 and the revenue R7,839'80, giving a nett profit of R2,699'44. The expenditure include, besides the annual staff expenses, the building enclosures and the purchasing of stallions. The experiment has so far been a success financially, but I do not so much regard the making of revenue as the protection and improvement of these ponies, which are so hardy and useful in a climate like North Ceylon, where Australians cannot be

kept. From the breeding point of view the experiment has been successful, and the cross of the Delft with the Arab has produced a very much improved young stock, which is now coming on for sale. After another year all the young stock will be either half-bred Arab or half-bred Indian. The only drawback has been an excessive mortality, which has arisen in two ways:—(1) Anæmia and 'poverty' among the young foals on Delft arising from "tics"; (2) the mortality on Iranativu among apparently healthy fat horses, the cause of which we have been unable to ascertain. During the months from August to October we have lost about twenty-five per cent of the stock.

(1) This has, I think, now been controlled. By the advice of Mr Sturgess, Government Veterinary Surgeon, the foals have been rubbed fortnightly with an oil mixture, and since 1899 very few foals have died from preventable causes. It is now proposed to build a bath and drive the foals through a solution in the manner used in Australia and South Africa, for hand rubbing is impracticable where a large number have to be dealt with. I am indebted to General Olivier for some valuable suggestions as to the methods used in South Africa.

(2) The mortality at Iranativu is still unexplained. Last year Mr. Sturgess found the ponies suffered internally from parasitic worms, and we attributed the death to this cause. The disease disappeared by treatment, but, although the water-holes were carefully cleaned and fenced, the same mortality occurred at the same time. One of the finest colts was seen, apparently quite well, in the morning by the Stock Inspector, who was on the island, and was found rolling on the ground in the evening, and died before any treatment could be applied. Unfortunately the intestines were too far gone for *post-mortem* purposes of examination by Mr. Sturgess.

The occurrence of some poisonous plant at this time of year seems to be indicated, and a botanical examination of the island becomes very necessary. I shall be glad to have the help of a botanical expert, whose researches might be able to throw light on this hitherto obscure cause of mortality. It is noticeable that there is no mortality among the cattle, sheep, or goats, which graze freely over the island at this time, nor does it appear in Delft. If the mortality could be controlled, the profits would be very largely increased, as well as the supply for the public, which at present falls short of the applications. I have written at length on this subject, which, though a trivial one in administration and revenue, is of great interest and real value to persons who have need of such animals. The experiment has proved a success, and it may be extended now, with satisfactory results. I was unwilling to ask for any considerable expenditure until I could show that the business was on a sound basis, and for this experiment was necessary. I have now no hesitation in recommending that Government should take up the business in earnest, and, it carried on upon the lines that experiment has proved to be successful and with regard to economy, I believe the Islands will be a source of both revenue and public advantage. Indeed, if this establishment pays its way without profit, it would be sufficient. But I must admit I prefer to conduct it on "business principles."

I observe that country and Indian 'tat' ponies are now being advertised as 'Delft' ponies. No

ponies under 13 hands are now sent out for sale; most of them run to 13·2 to 13·3 hands, and they are not 'cow-hocked' like 'tats.' It can therefore be easily seen whether the description is correct.

CATTLE BREEDING.

I am very anxious to improve the cattle in Delft. As cattle disease never occurs there, it is quite an ideal place for raising a good breed. But from over-numbers the cattle have greatly deteriorated in the last fifty years, and the Island cannot support the 14 000 heads which are at present on it. The people are very ignorant and suspicious, but I hope by means of village rules for limiting numbers and castration or sale of poor-quality animals, and the introduction of Scinde bulls, to show the people that they can get more profit from even half the number. During the year (1901) 831 animals are reported to have died on the island from insufficient grass and water. Such (preventable) mortality is shocking. I have received good accounts of the Scinde bulls placed at Mannar, Vavuniya, and Iranativu. At the end of the year I placed two Scinde bulls on 'Delft.' This breed is excellent for milk produce, but the bulls are rather too small in height. I think we should try some other, possibly South Indian breed. The difficulty about these, however, is that they deteriorate unless highly fed.

TOBACCO IN BRITISH CENTRAL AFRICA.

A correspondent in Nyassaland writing to us in April last, says:—In the early days of this Protectorate tobacco was cultivated for consumption within the Protectorate by Messrs. Buchanan Bros. Subsequently it has been grown by Messrs. Hynde & Stark, and by Mr Henry Brown of Manje. At the present moment, perhaps, the largest cultivators of this produce are Blantyre and East Africa, Ltd., and Mr. Brown. Considering that we have no experts in curing tobacco, no market has been found for it in Loudon, and with the exception of a small quantity sent to South Africa the remainder is consumed locally, as cut tobacco and cigars. It is thought that in the event of our joining the South African Customs Union, we shall be able to trade in this article to better advantage.

Taking this country as a whole, the land suitable for tobacco cultivation is almost unlimited. By planting the young seedling tobacco plants early in the wet season three or four cuttings or crops may be secured in the year. In the "Journal of the Society of Arts," for January 31st, 1902, is a note on "Tobacco Culture in Hayti," in which the length of leaf is given as 20 in. Here we can grow it fully 30 in. and broad in proportion without blemish. So that it is not want of proper material, but the correct method of curing which is our desideratum. Havana tobacco is the variety most in cultivation, though this year our Scientific Department distributed to planters seed of a number of the best varieties.

Nowhere in B.C.A. is tobacco found growing in a wild state, but, as a remarkable instance of the longevity of tobacco seed, it is worthy of note that after a coffee plantation is first cultivated there are sometimes numerous kitchen middens exposed, and almost exclusively composed of wood ashes; on these, particularly in the Namasi district, tobacco plants grow spontaneously. At

the time (1861-2) of the first missionary occupation of this district it was densely populated, but when it was first opened up by coffee planters no people lived there, so that it was overgrown with timber of an average height of 30 to 60 ft.,—ample proof that this seed has remained in a fertile condition for forty years more or less. This variety of *Nicotiana* is probably *N. rustica*, also found on the West Coast of Africa and elsewhere.—*British Trade Journal*, June 1.

PLANTING IN THE MALAY STATES.

(Extracts from the Report for 1901 of the United Planters' Association, F. M. S.)

EXPORT COFFEE TO EUROPE.—With the idea of eventually placing regular monthly consignments of 10 piculs upon the London market to attract attention to our coffee, several of your members combined and sent a trial shipment of 80 piculs. This was bulked in the Port Dickson Co. Mills, and sold through Messrs. Frame, Alston & Arbuthnot. The price realized was 32s per cwt. which worked out to \$17.78 per picul. This result was not sufficiently encouraging to provide any inducement for persevering with the experiment, and no further shipment of any size was made. A small parcel of 12 piculs was, however, purchased to test the respective merits of sun-drying and storing in Port Dickson and Aden; 7 piculs of this, which the Port Dickson Coffee Curing Co. took in hand, were sold in London at 30s per cwt., whilst the 5 piculs sent to Aden realized only 26s per cwt. There were grounds for believing that the Aden shipment was not properly looked after, and therefore no information of any value was derived. A large parcel of good 3-year-old Coffee was disposed of at \$2 per picul less than No. 1 fresh from the plantations, and the idea has gained ground that to speculate by holding, on the assumption that coffee appreciates in value with age, is a very doubtful policy. There may be markets where old coffee is eagerly competed for, but Singapore is certainly not in touch with any of them. Reports from London Brokers favour shipments of coffee dried in the cherry before peeling, and report such coffee to be sweet and suitable for home consumption, but it is suggested that a market for this description must be gradually built up, and no shipments of any size are known to have been made.

YIELD OF COPRA.—In response to a request for information on this subject, the Manager of the Singapore oil mills kindly favoured us with the following communication which your Committee think they cannot do better than reproduce "in extenso."

Mr. E B Skinner, Secretary, the Planters' Association, Selangor, Singapore, October 11th, 1901.

Dear Sir,—I am in receipt of your letter of the 19th ult. re the various copras and their comparative yield of oil. The copras arriving in Singapore usually go under the name of the Island or State they come from, as for instance Bally, Macassar, Selangor, Kelantan, etc. These copras are more or less the same, the real difference being that, while some qualities are made from ripe and fully-matured nuts, others contain 50 per cent of copra made from half-ripe nuts; consequently the yield of oil from the latter is much below that of the former.

Formerly Bally copra was recognized as the standard for "Sun-dried Quality." It was thick, dry, and rich in oil. Evidently great care was taken in picking only the ripe nuts, and it was properly dried before being packed. This copra has fallen from its first position and is now very inferior, being no better, if as good, as the poorest qualities.

Some samples of copra from Peuang and Kelantan have given good results but, as mentioned above, all depends on the percentage of unripe copra in the parcel, and where you may get one shipment with, say, 5 per cent of unripe in it, the next lot from the same place and dealer may have 50 per cent.

Occasionally a small parcel will arrive from the Nicobar Islands. This copra is evidently made from a nut much smaller than those usually seen in Singapore, the kernel is very thick and rich in oil. Our Chinese dealer says it is made from the "Klappa Raja." Ceylon copra is also noted for its richness in oil, yielding about 3 per cent more oil than the Straits article. Yours faithfully, (Signed) The Manager, Singapore Oil Mills.

EXPERIMENTS MADE WITH FIREWOOD, to decide the respective merits of Casuarina, Bakau (mangrove) and ordinary wood, were undertaken by the State Engineer with the following result.—

Firewood.	Hours worked.	Consumption in lbs per hour.	Consumption in cubic feet per hour.	Average time taken to get 50 lbs. steam.	Average steam pressure.	Average weight per cubic foot of firewood.
Casuarina	105½	56.44lb.	1.22c.ft.	2 hours.	81.7lb	46lb,
Bakau	57½	78.25 "	1.21 "	2 "	81.6 "	64½ "
Ordinary	62	75.8 "	1.36 "	1.68 "	87.5 "	55½ "

The above trial very clearly demonstrates the superiority of Casuarina. This tree has been largely planted in Southern India for future fuel reserves, and, as seed is easily procurable at an almost nominal price, it would seem sound policy for the F M S Forest Department to follow the example of India in districts which have been largely denuded of jungle.

RUBBER IN MEXICO.—On the 24th October your Chairman addressed a letter to H B M Consul, Mexico City, D F Mexico, asking for further information regarding the "wild rubber" in Mexico and any cultivated varieties in that republic, but so far no reply has been received although your Chairman's letter was the outcome of a communication from the Consul to the Singapore Chamber of Commerce.

RHEA FIBRE.—The cultivation of this product has attracted little or no attention during the past year, owing mainly to the uncertain market for ribbons. Upon information received from Sir F Abel, Director of the Imperial Institute, to the effect that a firm of high standing in London were prepared, for several years to come, to purchase Rhea ribbons at £15 per ton, the Government by notification in the different "Gazettes" gave wide publication to this offer. When a member of your Association however interviewed the firm in question in London, he was told that they would take 100 tons at £15, after which they could not guarantee a price. Such a rapid change of front was not allowed to pass without comment, and your Committee are pleased to be able to report that H E the Governor considered the matter of sufficient importance to refer to Sir F Abel, who has dealt with the complaint in a manner leaving nothing to be desired.

CATCH CROPS.—Very little success has attended the efforts of those who have endeavoured to keep down expenditure by the cultivation of subsidiary products. The outlets are too small and markets are in consequence easily swamped. As long as prices keep up, the Chinese sub-lessees will maintain their kladdie or pumpkins, as the case may be, in fair condition; but directly a slump occurs, they cease to weed and indeed to put any more labour into the undertaking at all, with the result that the Superintendent has to devote a lot of valuable time to trying to get things straight, and usually meets with very indifferent success. It is generally recognised now that, if more than one product is to be cultivated upon the same ground, the best combination is Coffee and Para Rubber, the former planted close, to yield maximum crops within a limited period, and the rubber at whatever distance may most commend itself to the individual proprietor.

COFFEE.—The export returns for Perak, Selangor and Negri Sembilan show an increase in 1901 of 6,476 piculs; this must be considered a satisfactory result in view of the fact that prices averaged \$18.29 per

pical as against \$20-80 in 1900. Moreover exchange fell from 2, (demand selling rate on London) in January to 1/10½ in December, but for which fact, dollar quotations would presumably have been lower still. A good deal of Coffee has nevertheless been planted in 1901, mostly in conjunction with Para rubber, and cultivation has been well maintained, whilst quality has improved, and complaints on this score have been much less frequent. Reports from Brazil go to show that the coming season's blossoms have to a great extent failed, and there is a widespread belief that 6,000,000 bags will be the limit of the crop actually gathered in Rio and Santos, though the unloading of heavy stocks may to a great extent counteract the hardening effect which such a phenomenally poor crop should exercise upon the market. It is a somewhat debatable point whether the failure of the blossoms in Brazil is to be attributed to the impoverished condition of the trees, consequent upon inadequate cultivation and a succession of abnormally heavy crops, or whether the season has been unpropitious. If the former assumption be correct, then there can be little doubt that a steady and continued improvement may be confidently anticipated, but advices are so conflicting that it would be premature in the extreme at this stage to attempt any reliable forecast.

COCONUTS.—Owing to the ravages of beetle and the cost of keeping the trees clean, Coconuts are not as much planted as their fine growth would lead one to suppose that they would be. Doubt has also been expressed as to whether the soil, except that actually on the sea-board, is suitable. The Selangor Planters' Association Annual Report however states that, on a small holding in the Klang District, trees from 10 to 12 years old have yielded an average return of over 51 nts per tree, although this plantation was opened by Malays and considerably neglected during the first eight years of its existence. Such a return is under the circumstances decidedly satisfactory, and your Committee are of opinion that the cultivation will always be a remunerative one as long as it remains possible to keep the beetles under without incurring a prohibitive expenditure in doing so.

GUTTA REMBONG (FICUS ELASTICA).—The unsuitability of this tree for planting amongst Coffee, to some extent accounts no doubt for the preference shown to Para. Nevertheless when put out on soil which it likes, growth has been very fine, but it has shown itself to be a tree which will not flourish anywhere and everywhere, and for it to make a vigorous start it appears essential that there should be a fairly rich surface humus or lots of ash after a recent burn. On rain-washed and impoverished hill-sides, it silks from the day it is planted, but grows splendidly on practically bottomless peat, if well drained. Mr. Derry of Perak has interested himself more than anyone in this variety of Rubber, and is very sanguine of its eventual success, though he thinks that "perhaps eight years may have to elapse before the tree can be profitably tapped." In Malacca 4-5 years old trees are however being worked by a Chiuaman who professes to be quite satisfied with the results, but his figures of yield and cost are considerably involved and difficult to follow. In Perak two 19 year old trees each yielded 25 lb. in one year, and of these Mr. Derry reports "the tapping was far short of being exhaustive." The value of this rubber is slightly less than para, and the method of collecting differs, in that the latex of the "Ficus" appears to coagulate on the trees, whereas that of Para runs freely, down the cuts made in the bark into tins.

HEVEA BRAZILIENSIS: PARA RUBBER.—With the decline in the price of coffee this product have been largely planted throughout the Federated Malay States, and when kept clean of weeds has everywhere come on in a fashion which clearly indicates that soil and climate agree with it admirably. The wintering habit of the tree, which is almost universal, seems to afford a further proof of this country suiting it. Some experimental tapping of young trees, which has been

undertaken, goes to show that in 4 to 5 years from planting about 6 oz. of dry rubber may be regarded as the average yield of the best grown trees, and some 6 years old trees have yielded over a pound at their first tapping. The coming year will undoubtedly provide many returns of experiments for comparison, but at the present juncture very few Estates have any large number of trees ready for tapping.

INDIAN SALES OF CHEAP TEA BY LOTTERY.

Yercaud, June 20.—It has lately come to my notice that small packets of tea, containing about an ounce, are being sold up here by the Postmaster of Nagalore, for the small sum of three pies each! and he is allowed a commission of 10 per cent. on all he sells—from Messrs. Andrew Yule & Co., Calcutta. On the packet are the words "Indian Tea Markets Extension. The World its Field. Andrew, Yule & Co., Calcutta." Each envelope is marked with a letter and a number, the one with me now is G. 47,744, and it is stated that monthly prizes are awarded to any one holding the envelopes with the numbers drawn as prizes. There is one prize of R50, five of R5 each, ten of R2 each, and fifty-five prizes of R1 each; in all R150 a month is disbursed in prizes, or rather was disbursed in May. This is certainly a very sporting endeavour to push the sale of cheap tea. Those who are in authority, and have the interests of the coffee planting industry at heart, should bestir themselves with their product of coffee, and go and do likewise. —*Madras Mail Cor.*, June 21.

THE DRUMMOND DEANE GREEN TEA PROCESS.

(Extract from a letter to *Indian Gardening and Planting*, June 19.)

From the commencement of the process the Drummond Deane system has the advantage, for it is possible with the machines to treat the green leaf in large quantities at a time, and a whole roll of leaf can be prepared by the work of a single coolie attending the machine and be ready for the next process in two or three minutes. But so rapid is the process of preparing the leaf that most concerns prefer to take Green Tea machines of smaller capacity and find that they are able to keep pace with the rolling machines in working off the leaf as the half hour or so required for rolling gives ample time to pass sufficient leaf through the Green Tea machine to be ready for the next roll. There is also an absolute certainty that all the leaf that is put through the machines

will be thoroughly prepared automatically and brown leaf showing semi-fermentation never disfigures the outturn of a Drummond Deane tea, as too often proves the case with leaf prepared on the old Indian system. I do not say that semi-fermented leaf must occur in the old style Green Teas, but that it requires great care and constant supervision with our inefficient coolie labour to prevent the operation of preparing the leaf on the old system being carelessly performed, and then a certain proportion of the green leaf will escape proper contact with the hot pans on which the leaf is prepared on the old system, and these are bound to ferment later and spoil the true character of the tea. It is not possible to detect any lapse of this sort on the part of the coolie until the tea is made, when the mischief is done.

It is possible, of course, to ensure that the process shall be thoroughly carried out, but this, as every planter and tea-maker knows, means extra supervision and consequent throwing up of cost of production, which, with prices now to be obtained for tea of any description, is not to be incurred if it can be avoided. On the other hand, with the Drummond Deane machine every leaf is equally treated; it is only necessary to open the valves and set the machinery in motion by means of the change wheel and driving belt and the machine automatically does what is required, discharging the leaf thoroughly ready at the end of a minute or two. One man can treat up to three maunds at a time on the limit of sizes that have been found most convenient. It is the old story of machine *versus* hand labour, and it does not take a prophet to tell which must go to the wall. In the rest of the processes in the Drummond Deane system the ordinary black tea machinery is utilised, though of course the processes are greatly modified, and in these modifications the skill of the inventor, Mr Drummond Deane, has been shown. It would be futile to attempt to make Green Tea on the ordinary black tea machinery without the instructions of the inventor, as a good many have found out to their loss, and naturally these special instructions are guarded and only issued to those purchasing the machines. The whole process also compares with great advantage with the old system in point of time, and it is very true in tea as in other things that time is money. In some three to four hours the green leaf should be turned into finished Green Tea, uncoloured. The colouring or finishing process is just as applicable to these new style teas as to the old style, and if Mr Leslie Rogers were here I could show him samples which he would be fain to admit compare well with anything he has seen on the old system. With regard to the question of time taken in manufacture, a notable advance has recently been made by the new Deane-Judge machine, which we are now about to introduce. This new machine performs a supplementary process which much improves the condition of the leaf and very materially shortens the time taken in manufacture, beside making the process entirely automatic.

With regard to the finished product, it is just as feasible with suitable processes to colour and finish Drummond Deane Green Teas to any required appearance, and the only difference they present to the old style Green Teas when so treated is in the absolute purity of their cup and the uniform green colour of their infused leaf, points in which old style Green Teas are apt to be faulty, un-

less a very thorough and consequently expensive supervision has been given. But it is a moot point whether the colouring process is necessary to the advance of these Green Teas; the Japanese are more and more dispensing with the operation which adds nothing to the quality of the tea, and only satisfies a prejudice in point of appearance. Compare the beginning of the Ceylon Green Tea industry; it began about four years ago with a few thousand pounds; in the third year it reached nearly two million pounds; not much, it is true, in the eyes of those who want to rush everything and failing immediate success abandon the attempt, but sufficient to show that we are driving ahead in the same way as we did in the early days of black tea. The great point is that the motion has all been in a forward direction.

With regard to the Afghan market, the North-West planters cannot pretend to make a preserve of it. If their old style Green Tea is so much better, they are so favourably placed that the Bengal planters should not be able to compete with them. It was the special appreciation of the Manabarie teas made on the Drummond Deane system that drew the attention of the Bengal and Surma Valley planters to this Trans-Frontier market and the Association had nothing to do with it. Mr Rogers may be right as to the necessity of colouring the teas to the appearance with which the Afghans are familiar, for the Envoy judged them on the merits of their cup in which the Drummond Deane teas stand pre-eminence. But that circumstance will not prevent these teas making way. We are prepared if necessary to colour them to any shade that the Afghans may prefer, even to painting them all the colours of the rainbow, like Joseph's coat or a German Jubilee design.

THE AGENT,

Drummond Deane Green Tea
Process and Machinery.

Calcutta, 16th June, 1902.

THE TEA MARKETS EXPANSION COMMISSION.

Messrs Andrew Yule and Co, the Commissioners appointed by the Advisory Committee of the Indian Tea Association to extend and expand tea markets in India, have issued their seventh Report. We learn from it that the support accorded them has been steady and progress satisfactory during the three months in question, viz., March, April and May. The Commission, it will be remembered, came into being about the middle of last year, helped with a grant-in-aid of R49,000 from the Indian Tea Association and contributions of tea from planters up to 700,000 lb. The work has been continued on the lines that we have noticed before in these columns, and the reports received of its progress in all directions are encouraging. Of the 372,879 lb of tea, that up to the 31st ultimo had been contributed or purchased, 273,574 lb have been disposed of. The demand for the pipe packets continues satisfactory, no less than 594,734 having been sold. The price of them is the same all over India, viz., one pice each. The total number of cups of brewed tea, which also are sold at one pice each, has risen to 219,244. Pipe packets are now to be procured at 695 extra-departmental post-offices as against 70 on the 28th of February last, and applications for agencies are still coming in. Brewed and dry tea is now on sale to native passengers at 13

stations on the East Indian Railway, on the Oudh and Rohilkhand Railway, and on 17 stations on the East Bengal State Railway. Tea is also supplied on the latter railway by men travelling on the line, to whom the manager has kindly granted free passes. The Indian General and River Steam Navigation Companies have also kindly granted permission for the sale of tea to native passengers on their steamers and have offered to give free passes to the men employed by the Commission for that purpose.

The receipts during the three months to which this Report refers total up to R35,205-3-7, which is a very satisfactory increase; and the balance in hand on the 1st June was R69,879-7-7. The cost of working during these three months has been roughly R13,000, making a total of R30,000 to the end of May. The support accorded to the Commissioner to the same date, exclusive of the Indian Tea Association's Grant-in-aid, amounts to R97,474-10-7 in cash and tea—the average value of the tea supplied being taken as 3 annas 11 pies per lb. The Commissioners, in concluding their Report, which they hope will be considered satisfactory, trust that contributions in future will be made as much as possible in cash instead of tea, on the basis of, say, 4 annas per lb. They claim that the advantages of cash contributions are twofold; *firstly*, the Commission would be enabled to purchase tea of exactly the style required, and in such quantities as to avoid unnecessarily running into stock, and *secondly*, the purchase of tea at public auction would tend to stimulate competition, and thus indirectly return an immediate benefit to the contributors. At the same time the Resolution which was passed at a Meeting of the Advisory Committee of the Commission on Tuesday last, as reported among our telegrams, urging on all Tea Companies, proposing to destroy large quantities of tea in order to prevent a slump in prices, to make it over to the Expansion Commission to supply the growing wants of the new trade in India, is an eminently practical and sensible suggestion. This is in reference to the telegram from London recently received, which stated that at a Meeting of Indian merchants representing tea interests in India to the value of £1,000,000 sterling, which was held there towards the end of last month, those present strongly favoured a proposal to throw away all tea from the 1st to the 15th August, the most prolific month. It was estimated that 10 million lb. of tea would thus be kept off the market.—*Madras Mail*, June 26.

TROPICAL CULTURE.

(From a Correspondent)

The Official "Bulletin Economique" of Indo-China seems only of local interest; but I read that a Tonkin planter is going to plant *Momordica luffa* of which the fibrous sponge has several industrial uses.—One kind grows wild in the lowcountry here; another is cultivated as a vegetable. For the above purpose there is an Egyptian variety, very large, of which the fibrous part of the fruit is sold as vegetable sponge. I think it would be a very paying product for natives to cultivate.

The French Government is going to experiment on the action of phosphates on cultivation, rice particularly, in the different parts of Indo-China. I think that in Ceylon, where the yield of paddy is generally so small, our paternal Government ought to do the same. Better try and double the crop of the land in cultivation, than construct or restore costly tanks to double the area which might be cultivated?

In the February and April numbers of "Société d'Etudes Coloniales" appears a translation from German of a recent work on cacao by Dr.

Paul Preuss.* It is very interesting for cacao planters. There is no mention of "Traduction réservée."

MR. GREEN'S CIRCULAR ON HELOPELTIS.

(To the Editor, local "Times.")

SIR,—May it not be possible that, like the mosquito, *helopeltis* breeds naturally in swampy places and standing water? It certainly hates the sun and lives by suction, and I have noticed that when a field is attacked *helopeltis* appears at the lower end near a stream or standing water first. It might be worth some low-country man's while to investigate for, if this were proved, *helopeltis* might be kept in check by sprinkling kerosene in all wet places, as is being done to eradicate the mosquito. It has always appeared to me that such pests as *helopeltis* and caetdis worm might be kept in check by burying prunings with a sprinkling of lime, or better still basic slag. Burying prunings has checked grey blight on this estate to an enormous extent; many fields which were a mass of blight are now almost free. That *helopeltis* is coming up-country is an undoubted fact. Mr Green mentions Nawalapatiya. I saw signs of *helopeltis* just below Ginegatanne Gap a day or two ago—this is very much higher than Nawalapatiya. I have never seen tea in the Kelani valley so badly attacked by *helopeltis* as it is just now. On one estate the best field was absolutely ruined. I doubt if coolies could have plucked a five lb average. I noticed in some paper the other day that the farmers in South Africa had found treacle and arsenic to be a perfect cure for locusts. Would this be useful for checking white ants which do far more permanent damage than *helopeltis*? Treacle made out of jaggery would be very easy to procure, and very cheap. Each pruner as he finishes pruning a bush might smear a little of the mixture round the stem. This might also keep borer and other pests in check.—Yours, &c.,

D. G. BRENNER.

Kew, Norwood, June 21.

REPLY TO MR. BRENNER'S LETTER.

SIR,—With reference to Mr Brennan's letter, in your issue of the 23rd instant, the breeding habits of the *Helopeltis* insect are well known. The eggs are embedded in the shoots of the tea plant. All members of the family *Capsidae*, to which the *Helopeltis* belongs, have an exsertile horny ovipositor, which indicates a similar habit of oviposition. It is quite out of the question that they could "breed naturally in swampy places and standing water," as suggested by your correspondent. Under these circumstances, the sprinkling of kerosine over the swamps could have no direct effect upon the pest. It may be true that *Helopeltis* is more prevalent in damp places; but such a fact (if fact it is) might be due to many other causes. The insect may prefer a sheltered situation, and swampy spots are usually in hollows. The insect almost certainly prefers trees weakened from any cause and trees growing in damp spots are frequently unhealthy. The supposed fact is, however, open to question. I have been collecting particulars of the work of *Helopeltis* for several years, and have frequently received reports that the attack has been most severe on exposed ridges with poor soil. I have always advocated the burying or destruction of prunings as a means towards the check of all insect pests. The application of treacle and arsenic to the stems of pruned tea bushes—if otherwise practicable—would probably have little effect against white ants, as the syrup would im-

* Paul Preuss I met in Cameroon in 1892. He was already then Director of the Government Botanical Gardens.

mediately attract hordes of the more active true ants, which would speedily remove all traces of the mixture, though thousands would perish in the achievement. The wholesale destruction of these ants would be a distinct misfortune, and would probably result in a marked increase of real pests, upon many of which they prey. Application of an arsenical preparation—such as Arsenite of Copper, or “Green Arsenoid”—*without* the treacle, would be more effective against the attacks of white ants, as it would not attract the attention of other insects.—
E. ERNEST GREEN.

Peradeniya, June 25.

LAGOS FOREST RESERVES AND RUBBER.

In October, attention was drawn in the paper “West Africa” to the fact that indignation was felt in Lagos at the Ordinance introduced into the Legislative Council by the Governor, in September (called the Forest Reserves Ordinance), with the object of protecting the rubber trade, by which it was sought to impose the requirement of a licensee before rubber trees could be tapped or the produce could be sold. It was stated that the natives regarded the proposed legislation as an unjust interference with the rights of the owners of land, and that great dissatisfaction was felt respecting it.

The Section determined to address the Colonial Office on the subject, since, while recognising and sympathising with every endeavour to protect the rubber industry, it felt it necessary to protest against one clause of the Ordinance as likely to cause much unnecessary friction. The following letter was consequently addressed to the Colonial Office:—
“Manchester Chamber of Commerce,” Nov. 23, 1901.

“SIR,—I am desired by the President of this Chamber to address you on the subject of the Lagos Forest Reserves Ordinance, which has been under the consideration of the African Section of the Chamber. The Section is strongly impressed by the necessity of preserving the productive capacity of the rubber plant in the interests alike of the Colony and of British trade with Lagos. It is apprehensive, however, that some parts of the Ordinance, especially Clause No. 1 of Section 5, are very likely to create alarm and irritation in the native mind, since they will almost certainly regard it as an encroachment on the just rights of native landowners. It is believed also that the clause requiring every native selling produce to take out a licensee will prove a source of discontent. I am to suggest that before your assent is accorded to this measure it may be revised with a view to removing all ground for reasonable objection on the part of the natives. I am further respectfully to express the regret of the Section that opportunity was not given, before the publication of the Ordinance in the Colony, to the Home Chamber of Commerce interested in trade with Lagos to consider and report to you upon its terms,—I have, &c.,

“ELIJAH HELM, Secretary.”

“The Right Hon. JOSEPH CHAMBERLAIN, M.P.,
“Colonial Office, London.”

“Colonial Office, Downing Street,
“December 26, 1901.

“SIR,—I am directed by Mr Secretary Chamberlain to acknowledge the receipt of your letter of November 11 on the subject of the Bill recently introduced into the Legislative Council of Lagos to provide for the regulation of the forests in the Colony and Protectorate. 2. Mr Chamberlain is glad to see that the Manchester Chamber of Commerce recognise the necessity of preserving the productive capacity of the rubber plants. It would, in his opinion, be to the advantage of the country as well as in the best interests of trade that the Governor should have power to regulate, not only the collection of rubber, but also the cutting of timber,

as proposed in the Bill introduced into the Legislative Council, but, in view of the objections taken to the manner in which it was proposed that the regulations should be enforced, the Bill will not be proceeded with in its present form. Mr Chamberlain hopes, however, that further discussion will convince the native authorities in the Protectorate of the necessity of taking measures to prevent the forests from being exploited at the expense of the future, and that it will be seen that the effect of regulations such as those proposed would be not to encroach upon the just rights of the landowners and people in the Protectorate, but to protect them against the operations of persons who are only interested in obtaining an immediate profit. 3. I am to add, with reference to the last paragraph of your letter, that the introduction of a Bill into the Legislative Council is the method prescribed by the constitution of Lagos to afford opportunity for the discussion of measures before they are passed into law.—I am, &c., “C. P. LUCAS.”

“The SECRETARY,
Manchester Chamber of Commerce.”—*India Rubber Trades' Journal*, May 26.

COFFEE IN ABYSSINIA.

It is reported in letters received from Harrar that Mohamed Aia Bohra, a leading merchant of Abyssinia, has obtained from the King the monopoly of purchasing coffee in Abyssinia and Harrar. Coffee sells at Harrar at 6 shillings per maund of 36 lb and the monopolist may buy it at half this rate.—*Indian Witness*.

ASSAM TEA GOING OUT OF CULTIVATION.

Read letter dated 4th June, from Messrs. Shaw, Wallace & Co., pointing out, in reference to the “Report on Tea Culture in Assam” for the year 1901, just issued by the Assam Secretariat, the large amount of Tea land which appeared to be going out of cultivation. The method adopted by the Assam Secretariat in compiling the returns was to transfer tea, which had been planted out three years, from the “immature” to the “mature” column. For instance, in 1898, the nett addition to the area under cultivation was shewn at 14,997 acres, but the increase in mature tea in 1901, as shewn by the Report was only 7 234 acres. It would thus appear that 7,733 acres had disappeared from cultivation. Mr McMorran also submitted a digest, which he had prepared from previous reports, shewing similar discrepancies. It was decided to draw the attention of the Assam Administration to the differences, in the figures which had been pointed out.—*I. T. A. Minutes*, June 17.

FORESTRY AND FRUIT-GROWING IN THE ORANGE RIVER COLONY.

Bloemfontein, June 4.—Recent reports from the Government forest nursery which has been laid out near Thaba Nchu show that surprising progress has been made. Over 100,000 seedling trees, mainly eucalyptus and pine, are now ready for transplantation. Experiments have also been made in the cultivation of oak trees, of which eight acres have been planted, and the wattle area under cultivation is being continually extended. The construction of dams and water furrows is proceeding. It is intended to establish plantations generally, and wherever the Government acquires land a portion of it will be preserved for forestry.

Mr G S Scott, the Government fruit expert, will arrive in Bloemfontein next week, after spending a year in Cape Colony inspecting the method of culture adopted on Mr Rhodes' fruit farms at Pearl and the tobacco farm in the Ouitchoorn district. Recently Orange River Colony tobacco has practically replaced that of the Transvaal, although it is being sold under the latter name, and there are prospects that the industry will be most profitable. Mr Scott will later act as itinerant instructor in various districts. Similar arrangements will be made in other branches of agriculture in the future.—*Laffan*.

INDIAN TEA FOR PERSIA: A FAILURE.

The Holtz Company report considerable disappointment in the attempt to exploit the Persian market following on the representations made to the Indian Tea Association last year. The Directors say: A consignment of 10,065 lb was sent to Persia by caravan *via* Seistan. With reference to this, we may mention that we joined with other large proprietors in the valley in equipping a caravan for Persia. We were led to suppose that tea would meet a ready sale in Persia at prices which would give a very much better return than those obtainable in either the Calcutta or London Market. We regret to say that these hopes have not been realised, and we are afraid we shall not get much more than will cover cost of production and transport to Persia. The tea is as yet unsold, but the agent in charge has instructions to sell as quickly as possible, and return. *Indian Gardening and Planting*, June 26.

PLANTING NOTES.

WIRE TRAMWAYS.—An interesting paper on Wire Tramways by Mr. W. R. Shaw, M. E. (Queen's) M. Inst. C. E., Consulting Engineer for Railways, Bombay, is reproduced on page 111 from the *Indian and Eastern Engineer*. We invite the attention of our readers to the article.

SPINELESS LIME TREES.—In 1892 on Shawford estate, Dominica, a lime tree was noticed without the usual formidable spines. Seeds from this apparent 'sport' were collected and sown. Some 75 per cent came true and a plot of spineless limes forms an interesting feature in the Dominica Botanic Garden. The plants in this plot are now bearing heavily and the Curator, Mr Jones, reports that 90 to 96 per cent of the seedlings raised are coming true. The fruit of the spineless variety is slightly below the average in size, and it remains to be seen whether, for estate requirements, the new variety is an improvement or not.—*Agricultural News*, May 24.

LAGOS SILK RUBBER AT TOBAGO.—A plot of the African or Lagos silk rubber (*Funtumia elastica*) was planted at the Botanic Station, Tobago, in April 1901. The Curator reports that the plants have made good growth and flowered for the first time this month. Mr Millen adds that in a young state the plant assumes a shrubby habit, but by pruning it can be made to form a trunk. In Lagos it attains a height of from 90 to 100 feet before branching. This makes it easy for the collector to tap the trunks. The latex flows readily and rubber is easily produced by the hot and cold water process, no chemicals being required as in some rubber-producing trees. From its rapid growth the tree is apparently adapted for cultivation in Tobago.—*Agricultural News*, May 24.

COCONUT PALMS—are growing apace in the Kelani Valley (and so is Rubber); but porcupines are reported to be a terribly troublesome enemy, entailing much expense in watchmen. Do planters know of the Sinhalese trench traps for porcupines? When well baited, they are generally successful and all Sinhalese villagers must know the plan.

A U.S.A. EXPERT ON RICE-GROWING IN THE EAST.—Professor S. A. Knapp, President of the Rice Association and Special Commissioner of the Department of Agriculture, United States, who was sent to Asia and the Pacific Islands to investigate the rice industry and learn what varieties were best adapted for cultivation in that country, recently made a report to the Secretary of Agriculture. Professor Knapp visited Japan, China, the Philippines, Hawaii, Siam, Ceylon, India and Burma. In speaking of his investigations, he said:—

"The United States can profit from the experience of the Oriental countries in the varieties of rice, but nothing can be learned from them in the cultivation of the plant. What the United States needs is the introduction of more early varieties of rice. I do not think the United States has anything to fear from Oriental competition."

TEA IN RUSSIA.—The Dutch Consul at Warsaw has been giving the imports of tea into Russia as follows, we changing his kilogrammes into lbs. :—

Total import, over	...	116,600,000 lb.
Brick tea =	75,680,000	
Black tea =	39,600,000	
Tablets tea =	2,145,000	
Green tea =	672,000	
Yellow tea = (small quantity)	= 118,097,000	

We are not responsible for the discrepancy. The estimate of Brick tea is singularly near that of the Shanghai Tea Committee some years ago, which was 76,949,200 lb.; and Green tea was given (shipped to Batoum) at 631,733 lb.; but the estimate of black tea was much larger or 45,179,066 lb.—a good deal of which may have been for Central Asia and adjacent lands. The grand total of the Shanghai estimate was above 133 millions lb.; and it is more likely that with Ceylon and Indian tea now (and perhaps less China), some 150 millions of lb. of tea must be taken in a year, by Russian merchants or on Russian account, to supply the markets not only of Russia in Europe and Asia, but the adjacent territories which have their tea requirements met through the Russian trade routes. We simply go on the fact that a Tea Sub-Committee of Shanghai Merchants—who must have known what they were about—gave detailed figures showing that in 1896 Russia had taken, by four different routes, 132,567,866 lb. of tea from China. This was apart from Indian and Ceylon tea sent direct or *via* London—so that the total demand was not then much under 140 millions lb. In the past six years in a tea-consuming country like Russia there must be a steady if slow increase in the imports, so that we do not think 150 millions lb. can be an over-estimate of the total requirements, in all kinds of tea, at the present time.

A CALCUTTA INTERVIEW WITH MR.
DRUMMOND DEANE.
HIS OPINION ON CEYLON TEA
AFFAIRS.

While Mr Drummond Deane, the well-known Ceylon and Travancore planter, was in Calcutta last week, a representative of this journal took the opportunity of eliciting his views on tea subjects generally. Mr Deane in reply to questions said :—

"Coming to Ceylon affairs," he said, "do you think it is practicable to amalgamate Indian and Ceylon interests in a joint campaign as has been suggested?"

"Well, I think in the present state of tea they are practically identical. The present sluggishness of Indian tea on the markets is a distinct clog upon Ceylon. The weight of Indian tea on London adversely affects Ceylon prices in the market to which the greatest part of her crop is still sold. So, considering that Indian progress is evidently fated to be slow for some time yet to come, I think it would be wise of Ceylon to come forward and help what some people call her rival out of the ditch, if possible. It is a question from which sentiment should be excluded; the question Ceylon planters have to ask themselves is whether India will not do them more harm by wallowing in that ditch and bringing down tea prices generally than by getting on her legs by drawing off a certain proportion of the good of Ceylon efforts. I am not sure that it would not be sound policy to include Java in a general scheme of mutual help. I certainly advocate a combined movement for India and Ceylon. Of course, in the present state of Indian finances the Ceylon people would be bound to think that we in India were trying to get too much out of them, but if left to herself, so far as I can see, India will cause a greater loss to Ceylon by overloading London, and so bringing down tea prices. And in this last contingency no one at all will profit."

"How are Ceylon men likely to view this?"

"Well, perhaps they are hardly educated up to it, though some of their leaders believe in it. In the Green Tea development alone there have been some very unsound views put forward with regard to India and Ceylon. It was considered as a sort of injury that India should take up this industry which Ceylon had started. Now this is capable of being turned to the real benefit of Ceylon planters. Every pound of Green Tea made in India leaves a chance for another pound of black tea made in Ceylon. The island cannot develop the whole of the Green Tea market in America. Taking it at that alone, there is enough room and to spare for both countries. But Ceylon has not enough of tea lands suitable for the Green Tea development. After producing about 10 million pounds Ceylon would have to stop, while India at a moderate computation has land on which Green Tea cultivation is advisable sufficient to produce four times as much. The qualities of Green Tea in favour have little strength. In Japan the flushes come on so rapidly during the short season that they are only fit to produce a washy sort of tea, the Indian bheel gardens of Cachar and Sylhet

especially are, I am sure, just fitted to produce these qualities, and have the additional advantage that they can be worked at a very cheap rate, and also a practical inducement that, however tea may recover, these gardens with their heavy flushes of watery leaf will never attain high prices for their black teas. Now in Ceylon with any recovery in tea prices brought on, say by increased Green Tea production lightening the black tea market, it will pay Green Tea producer except in a fairly small proportion of acreage to return to black tea. Therefore I consider it would be to the real benefit to Ceylon proprietors to actually induce India to go in for Green Teas as she is more likely to stick to the manufacture and thus make a permanent withdrawal of a percentage of tea from the black tea market."

"You advocate, then, a joint propaganda between India and Ceylon in America in green tea as well as black?"

"Certainly, though India has not much money at present to help, it would be well for Ceylon to let her do as much as she can in the joint effort and to supply the deficiency, including Indian tea in Ceylon advertisements for a contribution as great as circumstances will admit. Even if India gets her Cess she will still be behind Ceylon in the matter of money. This might seem too unselfish a course to follow to most, for selfishness and exclusiveness are rather prevalent; but I believe it is unselfishness that would pay Ceylon in the end."

"Well, Mr Deane, it may come off, but certain people in Ceylon will need a deal of persuasion. What, for instance, do you think of Mr Rosling's remarks on the subject of the Indian Cess, contributed last year to the Colombo press, where he wrote that it was not to Ceylon's interest that India should get her Cess?"

"I think he was so obviously wrong and short-sighted that it is quite sufficient to leave it to the intelligent reader to pick out the fallacy for himself."

"To sum up the present situation, what do you consider we immediately need?"

"At present we can only hope for the Cess to give us a chance to work off our surplus; another thing which would relieve us we are, it seems, not likely to get—reduction in exchange. The present artificially inflated rupee presses hard on those who sell produce from India. With regard to the Cess, we ought to have the sympathy of the Viceroy, because, if I remember right, it was he who, when addressing the Assam planters, impressed upon them the necessity of helping themselves by getting off their tea on new markets, and the Cess movement is nothing but the practical embodiment of the policy he advocated and recommended. The Cess, however, will be a serious responsibility upon those who administer it, and I trust that London will not get a preponderating influence, or there is no saying what things we shall see. Every district in India should be fully represented on the model of the Ceylon Thirty Committee and by men whose chief interest does not lie in tea trading to London particularly but who are devoted to the growing of tea and its disposal in the most judicious manner possible, no matter on what market; a body in fact who can be trusted to take care of the general interests of tea growers without any leaning to any particular trade."—*Indian Gardening and Planting*, June 26,

CEYLON COCOA IN GERMANY.

A HINT FROM MR. RENTON.

Ceylon cocoa growers will feel grateful for the keen interest displayed in their interests by Mr. Renton. Today through the courtesy of Mr. Philip we are enabled to publish a hint which Mr. Renton sends to cocoa growers in Ceylon and which is specially applicable to those who export their produce to Germany. A valued correspondent with considerable knowledge of the subject gives us the following information of interest:—"The washing of cocoa and consequent removal of mucilage is pretty general in Ceylon, though there are, I understand, two or three estates where cocoa is not washed and mucilage is allowed to dry on the bean. I sent a sample of cocoa home some weeks ago, with mucilage dried on. Brokers reported "dark stained skin, good brownish *break*, well fermented and of even colour. The dark stain on skin would prevent its sale on type. Bright fiery skin is preferred, and, if this can be obtained, coupled with 'break' same as sample, a fancy price might be secured." I do not suppose it is possible to get the bright appearance when the slimy mucilage is dried on the bean. Of course, if buyers generally began to realise that the "break" of the dark-skinned beans was always better, the fiery skin would cease to attract. Fiery skin has hitherto, I expect, generally indicated probable good "break." Enclosed are 2 samples: A, washed, B, unwashed. The latter has suffered in the keeping somewhat but not a great deal." (To the unpractised eye at any rate the washed beans look the most attractive.) What Germany wants, it is evident from the above, is not wanted at home. It would be interesting, however, and would save others experimenting, if some of those who export "unwashed" cocoa would give their opinion on the extract sent by Mr. Renton.

COMPRESSED TEA TRADE OF RUSSIA.

According to the Dutch Consul at Warsaw more than 53,000,000 kilograms of tea are annually imported by Russia, of which 34,400,000 kilograms consist of brick tea, 18,000,000 kilograms of black tea, 975,000 kilograms of tablets, and 280,000 kilograms of green tea. A small quantity of yellow tea is also consumed, which, however, is too insignificant to be taken into consideration. Green tea is rarely found in Russian households, and the great majority of Russians have never tasted it.

TEA IN TABLETS.

These tablets are manufactured with tea leaves of inferior quality. They are 130 millimetres long, 40 wide, and 20 thick, and each tablet is divided into eight sections. The tablet weighs $\frac{1}{4}$ lb (Russian) and is enclosed in paper bearing the name of the manufacturer. For packing purposes tin-lined cases, each containing 126 Russian lb, are used. The retail price at Moscow is 1 rouble 10 copecks per Russian lb (about 2.7d per English lb). All the tablets used at Warsaw bear the name of a firm at Hankow.

BRICK TEA.

Brick tea is also manufactured at Hankow. There are two qualities, the first quality measuring 227

millimetres long by 160 wide and 11 thick, and weighing $\frac{1}{2}$ kilog each. Bricks of the second quality measure 287 by 183 by 22 millimetres, with an average weight of 1.160 kilograms.

These bricks are packed in wooden cases, holding from 216 to 240 lb (Russian). The retail price at Warsaw is 70 copecks per Russian lb (about 1s 8d per English lb) for the first quality, and 60 copecks (1s 5d) for the second quality.

NOTE.—Kilog=2.2 lb. Millimetre=.03937 inch.
—*Chamber of Commerce Journal*.

FARMING IN ORANGE RIVER COLONY.

Bloemfontein, June 24.—Among the officials of the Orange River Colony Agricultural Department the opinion is held that it will be of the gravest importance for the success of this agricultural country that the class of intending settlers shall be most carefully selected, preference being given to real working farmers and men with families who can till with their own hands and be independent of outside labour. To such settlers large incomes will undoubtedly accrue. Land for settlement purposes is being acquired each week, and it is expected that farming will quickly become one of the most important industries of the Orange River Colony. Hitherto nine-tenths of the milk produced has been wasted, but now every cow is producing, and half is being turned to account.

With reference to the re-stocking of the colony with cattle, it has been found that more cattle are still in the country than was generally believed. If the supply, however, locally fails, it is thought that the competition between oversea colonies will be so great that prices cannot be exorbitant. On account of the deaths among the young that occur in imported stock the local supplies will be drawn upon as far as possible. At least half the quantity required, about half a million, for re-stocking the Orange River Colony is now in sight. The majority of the farmers will arrive on their farms in time for spring ploughing and sowing, and it seems likely that the country will not take a great time to recover its normal state. A large quantity of tobacco will be planted in all suitable districts in the coming season. Poultry clubs, under the presidency of Major Gould Adams, are being formed in most of the districts, as the importance of poultry for producing a rapid supply of food is realised.—*London Times*, June 28.

TEA OVER-PRODUCTION AND THE LONDON MARKET.—A more feasible and desirable means of meeting the evil of larger supplies of tea being thrown on the London market at times than can secure fair prices, than any yet proposed, is an Indian and Ceylon Financial Combination of producers to enter the market as buyers and holders of tea whenever there is an over-supply. The object is to secure a more even distribution of the tea offering for sale, the purchases being made by the Combination to be re-offered at sales when the supply was less. We are assured on good authority that such a Combination is likely to be matured and got to work ere long.

THE TEA DUTY BEFORE THE HOUSE OF COMMONS.

The sitting of Tuesday, June 10th, was resumed at 9 o'clock. On Clause 2 (Duty on Tea), Mr FLYNN (Cork N) moved an amendment to exempt Ireland from the duty. The duty on tea fell on the poorer country with greater severity than on the richer; indeed, tea and maize formed more than 50 per cent of the expenditure of the poorest families in Ireland. He also claimed that the exemption he asked for would tend to equalise the balance between direct and indirect taxation as regards the sister isle.

The CHANCELLOR of the EXCHEQUER said that his experience in this country was that the poor were more particular about the kind of tea they bought than other people, and probably it was the same in Ireland. (Hear, hear.) He could not assent to the suggestion of the hon. member, and as he was engaged in raising taxation he regretted to say he must oppose the amendment. He did not think that the Budget resolutions had any bearing on the subject of the financial relations between the two countries.

Mr T W RUSSELL said that he did not understand that the question of the financial relations had been raised by the hon. member opposite. So far as he was concerned he was pledged to vote for any money that the Government required for the war. He would personally be glad to vote for the abolition of the tea duty all over the country, but if his hon. friend went to a division he should be compelled to vote against him.

SIR T ESMONDE (Wexford, N.) thought that under the special circumstances the burden on Ireland should be reduced.

COLONEL LOCKWOOD (Essex, Epping) said that though there was no doubt that many on his side of the House had, generally speaking not much sympathy with the views expressed by hon. members from Ireland opposite, they had during the last three or four nights felt considerable sympathy with the poor people in Ireland who would undoubtedly suffer from the incidence of this tax. He thought, however, that the hon. member for North Cork would see that it would be impossible to draw a line of demarcation between England and Ireland in this matter.

The Committee divided, and there voted—

For the amendment	...	69
Against	...	138
Majority against	...	—69

Mr CHANNING proposed an amendment REDUCING THE DUTY ON TEA TO 4D. PER LB. He said that figures furnished to him by one of the ablest co-operators in the country showed that an enormous contribution, as expressed in terms of income-tax, was made by the working classes towards the public revenue in respect of bread-stuffs, tea, sugar and tobacco. One working class budget of 35s a week showed a total indirect contribution *ad valorem* on these four articles of 19d in the pound, expressed as income-tax; in another case the amount was 248d in the pound. He contended that there was a strong case for making a reduction in the tea duty.

The CHANCELLOR of the EXCHEQUER thought there could be no question that, having regard to the expenditure of the year, they must retain the taxes as they stood last year. Taking the whole of the country, he could not see what possible grounds, there were for this amendment. He

passed by what the hon. member said as to the sugar duties, but with regard to the tea duties there had been a very considerable yield in the past year. This was very clear proof that the great bulk of the population continued to indulge in tea even to a greater extent than before. And why? Because, although the tax had increased, the price of tea had fallen. He considered that the proposal of the hon. member to reduce the tea duty was unjustifiable.

Mr E ROBERTSON (Dundee) said the great objection which they had to this kind of tax was that it fell upon a large section of the community who were unable to bear any burden at all.

Mr MCKENNA (Monmouthshire, N.) said he should vote for the reduction of every indirect tax until they had absorbed the surplus of £6,000,000 which the Chancellor of the Exchequer possessed, and the tax on tea should find a first place among the taxes to be reduced.

Mr BROADHURST supported the amendment.

Mr HEMPHILL (Tyrone, N.) said there was no tax which pressed more unfairly upon poor people in Ireland than the tea tax. Tea was becoming one of the first necessities of life among the poorest people in Ireland. Where formerly potatoes and milk were consumed, the fare in many Irish dwellings was now grilled cake, made of Indian corn, supplemented by tea. Equality of taxation meant equality of sacrifice. It was absurd to talk of maintenance of the proportion of direct and indirect taxation. The first duty of every Government was to see that none of the inhabitants of their country were dying of starvation, and if they taxed the first necessities of life this involved more or less starvation, or the workhouse as the alternative of starvation. There was no necessity for this taxation since the announcement of peace. The first duty of the Chancellor of the Exchequer when peace was assured was not to repay the Sinking Fund, but to relieve the poor of these burdens on the necessities of life.

Mr BRYAN ROBERTS (Carnarvonshire, Eifion) could not support the amendment. The tax reached a class which but few of the other taxes reached—the Nonconformist teetotallers. (Laughter.) These gentlemen ought not to escape any of the burden of war taxation. This tax was different from the corn tax inasmuch as it had no taint of protection about it.

Mr G WHITE (Norfolk, N. W.) protested against the tax on behalf of the agricultural labourers. In his opinion an undue burden of taxation had been placed on their shoulders as a result of the war.

Mr CHANNING complained that the Chancellor of the Exchequer had evaded the point established by the trustworthy figures he had given, that the portion of this tax paid by the poorer classes was far in excess of that paid by the wealthier classes.

The CHANCELLOR of the EXCHEQUER would not admit that it was so, but whether it was so or not there was no question that the amount paid to the revenue by indirect taxation was far less than the amount paid by direct taxation. At the present time there was no ground for this reduction.

MR. T P O'CONNOR (Liverpool, Scotland) regarded this duty as one of the worst and most illogical forms of taxation, and especially oppressive to the poorer classes. Accepting the principle that taxation should be spread over all

classes there was still the limitation that the means of bare livelihood should not be touched, a limitation recognised in the income-tax exemptions. Tea ought to be excluded from the operations of the Chancellor of the Exchequer. In the slums of London and in the congested districts of Ireland it was one of the main articles of food. Yet it was not only heavily taxed but the tax was levied unequally, being imposed alike on tea at 3s 6d and tea at 1s 6d per lb.

Mr. LOUGH (Islington, W) said that if the financial position had remained unchanged since the introduction of the Budget he would not have supported the amendment. But he supported it because the Chancellor of the Exchequer, with his surplus of £6,000,000, could easily spare the £2,000,000 which would be taken off the taxation by the acceptance of the amendment.

Mr. J DEWAR (Inverness) said he was unable to support his hon. friend on this occasion, as he thought the Chancellor of the Exchequer was taking up a sound position in refusing to remit this taxation. He opposed the corn tax, but the tea tax was in a very different position. As to the incidence of taxation, he maintained that indirect taxation bore very unfairly on men with small incomes.

Mr. GROES (Salford, S) said the Chancellor of the Exchequer was applying first business principles to the consideration of this question—namely, that one should pay off debts before contracting liabilities, and be just before being generous. (Hear, hear.)

Mr. J A PEASE (Essex, Saffron Walden) supported the amendment, believing that they would be wise if they called upon the agricultural labourers, as well as other classes in the community, to pay by a system of direct rather than by a system of indirect, taxation.

The Committee divided and the votes were—For the amendment 137, Against 229, Majority against—92.

Mr LOUGH moved to insert after the word "sixpence" the word "net." He said that the tea duty was not really sixpence, but sixpence with an addition of $\frac{1}{4}$ per cent to cover the cost of collection. This charge had been abandoned in respect of every other duty, and no reason could be given for its maintenance in regard to tea.

The CHANCELLOR of the EXCHEQUER said that the hon. member had confused two totally different things. There was a small warehousing charge of $\frac{1}{4}$ per cent. on all classes of goods which had continued for the last 40 years without complaint. If the hon. member had any particular grievance in regard to tea, it should be inquired into.

The amendment was by leave withdrawn, and Clause 2 was ordered to stand part of the Bill.—London Times, June 14.

RUBBER IN PERU.

THE DIFFICULTIES OF TRANSPORT,

Vice-Consul Robilliard, in a report from Mollendo (Peru) states that the rubber industry still occupies a good deal of attention, and although the quantity shipped this year only exceeds last year's output by 15 tons, this is accounted for by the fact that large quantities are being prepared in the interior ready to ship when the dry weather sets in—from the beginning of April. A few remarks on the difficulties that attend this industry may

be of interest. From the time of landing here about 15 days will be occupied in travelling by train, steamer, mule, and canoe to get to the rubber districts. The first range of the Andes has to be crossed at 17,500 feet above the level of the sea before the descent into the valleys can be effected. Sorata, in Bolivia, is the place at which nearly all the roads into the rubber and mining districts converge. The traveller will often be delayed for several days, as all the owners of beasts of burden take advantage of the scarcity of the means of transport, and extort the highest possible freights for their animals. Once work has been started, the cheaper plan is to buy mules and horses. All supplies have to be carried in, as scarcely anything can be purchased there. However, stores are gradually being established on the different claims. The descent is very dangerous in some places the incline being from 30 to 45 degrees, and the animals often slip and are thrown over the precipices. This part of the road 23 miles in length, takes 12 hours, when Pararani is reached, 4,600 feet above sea level. From Pararani to Mapiri the road is more practicable, and rubber, Peruvian bark, and coffee plantations are met. Mapiri is the centre of these regions, and from there one strikes off to wherever the claims may be. At least 90 per cent of the travellers fall sick with malarial fevers, more or less intense, although seldom fatal. From Mapiri, Guanay is reached in canoes, or rafts made of nine sticks fastened with vines; three of these rafts formed what is called a callopo, capable of carrying $1\frac{1}{2}$ tons of cargo. The distance is 62 miles and can be done in one day, going down stream, but coming back it takes three days, the current running six miles an hour. The Indians can only pull at the rate of $1\frac{1}{2}$ mile per hour. From Guanay there are roads that lead to the placer mines on the rivers Tipuani, Covahuira, Challana, etc, in which regions gold is found in abundance, but machinery is badly required, especially to dredge the rivers.—*M. Mail*, June 28.

RUBBER IN PORTUGUESE E. AFRICA.

BEIRA.—Exportation of india-rubber shows an increase on previous years, but this is mainly due to the action of the Mozambique Company in employing a large number of natives to tap the country in every possible direction for this particular article of commerce, by which they have no doubt injured this resource for many years to come.—*India-Rubber Journal*, June 9.

DUTCH COLONIES.

The following statistics are taken from the *Indische Mercuur*, of 30th May last:—

THE DUTCH EAST-INDIES.

Area: 735,000 square English Miles. Population: about 29,000,000.

Agricultural Estates: coffee 836, tobacco 410; sugar 254; sugarbitt 141; indigo 176, cinchona 131 tea 112; spices 215; rice 430; cocoa 173; coconuts 289; groundnuts 53; kapok 92; cassava 12; gutta-percha 40; timber 122, coffee hulling-mills 18; rice hulling-mills 53 sundries 61. Mining: grants up to January 1902: 205. Railways: Govt., length about 2,622 miles, private 6,205. Steam-tramways: Govt. 38 miles; private 1809.5. Capital: joint stock, £99,000,000, (besides capital in private commercial and industrial enterprises).

SURINAM.

Area: about 58,000 square Engl. miles; pop: about 68,000. Agricultural estates: cocoa 84, coffee 53, sugar 9; bananas 7), sundries 87. Capital; joint stock £3,000,000, (beside capital in private commercial and industrial enterprises).

WIRE TRAMWAYS: THE KANAN DEVAN, TRAVANCORE.

BY W. R. SHAW, M.E. (QUEEN'S), M. INST. C.E. (Consulting Engineer for Railways, Bombay.)

[The following is from a paper in the "Indian and Eastern Engineer" for June, 1902, accompanied by two pages of (or five) photographs.—ED. T.A.]

There are undoubtedly several places in India where a wire tramway would pay handsomely, and yet there are very few of these useful lines in the country. One reason for this is that capital is not over-plentiful, while labour is wonderfully cheap and the cost of carriage is low. Then, again, there are not many of these lines in England, so the engineer or planter who takes any interest in the subject is obliged to pick up his knowledge labouriously from various foreign technical papers.

Within the last year or two, however, there has been a decided advance in the subject of wire tramways in India. One promising line in Assam is now under consideration. A bold scheme has been outlined to connect Bengal and Thibet by means of a line 40 miles long over the Jalap La Pass, 17,000 feet high, to secure the wool traffic.

The present paper will give some of the main features of an unusually interesting wire tramway in North Travancore, which has been working now with the greatest success for the last eighteen months. The writer is indebted to Mr W. Kem'lo, the engineer who so successfully designed and constructed the line, for most of the following details and for the highly interesting set of photos.

The tramway is designed for the conveyance of stores and produce to and from a large estate in the Travancore Hills. It is divided into two practically equal sections, each over one mile long, and rises about 4,000 feet. When the scheme is complete there will be a branch line from the South Indian Railway to the lower station, and the upper station will be joined up with a 40-mile mono-rail tramway leading to the estate.

The route follows an old cooly track, and there were great difficulties in the setting out of the line on account of the feverish nature of the country in the lower section; in fact the climate was so bad that the home firms who were prepared to supply the materials would not undertake the work of erection, and it was finally decided to design and erect the line locally.

The line is on the running-rope principle. The two sections are geared together and are driven from a central station. The following are the details of the sections:—

	Vertical rise, distance.	
	Horizontal	Vertical
Upper Section	... 1,745	5,700
Lower Section	... 2,187	7,563
Total	... 3,932	13,263
Longest span	.. 427	1,533
Steepest span	... 246	558

Total length along rope 2.62 miles. In the upper section there are eight intermediate standards and twelve in the lower.

Two standards are about ... 40 feet high,
Remainder ... 13 do

THE ROPE.

The rope is $\frac{3}{4}$ inch diameter, best plough steel, hemp core and weighs 1 lb per foot run. It was sent out in eight pieces, each over 3,000 feet long, coiled on a drum. The drums were fitted to a locally-made stand, and the wire was hauled out by block and tackle and spliced on the spot.

THE GRIPS.

The grips on a line of such steep grades require to be very strong. Those in use were locally designed and will be patented. They grip the rope at any point automatically, go up to the top of the section, automatically leave the rope and run unto the shunt rail and are said to be a success in every way. The line is only meant for goods traffic, but if the grips are so reliable there does not seem to be any reason why passengers should not be also carried in specially-designed carriers to hold one or two persons.

POWER.

Water-power is obtained by an 8-inch steel pipe, giving a fall of 720 feet, connected to two Pelton wheels. Each Pelton drives a dynamo capable of giving 40 amperes at 500 volts. This power is transmitted to the centre station, 1,850 yards distant, by two copper wires. The two sections of the tramway are driven together at the centre station by one or both of two motors similar to the dynamos at the power station below. At the centre station the gear is arranged to drive the ropes at one, two or three miles per hour. The rope has been worked at three miles an hour, but at present it is worked at two miles an hour, as this speed is sufficient for the traffic at present. About 20 H.P. is sufficient to drive the line when the loads are uphill.

RESULTS.

The tramway has been working nearly continuously since August 1900 ten hours a day. About 40 carriers are used on the rope and all kinds of goods are carried, the load varying from one to three hundred weights. So far the greater part of the traffic has been up, but the down traffic is steadily increasing as the estates are coming more into bearing. Three round trips can be made in a day, giving eighteen tons of traffic or for a year of 350 days say 6,000 tons. The traffic was formerly carried by some 5,000 ponies, bullocks and donkeys, and it is estimated the line will save at least £1 per ton, or £6,000 a year, so that the line is in every way a success.

NEW INDIAN TEA PATENTS.

The 5th December, 1901—Specifications of the undermentioned inventions have been filed:—

No. 162 of 1901, Andrew Gilmour McMeekin, Tea Planter, of the Allynugger Tea Estate, Shamsheugger, South Sylhet, British India. Improvements in tea-firing machines. (Specification filed 22nd November, 1901).

No. 163 of 1901, Thomas Aubrey Hunt, Engineer and Tea Planter, residing at the Lackatooah Tea Estate, Sylhet, in British India. A marker for keeping the score at the game of "Bridge," to be called the "Simplex Bridge Marker." (Specification filed 22nd November, 1901).

No. 182 of 1901, James Begg, Tea Planter, of Hoolungorie Tea Estate, Assam, in British India. A new or improved machine for artificially withering tea leaf. (Specification filed 22nd November, 1901.—*Indian Engineering*, June 21.

[The figures for Local Sales are compiled from the weekly circular of Messrs. Forbes & Walker, while those for London Sales are from the telegrams received weekly.]

DOES THE MOON INFLUENCE VEGETATION?

In some countries, for example in the tropics, the bright moonlight is supposed to stimulate the growth, and it is believed that wood cut when the moon is waning from the full is apt to rot, perhaps because it has then more sap. M Bassieres, in the "Revue des Cultures Coloniales," from experiments made in Colombia, finds that phases of the moon do not seem to influence vegetation, but he asks for experiments to be made elsewhere in order to settle the question.—*Globe*.

VACCINATION FOR PLAGUE, CHOLERA AND TYPHOID.

A NEW PROCESS.

MM Roux and Besredka have brought a new process of vaccination against plague, cholera, and typhoid before the Académie des Sciences, Paris. Prevented serum injected into the blood of an animal only immunises it for a short time. On the other hand, if microbic bodies are injected, a longer immunisation is obtained but the animal does not feel well. M Besredka has combined these two existing methods by injecting a mixture of serum and microbic matter. The result is a prompt and lasting immunisation without discomfort to the animal.—*Globe*, June 13.

PERSIAN GULF PEARL FISHERY.

The season of the pearl fishery has just commenced in the Gulf, and Koweit people are very busily engaged in sending their boats. Koweit sends about 350 boats annually to the pearl fishery. Bahrein sends about 500 boats. Cassimin Thani of El-Bedaa, on the coast between Koweit and Bahrein, sends about 200 boats. There are besides those sent from Oman and the coast beyond. The pearl fishery commences in the Gulf in June and finishes at the end of September.—*M. Mail*, July 2.

ARTIFICIAL PROPAGATION OF OYSTERS.

Experiments of a somewhat remarkable character have recently been made at the John Hopkins University (U.S.A.) in the artificial propagation of oysters. A single female oyster of average size "lays" about 16,000,000 eggs, while a large specimen will produce from 30,000,000 to 40,000,000 eggs. The eggs are microscopic in size and an ordinary tumbler will hold about 100,000 eggs. Under natural conditions the eggs and milt are simply set free in the water of a river or bay and permitted to take their chances of coming together, which are so small that about one egg in a million is fertilised. The scientific manner is to open an oyster which is ready to spawn, and with the deep part of the shell downwards gently stroke, with an ordinary glass pipette, the upper surface away from the hinges, and should it be a female oyster it will pour out a fluid which will be full of eggs. In a tumbler of sea-water are placed a few drops of this liquid, to which is added a drop or two of this liquid similarly obtained from the male oyster, and fertilisation at once takes place. In about two hours afterwards all the eggs in the tumbler have been hatched, and in a few days' time they are ready to be placed in the water, and to attach themselves to some permanent object.—*Chamber of Commerce Journal* for June.

NEW TEA PATENTS.

ONE FROM MR. JAS. WHYTE, COLOMBO.

"Necessity is the mother of invention." The necessities of the tea growing business seem to be bearing the usual fruit. We have already noticed one or two developments which bid fair to become important, Mr C R Newton's enzymes and the soluble tea devised in Ceylon. The weekly reports of the Patent Office contain several others. Last week's list of patents applied for include a tea-drying and glazing machine, for which Messrs David Reid and John Dale of Baraooora, Sylhet, apply for protection. An improved method and apparatus for manufacturing green tea, patent applied for by Messrs Horace Drummond Deane and Charles George Landseer Judge. Improvements in apparatus for cutting teas sought to be patented by Mr James Whyte of San Sebastian, Colombo, Ceylon.—*Indian Gardening and Planting*, July 3.

INDIAN REDUCTION OF TEA CROP.

The local Committee of the Indian Tea Association have issued the following Circular to all producers of Indian tea:—

"We enclose copy of resolutions which were come to at an influential Meeting of Producers representing over 100 million lb. of Indian Tea, and shall be glad to know if you will join in the movement, and it so, please signify your approval on the annexed sheet, and return to the Secretary of the Indian Tea Association. You will doubtless recognise the importance of an early reply. Although it may be necessary to take the leaf off the bushes during the specified period, the undertaking provides that such leaf shall not be made into Tea from the 1st to 21st August inclusive." Later advices from London state that the London Committee have agreed to allow reduction of black tea crop by the manufacture of Green Tea, thus saving the leaf, if desired by growers. Producers who approve of the resolution for Restriction of Output, and agree to join in the movement on the terms named are asked to declare the amounts of their total estimates of crop for the current season and their outturn from the 1st to 21st August of last year.—*Indian Gardening and Planting*, July 3.

RAISING TOBACCO IN PENNSYLVANIA.

The Pennsylvania Board of Agriculture has decided to experiment in Pennsylvania with the raising of Sumatra and Cuban Havana tobacco under cover, and the eyes of tobacco raisers generally may be said to be turned toward Lancaster county, the scene of the experiment. While the growing of Sumatra tobacco in this country is beyond the experimental stage, as yet the centre of this new enterprise, strictly speaking, is Connecticut, and the recent report to Secretary Wilson of last year's crop in that state has awakened interest. The tobacco raised under the supervision of experts from the Department of Agriculture has been sold at an average price of \$1.25 a pound, and, as the cost was about 25 cents a pound, the profit was \$1 a pound. As the average farmer can raise 1,000 pounds of selected leaf to the acre, the growers all over the state are watching the local experiment. Connecticut will produce this year about \$1,500,000 worth of Sumatra leaf, which is about one-fifth of the annual importation of this particular tobacco. Under cover the leaf has been known to grow to the height of eight

feet. It is believed that the soil on the Pennsylvania tract is as good as, if not better suited, for Sumatra growing than, the Connecticut soil.—*Bradstreet's*, May 31.

CACAO AND RUBBER PLANTING.

SAMOA.—The Samoa Estates, Ltd., has just commenced operations in cacao planting, and great things are expected from it, which bid fair to be realised. Mr Hart, F.L.S., of Trinidad, recommends in his work on cacao the planting of *hevea* rubber trees between the rows as shade plants. Some of the experienced planters here do not favour this, on the ground that the *hevea* rubber tree is not profitable to cultivate, and say that the *castilloa elastica* is better; they also think that the rubber tree should not be planted amongst the cacao. However this may be, it may be regarded as certain that large planting companies should cultivate the *castilloa elastica* rubber tree which, I am informed, thrives here equally as well as cacao, and yields a return in from six to eight years, some say. It is not as subject to disease as the cacao, and could be planted, as experts may recommend, either between the cacao rows or in another part of the plantation. Whether it withstands hurricanes better than cacao, which is a very fragile tree, I cannot say. I strongly advise the companies who intend to carry on planting operations here not to depend solely on cacao, but to plant as well indiarubber trees, with other tropical products suited to the soil. Kola, too, bearing in ten years, should be cultivated by small planters.—*British Acting-Consul in Samoa*.—*British Trade Journal*, June 1.

TOBACCO-GROWING IN SOUTH AFRICA.

The modern smoker has such a wide range of tobacco from which to choose that the final selection of the brand which shall satisfy all his requirements is a matter of no little difficulty. Acting on the advice of various friends, he fits from one species to another, and finds, that so far as tobacco is concerned, there is no wisdom in the multitude of counsellors. Yet, even with the keen competition from oversea, South African—and especially Transvaal—tobaccos have hitherto held their own in public favour. And, now (says the "Cape Times") a new Cape rival has entered the field, and Transvaal growers will have to look to their laurels. It is about three years since Mr C W Leach, who had had wide experience as a tobacco-grower in the Rustenburg district of the Transvaal, first turned his attention to the Queenstown district as a favourable country for tobacco cultivation. He purchased the fine old farm in that district known as Poplar Grove, and there devoted himself to the cultivation of the "weed" on the most modern and scientific principles. The success of his operations has already been proved by the popularity of his tobaccos in the Eastern Province, but hitherto they have not been introduced to any extent in the Western districts, being only known to a fortunate few. Mr A Dowling, who represents Mr Leach, is now in Capetown with a view to introducing the Poplar Grove tobaccos in this city. The farm is now under cultivation to the extent of about 400 acres, on which at present about a million plants are grown. Estimating that each plant produces 3 lb. of tobacco yearly, the output works out at something over 3,000,000 lb. per annum. The consumption of Mr Leach's tobaccos already equals the supply, while the demand is far in excess, and consequently a large extension of the cultivated area is in progress, it being intended to cultivate no less than 3,000,000 plants during the present season.—*Natal Mercury*, May 27.

FRESH-WATER SHELL PEARL-BUTTONS.

During the last eight years the fresh-water shell pearl-button industry has developed in a greater degree than any other branch of button manufacturing. The fresh-water shell pearl-button industry did not exist in 1890, but since then vast quantities of mussel shells, formerly deemed valueless, have been taken from the Mississippi river and made the source of a revenue to the people of the states of Iowa and Illinois. In 1891 this country imported \$100,000 worth of pearl or shell buttons. This sum was added to in 1892, when imports were valued at \$292,332, but the next year, 1893, brought a slight decline, the values for imports for that year amounting to \$275,216. In 1894 there was a remarkable falling-off in taking from oversea, the imports being valued at only \$33,284. But in 1895 the loss of the previous year was entirely regained, imports being worth \$375,886, the largest figures reached during the decade 1891-1900. From 1895 down to 1900 the value of such imports steadily dwindled, until in the latter year they amounted to only \$36,262. In 1900 the output of fresh-water shell pearl-buttons amounted to 4,308,584 gross, valued at \$1,176,285, and the production of ocean pearl-buttons was 4,049,452 gross, valued at \$1,951,558; the respective items representing 20·3 per cent and 19 per cent of the entire button output of the country, which in 1900 amounted to 21,254,018 gross, valued at \$6,467,373. The average price per gross received in 1900 for fresh-water pearl-buttons was 27 cents, as against 48 cents for ocean pearls. Photo and celluloid buttons brought in 1900 an average of 74 cents a gross, while bone and vegetable ivory buttons fetched 46 cents and 43 cents the gross respectively. Here it should be noted that United States Consul-General Jussen, in a report dated December 30, 1887, remarked "the manufacture of pearl buttons is not an industry of the United States and probably never will be." But on April 29th, 1898, Consul-General Hurst, writing apropos of the same subject (our imports of Austrian-made pearl buttons), noted that "the pearl-button industry of Austria-Hungary, which in former years occupied a prominent place among the flourishing industries of the monarchy, has dwindled of late to such an insignificant figure that pearl buttons can no longer be regarded as one of the principal articles of export to the United States. This may be attributed to the development of the industry in the United States." Nevertheless, by 1900 the making of these buttons constituted the second most important branch of the general industry. To Mr J F Boepple, of Muscatine, Iowa, belongs the credit of having started the industry in the United States, which he did in 1891. A few years ago mussel shells were delivered at the factories in Iowa and Illinois at about fifty to sixty cents per one hundred pound, but by February, 1893, prices averaged \$18 to \$20 the ton. In July of the same year, however, they were selling at thirty cents per one hundred pounds. The cheapest grade of ocean shells are the Panama, which sell at ten and half cents per pound.—*Bradstreet's*.

INDIAN GREEN TEA PRICES.

The sale of Indian Green Tea at last Friday's auction deserves special mention. Some 67 chests of uncoloured green tea made on the Drummond Deane process at Manabarie Estate, Doonars, were put up and sold at the following very decent prices: No. 1 or young hyson, 11 chests, 6-3. do, 11 chests. 6-4. No. 2 or hyson No. 1, chests, 5-3. No. 3 or hyson No. 2, 21 chests, 4-6. The above prices for green tea at last Calcutta sale compare very well with the prices realized for the majority of invoices of black teas offering at the same sale, and we are informed that there is no special difficulty for gardens now producing black teas of ordinary description, which

now sell very low owing to the glutted market for such, to make green tea which will sell at better rates than those procurable for common blacks on the depressed market. Most leaf will make decent green tea; there is no fermentation in the process to give different classes of leaf a chance to develop in different ways.—*Indian Gardening & Planting*, July 3.

PLANTING NOTES.

THE RUBBER EXPLOITING COMPANIES.—The work of organisation of the Congo and Sangha Development Co., mentioned in the last *India Rubber World* as having been incorporated in New Jersey to acquire the concession of the Société de la Sangha Equatoriale, in the French Congo, has been in progress during the past month, but as yet no further details have become available for publication. Meanwhile, the promoters of the company have been in receipt of samples of rubber produced by the *concessionaire* company in Africa, which are regarded as the most attractive rubber from that continent ever seen in New York.—*India Rubber World*, June 1.

COMPTOIR COLONIAL FRANCAIS BANKRUPT.—The Comptoir Colonial Francais was adjudged bankrupt by the tribunal de commerce de la Seine, Paris, in a decree dated April 7, 1902. This is a joint stock company constituted in Paris in May, 1899, with 9,000,000 francs capital, for objects of colonisation and commerce, and particularly the exploitation of Caoutchouc. With headquarters in Paris, at rue des Petites Ecuries, 54, the company conducted trading operations at Para and Manaos, Brazil; stations on both sides of the Rio Javy, in Brazil and Peru; at Conakry (French Guinea), and St. Louis (Senegal), West Africa.—*India Rubber World*, June 1.

MOSQUITO-HUNTING—has had marvellous effects in Cuba. Yellow fever and malaria are disappearing, and the "Pearl of the Antilles" is now fit for an Anglo Saxon population. In October, 1900, there were 74 deaths and no cases, Dr Grogas of the United States Army, writes:—"The disappearance of yellow fever is, I think, almost altogether due to the killing of the infected mosquitoes at the infected point. We do this by burning pyrethrum powder in the infected house and all the neighbouring houses. It has been extremely gratifying to see how promptly the focus of infection is stamped out in this way." Sanitation is being carried out energetically in Cuba all round, and in a few years the invasion of the American army into Cuba will have saved more lives than it cost."—*Australian paper*.

TEA AND OUR GUESTS.—We are heartily glad to learn that the suggestion made by the *Ceylon Observer* (June 24th) that a present of tea should be made to each of the Boer prisoners has been taken up by the Ceylon Planters' Association and that that body had, through Messrs. Crosfield, Lampard & Co., presented a 5-lb. box of tea to each of those who sailed by the ss. "Templemore" early this week. As the subject is one which is to be discussed by the "Thirty Committee" in a few days we hope to see the step imitated in every case where the prisoners return direct to South Africa—though as yet the firm who acted in this case have had no further instructions. The writer of the following lament will, or one, be gratified:—

"Sad to read how the first lot of Boers—and the loyalst—got away; and a good advertisement of tea lost. Can nothing be done even now? I shall gladly give my mite, either in kind or in cash to a Fund."

TO THE PLANTING WORLD.

Seeds & Plants of Commercial Products.

Hevea Brasiliensis.—Orders being booked for the coming crop August-September delivery 1902, booking necessary before the end of April, quantities of 100,000 and over at special low rates. Plants available all the year round, 100,000 and over at special low rates. A leading Rubber planter in Sumatra, who purchased 50,000 seeds in 1897, and 100,000 in 1900, writes us, under date 15th November, 1900 :—"I received your letter of 20th October, from which I learn that you added another case of 5,000 seeds to replace the loss, &c. I am satisfied hereby, and even after this adding I am satisfied by the whole delivery of this year." Special offer, post free on application.

Castilleja Elastica.—True superior variety cultivated in Mexico, seeds from specially reserved old untapped trees. Orders booked for August-September delivery 1902, immediate booking necessary; large quantities on special terms; Plants in Wardian cases.

A foreign firm of Planters writes under date 11th October, 1901 :—"We beg to enquire whether you would procure us 100,000 Castilleja seeds, in which month we might expect them, and what would be the average price." Special offer, post free on application.

Manihot Glaziovii.—Seeds and Plants available all the year round, 100,000 and over at special low rates. A Mexican planter in sending an order for this seed wrote on the 22nd August, 1900 :—"If they arrive fresh and germinate easily I may send you larger orders, as they are for high ground where the Castilleja does not thrive."

Ficus Elastica.—Seeds available in May-June; booking necessary before the end of March; also plants.

Mimusops Globosa (Balata) wood of the tree is much sought for buildings, fruits sweet like a plum and eaten, oil from seeds, said to yield as much as 45 lbs. of dry rubber per tree per annum, the milk is drunk and when diluted with water used as cow's milk, grow from sea-level up to 2,000 feet, orders being booked for seeds and plants, price on application.

Cinnamomum Zeylanicum (Cinnamon superior variety).—New crop of seed in April to June; booking necessary before the end of February; also plants.

Coffea Arabica, Liberian Hybrid and Maragogopic Hybrid.—New crop March-April; immediate booking necessary.

A foreign Agricultural Department writes dating 9th September, 1901 :—"Please accept our order for 175 lbs. of Tea seed and for 2,000 Coffee beans. In regard to Coffee seed I would say that this will be the first importation made by this department, and we will leave the selection of the varieties to be sent to your judgment."

OUR DESCRIPTIVE PRICE LISTS.

The following six Descriptive Price Lists are now being forwarded with Circulars and special offer of Seeds and Plants of Rubber and other Economic Products :—

1. Tropical Seeds and Plants of Commercial Products, enlarged edition for 1902.
2. Seeds and Plants of Shade, Timber, Wind-Belts, Fuel, and Ornamental Trees, Trees for Roadsides, Parks, Open Spaces, Pasture Lands, Avenues, Hedges, and for planting among crops (Tea, Coffee, Cacao, Cardamoms, &c.)
3. Seeds and Plants of Tropical Fruit Trees including Mango grafts.
4. Bulbs, Tubers and Yams.
5. Orchids—Ceylon and Indian.
6. Seeds and Plants of Palms, Calamus, Pandanus, Cycads, Tree and other Ferns, Crotons, Roses, Dracinas, Shrubs and Creepers.

Special Arrangements made with foreign Governments, Botanical and Agricultural Departments, Planters and others for supplying seeds and plants of Commercial Products in large quantities.

"SOUTH AFRICA."—The great authority on South African affairs of 25th March, 1899, says :—"An interesting Catalogue reaches us from the East. It is issued by WILLIAM BROTHERS, Tropical Seed Merchants of Henaratgoda, Ceylon, and schedules all the useful and beautiful plants which will thrive in tropical and semi-tropical regions. We fancy Messrs. Williams should do good business, for now that the great Powers have grabbed all the waste places of the earth, they must turn to and prove that they were worth the grabbing. We recommend the great Powers and Concessionaries under them to go to William Brothers."

Agents in London :—MESSRS. P. W. WOOLLEY & Co., 90, Lower Thames Street.

Agent in Colombo, Ceylon :—E. B. CREAMY, Esq.

Agent in British Central Africa :—T. H. LLOYD, Esq., Blantyre.

Telegraphic Address :

WILLIAM, HENARATGODA, CEYLON.
Liber's, A.I. and A.B.C. Codes used.

J. P. WILLIAM & BROTHERS,
Tropical Seed Merchants,
HENARATGODA, CEYLON.

TEA SALES AND AVERAGES.

WE direct attention to the letter of "A Planter" on this subject and especially the attention of the Brokers both here and in London. We fear the labour involved in working out the fuller information desired by our correspondent would be deemed prohibitory of the adoption of the plan. As matters stand, the detailed lists of each sale are open to each reader, showing how many grades are included, and of course no merchant, agent, proprietor, or practical planter is deceived by the high averages reported when only the highest grades have been offered for sale. At the same time no doubt the impression left on the mind of the ordinary reader is an unfair one, by the selection in our local paragraphs, or on the front page of London circulars, of the estates securing the highest averages without specifying the grades included in each case. So far as we are concerned, we must in future confine ourselves to the highest prices obtained for the same grade—thus the highest price for Orange Pekoe at yesterday's sale was 54 cts. for St. John's estate; for Broken Orange Pekoe, Devonford, 78; and for Broken Pekoe, Poonagalla, 56; and so on through all the grades. In this we suppose there will be much less unfairness, although even then comparisons can never be quite equitable; because an estate may pay special attention to a very few grades; while another Manager is bound by orders to do justice to all grades. In fact, only a rough approximation to fairness (by way of comparison) can be attained in any system of quoting prices or averages for our tea sales.

THE PROSPECTS OF "INDIA RUBBER."

Very full and interesting is the information which we this month receive from America, regarding the enormous Rubber industry and its several developments along the great Amazon river and its many affluents through Brazilian, Bolivian and Peruvian territory. We must quote in full in our *Tropical Agriculturist* some very interesting reports as to the different modes of treating forests of *Hevea* (Para) and of *Castilloa Elastica* respectively. But, in the meantime, we may mention that in the back valleys of Peru—near the region reported on by Messrs. A. Sinclair, the late Alex. Ross and P. D. G. Clark—the latter tree is said to grow profusely and "it is invariably cut down as it yields milk from the whole of the trunk; while the *Hevea* is only tapped, as it only yields juice from between the bark and stem." Again here is an astonishing statement in the same report:—"although entire forests of *C. Elastica* (Caucho) have been destroyed, the ground is quickly covered again with the trees from the roots or seeds left in the soil and in six years are fit to be again felled, so rapid is the growth." This fact—if fact it be—coupled

with the accounts of the vast Rubber-growing regions still to be exploited, is not very encouraging to Eastern planters of rubber. On the other hand a botanical authority has pronounced that there are at least three kinds of *Castilloa* and that one of them is valueless, so that grave doubts are expressed if all the *Castilloa* plantations formed in Mexico will prove productive. It is generally considered that *Hevea* is the safer tree to cultivate. Here is another kind of warning from Mexico:—

James Maunder writes from San Juan Evangelista, Vera Cruz, to *The India Rubber Journal* (London): "I know of the disasters which befell some of our people who purchased a going concern—rubber—in this country; there is another concern going to be offered in London pretty soon, but take *Punch's* advice, 'Don't.' There is good wild land here to be had, near rail and river, for from 21 shillings per acre, and lots of money to be made, but the manager should be a man of experience in tropical agriculture."

The very extensive Acre (Rubber) concession granted by Bolivia to an Anglo-American Syndicate is likely to cause trouble with Brazil which is preparing to prevent access to the territory, if necessary, by force.

Finally, we draw the special attention of our Rubber planters to the article we reproduce on our sixth page from the *India Rubber World* of New York, as affording practical information on the difference between Para rubber produced in the Straits Settlements and that got from Brazil. In the editorial remarks, however, we fail to find discouragement to rubber planters, whether in Perak or Ceylon—quite the contrary. We do not think that London Brokers would give so good a price for the "clearly-prepared" Para rubber from the East unless they were well assured of its appreciation by manufacturers.

TEA AND COFFEE IN INDIA IN 1901-2.

AN elaborate review of the Trade of India for 1901-2 by Mr. J. E. O'Connor, C.I.B., Director-General of Statistics to the Government of India, has just come to hand, and we may at once quote the remarks made on our staple. First, as to its importation to the value of Rs. 1,603,936 in 1901-2, we are told:—

The importations of Tea declined to about the level of 1899-1900, the fall indicating a diminished use of Bombay as a depot for the shipment of teas to the regions served from the Persian Gulf and Afghanistan. Moreover, the prices of tea in the Indian market ranged on too low a level last year to offer an inducement for importation on an extensive scale for local consumption. The operations at present in hand for extending the consumption of Indian tea in India should have some effect presently on the importations of China tea.

But on the Export trade the report is naturally much fuller and more varied. Let us first quote some figures:—

	1898-99.	1899-1900.	1900-01	1901-02.
Tea	8,04,48,038	9,09,21,120	9,55,09,301	8,14,94,893
Coffee	1,74,93,242	1,48,47,146	1,22,84,498	1,25,02,200

This is what Mr. O'Connor has to say as to the Cess, improved cultivation and consol-

ation of estates, and it will all be read with interest :—

	lb.	R
	(ooo omitted)	
1897-98	.. 151,452	8,05,86,233
1898-99	.. 157,471	8,04,48,038
1899-1900	.. 175,038	9,09,21,120
1900-01	.. 190,305	9,55,09,301
1901-02	.. 179,685	8,14,94,893

The principal consumers of Indian tea were found in the countries specified below in the last two years (in lb, ooo omitted):

	1900 01	1901-02
United Kingdom 166,171	159,014
Australia 10,439	8,575
Turkey, Asiatic 3,240	2,626
„ European 618	144
Persia 2,429	2,530
Canada 1,725	1,659
China 1,143	1,337
Germany 838	638
Russia 772	1,624

These are direct exports as declared in India and do not include re-exports from the United Kingdom.

For the first time in ten years there was a decline in the quantity exported, but the decline of 11 million pounds was hardly sufficient to do more than arrest the downward trend of prices which tried the industry so severely in 1900. Until towards the end of 1901 that year was as discouraging as the one it followed, and the small recovery which then occurred has hardly been maintained, as regards the superior description, at any rate. The owners of tea estates are still, struggling with the difficulties created by the too rapid extension of production and the consequent fall in prices; nor do they see their way clearly as yet to a sound position, although prospects are not so cheerless as in 1900 and the struggle not so intense. The small contraction of production was consequent on climatic influences in Assam and Cachar in a larger degree than on the action of growers in fine plucking. No special endeavour was made in the year to win new markets for Indian tea, and the exports to foreign countries generally, Russia excepted, did not expand and in most cases were on a restricted scale. The voluntary contributions from estates for the purpose of developing external markets were not as freely and satisfactorily paid as was to be desired, and a proposal was made to the Government to levy a cess in the form of a small tax on each chest of tea exported, as is done in Ceylon, the proceeds to be applied to the cost of opening up external markets. This proposal, in which the owners of about two-thirds of the acreage under tea acquiesced, is still under the consideration of Government. But while the means and methods of securing wider external markets are still under discussion, the practical efforts to find an Indian market for Indian tea have been successfully continued by the firm who undertook the business last year, and it is understood that the results obtained so far are full of promise and encouragement.

The area and yield of tea in India, as far as these have been reported, were as follows in the last two years:

	Area (acres.)		Yield (lb.)	
	1900.	1901.	1900.	1901.
Assam and Cachar... ..	337,327	338,186	141,118,644	134,896,317
Bengal	134,572	135,129	46,533,255	46,203,930
Madras and Travancore... ..	31,309	31,463	5,105,196	5,434,749
Punjab, U. P. of Agra and Oudh, Burma	19,279	19,989	4,703,569	4,695,727
Total...	522,487	524,767	197,460,664	191,230,773

In the competitive conditions with which the tea industry has to contend today, it is certain that the time for empirical cultivation and manufacture has passed, and that rational, that is, scientific, methods must be pursued if Indian tea is to maintain its reputation and be sold at remunerative prices. The cultivation must be based on careful study and selection of soils and fertilisers, the parasites that infest the plant must effectively dealt with, the conditions which result from infrequent and frequent plucking of the leaf must be ascertained by competent observation, and the manufacture must be based upon a scientific study of fermentation. The necessity for scientific teaching in all these respects is recognised by the Indian Tea Association which has taken a useful practical step by the engagement of a skilled chemical adviser who has done excellent work within the opportunities available to him. The opportunities, however, are but limited, and one man cannot be expected to do all that is needed when his operations extend over an area of little less than half a million acres in two large provinces, especially when the means of communication between the estates do not permit of swift movement. To make such teachings really efficient time should be given to the personal instruction of planters. The instruction should be based upon careful and prolonged experiment in an agricultural station, or more than one station, suitably located in the tea districts, and sufficiently manned to admit of the deputation of scientific assistant to stay at an estate for some days, long enough to give the manager detailed lessons on the points on which instruction is needed. Such a station it is intended to establish in Behar for the instruction of indigo planters in the theory and practice of processes of cultivation and manufacture of indigo, sugar, and other crops, and nothing could be better devised to attain the end desired. A station of the kind for tea in Assam, or in the Darjeeling district, or in both, is equally needed, and would have an equally good effect. But no association of tea-owners can provide the funds requisite for such stations, and it is necessary for the State to assist and probably to manage them. If the proposed cess on exported tea is partly applied to defray a proportion of the cost of such a station it would be well expended.

Another matter that now presses for attention is the consolidation of tea estates in order to reduce the cost of direction, agency, and management. The average tea-bearing area of each estate is, in Assam 420 acres, in Bengal 299 acres, and it cannot be denied that three, four, six or more, of such estates might, with advantage, when lying adjacent to each other, be consolidated under one management, with one agency at the port, and one board of directors.

TEA SALES AND AVERAGES.

We direct attention to the letter of "A Planter" on this subject and especially the attention of the Brokers both here and in London. We fear the labour involved in working out the fuller information desired by our correspondent would be deemed prohibitory of the adoption of the plan. As matters stand, the detailed lists of each sale are open to each reader, showing how many grades are included, and of course no merchant, agent, proprietor, or practical planter is deceived by the high averages reported when only the highest grades have been offered for sale. At the same time no doubt the impression left on the mind of the ordinary reader is an unfair one, by the selection in our local paragraphs, or on the front page of London circulars, of the estates securing the highest averages without specifying the grades included in each case. So far as we are concerned, we must in future confine ourselves to the highest prices obtained for the same grade—thus the highest price for Orange Pekoe at yesterday's sale was 54 cts. for St. John's estate; for Broken Orange Pekoe, Devonford, 78; and for Broken Pekoe, Poonagalla, 56; and so on through all the grades. In this we suppose there will be much less unfairness, although even then comparisons can never be quite equitable; because an estate may pay special attention to a very few grades; while another Manager is bound by orders to do justice to all grades. In fact, only a rough approximation to fairness (by way of comparison) can be attained in any system of quoting prices or averages for our tea sales.

THE PROSPECTS OF "INDIA RUBBER."

Very full and interesting is the information which we this month receive from America, regarding the enormous Rubber industry and its several developments along the great Amazon river and its many affluents through Brazilian, Bolivian and Peruvian territory. We must quote in full in our *Tropical Agriculturist* some very interesting reports as to the different modes of treating forests of *Hevea* (Para) and of *Castilloa Elastica* respectively. But, in the meantime, we may mention that in the back valleys of Peru—near the region reported on by Messrs. A. Sinclair, the late Alex. Ross and P. D. G. Clark—the latter tree is said to grow profusely and "it is invariably cut down as it yields milk from the whole of the trunk; while the *Hevea* is only tapped, as it only yields juice from between the bark and stem." Again here is an astonishing statement in the same report:—"although entire forests of *C. Elastica* (Caucho) have been destroyed, the ground is quickly covered again with the trees from the roots or seeds left in the soil and in six years are fit to be again felled, so rapid is the growth." This fact—if fact it be—coupled

with the accounts of the vast Rubber-growing regions still to be exploited, is not very encouraging to Eastern planters of rubber. On the other hand a botanical authority has pronounced that there are at least three kinds of *Castilloa* and that one of them is valueless, so that grave doubts are expressed if all the *Castilloa* plantations formed in Mexico will prove productive. It is generally considered that *Hevea* is the safer tree to cultivate. Here is another kind of warning from Mexico:—

James Maunder writes from San Juan Evangelista, Vera Cruz, to *The India Rubber Journal* (London): "I know of the disasters which befell some of our people who purchased a going concern—rubber—in this country; there is another concern going to be offered in London pretty soon, but take *Punch's* advice, 'Don't.' There is good wild land here to be had, near rail and river, for from 21 shillings per acre, and lots of money to be made, but the manager should be a man of experience in tropical agriculture."

The very extensive Acre (Rubber) concession granted by Bolivia to an Anglo-American Syndicate is likely to cause trouble with Brazil which is preparing to prevent access to the territory, if necessary, by force.

Finally, we draw the special attention of our Rubber planters to the article we reproduce on our sixth page from the *India Rubber World* of New York, as affording practical information on the difference between Para rubber produced in the Straits Settlements and that got from Brazil. In the editorial remarks, however, we fail to find discouragement to rubber planters, whether in Perak or Ceylon—quite the contrary. We do not think that London Brokers would give so good a price for the "clear.y-prepared" Para rubber from the East unless they were well assured of its appreciation by manufacturers.

TEA AND COFFEE IN INDIA IN 1901-2.

AN elaborate review of the Trade of India for 1901-2 by Mr. J. E. O'Connor, C.I.E., Director-General of Statistics to the Government of India, has just come to hand, and we may at once quote the remarks made on our staple. First, as to its importation to the value of Rs. 1,603,956 in 1901-2, we are told:—

The importations of Tea declined to about the level of 1899-1900, the fall indicating a diminished use of Bombay as a depot for the shipment of teas to the regions served from the Persian Gulf and Afghanistan. Moreover, the prices of tea in the Indian market ranged on too low a level last year to offer an inducement for importation on an extensive scale for local consumption. The operations at present in hand for extending the consumption of Indian tea in India should have some effect presently on the importations of China tea.

But on the Export trade the report is naturally much fuller and more varied. Let us first quote some figures:—

	1898-99.	1899-1900.	1900 01	1901-02.
Tea	8,04,48,038	9,09,21,120	9,55,09,301	8,14,91,893
Coffee	1,74,98,242	1,48,47,146	1,22,84,498	1,25,02,200

This is what Mr. O'Connor has to say as to the Cess, improved cultivation and consolid-

ation of estates, and it will all be read with interest :—

	lb.	R
	(ooo omitted)	
1897-98	.. 151,452	8,05,86,233
1898-99	... 157,471	8,04,48,038
1899-1900	.. 175,038	9,09,21,120
1900-01	... 190,305	9,55,09,301
1901-02	... 179,685	8,14,94,893

The principal consumers of Indian tea were found in the countries specified below in the last two years (in lb, ooo omitted):

	1900 01	1901-02
United Kingdom 166,171	159,014
Australia 10,439	8,575
Turkey, Asiatic 3,240	2,626
„ European 618	144
Persia 2,420	2,530
Canada 1,725	1,659
China 1,143	1,337
Germany 838	638
Russia 772	1,624

These are direct exports as declared in India and do not include re-exports from the United Kingdom.

For the first time in ten years there was a decline in the quantity exported, but the decline of 11 million pounds was hardly sufficient to do more than arrest the downward trend of prices which tried the industry so severely in 1900. Until towards the end of 1901 that year was as discouraging as the one it followed, and the small recovery which then occurred has hardly been maintained, as regards the superior description, at any rate. The owners of tea estates are still, struggling with the difficulties created by the too rapid extension of production and the consequent fall in prices; nor do they see their way clearly as yet to a sound position, although prospects are not so cheerless as in 1900 and the struggle not so intense. The small contraction of production was consequent on climatic influences in Assam and Cachar in a larger degree than on the action of growers in fine plucking. No special endeavour was made in the year to win new markets for Indian tea, and the exports to foreign countries generally, Russia excepted, did not expand and in most cases were on a restricted scale. The voluntary contributions from estates for the purpose of developing external markets were not as freely and satisfactorily paid as was to be desired, and a proposal was made to the Government to levy a cess in the form of a small tax on each chest of tea exported, as is done in Ceylon, the proceeds to be applied to the cost of opening up external markets. This proposal, in which the owners of about two-thirds of the acreage under tea acquiesced, is still under the consideration of Government. But while the means and methods of securing wider external markets are still under discussion, the practical efforts to find an Indian market for Indian tea have been successfully continued by the firm who undertook the business last year, and it is understood that the results obtained so far are full of promise and encouragement.

The area and yield of tea in India, as far as these have been reported, were as follows in the last two years:

	Area (acres.)		Yield (lb.)	
	1900.	1901.	1900.	1901.
Assam and Cachar...	337,327	338,186	141,118,644	134,896,317
Bengal ...	134,572	135,129	46,533,255	46,203,930
Madras and Travancore...	31,309	31,463	5,105,196	5,434,749
Punjab, U. P. of Agra and Oudh, Burma ..	19,279	19,989	4,703,569	4,695,727
Total...	522,487	524,767	197,460,664	191,230,773

In the competitive conditions with which the tea industry has to contend today, it is certain that the time for empirical cultivation and manufacture has passed, and that rational, that is, scientific, methods must be pursued if Indian tea is to maintain its reputation and be sold at remunerative prices. The cultivation must be based on careful study and selection of soils and fertilisers, the parasites that infest the plant must be effectively dealt with, the conditions which result from infrequent and frequent plucking of the leaf must be ascertained by competent observation, and the manufacture must be based upon a scientific study of fermentation. The necessity for scientific teaching in all these respects is recognised by the Indian Tea Association which has taken a useful practical step by the engagement of a skilled chemical adviser who has done excellent work within the opportunities available to him. The opportunities, however, are but limited, and one man cannot be expected to do all that is needed when his operations extend over an area of little less than half a million acres in two large provinces, especially when the means of communication between the estates do not permit of swift movement. To make such teachings really efficient time should be given to the personal instruction of planters. The instruction should be based upon careful and prolonged experiment in an agricultural station, or more than one station, suitably located in the tea districts, and sufficiently manned to admit of the deputation of scientific assistant to stay at an estate for some days, long enough to give the manager detailed lessons on the points on which instruction is needed. Such a station it is intended to establish in Behar for the instruction of indigo planters in the theory and practice of processes of cultivation and manufacture of indigo, sugar, and other crops, and nothing could be better devised to attain the end desired. A station of the kind for tea in Assam, or in the Darjeeling district, or in both, is equally needed, and would have an equally good effect. But no association of tea-owners can provide the funds requisite for such stations, and it is necessary for the State to assist and probably to manage them. If the proposed cess on exported tea is partly applied to defray a proportion of the cost of such a station it would be well expended.

Another matter that now presses for attention is the consolidation of tea estates in order to reduce the cost of direction, agency, and management. The average tea-bearing area of each estate is, in Assam 420 acres, in Bengal 299 acres, and it cannot be denied that three, four, six or more, of such estates might, with advantage, when lying adjacent to each other, be consolidated under one management, with one agency at the port, and one board of directors.

Finally, we quote what is said about our old staple, though of no account in our Ceylon trade now:—

COFFEE.—The exports have been:

	cwt.	R
1898-99	... 270,056	1,74,98,242
1899-1900	... 281,353	1,48,47,146
1900-01	... 246,431	1,22,84,498
1901-02	.. 255,042	1,25,02,200

There was a small recovery in the exports, but the quantity was still much below the level of former years, and it cannot be said that the trade is progressive. The quality of Indian coffee is good, so good that it is appreciated by Arabs and Turks, but the world's markets are dominated by the great abundance of the supply of the cheaper kinds from Brazil which gives three-fourths of the production of the world, and last year's exports from that country were so excessive that prices fell to a lower point than ever. Indian coffee remains depressed in price even when the available supply is restricted either by an unfavourable season or by the ravages of disease. It is difficult, however, to ascertain with accuracy the area, yield, or condition, of the coffee estates of Southern India, the planters being averse, for some unstated and un conjecturable reason, to communicate statistical information relating to the industry. The menace of differential treatment of Indian coffee in France (to which a full third of it is exported) by applying to it the duties leviable under the general tariff while Brazilian coffee is charged at special minimum rates, has not yet taken effect. The *modus vivendi* under which the minimum tariff is provisionally applied to Indian coffee has been prolonged from time to time and will continue for a few months longer.

“IS TEA INTOXICATING.?”

A NEW ZEALAND EXPERT AND THE “CEYLON OBSERVER.

Mr A H S Lucas, tea expert, referring to our published quotation from the *Ceylon Observer* under the heading, “Is Tea Intoxicating?” writes:—As this query affects the whole community, tea being a national beverage, I should like you to give a few facts that have come under my notice during the last fifteen years' experience as one of a number of tea-tasters. Dr D H Lord states that more poison can be obtained from an equal quantity of tea than from beer, and yet, after perhaps some hundred years of continuous tea-drinking, the nations of the earth do not trace any bad effects to its use. Marvellous, but true, and one would think that the house on the corner had the doctor's full sympathy; not but that alcohol has its full merits, when used with discretion. I might say that most nations have their harmless national beverage, and, without fear of contradiction, I state that tea is the one most used. For instance, the Chinese and Russians drink China tea; the Britishers, colonials and Americans consume Ceylon and Indian teas; the Japanese take Java and China teas; in Mauritius they make tea from the leaves of an orchid; in Peru they drink Mate, a tea made of a species of holly; the Abyssinians make a tea with the leaves of “*Catha edulis*,” which has strong stimulating properties; last, but not least, the Fijians are now growing their own teas, the plants being imported from India and Ceylon. At an

average of fifty cups tasted daily, 39,125 grains of theine are swallowed annually by tea experts—a quantity sufficient to kill 7,825 rabbits.—*New Zealand Mail*, June 11.

TEA CULTIVATION IN INDIA:— ABANDONMENTS vs. EXTENSIONS. THE EXPERIENCE OF THE PREMIER INDIAN TEA COMPANY.

From the London *Times* of June 17th we take the following interesting report of the proceedings at the annual meeting of the Assam Company. The Chairman's speech is worth noting as typical of the feeling prevalent among the Directors of large Indian Companies. It will be seen that “extensions” were called for, “abandonments” hinted at, and plans for discontinuance of plucking or destroying crop—over which so much time and talent have been wasted—were scouted:—

The annual general meeting was held yesterday, June 16th, at the offices, Laurence Pountney-hill. Mr. J Graham, K C., presided, and, in moving the adoption of the report, said that the directors were very glad to be able to present a more favourable statement than that which they submitted a year ago. Owing to the great fall in the value of tea, and to the difficulties in the way of the trade, the result of the company's working in the previous year was that there was nothing to divide, but for the year under review they were able to pay a dividend of 7½ per cent., which, he thought, would be considered satisfactory in the present condition of the tea trade. He hoped in another year that they might do better, but at present the trade was in a transitive state. In the opinion of some it was just about reaching the lowest point, but others thought that an amendment was taking place. The tea produced in the past season had been excellent, but prices remained very low indeed, and there did not seem any immediate prospect of an advance. This was owing to the immense over-production in the past, and at the present time stocks were very large. Probably the area of cultivation would be decreased. In the past year 10,000,000 lb. of tea less were produced. Many persons had thought that it would be a panacea for all the ills of the trade if the production of Ceylon and Indian teas could be reduced by 10,000,000 lb., but although that had been done, there did not appear to be any material market improvement. There was, however, no saying how much reduction might go on in the future owing to low prices, and the smaller the quantity of tea produced the greater the chance for those who had it to sell. In the past year the company produced about 3,500,000 lb. or 900,000 lb. less than in the previous year, when, however, the tea was of very poor quality indeed. The actual price obtained by them for their tea last year was about 8d a pound only, whereas in the year under review they obtained within a fraction of 2d a pound more. This improvement and the great reduction which had been effected in the expenses in India had resulted in their making a net profit of about £16,000. The decrease in the expenses had been very large—about £2,25,000, or about £14,000, and the saving had been effected without in any way impairing the efficiency of the work, which had gone on as well as ever. Their estimated production for the

current year was about 4,000,000 lb.* and the directors hoped that prices would certainly not go down. At present, however, all these estimates were uncertain, and the shareholders must take them for what they were worth. All the indications pointed to a more favourable state of things than had lately prevailed. Mr. Albert B Fisher (deputy chairman) seconded the motion. Mr. Fergusson congratulated the directors on the improved results shown in the past year. Mr. Reed stated that, judging from the returns, some of the company's gardens must have been working at a dead loss, although it was gratifying to see the satisfactory working of the Towkok garden. In view of the condition of the old gardens he strongly advised the necessity of extensions. Mr. McMichen thought that the cost of working each garden might be given; and he drew attention to certain expenses which he thought might be reduced. Mr. Seton also thought there was room for further economies. He advocated the abandonment of unremunerative areas of cultivation or reducing the expenditure on them to the lowest possible limit. Mr. Bullock stated there was a proposal on foot to meet the great over-production by stopping plucking from the end of July for three weeks, and he desired to know if the company intended to join in this movement. The chairman, in reply, stated that they were not willing to agree to the measure referred to by Mr. Bullock; it would not suit the company to do so at present. The position would be different if the factors in all cases were the same, but the directors' view was that all these combinations fell through. With reference to the amount of the medical charges, there were about 14,000 coolies,* besides children, to look after. Nearly all the vacancies in the different gardens had been filled up. The company had about 20 gardens, only two of which did not pay their expenses last year, although the deficiency in both cases was very small—£350 and £29. Several portions of gardens which were not remunerative had been abandoned; and for the last 15 or 20 years, indeed, the course had been followed of shutting old gardens and opening new ones. The motion was adopted.

PARA AND RAMBONG RUBBER IN THE STRAITS.

VISITED BY CEYLON PLANTERS.

In commenting on the annual report of the Negri Sembilan Planters' Association for 1901, just issued, the *Straits Times* says:—"Para-Rubber appears likely to be the salvation of the coffee planter. On most estates it will be found planted through the coffee to which it appears to do very little damage. Recently two well-known Ceylon planters, who are largely interested in Para cultivation in that island, visited the State. They seemed to be very pleased with the prospects of Para there and fancied that the trees there, when compared with those of a like age in Ceylon, showed freer growth. At present, so far as is known, the rubber is of a superior quality, but tapping appears difficult in the case of young trees. The report urges that Government should, with advantage to itself, advertise

* The Company must have about 11,000 acres in bearing, thus giving about 360 lb average per acre and about 1 1/3rd cooly per acre.—ED. T.A.

at home, say, the grant of free blocks of land for this cultivation with a view to attracting new blood and capital into the State."

PROPOSAL TO PROHIBIT THE SALE OF TEA DUST.

The tea industry is in a very critical position. If the season is favourable for growth it probably means bad times for several concerns; if the season turns out to be a bad one for yield, we shall no doubt exist another year, but we have the same "bugbear," over-production, staring us in the face at the end of it. The idea of not plucking from 1st August to 21st August will not commend itself to any planter. Moreover, I hardly think it would be carried out. No doubt if it were loyally done, it would be an excellent thing.

I beg to make a suggestion. The scheme is to prohibit the sale of tea dust, say, for three years. Assuming four per cent of dust is made it would reduce the total crop quite eight per cent, because 1 lb. of dust makes about 120 cups of tea, whereas 1 lb. of pekoe souchong makes about 60 cups.

A great deal of dust is brought by natives in the bazaars, and if they could not get it they would buy twice the weight of pekoe souchong or other cheap teas.

The dust need not be thrown away; it could be sold at nearly an anna per lb. for making Caffeine, etc., and packed in bags or other old boxes without lead.

It costs quite one rupee and four annas per maund to pack dust in leaded chests. This would be saved so that the loss to producers would roughly be, say:—

1 maund of dust worth	12	8	0
		Rs. As. P.			
Less packing charges saved	...	1	4	0	
Less received for dust sold as tea waste	...	4	0	0	5 4 0
					Rs. 7 4 0

per maund of crop or a little less than 1 1/2 anna per lb.

In any scheme for abandoning acreage, not pruning or not plucking certain areas, or throwing away a percentage of crop, a garden would lose income on so much crop, at the average price realised for the remainder of the crop.

Say for instance it was determined to temporarily abandon eight per cent of the area of yielding tea. Take the case of a 1,000-acre garden making seven maunds per acre and getting a five-annas average.

A garden making seven maunds per acre and an average of five annas per lb. would abandon 80 acres at seven maunds equals 560 maunds tea at five annas per lb. and lose an income of ...	14,000	0	0
By the scheme I suggest eight per cent of the reduction would equal 280 maunds dust, i.e., four per cent on a crop of 7,000 maunds at a loss of 1 1/2 anna per lb. ...	2,100	0	0
Amount of income saved	Rs. 11,900	0	0

Although the quantity of the crop is practically reduced by the same amount of tea.

In America if teas contain dust the customs won't pass them I believe. Perhaps our customs might do the same for us; that is, if the Agents and Tea Brokers could not prevent dust being mixed in and sold.—*Englishman (Cor.)*, June 30.

THE NEW "PARA RUBBER" FROM THE EAST: CEYLON'S HIGH PRICES.

At a recent auction sale in London six cases of fine rubber from Ceylon, the product of cultivated trees from Para seed, brought 3s 4 1/2d, or about 31 4 cents, whereas the highest price for real Para rubber reported during the week was only 3s 0 1/2d per

pound. This is not the first instance of exceptionally high prices obtained in the London market for "Para rubber" from plantations in the East. The declining profits of coffee growing have forced the planters in that part of the world to seek some more remunerative planting, and already thousands of acres are covered with rubber trees under cultivation. Not unnaturally attention has been turned chiefly to Para rubber, on account of the universally higher price which it commands, and now that the first trees planted are becoming productive the result of the sale of every little lot exported seems to the planters to confirm their choice. There is no computing how much planting of Para rubber since 1900 has been due to the sale of 327 pounds, sent from Perak to London in that year, at 3s 10d.

It is not impossible that these planters may yet be disappointed, for the reason that it remains to be seen whether what they are producing is really "Para rubber." The tendency in nature is for all species to be influenced by a change of habitat. It appears, for example, that trees of the genus *Hevea*—the source of Para rubber—when grown in the East, become productive at an earlier age than in the Amazon valley; again, it is stated that, while in the Amazon forests the seed pods of the *Hevea* uniformly contain three seeds, the number is irregular on the trees in the Malay States, and there are other indications of a tendency to "sport." It is possible that, under cultivation, the tree might in time develop different characteristics even in Brazil, where thus far it has existed only under natural forest conditions. Ultimately new species of *Hevea* may exist, as a result of change of soil and climate, and of transfer from forests to plantations.

We have already expressed our opinion of samples of the cultivated rubber from the Malay States, which, while attractive in appearance, do not really resemble the fine Para rubber now in use. It is much softer than the Brazilian product, and of much shorter "fibre." It could not be used, for example, in thread, elastic bands, or any fine pure gum goods. In solution it quickly loses its tenacity, so that it would not do for high grade cements. And it readily softens with age. Perhaps some of these defects might be removed by the introduction in the East of the methods of coagulation employed in the Amazon rubber camps, but we are disposed to believe that the Eastern planters have really produced a new grade of rubber, and that the Para article can never be wholly duplicated by them. It is to be understood, of course, that the rubber is valuable and will find a ready market at a price which is likely to yield a profit, but such samples as have reached us, valued from the manufacturer's standpoint, would rank at least 25 per cent below fine Para.

The good prices realised in London, doubtless, have been due to the cleanly appearance of the new rubber; and they have been based on the judgment of brokers, rather than results of practical tests in the factory. It would seem that the better course for the planters' associations would be, not to try to find how much money can be obtained in the open markets for their sample lots—which then become lost to sight—but to send them direct to a well-equipped factory, to be made up in various forms of goods. The manufacturers' test is the one by which the value of this rubber will be judged finally, regardless of what may be the judgment of brokers today. We do not mean to damp the enthusiasm of the planters, but there

is such a thing as basing their plans upon estimates of profits that are impossible.—*India Rubber World*, June 1.

INDIAN TEA PATENTS.

Specification in respect of the undermentioned invention has been filed, under the provisions of the Inventions and Designs Act of 1888, in the office of the Secretary appointed under that Act:—No 179 of 1901.—Frank Edmund Winsland and George Ernest Moore, Engineers, both of Joyhing tea estate, North Lakhimpur, Upper Assam, India. Improvements in apparatus suitable for packing tea. (Specification filed 30th November 1901.)

Application in respect of the undermentioned invention has been filed, under the provisions of the Inventions and Designs Act of 1888, in the office of the Secretary appointed under that Act:—No. 20 of 1902.—William Martin Glynn, tea planter, at present residing at the Adelphi hotel, Calcutta, British India. A new or improved process for equalising tea leaf, and apparatus therefor.—*Indian Engineering*, June 28.

INDIAN TEA ASSOCIATION.

THE RESTRICTION AND EXPANSION RESOLUTION.

Calcutta, July 1.—Read copy of Minutes of a Meeting of the Advisory Committee of the Indian Tea Markets Expansion Commission held on 24th June, forwarded for information by Messrs Andrew Yule & Co. At this meeting the following Resolution had been adopted:—

"That with reference to the recent suggestion from London that growers should stop manufacture of their crop from 1st to 21st August inclusive, so that the anticipated over-production may not cause a slump in prices this Committee after reading the report of the Indian Tea Markets Expansion Commission now before them, are more than ever convinced that the relief for the Industry in the matter of over-production can be found in India, and they strongly urge Proprietors, Managing Agents, and every one connected with the Tea Industry to contribute the Tea it is proposed to destroy to the Indian Tea Markets Expansion Commission, so that no portion of India need be left untapped in the matter of pushing sales of tea."

The Commissioner (Messrs Andrew Yule & Co.) had been requested to forward a copy of the Resolution to the General Committee of the Indian Tea Association and to urge that the matter should be laid before the Indian Tea Association, London, and also before the signatories to the suggested restriction scheme. Further consideration of the matter in a modified form was postponed until receipt of a reply from London as to the exact position in regard to the restriction scheme.

ADVERTISING IN AMERICA.

A short discussion then took place regarding the effect on the American trade of the stoppage of advertising of Indian Tea. From all accounts it appeared that while the demand for Indian Tea in the United States had fallen off in a marked degree, Ceylon teas which were advertised freely, were steadily increasing in favor. It was recognised that the whole question turned upon the want of funds to advertise freely and continuously. Spasmodic efforts for advertising on a small scale were of little avail, and matters, it seemed likely, would go from bad to worse unless ample funds were forthcoming to enable a vigorous campaign to be opened. Relief could only be looked for from the sanctioning by Govern-

ment of the Tea Cess Scheme, and, as the area supporting the proposal now amounted to about 80 per cent of the total acreage under tea, it was decided to again invite the attention of the Government of India to the memorial submitted in March last.—*I. T. A. Minutes.*

TEA EXPERIMENTS IN THE PHILIPPINES.

An experiment in tea culture is being made by Mr. T. H. Donaldson-Sim at Benguet in the Philippines.—*Overland China Mail*, June 30.

CEYLON PATENT.

A list of fourteen patents is given in the *Gazette* as having been granted under the Inventions Ordinance during the half-year ended 30th June last. Of these no less than six are of immediate interest to us in Ceylon, and they have been granted to the following:—

698.—Montague Kelway Bamber, of the Laboratory, Hyde Park Corner, Colombo, Ceylon, Agricultural Chemist, and John Roger, of 6, Coningsby road, Finsbury Park, London.—An improved method of filtering and the separation of suspended solids from a fluid.—February 4th, 1902.

699.—Montague Kelway Bamber, of the Laboratory, Hyde Park Corner, Colombo, Ceylon, and John Roger, of 6, Coningsby Road, Finsbury Park, London.—Improvements in producing a pure and soluble extract of tea.—February 6th, 1902.

712.—James Begg, of Hoolangone Tea Estate, Assam, British India.—A New and Improved Machine for artificially withering tea leaf.—February 22nd, 1902.

286 of 1896.—Alfred Brown.—Invention for improvements in machinery for rolling tea leaf.—Extended for a further term of 14 years.—February 27th, 1902.

725.—Alfred Baur, of Colombo.—Disintegrating fish and other articles.—April 5th, 1902.

719.—John Thomas Mitchener, of 33 T, Juniper Street, Shadwell, London, England, and William Stanning Ross, of 10, Church Court, Wapping, London, England.—Improvements in chests for tea and other substances.—May 13th, 1902.

THE PINE-APPLE AS A DIGESTIVE AID.

The partaking of a slice of pine-apple after a meal is quite in accordance with physiological indications, since though it may not be generally known, fresh pine apple juice contains a remarkably active digestive principle similar to pepsin. This principle has been termed "bromelin," and so powerful is its action upon proteids that it will digest as much as 1,000 times its weight within a few hours. Its digestive activity varies in accordance with the kind of proteid to which it is subjected. Fibrin disappears entirely after a time. With the coagulated albumin of eggs the digestive process is slow, while with the albumin of meat its action seems first to produce a pulpy gelatinous mass which, however, completely dissolves after a short time. When a slice of fresh pine-apple is placed upon a raw beef-steak the surface of the steak becomes gradually gelatinous owing to the digestive action of the enzyme of the juice. Of course it is well-known that digestive agents exist also in other fruits, but when it is considered that an average sized pine-apple will yield nearly two pints of juice it will be seen that the digestive action of the whole it must be enormous. The activity of this peculiar digestive agent is destroyed in the cooked pine-apple, but unless the pine-apple is preserved by eat there is no reason why the tinned fruit should not retain the digestive power. The active digestive principle may be obtained from the juice by dissolving a large quantity of common salt in it, when a

precipitate is obtained possessing the remarkable digestive powers just described. Unlike pepsin, the digestive principle of the pine-apple will operate in an acid, neutral, or even alkaline medium, according to the kind of proteid to which it is presented. It may therefore be assumed that the pine-apple enzyme would not only aid the work of digestion in the stomach but would continue that action in the intestinal tract. Pine-apple, it may be added, contains much indigestible matter of the nature of woody fibre, but it is quite possible that the decidedly digestive properties of the juice compensate for this fact.—*Lancet.*

NEW CEYLON COMPANIES.

The following are registered in the *Investors' Guardian* of June 21:—

CEYLON AND INDIAN TEA CO., LTD., (74,001).—Registered June 10, with capital £5,000, in £1 shares (2,000 pref) to carry on the business of refreshment room proprietors, caterers and contractors, tea, coffee and cocoa dealers, bakers, confectioners, milk and butter sellers, dairymen, tobacconists, wine and spirit and beer merchants, ice merchants, etc. No initial public issue. Registered without articles of association by Dunn and Duncan, 87, Chancery Lane, W.C.

HENRY JENKINS, LTD., (74,043).—Registered June 13, with capital £10,000, in £5 shares, to acquire properties in Ceylon or elsewhere and any plant, machinery, stock in trade, book debts and other assessments connected therewith, to carry on the business of tea, sugar, cocoa, cinchona and coffee planters, manufacturers of and dealers in vegetable products, etc., and to adopt an agreement with Henry Jenkins. Minimum cash subscription £1,000. The number of directors is not to be less than 3 nor more than 5; the first are E G Hill, H Jenkins and W H Short; qualification £100; remuneration £100 per annum, dividend. Registered by Tilleards 10, Gracechurch St., E.C.

COCONUT PLANTATIONS IN THE MALAY STATES.

DEPREDACTIONS BY RATS AND BEETLES.

In his annual report for the year 1901, on the Federated Malay States, just published, the Resident General, Mr. W H Trencher, C.M.G., says:—Coconut plantations are said to have a bright future and the yield of fruit from palms on the alluvial flats is very large. Rats are proving almost as damaging to coconuts as to padi, and I regret to say that the hopes held out in my last report that Dr. Hamilton Wright would be able to cope with the rat plague by a system of inoculation have not been fulfilled. Beetles, likewise, are most destructive to coconuts. The provisions of the existing "Coconut Trees Preservation Enactment" must be more energetically enforced and if necessary strengthened.

BROOKE, BOND, AND CO., LTD.

THE ANNUAL MEETING.

The ordinary general meeting was held at Winchester-house yesterday. Mr. Hector M. Forbes presided, and moved the adoption of the report and the payment of the dividend and bonus therein recommended. He observed that the company had existed for ten years, and during that time had earned a net profit of £344,476, distributed to the shareholders in dividends and bonuses £176,126, built up a reserve fund, including premium on new shares, of £140,000, wiped out £100,000 goodwill, accumulated a provident

fund of £2,500, established an insurance and contingency fund of £5,000, and written down machinery, fittings, &c., at 15 per cent. per annum. A considerable amount of the reserve fund was in gilt-edged securities. The output had grown immensely during the ten years, but the percentage of net profits had decreased. The grocery trade had not been in the most satisfactory position during the past year. Competition was severe and continuous, and it was only by rigid economy, prudence, and forethought that a cash business could prosper. Notwithstanding the depressed trade of the country and the keen competition, the board came before the shareholders with a record balance-sheet. They proposed to pay a dividend of 15 per cent. and a bonus of $2\frac{1}{2}$ per cent. per annum, to transfer to the provident fund £500, to put £13,000 to reserve, to allocate £441 to insurance and contingency fund, and to carry forward £2,241. It was his wish, as the second largest shareholder, to persevere in increasing the reserve fund until it amounted to £150,000 (the total amount of the capital of the company), invested in gilt-edged securities. For the past three years the trade had been agitated by the problem of increased duty. He thought that the company's grocer customers might safely dismiss from their minds all fears that any Chancellor of the Exchequer would again increase the duty on tea, and the conviction of the board was that the present Chancellor or his successors would bring that duty down to 4d., the amount at which it stood before the first war Budget was introduced. Tea was a necessity of life to the great majority of the toiling millions of the British Empire, and the consumption per head was steadily growing. The Indian and Ceylon tea-growing industries were suffering from the increased taxation. It seemed unreasonable that tea should pay an impost of nearly £6,000,000 upon a value of £7,500,000. In Indian and Ceylon producing circles there were rumours of combinations and restricted output, but the board believed that these were doomed to failure. Mr. A. Richardson seconded the motion, which was adopted.—*London Times*, June 21.

PLANTING NOTES.

QUEENSLAND SUGAR PLANTATION: SOLD AT £5 AN ACRE.—Brisbane, June 19.—The Fairleigh sugar plantation at Mackay has been sold to a syndicate, representing Maryborough and Bundaberg investors, at a price variously stated from £40,000 to £45,000. The estate comprises 9,000 acres. It has nearly twenty miles of tramways and a mill capable of making ten thousand tons of sugar per annum.—*Australian paper*.

THE GREAT WESTERN TEA ESTATE COMPANY.—All concerned in the Great Western Tea Estate Company of Ceylon are to be congratulated on the rosy tale which Mr. J. C. Dunbar, the Chairman, was able to tell at the annual general meeting. A dividend of 11 per cent was declared, a result which in the present state of the industry must be considered remarkable. R74,283.75 were available for distribution. A sum of R6,833.70 was set aside for depreciation; R7,500 was placed to reserve account and a balance of R2,543.75 and the remaining R64,240 is absorbed by the dividend. The Chairman's remarks make interesting, and to the shareholders in the Company, delectable reading.

GREEN TEA-MAKERS—should note the account of the Drummond Deane process, given by "The Agent" and quoted in our daily and *T. A.*

CEYLON TREES AND FLOWERING PLANTS.—We have to acknowledge receipt of a copy of a descriptive catalogue of the more useful trees and flowering plants of the Western and Sabaragamuwa Provinces by Mr. F. Lewis, F.L.S., of the Forest Department. It has been reprinted, at the Government Printing Office, from the Asiatic Society's Journal.

A COLLECTION OF DWARF TREES IMPORTED FROM JAPAN—by Messrs Barr and Sons—is exhibited at the Royal Botanic Society's Gardens, Regent's-park. Several of them are of great age, a fine 'thuja obtusa' being stated to be a century old, and all have been carefully trained with that skill and patience which the Japanese bring to bear on this novel form of arboriculture. There was quite a forest of pigmy trees. These trees can be successfully kept in health, despite the vagaries of our climate, with very little trouble.—*L. and C. Express*, June 20.

PRICKLY HEAT.—This, in some cases, is a troublesome affection during the hot season. The writer has found the following treatment effective, especially in the early stages. First, moisten the parts affected with water, then dust over with a small quantity of white oxide of zinc and rub gently with wet fingers until it forms a paste. This will soon dry and leave the appearance of a white wash. Repeat night and morning until the itching and red appearance have entirely disappeared. Sometimes the ointment of white oxide of zinc is used, but this is greasy and disagreeable. Where there is a general tendency to prickly heat, immediately after the morning bath dust over with powder composed of one-third parts of each of the following, viz: white oxide of zinc, boric or boracic acid in powder and starch powder well shaken together.—*Agricultural News*, June 7.

"MUIR" TEA COMPANY REPORTS.—The report of the Amalgamated Tea Estates Company, Ltd., for the year ending 30th November, which appears in our daily and *T. A.* is fairly satisfactory. The crop gathered from the Company's estates was some 180,917 lb. in excess of the previous year; but the prices obtained fell 63d per lb. This is attributed to the general "low range of values for Darjeeling tea in the London market." The Managing Agents and the London Agents have renounced the emoluments due to them which has somewhat relieved the revenue account. Dividend at the rate of 5 per cent per annum is paid on the first 6 months of the year; but in the latter half they have had to content themselves with re-invigorating the Reserve account by £5,000 and carrying forward to next year £8,002 15s 3d. The Consolidated Tea and Lands Company, Ltd., whose report we published also had a considerable shortage of crop having plucked finer and secured a rise in their prices of 4d per lb. Notwithstanding they were unable to pay a dividend, but placed £41,634 0s 7d to Reserve, and a sum of £2,055 9s 5d to the preliminary expenses account. The report, however, predicts good times to come.

Correspondence.

To the Editor.

CEYLON MEN IN SOUTH AFRICA:— LANTANA AND ITS PEST.

Heidelberg, Transvaal, May 31.

DEAR SIR,—I have had the enclosed cutting in my pocket for many weeks, intending to send it to Ceylon (my old home). You will see that at the Cape they are very much afraid that the lantana "hedges" may be destroyed by the scale insect. Perhaps this same insect might be of some use to you in Ceylon.—The only thing is, will it enjoy the tea more than the lantana? Experiments might be made by some specialist:—

Growers of coleus plants and gardeners generally may recollect articles which appeared in the *Agricultural Journal* and the public press during the year 1893, calling attention to the discovery of the scale insect pest, known as the *Orthezia insignis*, in the suburbs of Cape Town. It was hoped that through the active measures then taken, the outbreak had been nipped in the bud, more especially as an inspection of the various floral establishments in town had failed to reveal the presence of the pest. Unfortunately this hope has not been realised, and the insect has now again made its appearance in a Lantana hedge near the Camp Ground, Rondebosch, and in several similar hedges on an old estate in Mowbray, and it is probable that it has already become widespread. Much of the young growth of the Lantana is killed by the *Orthezia*, and the wood and remaining foliage becomes discoloured by a soot-like fungus that grows on an exudation from the insect, entirely spoiling the appearance of the hedge. *Orthezia insignis* is particularly partial to the lantana, but is also frequently found on other garden plants, such as verbena, lavender, fuschias, etc., and is death to the coleus. With a view to prevent, as far as possible, the spread of the pest, the public are recommended not to plant hedges of lantana, and are urged to take active measures for checking the spread of the scale by rooting up and destroying a hedge as soon as the appearance of the scale insect therein is noticed.

We are expecting peace daily, but in the meantime our search-light plays around here every night as usual.—Yours truly,

H. BAYLEY.

[Tea has enough to fight with; and lantana near Peradeniya and Campola has been freely destroyed to prevent the scale insect pest spreading.—ED. T.A.]

THE NEW MANURE.

London, E.C., June 13th, 1902.

SIR,—I enclose a copy of a reprint of my paper in the "Bath and West of England Journal," and on page 14 you will see an account of the experiments with radishes dressed respectively with ordinary superphosphate and with the new manure, basic super.—Yours truly,

JOHN HUGHES.

[We quote as follows:—

The manure has been sold during the last season in 187 places in England, 72 in Scotland, and 13 in Ireland. Many of the deliveries were in quantities of ten to thirty tons, so that the actual trials must have been more numerous even than these figures suggest. Notwithstanding the late application of the manure, due to the short time during which it has been on the

market and also to the very dry season, the reports received have been generally satisfactory and most encouraging. The first experiment made public was conducted by Mr. William E. Bear, of Hailsham, Sussex, and though only on a small scale deserves to be noticed on account of the care with which the comparative trials were carried out, and because the soil had previously been fully analysed by Dr. Dyer, whose results add very much to the value of the experiment. It is unfortunate that such soil analyses are too often omitted in manurial experiments.

DR. DYER'S ANALYSES OF THE SOIL IN WHICH THE RADISHES WERE GROWING.

Mr. Bear, who has kindly allowed the analyses to be used for the purpose of this paper, in a communication in the *Agricultural Gazette* of July 15th, 1901, headed "An Experiment with Basic Superphosphates," over the letters W E B, wrote as follows:—

"Soil from a field somewhat deficient in lime was placed in two 4½-inch flower pots, and in one ½ oz of basic superphosphate was placed, while an equal quantity of ordinary superphosphate (30 per cent soluble phosphate guaranteed) was put in the other. On June 8th, thirteen seeds of French breakfast radish were sown in each pot. Nine grew in the basic pot, and seven in the other. From the first the radishes in the basic pot grew away from the others; and, on being pulled and washed, seven (taken as they came out of the basic pot) weighed 2½ oz, tops included, while the seven out of the other pot weighed only 1½ oz. In each case the scale (a letter-weighter) plumped down well, so that there may have been an eighth of an ounce more of each. However, seven of the radishes grown with basic superphosphate weighed 66 per cent more than an equal number grown with ordinary superphosphate in the same kind of soil, although the soil and manure of the basic pot had to support two more plants than those of the other pot." The proportions of manure employed in the above experiments calculated per acre are certainly much more than would be applied in ordinary farming, but as the same quantities of the two manures were used in each case it is evident that basic super was the more suitable manure for the soil. The important point to notice in connection with these results is that the soil represents exactly the description of land upon which the new manure is most likely to produce an improved yield, for it contains considerably less than 1 per cent of lime, the figures being 0633 in the surface and 0216 in the sub-soil.

—ED. T.A.]

GREVILLEAS (THEIR VALUE AS TIMBER)
AND WHAT THEY ARE SUFFERING
FROM.

Maskeliya, June 16.

(To the Editor, "Tropical Agriculturist.")

SIR,—I enclose copy of a letter I wrote to Mr. Carruthers about the Grevillea tree which may or may not be of use to you.—Yours faithfully,

R. MACLURE.

(Copy.)

Maskeliya, June 9, 1902.

DEAR MR. CARRUTHERS,—I am sending one of my young Grevillea trees with the symptoms (rustiness of the foliage) which are so common amongst them here. I shall be glad to know if this tree has any canker or fungus, or whether you think it is merely a case of uncongenial surroundings. I have isolated pronounced cases of canker among my older trees. There is no mistaking them. I suppose it is better, when they are very far gone, to uproot these trees to prevent the spread of the canker. You said you came to our meeting the other day to get information. I am afraid you did not get much, but I will try and give you all the information, such as it is, I possess about the tree. A good many men think it is not worth growing, or taking any steps to combat disease. On some places, in this district and elsewhere, the growth is certainly poor, but even in such cases I think a good deal can be done by cultivation. Here they have been a source of great profit to the estate. I have sawn up over 30,000 feet of planking out of the older trees, and hope to saw at least 20,000 feet more in the next two years. The planking makes excellent withering tats, and, if planed and polished, the wood makes beautiful furniture. I reckon a Grevillea tree at 15 years old is worth R3'40 in ordinary soil, less in poorer soil, and much more in richer soil, such as they have in some parts of Dimbula. I arrive at this valuation as follows:—

Value of planking which a tree of 15 years will give, 60 feet at R8 per 100 feet, advertised price	R4'80
Less cost of sawing at R4 per 100 feet outside rate	R2'40
	<hr/>
	R2'40
Value of balance of tree as firewood, $\frac{1}{2}$ cubic yard at R2 per cubic yard	R1'00
	<hr/>
	R3'40

There is then the value of the Grevillea tree:

1. For timber and firewood.
2. To improve the soil it takes from the sub-soil and adds to the surface soil by the deposit of leaves.
3. This deposit not only adds to the soil but prevents wash and the growth of weeds.
4. As a windbelt in exposed places.
5. To diversify the cultivation. We were told, when leaf disease attacked and ruined our coffee, that—in planting it up, as we did, in one unbroken sheet, with no trees or belts of timber interspersed,—we transgressed the laws of nature, and suffered in consequence. We were careful to avoid this mistake when planting Tea.

My idea is that, although canker is certainly prevalent, and perhaps increasing, with the great majority of the trees with this "shuck" appearance, it is simply a case of the "survival of the

fittest." The tea, as it is getting older, is taking more from the soil at the expense of the Grevilleas. In some places the latter are far too thick, a judicious thinning out of the weaker trees would improve matters. Where a Grevillea tree is being crowded out by the tea growing too close for its comfort, I would not hesitate to sacrifice the tea. A tea bush is worth at the outside 4 cents. Then a little application of cattle manure or artificial manure, or even silt from the drains, forked in, would help the trees.

I do not know whether all this will be of any value to you; it does not bear much on disease, but my idea was more to try and demonstrate that Grevilleas are worth some care and attention and not to be despised.—Yours very truly, &c.

R. MACLURE.

"THE ALLEYN SYSTEM OF
PLUCKING."

July 1.

SIR,—“Old Harry”'s letter does not call for an answer on my part, for your footnote is already quite a sufficient refutation of his somewhat confused ideas. Yet at the same time I cannot refrain from protesting against his insinuation that a saving of thirty per cent in cost of plucking, as compared with neighbouring estates, is explainable by a casual reference to superior management or to over-manuring.

The first statement is decidedly uncalled-for and is, I consider, in the worst possible taste. It reflects not only on the planters of this district, but also on the general planting community, and would imply that, unless a superintendent can pluck at the Merria Cotta rates, he is incompetent to manage an estate. For on a property of average size the difference in the majority of cases varies from R3,000 to R6,000 on the year's working; and if by better management it is possible to show a saving such as this, the sooner a change in the superintendence is made the better for all concerned.

It might surely have occurred even to “Old Harry” that such a theory as the above is much more difficult to credit than the simple and actual explanation, viz., that the system of plucking advertised is “per se” novel, and a great improvement on existing methods. As regards the second statement, that the results obtained are due to over-manuring, it may be mentioned that a considerable proportion of Merria Cotta has not so far been treated. Further it is worthy of notice that some of the neighbouring estates in the district spend over 6½ cents per lb. of made tea in cultivation. Yet the cost of their plucking varies from 8½ to 9½ cents or more. Our actual increased expenditure on artificial manure for the past two seasons averages under R13 per acre per annum, excluding cost of experimental work.

That such experimental work will prove itself not only of benefit to our Company, but also of advantage to the tea industry in general, I have no hesitation in affirming. Later on, when certain arrangements are completed, your readers will have full opportunity to judge of the truth of this statement.

Again, if your unusually low cost of plucking is capable of such a simple explanation as your correspondent would have one believe, it is to say the least of it remarkable that the system should be in such general demand by the leading firms in Colombo and by the majority of the most experienced and practical planters in the island.

Those who have the best opportunity to judge of the value of our results—that is to say the agents of the estate, Messrs. Geo. Steuart & Co., and Mr. Joseph Fraser, who visits the property—have been among the foremost to accord me a full measure of support. Further proof of the utility of the methods advocated, if such were needed, is to be found in the fact that estates aggregating over 75,000 acres in tea have already applied for particulars of my “system of plucking.”—I am, sir, etc,

HENRY M. ALLEYN.

TEA SALES—LOCAL AND LONDON—
AND THE “AVERAGES”
AS REPORTED.

July 1.

DEAR SIR,—In looking over last week's Sale list and your paragraph showing the highest averages secured in the previous week's local sale, I notice that some estates' tea averages were mentioned, that I am rather inclined to think should not have been, for the following reasons:—I see (omitting names) *A.* was mentioned with 36 cts. average for four grades sold; *B.* was mentioned with 45 cts. average with three grades; *C.*, 41 cts. with three grades; *D.*, 41 cts. with two grades; *E.*, not mentioned with five grades and 40 cts. I think you will agree with me on consideration of this point that it would be well in future to start something quite new with regard to mentioning estates' averages weekly, *i.e.* to mention the Estate Name, No. of Grades in the Tea Sale, and the Average Price of the Invoice sold calculated on the number of grades in, which would then be seen at a glance by the public. It would not as now lead to the conclusion often jumped at that such or such an estate has a good average without looking into the matter to see whether that estate or this has more grades or less than the other; which is not quite as it should be in my opinion. I should, therefore, be pleased if you could see your way to effect this alteration in future from this week forward, as I think it would be a capital arrangement and quite fair to all: which in my humble opinion is not the case with the London announcements.

It would be well if London Brokers could have this matter suggested to them by the local press. Often an estate is criticised on the fact that they are not on the “line” of prices in averages, because on the one hand an estate sends all grades, whereas another estate sends its best grades for sale and is mentioned as having secured such fine prices. This report is a misleading account of the true state of the average for that estate, properly speaking, and other estates should

be mentioned that are not, for the reasons stated. The Superintendents again are often questioned as to why they cannot secure such fine prices as so and so. I think you will readily see the force of my arguments, that all should share on their true merits and not calculations based on artificial averages.—I am, Dear Sir, yours truly,

A PLANTER.

[We made a reference back in connection with the foregoing letter, and “Planter” writes further:—

“The inclination is to crack up an estate or its Manager, because his estate is on the “line” of averages, whereas that same estate might sell only its best grades in order to be mentioned and its worst grades under an assumed name or another time. Many estates sell what is termed, I believe, regular sampling breaks with everything in, and if their average was weighed on its merits, in all probability would be found a much better criterion as to what an estate, only selling its upper grades, is accomplishing. To put the matter in a nutshell, the present system is misleading in the majority of cases and therefore serves no good purpose in my humble opinion; but merely shows up at a glance those on the board, while you constantly hear so-and-so is on the gallery this week, whereas probably someone else should have been there instead. Many do not take the trouble in these hurried days to look through the number of grades and therefore jump at the conclusion that as such or such an estate is on the board, it is necessarily the best sale. The inside often reveals otherwise. If the mentioning of estate averages is not conducted on sound principles, do not you agree with me that it would be best to discontinue the mentioning of any estate on the outside leaf of either London or local sales? The Press or the Brokers, I feel sure, only wish to play fair to all and not to a select few,—which is not transacting business in the impartial way—which the press have the character of doing. I hope you agree with my view, for I feel rather strongly on the matter—not for myself, but I have so frequently heard estates and its Managers criticised on the merit of being mentioned, with perhaps three grades in, and another with double the number, or say two more, a half-penny less in average, passed over.”

—ED. T.A.]

OVERPRODUCTION AND MANURES.

July 7th.

SIR,—It seems to me absurd and irrational to advocate at this time of day—as a correspondent to your contemporary does—the exclusion from the island of so-called “forcing manures.” How are they to be defined as contrasted with the sustaining manures which are to be admitted *free*? I suppose rotten fish, castor cake and bones are *forcing* as well as *sustaining* manures; but they are simply indispensable to the maintenance of our industry. I doubt if there is any manure imported that “Science,” as represented by Mr. Kelway Bamber, would condemn as injurious to the tea bush.—Yours truly,

PROPRIETOR NO. 2,

CEYLON LANDS SUITABLE FOR
GREEN TEA.

Cochin, July 8.

SIR,—With reference to your comments on my remarks when interviewed by *Indian Gardening and Planting*, in yours of 2nd July, by my saying Ceylon had no very large amount of land suitable for green teas I intended to imply that it was probable that with the increase in price of high-grown teas, resulting from export of say 10 millions green tea in that country, and perhaps a larger quantity for India, only low-elevation gardens would continue green tea manufacture. By suitable lands, therefore, I mean land at low elevations in forcing climate where the flushes are very heavy and rapid and quantity rather than quality is of necessity the result.—I am, Sir, yours faithfully,

H. DRUMMOND DEANE.

CEYLON COCOA AND ITS WANT
OF AROMA.

Kandy, July 14.

SIR,—The annexed memorandum regarding Ceylon cocoa is sent for publication as of interest to cocoa growers and others.—I am, Sir, yours faithfully,

A. PHILIP.

Secretary, Ceylon Planters' Association.

CEYLON COCOA

is objected to by manufacturers in Germany on account of its want of aroma. One manufacturer told me some time ago he feared we washed it before drying and thus all the mucilage on the pod was taken off. He now advises me he has induced a Java firm to give up the washing of the bean both before and after fermentation. It is dried in the pod and he maintains that the first consignment treated in this manner gives a quality vastly superior to any sent hitherto from Java. He recommends the Ceylon planter to give up all and every washing of the bean.

(Signed) J. H. RENTON.

GREEN TEAS AND ——— GREEN TEAS

The Watte, July 15.

DEAR SIR,—Is it, or is it not, a fact that medium and high-grown Ceylon "green teas," if treated according to the Japanese plan, —which does not impair the purity of the tea, —will fetch a price far above that got for common green teas?—Truly yours,

WILLING TO LEARN.

[We think our answer may be in the affirmative, judging by the prices already got for the greens manufactured at Ambe-watte Mills. But then it is not open to the ordinary planter to import an expert, or to get a hold of the secret at present monopolised in Ceylon in the aforesaid mills, whereas ordinary greens by Mr. Drummond Deane's method can be made with little trouble in any ordinary factory. This is how we understand the matter at present.—ED. T.A.]

GREAT WESTERN TEA COMPANY.

REPORT OF THE DIRECTORS.

The Directors submit their annual Report and Accounts for the season ending March 31st, 1902.

The yield of Tea has been 440,978 lb being an increase of 12,468 lb on last season's crop: the price realised on 406,485 lb for which account sales have been received at 46'91 cents per lb., against 48'91 cents last season and 48'96 cents in 1899-1900; but telegraphic advices show that the balance of the crop has sold at a net average of 8'61 pence, making the average for the whole crop about 47'37 cents, which in view of the lower range of prices is satisfactory.

The cost F O B Colombo is 29'05 cents per lb. (including 3'80 cents for manning) against 31'71 cents (including 4'77 cents for manning) last season.

The amount available for distribution, after setting aside R6,833 70 for depreciation, is R 74,283'75
out of which the Directors recommend the payment of a dividend of 11 per cent absorbing 64,240 00
To place to Reserve Account a sum of 7,500 00
And to carry forward the balance of 2,543'75

R74,283'75

The result of the year's working is better than that of the previous season in spite of a lower market, while the general condition of the Estate is at the present time still further improved, and the Directors wish to record their appreciation of the good work done by the Superintendent.

The Estimated Crop for the current season is 430,000 lb to cost R128 689'38 being at the rate of 29'92 cents per lb. tea inclusive of 3'10 cents for manning, and this the Directors consider a safe Estimate.

The acreage of the Estate is:—

A.	R.	P.	
921	2	12	Tea in bearing.
39	0	0	Fuel Clearing.
38	2	4	Ravines.
17	1	12	Grass Field.
11	3	13	Building and Gardens.
30	0	14	Cart Road and Roads.
23	2	25	Railway

Total 1,082 0 0

During the year Messrs. A Cantlay and James Ryan retired on leaving the Island, and Mr. John Anderson was appointed on the Board.—In terms of the Articles of Association Mr. J C Dunbar retires by rotation and being eligible offers himself for re-election.—It will be necessary to appoint an Auditor for season 1902-1903.

By order of the Board of Directors,

THE DECLARATION OF A DIVIDEND: 11 PER CENT.

J M ROBERTSON & Co.
Agents & Secretaries.

Colombo; June 11.

AMALGAMATED TEA ESTATES COM-
PANY, LIMITED.

Report for the year ending 30th November, 1901, to be submitted to the sixth annual ordinary general meeting of Shareholders of the Amalgamated Tea Estates Company, Limited, to be held in the Registered Office of the Company, 22, West Nile Street, Glasgow, on Thursday the 19th day of June, 1902, at 2 o'clock p.m.

Directors:—Mr A K Muir, Chairman, Sir Robert D Moncreiffe, Bart, Mr A B Murray, Mr A M Brown, Mr Robert Scott, Mr R H Sinclair and Mr J F Muir.

The Directors beg to submit the accounts for the year ending 30th November, 1901.

The crop gathered from the Company's estates was 2,763,574 lb compared with 2,582,657 lb in 1900. The average price obtained was very disappointing, being only 9'27d against 9'90d and 10'29d respectively in the

two previous years. Unfavourable weather in the Darjeeling district, which seriously affected the quality, and an unusually low range of values for Darjeeling Tea, generally, in the London market, were the main causes of this regrettable fall in price. Adverse weather similarly affected the results of the Anglo-American and Kanan Devan Companies, in which this Company is largely interested.

For some considerable time past, in view of the adverse circumstances affecting the Tea-growing Industry, the directors have had under consideration the terms of the agreement between the Managing Agents and the Company. While it was recognised that at the time the agreement was entered into its terms were reasonable, the Agents, on being approached, expressed themselves as perfectly willing to consider a re-arrangement, and they voluntarily offered in future, during the continuance of the present depression in tea, and, while reserving their rights under the agreement, to restrict their charges as Agents of this Company to their actual outlay, plus a commission of 3 per cent on the nett profits.

The Managing Agents have also, in view of the disappointing results of last season's working, voluntarily agreed to give up to the Company, for the benefit of the Revenue Account of 1901, the whole of their Commissions for that year; and the London Agents have also agreed to return one-half of their Commissions.

Giving effect to the above concessions, so far as they affect the year under review, the Accounts now submitted show a balance at credit of Profit and Loss account of £31,900 : 10 : 4, against which are chargeable:—Commission on Profits to Estate Managers and Secretaries, Interest, Discount on Bills, &c., and Dividend at the rate of 5 per cent. per annum for six months ended 31st May 1901, paid to the Preference Shareholders on 15th June 1901, which total £18,897 : 15 : 1, leaving a balance of £13,002 : 15 : 3. The Directors propose to transfer £5,000 to Reserve Account; leaving £8,002 : 15 : 3 to be carried forward to next year.

The planted area of the Company's properties is now 13,494 acres. No extensions are in hand or contemplated.

The estimate of yield for the current season is 3,175,230 lb of Tea. The increase expected is mainly from the Company's young Estates in Assam which are now coming into bearing, and which being planted with a high-class jat of Tea should help to improve the average price of the Company's produce.

[Here follow paragraphs identical with those in the "Consolidated" Company's report quoted yesterday, alluding to foreign markets consumption and Mr A K Muir succeeding Sir John Muir as Chairman.—Ed. T. A.]

In terms of the Articles of Association, one of the Directors, Mr Robert Scott, retires at this time, and is eligible for re-election. The Directors regret that Mr A B Murray finds it necessary to retire on account of his health, and they have considered the question of filling his place. They approached Mr D M Hannay, of Messrs Kelly & Co., Exchange Square, Glasgow, and he has expressed his willingness to be nominated for a seat on the Board.

The Auditors, Messrs. Alexander Sloan & Co., C A, retire, and offer themselves for re-election. By order of the Directors, JAMES FINLAY & Co.,
Glasgow, 11th June, 1902. Secretaries.

THE ANGLO-CEYLON AND GENERAL ESTATES COMPANY, LTD.

REPORT OF THE BOARD OF DIRECTORS.

To be presented to the stockholders at the sixteenth annual meeting to be held at 20, Eastcheap, London, E.C., at noon on Thursday, July 10th, 1902.

The Directors herewith submit their report, and the accounts for the year ending 31st March, 1902.

The net profit, with the balance of profit carried forward from the previous year, after debiting the debenture interest, as shewn in the audited accounts annexed hereto, amounts to £21,311 19s 7d, and the Directors recommend a payment thereout of a dividend of four per cent on the Consolidated Stock of the Company, leaving a balance of £11,311 19s 7d, to be carried forward. It is proposed to pay the dividend on the 11th July, 1902.

The year in Ceylon was by no means favourable to the tea industry. The crop, which in the previous year amounted to 2,180,675 lb. from the estate leaf, and 133,672 lb. from the bought leaf, consisted in the present year of 2,269,718 lb. of estate, and 87,384 lb. of bought leaf. The crop of cocoa was a short one, owing to drought, and amounted to 1,570 cwt. as against 2,285 cwt. in 1900-1901. The gross price of the Company's tea was equal to 7.39 pence per lb in the London market, as against 7.68 pence per lb in the year 1900-1901; but it compares well with the Ceylon average. The price realised for cocoa was 58s 6d per cwt, as against 74s 3d in the previous year.

In Mauritius the crop of canes was somewhat disappointing and difficult to work, and this combined with the exceptionally low prices, which resulted from the excessive supplies of beet sugar, made the year comparatively unremunerative. In all 76,698 tons of cane were handled on the estates in which the Company is interested, and produced a crop of 7,553 tons of sugar, as against 8,565 tons in the year 1900-1901.

The result of the working of the estates in Ceylon and Mauritius, respectively, is given in the profit and loss account, calculated at the average rate of exchange of 1s 4.3-16d, as against 1s 4.4d in the year 1900-1901.

The crop prospects of the current year, and the condition of the estates, both in Ceylon and Mauritius, are reported to be good; and a favourable feature in the outlook of Mauritius is the recent imposition of additional duties on beet sugar imported into India, with a view to countervail the large karteel bounties of Germany and Austria. From Selangor the reports of the progress made by rubber, coconuts, and other products, continue satisfactory. A statement of the acreages is given in the schedule annexed hereto.

Mr. Stuart C Mackenzie, K.C., under the provisions of the Articles of Association, retires from the Board, and being eligible, offers himself for re-election.

The auditors, Messrs. Welton, Jones & Co., also retire from office, and have expressed their readiness to act, if re-elected.

BOGAWANTALAWA DISTRICT TEA COMPANY, LIMITED.

REPORT.—To be presented at the fifth ordinary annual general meeting of the Company, 2nd July.

The Directors have the pleasure to submit the balance sheet and accounts of the Company for the year ending 31st March, 1902, duly audited.

The yield of tea fell short of the estimated quantity by 53,414 lb., the shortfall being attributable to the great deficiency in rainfall as compared with the average. The profits for the year were also affected by the further fall in the price of tea, the market having continued in a very unsatisfactory state. The expenditure was as low as could be expected under the circumstances, and includes the amount spent on new clearings, buildings and machinery.

The total yield was 1,134,586 lb. tea plucked off 2,185 acres, being at the rate of 519 lb. per acre all round, costing free on board at Colombo 24 cents or 4d per lb. The gross average price of the 1,118,555 lb. sold in London was 7.32 per lb.

The crops for the current season are estimated at 1,206,000 lb. tea.

The gross average at which drafts were negotiated was 1s 4 3-16d per rupee against 1s 4 1-4d in the previous year.

The Directors desire to place on record their appreciation of the services of their Manager and his Staff in Ceylon.

STATEMENT SHOWING RESULTS OF WORKING FOR THE FOUR YEARS ENDING 31ST MARCH, 1902.

Season.	Acreage plucked	Total Tea Crop.	Yield per Acre.	Cost of Crop per lb. f. o. b. Colombo.	Gross Avg. per lb. Tea sold in London	Average rate of Exchange per Rupee.	Dividends.	
							Preference.	Ordinary.
1898-1899	2,081	1,031,782	495	4 12 8 7/1	1 1/4 5 32	6	7 1/2	
1899-1900	2,185	1,209,451	553	3 69 7 9/8	1 1/4 5 16	6	7 1/2	
1900-1901	2,185	1,236,272	565	3 93 7 5 1/4	1 1/4	6	6	
1901-1902	2,185	1,134,586	519	4 00 7 22	1 1/4 3 16	6	4	

The profit for the year amounts to £10,354 3s; To which has to be added Interest £160 2s 1d; And the balance from last year of £753 2s 3d. Total £11,267 7s 4d.

Interested on the Mortgage Debentures has been paid, less Income Tax £395 10s; Dividends on the 6 per cent Preference Shares for the 12 months were paid on the 1st Oct. 1901, and 2nd April, 1902, less Tax £5,254 10s; Income Tax to April 1902 has been paid £848 8s: It is Proposed—To pay a Dividend of 4 per cent on the Ordinary Shares, which will require less Tax £3,766 13 4d; To transfer to Reserve (increasing this account to £5,000) £500; And to carry forward to next year the balance of £502 6s. Total £11,267 7s 4d.

The Director retiring on this occasion is Mr Henry Bois, and being eligible he offers himself for re-election.

Mr. John Smith, the Auditor, also retires and offers himself for re-election.—By Order of the Board,

ROBERTSON BOIS & Co, Agents and Secretaries,
12, Fenchurch St., London, E.C., 20th June, 1900.

THE CONSOLIDATED TEA AND LANDS COMPANY, LIMITED.

REPORT for the year ending 30th November, 1901, to be submitted to the Sixth Annual Ordinary General Meeting of Shareholders of the Consolidated Tea and Lands Company, Limited, to be held in the Registered Office of the Company, 22, West Nile Street, Glasgow, on Friday, the 20th day of June, 1902, at Two o'clock p.m.

DIRECTORS:—A. K. Muir, Esq., Chairman, Sir Robert D. Moncreiffe, Bart., A. B. Murray, Esq., A. M. Brown, Esq., Robert Scott, Esq., R. H. Sinclair, Esq., D. M. Hannay, Esq., J. F. Muir, Esq.

The Directors beg to submit the Accounts for the year ending 30th November, 1901.

The crop of tea from the company's estates was 11,742,418 lb, or 1,590,836 lb less than that gathered in 1900. A rather finer class of leaf was taken off the bushes, but the main cause of the shortage was the severe drought experienced chiefly in Sylhet at the beginning of the season under review. A slightly higher price has been obtained for the produce, viz., 6 67d per lb, against 6 43d per lb in 1900, or an improvement in price of about 1/4d per lb, but in view of the shortage in the general output from India and Ceylon, it is disappointing that better prices have not been forthcoming. Unfavourable weather similarly affected the crop returns of the Kanan Devan and Anglo-American companies, in which this company is largely interested. For some considerable time past, in view of the adverse circumstances affecting the tea-growing industry, the directors have had under consideration the terms of the agreement between the company and its managing agents in Calcutta and Colombo. While it was recognised that, at the time the agreement was entered into, its terms were reasonable, the agents, on being approached, expressed themselves as perfectly willing to consider a re-arrangement and they voluntarily offered in future, during the continuance of the present depression in tea, and while reserving their rights under the agreement, to restrict their charges as agents of this company, and of the other tea companies in which this company is interested, to their actual outlay plus a commission of 3 per cent, on the net profits. This offer, which the directors regard as a most favourable one for the company, would, of course, supersede the arrangement with the Calcutta and Colombo Agents referred to in the directors' report for year ended November 30, 1899. With the view of enabling the directors to make up the full sum drawn from the reserve account, and place the company again in a dividend-paying position as soon as possible, the managing agents have voluntarily agreed to give up to the company, for the benefit of the revenue account of 1901, the whole of their commissions for that year. The directors have returned one-half of their fees, and the London agents have also returned one-half of their commission. Giving effect to the concessions referred to in the preceding paragraph, the accounts show a balance at credit of profit and loss account of £79,053 1s 9d. Against this sum are chargeable: Commission on profits to managers of estates and secretaries, interest and discount on bills, &c., interest and proportion of charges on debenture stock and income-tax, amounting together to £35,363 11s 9d. This will leave a balance of £43,689 10s, of which £41,634 0s 7d will fall to be replaced to the reserve fund in accordance with the resolution to that effect passed at the annual general meeting of the company held on August 30, 1901. The reserve fund will, with that addition, stand at £65,000. The balance remaining at credit of profit and loss account—namely, £2,055 9s 5d—the directors propose should be applied in reduction of the amount standing at the debit of preliminary expenses account. No extensions are in progress or contemplated, and the planted area of the estates of the company, which have now been practically all surveyed by European Surveyors, aggregates 28,473 acres. The estimate of yield for the current season is 13,572,880 lb. The weather upon the whole has, so far, been generally favourable to growth, in consequence of which an improvement is already noticeable in the out-turn. The estates of the company are in excellent condition, and when the present crisis is over they will undoubtedly again earn good profits, especially as, in spite of hard times, they are being cultivated and upheld as liberally as ever. Efforts continue to be made to increase the consumption of Indian and Ceylon teas in countries other than the United Kingdom, and especially in America and Russia; while a strenuous endeavour is being made by producers in India, including this company, to encourage tea drinking amongst the native population, and it is hoped that in time an appreciable quantity of tea

will be consumed there. Moreover, there are signs that Indian and Ceylon growers in addition to realising the necessity of opening up new markets, are also now more inclined to look with favour on a combination for, amongst other things, a general restriction of output for a year or two. The directors are hopeful that some scheme may be brought forward which will bring together the greater part of the industry, and they are prepared to send their cordial support to any feasible proposal. Such a combination would undoubtedly tend to at once raise the price of tea. The directors regret to state that Sir John Muir, who has acted as chairman of the Company since its formation, has been obliged to resign as a member of the board on account of the state of his health. They hope that after a time he may be able to again preside at their meetings. In the meantime, Mr A K Muir, who was offered and accepted a seat on the board, has agreed to act as chairman. Mr Muir has been in India for the last eleven years, latterly, as senior manager of the Calcutta agents' firm, and during the greater part of that time has been connected with the management of the company's estates. In terms of the Articles of Association two of the directors, Mr A B Murray and Mr R H Sinclair, retire at this time. The directors regret that Mr Murray finds it necessary to retire on account of his health, and they have considered the question of filling his place. They approached Mr J T Tullis, of Messrs John Tullis and Son, Limited, Glasgow, and he expressed his willingness to be nominated for a seat on the board. Mr Sinclair is eligible for re-election.

The Auditors, Messrs. Alexander Sloan & Co., C.A., and Messrs. Jackson, Pixley, Browning, Husey & Co., C.A., retire and offer themselves for re-election.

JAMES FINLAY & Co.,
Secretaries.

Glasgow, 12th June, 1902.

PLANTING NOTES.

HONOLULU IN THE HAWAIIAN ISLANDS— as the result of 13 years' Observations shows an average temperature in the shade of 74.1, the extremes being 57 deg. in February and 87 deg. in August. The rainfall is very low—only 28.39 inches as the annual average of 18 years: the maximum 49.82 and the minimum 13.46 inches. The place of observation is 50 feet above sea level. All this we learn from tables in the "Hawaiian Planters' Monthly."

SCIENTIFIC PRODUCTION AND MANUFACTURE.—Commenting on the Review of the Trade of India by JEO'Conor, Director-General of Statistics, the *Pioneer* of July 10th says:—In all the great staple industries of India—in tea, indigo, cotton, sugar, etc.—the time has come for the application of up-to-date scientific production and manufacture, and India can only hope to hold her own in so far as she makes use of labour saving methods and of the advantages which science places at her disposal. In discussing the export of animal bones, which averages about 100,000 tons annually. Mr. O'Conor says that Indian bones are also sent to Ceylon, where they fertilise the fields on which is grown the Ceylon tea that undersells Indian tea—not only out of India, but in India itself. This statement of the facts seems to point to the absence of capital, skill, and enterprise in undertakings dependent on agricultural operations.

THIRTY THOUSAND YOUNG TROUT—this season's hatch at the Matlock Fishing Association's hatcheries, have been destroyed. The cause is attributed to poisoning by river pollution. The association has appealed to the Government for an official inquiry to be held.—*Morning Leader*, June 14.

THE HOLTA TEA COMPANY OF KANGRA VALLEY report that encouraging results followed in the manufacture of 20,000 lb. green tea for the American market last year. This year it is proposed to make 60,000 lb. of the same. For this purpose the Company have installed the Drummond Deane system and machinery, which is a good testimonial, coming as it does from a Kangra garden.—*Indian Gardening and Planting*, June 26th.

SUGAR GROWING IN THE EAST INDIES.—Mr. R. W. Egerton Eastwick, lately secretary to the Penang Chamber of Commerce and Agriculture, writes to the *London Times* of May 21st on the subject of the existing depression in the sugar industry in the West Indies. At the very outset he denies that the depression will cease when the bounties have been abolished. To support his assertion he points out that although the prosecution of the industry has ceased to pay in the West, yet in the Eastern part of the Empire sugar-growing is regarded as a profitable undertaking. "In British Malaya" he goes on, "encouraging results have long since been succeeded by permanent prosperity." He points out that the conditions under which the industry is followed in the West Indies and in Malaya are very similar. Both countries, he allows, will benefit by the abolition of the bounties but not to any appreciable extent, "but the change which would materially benefit the West Indies is one of currency. A silver currency prevails in British Malaya, where labour is paid in silver. Might not the gold standard be dropped in the West Indies, and might not British and Mexican dollars take the place of sovereigns, with a varying rate of exchange?"

THE REAL RUBBER TREE.—The so-called rubber tree, with its thick, glossy, green leaves, common in hot-houses and gardens, is that which produces the gutta percha. It is little like the great tree from which comes the best rubber of commerce. The real rubber tree is not unlike other forest trees, resembling the English ash and growing to a height of more than sixty feet. Its bark is silvery gray, where it has not become black from being tapped. Its trunk is about as big as a man's waist. Where it has been tapped it often swells out at the base, so that it is much larger. It blossoms in August, being then covered with little white flowers. It bears nuts and in December and January, when they are ripe, the shells burst with a noise like a fire-cracker, throwing the nuts some distance. There are so many nuts on each tree that a man could easily gather enough in a day to plant a hundred acres of land. The tree can be easily grown in the right soil, and they thrive without cultivation; but to yield rubber they must be 15 years old. Fifteen years is too long a time for a man to wait in Australia, and at present the trees which produce rubber are wild.—*Journal of Department of Agriculture, W.A.*

A RECORD BANANA EXPORT.—The Jamaica *Gleaner* reports that the exportation of bananas for the year ending March last is likely to amount to a total of over ten millions of bunches, a record for Jamaica. The returns are compiled according to the computation of the companies, so that two small bunches are counted as one bunch. The total number of actual bunches therefore greatly exceeds ten millions.—*W. I. Agricultural News*, June 7.

BUDDING ORANGES.—The practice of budding oranges is becoming a part of the regular routine at all the Botanic establishments in the West Indies. In the interesting *Bulletin* of the Botanic Gardens at Trinidad, January 1902, Mr. Hart writes:—"Some advance has been made in the propagation of the imported kinds of oranges during the present year, and a fairly good stock of strong budded plants is now on hand. This, it is trusted, will do away with the complaint, so frequently heard, of oranges proving sour when raised from seed, a case of which occurred during the present week. The stock used is that of the Seville orange which does not suffer in our climate from stem-rot or mal-digonima, as do the best of our St. Michael's and Tangerine kinds. The 'Washington Navel' is among the varieties successfully budded. I learn that in some instances the pupils who attended the recent Agricultural Lectures are meeting with fair success in budding and grafting.—*W. I. Agricultural News*, June 7.

COCONUT BUTTER.—The Journal of the Royal Horticultural Society for April contains this note on an article by Mr. J R Jackson, which appeared in the *Gardeners' Chronicle* for December 1901:—"This substance has lately attracted a good deal of attention; its manufacture in this country [England] and on the Continent is now very considerable. It is manufactured from the kernels of coconuts, and is used as a substitute for butter or lard in cooking. It is sold in Germany at about 8d. per lb. It is claimed that it contains more than 90 per cent of vegetable fat, and that it is more wholesome and easier digested than the ordinary fat used for baking and cooking. It is said to be much in demand amongst vegetarians, Jews and Mahomedans. In English trade it is known as 'Nucoline.'—We might add that coconut suet also figures in the English market under the name of 'Vejsu.'—*W. I. Agricultural News*, June 7.

PRESERVING EGGS.—The following methods of preserving eggs are given in the July Part of "Work":—"Add 1 pt. of unslaked lime to 1 gal. of water, boil, stirring it well, then pour it into a bucket and allow to cool, and the lime to settle at the bottom. Now fill some glazed earthenware jars with new-laid eggs, then pour on the clear lime water to cover the eggs, tie a piece of bladder or some non-porous material over the top of the jars, and store away in a cool place. This is an old-fashioned method and it has the objection of making the shells brittle, and to some extent gives the eggs an unpleasant taste. Anything that will seal up the pores of the shell will preserve the eggs, and coating with white of egg, or painting with gum-water, or greasing, will keep them fresh for a time. At a recent show in Birmingham, some eggs were preserved by rubbing with vaseline and packing in bran, and some were rubbed with lard and packed in peat mould. Water glass is now often used for preserving eggs. Water is boiled and allowed to cool, then one-tenth of its bulk of water glass is added, and this is used in a manner similar to that employed with the lime-water described above.

FLOWERING OF THE VICTORIA REGIA AT KEW.—Notwithstanding the late season and the absence of bright sunlight, writes the head gardener, Mr Hawes, the *Victoria Regia* growing here opened its first flower on the 14th instant, Saturday last, and nearly a month ahead of last year. The leaves are already 5 feet 6 inches in diameter, and another flower will open in a few days.—*Gardeners' Chronicle*, June 21.

LAGOS SILK RUBBER.—The tree yielding this rubber is being gradually established in the West Indies. The name *Kickxia* has now been replaced by *Funtumia*, derived from the West African name of the tree. It is noticed that the young plants, if left to themselves, are liable to form a bushy habit and thus rendered less valuable for rubber-yielding qualities. To correct this it is recommended that the trees be pruned by gradually taking off all the lower branches and that one central, clean stem be encouraged. Even when the trees are tolerably large this is still required to be done if they are to be tested, as they should be, for yield of rubber. The Central American rubber tree (*Castilloa*) and the Lagos silk rubber tree (*Funtumia*) evidently are the most promising rubber trees for cultivation in the West Indies.—*W. I. Agricultural News*, June 7.

THE NAVEL ORANGE IN CALIFORNIA.—Referring to Mr Tidmarsh's note on p. 225 of your issue of April 5, I write to say that the Bahia, or as it is here called the Washington Navel, is the principal shipping Orange of California, furnishing over three-fourths of, 20,000 train-car loads of Oranges exported from California in the season of 1899-1900. With us it is a good bearer, but in Florida it is said to produce but shyly. It is by no means an infrequent occurrence to find a second Orange at the apex of the first, and all stages of development between the ordinary "Navel" and the well-developed second Orange are often found. Writing in *Meehan's Monthly* some time ago (the reference is not accessible to me), Prof. W W Bailey, of Brown University, says:—"We take it that in the Navel Orange the branch or shoot continues to grow, producing another tier of carpels above or within the first set. The lower set is more vigorous, presses upon and crowds the inner, forming, at last, the characteristic dimple or navel which gives the fruit its name. Such proliferation of a flower-branch is seen any day in the two or more storeyed inflorescence of Chinese Primroses; or in the still more striking cases where a Cherry, Rose, or Apple-blossom continues a leafy shoot through its middle." The figures referred to by Mr Tidmarsh are to be found on p. 56 of a publication of the California State Board of Horticulture, entitled *Culture of the Citrus in California*, by the late B M Lelong, Secretary, "assisted by experienced horticulturists"; it was published in 1900. Another illustration will be found in Dr H J Webber's article on "Citrus" in Bailey's *Cyclopaedia of American Horticulture*, p. 322. Another account of the Bahia occurs in the same work under "Orange," pp. 1152 to 1160, together with other information of interest and value to Orange-growers. A more extended and thoroughly reliable account of the Orange industry in California is contained in Wickson's *Californian fruits and How to Grow them*, ed. 3, San Francisco, Pacific Rural Press, Joseph Burt Davy, Assistant Botanist, Agricultural Experiment Station, Berkeley, California.—*Gardeners' Chronicle*, June 21.

CEYLON COCOA IN GERMANY.

A HINT FROM MR. RENTON.

Ceylon cocoa growers will feel grateful for the keen interest displayed in their interests by Mr. Renton. Today through the courtesy of Mr. Philip we are enabled to publish a hint which Mr. Renton sends to cocoa growers in Ceylon and which is specially applicable to those who export their produce to Germany. A valued correspondent with considerable knowledge of the subject gives us the following information of interest:—"The washing of cocoa and consequent removal of mucilage is pretty general in Ceylon, though there are, I understand, two or three estates where cocoa is not washed and mucilage is allowed to dry on the bean. I sent a sample of cocoa home some weeks ago, with mucilage dried on. Brokers reported "dark stained skin, good brownish *break*, well fermented and of even colour. The dark stain on skin would prevent its sale on type. Bright fiery skin is preferred, and, if this can be obtained, couple with 'break' same as sample, a fancy price might be secured." I do not suppose it is possible to get the bright appearance when the slimy mucilage is dried on the bean. Of course, if buyers generally began to realise that the "break" of the dark-skinned beans was always better, the fiery skin would cease to attract. Fiery skin has hitherto, I expect, generally indicated probable good "break." Enclosed are 2 samples: A, washed, B, unwashed. The latter has suffered in the keeping somewhat but not a great deal." (To the unpractised eye at any rate the washed beans look the most attractive.) What Germany wants, it is evident from the above, is not wanted at home. It would be interesting, however, and would save others experimenting, if some of those who expert "unwashed" cocoa would give their opinion on the extract sent by Mr. Renton.

THE CEYLON, JUNGLE-FOWL.

Gallus lafayetii, Blanford, Faun. Brit. India^s Birds, Vol. IV.

Native names:—*Weli kukula* (the male) *Welikikil* (the female) Cingalese, *katu koli*, Tamils of Ceylon.

The cock of this species bears a strong general resemblance to the red jungle-cock, but is orange red below as well as above, the breast feathers being glossy and pointed—very like hackles, in fact. The secondary quills of the wing are also purple black instead of chestnut. The throat and most of the rump-feathers, which are not so long and hackled as in the continental bird, are glossy violet, and the tail has a purple rather than a green gloss. The comb also in this species has a yellow patch in the middle; the face and wattles are darker, and the legs are yellow instead of slate colour. The hen is quite as different in her way from the red jungle-fowl hen; she is of much the same partridge-brown hue above but has no distinct hackle on the neck; her wings are

boldly barred with black, and her underparts not cinnamon but mottled black, brown and white, becoming lighter further back. Her legs are yellow like the cock's. She has no wattles, and is feathered on the face. Young cocks are redder above and darker below than hens. The size of this species is about the same as that of the red jungle-fowl, except that the cock's tail is longer; the hens, on the other hand, appear to be shorter in the species.

The Ceylon Jungle-fowl is confined to the island "where every prospect pleases"; but the parts thereof that especially gratify the tastes of the bird are the northern jungle and the southern hills. There seems to be a good deal of variation in the breeding season and also in the number of eggs laid, which is given as from two to twelve by different authors. There is nothing noteworthy about the appearance of these eggs. The crow of the Ceylon cock is very different from that of the rival chanticleer of India, being two-syllabled and commonly rendered as a call to one "George Joyce." A Ceylon planter, however, told me recently that the general opinion now-a-days was that the bird's friend's name was "John." The cock is a gentleman of somewhat Don Juan-like instincts and apt to intrude on the domestic happiness of village roosters, without the excuse that the red jungle-fowl can offer of community of descent. But there is as yet no proof that the offsprings of these *mesalliances* is fertile, much as the present species resembles the Indian ancestor of the domestic fowl.—"The Indian Forester," July.

RUBBER CULTIVATION IN CEYLON: CASTILLOA (AND PARA): VALUABLE RESULTS FOR THE FORMER IN MATALE DISTRICT.

We are well-pleased to stand corrected in the following letter from Major Gordon Reeves, which affords such practical and valuable information as we feel sure must lead to a new departure in regard to rubber cultivation in the drier districts not suitable for "Para" which can only be grown in a limited area in Ceylon. Undoubtedly we were wrong in saying in general terms that "Para" was the safer species to plant. Our warning should rather have been to take care about imported seed or plants of Castilloa being of the right kind. But let Major Reeves give his experience:—"I read your leading article on rubber in a recent issue with interest, but I am at issue with you when you state generally that Para is the kind to cultivate. The cultivation of rubber must, I imagine, be governed by climatical conditions. Para rubber will flourish in a moist climate even in marshy land, where Castilloa and Ceara would refuse to grow at all. Because there may be even a dozen species of Castilloa that are practically worthless, is that any reason why the species that is really valuable should be rejected by those owning land suitable for its cultivation? Planters were wise enough in their generation not to base their action on that argument, in the case of cinchona.

"The good species of Castilloa are doubtless as well-known and distinguished as those of the cinchona. My own experience is most decidedly in favour of Castilloa as against Para in such districts as Matale. Experiments carefully carried out at Wiharegama by Mr. G. H. Gibson, extending over *six months* proved that a yield of 1½ lb. of rubber, valued

in Liverpool by Messrs. W. Wright & Co. at from 2s 11d to 3s 6½d per lb., could be secured off trees with a diameter of from 10 to 12 inches.

"I will refer to the subject of growth later. In the meantime it should be noted that the above experiments were carried out in the absence of any scientific knowledge of the principle of tapping and curing as at present obtain, and that the rubber was partly sun-dried. Messrs. Wright & Co. remark: 'We think the rubber, if equal to the samples, would meet a steady sale in the market; No. 1 is very like good scrappy Negro Head (Para) No. 2 like Peruvian Slab.'

"In a recent issue of your paper, an extract appeared in which Mr. Morris speaks very highly on the yield of Castilloa and Mr. Morris is a man whose testimony cannot be lightly rejected. The general opinion went to show that an average yield of about 2 lb. of rubber per tree per acre could be expected, although instances of a very much greater yield were proved. You will note that the Wiharegama experiments support these views for, although they extended over six months only, it is probable that during the drier season, January to July, the quantity yielded would be comparatively small. We shall, however, have further evidence to present on the subject.

"As regards growth here again in the Matala Valley, as in yield, the Castilloa has the advantage over the Para rubber. 8-year-old trees at Wiharegama, planted under cacao and dadaps, show a height of about 30 to 40 feet with girth of 30 to 36 inches. The statement below which has been furnished by Mr. B. H. Jenkyns as regards the growth of Castilloa on our new clearings at Ambanganga, North Matala, where the Cacao and Castilloa have been put out simultaneously, seems to show that the older trees in Wiharegama have been at a disadvantage in being put out under established Cacao:—

Height Girth			Height Girth				
No.	Ft.	In.	No.	Ft.	In.		
1	12	17	...	6	12 2	16	
2	14	18	...	7	13 1	17	
3	13	17	...	8	12 3	13	
4	11	7	19	...	9	12 1	18
5	13	4	18	...	10	12 2	18

—girths measured at 1 foot above ground level. The trees from which the above measurements are taken are just over 2 years old, and although they have come through a prolonged and trying drought show no sign of distress. The advantage of the Castilloa in dry climates over the Para tree lies chiefly in cost of production, the flow of latex at all times being much freer. I make this statement without prejudice, inasmuch as the Para rubber has so far a large representation, and I should be only too pleased to record of it equally good results. At the present time the price of rubber allows a profit, even a handsome profit, along with a very heavy cost of production, but most of us have to look forward some 6 to 8 years. When that period has passed the man who possesses the species of rubber yielding suited to his climate and soil will undoubtedly score. *Note.*—According to Messrs. W. Wright & Co. the difference in

value between our unscientifically-cured Castilloa. No. 1 sample, and *fine Para* was 6½d per lb."

TEA PLANTING IN NATAL.

Tea planting in Natal is in an exceedingly prosperous condition, according to Reuter's. Upon Messrs. W R Hindson and Co's estates, the second in importance in Natal, there is an aggregate of about 800 acres under tea of all ages. The output in 1901 was given as 400,000 lb, and this year it is hoped it will be increased by 50 per cent. Wholesale prices obtained by Natal tea estates upon the South African market run from 7d and 7½d per pound for the lowest quality to 1s 6½d per pound for the highest quality.—*Daily Mail*, June 28.

PRICE RANGES OF CEYLON COCONUT OIL.

The subjoined table shows the highest and lowest price quoted for Ceylon coconut oil in the New York market each month during the past five years, and also the highest and lowest points touched each year. The figures are based on the closing quotations of each successive week:—

INDIA-RUBBER INDUSTRY.

PERU—BOLIVIA.

H.M Consul-General at Callao also remarks that the india-rubber industry is likely to progress, as, from all accounts, the forests of Peru contain innumerable rubber trees. From 1st July, 1900, to 30th July, 1901, grants amounting in the aggregate to 1,240,000 acres of forest land, said to contain valuable rubber trees, have been made by the Government. These lands lie in the Departments of Huanuco and Cuzco. The periods of the grants are, either five or ten years. The royalty claimed by

the Government is 2s for every quintal of rubber which is exported. During the same period six other concessions were granted under somewhat different conditions. One of the grants comprised 4,942 acres and the others 1,235 acres each. These grants are divided into plots called "estradas." Each "estrada" contains within its boundaries 150 rubber trees. The royalties levied in this case are 20 cents annually for each "estrada" and 20 cents for each hectare of land which the estradas cover. Here it may be mentioned that vast tracts of land, known as the Acre or Aquiry territory, forming the hinterland to Peru from the 7 deg. to 12 deg. of south latitude, have quite recently been made over by Bolivia to a syndicate. The syndicate have been granted extensive powers, such as the right to administer the territories in question and to organise an armed force. However, their chief object appears to be the extraction of rubber. The territories thus placed in possession of the syndicate are vaguely described as being bounded on the north-east by Brazil, on the west by Peru, and on the south by the River Abuna and a line drawn from that river to the confluence of the Inambari with the Madre de Dios. Matters are so far advanced that a scientific commission sent out by the syndicate is already engaged in exploring a portion of that district.—*Foreign Office, Annual Series.*

CEYLON GREEN TEAS GRANT, 1901-1902.

Memo showing number of lb. on which payment was made monthly during 1901 and 1902 respectively.

A. PHILIP.

Kandy, 1st July, 1902.

THE TEA TAX AND THE TEA TRADE NEW MARKETS AND GREEN TEAS.

The story of the tea trade for the past season is not a very hopeful one on which to base optimistic forecasts of the future, and it is not surprising to find that Messrs. W J & H Thompson, in their annual review, have not been able to pump up over much enthusiasm over the outlook. We would gladly see the tax on tea removed if it were possible, but it seems a very poor policy

to suggest that, because one industry is suffering from the oppression of a tax, others should be similarly burdened; and they fail in the first place, to prove that the tea trade is oppressed in this manner, probably because they do not really feel sure themselves that such is the case. These gentlemen assert that the theory that the tax is paid wholly by consumers has broken down under the practical experience of those engaged in trade; that every grower abroad, every shareholder at home, pays part of the sixpence levied here; shippers of China and Japan teas have suffered from the 10 cents war tax in the United States, and traders all the world over are hampered by duties almost everywhere imposed, and to this they attribute the lower prices obtained. But, if the producer pays the tax, how is the following statement to be explained? Opponents to this pet theory of the Protectionist, we are told, seem hardly to realise that when more of the buyers' capital is taken for payment of tax, less of it remains for purchase of tea, an argument which would appear to demolish the previous one entirely. The truth of the matter is that, although planters have now realised the folly of the reckless extension indulged in in the past, and are endeavouring to counteract the evil results as much as possible by restricting their output, that output is still too large to be absorbed through existing channels, and the inexorable law of supply and demand is the sole cause of the present depression. As for the finding of new outlets, little progress has been made in the United States, chiefly, we believe, because our planters will not accept the suggestions so often made to them and go in for producing green tea instead of black, Indian teas shipped to that market have grown gradually less and less, and although the quantity of Ceylon tea has risen, the gain has not been in proportion to the loss in Indian, and considering the opportunity afforded by the interruption to the China trade, cannot be regarded as at all satisfactory. The outlook for India for the immediate future at least, is disappointing. Once more an Indian industry seems destined to share the fate of so many others that have preceded it—flourishing and full of promise for a time, and then glut or decay.—*Investors' Review*, June 28.

GOLD-MINING ON THE NILGIRIS.

AN APPLICATION TO PROSPECT.

Mr. J C C Herklots, proprietor of Benhope Estate on the Nilgiris, has applied to Government for a gold prospecting license for about 40 acres of land. The application comprises private lands, as well as Government reserved forests, and is over a mile in length and 300 feet in width. The District Officer, to whom the application was referred, considered that any slight derangement of the soil might occasion landslips. Mr C M Mullaly, the Acting Collector of the Nilgiris, considered that the application was of considerable importance for several reasons, viz, (1) Indications existed of a reef running in the block, and the object of the application was to obtain a sufficient length to induce a leading firm, (Messrs Taylor & Co.) to take up the work of prospecting. While duly safeguarding other interests, every encouragement should, he thought, be given to *bona fide* prospectors for gold. (2) Safety of the Railway and the two Ghaut roads. (3) Beauty of the landscape and preservation of the forest. The Board of Revenue upheld the Collector's

views and recommended that facilities for prospecting in the tract, which exhibits indications of an auriferous reef, may safely be given by assigning a plot near the Coonoor River and another at the top of the Burliar Valley. The Government has accordingly sanctioned a license being granted to Mr Herklots on the terms proposed by the Board of Revenue.—*M. Mail*, July 15.

TEA IN FORMOSA.

The Osaka *Asahi* publishes an interesting letter from Taipeh, as follows :

Seven years have now elapsed since Formosa was acquired by Japan. The first three or four years were spent in investigations, and it is only recently that practical experiments were made and public works started in earnest. Experiments for the improvement of the tea plants are still being made. The examination of manure was taken in November last. Tea-culture experimental stations are established at Bunsanbo and Tokanbo, under the charge of Mr Fujie, an expert. Last year 1,880 yen was appropriated to this department, and all the arrangements required were completed. This year 3,500 yen has been granted, and the testing of manure has been commenced. People of the island who are interested in tea cultivation say that the plants, given manure, produce more leaves, but they lose the natural flavour of the Formosa tea, so that they are unfit for making the best Oolong variety. If the results of the experiment be as anticipated, the production of tea can be doubled, and as it is intended to use machines for preparing the leaf, the result will be a reduction in the price and in the manufacturing expenses. Formosa tea may compete in price with the tea market of the world. The expenses appropriated to the four agricultural experimental stations in the island amount to 24,259 yen.—*Hongkong* July 16.

PLANTING NOTES.

A BLUE ROSE—grown by a head gardener named Macdonald, in the United States—has been sent to Kew Gardens. As a rarity it may claim rank with the choicest new orchid, and it is therefore not surprising to learn that on the way over the Atlantic it received the most careful attention, and was protected in a specially-constructed miniature greenhouse—a care which was rewarded by its arrival with blooms in excellent condition.—*B Weekly*, June 26.

CYPRUS—is one of the most beautiful and interesting of our possessions, and at one time it was the richest and most luxurious spot of the classical world. It is even yet exceedingly fertile, and possesses, moreover, a fair climate; but, for all its natural advantages, it seems to be held of little account by the Government, which, however, has recently constructed some excellent roads between the principal towns along the coast, whereby travelling is rendered much easier than it used to be twenty years ago. At present, unfortunately, there is only one decent hotel in the island—that at Larnaca, which, by the way, Mr Haggard says (in "A winter pilgrimage through Palestine, Italy, and Cyprus," just published) is "absurdly cheap," a distinct advantage in these times. Larnaca, where we have our Consulate, might be made the headquarters for an interesting tour of the island, including Famagusta, and the Ruins of Colossi, Amathus, Curium, Nicosia, and Kyrenia.—*Home paper*.

ENSILAGE.—The Board of Agriculture desire to acquaint persons desirous of making silage that copies of a leaflet containing information on the subject of ensilage may be obtained, post free and free of charge, on application to the Secretary, Board of Agriculture, 4, Whitehall-place, London, S.W. Letters of application so addressed need not be stamped.—*London Times*, June 27.

BROOKE BOND & CO.—This famous tea distributing Company's annual meeting will be found reported in on page 121. A dividend of 15 per cent, with 2½ per cent bonus—and another £13,000 to the reserve which is to be brought up to £150,000, the original capital!—shows how little it has been affected by trade depression. Mr. Hector Forbes, the Chairman, protested against producers having to pay £6,000,000 in duty on a total value of £7,500,000; but he had no confidence in any 'reduction of output' scheme.

THE MANUFACTURE OF PAPAIN.—In the course of a notice on the paper on this subject, which appeared on page 4 of the *Agricultural News*, the *Montserrat Herald* says:—This article is pretty well exported from here. There are not less than three drying stoves in the island of Mr. Watts' description, so the mode of preparation is not new to those who are engaged in its manufacture. But we do not think that it is generally known by those who sell the juice that "it is essential that no iron knife or iron utensils should be brought into contact with the milk. Wood and bone should be employed, and the milk should be collected in earthenware basins or cups, or in glass vessels, and not in tins which are sure to blacken it."—*W. I. Agricultural News*, June 7.

SYNTHETIC RUBBER.—A process for the manufacture of "synthetic rubber" from cotton-seed oil and fibre has been invented by Messrs John Burdon & Company, which should, if it proves to be commercially of the value claimed for it, do much towards cheapening the cost of all manufactures involving the use of rubber in any shape or form. The inventors assert that a mixture containing 25 per cent. of pure rubber produces at a considerably lower cost an article of equal value for almost all commercial purposes, and if this assertion can be made good by the test of actual working there is certainly room for the new industry which will arise. At present the cost of pure rubber is 4s per lb, or £20 per 100 lb, whereas it is estimated that the new discovery can be produced for £6 17s 6d. per 100 lb, including £5 for 25 lb of Para rubber.—*Investors' Review*, June 21.

VANILLA IN TAHITI.—The Journal of the Board of Trade for January 23, 1902, reports that the French Government has fixed '1,000 Kilograms [22,046 lb] as the quantity of vanilla produced in French establishments in Oceania (Tahiti and its Dependencies) which during the period from July 1, 1901, to June 30, 1902, is to be allowed a reduction of 50 per cent of the ordinary import duty on importation with France. In 1899 Tahiti exported 130,113 lb of Vanilla. The price realised was very low, only 4s 5½d per lb, owing largely to faulty preparation. The Consular Report on the Trade of the Society Islands for 1899 says that 'Tahiti vanilla properly cured before shipment generally finds a fair market, although it cannot compete in quality with that from Bourbon, Seychelles, Fiji and the West Indies.—*Agricultural News*, May 24.

KEPPETIYA AND BETEL.

R. George Weerakoon, Mudaliyar of Wellabodde Pattu, writes :—" All vegetable substances are no doubt useful for manurial purposes, but some Ceylon plants are more

greatly favoured than others for fertilising the soil. One of these is Keppetiya. As you know, it is a favourite manure, and almost the only fertiliser used for Betel and Chillies. It is also used in paddy-fields, and I have tried it myself with very good results. I have no doubt if examined by the Chemist it will be found to prove its reputation as a manure.

Speaking of betel, it is as you are aware, a *sine qua non* with the villager—almost a part of his diet, so to speak,—though not much in vogue as a masticatory among the anglicised portion of the Sinhalese community. As for myself, though I do not indulge in betel chewing, I see no harm in countenancing the habit which, in my opinion, is to be preferred as less objectionable and deleterious than the "fragrant weed" of Ceylon, provided it is done at the proper time and place without offending the eye. Apart from the regular cultivation of betel in "kottuwas," there is hardly a plot of ground near a dwelling-house that has not got its casual betel vine. As a cultivated product it is decidedly remunerative, and enormous quantities of leaves are sent to upcountry stations, such as Nawalapitiya, by rail. The betel, according to the Sages, has such extraordinary virtues that it is in demand even in the abode of the gods!"

Keppetiya (*Croton lacciferus*) apart from its value for manurial purposes and as a medicinal agent, is a source of lac, as its name implies. Trimen in his *Flora*, referring to the plant, says :—"A small red coccid occurs on the bark of the older trees, and is collected in districts where it is abundant to mix with the colours used in lacquer work. This lac is collected in the dry season near Matale for the Kandyans lacquer industry. It is melted in a metal pot over the fire and is then called Keppetiya resin.

As regards betel (*Piper betle*) we agree with our correspondent that the practise of chewing is "in loco" by no means objectionable or deleterious, and is even to be encouraged among those who have a *penchant* for the habit; for when mixed with the usual concomitants it is undoubtedly useful as a digestive, corrective, and (for the teeth) as a preservative agent. The leaf contains an invaluable oil, which is employed with great success in many ways. In this connection we doubt not our readers, including our correspondent, will be interested and perhaps also amused, by an account of betel-cultivation in India which we give on another page.

OCCASIONAL NOTES.

Since the issue of our last number a great event has been prevented by the stern decree of Nature, under circumstances solemn and almost tragic. We refer to the enforced postponement of the Coronation of King Edward VII, which was to have taken place at Westminster on the 26th June, 1902, owing to the sudden and serious illness of His Majesty. All present danger to the person of the King has now passed, and before the month is out, the great ceremony will, we doubt not, have been consummated.

On July 22nd Dr. Willey, the Director of the Colombo Mesnem, visited the School of Agriculture, and spent some time working with Mr. Driberg in the apiary, where the hives were examined and overhauled, and the bees (*Apis indica*) handled without accident.

Quot homines tot sententiæ. One very successful coconut planter lately stated to us that he would not have any of the sensitive plant (*Mimosa pudica*) on his estate for all the nitrogen it imports into the soil. But he was an æsthetic and kept his property almost as clean as the Galle Face *Maidan*. Another planter was an ardent admirer of the "modest mimosa" which had only to be kept down and taken full advantage of. His sole objection to the plant was that it made things a bit inconvenient when the plucking

and gathering of the nuts had to be done, but he would sooner supply the pluckers with protection for their feet than go without "midikumba."

The Florida velvet bean is credited with containing a deleterious principle which is said to be the cause of colic in consumers of this prolific legume, and many people have given the vegetable a wide berth in making up their daily bill of fare. The truth is that the velvet bean requires rather more careful preparation than most vegetables, though even the ubiquitous potato demands some care to make it as wholesome a food as it is. The manioc—at least one variety of it—has to be very well cooked to rid it of the volatile poison (no other than the deadly prussic acid) with which it is associated. A reliable authority informs us that there is now quite a run on Florida beans for vegetable curry, and that the natives have overcome their prejudice against the vegetable by discovering that the beans when first boiled in water with turmeric and salt, lose any noxious properties they may possess. To prepare the curry the whole beans (with of course the hairs all rubbed off) are, after boiling in the way referred to, fried with onions, &c., and then mixed with the ordinary curry ingredients. If any bean is worthy of being called the "poor man's vegetable" we think it is this hardy and prolific legume, and we are glad to hear that its use is likely to extend. We shall be glad to supply seeds on application.

In our June issue we speculated as to what tree could be traced the peculiar odour of chlorine. We have now found a tree, the wood of which when freshly cut emits a decided and strong odour of iodine or iodoform.

PLANT LIFE.

[A SERIES OF SIMPLE LECTURES INTENDED FOR A CLASS OF JUNIOR STUDENTS.]

LECTURE VI.

From what I have already said you will infer that the greater part of the food of plants is got from the soil. We have been considering the nature of the atmosphere and the important element of plant food which it supplied. We might therefore make some enquiry into the nature of soil and its relation to plants. The soil we said is the medium in which the plant grows. Soils differ in texture, that is they may be loose in texture or more or less close or firm. Soils are generally classified according to the proportion of sand, clay, organic and calcareous matter which go to compose them. These substances are familiar enough to you. Now a soil consisting almost entirely of any one of them will, as you must admit, be an unsatisfactory soil for the growth of plants. Good soils consists of a mixture of sand, clay and decayed organic matter with some proportion of lime (carbonate of lime). Experience proves that a soil is best adapted for purposes of cultivation when it contains from

50	to	70	per cent	Sand
20	"	30	"	Clay
5	"	10	"	Humus
5	"	10	"	Carbonate of Lime.

Such a soil contains enough sand to make it warm and permeable to air and moisture; enough clay to render it tenacious or cohesive and retentive of manures; enough humus to keep it moist and porous and to assist in supplying the nitrogenous food of plants, as well as to keep up the supply of carbonic acid in the soil; and lastly, sufficient lime to meet the requirements of plants and help in the decomposition of organic matter.

The reason why alluvial soils (found near rivers) are so fertile, is the mixed character they possess, having been so mixed by the action of running water. Most soils, however, are not of such a perfect character, and have generally an excess of one or more of the constituents above named.

A pure sandy soil is deficient both in physical and chemical properties. On such a soil plants are unable to get a hold for their roots, they would have little or no moisture supplied to them, and derive nothing in the way of nutriment from it. But as an ingredient of soils sand is of the greatest importance, since it gives them a loose texture so that they are permeable to air, moisture and warmth.

Clay has properties very different to those of sand. A soil of pure clay would be as unsatisfactory as one of pure sand. Such a soil would be too cohesive and impermeable to water, cold and damp, and in dry seasons would bake as hard as a brick, while from a chemical point of view it is of no value as a source of plant food. But as one of the constituents of soil clay is of the greatest value, absorbing gases from the atmosphere, keeping a soil moist and cool, giving tenacity to it, and retaining useful plant food which would otherwise be washed out of the soil.

But there are always associated with sand and clay (or, to use their scientific names, silica and hydrated silicate of alumina) certain impurities which are of the utmost importance, and it is to these impurities, viz., potassium, magnesium, calcium, iron, &c., derived from the original rocks from which the soils were formed) that the plant must look for its mineral food.

Sand and clay are the ingredients which form the bulk of soils. Lime or limestone is useful as supplying an element of plant food, but it also aids in the decomposition of organic matter, and thus helps to prepare the nitrogenous food of plants. Limestone generally contains as impurities phosphates or sulphate of lime, magnesia, &c., which are valuable as plant food, while it also has the effect of keeping soils in a friable (*i.e.*, in an easily worked) condition. Humus or decayed organic matter is very important from a chemical point of view. As a mechanical agent it keeps soil open which would otherwise be stiff and gives body to light soils, while it is also an absorber and retainer of moisture. The ultimate products of the decomposition of humus are carbonic acid, ammonia and water, all valuable agents in the nutrition of plants. A soil wholly composed of organic matter is as you well know [an unsatisfactory one for the cultivator.

I have already given you an idea of what a typical soil should be, and it should be the aim of every cultivator to bring his soil as near as possible to this type. Of the four most important ingredients of plant food (the available supply of which is liable to run short) viz., nitrogen, phosphoric acid, potash and lime: nitrogen is at its highest in peaty soils and at its lowest in sandy soils; phosphoric acid is found most in a clay soil and least in a sandy soil; potash is at its highest in clay and lime in calcareous soils, while both are very deficient in sandy soils.

We have to look upon the bulk of soil as the element in which the roots of plants live—as fish live in water—and travel about in search of food and moisture. The actual nutriment is present in comparatively very small proportions, as will be seen from the following statement showing the percentage composition of a loamy soil:—

* Organic matter and loss on heating	5.07
Oxide of Iron	3.63
Alumina	3.51
Carbonate of Lime	1.48
Sulphate of Lime	.34
Magnesia	.42
Potash	.30
Soda	.01
Phosphoric acid	.10
Insoluble Silicates and Sand	85.14
	100.00

* Containing Nitrogen	..	.23
Equal to ammonia	..	.19

THE AGRICULTURAL OUTLOOK IN SOUTH AFRICA.

Mr. W. Willcocks, C.M.G., M.I.C.E., in a report on irrigation in South Africa addressed to H.E. Lord Milner remarks that the permanent development of the country will depend on irrigation and irrigation alone. The Colony, it is said, has remained strangely stationary, apart from the development of its gold, diamond and coal mines. Fifty years ago it was a pastoral country importing cereal and dairy produce and even hay from foreign countries; and it is the same to-day. Half a century ago it needed a farm of 5,000 acres to keep a family in decent comfort, and things are not altered since then. This is the picture drawn by the writer of the report. Except in the south-west corner of Cape Colony, we are told, agriculture has scarcely been attempted except on the most primitive lines and on insignificant areas. Farmers trek from the high velt to the low velt and back again with the seasons. And the reason of this want of development of the agricultural resources of the country is said to lie in the fact that the rainfall of the three colonies, with the exception of the south-west corner, is uncertain and erratic: it is constant and heavy in autumn, which is followed by a severe winter without any moisture in the air. As Mr. Willcocks pithily puts it—when rainfall is wanted it is not there, when it is not wanted it is invariably present! For countries so situated the only possible means of development lie, he thinks, is storage of water and irrigation. If these countries are ever to develop their immense agricultural wealth, we are told that they must be proclaimed a semi-arid region, and legislation framed accordingly.

Mr. Willcocks goes on to refer to his experience in the Indian and Egyptian Irrigation Departments, and points to the immense benefits derived from irrigation in these countries and in Italy. Referring to the Transvaal he remarks:—There the mineral wealth is extraordinarily great, but it is exhaustible—some say in 50, some in 100 years. It would be a disaster indeed if none of the wealth were devoted to the development of agriculture. If the companies working the various mines were by decree required to devote a percentage of their gain to the execution of irrigation works, then when the mineral wealth of the country had disappeared, its agricultural resources would have been put on such a solid basis that the country will not have to fall from the height of prosperity to the depth of poverty. "The permanent development of the agriculture of South Africa will depend on Irrigation and Irrigation alone."

The plea is a strong one, and the prospect it hints at is bright, and we have no doubt that the wise men at the head of the new administration will not lose sight of the possibilities which irrigation can secure for the country.

BETEL CULTIVATION IN INDIA.

In cultivating betel in the Madras Presidency the land is first planted with *Sesbania grandiflora* (Sin, Katurumurunga), and the cuttings of

betel from a two-year old garden are planted between, two to each tree, to which they are tied with plantain fibre when sufficiently grown. There the vines are apparently well supplied with animal manure half-yearly. At the end of the first year the leaves are picked daily for about 16 months in good and well-manured soil. The best monthly yield per acre is put down at 25 bundles (of hundred leaves each) worth Rs. 30, or for the 16 months of the crop Rs. 480.

It would appear that in the N. C. Province betel cultivation is confined to a special class or "brotherhood of old standing," forming an independent section in the village who pay their rent to the landowner through the head of their body. A portion of the village lands is recognised as belonging to this caste, and in this they dig wells, make their gardens, and, being careful and steady cultivators, contribute much to the general prosperity of the neighbourhood.

The cultivation of betel would thus be considered an honourable pursuit over in India; but wonderful to relate there are dangers to be faced, for we read that in the Central Province, tigers fully appreciate the cool and grateful shade afforded by a betel garden in the hot months, and the cultivators on going to work, not unfrequently find one of these animals entangled in the maze of creepers.

But even the Ceylon villager will smile when he is told that in the neighbouring Continent, when the plant is young and delicate, it is sometimes fed with milk which is found to be an "excellent manure." No doubt!

Regarding the "betel brotherhood" we are told they are so industries and so respected, that landholders allow them many privileges. Thus custom has prescribed that no rent is to be demanded during the time the land remains uncultivated. Rent, too, is only paid in the exact quantity of land sown. Though all the members of the caste give their labour towards the construction of the garden, and share in expenses of watering, weeding, watching, &c., yet each individual is the owner of a portion of the garden, the produce of which he himself gathers and disposes of on his own account, and each has an independent interest in the undertaking. In the Central Province the vines are not kept after the second year when the ground is allowed to go fallow for from 2 to 3 years according to the soil. But in Nimar a garden well established is said to yield steadily for 10 or 12 years. Here the shade trees to which the vines are attached consist of *Sesbania Egyptica* (Tamil, Chittakatti) a tree which shoots up rapidly and affords good shade for 2 or 3 years, while the plantation is surrounded not, as in other parts, with plantains, but with poles of *Eythrina indica* (Erabodu) When the *Sesbania* trees die down, they are replaced by poles of *Boswellia serrata* of which the bark is believed to give a specially favourable hold to the climber. Every year after the leaves have been gathered the creeper is coiled down at the root until only some 3 feet of it are left above the ground; a fresh root is thus struck and the old coil is next year cut away altogether. Except during the rains the crop is steadily irrigated, and at the beginning of each hot season

the plant is pruned, manured and freshened up with transported soil. The level of the land thus become raised about 2 feet in the 10 or 12 years.

The above system is said to be preferable to the ordinary method, entailing less labour, less retardation of profit, and with the annual supply of fresh earth should produce as good a yield. It is practically the same method, combined with artificial shade, followed in Bengal and other places where cultivation is extensively carried on.

In many parts the betel plantation is covered on all sides with bamboo and mat work.

We shall have more to say on this subject in subsequent issues.

THE PROPER METHOD OF PLANTING TREES.

In an article on "Planting" by Mr. A. Despeissis, to the Journal of the Department of Agriculture, Western Australia, the writer gives many useful hints on the subject, which we reproduce for the benefit of our readers.

After marking off to ensure straight planting the holes are dug at the required distances. Holes for fruit-trees should be wide enough to admit of the spread of the roots: the wider the better. In heavy and retentive soil the holing should not be deeper than the drained layer of soil, otherwise the hole would act as a basin. Many trees are killed through the roots decaying instead of growing in a healthy condition.

Before digging the holes, and to insure that the tree will occupy the exact spot the stakes were in, a simple contrivance known as the "tree-setter" is of great use. It consists of a light piece of board 1 inch thick, 4 inches wide, and 4 to 5 feet long. Cut a V-shaped notch in the centre and either bore a hole $1\frac{1}{2}$ inches in diameter 3 inches from each end, or instead of the holes cut notches at each end of the board.

To use the tree-setter, the V-shaped notch is put against the stake which marks the spot the tree is to occupy. Through the hole at each end or in the notches, drive into the ground pegs 1 to $1\frac{1}{2}$ inches in diameter and 12 to 15 inches long that will easily pass through the holes. This being done, remove the central stake, lift the board over the terminal pegs which are left in the ground and dig the hole. When planting replace the tree-setter over the two pegs, and place the stem so that it will occupy exactly the spot the stake occupied before.

The hole should be three feet square, convex in the centre or of the shape of an inverted saucer. This is done by heaping up some loose surface soil, so that when the tree is planted its base stands a little higher than the roots which spread out evenly round, radiating outwards with a slight dip downwards.

In the case of a hard impenetrable bed it is recommended that the bottom layer in the hole should be shattered by means of cartridges of dynamite or $1\frac{1}{2}$ lb. charges of black blasting powder rammed into holes two inches in diameter bored through the hard pan. By this

means numerous crevices will be formed which will promote the drainage of the land and permit the roots of the plants penetrating and gaining access to the subsoil beneath.

Every tree to be planted should be carefully examined for any indication of root galls, scale insects, borers or fungoid growth, to ensure immunity from which it should be dipped either in warm whale-oil soap suds or in kerosene emulsion for a couple of minutes in the case of insect pests, or in Bordeaux solution in the case of fungoid disease.

Trees that have to be kept till required for planting should be put slantwise into a trench in moist well-drained soil and loose well-pulverized earth banked up round the roots and every part of the stem. The trees should stand thus till required for planting.

It happens that they are sometimes bark-bound, showing a leathery shrivelled bark. In that case they should be thoroughly drenched first and then covered up with moist loose earth or sand, stem and branches, for a couple of days or so, when, unless, too far gone, they assume their healthy look again.

Before planting in the hole make with a sharp knife a clean cut of any bruised root, and with a few shovelful of earth raise the bottom of the hole so that the collar is level with the surface of the ground. The tendency hitherto has been to plant trees too deep, with the idea that in dry seasons there may be no lack of moisture. Collar rot, rotting of roots, stunted growth, are all due to this, and to the same cause must be attributed the loss of many fruit trees. Deep planting, insufficient pruning, deficient cultivation, neglect of pests all bring about failure.

In planting note that with heavy soils trees should be planted a trifle shallower than usual and *vice versa*.

In careless planting a deep narrow hole is sunk into the ground, the tree is let down with its roots twisted any how, and covered with soil, or, worst of all, soil with stable manure poured over them. If the ground is at all heavy the roots with difficulty penetrate through the wall of such a hole, the earth packed round the bark will prevent the bulk of the tree expanding, the bark will lose its elasticity and will set tight round the tree which will either die of collar-rot or will always be stunted and live a miserable life.

On the other hand too shallow planting results in the tree being blown down or its roots affected by the heat of the sun which in dry weather will effectually desiccate them.

Between the two extremes lies the right way of setting a tree.

If the weather be dry at the time of planting, it is advisable to pour a bucket of water around the stem to settle the earth well on the roots.

Mulch the ground about the newly-planted trees with a light coating of stable manure or of straw.

Manures are sometimes used at the time of planting for giving a good start to the trees, but avoid putting farmyard manure under the roots of the plants, as it would in many cases

attack insects and favour the growth of parasitic moulds that would be injurious to the tree. Whenever farmyard manure is used, it should be in the form of a mulch on the top of the soil as its benefits will then be twofold: the plant food it contains will be washed from the surface down to where the roots are established, and it will act as a screen to prevent evaporation of moisture and smother weeds round the trees. A couple handfuls of phosphates and potash manures mixed well with the earth round the roots prove of great value.

On freshly-cleared ground it is an excellent plan to spread 6 or 7 lbs. of lime round the stakes marking the places for the trees. This will correct the sourness and stiffness of the soil and induce a healthy growth.

An important operation that now remains to be performed is the cutting back, or shortening in, of the newly-planted tree, which would otherwise be checked in its growth and often perish. No matter how carefully a plant is lifted, many of the fine feeding rootlets are torn and bruised, and the feeding capacity of the tree is no longer in keeping with the amount of shoots it carries, and unless the superabundance of these is cut back and the balance re-established between the feeding and the breathing and evaporating organs of the plant, it will make a miserable struggle for existence and in many cases perish.

THREE CHENA CROPS.

[The following extract is from a lecture by Mr. J. M. Orpen, Administering Agricultural Department at Salisbury, Rhodesia, on "The Diet of Native Labour," published in the *Agricultural Journal* of Cape Colony. The three chena crops referred to are *Andropogon sorghum* (Karal-iringu), *Eleusine coracana* (Kurakkan), and *Penisetum typhoideum* (Kambu).]

Kaffir corn or great millet is known in Science as *Andropogon sorghum*. It is less used in Mashona land than some smaller grains presently to be mentioned. It may be used, as it is used by Kaffirs and Basutos, both boiled whole or after ridding it of the husk by stamping; the meal is generally used boiled as porridge or sometimes in a much thicker tough mass which may be called bread; or it is made into "leting," a fermented non-intoxicant or again into the intoxicating "Kaffir beer." The grain is much grown through a great part of Africa and Asia, and more or less in Europe and America.

There is one other way of making a very light, easily digestible, nourishing food from Kaffir corn which I had better mention. It is the food which the Bosutos always use on long tramps. I have used it myself. They call it "dipabi." To make it, Kaffir corn is parched in a pot highly heated over a strong fire. The grains generally burst open with a jump and turn themselves more or less inside out. Colonists call this "springing," and they call such grain *sprung* grain, i.e., sprung Kaffir corn or sprung mealies. In America it is called "popping

corn." This the Basutos grind with a very little salt; they carry it in small kid-skins on their backs when travelling, or in leather bags on pack animals. It is simply chewed with an occasional sip of water.

In December, 1873, having suddenly received orders to that effect, I called out a little army of about 200 native mounted infantry to co-operate with other forces against Langalibalele. We had it in prospect that, before reaching our food supply, we should have a fortnight's march up and down the highest mountains in South Africa, the Maluti of Basutoland, a then uninhabited part of that country. I ordered all the women in the neighbourhood to prepare "dipabi" that night, and I provided a little salt to grind with some of it, and a little sugar with the rest. It was cheap; the whole expedition of six weeks' duration cost the Government £1 per man, with his food, horse and ammunition. On this "dipabi," and meat killed on the road, and but sparingly used, we marched, generally leading our horses, and walking and running as mounted infantry should, till we got into the inhabited part of the north of Basutoland. The men did excellent marching, and could have done so without the meat. I mention this to show another way of giving variety with the same article of food. I have heard of Basutos marching hundreds of miles on "dipabi" alone, carried on their backs. I have often wished our sometimes stunted soldiers marching near Basutoland could have had it. In any case it gives variety. I am sure there is considerable chemical change in the parched and burst grain, and that analysis would easily show the reason of its nutritiousness.

Rukweza, or Rapoko (known in science as *Eleusine coracana*), is a very small, hard, red grain, looking like Kaffir corn, but from a wholly different, low-growing plant. It is said the Mashonas have six varieties of it differently named. I learned from Mr. George Watt, a Government officer stationed in the Indian Museum, Calcutta, whose special duty it is, as Government "reporter," to investigate matters connected with economic products, that this grain and munga (of which presently) are both largely grown and used in India as articles of food, but are supposed to have been introduced from Africa. They are probably the original food grain of Mashona-like tribes of Central Africa, and, like other grain, developed from a grass. I learn also that *Eleusine coracana* is now much grown in Japan, so it is extending its range, and suits a wide range of climate. Under European cultivation "rukweza" grows much later, tillers much better, bears more and develops larger grain than when cultivated by natives. Probably, like maize and "pedigree wheat," it might, by repeated selection and careful cultivation, be bred to have a less flinty and a thinner husk, while its size might be progressively increased. At present its diminutive size and hardness give it an advantage in one respect:—it is impenetrable by weevils. It appears to me the most nitrogenous of farinaceous grains. Natives consider food prepared from it more nutritious and satisfying than that from any other grain. Rice-eating

natives from other countries quickly learn to prefer food prepared from "rukweza." It and "munga" can be sown late, after other native grain crops show they will fail from drought, locusts, etc., so they are anti-famine crops. As yet, a disadvantage in these two crops and Kaffir corn is that winnowing them is a slow, laborious, difficult process. They do not lend themselves to present methods of machine-threshing or milling. I propose to submit to the Scientific and Technical Department of the Imperial Institute specimens of these three, in the grain and in the ear and straw, for examination and advice as to the possibility of machinery being adapted or devised for threshing, grinding, husking and other treatment. I propose to place before that very strong and well-equipped Department which has been instituted to aid and advise all parts of the Empire, the following questions:—

(a) Have any systematic efforts yet been made to improve these grains, and for the above objects, and, if so, with what results?

(b) Is it probable that by careful and continuous selection for a few years with improved cultivation, the hard husk of Kaffir corn, rapoko and "munga" could be reduced to a minimum and the grain enlarged, as has been done with mealies and wheat, and with quicker maturity?

(c) Is it probable that by developments of machinery, these grains could respectively, in an improved manner, be harvested, cleaned, husked and milled, and this on a commercial scale, and that they could be cooked in a simple way on a large scale?

(d) Would it be well to have them analysed to ascertain their relative value in food constituents?

(e) How would the desired results best be promoted: by departmental experiments, or by stimulating scientific investigation, cultivation and invention by offers of rewards by Governments or Departments?

My impression is that Agricultural Departments of England, America, India and Africa and other countries, and the Imperial and Smithsonian Institutes, should cause these enquiries and experiments to be made, for individual efforts can effect little, and only slow, improvement.

When I was administering Basutoland some twenty years ago I found that for years early rains had been failing and that the staple crop, Kaffir corn, had not time to grow, so partial famine was produced. I made such enquiries as I could as to quicker maturing varieties of that slow-growing grain, and obtained in consequence, at my own expense, one variety of Kaffir corn from Abyssinia, and "amber cane" from Missouri; but I left, and could not press on the experiments.

What is wanted is to see whether this quick maturing, etc., cannot be accomplished, and whether rapoko and munga may not have serious value as, at least, a supplementary crop to save the situation when rains will not fall in time. These grains appear not only to have come to stay, but to be extending in the world's cultivation, and it would seem worth while to improve them.

It may possibly aid the Institute's department in its enquiries if I mention that I was once shown, and ate, at an isolated American Mission, a very light cake made of rapoko, and advantageously used by a person whose indigestion had been impaired by illness. The rapoko was "sprung," then well ground, and then "bolted" through some fine stuff so as only to leave a fine flour of which the cake was made. I do not mean to suggest that native labourers are to be fed on cakes.

Natives complain, perhaps with some little truth, that all their grain is rendered disagreeable or injurious to them by European methods of grinding. It must be remembered, however, that Basuto and others grind Kaffir corn without husking it, and even eat it boiled whole. At home, as I have said, the Mashona women always stamp "rukweza," etc., in stamp blocks to get rid of the hard husk before they grind it into a fine meal. They mix it with sufficient water, and boil it about half-an-hour, continually stirring it with a stick, to make their porridge. With it they use salt, which they now obtain from Europeans. They used to obtain it by burning a certain grass growing besides the rivers, putting the ashes in water, filtering it through sand, and boiling the water till a sediment of salt was produced. Each village used to have its salt manufacturer. (Native labourers will require to be well provided with salt.)

"Munga," or "nyautzi," as the Zulus call it, is *penisetum typhoidum*. It is a small whitish millet-like grain growing on a head or cob something like a large bulrush, at the head of a stalk something like that of Kaffir corn. Natives particularly dislike the meal made from this grain by grinding it in European mills; they say the porridge from it gives them internal pains and dysentery, from the presence in it of particles of the flinty husk. They only eat it at home after this husk is got rid of by stamping, and it has been finely ground and made into porridge.

THE PACKING OF FRUITS AND SEEDS

BY J. H. HART, F.L.S.,

Superintendent, Royal Botanic Gardens, Trinidad.

(1.) FRUIT.

My first experience of packing fruit for ocean transit was in October, 1873. In that year I sent a box of Nova Scotia apples from that country to England. I ventured to mention at the time to Dr. Masters "I think Nova Scotia bids fair to become the apple-producing country of the future." How far this has been realised is within the knowledge of many who have seen these apples in the English market. My consignment was a successful one; Dr. Masters reported: "They were packed in coarse sawdust and came to hand almost without a bruise." These apples were among the first, if not the first, sent to England from Nova Scotia. To-day the trade is of considerable dimensions. I mention this to show that by good packing much may be done in the way of exciting interest in new productions in suitable markets.

Some people hold that only valuable goods are worthy of good packing, and that cheap things will not pay to pack well. Such arguments are fallacious. So far as my own experience goes, whatever is worth packing at all is worth packing well, for even if the packing costs more than the article itself it should nevertheless be put upon the market in the best possible condition. Cheap and ineffective packing is dear at any price. It is clear that it is better to expend 20 per cent. on packing, rather than lose 40 per cent. or 50 per cent. of the returns owing to defective packing. West Indian orange growers have been heard to say: "We cannot afford to pack the same as the Mediterranean people." The reply is clear. "Then do not expect to get a market for your goods." There can be little doubt that in the fruit trade the profit comes chiefly in the economy with which the packing is carried out. By economy, I do not mean cheapness. It is certainly false economy to pack *fully ripe oranges* in barrels for cheapness.

With fruit, as with plants the material must be in good order. It will never pay to shake down the oranges from the tree to the ground, carry them for miles in a cart and then shunt them into a barrel. Success can never attend such handling, for all fruit must be handled as carefully as eggs. A blow that would crack an egg, will certainly destroy a fruit; and if such fruit is packed, no matter how carefully, it will assuredly arrive at its destination in bad order. To secure arrival in good condition all fruit must have been carefully gathered, and, without exception, treated in the most careful manner to prevent bruising.

Fruit also requires certain treatment previous to packing, to assist in securing safe transit. This treatment is what I would call "hardening." No fruit should ever be packed when freshly gathered, but how long it should remain must be learnt by experience, as a great deal depends upon the state of the weather. Oranges should be picked at least three or four days before packing, and laid out in single layers until all the moisture or what is known as the "sweat" of the fruit has disappeared. To pack fruit when wet or damp is to court certain failure. The full details of packing are too long to include in a paper of this kind.

There is one point in connection with temperature which must be taken into account. If fruit, such as bananas are kept at too low a temperature they become "chilled" and will rot before they will ripen. It has been frequently stated that to carry fruit successfully, it is necessary to use ice chambers. I believe this idea to be a mischievous one, and it has hindered in no little degree the problem of the safe transit of fruit. The Jamaica No. 11 mango was safely sent to England from Jamaica in 1873, when the transit took 21 days from port to port. In 1875, and again in 1891 the mangosteen reached home from Trinidad in good condition. In no case was cold storage used. Apples which reach the West Indies in ice vessels, if packed near the ice are valueless for flavour, while those brought over in well ventilated packages, stowed properly in a cool part of the ship arrive in

excellent condition, and keep their flavour for a great length of time.

The exact degree of temperature suitable for the cold storage of fruit is not sufficiently well understood. Some people take it to be at or near freezing point, while others adopt temperatures of say 40° or 50° Fah. This latter, I believe, would be a good temperature for fruits grown in a temperate climate, but if we are dealing with tropical fruits it is probably too low. Cold storage at freezing point may do for dead meat, &c., but it is not suitable for the preservation of fruit. Still, we must have *cool* storage, and how to obtain the desired temperature must be decided by ship owners and by shippers of fruit.

What is required is a well ventilated hold, maintained at a certain minimum temperature which should be some 10° or 15° below that at which the fruit matures. Fruit will stand considerable hardship, provided it is carefully gathered, well dried and well packed. It is not easy to say, however, which of these three conditions is essential. If a fruit is bruised in the picking, it is inevitably doomed to rot. If not carefully dried, it will almost as surely ferment and rot, and if squeezed or heated in the packing, it must arrive in a bad condition.

The best cases for packing oranges are those furnished with trays admitting one layer only, with bars to take the weight when set on end. A very good and serviceable case is one having a capacity of two cubic feet and divided in the centre. In a barrel the lowest row has to sustain the weight of all those above it, which may amount to something like three to four pounds per orange. *The continued use of the barrel for oranges and similar fruit helps to bring our beautiful West Indian fruit into grave discredit.*

The package of pine-apples has to be conducted on the same principle. They should never be packed in barrels but in light crates, each fruit having a separate compartment. Small and indifferent fruits are rarely worth shipping, and if in abundance should be preserved or sold locally.

Mangoes can be safely sent, if picked in the condition known as "full," so as to gradually ripen during transit. In this case, it is also necessary to separate the individual fruits, and high class fruit should be packed in the manner adopted for apricots and peaches by European growers, namely in single compartments with soft packing material.

The actual business of packing fruit is an art which only practice can perfect, and most of the failures are due to imperfect knowledge of the conditions which are necessary to success.

A common idea exists that cultivators can, by planting at certain times of the year, get fruit such as mangoes and pineapples to ripen at certain seasons. This may sometimes be possible, but I am of opinion, after a quarter of a century's experience, that the control which can be exercised by the grower over the time of ripening is small, and cannot be depended upon for successive seasons. If we could control wet and dry weather, in the same way as under glass cultivation, something might be done; but until

we are in a position to do this, the mango and pine-apple season will be in June, July and August, the coffee crop will come in November and December, and cacao will ripen in June and November, with variations of dates in accordance with the season.

There is great need for study of the possible means to get a crop of fruit out of season, for fruit out of season is well known to pay. I think however that more success will come, if the attack is carried on from a different direction. It is true that we might by withholding water imitate the dry season, and by giving water imitate the wet season; but still uncontrollable differences would yet remain, for it is clear that we could not control the state of the atmosphere surrounding the branches even if we kept the roots dry, and we could not give the dry air coincident with the dry season, during rainy weather, and if we kept a plant well watered, its branches would still be affected by the drought.

The best means to obtain the end in view, would be to seek plants which ripen earlier or later than the general crop, and by selection obtain varieties which come in extremely early, or conveniently late, and thus meet the demands of the "out of season" markets. Selection of this kind is carried out in Europe and America, and might equally well answer in the tropics if a little attention was devoted to the subject.

I have digressed somewhat from packing and transport of fruit but, I must plead the excuse, that we must know how to get our fruit before we can pack or transport it.—*West Indian Bulletin.*

(To be Concluded.)

NATURE STUDY LESSONS.

FIRST COURSE IN THE STUDY OF PLANT LIFE.

Introductory.

This first course is intended to induce school children to observe the external features of plants, as seen in stem, roots and leaves, and the modifications of leaves including the flower and fruit.

The second course will necessitate a fuller study of the structure and functions of the parts of plants.

The soil, water and air will form the subjects of a later course.

N.B.—It must be borne in mind that every fact here mentioned should be verified by actual observation. Examples are given for the sake of convenience, but where these are not at hand, others must be sought for in order to prove each statement and fix it on the memory.

In looking at any collection of trees in Nature, you will observe that they differ considerably one from another. This is due to differences in the development of the parts of the trees.

A tree may be said to consist of (1) a stem bearing, (2) roots below, and (3) leaves above. Take any tree or plant in your school garden and see if you cannot divide it thus.

Let us take the stem as the most convenient part to start with and note certain facts about it.

THE STEM.

A stem may be erect, that is it may stand upright from the ground. Most large trees have stems of this kind.

An erect stem may be unbranched as in the coconut or branched as in the mango. In the coconut observe that all the leaves are borne at the top of the unbranched stem; in the mango the stem divides and sub-divides into branches of decreasing size, and the leaves are borne by the smallest twigs. Notice the unbranched and branched stems of trees near your school; observe that some trees are more branched than others, that the method of branching regulates the shape of the tree (compare the ironwood with the banyan tree), and that some trees, like the wild breadfruit, form a denser shade than others like the suriya tree.

A stem may be hard and woody. This is the case in trees which last a long time, as most forest trees. Many of these hard stems consist of wood yielding useful timber for building and other purposes. The Forest Department looks after such trees in our forests, and sees that the supply of useful wood does not become exhausted. Make a list of as many useful woods as you know, and say what they are used for.]

A stem may be very tall as in the red-flowered cotton tree, or inclined to be short as in the cashew-nut tree; it may be thin as in the arecanut or thick as in the coconut, or very thick as in some timber trees as Hora; it may have a rough bark as in mango or smooth as in the gauva.

But there are many stems which are more or less soft and pliable. In the young stage the stems of all trees are of this character, while plants which last only for a short time, and do not grow to any size, have also soft stems. Most of the vegetables you grow in your school garden are instances of the latter, e.g., spinach.

A stem may be contracted, that is undeveloped in length, so that the leaves are more or less brought together, as in lettuce, or the common "aloe." Observe the plants with contracted stems near the school, and notice that before they flower their stems become elongated and bear leaves separated from one another. This is well seen in the lettuce.

Some stems are so slender that they cannot grow erect. Such stems may creep along the ground, as in the case of the sweet potato, or support themselves by twining round other trees as does the common long bean.

The long bean, like most twining plants twines from left to right. [Do you know of a plant that twines from right to left? If not, try and find one.] The grape vine has got some of its branches specially adapted for supporting itself. These branches are in the form of coils which attach themselves to any support. In the common creeping Bignonia the branch is modified to form a claw-like structure consisting of hooks for climbing, [Hence the specific name of the plant, viz., *unguis-cati*, signifying the claw of a cat.] All these structures should be carefully examined. Leaves are also modified to enable stems

to support themselves, but of these we shall speak later. Some trees (like the Allamanda) have no special arrangements for climbing but scramble up other trees for support.

The stem of a tree sometimes bears sharp structures which are modifications of parts of the stem. The thorn of the orange is a strong woody structure, which, much as you may try, you cannot break off with your hand. The prickle of the rose on the other hand is a superficial outgrowth that can be removed without very great difficulty.

Stems do not vary much in colour, being generally green when young and brownish when old, but we have a red stemmed spinach. Do you know of other exceptional cases?

Stems are usually cylindrical. Some are square (madurutala), or triangular as in many sedges (e.g., Tunhiriya). Exceptionally it is very irregular in form as may be seen in the different varieties of Prickly Pear (Katupathok) which takes very strange forms, being flat and leaf-like in the common variety.

The stem is, as a rule solid, but some stems are hollow as in the bamboo (*una-gas*).

Besides the stems that we find above ground, we have also underground stems, some thin and long as in the common conch grass (*etora*); others thick and short as in ginger (*inguru*); others again much swollen and sometimes forming large masses as in the yams. Such swollen underground stems can be distinguished from swollen underground roots like the radish (*raba*) or manioc (*manyoka*) by the former having scaly leaves as in arrowroot (*hulunkiriya*) or minute buds as in the potato (*arthapal*). In the onion the stem is reduced to a very small structure round which the succulent leaves which envelope it are closely packed.

THE ROOT.

The parts of a plant which grow underground are generally spoken of as the roots. I have told you, however, that there are cases of underground stems such as the common conch grass (*etora*) which is such a troublesome weed because every piece of the underground stem left in the soil gives rise to a new plant. True roots have not this power of growing.

But there are also cases of roots which are produced above ground. Such are the hanging roots of the banyan (*maha-nuga*) and the thick roots given out by the screw pine (*wetakeyia*), which tend to reach the ground and become fixed in it. Notice that the hanging roots of the banyan eventually become woody and stem-like, so that the tree appears to be supported by a number of columnar stems. The old underground roots of large trees also become hard and woody like the stem, and give rise to new plants, like the breadfruit tree and other trees that you may know of. Hard woody roots sometimes grow out of the ground almost plank-like structures as in the Java forming (*kekuna*).

When speaking of plants with climbing stems I told you that there were other arrangements for climbing besides those I mentioned in the lesson on the stem. Well, plants sometimes climb with the aid of roots. Pothos (*potawel*) commonly found on jungle trees, climbs by means of its roots which attach themselves to the back of trees. The

main roots, however, are in the ground, while the climbing roots—which are quite distinct and different in appearance are specially adapted for clinging on to other trees. But there are plants which have no need to have their roots in the ground at all. Certain plants are known as parasites because they live on other plants. An instance of this is *Loranthus* (*Pilila*) so common on old mango and other trees. Plants such as this allow their roots to penetrate into the stems and branches of other trees on which they depend to a great extent for their nourishment. These useless parasites which rob useful plants of their food, and so weaken them, should be always carefully removed as soon as they are found.

Plants like orchids (*e.g.*, *wesakmal*) are spoken of as "air plants," because though they grow on other trees they get their food from the air and the solid particles brought to them by the wind.

Some underground roots become thickened and swollen, *e.g.*, the radish (*rabu*) and manioc (*manyokka*).

There is a very large class of trees which when young have one main root from which all other roots spring. Pull up a young *jak* (*kos*) plant and you will see that this is the case. The main root will appear as a continuation of the stem. There is another large class of plants which start with a number of distinct roots at the bottom of the stem. Pull up a paddy plant and compare the roots with those of the young *jak*. Plants like the paddy have no main root.

[Native names of plants not given above: Coconut, *pol*; mango, *amba*; ironwood, *na*; red-flowered cotton-tree, *katu-imbul*; cashew-nut, *caju*; arecanut, *puwak*; spinach, *niviti*; lettuce, *salada*; aloe (American) *goni-gas*; long-bean, *mé-*

karal; grape, *mudarapala*; allamanda, *wel-rukattuna*; orange, *dodan*; wildbread-fruit, *del*; sweet potato, *batala*.]

GENERAL ITEMS.

The following is a hint worth the attention of growers of the Cauliflower:—tying up is the main thing, for no matter how large they are, they will not sell well unless snow white; but it is not only tying up that does it, but vigorous growth and plenty of leaves shading the head. There is quite a knack about tying up. If done too soon or close they become stunted; if not tied close enough they become discoloured and look bad. The best way is this. Take a ball of string and wind it round from hand to elbow, then cut open the skeins, when the cut portions will be found of the required length. Gather just enough leaves to shade the head perfectly and no more than necessary, and tie them as low down as possible, just so low that the string is a trifle above the head, thus allowing the tops of the leaves to spread out somewhat in the air and not retard the growth of the plant. Tying should not be done till the Cauliflowers are about the size of an egg, or larger if the plant is extra heavy and the head well covered with leaves. The beds should be gone over about thrice a week.

In Edinburgh city a cattle dealer named Robert Stewart was fined £50 for "being the owner or consignee of a live cow and live heifer with the intention of disposing of them for food, while they were diseased and unfit for food."

How many of our local cattle-dealers deserve a similar fine!

COLOMBO, SEPTEMBER 1ST, 1902.

No. 3.

PLANTING IN TRINIDAD.

(Extracts from Annual Report of the Superintendent
Royal Botanic Gardens for the year 1901-2.)

BEE KEEPING.

BY desire of His Excellency the Governor the Superintendent undertook to form an Apiary on the Station, and with a view of securing for the Colony a good class of Bee, tested Italian Queens were introduced from Jamaica; the majority of which were distributed amongst local bee keepers, sufficient only being retained at St. Clair for the formation of breeding Colonies. These have done well, and there are now several good strong Colonies of the introduced kinds, from which it is hoped shortly to raise sufficient Queens for local distribution. The common or black bee was used as a *nucleus* for the young Colonies raised with the imported Queens. When strong enough the latter were removed to suitable protection at the old Garden to prevent hybridization. Some excellent "sections" of honey have been obtained during the flowering season of the logwood, and the honey pronounced of fine quality, but the supply of honey is far from being abundant as the bees do not bring in large quantities. The young men in training at the Station assist the Superintendent in the management, and take great interest in the work. A short report on bee keeping was prepared by the Superintendent at the request of the Agricultural Society.

ECONOMIC PLANTS (RUBBER).

Castilloa elastica, planted in 1893, is now over 25 feet in height, and some of the trees have stems 5 inches in diameter. It has been found on test that Rubber fluids or *latex* from these young trees produce rubber, inferior in quality to older trees. Some few years ago, I published an informal account of an analysis of a year old tree, made by a gentleman who had undertaken the study of the *latex* of *Castilloa*, and he reported finding 8 per cent. of rubber; but it is now evident that although rubber material may have been

found, it was of inferior quality, and only the larger trees eight or ten years old, can be depended upon to furnish rubber of good quality. It was anticipated that rubber material could have been extracted from one year old trees, but this has proved illusory, for although chemically, the rubber is there, yet it is not in such a condition as to make it of market value and up to the present no chemical process has been devised which will change the soft and sticky material obtained from young trees into the hard and elastic produce afforded by mature trees.

Plantations of this rubber in Trinidad and Tobago are now yielding large quantities of seed annually, and consequently the demand at the Experiment Station, has largely decreased. Good seed can be obtained according to season from March to June of each year. The seed has, however, a very fugitive vitality, and even with the best packing, it is very difficult to send it long distances in good order.

PARA RUBBER.—*Hevea brasiliensis*.—Our plants, put out in 1893, at the same time as the *Castilloa* trees, fully equal the latter in height, but have not so large a stem circumference. They are, however, doing well, and will certainly thrive in our climate. Our crop of seed from original trees was very small during the official year 1901-2. From recent literature it is gathered that this tree thrives in South America in interior districts, and not only on flooded river sides as has been formerly understood. The occurrence of these trees in the deltas of large rivers is said to be due to the wash of the seeds from higher grounds. If this is actual fact (and the authority appears reliable) it will give considerable encouragement for inland planting. Confirmation of this report is afforded by Dr. Bovallius who brought down seed of trees found on the upper reaches of the Orinoco, plants of which are now at St. Clair and growing freely. It may be stated however that the seed, as received, was much smaller than that grown at lower altitudes and therefore it is possible, that the high land *Hevea* may prove to be a new variety.

WEST AFRICAN, "IRE," OR LAGOS, "SILK RUBBER."—*Funtumia elastica*.—Staph. These trees have made splendid growth during the year. Some are

now over 20 feet in height with a stem diameter of four inches though not yet four years old. Considerable variation has been noticed in the form of the seed vessels among the trees of our plantation, but it may be, that is only normal seed variation, but at the same time there appears some reason to suspect that two or more species may be found to be present. One of the forms, has its follicles long, narrow, and pointed; while the commoner form has follicles stout and thickened at the apex. The quality of the Rubber afforded by each kind has not been, as yet, well tested; but it appears on superficial examination to be of equal value. Latter tests will decide this. The trees have given a fine crop of seed during the past season, and a large quantity of plants have been raised. From present appearances it is a tree that will stand, probably, more hardship than any of the other Rubbers, as it can bear exposure to the sun although it does not grow fast in such situations. In my paper on Rubber Planting published in the West Indian Bulletin (Dulau & Co., London, this rubber is more fully discussed. A section of this rubber has been planted at three feet apart and in the full sun, in order to test its growth under the conditions of close planting and growth without shade.

CEARA RUBBER—“*Manihot Glaziovii*.” Our soil at the experiment Station appears quite unsuitable for the growth of this tree, as it makes little progress. In some districts of the Colony however, it is reported to be growing well.

LANDOLPHIA SPECIES—*Landolphia* give excellent rubber fluids which easily coagulate. At the experiment Station several species are growing well, planted against trees of “*Pithecolobium Saman*” Several kinds are under cultivation, but it will be some time yet before any quantitative returns can be given, as is the case with many tropical products.

FIBRE PLANTS—A stock of Fibre plants have been kept on hand. This includes “*Agave rigida* var. *sisalana*,” the “*Sisal Hemp*” which grows quickly and well. This plant is established in Several Stations in Trinidad and Tobago, but as yet, there is no output of Fibre. Several species of *Sansevieria* are also in cultivation. This affords the Bowstring hemp of Commerce “*S. Longiflora* is well acclimatized, and is now in some demand for planting. “*Musa textillis* or “*Manilla Hemp*” is grown in small quantity only.

CITRONELLA GRASS—“*Andropogon Nardus*.” This is seen to differ much from the common “*Lemon grass*” “*(Andropogon Schoenanthus)*” usually found in the West Indies and its oil is also found to differ considerably from that obtained from the latter grass. Specimens of each were manufactured in illustration of the paper read by the Superintendent at the Annual Conference, Barbados, previously mentioned. The grass grows readily here, and flowers freely while the Common “*Lemon grass*,” seldom produces flowers.

CAMPHOR—*Cinnamomum Camphora*, *Nees*.—The interest arising in Camphor production, owing to certain monopolies in Formosa, has caused enquiry to be made, as to the possibility of growing Camphor on a commercial scale, in other places. In Trinidad it grows rapidly but never makes a large tree. The wood contains a fair amount of camphor, and some camphor oil, specimens of which were lately manufactured at St. Clair, an account of which was included in a paper read at the Annual Agricultural Conference held in Barbados, January, 1902. The Camphor was of good quality, and the Camphor oil was excellent, more of the latter being produced from the young wood than from the older stems. The sample made, is probably the first on record of West Indian manufacture. It is intended to grow a plot, with a view of testing the feasibility of growing it on a commercial scale for camphor and for oil. Trees planted three years ago are now ten feet in height. It propagates readily by layers.*

* A recent account of Ceylon experiments appears to show reasonable hope of establishing a remunerative industry in Camphor.

MULBERRY—*Morus rubra*.—This tree grows into bushes of several feet in diameter and ten or twelve feet in height. It may be of future importance, were silkworm culture taken up in this island.

LONG PEPPER—*Piper longum*.—This pepper grows well and rapidly covers the ground, coming into bearing very quickly.

BLACK PEPPER—*Piper nigrum*.—The section devoted to this plant has made fair progress, but the plants have not as yet reached their fruiting stage. The small plantation at the old gardens have however given annual crops, and the fresh seed has been in demand by European seedmen for raising plants intended for West and Central African plantation. It is not readily obtainable elsewhere than in Trinidad where it is first fruited, on this side of the world.

VANILLA—*Vanilla planifolia*.—The Vanilla is planted to cover trees of *Erythrina Corallodendron* a dwarf growing Immortel. It has made fair progress, but has not yet reached its flowering stage.

PIMENTO—*Pimento officinalis*.—The plants of this spice tree, are over ten feet high, at three years old, and are evidently true. The seed was procured from Jamaica. The popular idea that seed will not grow unless first eaten by birds has therefore been disproved. It is curious to note that while *Pimento acris* (the West Indian “*Bay Tree*”) is common on the island, the true Pimento appears to have been unknown here until the recent importation. The plants are doing well, and are very healthy and vigorous and may be expected to fruit in a year or two.

IMMORTEL—*Erythrina Sp.*—A small and irregular section on the boundary of the Station has been devoted to the growth of the two species of *Immortel* which are used almost exclusively for shading Cacao estates. One is known as the *Anauca* suitable for highlands, and the other as the *Bocare*, suitable for lowlands; Botanically known as *Erythrina umbrosa* and *Erythrina velutina*. Discussion has been current on the nitrogenous value of the flowers of this tree during the year, and the manurial value of the flowers has been placed by the Government Analyst of Trinidad at the very high figure of 6%.* This has however not yet been confirmed by independent analysis. As shade trees there can be no possible doubt of the value of the *Immortel* for Cacao estates, and no apology is needed for their use, but the fact remains, that good cacao is grown under other shade; and moreover we constantly receive enquiries for substitutes that will give a remunerative return, as the wood of the *Immortel* tree is useless even for fuel. The *Saman* or *Zaman*, a Central and South American tree, is coming gradually into use on some estates, as it is not so liable to fall and damage the cacao. The Nicaraguan tree—*Gibberia maculata* has been planted at the station, and grown after a certain plan, it forms an efficient shade for cacao, as may be seen from the results obtained by its use. *E. Corallodendron* is in use as shade for *Piper nigrum*, and *Vanilla*, as mentioned in another paragraph. In a recent letter, a prominent planter regrets his inability to manure Cacao, shaded with *Immortel*; owing to the shade tree abstracting the value of the manure before the cacao tree has time to benefit by its application.

CLOVE—*Caryophyllus aromaticus* L.—one tenth of an acre is devoted to the growth of Cloves. The same difficulty found with the Mangosteen, is experienced with the Clove. They grow well when established, but are very difficult to rear through their juvenile stages. Our section has several plants growing fairly well, but it needs many supplies.

CINNAMON—*Cinnamomum Zelanicum* *Breyn.*—The Cinnamon plot is now well established and the trees are growing freely.

TOBACCO—*Nicotiana Tabacum*, L.—Several varieties have been grown, but as the crop is now undergoing fermentation, it is too early to report on its quality. The leaves of some varieties are of good

* Since reduced to 4.3 per cent.

size and texture, and if it cures well will serve for good Cigar Tobacco. The crop of 1901 season, which finished curing in the early part of the year was a small one. It was of the Virginia variety, which appears to stand our climate better than the finer leaved kinds, the leaves of the latter becoming spotted by the weather.

TUMERIC.—*Curcuma longa*.—A plot of this yielded at the rate of over two tons per acre, of the green tubers.

BHABUR GRASS.—*Ischnemum angustifolium*.—The crop of plant harvested, showed produce at the rate of 6,600 lb. per acre of the dried grass.

GINGER.—*Zingiber officinalis*.—A plot devoted to this product yielded at the rate of ten tons per acre, of the undried rhizomes are of excellent size. There can be little doubt, as Mr. Meaden proved long ago at the Convict Depot at Chaguana; that Ginger can be very successfully cultivated in Trinidad. It must however be harvested and cured in the dry season.

COEA.—*Sterculia acuminata*.—this plant grows fairly well at the station but as it takes some years to come into bearing, no results have yet been obtained.

FRUIT TREES.

MANGOES.—*Mangifera indica*.—I reported last year that a consignment of Mango trees had been received from the East Indies. Subsequently, an additional consignment was received, which arrived in good order. Those plants which were healthy on arrival made good progress, and fourteen trees are now planted out to the North of the office in permanent positions, and making vigorous growth. Eleven more are now ready for the open ground. These consignments, coming as they have from several different provinces, are expected to give us varieties differing from our West Indian seedling kinds. The sale of the varieties of named Mangoes has been large, and a decided choice has been made of the grafted varieties in preference to seedlings, which cannot be depended upon. Some of our best young trees three years planted gave a few fruit last season, which showed them true to name. It is to be hoped that the Mango trees will prove more prolific in the St. Clair soil than at the old garden where many trees exist which have not fruited for years. The trees are old and the soil worn out, as might be expected, cultivated as they are on land which has been planted since 1824 or 78 years. A large number of stocks were grafted during the year, and plants may be obtained of most of the best named varieties formerly described in *Bulletin* reports. The section devoted to the growth of seedling varieties, raised from the best imported kinds, has made good progress; and it is hoped will give fruit one year hence.

ORANGES.—The imported kinds of Orange secured some few years since from Florida and planted at Experiment Station in 1898, gave a good crop for their size, during 1901; enabled their quality to be correctly estimated. Many of the trees have borne Oranges of excellent quality, suitable for market in any part of the world. Those known as "Pine Apple" Runby and St. Michael's being especially good. An Orange of the Tangerine type, and evidently a variety of *Citrus nobilis* has a beautiful coloured interior and is of excellent flavour, but appears to be less vigorous than others. The variety of Tangerine imported at the same time, is far from being equal to the Trinidad kinds. Our latest Orange to ripen is a variety called "Mandarin," a small fruit with a deep coloured rind. When immature, this is very acid, but if allowed to hang upon the trees, it becomes a most delicious morsel. As mentioned in previous reports the words "Mandarin" and "Tangerine" are applied to a numerous variety of seedling fruits, and similar fruits are named differently in the various districts. A seedling Orange produced from a Grenada variety of *Citrus nobilis*, gives very large fruit with a thick spongy skin, but the interior parts are simply "bags of juice" sweet, with a

slight, though not unpleasant taste of the bitter flavour of the ordinary Shaddock, which the fruit is actually resembles in form. Several of the named kinds have been successfully budded on sour Orange stocks, and are now strong plants, for which we have more applications than we can at present supply; but measures are been taken to meet the demand. Many of our growers appears to doubt the feasibility of sending Oranges to distance markets from Trinidad. Oranges have however been successfully sent to England in ordinary packages by Royal Mail Steamer for several years in succession, and there can be no doubt that properly prepared and packed they can be safely transported in good order.

The following rules in packing should be complied with to ensure this result:—

1. Pick on a dry day, without bruising, "stem cutting" the Orange from the tree, not pulling or shaking down the fruit. Any Orange which falls, should be rejected, as it will assuredly spoil others.

2. Dry for two or three days by spreading carefully in a single layer on a boarded floor, where there is plenty of air—until the skin becomes slightly leathery.

3. Wrap each Orange singly, and pack in boxes containing not more than a single cubic foot in each division, and pack tightly so that they do not bruise each other in transit. The boxes should be made with air spaces between the slats. It is important to remember that "Oranges are as tender as eggs" and should be handled as carefully.

SHADDOCK—*Citrus decumana* L.—Some years since the Department obtained grafts of the pink fruited Shaddock. These were grafted on seedling stocks and two plants were obtained. These have fruited the first time during the past season. Mr. McGillvray of Tobago, was good enough to present these, and sent us at the same time a fruit which was certainly the finest of its kind in size and flavour which has been seen here. We have been successful in getting some budded plants from these trees during the year which are now on sale in the nurseries in limited quantity.

CITRON.—*Citrus medica*.—A few years ago seed was presented to the Department, of the "Cedrat" or true Citron of Commerce. These were sown and the plants have fruited. Only one however is true to the original. It is intended shortly to take buds from this plant, so as to obtain the best fruit possible, as it is seen that seedling varieties are unreliable.

BERGAMOT ORANGE.—*Citrus Bergamia*, *Risso*.—Seed was obtained of this Orange several years ago from Southern Europe, and plants were raised sufficient to plant one-tenth of an acre. These appear to vary largely, and it is probable that but few will be found to produce fruit of the required character. To obviate this, a small consignment of rafted Bergamot plants was imported, which it is hoped will afford the true *perjume* producing fruits. These will be propagated by budding and grafting as soon as the quality of fruit is determined.

LIMES.—A section of our best seedling Limes was planted in 1898, and the trees are now coming into bearing, selected varieties will be propagated by budding for distribution as stocks are available.

THE TRINIDINE LIME.—*Citrus medica*, *var. acida*.—This is a variety of the lime, as large as an ordinary Sicily lemon, of like flavour, but slightly different from the ordinary Lime, and containing over twice the quantity of juice. This variety is one which appears to have originated at the old Gardens, where it was found established some fifteen years since. I am of opinion that this would become an extremely popular fruit in English and American markets once well known. A tenth of an acre has been established but here again was found the impracticability of reproducing Citrus fruits true from seed. Variation is considerable, and a selection of the best must be made, before propagation by budding is attempted.

LEMONS.—*Citrus medica*, var. *Limonium*.—A section devoted to Sicily Lemons has shown but slow growth and considerable variety, and the practice of budding and grafting, must be again applied to ensure the production of good marketable fruit. In the operations of budding and grafting, the seville or Sour Orange stock has been exclusively used; as this is said to resist the attack of the fungus commonly known as the "Mal-de-Gomma" or "Koot rot," from which many trees of the Genus suffer very considerably notably the seedling "Tangerine," of which over 25% have succumbed during the present dry season notwithstanding treatment with copper solution. Some plants were imported budded on stocks of *Citrus trifoliata*, a stock hardy in a cool climate. This stock itself is tender here, and the growth of the plants show that it is unsuitable for our work.

MANGOSTEEN—*Garcinia mangostana*, *Linn.*—In some places this fruit is confused with the Mango; a variety of the latter fruit without fertile seeds being actually known as the Mangosteen. *Spondias dulcis* the "Pomme d'or" or Golden Apple, is also known as Mangosteen, in some of the West Indies. The true Mangosteen however belongs to the order *Guttiferae*, while the mango belongs to *Anacardiaceae*. The Mangosteen is given in Index Kewensis as a native of Indian and Malay States. It was introduced to Trinidad many years ago, and there is now a large tree which bears annual crops of fruit, more or less, in accordance with the seasons; sometimes several hundreds, other years only a few dozens. The fruit has been estimated to be quite equal in size and flavour to produce found in the markets of the East, by those who have been resident in both countries.

COFFEE.

HYBRIDS.—The distinct varieties, described in my last report as having been raised from home grown seed of *Coffea stenophylla*, having fruited this year. The berries differ much in size from the type, but are of the same purple colour. The beans when cleaned are about the same size as ordinary *C. Arabica* while the type is much smaller than the variety. The berries are fairly large, with a thin skin, but the interior parts have some characters in common with Liberian, but intermediate between that species and *C. Arabica*. The beans are dark in colour but their inner or "silver skin" distinctly resembles that of Liberian though considerably modified. Roasted and tested for flavour, it was found to be indistinguishable from good Arabian. The varieties raised, vary somewhat in size of bean, and in the prominence of the Liberian character. There can now be little doubt that these Coffee plants are natural Hybrids between *Coffea stenophylla* and *C. Liberica*, as previously anticipated, but there is no direct proof that they are really so. Some of the varieties are more fruitful than others and it is intended to give the best varieties local names, and propagate them by grafting. One has been named "Commissioner" Coffee, and several successful grafts have been taken from this kind. The stock used being the strong growing Liberian. This strain is of course unknown upon the London market as the trees are special individuals, selected from seedlings, having characters differing from any known kind. They are in fact, NEW COFFEES, which it appears highly desirable to grow on for experiment. The value of the coffee from a grower's point of view is that it grows faster and better and fruit earlier than any variety of *Coffea Arabica* and does not require so much shade, while it is not so tall growing as the Liberian, that is to say, the varieties appear to promise a hardy and easily cultivated strain of considerable value.

"CREOLE COFFEE" *Coffea Arabica* varieties.

1. Mocha.
2. "Hybrid" Mocha.
3. Maragogipe.
4. Minerva, or narrow leaved.
5. Ordinary "Arabica" or Creole.

These plants have grown well where sufficient shade has been available but in some sections where there

was not sufficient shade at certain times of the day the growth has been much retarded.

As the experiment stands at St. Clair, it is readily seen that whenever the sun obtains access at the hours mentioned, the growth is feeble, weak and wanting in vitality, and proves that coffee requires a certain amount of shade at this elevation. The more robust Hybrids and Liberian can stand much more sun than the Arabian varieties. The most fruitful of our Arabian varieties are the 'Hybrid Mocha' and 'Minerva' coffees. The 'Maragipe' is a large beaded coffee, but is wanting in colour in ordinary seasons. The type trees of *Coffea stenophylla* produced good crops, and the trees are healthy, and appear well adapted for cultivation.

COFFEA RUSTRA, *Linden*.—This is a new species of coffee from The Congo. It has flowered and fruited during the year. It produced large clusters of pure white flowers having an exquisite perfume, and bears small globular red berries. The crop produced has all been used for seed. The tree has somewhat the habit and size of leaf of Liberian coffee, but is quite distinct from that variety. It is reported that the flavour of this coffee is superior to many other species. This trees have again flowered, and a larger crop is anticipated during the coming season.

CACAO.—*Theobroma Cacao* and other species.—The section devoted to Cacao has done remarkably well, and several Cacao planters have expressed a high opinion on the method of cultivation pursued. Plants of pure Criollo are now bearing for the first time, and are giving excellent fruit. Distinguishing characters of this variety are, the white interior of the seeds, and the bottle shaped neck of the fruit. It has been found that 'outside colour,' red or yellow, has little or nothing to do with variety, as red comes from the seed of yellow, and yellow from the seed of red pods. A Venezuelan variety has done extremely well and is also carrying its first crop.

Theobroma pentagona is also in fruit. This plot was planted in December, 1898, and is consequently just over three years planted. It is shaded partly by *Pithecolobium saman* and partly by *Gliricidia maculata* the Nicaraguan shade tree. Our soil being a dry one, it is necessary to give some protection to the roots. This has been effected by covering the ground with vegetable refuse as a mulching, which has been effective in preserving the trees during a lengthy dry season. Grafting has been successful with all of the varieties, and there are now on hand, plants grafted upon stocks of *Theobroma bicolor* and *Herrania albiflora*, a genus nearly allied to Cacao; and a further attempt is now being made to graft upon stocks of *Cola acuminata*. The future must decide whether any advantage will accrue from the use of these stocks but the experiment so far is a successful one. I am more convinced daily that the practice of grafting Cacao of the best kinds will result in the production of samples for market, far superior to any now harvested. The process followed is to select trees having 1st, plenty of vitality, 2nd, of good size, 3rd, good croppers, 4th, bearing beans of the best quality. Plenty of such trees exist on many of the Trinidad estates, and it stands to reason that if a plantation of this kind is raised by using grafted plants a uniform sample of produce would be obtained of the highest excellence.

RAMIE.*

A. RIVIERE.

DURING the last fifty years Ramie and China-grass have been regularly cultivated in the French colonies, as well as in other countries, particularly in India and the Dutch colonies. During the American war the European manufacturers tried this textile material, but the production being insufficient, and the treatment difficult, the use of it soon came to

* Extracts from the Report of the International Conference held in Paris in 1900. M. Maxime, Paris, 1901.

an end. The Universal Exhibition of 1878 gave it a new start, however, but the trade was still stopped by the inherent difficulties of decorticating and degumming the plant. It was thought that the Exhibition of 1889 would provide a solution of the difficulty, but the results of the international Congress did not modify the position of the subject which was interesting the whole Colonial world. It is evident that the peculiar glutinous and insoluble matters which surround the fibres in the cortical layers present great obstacles to the mechanical and chemical treatment necessary for degumming. It made one fear that because the Ramie could not be prepared in a perfect and economical manner it could take no particular place in the textile industry, which was already well supplied with the principal known fibres—hemp, flax, and cotton. In other words, a new textile, dear and difficult to use, equal perhaps to flax but inferior to silk, was not wanted.

This was the situation in the French industry, particularly as our production of hemp and flax sufficed for its requirements. But this opinion altered sensibly in Europe when our crops were in danger of failure, and people began to ask if some day we should not be unable to obtain cotton, which our colonial possessions do not produce. The supply of textile raw material might fail from some cause or other, and already the cultivation of flax and hemp has nearly ceased in France, in spite of the premiums offered, which, in 1889, amounted to 2,500,000 francs (£100,000), equal to 92fr. 50c. per hectare about 30s. per acre.) France would then have to obtain from abroad all the raw materials used in her manufactures, and the question arose whether her colonies could not furnish to the home factories Ramie fibre, which seemed to be an excellent material, and could be largely used. Similar opinions seemed to influence other nations in their attempts to utilise Ramie. All colonial agriculturists seemed to think the easy cultivation of this perennial plant would admit of its competition in certain cases with cotton, while the manufacturers also hoped to find in its textile fabric an exceptional quality and firmness. The situation has thus changed. Ramie is really wanted by the textile trade, and its use cannot be prevented merely by some difficulty in its defibration—as that will be overcome.

The case is as follows:—The China-grass supplied by the Chinese to European manufacturers is insufficient for their needs. Its price is very variable—often very high. This raw material is sent to our market in the form of strips, which have been obtained by sundry manual operations.—scraping, soaking, drying,—which have caused it to lose a large quantity of the gum.

The manufacturers ask:—

- (1.) If the culture of Ramie, which is at present confined to part of Central Asia, cannot be extended to other localities having similar or more favourable climate.
- (2.) If the manual labour of the Chinese can be replaced by mechanical or chemical processes, so as to produce a cheap article, and at the same time preserve the quality of the fibre.
- (3.) If the cultivation and manufacture of Ramie would pay, based on a similar price to that of China-grass, or even higher than the latter, according to the state of preparation.

DIFFERENT KINDS OF RAMIE.

There are two kinds of Ramie plants which, if properly grown and prepared, would be bought by the textile trades in Europe in any quantity and at a very remunerative price,—

- (1st) *Urtica (Boehmeria) nivea*, or white China-grass.
- (2nd) *Urtica utilis*, or *tenacissima*, green Ramie from Java and the Indian Archipelago.

The first will grow in temperate zones, but the second only in tropical or semi-tropical climates.

White Ramie.

One of the characteristics of this plant is the annual up-growth of the stems, which disappear in the autumn after having fructified. Another is the white down covering the undersides of the leaves.

This plant originates in China and Oriental Asia, having been cultivated for centuries by the Chinese for their own use, the excess of production being exported to England under the name of China grass. It grows in temperate zones like the olive and orange, and flowers in the autumn, after which the stems dry up, showing apparently no life until the following Spring. It is of importance to cut the stems before the flowering, or the fibre is spoiled. After experiments made in different climates it has been found that the *Urtica nivea* is unsuitable for tropical or semi-tropical countries, as the abnormal growth and constant flowering prevent the stems from maturing, and reduces both the quality and quantity of the fibre. It thrives, however, very well in temperate zones, where the heat is not excessive in the Spring and Autumn, and where only slight frosts occur in the Winter. It may be laid down as a general rule that the growing of *Urtica nivea* will not give good economical results in any but a temperate zone, the extreme limit of which is to where sugar-cane and bananas can be grown. This plant fructifies abundantly and the seeds are fertile; in the experimental farm in Algiers, very large crops have been obtained during the last 40 years.

Green Ramie.

This species, *Urtica tenacissima* or *utilis*, is distinctly characterised by having perennial stems and the undersides of its leaves almost green, but sometimes very slightly covered with white down. It is a native of Java and the Indian Archipelago, and for industrial purposes ranks equal, if not superior, to China-grass. It grows like a shrub; the stems speedily throw out branches and become ligneous, rapidly increasing in height and diameter. It lives for several years, and the flowering is not followed by the drying of the stems, as is the case with the white ramie. The flowering periods are not numerous, and it rarely produces any seed. In good moist soil, this nettle will take the form of a shrub up to 16 feet high, but in poorer dry soil it becomes a mere bush. The green ramie with its enormous growth is thus most suitable for tropical districts having constant rains or irrigation in periods of drought. Under such conditions this plant rapidly produces stems 6 to 7 feet in height, which should be cut for treatment in the green state, before the appearance of the side-shoots, but when having arrived at a certain degree of maturity. A peculiar characteristic of this ramie is that when a stem is cut, leaving a fair size stump, this stump will throw out side shoots which develop into high stems. This, on the contrary, never happens with the white ramie, the stems of which are annual, while the shoots spring from the root. There was for some time a doubt as to the industrial value of green ramie, though its richness is magnificent, strong fibres was well known; but lately the difficulty in its mechanical and chemical treatment has been overcome, and many manufacturers now prefer it to the white ramie.

This is of importance to the cultivator operating in warm climates, as the constant and exuberant growth of this species enables him to get several crops and a correspondingly better financial return.

This ramie is now sufficiently well known in the trade and should give any grower an excellent result in suitable localities, that is, in warm, moist climates, where the vegetation is not interrupted by insufficiency of rain, or where irrigation can be applied during dry periods.

TREATMENT OF RAMIE IN A DRY OR A GREEN STATE.

The methods of treating the stems are of great importance to the grower, as the price obtained

depends on delivering to the manufacturers the article most suitable for their machinery.

The treatment when in a dry state necessitates full grown stems, which in temperate zones will only permit of two crops per annum; while, on the contrary, when treated in a green state the stems need not be so fully developed, and several crops can be obtained.

Treatment in the dry state.—It is difficult to explain why so much attention has been paid to this mode of treatment. No earlier records give any indication of it; in fact the people of Asia, notably the Chinese, who for many centuries have used the nettle fibres, have never prepared them in a dry state like flax and hemp; on the contrary, they decorticate them absolutely green, and remove the bark while the stems are growing. It would be a false economical basis for one to compare ramie with flax and hemp; believing that unique advantage of the dry treatment consists in the ability to store it in stacks or sheds, until an opportune time for decorticating. The grower might then perform this work in the winter time when other labor is slack. In France, and even in those parts of Europe most favoured by the climate, it would be almost impossible to dry the stems in the open air. Moreover as regards France, the growing of ramie does not seem to have given very satisfactory results. Even in the colonies the moisture of the air is too great to enable us to obtain, by open-air drying, stems sufficiently dry to suit the decorticating machines at present in use. In India and China where the growth of ramie is very abundant, and labour very cheap, it is impossible to get the stems, even comparatively, dry in the open air, and any attempt at storage will lead to fermentation, and consequently the fibre will be spoiled.

The dry stem is also hygrometrical, and rapidly absorbs the moisture in the air, as has been proved by experiments with stove-dried plants.

Insufficiently dried stems cannot be decorticated satisfactorily, as the beaters and scrapers of the machines acting upon a soft spongy matter, weaken, and soil the fibres, without fully removing the woody part, or even the cuticle. When exposed to the air this latter becomes of a brownish colour, hard and horny, resisting all efforts to remove it by machinery.

The strips thus obtained can only be cleaned and deprived of cuticle and gum by means of chemical baths, which often have to be so strong that they damage the quality and strength of the fibre.

The machines for dry work require to be fed with well-grown stems of fairly uniform diameter, in order to produce good strips.

If the stems are cut before maturity they often become flat and out of shape in drying, and the machine does not act uniformly on all the surfaces, but leaves a good deal of woody substance in the strips. With well grown and perfectly dried stems, certain machines do good work in removing the bark and woody part, but the strips retain the cuticle, which is very difficult to get rid of by the chemical baths used for the purpose at present. All these objections apply when the stems are passed through the machines as a first operation after being dried; but we hear of a new method of first submitting them to chemical action, and then decorticating.

So far the decorticating has been found very difficult, particularly in tropical humid climates, where the crops are very heavy.

It often involves manipulations very costly to the cultivator, and is some times impossible if he has to cut the crop and spread it over large areas to dry.

Some authorities contended that drying in stoves is the only effectual mode of getting rid of the moisture but that is impracticable, and would greatly increase expenses.

Treatment in the Green State.—It is very easy to decorticate the ramie stems in a green state, and the Asiatics use only this method in treating their fibre

nettles. Immediately after the stem is cut there is no difficulty in removing the bark and woody part, on account of their moist state, without many fibres adhering to them. The Chinese, in fact, often decorticate the plant while growing. Many decorticating machines have failed to give satisfactory results because they have been fed with only comparatively green stems, which have already lost a good deal of their vegetable moisture. This leads to a question important for both cultivators and manufacturers. At what stage of its growth ought the ramie to be cut, or in other words what is meant by green stems? Recent experiments demonstrate that the best time is just after the stems have reached their full height, when still herbaceous, soft, and succulent, and when the bark has formed, but not become brown. At this period, before the appearance of the eyes at the axils of the leaves, the primary useful fibres are already formed, and have sufficient strength; but afterwards only layers of useless fibre are produced. It is therefore clearly a mistake to let the bark thicken, hardening the epidermis and increasing the woody part. In time the fibres lose their fineness, flexibility, and whiteness, in short, their most valuable quantities, and become more and more surrounded by the hardened cuticle and gum, two substances which are very difficult to get rid of when ancient.

To minimise the formation of these deleterious substances the plants should be pretty close-set and well watered, to induce a rapid lengthening of the stems. In a thick plantation, there are very few leaves at the base of the stem, the ramifications are not developed, and the atmospheric influences act less directly on the cuticle, which consequently remains softer and thinner.

In warm and temperate climates, with good irrigation, as many as five successive full-grown crops have been obtained per annum; and in tropical climates with regular and abundant rains, still more. The use and value of green ramie stems depends entirely on their treatment, and if by certain instruments or machines, the bark, woody matter, and cuticle can be removed without damaging the fibre, and the liquid gum pressed out, strips of fibre will be obtained divided in numerous filaments, and free from a great portion of the useless elements. Care must be taken, however, that the beating and scraping be not too violent or the fibre will be injured.

In order to prevent the hardening of the remaining gummy matter, some authorities recommend that the strips should be placed in a chemical bath, immediately after being taken from the machines. Other authorities would soak the green stems first, or subject them to the action of a certain gas, then dry and work them mechanically. This preliminary treatment by liquids or gas would change the gummy matter to a powder, and when the stems were afterwards well dried, decortication would be easy, by means of beaters or stripping machinery.

These operations refer to the green stems, which do not require to reach maturity in order to provide good fibre, and taking everything into consideration are much easier to treat than the dried ones. The fibres are of a superior quality, and one may cut four times the number of crops—which point is of vast economical importance in warm climates where the stems reach a height of about 5 feet in thirty-five to forty days, when well watered by regular rain, or irrigated.

THE WEIGHT AND VALUE OF THE CROPS.

The results of the crops vary according to the localities, the number of cuttings per annum, the system of treatment, and the skill of the labourers, which makes it impossible to fix a general standard revenue per acre. In taking the gross weight of the yield per acre of green or dried stems, we only obtain a very approximate estimate of the initial value of the crop, as the quantity of useful fibre is not in proportion. The weight of the green

stems is generally taken by the purchaser as a basis for his calculations; but this is subject to great variations, and often a great loss of vegetable liquid takes place in an incredibly short time, when the atmosphere is dry. Then the stems have more or less leaves and are more or less compact, according to the season, which causes the weight to vary. In fact, some stems grown in the summer have been found of inferior weight to those grown in the spring, though of the same dimensions. In a carefully cultivated hectare (2½ acres) we find from thirty to forty stems per square yard, about 64 inches high, which means 400,000 stems per hectare each crop. The average weight of free fibres is about 3 to 3½ grammes per stem, or 1,200 kilos (one kilo=2½ lb.) for 400,000 stems, and for four crops per annum 4,800 kilos of "filasse" (fibres not quite completely degummed). Supposing, in round numbers, a yield of 4,000 kilos of degummed fibre per hectare, the sum realised at the present price of 850 fr. per ton would be 3,400 fr. (£135, or £45 per acre). It is impossible to estimate the exact profit to the grower on account of the varying conditions of production in different localities, but an average minimum of £10 per acre may be counted on, and though the first cost of planting is considerable, the maintenance of the plantation is very simple and inexpensive. To estimate the value of the crop by the gross weight of the stems often leads to serious discrepancies. Though 400,000 green stems weigh, as a rule, 18 to 22 tons, they lose rapidly in weight by evaporation and falling of leaves, and sometimes the same number of stems only weigh 15 to 13 tons, though containing no less weight of fibre than the heavier ones. This depends on the season, the quantity of moisture they hold, and the number of leaves. The profits on ramie growing depend on—

- (1) Whether the cultivator sells his crop growing.
- (2) Whether he prepares it more or less by decortication or other means, when he will have the profit also on this supplementary work.

In the latter case it is the production in fibre which must be considered, but this varies in quality and cost, according to the processes it passes through, and which are more or less costly.

Those interested in ramie seem to have constantly tried to obtain, by mechanical treatment, an article equal to China-grass, and have not thought it necessary to preserve the original great length of the fibres or their parallelism. Some of the decortication machines, which operate quickly and have a large production, cut the fibres. This, however, makes it more convenient for the manufacturer, as, when entangled, the long filaments are difficult to comb.

It is quite clear that if we, by a simple preliminary process can eliminate the expense and risk of degumming the raw material later, the product from this treatment will have a very different value to the manufacturer from that of the ordinary coarse strips, and a large daily production does not necessarily mean a larger profit. The growers and manufacturers have, perhaps, hitherto been wrong in seeking only to produce a rich and superior article, and the description of ramie, as a *vegetable silk*, has done harm. The large textile factories seem really to require a fibre of good quality, but ordinary preparation, which they, by ulterior manipulation, can convert into superior goods. The aim should be to produce ramie fibre at a price between that of cotton and linen, when, according to certain economists, the consumption would be unlimited.

THE CLIMATE MOST SUITABLE FOR RAMIE GROWING.

A warm climate with frequent rains, amounting to a total of 8 feet or more per annum, or abundant irrigation in places where there are dry periods, suits the ramie plant best, and where the temperature does not fall below freezing point.

MODE OF CULTIVATION.

There is no doubt that plantations on a large scale, where machinery can be used for cutting and decorti-

cating, will pay best, as the manufacturers require large quantities of a uniform quality, which can not be assured when buying small lots grown in different parts. Decortication and degumming should be done on the spot to prevent fermentation, as it is almost impossible to avoid damage—at any rate to the interior of bales of gummy fibres when shipped long distances. China-grass can be transported safely because it only contains about 25 to 30 per cent. of the original gum.

The cultivation of ramie is very simple, and consists principally in a thorough preparation of the soil. It should be planted in good deep soil, the clayey, silicate, calcareous, and that rich in humus being the best for the rapid production of good crops. In regions where there is not a regular rainfall irrigation must be resorted to.

The preparation of the soil consists in—

1. A deep ploughing (by steam plough preferably).
2. Working the surface light.
3. Making irrigation channels spaced according to the volume of water at disposal.

The land should be level, and the plants or roots placed 10 to 12 inches apart in shallow furrows, spaced about 12 inches. After closing the furrows the plants must be watered. Planting in ridges is not to be recommended. After the soil becomes dry it should be worked over again twice.

In a plantation spaced as above it will be found impossible to dig after a lapse of two months, and irrigating only has to be attended to. In a few months the growth will have become so compact that all labour is impossible and useless. The annual work is then limited to irrigation and to applying periodically artificial fertilisers, such as nitrates and superphosphates. In fact, the principal cost of growing ramie is at the commencement, and may be calculated according to the price of labour in the locality—

1. Deep ploughing.
2. Keeping the soil light.
3. Planting 1 hectare (2½ acres)=two or three days' labour.
4. Cost of plants.
5. Digging up several times.

The price of plants in a locality where ramie is grown is about 4s. per 1,000, but of course in other places one may have to pay considerably more.

A good European mower can cut by hand and put in small bundles about 2,500 stems per hour; but the mechanical reaper is quite suitable for green ramie. If the process of treatment necessitates the stripping of the leaves, an adult woman can do about 400 stems per hour, and it is best to do it before cutting.

A good ramie field should show close and even growth like a field of wheat when the stems will be straight, have few leaves at the base, and the sun less tendency to harden the cuticle. On an average, one should have about forty stems per square metre (=33 per square yard) as a minimum, but we often find as many as fifty-eight large and twenty small stems of white ramie and forty-five large and fifteen small ones of green ramie per square metre.

The diameter of the stems of the green ramie is generally larger than that of the white.

If cultivated under favourable conditions, the annual fibre production per acre is superior in quantity and quality to the high-priced *abaca* and *sisal*. This will give an important place to ramie in the textile industries, if the preparation is economical.—*Agricultural Gazette of New South Wales*.

GOVERNMENT HELP TO SELANGOR PLANTERS.

THE BEE HAWK MOTH.

SIR,—So many of your readers are now either directly or indirectly interested in the Malay Peninsula, that I make no apology for asking you to allow me to utilise your columns to record another of

the many instances of Government assistance which has been extended to planters and others in the Federated Malay States, when cases of real urgency have arisen.

About six months ago, an estate which I visited, the property of a Company which has large Ceylon interests also was attacked by the caterpillars of the bee hawk moth; for some time we were able, though only at a heavy expenditure, to keep pace with the pest, and to an inexperienced eye, the coffee showed scarcely any signs of being denuded of leaf. In June last, however, owing probably to some climatic change favourable to the rapid development of the insects, there was a terrible increase in their numbers and it became apparent that, unless a large force of coolies could be at once concentrated on the spot, the most serious result must ensue.

Neighbouring planters came to the rescue, and lent every coolie they could spare, but still we could not keep up with the caterpillars. I then appealed to the Government and at once a special train was put on and nearly 200 coolies daily were sent down. These men had to walk, in some cases, a long distance to the railway station, and on arrival at their journeys end, nearly four miles more to the estate lay before them. After work they had to go all the way back again. There was no suggestion that such a day's labour was an impossible task, and the men all worked cheerfully and well. With this help we were able to get the pest in hand and in the end were only called upon to pay half the cost, the Government defraying the rest.

You will agree, I feel sure, that such ready sympathy and liberal and prompt assistance are not to be met with in official quarters all the world over, and deserve to be made known, especially in quarters where the proper significance of the thing can be appreciated.

Mr. Ernest Green, with whom I have been in communication, tells me that the bee hawk moth is well-known in Ceylon, but is not epidemic over with you owing to some fungal or bacterial infection, and this it is to be hoped may in time become an established condition here too; but, meanwhile, we can do nothing but "hand pick" eggs, caterpillars and chrysalids, and meet every flight of moths (which are day insects and therefore not to be caught in the meduse acetylene lamps) with as many butterfly nets as we can muster coolies to use them.

Somewhere about 1895, many of your readers will remember how the cinchona was absolutely stripped of leaf by a huge hawk moth caterpillar, which appeared in such numbers that one even found them crawling over the bungalow walls. The Badulla district in particular had a bad time of it, but finally thousands and thousands of crows came to the rescue, and absolutely cleared the caterpillars out. Having this in my mind, I approached the Resident-General with the object of seeing whether the Government would negotiate with Ceylon for the supply of a few thousand of crows, these useful birds being very few and far between over here unfortunately; and I am glad to say that, instead of treating this suggestion as a huge joke, as many men might have done, Mr. Treacher has at once put himself in communication with your Government on the subject.

I hope, Sir, if you notice the matter at all, you will accord your support. You might send us over 100,000 crows and never miss them; in fact, the effect would probably be as beneficial to the remaining stock as shooting over a moor which has for years remained undisturbed—Yours, &c., E. V. CAREY,

Kiang, Selangor, Federated Malay States, August 3rd 1902.

FEVER IN PLANTS.

Although animals and plants seem, at first sight, to be two absolutely distinct groups, and to have little in common, closer investigation points unmistakably to the fact that they are very similar and

very closely related to one another. Further, many organisms are known which it is impossible to class with certainty as plants or animals. Let us confine our attention for a moment to one of the ordinary recognised signs of life, namely, breathing or respiration. Both animals and plants breathe. In both oxygen is taken in from the air, and after certain changes carbon dioxide is given out. This process, it is true, is masked in green plants, during exposure to sunlight by another process in which carbon dioxide is taken in and oxygen given out. It goes on, however, in a plant as steadily as in an animal, and there is no essential difference between the respiration of man and that of the humblest vegetable he cultivates. In man it is not uncommon to find that when the health is affected his temperature rises; in other words, he becomes feverish. At the same time the rate of breathing is often increased. Is this true of plants also? Can we throw a Potato or an Onion into a fever? The idea seems absurd. Yet it is an ascertained fact. It was shown by Mr. H. M. Richards (*Annals of Botany*, vol. xi., p. 30) that if Potatoes or Onions were sliced—that is to say, wounded—their temperature rose, and their breathing became more vigorous. They exhibited in fact two of the characteristic symptoms of a feverish person. The rise of temperature was carefully measured; in some cases it was as much as 3° C. The course of the fever was followed, and was found to reach its height usually about twenty-four hours after the injury, the temperature then began to fall, and reached the normal again on the fourth or fifth day. Experiments such as these help to bring home to one in a striking manner the fundamental relationship between animals and plants.—*Agricultural News, Barbados.*

PLANTING NOTES.

SWEET PEAS IN QUANTITY.—We are informed by Messrs. E. W. KING AND Co., Coggeshall, Essex, that they have now in flower 6 acres of Sweet Peas, including seventy-two choice varieties cultivated for seedling purposes.—*Gardeners' Chronicle.*

MANURE FOR ROSES.—Artificial manure, says a German contemporary, if properly chosen and applied, are the most useful, as by their use vigorous growth and fine flowers are obtained. Raw bone meal, in point of usefulness, is preferable to manures containing phosphoric acid; but the manure most to be recommended is potash, and two dressings afforded during the summer have all the favourable results which one can desire from a manure.—*Ibid.*

A NEW USE FOR THE ONION.—The onion has been recommended as a beneficent remedy for diseases in poultry on account of the essential oil, which causes tears to flow from the eyes; hence therapeutic qualities of great value are attributed to it in the case of throat affections in said poultry, which, as we well know, is the disease which decimates our poultry yards. The administration is very simple: Once or twice a week cut up the onion into very small pieces, and feed it to the poultry. It will keep them in excellent condition for fattening and producing plenty of eggs.—*La Indus tri, Nicaragua.*—*Ibid.*

"AGRICULTURAL NEWS."—We have before us the first number of a fortnightly periodical, published at one penny at Barbados. It is one of the many evidences of the activity of Dr. Morris in all that concerns the development of the agricultural resources of the West Indies, and lays no claim to public recognition beyond an earnest desire on the part of the Imperial Department of Agriculture to instruct and assist all classes of the community, and to promote the agricultural interests of these colonies. The contents, though naturally devoted almost exclusively to colonial affairs, are varied and interesting.—*Ibid.*

VANILLA.

CULTIVATION IN THE SEYCHELLES.

In various localities in the West Indies attention is being directed to the cultivation of Vanilla. Experiments on the growth of the plants and curing of the pods are being conducted at some of the Botanic Stations, and planters are also putting the question of the possibility of the industry in the West Indies to a practical test. We have already referred in these columns to the vanilla industry of the Seychelles (*Agricultural News*, p. 60.) The most complete and exhaustive account of the cultivation as practised in those islands is that of Mr. S. J. Galbraith, published in 1895, as *Bulletin No. 21*, Division of Botany, of the U.S.A. Department of Agriculture. Mr. Galbraith was for many years a successful planter in the Seychelles and in a most favourable position to write on the subject.

We propose to reproduce the greater portion of this valuable publication in these pages. The present article contains a summary of the general conditions of the industry in the Seychelles and the directions for the arrangement of trees on which to train the vines:—

GENERAL CONDITIONS.

"If kept free from disease the vanilla is a plant of extraordinary vitality; and in the Seychelles, where moisture and heat, its main requirements, are both ample, the sort of soil it is grown seems to be of no great importance, provided that, if it be very poor, the roots are kept well supplied with manure. It is cultivated in the Seychelles from near sea level to 1,800 feet altitude, and does well (except for disease) at all altitudes between those extremes."

The rainfall is about 100 inches in the low lands and 10 to 30 per cent. greater in the hills. The fall is fairly evenly distributed throughout the year, but a dry spell, which is necessary to bring vanilla into flower, is to be looked for in July, August, or September, while the heaviest rains most frequently come in December. The range of shade temperature for day and night, from sea level to 1,800 feet, may be put at 90° to 70° F. The former is exceptional, the latter frequent. The plant does well in three very different types of soil,—a rich vegetable mould, a greasy red clay, and a coarse quartz sand. Though so unpromising to look at, the latter is, perhaps the best of all. It gives free drainage to the roots, and in wet years plants fixed on it are more likely to crop than those on closer soils, while with ample manuring they grow remarkably well.

ARRANGEMENT OF PLANTATION.

The manner of setting out plantations in the Seychelles has undergone changes within the last years. Formerly plantations were seen with the rows of vines planted so close together as scarce to leave room for workers to pass between them. The yield per acre under such conditions was sometimes enormous, but when disease once started in a vanillery thus arranged, its destruction was rapid and complete, so this system has been mostly given up. Since the loss of so many close-lined plantations, the distance between the rows has been increased. Living wood, i.e., small trees, are used as supports for the vines, these being festooned from fork to fork, but many planters have made use of hard wood posts and bars, the former being notched on top and the latter laid in the notches resting thus from 4 to 6 feet from the ground, according to fancy. Over these bars the plants are hung being looped up as growth is put on. Wire is sometimes also used instead of horizontal bars. It is much cheaper, but otherwise has disadvantages notable among which is that it sways with wind and is liable to break the vines, the curvature being too sharp over such a small round surface. However, when plants thicken into a mass this last drawback mostly disappears.

A third, and, as the writer believes, much better way of growing vanilla, is now more generally coming

into practice. This is to plant each creeper on a tree of its own, and where land is cheap it is an advantage if these are well apart. So arranged, the general maintenance of a vanillery is certainly more expensive, inasmuch as isolated plants require more manure than when the same number are closely grouped together. The work of flower pollination and crop gathering is also more laborious. But more than a counterpoise to these disadvantages in the increased security this method of planting gives against wholesale destruction from disease; for when so arranged a sick plant can be removed and destroyed with greater chance of this being done before any of its neighbours become affected; whereas when growths of different plants are interwoven, either in their roots or shoots, it is difficult to know when enough has been taken up and there is every likelihood of the disease becoming established beyond control.

USE OF TREES AS SUPPORTS.

To give some notion of how a vanilla plantation is set out and carried on in this Colony, it will be convenient to assume that the tree method of planting is the one adopted. A great variety of trees will serve the purpose. Here, on most properties, there is an abundance ready for the work; but of course where this is not the case, suitable trees must first be planted. In selecting trees those should be chosen which do not grow too large, but give moderate foliage (about half shade) without ever losing all their leaves at once, and having plenty of branches from 5 to 7 feet from the ground, affording forks enough to train the vines through.

No hard and fast rule can be laid down as to the distance trees should be kept apart. Here, formerly as above stated, vanilla was grown in dense masses with great success for a time. Elsewhere it may be advantageously so grown now. However, it is safe to state that overcrowding in any kind of planting invites disease, and the farther plants are kept apart the more likely are they to remain healthy. A 4-foot radius would be a moderate allowance for the roots of a vigorous vanilla plant, and if 1 foot is kept clear around the circle allowed to each plant's roots this would give 9 feet as the distance between the trees. It would be difficult to insure the plants being kept distinct in less space. Where suitable trees are already growing on the land to be planted these can be thinned out if too close, or they may be left in small lots of three or four or more together, a sufficient clear space intervening between each lot; but in that case if one vine of a group showed disease the whole would have to be removed. Many trees stand topping, and it is a great advantage when they do, for on being cut 7 feet or so from the ground branches spring from near the cut part at a convenient height, and the best situated of those can be chosen to train the vines through, the rest that grow awkwardly being removed. About 5 feet from the base is low enough to allow any to grow.

PLANTING.

Trees being in readiness, planting may be done at any time of year here. If during a wet spell, vanilla will sprout all the quicker; should it be dry, the plants will delay a little, but there is no fear of their missing if properly planted, and the one danger point to guard is where the vine leaves the earth. This part of the vine is hurt through if not shaded with grass or leaves. However, this also would only mean a little delay in the start of growth; for though they take some time longer about it, vanilla cuttings will grow well enough if merely tied to the trees with their lower ends some inches clear of the ground. Illustrative of the extreme vitality of plants under adverse conditions, it may be mentioned that in neglected plantations, where the vines have been allowed to climb well up into the branches of good-sized trees, and then been broken in attempting to get them down, the broken portions, sometimes partly swinging free, have remained green and capable of

growth for upwards of a year, sending down long aerial roots 15 or 20 feet in length, and in some cases where these have escaped injury the broken plant may re-establish connexion with the soil and start to grow again. If planted clear of the ground and merely tied to the supporting tree, it is advisable to tie two or three large leaves round each vine for the distance of 3 feet up; thus shaded the aerial roots quickly burst through the stem, and getting something to cling to at once, soon make their way to earth without injury.

LENGTH CUTTINGS TO USE.

In starting a new vanillery, where the estate has no plants these are readily purchased here at small cost, from 2 to 3 rupees (55 to 99 cents) per 100 fathoms is the usual rate for cuttings, the fathom being what a man can span with outspread arms, a goodsweep of the vine hanging in a curve between his hands. Where choice is possible, although oldish cuttings will grow pretty well, it is best to have the plants of recent growth; in fact, growing shoots, cut off close to where they spring from the parent vine, are preferable. At their point of origin the nodes for some distance are close together, and though roots will strike from any joints, they have a natural tendency to do so quicker at the shoot's base. As to the length of cuttings to plant, opinions differ; but there can be no question that the longer cuttings produce cropping plants sooner than the short ones. If a 2 or 3-foot branch is planted, the shoot it gives is invariably more slender and slower of growth than would be that from a 6-foot cutting, and up to 10 or 12 feet every advantage lies with the longer plants, except the additional expense.

The question as to whether cuttings of that length are to be planted whole or divided into two or three plants should be settled by their cost. It is usual here to loosen the soil with a hoe where vanilla is to be planted, and bury the end, laid horizontally, an inch or two in the earth. Quite as good a way is merely to press the lower part of the plant into the soft soil until it is flush with the surface. On sloping land loosened soil washes away sooner with heavy rain, and in such situations it is better to leave the ground quite undisturbed. In any case the leaves on that part of the vine which rests in or on the ground are cut off fairly close to the stem, and an arm full of leaves, fern, grass, or forest sweepings laid on the top to the depth of 3 or 4 inches, for a couple of feet around the plant. Its roots will not need to be mulched for a greater distance than that for some months to come, and to cover a larger area would be useless. As new top dressings are laid on, which must be done when the first supply rots down and becomes thin, these can be gradually extended to allow of more root spread, till the limit of 4 feet radius is reached. If well covered, the roots do not run much; only starved vines run far with their roots, seeking nourishment; where this is plentiful they mat in and beneath it. Being entirely surface feeders, should any make their way beyond the cover they can be gently lifted and tucked under the decaying leaves, etc.; but this is a hint that the plant needs a new supply of top dressing. The number of joints laid on or in the soil will vary with the length of the plant, but should not be less than three for this mode of planting, while for long outtings six or seven joints are needed for a quick start.

SUPPORT FOR THE YOUNG PLANTS.

If of sufficient length, the free end of the planted vine is hung through a fork of the supporting tree, but it is also advisable to tie it in two or three places to the tree to hinder swinging and chafing. The material used for these ties here is a fibre called *Vacca** which rots in about a year, by which time the plants should have tendril-like roots enough to steady themselves. When once properly planted the

cuttings will need little or no attention for some months, but when the growth becomes vigorous the shoots must be looked after. Such of them as have grown clear of their supports are hitched up and if long enough, hung through one of the forks. An occasional tie here may also be necessary, but in general, a leaf or two of the growing part can be hooked on to some other fixed part of the vine, and in a few days unless blown loose, the tendrils will have fastened to the leaf, and thus support the plant. Shoots must not be allowed to climb very high among branches of the supporting tree, especially if there be many and close together, or there will be breakages in getting them down. For this purpose, when they get beyond hand reach, a forked stick 6 or 7 feet long is useful. The fork is worked between the tree and climbing vine, and its tendrils in succession are broken by pushing and twisting the stick when they are within the fork. The last two or three tendrils are easily broken or leave the tree without breaking, and care should be taken when the vine is nearly clear to catch the stem of it high up, within the stick's fork; it can then be lowered gently without fear of breaking.

Some judgement is necessary in selecting the fork of the tree through which each shoot is to hang, a fork whose height fits in with a natural bend of the vine, if it has one, being chosen; otherwise one whose height takes the vine between joints is best, since if bent at a joint the vine is apt to snap, especially so when in vigorous growth, being then full of sap and brittle. In good growing weather—i.e., warm, still, and moist—healthy, well-nourished vanilla vines grow very rapidly, an inch per day being no uncommon rate.

PREPARING THE VINES FOR CROPPING.

If the plants have done well they should be ready for such preparation in about eighteen months, more or less, according to the season. Formerly in this colony they were allowed to grow on until a spell of dry weather set in prior to the usual blossoming time. The growing ends were then cut off and all new shoots removed as they showed till flowers began to come or till the season for them was past. When the dry spell proved a long one, this seemed to answer pretty well; and, indeed, under these circumstances flowers would come in any case, whether growth was checked or not. But now it is more usual to stop the growing ends some nine or ten months, in the first instance, before flowering time. In the majority of cases the terminal bud will push, and this new shoot should also be removed when 5 or 6 inches long not earlier, else the next to the last bud is apt to grow.

After the second checking most vines will shoot far enough back to allow of the shoots being left. These grow on for the next year, and then stopped branches hang down with their lower ends a good foot or more from the ground, being generally from 4 to 6 feet in length, according to the height of the forks through which they are hung and the positions of the new shoots, though these generally spring just before the last buds of the checked branches, which are to be the cropping parts. The new growths behind these are supposed to drain them of their sap, and thus conduce to flowering. However that may be, these checked hanging branches, have certainly more tendency to flower than other parts of the vines. Flowers take some six weeks to develop from the moment they burst through the buds to their time of opening, but this period varies in length with the weather, continuous dryness retarding and moderate showers hastening their development when once started.

The growing branches of vines should now be checked again for the following year's crop. These will be less troublesome in putting out inconvenient shoots, as the plant's sap is more apt to go into flowering branches, when nourishment is now more needed. Could the whole work be performed in a few

*Obtained from a species of screw pine, *Pandanus utilis*.

days, this change in the direction of sap flow should be done preferably ten days or a fortnight before flowers begin to open. In a large plantation, unless the hands are very numerous or the shoots have been arranged beforehand so that there is little else to do than cut their ends, it will take some weeks to accomplish this, and therefore work must begin earlier or finish later. If the dry spell necessary for flowering has lasted a good while and can fairly be depended upon to continue long enough, the growing ends may be out earlier; but it must be borne in mind that if rain in quantity comes too soon and, in addition to the stimulus given by it, the branches intended for flowering have also the sap from previously growing shoots poured into them, the chance of their cropping well will be much diminished. Many a promise of a fine crop is ruined by too early rain here. The country, climate, and the planter's skill as a weather prophet must govern this undertaking.

An abundant supply of leaf mould should be in readiness for laying on the roots at this season, and should be applied when flowers begin to open, or a little before. If previous dressings have been so timed that vines are in a somewhat starved condition when flowering is expected, the chances of a good blossoming are increased, but the practice needs judgement, or a poor quality of pods will be the result.

There used to be a story current here, no doubt with some grain of truth in it, to the effect that in a very wet season the only vanilla planter who had any crop was one whose pigs had got adrift in his plantation and spent the night in grubbing up vanilla roots. This method of producing flowers is not recommended but it is quite possible that careful and systematic root pruning might be carried on with advantage in wet years, if one could tell beforehand when these were coming.

POLLINATION OF THE FLOWERS.

The work of flower fertilization (pollination)—for they have all to be fertilized by hand, and than on the day they open—is mostly done by women and children. The operation is a very simple one, and an average negro will acquire the knack after being shown a few examples.

[The illustration on the opposite page, reproduced from the *Kew Bulletin*, with its descriptive letter press will allow readers to follow clearly, Mr. Galbraith's description.—Ed. A. N.]

The flower is taken in left hand, three fingers being placed at its back and the thumb in front the column with organs of fertilization on top being supported against the middle speal behind. A bit of hard wood, cut to the size of a toothpick and scraped smooth and flat at one end, is the only tool required; this is held in the right hand. To get at the organs of fertilization easily, the sack which grows from the side of the column enveloping its front and marking the sexual organs is pressed down by the bit of wood, or this is run through its base, and the sack torn up, or the whole sack may be plucked off with finger and thumb, it matters not how it is laid open, so long as this is done quickly and without injury to any other part of the flower. The smooth end of the fecundating instrument is then laid flat on the front of the column just beneath the organs of fertilization, and being pushed up it catches under the flap which keeps the pollen from coming into contact with the stigma. The flap is raised along with the stick till it lies flat against upper part of the column, being held in that position by the bit of wood. The stamen, at first raised along with the flap, now falls down again in its original position, and the flap being out of the way the pollen comes into contact with the stigma, and a slight pressure of the thumb on the stamen lodges pollen in the position required; the bit of stick being then quickly but gently withdrawn, the operation is complete.

The whole affair is very much easier done than described, and with flowers fairly numerous, an ordinary hand will fecundate a hundred or so per

hour. Early morning, from 7 to 9, is the best time for fertilizing; but the work may be started with sunrise and carried on well into the afternoon, though about mid-day flowers begin to close some and the work goes slower. Most plants in full crop produce many more flowers than it is advisable to fertilize, for other parts of the vines, besides the checked hanging branches, blossom in favorable seasons and the number of pods which a vine is able to mature properly must be estimated from the plants size and condition. In the course of four or five years, though by that time the plant cutting will be spent, if well cared for it will have grown a large quantity of vine; and as each new shoot, when long enough, sends down aerial roots in its own behalf, it becomes, so to speak, an independent plant and the parent of others. If none of the shoots from a strong growing vine have been removed the mass of growth in time becomes enormous, and may be equal to maturing a hundred or more good pods. When the supporting tree is stout and furnishes forks enough to admit of the vine being spread out so as to let plenty of air through it the vine may be allowed to accumulate to this extent, and if it gives, twenty clusters, each yielding ten or more flowers, five or six might be fertilized on each.

But, generally speaking, about 30 pods to a vine is as many as should be left, and he would be a lucky planter who should average that number. In selecting flowers to fertilize those should be chosen which spring from the lower part and from the sides of the flower stalks, from which position they grow straighter pods than those coming out on top. In favourable weather, i. e. moist but not heavy rain (which latter often washes the pollen grains away before they germinate), only a small percentage of flowers will fail of fecundation. In case of failure, the flower drops off in three days or less, but otherwise remains attached to its stalk and slowly withers; the *gynostemium* adheres to most pods till they begin to ripen; thus it is easy to see the number successfully fecundated in each bunch, and where enough are secured the rest can be broken off. Later it is advisable to cut clean off with a knife the flower stalk a quarter of an inch or so beyond the last fertilized flower. Some planters plaster a bit of sticky clay on the cut surface to prevent it rotting back. Dry lime is perhaps better; this may be dabbed on with a piece of cloth dipped in the powder.

Pods grow to their full size in five or six weeks, but take some eight months, more or less, according to the altitude at which they are grown, or the amount of shade over them, before they ripen. The indication of ripening is a slight yellowing of the whole pod, which is more marked near its free end. When under too much shade the change in colour is less noticeable, and many pods grown in such places split before they are gathered, and for that reason lose in value. To guard against splitting, and yet gather them at perfect ripeness, they should be gone every other day. In removing them from the flower stalks the pods are grasped one by one near their attached ends, very slightly twisted, and at the same time pressed aside with the thumb. They must be taken off quite clean. If a bit of the flower stalk comes away with a pod, as sometimes will happen it should be cut off smoothly. Any break or crack in the pod itself, however near its butt, ranks it as an inferior quality. Buyers are very particular in this respect. After each day's gathering, before the pods are started on their first stage of curing, it is well to sort them roughly into four classes: 1, long 2, medium; 3, short and 4, split.

1—portion of stem of Vanilla plant, with leaf, aerial root, and cluster of flowers; a, front view of Vanilla flower; b, side view; c, aerial root, with root hairs. 2—Single flower of Vanilla, exhibiting the first stage in the process of artificial fertilization. The operator, provided with a finely-pointed piece of bamboo, divides the lip or labellum medially, so that the central lobe is separated from the two side lobes. This exposes

the column and organ of fecundation. The instrument is represented as placed against the column, ready to press upwards the anther *a*, and bring the pollinia in contact with the stigma *b*.

3—Single flower of Vanilla, exhibiting the second stage in the process of artificial fertilization; *b* shows position of column exposed by division of the lip [the middle lobe of lip is pulled forward and curled upon itself to show the position of the column; the side lobes of lips, separated as shown in Fig. 2, are represented at back of the column]; *a*, the position of pollen masses, taken from the anther and placed on the stigma.

4—Enlarged front view of top of the column; *a*, the anther.

5—Enlarged side view of top of the column; *a*, the anther; *b*, the stigma or viscid surface on which the pollen masses must be placed to ensure fertilization.

6—Enlarged section through top of the column; *a* one of the pollen masses *in situ*; *b*, the stigmatic cavity.

7—Enlarged section through top of the column; *a*, the pollen masses, having been transferred from *a*, Fig. 6, are now represented in contact with the stigmatic surface. [Although diagrammatically shown, these figures give a tolerably good idea of what is actually necessary in order to produce fertilization in a Vanilla flower.]—*Agricultural News*.

TEA, COFFEE, AND OTHER PRODUCTS IN ZANZIBAR.

THE FIRST LB. OF TEA.—COFFEE LEAF DISEASE.—

RUBBER AND FIBRE.—CEYLON PINE APPLES.

We have received a copy of the Annual Report (1901) of the Agricultural Department of Zanzibar, and it is interesting to read of the results of the experimental cultivation of various commercial products, most of them only recently introduced into the country. The subjects dealt with in the Report range from tea to the minor products, everything grown in Ceylon flourishing with more or less success in Zanzibar. The cultivation of vanilla seems to be progressing, and the fertilization of the flowers is attended to by native boys who have learned the work. Cocoa and Kola have not made satisfactory progress, the trees having suffered from some blighting influence which attacks the growing points. Coffee, which is also a new product, is now experiencing the leaf disease. The plantation of Liberian Coffee laid in 1899 was growing vigorously and the trees were carrying their first crop. The Arabian Coffee trees, planted in 1900, also had a light crop. Leaf disease (*Hemelia vastatrix*) had appeared among the trees, though it had not yet done them any serious harm. The disease is not new to the island, it having been observed on some Liberian Coffee trees at Mweni in 1898. The Arabian coffee had also been infected by a borer and by an insect which attacked the leaves and spun upon their interior surface a white downy webbing, which curled them up into the form of a big pen at the ends. The tea—raised from seed imported from Ceylon—appears to have been attacked by a pest, while the growth of the plant has proved erratic. We extract a part of the Report which affords interesting reading:—

"We made our first plucking on January 10th, but obtained little more than a pound of made tea. On May 29th we plucked a second time, previous to topping. Growth then remained stagnant till September when light flushes began to appear. By the end of November we were plucking every ten days, and this continued till January 16th (1902) when flushes again stopped owing to dry weather. We plucked nine times during 1901 and obtained 46½ lb. of made tea. During the cool months, when flushes ceased, the trees showed great tendency to run to seed, and we were frequently compelled to send the boys through the garden to pluck off the buds and flowers. The trees have not escaped infection. A blister blight

appeared which curled and dried up the leaves. Some specimens were in 1900 sent home to Kew and the authorities there stated that 'The blistering and crumpling of the leaves is caused by a parasite fungus called *Exobasidium vexans*, Massee, which is stated by Watt to have done a large amount of injury to the tea plantations in Assam. It would be interesting to learn how this disease reached Zanzibar. Have the plants been imported from Assam?' Our tea seed came from Ceylon, but it is an Assam-hybrid variety. The attack declined with the survival of growth. At the beginning of 1901 we sent home some more diseased tea leaves which were stated to be infected with 'Gray blight fungus, *Pestalotia Guerpini*, Desm.' But on the whole we can report fair progress with this product."

With regard to rubber, the experimental clearing at Dunga are progressing satisfactorily. Four varieties were cultivated, viz., Para (*Latex Braziliensis*); Ceara, (*Manihot Glaziovii*); Central American (*Custillia elastica*), and Assam (*Ficus elastica*). Fibre cultivation was also receiving attention, and the plants in cultivation at Dunga and Mpapa were the American Aloe (*Agave Americana*); Sisal hemp (*A. rigida*, var *Sisalana*); Mauritius hemp (*Fourcroya gigantea*); *F. Macrophylla*; *F. Lindeni*; *Sansivieria* sp.; and China grass (*Bohemeria nivea*), all these grew well with the exception of China grass, which barely holds its own. Chillies, cloves and coconuts are next dealt with as also fruit cultivation.

In May last the Department obtained from Ceylon 144 plants of Kew pineapple which had been planted at Dunga and Mpapa. It is hoped in the course of the year to exhibit from these plants pines that will be some improvement upon the native product. Pineapples sell for a pice each in the plantation; the season begins in December. Bananas were thriving and were largely planted for shade; jack fruit was bearing well; arecanut had proved unprofitable; the mango crop had turned out a poor variety; the silk cotton tree (*Eriodendron anfractuosum*) bore satisfactory annual harvest; Cassava cultivation was paying, and sugar-cane was planted to feed the cattle; a few trees of cinnamon and cocaine had maintained a healthy, though leisurely, growth; anatto was growing like a weed; silver oak (*Grevillea robusta*) had been set out for shade for vanilla, tea and coffee; *Eucalyptus citrodora*; *E. viminalis*, and *E. teriticomis* were all doing well at Dunga; Bois immortelle (*Erythrina umbrosa*) grew rapidly, but was one of the few trees subject to scale attack; kus kus grass (*Andropogon muricatus*) was one of the most useful of the minor plants; lemon grass (*A. Schaananthus*) is also planted, but it dies out after four years. The interesting publication concludes with a report on a labour bureau which had been organized at Dunga.

GUTTA PERCHA FROM A CHINESE TREE.

(*Eucommia ulmoides*, Olive.)

Between 1887 and 1890, from several localities on the middle Yangtze-Kiang river, Dr. A. Henry sent to Kew fruiting specimens of a peculiar Chinese plant, with the statement that its bark is a most valued medicine in China, where it is named "Tu-chung," and that the tree is cultivated for it. "I have never seen it wild," he adds, "but I was informed it occurs so in Fung and other districts to the north." Fung is the name of a region near the middle part of the Yangtze-Kiang in the province of Hupei.

This plant Prof. D. Oliver described (*Hooker's Icones Plantarum*, t. 1950) as *Eucommia ulmoides*.

Flowers not being available, and what material he had so peculiar that its relationships were not obvious, Prof. Oliver left the determination of the order of *Eucommia* open, merely adding that the tribe Phyllanthæ of Euphorbiaceæ occurred to him as of probable affinity.

The interest to us lies not so much in this as in the indication of the presence in the tissues of gutta percha. The discovery he made known in the following words:—

"The most singular feature about the plant is the extraordinary abundance of an elastic gum in all the younger tissues—excepting perhaps the wood proper,—in the bark (in the usual sense of the word), the leaves and petioles, and pericarp; any of these, snapped across, and the parts drawn asunder, exhibit the silvery sheen of innumerable threads of this gum."

His account continues: "The morphological relations and general histology of the cells which give rise to the substance, we hope to have the opportunity of describing from specimens in fluid or living, which, through Dr. Henry's kind offices, there is probability we may soon receive."

When the promised specimens arrived Mr. (now Prof.) F. E. Weiss undertook the examination of them, and from the account of his investigations, published in the Transaction of the Linnean Society (Series 2, Botany, iii., p. 243), the following sentences are drawn:—

"The threads of *Eucommia* consist of caoutchouc, for they are insoluble in alcohol, acids and alkalis, though they become soft when treated with ammonia. They dissolve in chloroform and turpentine, and swell up in ether. When heated they melt, and they burn with the characteristic smell of burning rubber.

From the bark the rubber can very readily be extracted. If the bark be broken in pieces and pounded in a mortar, the mass can be roughly separated into two parts, one consisting of the tangled elastic threads, with small bits of broken bark adhering to them, the other chiefly of bits of bark containing, no doubt, smaller pieces of the threads. From both parts chloroform will dissolve out caoutchouc, a larger amount naturally from the portion which consists chiefly of the threads. Thus, a sample of the threads and bark weighing 443 mg. gave as much as 25 mg. of caoutchouc, while the remaining bark, weighing 607 mg., yielded only 6 mg. Taking the two quantities together, the yield of caoutchouc was 3 per cent. of the weight of the dry bark, and the same figure was arrived at independently by Prof. F. W. Oliver with another sample. The threads are clear and homogenous, and the only impurity in the chloroform extract seems to be a little resin, which can be washed out with alcohol. Whether the bark can be made use of commercially I must leave to those who are more experienced in technical matters. The distribution of the caoutchouc-containing cells I had been able to determine from the dry material which I first examined, and these observations were confirmed by the examination of the material preserved in alcohol. They occur in the inner portions of the cortex, very much in the position in which the latex cells of *Euphorbia* are found, but are even more frequent in the secondary phloem, where they run between the companion cells, and in both cases present the appearance of very long narrow cells, attaining such a length that one only occasionally finds their ends. In the leaf a group of caoutchouc-containing cells accompanies the ramifying fibro-vascular bundles, running just below the phloem, while in the petiole and all along the bundle of the midrib they form two groups at the sides of the bundle, and do not run below it. The pericarp of *Eucommia*, which resembles in appearance that of the elm is especially rich in these caoutchouc-containing cells. Below the epidermis we find a few layers of large chlorophyll-containing cortical cells, which become very much compressed in the dry fruit. Within these are the fibro-vascular bundles, the main trunks running longitudinally, and connected by branching and anastomosing lesser bundles. The longitudinal bundles have a strong group of caoutchouc-containing cells accompanying them on their inner side, and immediately beneath them we find a large mass of circularly

running cells of the same nature, forming quite a dense coat of hyphæ-like thin-walled cells, showing their cell-walls very distinctly when the caoutchouc has been dissolved out by chloroform."

These investigations did not settle the position of the genus, and Mr. Weiss left the matter with the remark that perhaps the tribe Crotonæ might include *Eucommia* in preference to Phyllanthæ of the same order—Euphorbiaceæ.

Since these first researches, made on imperfect material, further knowledge has been due to the success of scientific and horticultural establishments in Paris in obtaining first dried flowering specimens and now living plants. From the museum of the Jardin des Plantes came the material whereby Prof. Oliver was enabled to publish a second figure (*Hooker's Icones plantarum*, t. 236) and Dr. Solereder's researches (*Berichte der Deutschen botanischen Gesellschaft*, xvii, 1899, p. 387) were made upon flowers sent to him from Paris and fruits supplied from Kew; while the living plants in cultivation at the Jardin Colonial in the garden of the Faculty of Medicine, and by the firm of Vilmorin, Andrieux, & Co., have supplied material for the anatomical investigations of M. Barthelat (*Journal de Botanique*, xiv., 1900, p. 55) and the economic inquiry of MM. Dybowski and Fron (*Comptes Rendus de l'Académie des Sciences, Paris*, cxxix., p. 558).

Examination of the dried flowering specimens which had been received in 1894 from a French missionary—Pere Farges—and were taken from trees cultivated in Szechuen, caused Professors Oliver and Baillon to agree in placing *Eucommia* in the order Trochodendraceæ. Solereder refers it to Hamamelidaceæ. It is impossible to discuss here the cause of this difference of opinion; let it suffice to say that it indicates the difficulty experienced in assigning to its true position this peculiar genus. Wherever from external morphological characters we place it, the allied plants are not rubber-or gutta-yielding plants. Solereder observes this, and compares in justification of his view the Hippocrateaceæ, in which caoutchouc cells are found in certain species.

There are great differences between the caoutchouc cells of *Eucommia* and of the Euphorbiaceæ. In the latter the whole system is one complicated network arising from the branching of cells which are present in the embryo, which grow with the growing plant, ramifying and uniting, so that the outflow of one cut vessel is more than its contents, because other vessels feed it as it bleeds. In *Eucommia* the caoutchouc vessels do not branch and unite, nor are they present, according to Barthelat, in the embryo. Their contents, too, are more of the nature of gutta percha than indiarubber; and in structure they are much more similar to the cells which yield the gutta percha in *Dichopsis* than to the laticiferous vessels of *Hevea*, *Manihot*, *Sapinum*, and other Euphorbiaceous plants.

To Weiss' description of the anatomy Barthelat adds somewhat. He found that the cortical parenchyma of the young stem contained abundant caoutchouc cells, sometimes running singly, sometimes two or three together. In the roots he found the same cells in the phloem, and in the petioles both in and below the phloem; while in the leaf-blades they were very plentiful, running with the nerves and branching from them to end in a swollen extremity under the palisade parenchyma of the upper surface.

Caoutchouc is thus seen to be present in every part of the plant except the wood and the outer layer of parenchyma of the young roots.

We may now leave the anatomy of the plant to quote from the paper by MM. Dybowski and Fron of the economic possibilities which *Eucommia* may possess. The following statements are translated from pp. 559-560 of their paper:—

Our attention was called to the similar way in which the contents of the laticiferous vessels of *Palaquium* and *Eucommia* become evident when the

leaves are carefully broken; and so we were led to apply to the different organs of the latter plant the procedure recommended by M. Jungfleisch for extracting gutta-percha from the leaves of the former. We experimented first on some fresh leaves of a plant of *Eucommia* grown in the Jardin Colonial. The leaves are 3 to 3½ inches long and 1½ to 2 inches wide. They are oval, pointed at the end, finely dentate, have short stalks, and in length resemble those of our common elm. Operating upon 20 grammes of dried leaves, we obtained 0.45 gr. of product soluble in toluene which corresponds to a return of 2.25 gr. per cent. This return is poor, remembering that the fresh leaves contain 70 per cent. of water. The bark is full of laticiferous vessels. But the plant which we possess being still very young, we have not been able to take any branches away for examination.

A second series of observations was made upon the fruits. The fruit is a samara, the length of it being 1½-1¾ inches, and the width nearly ½ inch. Two hundred fruits weigh about 13 to 14 grammes. The extraction of matter soluble in toluene has given us the following results:—

1st attempt, 15 grammes yielded 4.09 gr. soluble in toluene

2nd attempt, 15 grammes yielded 4.12 gr. soluble in toluene.

i.e., 8.20 gr. from 30 grammes of matter, or a yield of 27.34 per cent. We worked with fruits not dried. The fruit contains a small proportion of water, equal to 7.4 per cent.

The product obtained is of a brown colour with metallic reflections on the surface. Plunged into hot water it becomes soft again, stretches out in thin flakes like goldbeater's skin and under pressure will take the impress of metal. In cooling it loses its suppleness and becomes quite hard.

"We have submitted the samples to M. Leaute, an authority on the subject, and he has been so kind as to authorise us to say that he considers the gutta-percha of good quality. We have but one plant under observation in the Jardin Colonial, but experiments are being made as to the methods of propagating. As at present *Eucommia ulmoides* is only known to exist in China, it is not easy to get a quantity of seed; and further, germination seems slow and irregular. One sowing produced a single seedling after the lapse of six weeks, a second after five months, and others later. Fortunately outtings seem to give better results. They will strike root at any season, and give vigorous plants; but spring, when the branches are still leafless, seems to be the most favourable time for taking them.

Eucommia ulmoides promises to be hardy at Kew. In November 1897, M. Maurice L. de de Vilmorin presented a plant to the Royal Botanic Gardens, where it has been grown successfully in the open without protection.

In Paris, where the winters are more severe than at Kew, the plant has survived through them, as testified by the following answer dated November, 18, 1899, kindly sent by M. M. de Vilmorin to a question from Kew:—

"Two plants of *Eucommia ulmoides* remained unprotected against a wall in our Paris garden during the two last mild winters, and stood uninjured through as low a temperature as 18° or 19° F."

The Jardin Colonial has already experiment in hand in Annam, Tonkin, and North Africa.

The bark of *Tu chung* had attracted attention long before the discovery of the tree to which it belonged. The following notice appeared in the Kew Report for 1881, p. 47:—

Chinese collections of *Materia Medica* often contain specimens of a drug consisting of blackened fragments of bark and small pieces of twigs. These when broken across are seen to contain an abundance of oacothouou which can be drawn out in fine elastic threads as in the East African *Landolphia*s. Specimens have reached the Kew Museum from the Paris Exhibition

of 1878 (with the Chinese name *Tu chung*), and from the Smithsonian Institution, Washington. The botanical origin has been hitherto altogether uncertain. It seems, however, probable from a notice by M. L. Pierre, Director of the Botanic Gardens, Saigon (*Excursions et Reconnaissances*, No 11, Saigon), that this drug is the produce of *Parmeria glandulifera*. This is an apocynaceous climber, ascending to the summits of the highest trees; it is common in the forests of Cochin China. Specimens which M. Pierre has obligingly communicated to Kew prove that the plant is identical with a species which abounds in Southern India. M. Pierre states that "the sap which flows from the stem has exactly the appearance of milk, and may even be used as a substitute for it; and it has a slight nutty flavour. In the liquid state it is often employed in medicine by the Annamites and the Cambodians. The bark, after being dried ordinarily in smoke, is sold at 20 to 25 francs the picul=133½ lbs.), and exported to China. The bark is a medicinal product esteemed by the Chinese."

The real source of the drug was cleared up when the specimen of *Eucommia*, collected in Hupeh in 1887 by Dr. A. Henry, was described in 1890 by Prof. Oiver in the *Icones Plantarum*. Dr. Henry's specimens were accompanied by the following note:—

The *Tu chung* tree 20-30 feet. The bark of this tree is a most valued medicine with the Chinese, selling at 4s to 8s a lb.

Mons. Pierre concurred that the suggested identification with *Parmeria* must be abandoned.

Subsequently further specimens were received from the Museum d'Historie Naturelle, Paris. These had been collected in Szechuen in 1874 by Rev. Père Farges. They were accompanied by the following note:—

Lorsqu'on brise l'écorce les vaisseaux corticaux s'étirent comme des fils de soies; c'est pour cela qu'il est appelé aussi vulgairement *se mien*. Ecorce officinale utilisée dans les maladies des reins et comme une charpie dans les blessures.

Eucommia is a tree of mountainous districts. The name *Tu chung* is, however, applied by the Chinese to a tree of the plains, which is almost certainly a *Muonyms* and not improbably *E. hamiltonianus*, Wall. (See *Kew Bulletin*, 1899, p. 219.)

RUBBER CULTURE IN NICARAGUA.

The following report on the cultivation of rubber on the old Mosquito Coast by Mr. Gordon Waldron is interesting because of the conflicting opinions of those interested with regard to the possibility of successful and profitable growing rubber in this district.

Before 1898 there had been no rubber planting beyond a few fruitless experiments on the Atlantic coast of Nicaragua. In 1898, the work began on what may be called a large scale, and each year since the number of planters has increased. It is safe to say that in this vicinity about £10,000 in gold value is now being expended yearly in growing rubber exclusively.

PLANTING.

The method of planting followed here by all who have achieved any success has been to grow rubber entirely without shade. The best practice is to fell the primeval forest early in the dry season, viz., during March and April - to top the branches and brush closely, and, when the whole has become dry enough, to fire it, with the result that everything is burnt but the trunks and large branches. Stakes are then set out at regular intervals over the burnt field. From the 1st or 15th of May to the 15th of June, the land is planted by setting a rubber seed to each stake, or, if seed is plentiful, two seeds, so that if one fails there may still be a tree. Where two plants come up at a stake, one is removed, and the other is left to grow permanently.

There has not been uniformity of practice as to the distance between stakes or trees. Some have planted as far as 20 feet apart, while others advocate 5 or 6 feet, the trees to be tinned out by excessive bleeding when they may be found too close together to grow fast. Opinion seems to be fixing on 10 feet as the best distance for a permanent plantation. Land measure here is in manzanas of 100 varas square—that is to say, an area of 10,000 yards or 320 square yards more than 2 acres. The number of trees, therefore, which may be planted 10 feet apart each way on a manzana is 900. No further attempt is made at logging or clearing away the remains of the forest. Decay is extremely rapid. The land is not plowed or cultivated in any way, except by repeatedly cutting down the weeds and vegetation, so as to allow the foliage of the young rubber to be completely exposed to the agency of the sun.

The trees planted in 1898 are now three years old, and their growth has been enormous. A large number of trees grown from the seed planted in June, 1898, measured in August, 1900, on an average, 17½ inches in circumference. A few of these trees measured in July, 1901, show an increased diameter of from 1 to 2½ inches. All the trees here spoken of are probably above the average of the whole. As to the average size of all the trees of the same age on a large area, it is enough to say that where there has been no difference of soil or attention, they have a regular and even appearance. A few planters believe that trees carefully grown and cared for will be large enough to bleed safely and profitably at five years of age. At all events, it is now established that the rubber trees can be grown to a large size in a few years.

It still remains for experience to prove the yield of the cultivated tree. That the hark of the tree is full of milk from the time it is capped by half a dozen leaves is beyond question, and why it should not yield as well as the wild tree, neither science nor ingenuity can suggest. A few months, or a year at most will settle the question in this locality.

As to cost, opinions naturally differ. It may be asserted safely that a careful planter; working a large area, may bring his trees to five years for 50 cents each, taking account of land, administration, labour, buildings, and equipment. The chief difficulty in the way of the foreigner planting rubber in this country is likely to be his inability to realize the need and cost of cleaning. This inability may lose him his first year's outlay. He may also stumble in trying to do too much. All the first planters suffered heavy loss, because they were unable to find seed, for love or money, to plant the land they had prepared. The young cultivated trees are now seed bearing, and in this locality there is now, in this respect to trouble.

In 1898, £200,000 would not have availed to plant successfully 200 acres. Minor troubles (which may become major, if one's temper be not serene) are the labour question and the deposition to leisure, which affects all natives.

WARNING TO INTENDING RUBBER PLANTERS.

Sane and modest planting enterprises promise well but a weather eyes should be kept on stock jobbers, who have out prospectuses for the development of large tracts of forest land, on which wild rubber trees of great value are said to be growing.

This warning is based only on knowledge of this coast, and it is not pretended to make it apply beyond, though it would not be bad judgement to conclude that similar conditions prevail all over Central America.

The bleeding of rubber began here in 1855. From the mountains to the Atlantic there existed vast numbers of rubber trees. A man could go out in the morning and come back at night with 100 lb. of rubber. The wealth and commerce of the coast was built up on rubber; but the rubber tree was practically destroyed by the ignorant and greedy hulero. Comparatively speaking, but a few scattered trees survive. These

are hidden in the depths of an almost impassable forest. However valuable they might be, if accessible, neither skill nor money could make them an important asset of a rubber company.

To prepare the land upon which they grow for rubber planting and save these trees is practically impossible. The trees are pretty sure to be torn down by the felling of others, or burned in the clearing fire. It may be added, in support of this estimate of wild trees, that the huleros, or rubber cutters, preferred to work in the camps of the rubber planters for about £2 4s. per month than to seek vast wealth in the forest.—*India-Rubber and Gutta-Percha Trades' Journal.*

CARDAMOM CULTIVATION IN COORG.

A correspondent writes to the *Madras Mail*:—The familiar cardamom of commerce is the produce of a plant which is botanically known as *Elettaria Cardamomum*, and is indigenous to the hilly parts of Cochin China, Travancore, Malabar, Coorg, Munjerabad and Nungur. It grows abundantly, both wild and under cultivation, in the moist shady mountain forests of North Canara, Coorg, and Wynaad, at an elevation of from 2580 to 5,000 feet above sea level. It is found truly wild in Canara, and in the Amamall, Cochin and Travancore forests. On the lower range of the Palney hills, near Dindignl, at an elevation of 5,000 feet above the sea, it is systematically cultivated in the shade. There is also a small Cardamom Island in the Laccadive group of atolls. The plant grows as a spontaneous seedling in woods of high land, the cultivation consisting merely of clearing the ground from trees. Fruitification occurs in the fourth year as a rule, after which the plant produces fruit for five or six years. A rich moist soil in a bracing hill climate, within reach of sea breezes and favoured by deep shade and partial sunshine, is most congenial to the plant, while it attains perfection in a light layer of vegetable mould, resting on decayed primary rock. In the vicinity of streams and in localities subject to mists and fogs it also thrives remarkably well.

Its cultivation by the natives of Coorg presents several interesting features. The people firmly believe that the plant will only grow in places where the ground has been shaken and opened up by the fall of large trees. In February or March, the cultivators proceed to the forest and map out the boundaries of gardens. Having selected some large trees for felling, all the undergrowth near them is promptly cleared away. A platform is erected near the foot of the tree selected to be cut down. All this has to be accomplished in a day. The following morning the felling begins, and is completed by noon—for to prolong the work further is considered unlucky. Several gardens are thus prepared, with spaces of jungle between each of them. Within three months of the felling, or during the first monsoon rains, the young plants shoot up on all sides, chiefly round the stems of the fallen trees. By the second year they are two feet high. Now regular weeding operations are carried out. Each plant is allowed six feet of clear ground around it, the weaklings being removed. Early in the third year long shoots bearing the cardamom pods shoot forth from the ground. They are marked with beautiful pale white solitary flowers. The fruit is an ovate triangular three-lobed three-valved capsule of a dirty yellow colour, enclosing numerous angular seeds, which form the valuable part of the plant, and which, if bruised, yield a pungent aromatic taste.

By September or October of the third year, the capsules ripen, and the first crop is gathered, a portion of it being offered to the deity. The next year a full harvest is collected, and then the plants go on yielding for about six or seven years. After this, they begin to weaken down, when large trees are again felled so

as to fall across the sickly plants. Young plants then spring up, while fresh stems shoot out from the roots of the old ones, and the new comers bear fruit in due course, dying down after five or six years, to be again succeeded by another generation produced by the process above described. The hill cultivators have their own superstitious notions, of course, but it is not difficult to explain rationally the good effects of the process of felling. The removal of the large trees admits a certain amount of sunlight; their heavy fall loosens the soil and opens it up to the action of the air. The cutting down of the undergrowth, which decays and dies where it drops, helps to fertilise the soil and to prevent its nutritive properties from being exhausted. The crushing of the plants at intervals of six or seven years by means of further felling merely serves to give them much-needed rest, after which they come up again, rejuvenated and vigorous.

Harvesting operations begin in September or October, and they present a really picturesque scene, though it is undoubtedly hard work for the harvesters, who have to put up with many discomforts and be prepared any moment for unpropitious showers of rain. They build little huts in the jungle, and in the centre of the floor a large pit is dug, about three feet deep, that will hold about eight or ten maunds of cardamoms. The sides of the pit are covered with leaves, and a circle of stones is arranged round the top to prevent dirt from falling in. At early dawn, one group of harvesters sets out to clear the gardens of weeds and undergrowth, and a little later, a second group follows. These pluck the clusters of cardamoms by hand, breaking off the racemes very close to the stems and dropping them into baskets made of leaves. At sunset, all return, bearing their precious loads. At night, after a simple meal, the capsules are picked from the branches and thrown into the pit—a task which is sometimes carried on late into the night. After a little sleep, the men rise betimes and proceed to the gardens, and the whole programme is repeated until the harvest has been fully collected.

Meanwhile, the women come from the villages to the huts, and measuring the cardamoms into bags, carry them to the drying ground. They are best dried by exposure to the sun, being spread out for the purpose on large mats, and taken in at night. Four days' good sun dries them properly, but too much exposure would result in the bursting of the capsules. After being dried, they assume a yellowish white colour. If rains come down, the drying is effected by means of the smoke of wood fires, but by this process the cardamoms turn a darkish colour, which reduces their value. The last process, before the dried capsules are packed in close baskets and made ready for market, consists in removing the fruit stalks and all impurities. Precautions are also taken to keep dry and green capsules apart; besides which, different qualities of capsules are carefully separated, those having the largest number of fruit bearing racemes on one stem fetching the best price and being technically known as "full crop."

The Coorgs have several superstitions regarding the cultivation of cardamoms. The felling of the big trees must be completed by noon, for it is deemed unlucky to fell in the afternoon. Tuesday and Friday are considered very auspicious days for beginning cultivation, whereas Sunday is always avoided as unlucky. The presence of certain plants, such as ebony, dammer, wild nutmeg and wild pepper, near the felled trees, is looked upon as a sure sign that the site cleared for new gardens is favourable for a rich crop. To ascertain this, a few big trees are sometimes felled one year and the following year, the presence or absence of the lucky trees just named is looked for, and only if they are found is the site used for a garden. Cardamoms serve a great variety of purposes, and possess, therefore, considerable commercial value. In commerce, several varieties are distinguished according to their size and flavour. The most esteemed are known as "shorts," being from a quarter to half an inch long and about a quarter broad. Following those

come "short longs" and "long longs," also distinguished by their size, the largest reaching about an inch in length. The "shorts" are more coarsely ribbed and of a brown colour. They are commercially called Malabar cardamoms or Wynaad cardamoms and reckoned the best of the tree. The "long longs" are more finely ribbed and of a paler colour, the seeds being white and shrivelled. The "short longs" differ from the latter only in being shorter or less pointed. Large cardamoms, distinct from these, are furnished by a different species of *amomum*.

In Travancore, where the cardamom grows spontaneously in the hills, in the deep shade of the forest, the cultivation has hitherto been almost entirely in native hands. The cultivators early in the season go up from the low country, cut the brushwood, burn the creepers and otherwise clear the soil for the growth of the plants as soon as the rains fall. The rainy months are terribly malarious, so the cultivators hurry back to return at crop time. Till a few years ago, cardamoms were State monopoly, but this system has been almost totally abolished and a system of land-tax introduced instead, with considerable profit to the Sirkar. In Coorg and Wynaad also, the industry is almost entirely in native hands, though the cultivators can always obtain remunerative prices from planters and European merchants. On the Anjer Kandy Settlement, near Tellichery, there are fine gardens, which yield very satisfactory returns.

The cardamom is not very largely used in English cookery, but in Northern Europe it is extensively consumed, being much in requisition for flavouring pastry. In India it is greatly prized, and is an article of almost daily use, being substituted for tobacco as well as for betel and pan, as well as partaken of in conjunction with these articles. The capsules are used by natives in flavouring sweetmeats and certain cooked dishes, while, when tender, they are pickled. The use of the spice both as a medicine and a luxury has gone up steadily, so that cardamom cultivation, systematically conducted, would be a suitable industry especially for native capitalists and planters. The cost of cultivation does not amount to much, while by the adoption of improved methods, such as timely transplantation, trenching, manuring and irrigation, quantity and quality of crop could both be substantially improved. The plant easily repays care bestowed upon it, almost the only necessary conditions being that it should be raised on congenial soil and harvested and cured with due regard to the needs of buyers and consumers.—*Indian Agriculturist*

VALUE OF WOOD ASHES.—The three valuable fertilising elements found in wood ashes are potash, phosphoric acid, and lime. The value of a sample of wood ashes was formerly measured by the amount of potash it contained, but now that the value of lime is more generally recognised, that element is considered. The value of any sample of ash will depend on the wood which was burned to produce it, and on the way it was burned. If exposed to the weather heavy rains will leach out some of the potash. It is probably safe to assume that the average ton of wood ashes kept under cover contains 5 per cent. of potash, 1½ per cent. of phosphoric acid, and 33 per cent. of lime. The phosphoric acid in ashes is insoluble, but the potash and the lime are both in good form for plant feeding. Wood ashes have a mechanical effect on soils. They bind the lighter sandy loams more closely together, thus making them better able to hold water. The lime acts beneficially on clay soils by pulverising them. The potash lye from the ashes, in solution, has power to dissolve organic matter, and thus making nitrogen in the soil available. Wherever wood is burned on the land very rank growth is sure to follow. This is not all due to the potash left in the ashes from the burning, but because that potash helped to make the nitrogen in the soil available for plant food.—*Journal of the Department of Agriculture of Western Australia*,

AIRBORNE TYPHOID.

BY LIEUT.-COLONEL R. H. QUILL, R. A. M. C.,

[LATE] SENIOR MEDICAL OFFICER, CEYLON.

At the late meeting of our Association, Dr Leigh Canney read a very interesting paper on the Etiology of Typhoid Fever, in which, while strenuously supporting the proposition that epidemics of typhoid fever are always waterborne, he vigorously denounced those who ventured to believe that such epidemics could sometimes be traced to an airborne origin. I should like to say, at the outset of the remarks I have to offer on Dr Canney's proposition, that I, in common, as I believe, with the officers of the R. A. M. C., as a body, hold that epidemics of typhoid fever are chiefly waterborne, and it is to the water supply we first turn our attention, when investigating the origin of typhoid cases, occurring sporadically or epidemically. But I am entirely at issue with Dr Canney when he lays down the hard-and-fast proposition that typhoid epidemics are invariably waterborne—never airborne. The subject is one of far-reaching importance, well deserving of full discussion. I will therefore, as briefly as possible, adduce evidence to prove that the waterborne theory will not *always* account for the occurrence of a typhoid epidemic. My facts will be drawn from our experience in connexion with the large camp in this Island where Boer prisoners of war are confined. In August, 1900, a large camp was formed at

DIYATALAWA,

in the hills of Ceylon, for the Boer prisoners of war. The first batch of prisoners arrived on August 9th, and succeeding batches quickly followed, until by the end of December 96 officers and some 5,000 men were under confinement. On September 21st, 1900, one of the prisoners who had arrived on September 5th reported sick. He was found to be suffering from typhoid fever of probably ten or more days' duration. This was the commencement of an epidemic of typhoid among the prisoners, which soon assumed formidable proportions. By the end of December 600 cases had been diagnosed as typhoid fever, and during the same period some 200 cases of simple continued fever occurred, many of which, it is highly probable, were mild cases of typhoid. We fully satisfied ourselves that this epidemic of typhoid among the prisoners had been imported from South Africa, but in that connexion I refrain from further remarks, as it has nothing to do with the proposition I have set myself to prove. It is here necessary for my argument that I should briefly describe the relationship which exists between the prisoners' camp and that of the surrounding camp, where is located the military guard. The prisoners' camp, situated on an undulating slope, is surrounded with a strong fence of barbed wire; outside that fence are inner and military guard lines. The "inner guard" consists of a number of sentry boxes at intervals of 100 yards, and placed only some 20 yards from the barbed-wire fence. The "outer guard" consists of guard huts occupied by strong guards, placed on rising ground some 200 yards further back. The latrines, urinals, washhouses, and hospitals for the prisoners are all situated close to the barbed-wire fence which surrounds the prisoners' camp as a whole. The guard for the prisoners was formed by the 2nd Battalion, King's Royal Rifles, who were a fine healthy body of men. No suspicious fever of any kind, prior to the outbreak among the prisoners,

existed among them. The battalion remained in a thoroughly satisfactory healthy condition until October 18th, 1900—that is, for over two months after its arrival at Diyatalawa, and for a month after the first case of typhoid occurred among the prisoners.

On October 18th a man reported sick; he was found to be suffering from fever, which quickly proved to be typhoid. From that date admissions for typhoid among the battalion occurred at short intervals, until by the end of December there had been altogether 24 admissions and 5 deaths. Now in attempting

TO ACCOUNT FOR THIS OUTBREAK OF TYPHOID FEVER AMONG THE MILITARY GUARD

at Diyatalawa Camp I commence by advancing the following evidence against the outbreak having been in any sense waterborne:—

1. The water supply was obtained from a mountain stream some three miles distant, and was brought into camp by underground iron pipes. The intake in the hills was so isolated that its pollution was, indeed, very remote. On the arrival in camp of the main iron pipes, smaller ones passed directly into four large Pasteur tank filters disposed about the camp in suitable positions, while in each barrack hut portable Pasteur or Berkefeld filters were placed and kept under careful supervision; thus all water used in the camp before its distribution invariably passed through a thoroughly reliable filtering medium. The water prior to filtration was subjected to a weekly chemical analysis, and the report always gave the water a high character; a similar verdict followed frequent bacteriological examinations. There has been no alteration in the water supply or filtering arrangements since the camp was opened, and no case of typhoid fever has occurred among the troops since December, 1900—that is, since the practical cessation of the epidemic among the prisoners of war.

2. No fresh milk was allowed within the camp precincts. When milk was required condensed milk (Milkmaid Brand) was used.

3. All aerated waters used in camp came from the Ceylon Brewery at Nuwara Eliya, and were identical with those used at that sanatorium. There has been no enteric fever at Nuwara Eliya.

4. No uncooked food or uncooked vegetables were used in camp.

5. No native hawkers of any kind were allowed to enter the camp.

6. Within the camp there were five or six native shops; these were under strict military supervision. No native drinks of any kind were sold in them. The aerated waters sold in them were invariably procured from the Ceylon Brewery at Nuwara Eliya.

7. All men leaving the camp for purposes of duty or pleasure were obliged to take with them a water bottle filled with filtered water.

8. It is to be remembered that for obvious military reasons the camp was situated in an isolated position in the hills, far removed from habitations of any kind.

As the foregoing considerations, in my judgment, completely put out of court a waterborne cause as being responsible for the typhoid outbreak in the military camp, I was driven to the conclusion that the infection was airborne, being derived from the adjoining prisoners-of-war camp, where at the time an epidemic of typhoid fever was raging. In support of that opinion I submit the following observations:

1. Guard huts, accommodating strong guards, surround the prisoners' lines, and are close to them. This for military reasons is unavoidable.

2. The men on sentry duty are during day and night posted at short intervals almost immediately outside the barbed wire enclosure which separates the prisoners from the military camp. Thus those on sentry duty (a numerous body of men) are in close contact not only with the prisoners, but with their latrines, urinals, and washhouses, all of which, as I have already stated, are situated close to the barbed-wire fence. The undesirability on health grounds of the line of sentries being placed so close to the prisoners' camp was fully recognised, but for military reasons it was not found possible to alter the arrangement. From the foregoing remarks it will be obvious that those on duty in the guard huts and sentry boxes must be to a very appreciable extent exposed to the emanations arising from the latrines used by the prisoners of war, especially during the time when the latrines are emptied—a frequent necessity. Now assuming that such emanations contained typhoid organisms—not a very far-fetched hypothesis when we remember that at the time typhoid fever was very rife in the prisoners' camp, and further assuming that typhoid infection can be airborne—the possibility, nay the probability of the infection being thus conveyed from the prisoners' camp to the military guards appears to be well-founded.

3. But in addition to the assumption that the emanations from the prisoners' latrines may have conveyed infection to the military guard, it has to be recorded that the soil of the prisoners' camp gave peculiar facilities for the spread of the infection. The rank grass which originally covered the slope upon which the previous camp was arranged very soon disappeared, giving place to a reddish soil, so friable that dust was much in evidence, notwithstanding that it was the rainy season of the year. Now it is not unreasonable to reject as pure the dust of a camp in which at the time a formidable epidemic of typhoid fever was prevailing.

4. Lastly, the possibility of the infection being conveyed to some extent by flies must be considered. During the whole period that typhoid fever was prevailing in the prisoners' camp, flies in that camp amounted almost to a plague, the military camp being also infested, but to a lesser extent. Now flies being well adapted for the carriage of infection it is plain that, under the conditions existing in the prisoners' camp, there would be nothing to prevent flies laden with typhoid bacilli migrating from the prisoners' to the military camp, and thereby conveying to the latter camp the poison they carried.

I have endeavoured in this paper to review dispassionately the evidence bearing on the causation of the typhoid outbreak which occurred among the military guard at Diyatalawa Camp, Ceylon, during the closing month of 1900. I submit that I have shown—

(a) That all water avenues through which typhoid fever could have been conveyed to the military camp at Diyatalawa, were efficiently guarded, and therefore that a waterborne origin must be abandoned.

(b) That the infection was airborne, resulting from emanations from specifically infected latrines, infected dust, or bacilli-laden flies.—*British Medical Journal*, Feb. 15.

ENGLISH MERCHANTS IN THE FRENCH CONGO.

RUBBER AND OTHER PRODUCTS.

(To the Editor of the "Times.")

Sir,—I have read with considerable surprise a paragraph in your issue of May 29 setting forth a communication from the French Colonial Minister relative to the position of the English merchants in the French Congo. I propose to deal briefly with this communication and to refer to the character and gravity of the conflicts of private interests, without misrepresentation or exaggeration.

It is quite true that the litigation has been between private firms; but this has arisen entirely from the action of the French Government in granting concessions to certain new companies in Paris, to the detriment of the old firms who have been established and trading in the colony for over 40 years. In my own case my experience extends over a longer period, and my firm has paid many thousands of pounds to the French colonial authorities for duties, patents, &c. The greatest cordiality existed between the Government and the merchants until the granting of these concessions. The trading was also uniformly carried on, without litigation or trouble, and, I venture to assert, to the benefit of the colony and the natives of the country.

To those unacquainted with the nature of the trade it may be interesting to state that the produce of the soil, indiarubber, palm oil, palm kernels, ebony, and the ivory tusks of the wild elephants, comprise what the native has to give in exchange for cotton manufactured goods and other imports. The commercial intercourse of the *Hinterland* is by a system of barter between what the native has to offer and the Europeans to give in exchange.

The French Government by the granting of these concessions has handed over large tracts of country to certain companies, who claim the produce of the soil which the native innocently believed belonged to him and which he is now prevented offering to the English firms, though most anxious to do so. The freedom of trade to which reference has been made used to exist, but does so no longer. It cannot be called "freely carrying on their business" to be shut up in a factory, on a piece of land about 100 yards square, and not allowed to buy any produce from the natives; yet that is the position these concessions have placed us in today. The monopolists have closed the trading routes against us, seized our produce, and by the course of litigation, already referred to, obtained damages against us, presumably for trespass and illegal trading. Some of these trading centres are in the conceded area, and the situation of others is uncertain, because, so far as I know, no complete boundaries have been defined, except on paper. In proof of the uncertainty to which I refer, I may instance a dispute which arose not long ago between two of the concessionaire companies, also a case in March last, when a seizure of a quantity of indiarubber was made from one of our traders at M'Beka. I do not know the exact position of this place, and although I have made inquiry, have not succeeded in getting the information, but am informed that there is a doubt as to which concession it belongs to. What the English firms complain of is that, having traded in the country so many years, before the advent of the French authorities in the *Hinterland*, subsequently under French rule by licenses

granted and paid for, and having invested labour and capital, they consider they have acquired certain invested interests which are now being taken from them without any consideration whatever. What the English firms say is, if you are determined to drive us out of the country, pay us for our factories and goods, also a fair sum for disturbance, and we are ready to leave the colony. We have endeavoured to do our duty as good colonists. Let the French Minister for the colonies inquire from the natives of the Ogowé and N'Gomie, far and wide, what they think of Hatton and Cookson, and then let the Minister realise that in relinquishing our position we are saying good-bye to very old and faithful adherents among the native population with sincere regret. I am, Sir, yours faithfully,

EDWARD H. COOKSON,
Managing Director, Hatton and Cookson
Limited, Liverpool.—*London Times*, June 16.

PLANTING IN B. C. AFRICA.

(From our Correspondent.)

Mlanje, British Central Africa, June 24.

I have been up for a change to our mountain sanatorium, and had to run from it owing to the cold. My house is at 6,800 ft. elevation. The thermometer registered 44 deg. at 6 a.m., 60 deg. at noon, and 50 deg. at 6 p.m. during the week I was there. How does that temperature compare with Nuwara Eliya?

COFFEE CULTIVATION IN BRITISH CENTRAL AFRICA

is not proving the successful enterprise that was anticipated some years ago. Much land was planted with coffee (like scrub or chena lands in Ceylon) which only gave a crop and pegged out. Even on good forest clearing with or without shade crops it cannot be depended on to come up to estimates owing to various causes, principally insect pests, thrips, bug, &c. &c. Labour is abundant now. The hut tax has been raised to 6s. I am turning away people daily who come for work, and I have none to give them, as I am as clean as a new pin, tea cut down, and coffee crop finished and despatched. Many planters, who have given up coffee, have gone to transport and trading work. Others are going in for tobacco planting which should yield them a good profit. I have got some 30 acres in cultivation this year. A very good market for tobacco is found in S Rhodesia, and if we get into the South African Customs Union there ought to be an unlimited market for us, which at present, is practically shut, owing to the protective duty. Food and labour are becoming cheaper instead of dearer. I know one man who paid his last gang of people off with Calico at the rate of 1s 6d for men, 1s for women and 6d for children, per month, last week. I am paying 2s for men, 1s 6d for women, and 1s for children.

OUR RAILWAY

seems as far off as ever, no start made yet. I hear that, owing to the war (which, thank, goodness, is now concluded) the whole amount of capital was not subscribed, and that the Government would not allow Messrs. Sharrers' Zambesi Traffic Company to begin work till all the capital was secured. Mr Stephen Robins, who was on Laelumza, the Nyassland Company estate, has secured a billet in the B C A administration and has gone to Fort Johnston, coffee ventures not having proved an Eldorado to him.—H. B.

P.S.—I enclose some photos. I regret my plates were spoiled with the damp during the rainy season. So no good results to show.—H. B.

TEA CULTIVATION IN NATAL.

Renter's correspondent in Natal, who, we believe, is Mr Charles H Lepper, formerly a tea planter in India, in describing the industries of the colony, devotes some space to tea. He says: "The more important tea estates are situated on the north coast in the vicinity of Stanger, a small village in the warmest corner of Natal, not very far from the mouth of the Tugela River, dividing Natal from the Province of Zululand. The estates are a few miles inland from Stanger, and have been connected with that place by a narrow gauge (24 inch) steam tramway, eight miles in length, by the enterprise of the local managing director of the most important of the tea companies. The two leading companies hold adjoining estates, the larger known as Kearsney, and the other belonging to Messrs W R Hindson and Co.; Limited, proprietors of four gardens forming one property. The Kearsney is considerably the larger of the two, and has about 1,750 acres under tea of all ages. The 'jat' upon this estate is a good strong Assam hybrid. The output of 1901 was close upon one million pounds. The soil is friable, sandy in places, and of the red loam class in others. The bushes in parts of the estate are very well grown and equal to those one sees in Assam and Cachar, and considerably better than the average in Dehra Dhuu. The vacancies are chiefly upon old sites of Kaffir huts, upon which tea cannot be got to grow, owing to the excess of potash in the soil. The bushes come into bearing in their fourth year, and are expected to yield in that year 400lb to the acre, or under favourable circumstances 500lb. When in full bearing, in the fifth year, the average yield is about 600lb, and in a good season reaches an average of 700lb. To bring an acre into its fourth year is estimated to cost £30, but there are considerable risks; as after seedlings have come on well during the first portion of their growth, should a hot wind come it will sometimes kill off every seedling of that season's planting, in spite of any shelter which can be provided. Happily the labour employed is almost exclusively that of Indian coolies, imported under 'indentures' for five years. The class of coolies imported into Natal, chiefly from Madras, the rest from Bengal and the North-West Provinces, is not to be compared, either in physique or in character, with those employed in Assam or Cachar. Like all the coolies imported into Natal, they are of a very inferior type, and most of them would not be able to earn their living upon an Assam estate. I also visited W R Hindson & Co.'s estates. These, the second in importance in Natal, possess an aggregate of about 800 acres under tea of all ages. The output in 1901 was given me as 400,000 lb, and this year it is hoped that it will be increased by 50 per cent. The wholesale prices obtained by Natal tea estates upon the South African market run from 7½d per lb for the lowest (very coarse) quality called 'extra fine Souchong' in metallic paper packets, or 7d per lb in boxes of 14 lb and upwards, up to 1s 6½d per lb for the highest quality (Orange Pekoe) in 1lb packets, or 1s 6d in boxes. A half-penny per lb extra is charged if purchases are of less aggregate weight than 600 lb."—*H and C Mail*, July 4th.

PLANTING NOTES FROM THE SEYCHELLES.

Specially written for the "Ceylon Observer."
Seychelles, July 10.

MR. R. W. SMITH OF THE CEYLON P. W. D. arrived here about a month ago from Ceylon via Mauritius. Why he was sent this round-about way, when there are direct steamers every eight

weeks between Colombo and Seychelles, is a secret known only to those who rule in your part of the world. He was accompanied by Mrs. Smith, a Sinhalese clerk and several coolies. After a day or two, arranging matters with our Administrator, the party went over in the Government cutter "Wave" to Félicité Island. Mr. Smith had left Ceylon under the impression that Félicité had only its name to recommend it and that he and his party would have a pretty rough time of it when they got there. However, being well supplied with tents and camping gear, they hoped to get along somehow. They were considerably and rather agreeably surprised on reaching Félicité to find a nice little stone bungalow, newly white-washed and painted, awaiting them. The coolies were lodged in the island hospital where they also soon made themselves thoroughly at home.

FELICITE

is an island of about 700 acres. It is Government property, but leased on a long term to Messrs. Baty, Bergne and Co. of Victoria. This firm are the principal holders of islands in this part of the world, they being lessees of the Aldabra and Cosmoledo and most of the Admiranté Archipelagoes. Félicité is a very mountainous island and planted partly in

VANILLA AND COCONUTS.

It produces at present about 50,000 nuts a month, but will soon produce considerably more when the younger plantations of coconut trees come into bearing. A large quantity of vanilla was planted on Félicité some years ago, but for some unknown reason it has never done well there.

This is not the first time that Félicité has been used as a

PLACE OF DETENTION FOR POLITICAL OFFENDERS. The ex-Rajah of Perak (Strait Settlements) was confined at Félicité for nearly two years before he was allowed to reside at Mahé. In the good old days, before the French occupation, Félicité seems to have been a rendezvous for pirates. At the north end of the island there are several old walls and other signs of a former occupation. Several Spanish coins of about 1650-1700 have been from time to time picked up in the neighbourhood and this gives colour to the belief that it was a pirate haunt. *Quién sabe?*

Mr. Smith was naturally very interested in seeing our

SEYCHELLES METHODS OF WORKING COCONUTS and comparing them with what is customary in Ceylon. To begin with, nuts are never picked off the trees. In fact, if even a labourer were caught doing so he would be severely punished. Coconuts here are largely converted into oil, and we believe that the longer a nut is ripening the larger the oil cells in the copra. Here nothing is done with the coconut husks, no coir is manufactured. Mr. Smith was also very interested in our methods of drying copra. All over the Seychelles we have what is known as *secheries* (drying houses). These are of two kinds, either fixed trays and sliding roofs or sliding trays and fixed roofs. The sliding trays or roofs are on wheels so that one or two people employed about the headquarters of an oil estate can protect in a few moments many tons of drying copra from a sudden shower of rain.

THE EXPORTS OF GUANO

from Seychelles are steadily increasing. The barque "Cape Race" sailed a few days ago with 1,000

tons for Falmouth for orders. A large Norwegian barque is loading a cargo for Antwerp, and the Colonial three-masted schooner "Ebenezer" is about to load 800 tons for Port Louis, Mauritius. Our Seychelles guano is a dark brown impalpable powder, something like cocoa, but without any smell. It is poor—very poor—in all manurial qualities except phosphates. It is not worth much in itself but a splendid stuff with which to mix other manures.

VANILLA PLANTING AND CULTIVATION.

The following memorandum has been issued from the Government House, Seychelles:—

MEMORANDUM.

No vanilla plantation should be started in Seychelles with a capital of less than £1,000, seeing that it takes three years to bring in a crop. Land suitable for vanilla, cacao, coffee and other tropical products cannot be secured for much under R300 per acre, and even at this price, it is not easily obtainable. The ordinary rate of interest in Seychelles is twelve per cent per annum. The local currency is the Rupee, the value of which may be taken as 1s. 4d. Under the old system (planting on bars, wires, etc.) from 1900 to 1900 vines were planted per acre. Vanilla is now planted on live trees, and the number of vines planted depends upon the number of trees existing on the land brought under cultivation. Cuttings of quick-growing shrubs are now often planted in vacant spots, and vines are grown thereon in the absence of trees, and within three months of the planting of the cuttings. Vines are planted 6 in. long, and began to bear three years after planting, but will only come into full bearing in three years more. Vines are worth per 100 from R3 to R5 according to district. Wages: men R14 to R16, and women R8 to R12 a month, without rations. On hill estates labourers are not easy to get, and most of the Africans prefer working on the share system. A man can plant 350 cuttings or vines per day, and can keep in good order, throughout the year, 2,500 plants. Women are employed for marrying the flowers *i.e.* removing the pollen from the anther of the flower and applying it to the stigma (fertilisation), without which operation the flower is lost. A woman can marry from 600 to 800 flowers per day. No flowers can be married after midday. Each vine can produce from 25 to 30 pods of different sizes, from 4 in. to 8 in. long. On an average 130 green pods go to 1 lb. of dry prepared vanilla. Pods shrink considerably in preparation, losing a quarter of their weight. Local prices: last year (1901) fine pods prepared fetched R6 to R10 per lb. Green pods are now being sold at R3 to R5 per hundred pods. The regular flowering season is from August to December. The cost of preparation varies from R1 to R1.25 per pound. The pods are gathered about nine months after the flowers have been married, and curing the pods takes from three to four months. In Seychelles, as elsewhere, there are bad seasons (too much rain), in which case the yield is poor. The climate of Seychelles is very healthy. The population on the 31st May, 1901, was 19,257. The death rate in 1901 was 18.77 per 1,000. The Seychelles are in direct steam communication with Aden and Mauritius by a monthly service of steamers of the Messageries Maritimes Company, and with Colombo and Mombassa by a bi-monthly service of steamers of the Imperial German East Africa Co. Steamers belonging to the British India Company call, from time to time, at Seychelles. The Eastern Telegraph Company has a station at Victoria.

The rainfall in 1901 in Victoria was 101.83 inches. The maximum shade temperature registered was 88.5, and the minimum 68.4; the mean for the year being 78.50.

Total revenue for 1901	...	R486,323.98
„ Expenditure for 1901	..	401,821.57

TEA BOXES:—VENESTA, LIMITED.

(Extracts from Proceedings at Fourth Annual General Meeting.)

It requires many tons or millions of feet of Venesta boards to amount to the total turnover of last year, namely £54,500, as well as a great deal of hard work in the manufacture, disposal, and shipment of the goods. Perhaps I may here point out that this turnover has been created on an available working capital of about £3,000—which may possibly convey to you some idea of the care and close attention that has been necessary in the management of the business. I am glad to be able to add that the six months now closing show further proportionate increases, and unless any unforeseen circumstance arise the totals for 1902, both in export and home trade, should show a larger turnover than in any previous year. The export department has been affected by the general conditions of the tea industry. Several of our buyers of tea chests held over rather large stocks of chests from 1900, and the restrictions in the picking of teas reduced the quantity of chests required for the season. As you will see by the report, our total shipment of tea chests for the year 1901 was 296,000 while for this year in this first six months I am glad to tell you we have sold 258,000 tea chests, and expect by the close of the year to finish with sales of about 350,000. Mr Penny, who has recently returned from Ceylon and Australia, has, as might be expected by his energy and ability, done good service for the company, and cleared up some important points of difficulty, and while visiting several of the tea gardens has brought the advantages of our tea chests practically before the managers and growers, from which good results may be looked for. I regret to have to tell you that the lead mill, which ought to have been completed last June, did not get to work until November, and then not successfully, and therefore did not contribute to the profits of the year. The reason for this was that our consulting engineer made some errors in his design of the mill, and consequently alterations have had to be made in the machinery, which has caused considerable delay in completing the plant, together with some loss of profit. You will, however, be pleased to hear that these difficulties have been overcome and that the mill is now in good working order and capable of turning out all the lead we require for all our trade. The working of this lead mill and the convenience we experience by being able to ship all the necessary parts and fittings of our tea chests from our own factory will greatly facilitate the working and contribute to the profits of the business. We have now a staff of experienced work-people (about 100), who have acquired an expert knowledge of how to put our boxes, casks, and fittings together, and we are also fortunate in possessing an efficient

foreman of each department, all of whom are controlled by our able and excellent works manager, Mr Whitt, who has always shown considerable interest and intelligence in the performance of his duties. The Russian business has shown further increase in the department of furniture, seating, hat boxes, &c. The works at Reval, which occupy a space of about thirteen acres, part of 54½ acres owned by the company, and employ about 1,500 hands, are well maintained, and consist of some of the most modern machinery suitable for the purposes of the business, worked by electricity of about 900 to 1,000 h.p. The factory specially erected for the manufacture of Venesta boards is capable of producing about 30,000,000 ft a year.—*Home and Colonial Mail*, July 4.

TREE-GROWING AT A HIGH ELEVATION IN CEYLON:

THE BEST-WOODED PLANTATION IN THE ISLAND:

ABBOTSFORD REVISITED.

We suppose we may, without presumption, speak of the Tea and Cinchona plantation identified with the name of the late Mr. A. M. Ferguson—and with that of his son, the present proprietor,—as, without exception, “the best-wooded” private estate in the island. The late proprietor took a special delight in getting seed and plants of trees likely to grow in the soil and at the elevation of Abbotsford from every quarter he could hear of in India, Australia, Java, the Straits and England or Scotland. There were, of course, many failures; but also many successes in his introductions and for the last six years of his life he had the great advantage of the counsel and aid of the present Manager of the Estate who knew a great deal about Forestry before ever he came to Ceylon. The result is that, so far as the introduction and cultivation of a great variety of Australian Eucalypts and Acacias, Javanese “Albizzias,” Himalayan Toons, Birches and other trees, Japanese and English Firs, with pines and oaks; and a considerable variety besides,—Abbotsford presents an “experimental plantation” in Upper Dimbula, comparable—*longo intervallo*—to even the “Hakgala Gardens” on the other side of the range facing Uva. Indeed the experienced and enthusiastic Superintendent of Hakgala was, some time ago, astonished and delighted to see the conjunction in Lower Abbotsford of so many palms—Australian *Coryphas* and even *Caryota* flourishing: difficult if not impossible to grow in his colder climate—along with English, Himalayan and Japanese introductions. One of the finest English oaks we have seen in the island is here—a tree of, perhaps, 25 feet high; but, curiously enough, it practically stopped growing six years ago and does not now make an inch a year in growth. An oak and a palm, within a few yards of each, form an interesting conjunction. We have not seen the Gangaroowa “Albizzias”—which are realising R15 each, no doubt greatly because of their proximity to the Kandy timber market—but it would be hard, we think, to beat the trees of this description on Abbots.

ford, some of them 17 to 18 years old and great giants. *Auracarias* here and there diversify the outlook. One of the most strikingly handsome trees, scattered over the plantation, is the Himalayan Birch-tree (*Betula Acuminata*)* which, though not tested yet, must offer a very substantial timber, perhaps too hard to work by the carpenter (in a land where bobbins are not in request)—but at any rate invaluable for rough building work on an estate and for firewood if the necessity should arise.*

EUCALYPTS.

Along the roadside, too, there are some magnificent trees of *Eucalyptus parviflora*; while there is one specimen of the attractive *E. Ficifolia* (rare in Ceylon) with its peculiar scarlet blossom; while higher up we noted grand specimens of *E. Calophylla*. Very striking also is the giant Eucalypt—*E. Amygdalina* or white gum—to which species in Australia belong the highest trees in the world. Here they grow to, perhaps, 100 feet; and the contrast is interesting between the red (*E. Rostrata*), and the other two gums growing alongside:—

THE RED, WHITE AND BLUE!

Of blue gum (*globulus*) not many trees remain; for the reason that they have chiefly supplied firewood for the Factory tea driers (power is got from the river fortunately) during the past ten years, so that there has been no trenching on the forest reserve.† A curious discovery

* We only identified the tree on our return to Colombo and from what is said by Dr. Watt in his "Economic Products," it will be seen that we are a little wide of the mark as to the value of the timber:—

"*Betula acuminata*, Wall; Brandis, For. Fl., 458; Gamble. Man. Timb., 372. Habitat.—A large tree, met with in the Himalaya, from 6,000 to 8,000 feet, in the Khasia Hills, the mountains of Manipur and the Naga Hills to Martaban.

"*Properties and Uses* :—Fibre.—The bark when mature peels off in larger slabs than in any of the other species, and is therefore not so serviceable for the purposes to which the others are put.

"*Food*.—On the mountain tracts of North-East Manipur, bordering on the Naga Hills, the Lahupas cut off the bark in large slabs just before the leaves appear. The inner layer of these slabs is carefully separated from the liber and sun-dried. This is either eaten like biscuits, or it is reduced to flour and cooked as an article of food. The tree is much prized by these naked savages, and in early spring yields a considerable portion of their diet. This remarkable fact does not appear to have been observed by any traveller, previous to my exploration in 1880 of the hill tracts of Manipur, and apparently the nutritious properties of the bark have not been discovered by other Indian hill tribes. (See remarks under *B. alba*.)

"*Structure of the Wood*.—White, moderately hard, close-grained. Weight 41 lb. per cubic foot.

"It is very little used, but Wallich says it is hard and esteemed in Nepal for all purposes where strength and durability are required. "The wood is close-grained and takes a fine satin polish. It is particularly good for door panels, and the examples in the Government House at Naini Tal show that it is a valuable acquisition for ornamental work." (Atkinson's Him. Dist. X., N.-W.-P. Gaz., 318.)"

† This is as true in regard to timber, planking, &c., as for fuel—all the timber required for buildings, lines, &c., has been got for many years by cutting and sawing introduced trees without touching original reserves and we fancy the Abbotsford Manager could more than confirm the useful figures sent for publication lately by Mr. Maclure of Maskeliya.

about the blue gum was that, while flourishing apace on the lower division up to 5,500 feet, it did not grow at all well on Upper Abbotsford—although strangely enough there are magnificent trees in and around Nuwara Eliya still higher up. The late Mr. Ferguson and his Manager were so convinced as to the comparative failure of this tree that they gave special warning to the Government Forest Officers not to waste time and money by trying plantations of it in the adjacent jungle clearings; but their advice was not heeded, with the result that today the five-acre clearings planted with blue gums in the jungle by the old road to Nuwara Eliya are poor affairs—and stand as exhibitions of stunted failures. The blue gum tree serves well for factory (fuel) purposes save that the exuded gum is apt to fix on the flues and in the case of steam-engine boiler flues, especially, to choke up the channels. Even in a domestic stove, the flue has been found blocked up after a time and has required hammer and chisel to cut out the adhering gum which had become almost as solidly fixed as if it were part of the iron!

One of the most attractive of the Eucalypts is *E. citriodora* (the lemon-scented gum tree, from the pleasant odour of the crushed leaves or broken stems). Several fine specimens (as indeed of all the Eucalypts) are to be seen at Hakgala, and with us at Nuwara Eliya; but we hear that the finest show of the lemon-scented, perhaps, on a private estate, is found at Mr. Gordon's bungalow on Rappahannock, Udapusellawa. Altogether there must be over a score of different Eucalypts—many of them strikingly handsome trees—in the plantation; but curiously enough there is no specimen of *E. Pilularis* which attracted attention some time ago on Carlabeck, for its size and good timber. —It is curious to notice the resemblance and the difference between the barks of three prominent Eucalypts—Jarrah (*E. Marginata*) Red gum (*Rostrata*) and Iron Bark (*E. Crebra*)—all doing well as growing trees.

Some of the Grevilleas here vie in size with the other large trees mentioned, and they and the "toons" (*Cedrela toona* of the Himalayas) are freely scattered over the property. But the former (the "silky oak" of Queensland) may be taken to have reached the limit of successful cultivation if regard be had to its full growth as a timber tree, on the neighbouring estates—Maha Eliya and Calsay—and again on Tangakelle, Ouvahkelle and Elgin which present a wonderful sight in the uniform and numerous interesting belts of grevilleas, where we can recall the wide expanse of cultivation being without a tree some years ago. Perhaps *E. Robusta*—which has become a favourite in these parts as at Nuwara Eliya—is a quicker grower than the Grevillea; while it also supplies a substantial timber. A grove of these between Abbotsford and Tangakelle shows very regular and successful growth; but the striking fact here is the way in which self-sown cinchonas have sprung up among the gums, groups of fine healthy plants showing how well shade agrees with the far-famed Peruvian

introduction. Had cinchona originally been grown under shade in Ceylon, we might even now rival Java in our exports.

A SPECIAL FAVOURITE.

But we must not forget to notice what is, in our experience, the best timber tree to grow in and around Nuwara Eliya and perhaps (judging by the specimens here) lower down, namely *Acacia Melanoxydon*. It is really a valuable cabinet wood, when fully grown; and we recall the late Rev. W. Oakley, the veteran Church Missionary, showing us with pride a book case and other cabinet-work he had made out of some Melanoxydon trees, having all the markings and dark colouring of Nadoon or Walnut. No straighter or more handsome tree in our opinion grows about Nuwara Eliya, nor one which better resists monsoon bursts and wind-storms, apt to level or break the tops off, a good many gums and other trees. On Abbotsford, and especially on adjacent Dessford, there is a large number of the finest specimens (for growth) we have seen of Melanoxydon; but, alas for the exigencies of the situation—as well as because of distance from market and absence of demand—a good many are being levelled and cut up for fuel purposes. It is a fact, however, that this tree, like most of the Acacias, is not a favorite with tea planters, because of its tendency to spread and throw up suckers, especially where the soil is stirred for cultivation purposes. On a piece of land reserved for timber trees this propensity does not so much matter: in fact it constitutes an economical means of planting up waste bits of land in or near the Sanatorium, where the tree flourishes apace, and in its lofty as well as symmetrical, pyramidal shape, it offers an attractive feature as an avenue tree, or in groups at certain vantage points.

ORNAMENTAL AND FRUIT TREES.

A very attractive-looking tree in its youthful prime—seed got from Java—is *Acrocarpus grandis*; as also *Svietenia macrophylla*, Mahogany plants from Peradeniya; but of slow growth up here; while Dr. Thwaites' favourite *Pekimbiya* (Sinhalese name of *Filicium decipiens* which he used to recommend to planters is not much more than a shrub at an elevation which not only sees certain palms but a fine *jak-tree* come to fruit; as also mango-trees in full bearing!

Of "Cupressus," and "Cryptomeria" there are many fine specimens on Abbotsford—though Hakgalla Gardens are the true show-place for giant trees in great variety of these. A tree which is encouraged as a good and handsome grower, especially suited as a windbelt, is the Himalayan *Bucklandia*, splendid specimens of which in huge well-formed trees (80 feet high or so), we observed on our way to Darjeeling from the *terai* upwards. It is very much used at Darjeeling for planking and for doors and windows.

BAMBOOS.

A feature on Abbotsford—and one which could be turned to mercantile account if a town like Colombo were near at hand—is the numerous groups of bamboos, of the giant variety especially, along the riverside and in many of the ravines, varied with

the tiny (and medium) varieties useful for basket making. The present Manager had to clear out a great many clumps of bamboos from ravines as not so useful as water or Mauritius grass.

CINCHONAS.

Revisiting Abbotsford after an interval of two or three years, one of the most pleasant sights was the number of healthy, vigorous-looking cinchona stems rising above and diversifying the tea fields, chiefly *Succirubra* and Hybrid. The smoother velvety leaves in some cases denote an approach to the more delicate and richer varieties. Altogether there must be quite 100,000 of these healthy stems from the old roots and from self-sown plants; while one of the original plants left to grow by the roadside, which was measured in our presence, is 72 feet high by 36 inches in girth at a foot above the ground. The age of this giant is 19 years.

CINCHONA PLANTING NORTH OF KANDY.

I am planting some cinchona seedlings from old Ledger. I don't find that they make much progress in old soil—sides of drains and roads—but on new land they do come away. I have been planting for fuel and it is between the lines I put the Cinchona, and I hope it will give back the outlay and leave the trees free.—*Planter*.

PLANTING NOTES.

CAPACITY OF CISTERNS.—When calculating the capacity of cisterns (or tanks) $31\frac{1}{2}$ gallons are estimated to one barrel and 63 gallons to one hoghead.

A CIRCULAR CISTERN ONE FOOT IN DEPTH.

Five feet diameter holds	... 122½ galls.
Six do	.. 176½ do
Seven do	... 240½ do
Eight do	.. 314 do
Nine do	... 397½ do
Ten do	... 490½ do

A gallon of water weighs 10 lb, and measures 277.274 cubic inches; a cubic foot of water contains 6.23 gallons, and weighs 62.35 lb; 1 cwt of water contains 11.2 gallons, and measures 1.8 cubic feet; 1 ton of water contains 224 gallons, and measures 35.9 cubic feet.—*Home paper*.

YARN FROM PEAT FIBRE.—The honour of inventing the first successful process to utilise peat fibre in the textile industry cannot be claimed by the German inventor whose achievements in this direction were recently recorded. A London wool merchant writes to say that a home industry is the pioneer in the industrial application of this new fibre, the various products of which are already on the market. "The finer yarns composed of peat fibre mixed with wool, which appear to be the dream of the German inventor, have not only been successfully produced, but the hosiery made therefrom is already manufactured by a leading Leicester firm. Further than this, yarns have been made fine enough for the manufacture of flannel equal in texture to the finest French cashmeres, and also cloths for athletic costumes, &c.

CACAO PREPARATION.—Is it because each Manager thinks he knows best and has some secret of his own, that there is so little interchange of opinions in regard to this product? In any case we are glad to have one planter breaking “the conspiracy of silence”—if such it be—although, possibly, all that is of much practical value is given already in Mr. Hart’s useful little Manual?

FISH CULTURE (THE MAHSEER) AND THE RAINBOW TROUT.—We direct the attention of all interested to an interesting letter and other remarks on the above subject to be found in our daily and *T.A.* We suppose the hardy and ubiquitous “rainbow” trout will flourish right along in the Mahaweliganga, almost from its source to its several mouths near to, and South of Trincomalee.

SEQUIA GIGANTEA PENDULA.—There exists in the pinetum at Bicton a specimen of this Conifer, 33 feet in height, the bole girthing 26 inches at 2 feet from the ground. A tree of this variety may not be out of place in a collection of Conifers, but as an isolated specimen it is, in my opinion, not a beautiful object. The plant was put into commerce in 1871, so that it is highly probable taller specimens are to be found in this country than the one alluded to above. **J. MAYNE BICTON.**—*Gardeners’ Chronicle*, July 12.

TEA CULTIVATION IN INDIA.—Some interesting figures published last month by Mr. O’Conor, Director-General of Statistics for India, will be found on page 174. The most important fact relates to the area of tea planted since 1898. For that year it is given at 31,561; 1899 is put at 13,978 acres; 1900 at 6,829 and 1901 at 2,234—or a total in four years of 54,602 acres. Ceylon compares much more favourably, thus:—1898=14,000 acres; 1899=6,000; 1900=3,000; 1901=500 (?); or a total of 23,000 acres; while 6,000 to 8,000 acres have been abandoned in 1900-2. The total capital of the joint stock Companies engaged in Indian tea is close on $\text{R}160,000,000$.—Some curious information regarding “extensions” in India are given elsewhere.

RAINBOW TROUT—are thus referred to by ‘J. B.’ in his 5-page paper on Angling in the Supplementary New Volume of the “*Encyclopædia Britannica*.”—

Rainbow trout (*Salmo iridens*) have now been so largely introduced into England that they certainly claim attention. As regards their beauty, sport-giving and edible qualities they rival the sea-trout, while they grow with astonishing rapidity when well furnished with food. They are easily reared, and are certainly a great acquisition. They have not yet had time to become acquainted with the methods of English fly-fishers, and rise freely at any fly and take all the ordinary trout baits. They succeed particularly well in lochs and other enclosed sheets of water. They appear to have migratory tendencies, but it has not yet been definitely ascertained whether this migration is simply in search of food from streams and rivers where they find themselves starved, or whether it is an instinct. A quantity which were placed in the Dove have, to the knowledge of the writer, remained there three years. They have disappeared from many streams,

RUBBER CULTIVATION.—The full and interesting information supplied by Major Reeves in a recent issue, respecting the culture of *Castilloa* Rubber is exciting much interest, to judge by enquiries made to us. Unfortunately, there is none of the seed of this valuable Rubber tree available locally for sale. We hear of a good deal more land being planted with this Rubber in Matale

COMPOSITION OF ARROWROOT.—The *Journal of the Chemical Society* for May records the following analysis of arrowroot rhizomes from Jamaica:—

Water	...	63.42	per cent.
Starch	..	27.84	..
Dextrin and Sugar	...	2.68	..
Crude fibre	...	3.94	..
Ether extract	..	0.19	..
Proteid	..	1.64	..
Ash	...	0.89	..

The ash consists chiefly of phosphoric acid and potassium carbonate. The pulped root, when steam distilled, yields a volatile oil.—*Agricultural News*, July 21.

THE TEA PRODUCTION OF JAPAN.—In regard to the production of tea, another of the principal resources of Japan, the prospect is no brighter, as far as the foreigner is concerned. “There would be trouble about wages, strikes and disturbances and the foreigner would be generally shown that he was not wanted.” What is required to increase the market value of the tea is the introduction of improved machinery for its manufacture, but the lack of capital, together with the indifference and indolence of the people, do not give much hope that this step will be taken. The melancholy conclusion, from a Western commercial point of view is, that “whatever value as a national resource the production of tea in Japan has, for better or worse it must remain in the hands of the Japanese, to be developed at their own gait, and that it offers no inducement for the investment of foreign capital.” *N.C. Herald*, June 18.

GREEN TEA IN CEYLON AND WHERE IT IS MADE.—We are obliged to Mr. Deane for his explanation elsewhere. There is, it is true a very large area of low to medium elevation tea, which gets no better prices than the dead lowcountry estates, about 70,000 acres in all, and it is the former which, for a time at least, would make green teas by preference. Higher-grown estates would scarcely go on making greens, if the market for finer qualities and flavours hardened considerably and the better demand for them assumed some permanence. At the present moment practically all lowcountry estates could manufacture green teas—say, a total outturn of 30,000,000 lbs. with the prospect of better results than by the manufacture of blacks, provided such general action on the part of proprietors did not swamp the green tea market. The 10,000,000 lbs. limit, put by Mr. Drummond Deane on Ceylon lowcountry greens, is much too low. The question is largely one of supply and demand. If 20 million pounds of Ceylon greens are manufactured, prices of blacks may be expected to advance to such a point as to make it desirable to resume the manufacture of black teas,

THE ÆTIOLOGY OF TYPHOID FEVER.

Dr. Thomas Cherry, Lecturer on Bacteriology in the University of Melbourne, gave an address on the Ætiology of Typhoid before the sixth session of the Inter-colonial Medical Congress of Australasia, held in Hobart last February, in the course of which he observed that the study of the bacteriology of typhoid was rendered difficult from the fact that the disease was not readily transmissible to any of the lower animals. The bacillus coli communis and the typhoid bacillus had so many points in common that they produced similar reactions, and were to be regarded as members of the same group of bacteria. One of the marked characteristics of the group was the extent to which variation took place amongst the descendants of a single bacterial cell. Although there were several tests by which typical typhoid and colon bacilli might be distinguished from one another, the gap between the two was completely bridged over by a series of intermediate forms, amongst which was the B. enteritidis, or Gaertner's bacillus. Many cases were on record which went to show the long periods of time that typhoid bacilli could exist without causing symptoms. All recent work tended to show that many mild cases of fever, often classed as febricula, were really typhoid, and might be an unsuspected means of spreading the disease. The direct evidence as to the mode of entry of the infection into the body was scanty. From a recent analysis by Schüder of 650 epidemics, occurring chiefly in Germany and England, it appeared that 462 epidemics were due to water, 110 to milk, 23 to other food stuffs, 12 to clothing or bedding, and 43 to other causes. Dr. Cherry stated that, whilst there could be no question as to the origin of the great majority of epidemics of the disease, there was often difficulty in accounting for isolated cases. Some of these were so peculiar that it must either be assumed that the bacillus could exist in a virulent form in water or soil for several years, or else that the colon organism in the intestine became transformed into typhoid, or, at all events, into the intermediate form, and thus the disease arose *de novo*, as Murchison taught. Several such difficult cases were quoted and discussed. The actual mode of conveyance of the bacilli to the patient might be by means of minute particles of faecal matter containing great numbers of bacilli which might get into water, or be carried on the feet of the flies on to articles of food, or be carried about in the dust. Dr. Cherry's general conclusions were as follows: (1) Many mild cases of fever, often classed as febricula, were slight attacks of typhoid, and might serve to distribute the contagion; (2) typhoid fever itself might be a composite disease, or series of diseases, caused by closely-allied organisms; (3) while from the bacteriological evidence the *de-novo* origin of the disease was not disproved, still a general survey of all the known facts enabled most cases to be explained without having recourse to this hypothesis; (4) typhoid fever at once disappeared from a community with the introduction of a proper system of disposal of excrement and household refuse; in towns this could best be done by a properly-constructed water-carriage system of sewage; (5) the disease was spread chiefly by the contamination of water, milk, and other articles of food; in hot countries, at least, flies and dust had a considerable share in bringing about this contamination; (6) the length of time during

which the bacilli could exist outside the body was unknown; there was evidence to show that the contagion hung about old cesspits and contaminated soil for several years.—*British Medical Journal*, May 17.

RUBIES AND GOLD.

Sir Lepel H. Griffin presided at the meeting of the Burma Ruby Mines, Limited, on June 14. He said the directors had hoped to have been able to pay something on the founders' shares, and to provide for the commencement of a reserve fund, which was exceedingly desirable, as no mining operations could be conducted with full security without a reserve fund; but they had not seen their way to do so. It might seem from the dividend proposed that they had had a very prosperous year. From one point of view that was no doubt the case, and they had at last reached the point—which he had prophesied for two years—of washing over 1,000,000 trucks of ruby earth during the year. On the other hand, it had not been a satisfactory year from many considerations. As business men the shareholders would be aware of the difficulties which industrial institutions of all kinds had met with during the past two years. India had passed through, and was still passing through, a time of great distress and anxiety. It had suffered very largely from plague, famine, and the influences of the war. The consequence had been, and this was the reason why they were not declaring a dividend on the founders' shares, that the local trade in rubies had almost entirely ceased. There were large stocks in hand which, if they had all been sold, would have enabled the company to pay a dividend of 20 per cent. But they remained on hand, and no doubt as matters improved, with the wearisome war at an end, and with things looking more flourishing in India, the company might hope to share in the prosperity which he could foresee and prophesy for all English industrial institutions. The company had not been successful with regard to its experiments in plumbago mining. They had not spent very much on it, and having taken expert advice, had decided that as they were a ruby-mining company principally, they would stop working for plumbago. There was plenty of plumbago, but it was not of that flake character which was of the highest value, and amorphous plumbago at present prices would hardly pay to extract and export. Perhaps in the future, when they had more leisure and more money, they might try again in other places, and perhaps get better results. They were making some experiments without much expense in the matter of gold mining. There was a good deal of gold in Burma, and though he did not wish to raise any hopes, he could say that the experiments they had made were satisfactory. It was thought necessary before any great expense was incurred to get a new lease from the Government, as their lease had only a few years to run. Application had been made for a new lease for 30 years, and, bearing in mind the attitude of the Governor-General in favouring English companies, they had every reason to anticipate that their application would be successful. Until that was settled they must delay any large and extensive works. In conclusion he had to tell the meeting that they had received a telegram from the manager stating that the returns from the new mine at Ohoangzone were now very satisfactory, and that the returns were very much improving. Mr Carl Meyer seconded the resolution for the adoption of the report, which was carried unanimously.—*Overland Mail*, July 4.

FISH CULTURE IN CEYLON.

We call the attention of the Ceylon Fishing Club Committee to the following important letter addressed to the Editor of the

London *Spectator*—and especially to the reference made to “the rainbow trout” which is expected to flourish in nearly all our Ceylon streams:—

“SIR,—In the *Spectator* of June 14th you draw attention most usefully to the vast uncultivated waste of water, both fresh and salt, in these islands. In Germany today there is hardly a pool, however insignificant, but is stocked with the fish suited to it. The Government popularises fish culture by exhibitions of hatcheries in the Zoological Gardens at Dresden, Frankfort and elsewhere, and also by public lectures. At Wittengau, in Bohemia, Prince Schwartzenberg is said to spend annually a quarter of a million florins on food for his carp ponds. In the German system the carp pond is dried every third year, and the residual fertilisers result in an immense yield of vegetables. In the United States the Department of Fisheries conveyed both the shade and the striped bass from the Atlantic to the waters of the Pacific. The Report of the Department for 1896 (p. 141) states that “the aggregate expense of introducing these fish to the Pacific Coast was under 5,000 dollars; the market value to the fishermen of the Pacific Coast of these fish taken between 1888 and 1896 was about 192,000 dollars.” When in Washington this year I called with a friend upon Professor Smith at the Department of Fisheries, and he informed us that it cost the Department at their Pacific nurseries a dollar per thousand to “strip,” hatch, and rear for six months young salmon; that at Clackamas, on the Columbia, they had marked five thousand “fingerlings” by shaving off the adipose dorsal fin with a razor; that the third and fourth year after four hundred and twenty-five of these marked smelts had returned from the ocean and had been captured of an aggregate weight of over ten thousand pounds. I am glad you draw attention to that splendid visitor from California, the rainbow trout; there is no fish so easy to rear, so rapid in growth, and so adaptable. The rainbow, unlike any other of the *Salmonidae*, thrives in lakes and ponds where the summer temperature rises to even eighty degrees.—I am, Sir, &c.,

MORETON FREWEN.

25, Chesham Place, S. W.”

We have been asked as to the climates of California and Florida: they are both on the whole semi-tropical, the mean temperature of San Francisco being 56°; but California extends over a vast range of latitude. In Florida, again, freezing-point is sometimes touched in winter, though in summer it is quite hot. Curiously enough in the account of both States in the *Encyclopædia* there is no mention of the “rainbow trout,” though many other fish in California are mentioned. In connection with local Fish culture, we may quote what a military officer formerly in Ceylon has to say, writing from Northern India on 10th July:—

“Kumaon is a lovely district and Bhim Tal is in the middle of the lakes. There are three lakes within a few miles of each other—Bhim Tal, Nankuchia Tal and Sath Tal. All are pretty, but Nankuchia is my favourite. It is quite like Loch Lomond near Luss. Sath Tal is lovely too, but has not the breadth or feeling of freedom there is about Nankuchia. The hills (all fir-clad) rise abruptly from the water round Sath Tal which nestles in their shadow. The waters of all the lakes are clear as crystal and they are full of

Mahseer which take the fly or baste freely. I caught over 200 lb. of fish while I was there, biggest 3½ lb.—1 lb., 1½ lb. and 2 lb. fish are very common and give excellent sport. I am not sure, if it would not have paid better, from a fisherman’s point of view, to stock the Nuwara Eliya waters with Mahseer instead of trout: they are quite as sporting a fish and much easier to establish properly. The lake at Nuwara Eliya would have suited them perfectly.”

PRODUCTION OF TEA IN INDIA.

AREA.—The area under tea at the end of 1901 extended over 524,767 acres, nearly two-thirds (65·4 per cent) being in the valleys of the Brahmaputra and Surma, which contain as much as 338,186 acres, namely, 205,352 in Assam (the Brahmaputra valley) and 132,834 in Cachar and Sylhet (the Surma valley). In Bengal the area under tea is 136,129 acres, or 25·7 per cent of the whole.

The number of acres added to the tea-growing area each year since 1897 has been:—

1897	...	36,838	1900	..	6,829
1898	..	31,561	1901	..	2,244
1899	..	13,975			

Under the discouragement of the low prices obtained for tea placed on the markets in excess of consuming capacity, endeavours have been made to restrict cultivation and production, and to supply the consumer with tea of better quality in smaller quantity. The net addition to the tea area made in the last two years was comparatively small, considerable areas on which tea cannot be grown with profit at the present range of prices having been abandoned.

In Assam reports were received from 305 estates, with an area under tea of 338,186 acres, the average area of an estate being about 420 acres. In Bengal 300 acres was the average for 452 estates, and in Travancore the average for 75 estates was 337 acres. In other localities the average area of an estate is much smaller: 137 acres in Madras, 110 acres in the United Provinces, and only about three acres in the Panjab, where natives grow tea in a very small way. These figures refer only to tea-bearing areas.

PRODUCTION.—The quantity of tea produced has increased in about double the ratio of increase in the area under cultivation; for, while the area has increased since 1885 by 85 per cent, the increase in production has been 167 per cent. Last year the restriction of the area under tea was accompanied by endeavours to reduce the quantity of leaf taken from the plant and improve the quality. These endeavours were aided by climatic influences, and there was a material restriction in the quantity produced.

The actual production in 1901 is reported to have been about 191½ million pounds, which is 57 per cent larger than the reported production of 122 million pounds ten years previously, in 1892.

On the average of the last five years, the yield to the acre, dividing the total yield by the area of the land bearing mature plants, has been as follows in Assam and Bengal:—

Assam—	lb.
Brahmaputra Valley	.. 333
Surma Valley	.. 478
Bengal—	
Duars	... 488
Darjeeling	... 278

CAPITAL EMPLOYED.—According to the published accounts, the paid-up capital of the joint-stock companies engaged in the production of tea approximates to sixteen crores (R15,82,44,000), namely—

Companies registered in India	2,01,69,000
London	£9,205,000=13,80,75,000

Thus between 87 and 88 per cent of the capital belongs to shareholders in companies whose head offices are in London.

Divided into the area actually under tea this capital stands at about R300 (£20) per acre. There is a further unknown sum engaged in the industry, representing the capital of individual owners, while on the other hand, the acreage includes areas worked by such private owners, including natives. On the whole, however, making allowances on both sides of the account, probably the capital value per acre stated above is not very far wrong.

PERSONS EMPLOYED.—The number of persons employed in the industry in 1901 is returned at 606,835 (permanently) and 90,946 (temporarily) or altogether a little more than two-thirds of a million (697,781 persons), which would work out to about 1.33 persons to the acre.

EXPORTS AND CONSUMPTION.—The tea produced in India is exported, mainly to the United Kingdom, to the extent of nearly 97 per cent of the average production. The subjoined figures give approximately the quantity of tea consumed in India, the figures representing the average of the last five years :—

	lb.	
INDIAN TEA	{ Produced	... 176,349,300
	{ Exported	... 170,790,208
	{ Left in India	... 5,559,092
FOREIGN TEA	{ Imported	... 4,961,607
	{ Re-exported	... 1,898,271
	{ Left in India	... 3,063,336

Thus more than eight and a half million pounds were left in India on the average, 5½ millions Indian and three millions foreign, the bulk of the foreign tea being Chinese, though a substantial quantity consists of Ceylon tea.

1895	... 97	1899	... 58
1896	... 84	1900	... 64
1897	... 64	1901	... 45
1898	... 61	1902	... 22

The production of tea in India and Ceylon has increased so much more rapidly than the consumption in the United Kingdom, which is the principal market for these teas, that there has been a heavy fall in price and the tea industry in 1901 passed through a critical period, but prospects at present are much less gloomy. The restriction of output to which reference has been made, and the reduction of the quantity exported, had the effect of elevating prices to some extent last season from the low level to which they fell in the preceding season.

J. E. O'CONNOR, Director-General of Statistics.

INDIAN TEA.

DIFFICULTIES WITH LABOUR AND EXTENSIONS :

MODERATE ESTIMATES AND LARGELY INCREASED CROPS !

Some curious facts came out at the General Meeting in London of the Makum (Assam) Tea Company the other day. The Chairman stated (*inter alia*) :—

It is almost impossible now to get coolies, except when they are recruited by our own Sirdars, and the difficulty of recruiting labour has been found of late

so very serious that a large company, the Assam Frontier Company, have just purchased an old tea Company in the recruiting districts in order to have a basis—in order to have a recruiting depot in the midst of recruiting districts. They have bought this company not to make tea, but simply to make coolies.

Mr. Thompson stated :—

There seems to have been £2,457 spent on the North Bank garden, and out of it we have only got something like £1,000 worth of tea under the present condition of affairs. I should therefore, think it would be wise on the part of the directors to abandon the North Bank garden to stick to the Margherita ground. A great deal of worry in the tea market is, not that there is not enough tea produced, but that there is a jolly sight too much produced. Therefore, if we produced more, it would make matters worse than they are.

But Mr. Densham (Mazawatte Company) thought otherwise :—

Growing, as we do, some of the finest tea that comes into the country, and whilst I am as strong as anybody—I spoke at a meeting yesterday on the same subject—for the abandonment of land that does not pay, yet our company is so very heavily capitalised—I might almost say grossly over-capitalised—that we are absolutely dependent upon extensions for making dividends. Inasmuch as we are growing some of the finest tea that comes into the country, I think it would be a most woful mistake to abandon a beautiful virgin soil like that. His (Mr Thompson's) remarks would be most forcible if applied to some other companies, but to my mind here they are not in keeping with the facts. I should say let us go on planting out tea every year ; it is our only chance of getting dividends ; it is money sunk in the business. Over in the North Bank garden it is all young tea, and we cannot match Makum tea, we want as much Makum tea as we can get into the country.

Mr. Seton :—The Chairman has indicated to us that the main reason why we are not succeeding now is the great difficulty of getting labour ; and yet, Gentlemen, although that is a patent fact, we are going on opening another garden, for which we have of course, still less labour, and are consequently deprived of a sufficient amount of labour for our Margherita estate.

I would remind Mr Densham that he is not taking account of the large amount of tea put in cultivation, the enormous additions of area which have been made comparatively recently. I should like to know whether you have decided at the present moment to stop making further extensions.

The CHAIRMAN :—Absolutely. It is quite settled. You may be easy in your mind about that.

Mr SETON :—Of course, the North Bank is too small to pay as a separate garden. That throws us back on the fact that we have got 400 or 500 acres only, and I am repeatedly told by people who have gardens in Assam that it is practically impossible to make 400 or 500 acres pay.

The Chairman regretted the small outcome from the garden, and said he anticipated it would increase. I hope it won't, for if it does we shall be in a still worse position than we are in now. I will give you some idea of why I say so. In the course of my business I have to examine nearly all the Companies' reports ; and I have not taken up any report in the past year in which the directors do not hope, anticipate, and estimate a larger crop for the next year. If their predictions are realised we shall probably see ten or twenty million pounds more tea. . . . I may appear to be talking a little strongly, but with a large number of friends, who have invested considerable sums in tea, and whose £10 are not worth £2 today, we feel, naturally, a little hurt. I have still to tell my friends that tea is a good thing, but that on all sides it is completely overdone, and that foolish and absurd competition increases the output. I can only defend myself in that way, and in a

company like this I can only try and beseech you that you will not put out any more area, and, if you can by any chance, throw some of the ground out of cultivation—throw it into the Brahmapootra, if you like.

Mr Sanderson: And let other companies extend theirs!

Mr Seton: I am speaking in the interests of all the shareholders, and what is the mind of the great leaders of the industry who are actually meeting together in solemn conclave to find out a scheme whereby they can take a certain amount of their tea off the market.

Mr Densham:—You are comparing sovereigns to pennies.

Mr Seton:—I hold that there is too much tea at a certain period of the year; but we have had a rude awakening in the last six months as to the extraordinary price to which good Assam tea can fall. In 1901-2 we had an extraordinary fall in fine Assam tea to tenpence, and now Assam is selling at sevenpence. That is a worse fall relatively, because the cost is so much greater. Then came a question, to which no answer was given:—

Colonel Nowell: I want to ask one question. Is it not a fact that the quality of Assam teas has not deteriorated during the last few years, but that the quality of the Ceylon teas has deteriorated, and is deteriorating year after year?

A practical planter, Mr. Jackson, stated:—

No doubt, while the difficulty of obtaining labour is so great, and the price of tea so low, it would be wise to stop all extension for a bit, but as soon as the opportunity offers extensions should be gone on with on that side in preference to the other side. I think that the present position of the company is chiefly owing to the fact that the difficulties of opening up in such a place as Makum were under-estimated at the very start. (Hear, hear.) The original scheme of the company was 2,200 acres for about £63,000; or £30 an acre; the actual scheme has been 1,860 acres for £150,000, or £80 per acre. On £80 an acre it is difficult to make tea pay, and if any tea could pay it would be Makum tea. Then, again, I think the extensions were originally pushed on so fast that instead of being able annually to fill up all occurring vacancies, young plants have been taken afterwards to fill up the vacancies left. The young plants are taken from the nursery; they are taken from virgin soil to virgin soil, but when you take them from virgin soil to five-year old tea ground and fill in, they never get up to the tea originally put in, and to a great measure that accounts for the small outlay. . . . The old garden, I consider, is unwieldy. As a rule we find that 1,000 acres is big enough for any garden, and on flat land there are generally two factories. In Makum matters are considerably worse, because it is out up by small ravines and streams. Even 1,000 acres would be unwieldy, but on one block we have there 1,400 acres, and the distance the coolies have to go causes tremendous waste.

All this is instructive; and finally the Chairman explained the over-supply of tea:—

It is entirely the result of the enormous extensions that were made four or five years ago when there was a 13d rupee. At that time tea was very profitable and extensions cost very much less than they would cost now. The result was that tea was put out to the extent of thousands and thousands of acres, and these thousands of acres are only coming into bearing now, and therefore the market for tea, I am afraid, will be gorged for the next two or three years, and that the weak companies will have to go to the wall. . . . There is plenty of Ceylon tea, but the quantity of Makum tea—tea of the quality of the Makum garden—is comparatively small, and we got a very good price for it last year.

And so the meeting no doubt got the idea that all Ceylon tea is inferior: a very foolish notion,

PEARL DIVING ON THE NORTHWEST AUSTRALIAN COAST.

One of our soldier readers, Mr Alexander Macdonald, late lieutenant of the Australian Bushmen, writes:—There are still a few corners of the earth which remain but little known to those who are content to glean their information of far-off lands from tourist guide-books and out-of-date geographies, and for a long time to come they are likely to remain immune from the visits of the orthodox traveller. One of the most interesting of these remote districts is that part of the North-West Australian coast which runs north-north-east from Cossack, under the 20th parallel towards Port Darwin, and thence further to eastward into the Gulf of Carpentaria. This vast "corner" of the Globe is but the fringe of the great Terra Incognita of Australia, whose grim mountains and trackless deserts have lured many an explorer to his doom. The shadowy Leopold Ranges in the north are known to contain much gold and other mineral treasure, but fiercely hostile tribes of aborigines infest the mountains and rigorously guard their domain, so that only strong parties dare venture near their chosen haunts. But if this dangerous division of the Island Continent demands only the reckless pioneer's attention its seaboard is comparatively free from the besetting risks of the interior and here a fascinating industry is carried on, the very existence of which is probably unknown to most people.

WHERE THE PEARL DIVERS WORK.

Seldom do strangers journey so far distant from civilisation as this lucrative coast of which I particularly write; even in the great Australian cities little knowledge can be gained of the North-West, and those who periodically return from that region are never inclined to be communicative regarding their work. And yet, along this mangrove-lined beach, extending seawards in some places for many miles, some of the world's finest gems are found. The rich "shallows" stretch right round the coast and into the Gulf, but the main area of operations lies between Cossack and King Sound; and Roebuck Bay, about midway between these boundaries, is recognised as the pearling centre for all the fleets engaged. The largest settlement on these waters is that of Broome, which is situated at the opening of a mangrove-fringed creek at the head of Roebuck Bay, and though my description of it will doubtless give much offence to those who have grown to love their reeking and evil-smelling "metropolis," still I cannot but say that it is one of the most "God-forgotten" camps it has ever been my lot to strike, and I speak as one who knows the world well.

THE PEARL-DIVERS' TOWNSHIP OF BROOME.

The population of this township is composed for the most part of Malays, Japanese and Manilamen, who form the crews of the various lugger craft. The Manilamen, as the natives of the Philippine Islands are termed, make good divers, and their wonderful vitality has been proved on many occasions when accidents to the pumps and diving-gear made their existence below water rather doubtful. When many ships come into port at one time, or when the Monsoon season renders diving work impracticable, the various nationalities combine in making day and night—especially the night—hideous with their drunken squabbles, and not infrequently knives are drawn and brutal

murders committed among themselves, though details of such occurrences rarely reach the outside world. The white members of the community are small in numbers, and totally unable to cope with any serious disturbance that might arise; and, besides, they are mainly responsible for the demoralised state of affairs usually existing. With one or two notable exceptions, the master pearler, be he captain of a schooner or lugger, does not remain on shore at this settlement any longer than is necessary for him to transact his business and engage his crews for the season, for any trip he may be contemplating. These exceptions, and one of them is very notoriously notable indeed, run the vile beer saloons, or "stagger juice factories," as they are often called, for the nature of the fluid vended is villainous in the extreme.

A TWO-MASTED PEARLING LUGGER.

The pearling lugger is a small two-masted craft, or schooner, varying from 30 to 35 feet in length, and having a beam of about twelve feet. It is specially peculiar in having a very low freeboard, so low, in fact, as to render its life on a choppy sea somewhat precarious; but this design is brought about because of the heavy-weighted diver's inability to climb or descend over a high gunwale without considerable assistance, which assistance can rarely be forthcoming, owing to the few men considered necessary for the proper manning of such boats. At one time aboriginal divers were in the habit of descending in the shallower waters without the aid of either helmet or diving dress, but the numerous sharks and octopoda have just put an end to that practice, though many lives were lost before any precaution was considered necessary. The average depth at which the pearl-shell beds are found is twelve fathoms, but now and again a rich strike may be made at the fifteen or even twenty fathoms level, though no diver cares to work for any time in these deeper waters, and with the present form of living-dress the pressure on the limbs is very severe even when but a few fathoms down. It is often stated that divers occasionally explore the coral deeps at thirty and forty fathoms, but such assertions are utterly absurd and the writer may say with truth that a colossal fortune awaits the inventor of a diving dress by which the lower shell levels of North-West Australia may be exploited.

HOW PEARL DIVERS WORK.

When above "a patch" the diver is lowered overboard with little ceremony, and commences his work when he recovers himself at the bottom, after first examining the plunger line, which has been his sole guide in the descent, and making sure that it has not sagged against the myriad coral cups surrounding him, for he may have to depend his weight on this line, should any chasms intervene in his course. The vessel above glides slowly onward with all sail furled, moving by the force of the various currents or the water's ripple only. The anchor is never used, for the pearl oysters are few and far between, and a score of yards and more may divide each pair of shells. So the diver follows below in the lugger's wake collecting his finds into a small net he carries attached to his left arm, and when this receptacle is filled he signals to be raised to the surface, where he is quickly relieved of his precious load. With luck a good diver may raise several hundred-weight of shell in a day, but more often he has to

be content with very much less. The owner of a lugger pays the diver by results, so that he is assured of the latter's conscientious effort, but sometimes days may pass without much return when new levels are being prospected. The shell is a very valuable commodity, and forms indeed the backbone of the fascinating industry, for pearls are scarce, and though commanding fabulous prices, they would not in themselves pay for the labour expended in searching for them. When it is calculated that mother-of-pearl is worth about £150 a ton, it is at once evident that the pearler pursues quite a lucrative profession even if he should never be fortunate enough to find a single pearl.

PEARL HUNTING IS SOMETIMES DANGEROUS.

The life, as may be imagined, is one strangely attractive, but at times a gloom falls over the entire fleet when some of the luggers' crews mutiny, and in their fiendish rage wreak a dire vengeance on the one or two white men at their mercy; for these coloured crews have a long simmering hatred against their employers, whom they judge by the standard of the renegade whites who, while dispensing their villainous intoxicants, cheat the poor wretches out of their savings. The Ninety-Miles Beach, in the summer season, is a favorite haunt of the pearl-liners. This coast extends from Cape Bossut southwards to Pot Headland, and scores of luggers then make Lagrange Bay their headquarters instead of Broome; and the supply schooners, also, rather than remain anchored at sea, seek the shelter of the numerous salt water creeks inshore, and thus they form a township of stranded vessels, which would strike the stranger as being a most peculiar sight indeed.

A MOSQUITO-INFESTED REGION.

It is no exaggeration to say that the mosquitoes of this region make one of the principal objections to the country. A "new chum" appearing in their midst would be positively eaten alive. The air is black with them, and at night their vague hum is intensified to a vicious shriek, which sounds as a long sharp note on the quivering air. Even the toughest whisky sodden specimens of humanity cannot withstand their attacks. I have known men imbibe an enormous amount of the afore-mentioned "stagger-juice" in order to remain unconscious of the "torpedoes" onslaughts, but I have also seen them wake up before midnight, sober as judges, cursing the torturing pests as only such men can.

"THE LEGION THAT NEVER WAS LISTED."

There are some very fine men engaged in the pearling traffic, as well as some of the worst products of humanity, but the former are well in the majority, and by them the whole industry is influenced. One well-known individual on the "grounds" at the present time is known as "Gentleman George." He has been for twenty years a self-exile from civilisation, and the probability is that he will never return to his native land; but many men with strange histories are encountered in the far remote corners of our Empire, and such cases arouse little surprise in the wanderer. This man, however, leads an active and useful life; he was the pioneer of the north-west coast, and has ever been a reckless dare devil, feared by many, yet respected by all around. His name was given him spontaneously many years ago, and he deserves his title in its true sense.—*New Zealand Mail*, June 25,

PLANTING IN THE STRAITS: COCONUTS.

We are in receipt (rather late in the day?) of the minutes of the annual general meeting of the United Planters' Association, F.M.S., held at the Selangor Club, Kuala Lumpur, on Saturday, 3rd May. *Present*.—Messrs. E V Carey (Chairman), T H Hill, C Meikle, W R Rowland, E B Prior, P W Parkinson, J G Glassford, O B Pfeningwerth, J M Halliday, A M Barnwell, A Irving, H M Darby, M S Parry, E B Skinner, *Visitor*:—Mr J L Anstruther. *By Proxy*:—S Moorhouse. The only matter of interest to us is the following in regard to coconuts:—

COCONUT BEETLE.—The following resolution was proposed by Mr C Meikle and seconded by Mr H M Darby:—"That the condition of the coconut cultivation is seriously endangered by the ravages of the coconut beetle and that the Government be asked to take such steps as will eradicate the pest as far as possible." Mr Meikle said that the condition of the trees in Kuala Lumpur and Klang was disgraceful and he thought the sooner Government started to adopt stringent measures the better it would be. Mr Darby said that the beetles down at Klang were very bad amongst trees ranging from 18 months to 2½ years old and in many cases trees were riddled by them. He had already reported to Government that a coconut estate belonging to Tamils was badly infested with the beetles. He considered that it would be best for Government to appoint special inspectors to go round, instead of doing it through the Penghulus. Mr Prior also attested to the bad condition of trees in Klang. Mr Parry suggested that if, after the matter has been reported to the District Government representative, no steps are taken in the matter, the complainant should then appeal direct to the Resident. Mr Rowland said that he had a coconut estate in Negri Sembilan, but so far had not discovered any beetles on it. Mr Hill stated that when Mr Birch was Resident in Negri Sembilan the Negri Sembilan Planters' Association had approached him on the state of the coconut beetle and that steps were at once taken by Government to control the pest with the result that there are very few places there now suffering from beetles. Mr Halliday suggested that owners of trees attacked by beetles who do not take immediate steps to clear them, should be fined as they are in Singapore. The Chairman said that Government would be only too pleased if planters would report places which were known to be infested with beetles. The resolution was carried unanimously.

CASTOR OIL MANUFACTURE.

Up to the present nothing has been done locally in the way of extracting oil from the castor oil plant. Briefly, the operations of oil extraction are by expression, by boiling with water, or by the agency of alcohol. A comparatively simple process can be tried by anyone interested, and a good oil should result if the seed is of the right variety.

First, cleanse the seeds from fragments of the husks and from dust, and submit them to a gentle heat, but not greater than can be borne by the hand, which process makes the oil more fluid and more easily expressed. A whitish, oily fluid is thus obtained, which is boiled with a large quantity of water, and all impurities are skimmed off as they rise to the surface; the water dissolves the mucilage and starch, and the albumen is coagulated by the heat, thus forming a layer between the oil and the water; the clear oil is then removed and boiled with a small quantity of water until aqueous vapour ceases to rise, and a small quantity taken out in a phial remains perfectly transparent and cool.

The effect of this is to clarify the oil and rid it of volatile acid matter. Care is necessary not to carry

the heat too far, as the oil would acquire a brownish colour and an acid taste. In India the seed is first shelled and then crushed between rollers, placed in hempen cloths and pressed. The oil is afterwards heated with water in a tin boiler until the water boils. This serves to separate the mucilage and albumen, the product being then strained through flannel and put into canisters. Any oil-press would suffice for extracting oil for ordinary purposes, and by decantation and some process of filtration it could be purified. Cheap wooden rollers would serve the purpose, and these could be driven by a horse-gear, after the fashion of driving the old horse-mills for crushing sugar-cane.—*Queensland Agricultural Journal.*

RUBBER PLANTING IN THE MALAYAAN PENINSULA AND BRITISH NORTH BORNEO.

A little while ago Mr. H. K. Rutherford pressed us to try and obtain statistics of the area planted in Rubber in the Straits, &c. It is a difficult matter to do so as there are so many different States and Districts embraced in the Malay Peninsula. But from the returns given in the Singapore and Straits' Directory for 1902 which has just reached us, we venture to compile the following figures, simply as a rough approximation:—

District.	Area under Rubber.
B. N. BORNEO	... About 100 acres
JOHORE	... " 200 "
NEGRI SEMBILAN	... " 678 "
PERAK	... " 540 "
PROVINCE WELLESLEY	... " 100 "
SELANGOR	... " 2,926 "

Total ... " 4,544 "

This is against 3,356 acres in Ceylon. But our local returns are far more to be relied on, than the guesses we have applied to the estates in the Straits, &c. It should be the duty of the Selangor Planters' Association to collect reliable returns of the actual extent of Rubber planted on each garden or estate, and so to correct the figures which we venture to put forward above.

THE LITTLE TIN TICKET.

Ramasamy, come hither, I've something to say
About the new system, the Government way
Of travelling free of all fuss and delay
With a numbered and lettered tin ticket.

You will find it will save you from bother and loss
Whenever you wish the 'black water' to cross,
And you need not be cheated wherever you doss,
If you've only a little tin ticket.

It is not exactly a 'circular note,'
But will bring you back free on the railway and boat
You may pay for your betel—for food not a groat:
That is done by the little tin ticket.

Kanganies will hoax you with charges for food,
They will take you to places whose names are not good,
And many false items your bill may include,
If you have not a little tin ticket.

Whenever you leave your beloved estate
Take one of these tickets across the dark strait,
It will help your return at a wonderful rate,
This little tin Government ticket,

You come to the depôt: the pass lets you in,
But not like the robbers of Taticorin,
Who would steal from the dying: their system of sin
Is checked by the little tin ticket.

You can travel by train and cross over the sea
And then come back again to the *totan* and me,
Paying nothing whatever: your bill comes to me.
If you 've only the little tin ticket.

If your brother can't get from his *dorai* a pass
As that *dorai* belongs to a curious class
Of animal known for its patience, alas!
He must go without any tin ticket;

But ere he comes back he can write him and say
He is ready to start on the very first day
That he 's able to travel with nothing to pay,
And he *must* have a little Tin Ticket.

NEWLYN PIERCE.

MERCANTILE LIFE IN COLOMBO 40 YEARS AGO.

(BY THE SENIOR ED. "C. O.")

A stirring and even romantic chapter might well be written on the "ups and downs" of mercantile life in Colombo during the past 70, 50 or even 40 years. We can merely touch the fringe of the subject in this preliminary note. Of course the traditions of the "thirties" and "forties" were familiar talk in the Fort in the early "sixties." We had a real *Fort* then, enclosed by walls as well as batteries, a deep wide moat crossed by drawbridges with sentry-mounted mediæval winding gates which bore the mark of Cohorn and the

DUTCH EAST INDIA COMPANY.

The 24 European mercantile houses in Colombo and their 60 to 70 resident partners and European Assistants* were naturally thrown much together; they had their cliques, likes and dislikes and yet approached nearly to one big circle of friends, living under the shadow of banishment from "home" with only a fortnightly mail (by P & O) via Galle, and no telegrams, while most of the travelling (and all the heavy freight) between Ceylon and England, passed round the Cape of Good Hope, a voyage of 15,000 miles occupying from 80 to 110 days according to the vessel and weather.

Among the early Fort traditions was the strong opposition of the Merchants to the Government of Sir Robert Wilmot Horton (1831 to 1837) and how (in 1834) they started the *Observer*, the first newspaper independent of Government in Ceylon, and placed one of their number,

MR. GEORGE WINTER

in charge of it as Editor. The Governor could get no European to enter the newly-formed Legislative Council and was obliged to fall back on pensioners or recognised Government proteges to fill the Ceylonese seats. The mercantile opposition gradually died down, however; Mr Winter got tired of his task; and the paper was sold to Dr. Elliott. With the next Governor, the Rt. Hon. Mr. Stewart-Mackenzie, the merchants worked amicably; but the ablest man amongst them—Mr. Acland—was always more or less in opposition. The burst into coffee and the great boom from 1837 to 1845 followed by the financial crash in the latter year, tried Colombo houses very severely and many disappeared. In the dull time that followed, there were some happy hits in money-making. One proprietary planter, but who had a Liverpool mercantile training, bought up all the

"NATIVE COFFEE"

—a big crop in those days—for "a mere song" (as he told us long after), shipped it round the Cape and it arrived in London six months after, to a vastly improved market, so that he cleared cent. per cent., and immediately founded a mercantile house in Colombo, with later on a branch in Madras, and both continued for thirty years until the partners having made fortunes in cotton, gradually cleared out. But the head could not be idle and speculating with the great "Collie's" lost his all and had to begin life again in his old age. What an extraordinary record of both planting and mercantile experience the story of "C.S." would afford, if he only continued the tale, from his last instalment in our columns published a good many years ago!

It may well make brisk young mercantile men of today to stare, to learn that forty years ago, it was not considered "good form" to advertise any special consignment—say of

QUARTER-CASKS OF MADEIRA!

—until your neighbour had got rid of his stock. To go and compete at a Kandy land sale with a man who had selected any particular jungle "block" for himself by going to the spot, was thought most dishonorable—up to the time that Tottenham got a number of Haputale forest lots put up, and the spirit of competition became too strong and old-fashioned arrangements broke down. [On one occasion thereafter, seven would-be purchasers met at the Kandy Kachecheri and finding that 7 blocks were to be sold, drew lots and arranged the matter amicably; but alas before the last two were offered, one or two strangers to the bargain, dropped in and there was a severe struggle and high prices to the advantage of the revenue.]

The American Civil War—1861-5—and the blockade of cotton, enabled longheaded Bombay and Colombo merchants to amass rapid fortunes. We compiled and printed a telegraphic Code for a local Firm to be used between Bombay, Madras and Colombo (there was no cable to Europe) and *sixpence* was the maximum we were ordered to put in for Tinnevely cotton (the price then being 2½d per lb.); but we ventured to compile up to the shilling—and yet in 6 months, the Code was useless, the price advancing to 1s 6d! Fancy cargoes of

TINNEVELLY COTTON

bought by Colombo merchants through their Brokers at from 2d to 4d a lb. being worth 1s, 1s 3d and even 1s 6d a lb. before they reached Liverpool or London four months after! E. J. Darley and his partner, S. Butler, whose names and Firm still continue; Alex. Gibson of Alstons, Scott & Co., Charles Shand and J. C. Fowle made the largest profits, —Wilson Ritchie & Co. and Crowe & Co. following later. Piece Goods too was a safe and profitable business in the early days, since a Chetty breaking his word or bond was, at that time, absolutely unknown! But most of the Firms of the early sixties stuck to "coffee" and their Agency work and among them were Geo. Stenart & Co. (with Messrs. Geo. Steuart and Geo. Mackenzie), J. M. Robertson & Co. (Mr. Murray Robertson, senr., Mr. Geo. Christian), Mackwoods & Co. (Capt. Wm. and F. Mackwood and Mr. F. Smith), R. B. Carson (now Carson & Co.), and some others not now in existence of which Geo. Wall & Co. and J. I. Strachan & Co. were the chief,

* In 1902, there are not fewer than 90 Firms in the Fort with nearly 400 Europeans on their office staffs.

There was also Nicol, Cargill & Co. of which was C. B. (country-bottled) Cargill who, afterwards became Premier of Dunedin or Invercargill Province, and of whose survival now in a good old age we heard the other day in a letter from New Zealand. We well recall cheery and stately Sylvester Trant Richmond* who was a partner in the Firm (and our great Military authority in those days) coming into our office with a copy of a Dunedin paper giving on the one page a speech by the Premier and on another an advertisement saying that C. B. Cargill sold Straw, Hay, etc. Everything is grist to the mill in a new Colony.

THE GEM TRADE OF CEYLON.

"GOES STEADILY ON."

VALUABLE CAT'S-EYES AND OTHER JEWELS.

Attention was recently attracted to the gem trade of Ceylon by the announcement that Messrs. M. Ismail & Bros., Jewellers, Galle Face Hotel, had become the possessors of two catseyes which at one time had been a single stone weighing 340 carats in the rough. The stone had been cut into two—one weighing 105 carats and the other 71 carats. The colour was between light and olive-green, of admirably oval shape, the hodies being neither opaque nor too transparent, setting forth bright silvery rays of a dazzling straight nature. The estimated value of these stones is R50,000 and R30,000 respectively; both were shipped to the London market, and it is time we heard of the result. [Not yet sold, we are told.]

Later on we had the pleasure of examining some most valuable jewels in the possession of another well-known firm. In particular we were shown a very magnificent catseye weighing over 100 carats and valued at £3,000. Of an olive green colour, with a perfect white ray, the gem exactly matches the description, in colour, given by Mr. Streeter in his book on gems. The gem has been in the possession of the firm for several years. Attempts have been made to purchase it—on one occasion an offer of R30,000 having been made for it on behalf of the Nizam of Hyderabad. The owner, however, finds the gem most valuable for advertising purposes and refuses to sell it under value. Among the other gems shown us was a smaller catseye of much lighter colour, weighing 40 carats. This jewel, although not so valuable as the larger one—being valued at R10,000—is much more attractive and has also a white ray running through it. A beautiful pink star stone, which along with the catseye, is the only jewel which defies imitation, was also shown us. The stone which is over 100 carats is a perfect specimen, with six rays. It was found in Ceylon and is valued at R5,000. A

*There was no Broker in Colombo in the "sixties"; but a well-known Broker of the present day who came out to be Assistant under Mr. Richmond in 1899, declares that he was the finest specimen of a British Merchant of the old school high-minded, honourable (straight and liberal) he has ever known, and to this, all who were acquainted with our old friend, will undoubtedly subscribe.

real Ceylon ruby, beautifully cut, weighing 20½ carats, is certainly the finest we have seen in Ceylon. It is valued at R25,000 but it has been so much admired that the owners are loth to part with it. The stone, along with a particularly good blue sapphire stone, weighing 30 carats and valued at R3,000, was found in the Ratnapura district.

These particulars tend to show that the gem trade of Ceylon is not the "baseless fabric of a vision" which of late years people have begun to suppose it is. Rubies, it is true, have not been plentifully found for the last four or five years; nor have there been any big finds recently until these catseyes of Messrs. Ismail and Bros., but the trade goes steadily and regularly on.

DESTRUCTION OF TROUT FRY AT OOTACAMUND.

Ootacamund, July 19.—I hear that the heavy floods in the Pykara River have breached the lately constructed fish pond in which the newly hatched trout fry of the Nilgiri Game Association were placed some weeks ago and that all the fry have been washed away. The Association has had consistent ill-luck in its efforts to introduce trout into the Nilgiri streams, and I hope that better fortune will attend the consignment of ova which Major Bagnall is to bring out with him from England.—*Madras Mail*, July 21.

PLANTING NOTES.

GROUND PUMPKIN SEEDS FOR FOWLS.—Fowls are very fond of cucumber and rock-melon seeds, and young cockerels will eat them in preference to wheat. They also are partial to pumpkin seeds broken up small. Where cows are fed on pumpkins there are always large quantities of seed, which are not fed to cattle. These, if cracked small, would form a valuable food for poultry. Those who have tried it say it increases the fertility of laying hens.—*Queensland Agricultural Journal*, 1st June.

BEST BREEDS OF FOWLS.—The following extract is taken from an interesting article by Mr W B Tegetmeier in *The Country* for April last:—The question may therefore be asked by those who keep poultry for practical and useful purposes, What breeds shall we employ, and what system of keeping shall we pursue? If eggs are the chief desiderata, the best breeds to adopt are those which do not incubate, such as those known at the present time as Minorcas, Leghorns, Andalusians, and Hamburgs. Of these the two former are unquestionably the best, inasmuch as they lay the largest eggs. But the system pursued varies greatly, as do the conditions under which the fowls are kept. It is almost needless to say that the most advantageous method of keeping fowls is in localities where they have an extended range, finding for themselves a great portion of their natural food—worms, insects, seeds and herbage of various kinds. Under these conditions, fowls only require a clean roosting-house and feeding twice a day to yield a good supply of new-laid eggs, provided the hens are kept for two years and not beyond that time, as the second year's laying exhausts the great prolificacy of any hen, when her services should be at once transferred to the stock pot.—*Agricultural News*, June 21.

CEYLON TEA AVERAGES IN LONDON.

FOR JUNE SALES.

Messrs. Geo. White & Co.'s highest results for each group of districts for June sales are as follows:—

1.—Udapusseilawa, Nuwara Eliya (6,200 ft), New Galway—Dimbula and Lindola. (From 3,500 to 6,500 ft). Outlet—Nanuwa (5,300 ft), and Talawakelle (3,900 ft).

A NEW PEPPER.

A new pepper from Kissi, Upper Guinea, on the frontier of Liberia, has been brought before the "Académie de Sciences," Paris. The corns are small, contain manganese, and are good for spice or condiment. It is called after M. Famechon, the discoverer, and is expected to become a colonial product.—Globe, July 4.

A FIND OF QUICKSILVER IN MALABAR.

Calicut, July 22.—Recently, while the Railway construction officials were working at Edakad, between Tellicherry and Cannanore, Mr A Sayers, Bridge Inspector, came upon deposits of quicksilver near a spot called "Sheitan Kunnu," or Devil's Hill. The deposits apparently exist to a profitable extent, for Mr J B Burnett, having inspected them, has already formed a Company under the title of the Tellicherry Quicksilver Syndicate to work the mineral. I learn that all the shares of the new Company have already been subscribed for, and it is to be hoped that Mr Burnett's commendable enterprise will prove profitable. It may not be generally known that so far back as 1858, the existence of quicksilver was reported in a bed of laterite at Cannanore.—M Mail.

THE ASSAM LABOUR SUPPLY.

CAUSES OF THE DECREASE.

Calcutta, July 23.—In 1901, 30,777 emigrants were despatched to the labour Districts of Assam, as against 65,190 in the previous year. The Government, in its Resolution published today, says that this great diminution is partly explained by the fact that the year 1900 was a famine year in Chota-Nagpur, and is also ascribed by the Commissioner of the Division to wild stories having been circulated, exaggerating the responsibilities incurred by garden Sirdars under the new Act. There is a further and, to the planter, a more serious reason. The coal mines in Bengal have increased rapidly of late both in number and size, and the mine owner is now a formidable competitor with the tea planter in the Districts of labour supply. He gives higher wages, and the mines have at least the attraction of being nearer to the Districts of recruitment.—*Madras Mail*, July 24.

MICA OR TALC.

The very large sheets of mica, which at one time used to fetch fancy prices on the London market, now seem to have fallen out of use, owing, we believe, to substitutes being used. At any rate at the sales held on 9th July the larger size sheets were neglected, the same as at previous sales, the demand being more for medium and small medium sheets, especially if clear and suitable for electrical purposes, and the prices realised for such were rather better than at last sales. Very small mica and films were out of favour and met with no demand at all. So all had to be bought in.

A GOOD TREE FOR TEA ESTATES.

A Dimbula Manager writes:—

"Re your article on tree growing, one tree that grows well upcountry, which has not received the attention it deserves, is the *Iolantha glandulosa*.* There are some fine specimens of this tree on Glasgow Estate, Agrapatnas, age about 10 years. It grows very nearly as quickly as the *Robusta* gum or Red Toon, and for growing amongst tea it is greatly preferable to either. I can say nothing as to its merits as a timber tree, but it should make good fuel."

How does it compare with the favourite *Grevillea*?—will be the first question asked.

A NEW INSECTICIDE.

We referred some American pamphlets, recently received, to Mr. E. E. Green, the Entomologist, who kindly writes:—"The one on Carbon Bisulphide, as an insecticide particularly interested me. I have always realised the important part this insecticide might play in Ceylon, if only we could procure it in quantity here. At present it cannot be obtained for love or money, except in small quantities as a drug. The shipping people are afraid of it and will not accept it as cargo. With the aid of Carb. Bisulph., white ants might be practically exterminated with ease. Then it is invaluable for destroying all the larger wood-boring insects without the necessity for hacking the tree to pieces."

* We cannot find this name in any of our botanical or Timber-trees' books of reference. To what country does the tree belong?—Ed, T.A.

PEAT TRANSFORMED INTO COAL.

A German and an engineer of Swedish nationality, named Fritz and Schöning respectively, have succeeded in transforming peat into coal. Coal, as Macaulay's Schoolboy knows, consists of metamorphosed vegetable matter which flourished ages ago on the earth's surface, the change having been brought about under the combined influence of heat and pressure. Messrs Fritz and Schöning simply imitated Nature in their experiments. They subjected peat to a pressure of one hundred atmospheres, that is one thousand five hundred pounds to every square inch and at the same time heated it. The resultant coal was found to have acquired the same heating properties as stove coal. Similar experiments might be made with Irish peat, which, from its low percentage of carbon (sixty per cent), constitutes a very poor fuel.—*Commercial Intelligence*, July 4.

COW-TAIL HAIR.

Although peace has been declared, the good demand that has existed so long for cow-tail hair still continues, and though the high prices of 11d and 11½d per lb. realised two or three years back are no longer obtainable, nice long hair, well-washed and free of skin and bone, is valued today at 7d to 8d per lb. according to length and quality, at which price there seems little doubt it pays shippers, especially in India, to send over this article in large quantities. Pig's bristles are rather dull; owing to a large failure in the trade some time back the market was considerably upset, but is now recovering itself and Indian shippers are doing well with their consignments; at least those who are in good hands seem to be, as it requires a great deal of trade knowledge and patience to place out the consignments to best advantage.

RESTRICTION OF TEA OUTPUT:

MR. ACWORTH'S REPLY TO THE LONDON

I. T. A. CIRCULAR.

DEAR SIR,—I am in receipt of your letter No. 529, dated the 11th instant, with enclosure re restriction of output, Circular No. 37. I am not one of those who believe in artificial methods of improving the position in tea—I mean such methods as cessation of manufacture, destruction of low grades and so on, and cannot therefore consent to support the amended scheme in Circular No. 37. I am, however, prepared to do this:—(a.) I will undertake to hold back 10 per cent. of my outturn during the current year, not put it on any market, but store it in my factory till better times; or (b.) I will hand it over to a Committee to be formed for the purpose of exploiting foreign markets. Either of the above will I do, provided that 135 millions of lb of the Indian tea crop consent to some sort of scheme for improving the position, either by cessation of manufacture destruction of lower grades, or whatever seems good to them. It seems to me that, should the Viceroy consent to a compulsory cess, and should growers agree to hand over 10 per cent of their outturn to such a Committee as I suggest, our position would be a strong one. We could use the cess entirely for bounties on green tea and for advertising, whilst we could follow up our advertisements with very cheap teas, so far as blacks are concerned. If we could only dispose of them at 3d per lb. it would suffice, for this would pay the grower for the leaf from the bush to the hands of the Committee, and would leave something in hand to cover freights and sale charges.

If these freely-given blacks were placed very cheaply on foreign markets, such as Russia, where there is already a taste for and large trade in blacks, it would

help to confirm the taste, now in its infancy, for British-grown teas, and once acquired the taste would probably remain. Germany, too, offers another field, where it would probably pay us to lay down very cheap blacks, particularly if it is true that tea is in future to be served out to the troops, and duty reduced to 1½d per lb. The taste, once acquired, will not be easily given up. The soldiers, when their period of service is over, returning to their families, will insist on having tea, will introduce it to their families, and thus the taste will grow and spread. It is by such means as the above that I consider we should extend the use of our produce. To subsidise shops in fashionable quarters of Paris and Rome is to my mind futile and a mere waste of money. We want to catch the masses, not the classes. Finally I think greens should be turned out by the million and not the 100,000 lb., and we naturally look to the North with its great Companies and large resources to show us the way. We are being beaten in the race by Ceylon, and there is no reason why we should be, if we get funds and use them judiciously.

I may mention here that we down here have been much disgusted by the refusal of the I T A in London to accept the offer of Mr. P C Larkin of Canada; indeed, we have lost all confidence in that Association. The suggestion to form a British Growers' Union is excellent, and will, I hope, be carried out in the near future.

As regards restriction of output, I have a word more to say. One scheme has been proposed which has not come before the public, and that is a scheme which has been suggested by Mr. Parker, the Chairman of our Association, which is contained in the following extract of a letter I have received:—"If artificial restrictions are to be imposed I wonder no one has thought * (perhaps he has, but I have not seen it) of giving the bushes an extra month's rest after pruning. It would do the bushes a lot of good and when the new shoots were cut or broken back to the required height, the tea made from the first flushes would be of decidedly superior quality to that made from ordinary 'tippings' and thus prevent a good deal of common tea being thrown on the market. The shortage too would be gradual all over Southern India and Ceylon and would be regulated by the date when different estates pruned their different fields, and would extend over a period of about two years. Being gradual, no one would feel the shortage very badly and the improved quality of the tea (by getting rid of the 'tippings') would probably fully compensate for a decreased quantity." I must repeat that I regard, artificial means of restriction with distrust, but this does seem the most sensible yet brought forwards provided you can get men to act on it. My private opinion is that you will never get men to act upon any artificial method."

The rest of the discussion on the Indian tea cess was conducted in Committee.—*M. Mail*, July 30.

CEYLON TEA IN THE UNITED STATES OF AMERICA.

The British Vice-Consul at Los Angeles, in his recent report, writes as follows:—"Heretofore coffee has been drunk here almost to the exclusion of tea. More tea is now being consumed, and as the quality leaves much to be desired, while the price is quite high, I should think when the demand increases pure Ceylon teas might be sold here to advantage. Several agencies for the sale of Ceylon teas have been established in the last 11 years and have not been successful, and the

time is not yet ripe to press the sale of good teas. I think, however, that there will be a market here in the future."—*Board of Trade Journal*, July 10.

TROUT-FISHING IN CEYLON.

TWO DAYS AT THE HORTON PLAINS IN APRIL 1901.

(Extracted from "*Recollections of Sport*" by James Cornway.)

"I reach the river by 10 a.m. and find the water looking rather dark, owing to the rain of the previous night, but it is quite clear. I put on a small fly, black with red hackle, and some silver tinsel in the body. I know of a few places where trout used to lie last year, and approach carefully. Rainbow may be expected this year in addition to the brown, as the streams were fairly stocked with that variety during the last season. They must all, however, be returned to the water if I chance to take any. I had little expectation, however, of finding them in such numbers as they proved eventually to be. The first fish I caught was a rainbow, as nice a trout as could be wished for, measuring just twelve inches, and weighing about as many ounces; this may be considered very good growth for a fish only twelve months old. All I caught ranged from ten inches to twelve, and were in fine condition. Their fighting powers are too well-known to need my enlarging upon them; but I would sooner have a one-pound rainbow at the end of my line than a three-pound brown trout. He gives infinitely more play, and is decidedly more beautiful to look at. He almost invariably leaves the water three or four times before giving in; and then is a picture with the different lights on his body. The way, too, in which they come at the fly, leaves no doubt of their intention.

"After proceeding some distance without raising anything, I came to a large pool which I knew to harbour brown trout, but here again my first cast saw me into a rainbow. He was off like a rocket half-way across the pool, then he took a leap of seven or eight feet and was gone. He was a fine fish of some two pounds in weight. I caught three more in this pool, and returned them. The next fish I rose was a brown of about one and a half pounds. He came at my fly twice, but failed to lay hold. I gave him a rest, changed my fly, and tried him again, but he was not going to be caught this time.

"By three in the afternoon I had almost given up hope of catching a brown trout at all as at every pool I came to, and generally at the first cast, I rose and hooked a rainbow. This, of course, disturbed the whole pool, and I began to be provoked with them. By four o'clock, however, I seemed to have left rainbows behind, as I hooked and landed two browns, each about one pound in weight, within a few yards of each other.

"There had been thunder in the distance for some time, and, as it was coming nearer, I made off for the rest-house; and a rather sharp storm followed, the lightning being very vivid, and the rain falling in torrents. By five o'clock, however, it passed off, and I went out again; but the thunder had affected the fish, as I hardly got a rise, and they were evidently off their feed. As a rule, however, trout out here do not seem to mind thunder, probably for the reason that it thunders almost every afternoon, and they get

* [Some one has: it was suggested in the *Ceylon Observer* early in June by a correspondent, signing "Indo-Ceylon."—*Ed. T.A.*]

accustomed to it. I have fished through the whole of a severe storm, and caught numbers notwithstanding. On this occasion, however, I was using one of Hardy's cane rods, with a steel centre, and it was safer to lay it aside while the storm lasted. Just as it was getting dusk I had a rise, and as I watched a long stretch of water for some time they were rising again freely all over the water.

"I now put on a small 'coachman' fly, and fished till it became dark, but did not catch another fish. Those that were rising were apparently all small, and not worth taking.

"Sleeping at the rest-house, I next morning went down to the larger water about four miles below. By nine o'clock I had taken two trout of one pound and fourteen ounces respectively. Rainbows were again provokingly to the fore, and I returned several of about eleven inches. One I killed accidentally, it being badly hooked and injured. I held it in the water for some time, but it was beyond recovery. It had nice pink flesh, and proved very good eating. The brown trout seem to have here lost their pinkness of late years; and they further seem decreasing in numbers. The reason for this may be that the fresh-water shrimps have decreased; crabs, however, are still plentiful in all the streams, and, I think, are a great source of food. I have seen a trout taken with a crab in its mouth, too large for it to swallow, and yet he managed to take a fly. Another had a frog half-way down its throat, the hind legs protruding out of its mouth at right angles, and yet this one also was greedy enough to take a fly. My best fish was a beautifully-marked yellow trout of two pounds, five ounces. I saw it some way below me in the deep water, swimming aimlessly about, and managed to throw my fly just over its nose; it at once took it, and after some play I got it safely into the landing-net. It proved to be a very thick female, in fine condition.

"A little lower down in the same pool, which is a very large one, about fifty yards across and 200 yards long, I saw another large trout of about three pounds lying at the surface. Until I got closer, I could not make out what it was doing. It kept coming up, and taking the foam or bubbles which were floating down stream, making a noise each time with its mouth something like the word 'soup.' Thinking it might like something more substantial, I sent my fly above it, and drew it across almost close to his nose. The fly was immediately followed, but the fish failed to catch hold, and I could not induce him to come again. I larded another of about two and a half pounds in the next pool, with beautiful spots. He gave me some good sport, and I was decidedly pleased with my morning, so far.

"About mid-day I began to retrace my steps towards the rest-house. On passing the large pool, some way up the hillside, I looked to see if the big trout was still playing with bubbles, and, sure enough, there he was. I tried to get behind him for a cast, but he must have seen me coming, for he slowly sank and disappeared. I fished several likely places on my return walk, rose two nice fish, and hooked a third, which, however, managed to break away just as I was getting him near the landing-net. Above Baker's Falls, in a rocky pool, I secured my next fish, weighing about one and three-quarter pounds. At first I took it to be a rainbow, as he sprang out of the

water several times, but he was too yellow, and, after a knock on the head, I found him to be a handsome golden fish with pink spots.

"By this time the afternoon thunder was rimbbling, and as I had still two miles to walk, I started for the rest-house. I was caught, however, in one of the worst storms I would like to be out in. The roar of thunder was deafening, the lightning uncomfortably near, and the rain fell with a violence which threw up spray from the water to the height of a foot or more. On reaching the rest-house I weighed my catch, and found the eight trout weigh exactly eleven pounds, I had returned to the water twenty-one rainbow, and five brown trout of eleven inches and under.

"Next morning I make an early start for the station, rather more than two miles across patna, down through two miles of jungle, a short cut of the roughest kind. I reach the station just as the train steams into it; and two hours later I am at my bungalow ready for breakfast; and as I think over the doings of the last forty-eight hours, I come to the decision that a take of thirty-four trout amid such scenery, such air, and with such exercise, is a pleasure not to be despised, and would compare not badly with some of my sport at home in the Highlands." G. G. R. C.

PLANTING &C. IN THE MALAY STATES.

From the Annual Report for the year 1901 on the Federated Malay States by the Resident-General (W H Treacher, C.M.G.) we make extracts:—

European COFFEE planters (Liberian) have again been disappointed by the poor prices ruling for that product, which were indeed lower than for the previous year—\$18.29 per pikul against \$20.89. Nevertheless, in Selangor and Negri Sembilan the European-owned estates are almost all in good order, there is a general improvement in the sample of coffee, and the planters are showing great determination to tide over the present long-continued crisis. The export of coffee for the year amounted to 51,239 pikuls as compared with 44,763 pikuls in 1900.

The reports as to the successful growth of Para and Rambong RUBBER are most encouraging and the cultivation of these species is being rapidly extended.

In Perak the cultivation of the SUGAR-CANE continues to prosper, flourish and extend, and, I am sorry to say, is in some places displacing padi, European and Chinese capitalists buying up padi land from the Malays, who, with some reluctance, part with their land, unable to resist the temptation of ready cash. The export of sugar from Perak amounted to pikuls 343,881, valued at \$1,500,000. The figures for the preceding year were pikuls 278,156, value \$1,315,974.

CENSUS IN THE MALAY STATES.—For the purposes of the Census the following areas were recognised, to which I have added the figures of population for the years 1891 and 1901, and the increase per cent:—

State	Area. Sq. mile.	Population. 1891.	Population. 1901.	Increase per cent.
Perak	6,500	214,254	329,665	53.87
Selangor	3,200	81,592	163,789	106.86
Negri Sembilan	2,600	65,219	96,028	47.23
Pahang	14,000	57,444	84,113	46.42
	26,300	418,509	678,595	62.14

It should be said that the figures of 1891 for Perak are considerably more reliable than those for the three other States. The total cost of the Census amounted to \$30,500, or under 9 cents per head of population. Mr. Hare's report abounds with interesting deductions from the figures at his disposal. I must content myself with the following remarks. Principal nationalities, exclusive of floating population and prisoners:—

Malays and other Natives of the Archipelago	312,456	increase per cent	34.9
Europeans and Americans	1,422	do	98.3
Eurasians	1,522	do	169.8
Chinese	299,739	do	83.4
Indians	58,211	do	188.8
Average density of population per square mile			25.7

Population of five principal towns:—Perak: Taiping, 13,331; Ipoh, 12,791, Selangor: Kuala Lumpur, 32,381. Negri Sembilan: Seremban, 4,765. Pahang: Pekan, 1,142.

Chinese population of two British Colonies and the Federated Malay States:—

Hongkong and Kan Lung	..	376,797
Straits Settlements	..	281,933
Federated Malay States	...	299,739
Total	..	958,

It is stated that during the years 1881-1900, 1,631,711 Chinese immigrants have come to Perak and Selangor. It is, perhaps, unnecessary to point out that the attraction to the Chinese in the Federated Malay States is the tin mines, that not one quarter of the Chinese population can be considered to be "resident," and that the disproportion of the sexes amongst them is very marked—the proportion of Chinese males over 15 years of age to Chinese females per 1,000 is 927 males to 73 females; the proportion of all Chinese males to all Chinese females per 1,000 is 910 males to 90 females.—*Mr. Treacher's Annual Report.*

SELANGOR EXPORTS.

Under the head of exports the principal increases are found under tin and tin-ore, mangrove-bark, charcoal, firewood, coffee and copra. It is to be regretted that, with an increase of nearly 3,500 pikuls in the amount of coffee exported, the value owing to the low prices ruling during the greater part of the year, was less than in 1900. The quantity of copra exported (5,544 pikuls), though not very large, was more than double the amount exported in 1900. The price of this product has been steadily rising since the end of 1900, and with the increased attention which is now being devoted to coconut growing copra should, before long, be one of the staple exports of the State. The principal decreases are to be found under ataps (the export of which was only about half that recorded in 1900), getah, betel nuts, gambier, blachan and salt fish. The value of the gold exported from Pahang *via* Selangor rose from \$366,369 in 1900 to \$400,960 in 1901.

manufactured. It is the industry which supports a large proportion of the population of those islands where it is extensively grown, and, according to the opinion of those most familiar with the trade, there is no danger of any over-production and a consequent decrease in the selling price of this product; at least so it is stated in an official report on the trade of the Philippines recently issued by the United States War Department at Washington. Manila hemp is used in the manufacture of cordage of a superior class. For ships' purposes it is superior to any other material, considering its cost and wearing qualities. The cultivation of hemp, while carried on extensively in the Philippine Islands, is conducted in a most primitive manner. It is found nowhere else in the world, and while it is now extensively cultivated, and large tracts of land are planted with it; it is still found growing wild in certain portions of the island, and in quantities which make it worth while to gather it for shipment. Hemp, or "abaca" as it is called in the Philippines, is a product of a species of plantain tree. In its wild state it grows to a height of from eight to twelve feet, but under cultivation it grows to a height of from fifteen to twenty feet, with a trunk from eight to twelve inches in diameter. The stalk of this tree is in appearance something like the banana plant—merely a collection of fibrous leaves, which are closely joined together, and which can be easily cut with a single blow of a sharp knife. The tree is allowed to mature, which requires about three years, this being dependent upon the soil and the elevation of the land upon which it is planted above sea level. When the tree has attained the proper age, it is cut down and divided into long strips which are put under a large knife, weighted with a lever, and under which the strips are drawn. This separates the stalk and juice from the fibre, and the latter is then spread out on the ground to dry. This work is all done at the plantations, and after the abaca or hemp is sufficiently dried it is gathered up and taken in bullock carts to the nearest waterway, and shipped to some port where it is made into bales ready for export. The production of hemp is carried on extensively by natives, by Spaniards, and by foreigners. The export business is practically all in the hands of foreigners—mostly English, Belgian, and German houses.—*Journal of the Society of Arts, June 27.*

VANILLA CULTIVATION IN SEYCHELLES AND CEYLON.

The following remarks by a well-known planter will be read with interest:—"I have read the memorandum issued from Seychelles Government House. The cost of land in the Seychelles is very high R300 per acre. There is land suitable for such cultivation,—viz., cacao, vanilla, and should include rubber—in the Matale and Dumbara Valleys, available at R60 per acre. The cost of labour is also dearer than in Ceylon. The cost of curing R1.25 per lb. about the same as in Ceylon. As Vanilla grows very well on Dadaps, it is just as well to have these trees cultivated along with cacao. The Seychelles' produce is probably superior to that of Ceylon: in fact, I believe, it to be the best vanilla produced. Five rupees per lb. is about as much as can be obtained at the present time for good Ceylon Vanilla on the spot. I find that Vanillas

THE PRODUCTION OF HEMP IN THE PHILIPPINE ISLANDS.

The principal industry of the Philippine Islands is the production of hemp. The southern part of Luzon Island, and all other islands to the south, are given up largely to hemp cultivation, all of the product being shipped to other countries to be

frequently commence to bear at 2 years. Each vine the memo states can produce from 25 to 30 pods, 4 inches to 8 inches long. This is surely a very moderate yield. I have frequently counted 70 to 80 pods or more on a single vine and well up to the measurement noted."

IMPROVED CEYLON GREEN TEAS.

We were enabled a few weeks ago to send the well known Indian tea authority Mr. J. B. Leslie Rogers, a few samples of the teas turned out by Ambawatte mills, Colombo, and we are pleased to give his report on the same as of general interest:— I have just been testing these samples, and the following is my opinion on the same. I may add that as I have more experience of the Asiatic than the American Green Tea Market, my opinions chiefly apply to the former.

No. 5 Samples.—Good Hyson quality. Rather broken leaf colour bluish Green and slightly uneven. Aroma good.

No. 6 Samples.—Good Young Hyson quality. Leaf fine and well rolled, but rather broken. Colour bluish green, but of a more desirable shade than No. 5. Aroma very good.

INFUSION.

No. 5.—Infused leaf, a good olive green. Pale straw green liquor, strong, crisp and full-flavoured. Fresh delicate aroma. Good in the cup.

No. 6.—A good even olive green. Liquor—a pale straw green. Strong, crisp and more delicately flavoured than No. 5. Fresh delicate aroma and very good in the cup.

GENERAL REMARKS.—Both high-class teas, which compare very favourably with the same qualities made in China and Japan. They would, however, in my opinion, be much improved if turned out a lighter green colour with less of the bluish tint. I would also suggest sifting out more of the small broken leaf, and disposing of the latter separately.

Messrs. Finlay, Muir & Co. are to be congratulated on these favourable samples. Similar makes with the improvements suggested, would undoubtedly "catch on" in the Asiatic Markets; and I also believe these teas will compete more successfully against Japans in America, than the other so-called Green Teas now being made in India and Ceylon. My views on this matter coincide entirely with the policy now being pursued by Messrs. Finlay, Muir & Co.; and I shall look forward with much interest to a successful termination to their important experiments in this direction.

SALE OF CEYLON ORCHIDS IN COLOMBO.

There was quite a lively time at the sale of Mr. Dodwell Browne's orchids by Mr. A. Y. Daniel this morning. Some 250 specimens were offered in about 100 lots, and the total realised was about R1,000. The highest price realised was R36 for the giant orchid, purchased by Mr. Macmillan, Curator of the Botanic Gardens, for the Lieut. Governor. His Excellency, indeed, secured quite a number of rare specimens.

Amongst those present were: the Hon Messrs H L Wendt and J H de Saram, Messrs F Dornhorst, Morgan de Saram, S P Hayley, P D

Siebel, R Daniel, Gigg, Geo. de Saram, Charles Perera, H F MacMillan, A W Andree, C Driberg, Dr A J Chalmers and others. Amongst the purchasers, many of whom bought several lots, were Messrs J H de Saram, MacMillan, S P Hayley, G de Saram, M de Saram, F J de Saram, Gigg S D Young, R Daniel, J H E Rodrigo, Chas Perera, P D Siebel and Dr Chalmers. The prices paid ranged from R5 to R36. Mr. MacMillan bought one *Sarcochilus Calceolus* (fragrant flowers) for R36 and also a *Grammatophyllum Speciosum*, described as the queen of orchids, for R33. Mr J H de Saram bought a pretty *Sac Blumei* (lately flowered, eight blooms) for R34, two *V. Suavis* and two *V. Sauderiana* going to Messrs P D Siebel and Geo. de Saram for R20 each.

FLORA OF THE MALAY PENINSULA.

The Asiatic Society of Bengal has received R8,750 from the Government of the Straits Settlements, being a contribution for the purpose of defraying the cost of publication of Sir George King's materials for a treatise on the Flora of the Malay Peninsula.—*M. Mail*, July 22.

BRAZIL COFFEE CROP.

There are 659,960,060 coffee trees in the State of Sao Paulo, Brazil, of which 525,624,435 are over four years old. During the present season the yield is on an average of 2 6-10 pounds net per tree. On some plantations with fully-matured trees, the yield has been as much as 12 to 14 pounds per tree. In commenting on the official returns of the coffee plantations, Messrs W H Crossman and Brother say:—"The State of Sao Paulo alone is capable of producing sufficient coffee to meet the entire consumption of the world; the fact that such a great quantity of trees exist, and such a large percentage of them below the age of four (4) years, proves conclusively that the planting has been going on successively during all the years, when it was proclaimed low prices meant heavy losses to planters, and that there was not sufficient labour to care for the plantations. It was claimed there were not enough hands to harvest a crop of nine million bags, and the Italians were leaving the country in great numbers; yet what do we see? Rio and Santos alone in one season are able to harvest a crop of upwards of fifteen millions, and have found time to continue clearing and extending plantations up to and including this very year.

It makes very little difference, in view of the monstrous supplies existing, whether the next crop is nine, ten, eleven or twelve millions. Any one of these quantities is much in excess of what is really wanted.—*Indian Gardening and Planting*, July 24.

COCONUTS AND WHITE ANTS AT ZANZIBAR.—Mr Theodore Burt of the "Friends' Industrial Mission," Zanzibar, writing from Pemba on 2nd July, reports:—

"Re white ants and young coconuts. Some time ago I removed the soil from the upper part of some hundreds of young plants in the nursery, and put wet sand straight from the shore in place of the soil close round the nuts and young shoots. For some weeks the white ants let them alone entirely. Today I see three have been eaten off. I will soak them with sea water and hope to let you know the result after a while."

AN ENGLISH RUBBER PLANTATION IN MEXICO.

While most of the interest in rubber planting in Mexico has been developed with capital from the United States, and principally under the control of large companies, there are some plantations privately owned by citizens of other countries. One, for instance, is that above mentioned, the property of George Cullen Pearson of England. In a statement from the manager of this plantation to *The India Rubber World*, under date of May 20, it appears that there are now growing on this property fifty thousand rubber trees (*Castilloa elastica*) which were four years old in June; one hundred thousand trees three years old; and two hundred thousand trees two years old; besides a large number of plants in nurseries. This plantation, by the way, is one which has been referred to in certain quarters—but not on the authority of the owner—as embracing a large number of rubber trees old enough to be tapped this year.—Mr Pearson's plantation is located two miles from the "Hacienda de Yale," owned by Alfred Bishop Mason, of Chicago, and president of the Vera Cruz and Pacific Railway Co. Mr Mason's two nephews, James Trowbridge and R Willis, are resident managers of this hacienda, on which a considerable amount of rubber planting has been done.—*India Rubber World*.

A CHINESE CAMPHOR MONOPOLY.

On the authority of the Japanese Foreign Office, it is now stated that the Chinese Government has decided to establish a Camphor Monopoly Office in Fokien, placing the manufacture and sale of camphor under the control of the Japanese. It is not correct, however, to say that the monopoly right of the camphor trade is to be conceded to the Japanese Government. In future the Japanese may be a party to the camphor business by contributing a part of the expenses of monopoly, but no definite arrangements have yet been made.—*Hongkong Press*, July 19th.

THE RUBBER FAMINE!

One of the subjects which might well occupy the attention of the much-talked-of colonial conference, which is to take place in Coronation week, is the rubber famine in West Africa. I hear from sources which are absolutely indisputable that rubber is becoming scarcer every day. The reason for this is not far to seek. In the first days of the rubber boom eager speculators rushed to West Africa, caring little what they did as long as they got rubber. As a consequence, the rubber trees were destroyed in a manner enough to make the heart of the most amateurish woodman sick with anguish. On the principle that you cannot eat your cake and have it, rubber—at least, the West African species—will soon become as rare as the Great Auk.—*Today*.

THE TROUBLES OF COCONUT PLANTERS IN THE STRAITS.

We are sorry to learn that another enemy to coconut planters has turned up in the *tikus besar*, that is so destructive also to padi crops. The "Mongoose" is their best destroyer, the introduction of which may prove beneficial. These creatures also keep a place remarkably free from snakes.—*Perak Pioneer*, July 29.

"HEMILEIA VASTATRIX" IN THE FRENCH COLONIES.

The French Minister for the Colonies has taken precautions against the hemileia vastatrix, a fungus which fastens on the leaves of coffee plants and destroys them. It is for the coffee planter what the phyloxera is for the vine-grower, and has played havoc in Ceylon. The French Colonies of Martinique, New Caledonia, Reunion, Madagascar, Guiana, and the Congo as well as Cochinchina and Tongking raise much coffee, and it is now forbidden there to import coffee plants. Even coffee beans must be immersed for half an hour in a 1 per cent. solution of sulphate of copper to kill the enemy.—*Globe*, July 18.

JAPAN TEA IN 1901.

YOKOHAMA CONSULAR REPORT.

District of Yokohama, 1901, by Mr Consul H A Bonar.—The raw tea season opened at the end of April with but little animation, and although the demand increased as prices steadied, the competition for early teas, which in former years was always a marked feature of the trade, was anything but brisk, and the inquiry continued slack until the end of July. The fact cannot be denied that the Japan tea trade is gradually contracting in volume, the annual export of the United States and Canada having fallen off by some 10,000,000 lb. during the last 10 years. The competition from India and Ceylon teas has not proved as dangerous as was expected last year. The efforts made by these growers have not met with much success in the United States, and it is now doubtful if they will ever make any serious inroads into the trade. In Canada, however, the Japan tea trade is certainly suffering from the competition of these teas and it is probable that, except in the lower grades of Japanese, used chiefly for mixing purposes, the Ceylon product will eventually supplant the Japanese growths. The total export from Yokohama in 1901 was 24,577,524 lb.—*L. and C. Express*, July 18.

TAMIL EMIGRANTS AND THEIR FOOD.

(To the Editor, "Madras Mail.")

SOME USEFUL NOTES.

Sir,—Dr. Haviland, of Perak, attributes the prevalence of dysentery among Tamil coolies from India to the full meals they get on the estate. It has been observed in the hospitals in the planting Districts in Ceylon that a meat diet does not suit the coolie patients. They do not recover health or strength by it. This proves the rule that one man's meat is another man's poison. What is good and wholesome for the hardier Chinese coolie may not be so for the Tamil coolie who is "transplanted" to a strange country where he has to face a different set of circumstances. A sudden change from the arid plains of the Carnatic to the wet regions of the Malay Peninsula might in itself cause diarrhoea and dysentery. Overloading the stomach with food stuffs to which one's system is not used may be another. But to say that dysentery follows good food is a startling statement. A full meal of rice and milk and vegetable curries will not lead to diarrhoea. But when the Tamil coolie imitates the Chinese coolie in eating

anything and everything at any time in a new place, he must necessarily get ill. There is nothing new in the case of the Tamil cooly catching diarrhoea or dysentery when he changes his diet. Without going far afield I may instance the case of the Tamil cooly in the Wynaad District when he is supplied with "raw rice." The Canarese cooly thrives on "raw rice" because that forms his ordinary food. But the Tamil cooly who is not accustomed to it gets diarrhoea when he lives on raw rice. The ordinary diet of the Tamil cooly in the high lands of Ceylon consists of rice, dhall and small dry fish called *nettali*. It has been found by experience that *nettali* soup nourishes the cooly patient, whereas mutton or chicken broth does not, because he has not been used to it. This does not apply to all coolies. There are some who are robust and well-fed like the Kanganies and the cooly employed in the planter's bungalow. The causes that lead to ill-health of the Indian cooly on landing at Perak are the following:—(1) the fatigue and starvation he has undergone on the sea voyage; (2) the change of climate which includes the "bad water of Perak"; (3) unwholesome food, such as eating plenty of plantains and other fruits and meat at irregular hours.

M. TISAINAYAGAM.

Kays, Ceylon, 24th July.

PANTING NOTES.

TEA BOXES FOR THE CANADIAN MARKET.—We attract attention to "Merchant's" letter on this subject, on page 200 as giving practical information of interest to shippers of Ceylon tea for Canada.

PLANTING IN SUMATRA.—Our planting readers will enjoy the racy letter we print on another page above the well-known signature of "W. T. McK." "Well-known" in Ceylon twelve or twenty years ago—but, alas, how many have come and gone since then!—and we fear if Mr. Turing Mackenzie revisited his old diggings in the Central Province, he would feel like a stranger among strangers, so far as his personal surroundings were concerned, although he would have a hearty welcome both from old and new. But the country is much the same, and his German or Dutch friend does not overrate the beauties of our Central Capital, uniquely situated in its cuplike valley guarded by the hills and the river, and with the grand Peradeniya Gardens close by. Someone the other day asked us "what about the future of Coffee?" The question made us feel a little guilty; for, in 1896, we ventured in a letter to the *London Times*, which appeared above our own name, to correct some remarks of Sir R. W. Herbert and to say that "coffee" (with the failures in Ceylon, Java and India) should be the product to go in for, where it would grow in the tropics. Alas! we had then no conception of what Brazil could do in almost doubling its exports. For the outlook at present, we cannot do better than refer to what "W. T. McK." says on another page.—As to the "King" coconuts wanted, we have no doubt some one with a good garden and wishful for new plants, will respond.

NORTH BORNEO.—We have had enquiries lately as to progress in British North Borneo. Such figures as the B.N.B. Company's Agent sends us (see page six), are the briefest answer and index to the growth of the country.

"HILL" FLAVOUR IN TEA.—The depressed spirits of planters are beginning to revive (says the *Indian Planters' Gazette*, August 2nd) especially those in Darjeeling, who almost began to think that the manufacture of teas of true "hill" flavour was a "lost art." Some of the gardens in the Darjeeling district have realised very satisfactory average prices for late invoices. Really good hill tea will always command full value, the same as any other "stand out" tea.

A NEW CURE FOR DYSENTERY.—We are always glad to hear of new and authentic cures. Have any of our readers information on the drug referred to in the following Indian cutting?:—"The ravages which dysentery caused among Europeans in the tropics before the disease was as well understood as at present were terrible, and now, although it is affirmed by many medical men that dysentery if taken in hand in time is practically always amenable to treatment, and but seldom fatal even when for a short time neglected, yet the number of deaths caused by it, especially among children, is still very great; and it is most certainly good news to hear that a new cure for it has been discovered in the seeds of the "*Brucea Sumatranæ*," which are said to be as much a specific for it as quinine is for malaria. Now that is news to the greater part of the world although probably known for long by the natives of the regions in which it grows. It is even found in Borneo, Java, Sumatra, the Philippines, South China and Australia. The plant is being raised from seed and in a short time the seedling will be ready for distribution, and already there have been very many applications received by Mr H. M. Ridley, the Director of the Botanical Gardens of the Straits Settlements."

BANANA RUBBER.—Substitutes for india-rubber appear to be getting more and more numerous. The latest idea is certainly the best! As recorded in the pages of "The Fruit Grower," the information must be of great value to its readers as well as to the manufacturing trade! The writer introduces his subject as follows:—There have been for many years past attempts to provide a substitute for rubber, the market price of which has in the past decade gone up by leaps and bounds. There is even talk at times of the supplies giving out. According to a report recently received in this country, a method has been patented for perfecting the manufacture of an artificial india-rubber from banana fruit skins, and a company is to be formed to work the process. Small cuttings of sheet rubber made a percentage of "banana rubber" and Para rubber have been exhibited in this country, and it is said to be difficult to tell the difference between this combination and pure rubber. It is claimed that banana rubber can be made at about half the price of pure Para rubber. When the skins of the banana (used according to this process) are proved to be worth more than the fruit itself, an enormous impetus will, of course, be given to the transport of bananas from West Africa and other parts of the world, where this fruit is so prolific. It is said that Messrs. Rowntree & Company, of York, who own large estates in the West Indies, are making exhaustive experiments in the manufacture of banana rubber.—*India-Rubber & Trades Journal*,

PLANTAIN-MEAL.

(To the Editor *Madras Mail*.)

SIR,—The green plantain, as you know, perhaps, forms a large item in the diet of the Hindus. Dressed, in various ways, it is not only palatable but highly nutritious, in which respect it is only inferior, if it is inferior, to the potato. Of late a good deal of attention has been drawn to plantain meal, and I presume that my personal experience in this respect may not be uninteresting. I use the meal a good deal in my family as a substitute for the flours of pulses, which, though possessing dietetic advantages, are not so digestible as plantain-meal. The way to prepare it is this. Pare the plantains, taking care to remove only the skin; then cut them into thin slices, which, after being dried in the sun for some days in boxes covered over with muslin, should be pounded fine in a mortar and the flour resulting be passed through a fine sieve, which will give a fine silky powder which should be put up in airtight tins or close-corked bottles to keep out the damp, to which it is extremely susceptible. My children all thrive upon it, and an infant of delicate constitution became after a congee made from it quite strong, gaining flesh rapidly. I think that in this meal is to be found a new industry which if worked with care and persistence, will yield considerable profit. There are all kinds of English foods in the market, but these being priced too high are beyond the reach of the poorer classes who would be glad of something nearly as good at a lower price. I throw out the hint, hoping to see it taken up by someone who cares to put his hand to a new venture. I am almost certain, judging from my experience, that he will not repent it.

V. KRISHNASWAMY MUDALIYAR.

One of the latest Reports on Plantain Meal is that of M. de Jong, of Surabaya, Java. He states that it is impossible to find a market for it in Europe. A big factory for making Plantain Meal according to the best methods was constructed in Java some years ago and recently went bankrupt. M. de Jong explains that very many attempts have been made to make a European market for Plantain Meal, especially as a food for infants; but in vain. The explanation given is that Plantain Meal is too rich in starch, which cannot be easily digested by infants. Nor can plantains be exploited for the starch itself, he adds, because of its dirty grey colour, which no chemical can get rid of.—Aug. 2nd.—ED.

PIERMONT MORGAN'S STAR SAPPHIRE,
LARGEST IN THE WORLD.

Mr Piermont Morgan has sent to the American Museum of Natural History in New York a star sapphire which is believed to be the largest in the world, and a yellow sapphire which is regarded as the most beautiful in existence. These gems will be added to the collection of precious stones previously presented by Mr. Piermont Morgan to the museum. This collection was shown at the last Paris Exhibition.—*London Times*, July 16.

THE "DJAGAGIRI" CINCHONA COMPANY, of Java, have declared a dividend of twelve per cent for 1901, the net profit being 33,533fl (about £2,800). The retiring director, Mr J R de Jong, was unanimously re-elected.—*Chemist and Druggist*, July 19.

RUBBER;—A CHOICE DESCRIPTION!

The crude rubber, as shipped by the natives, is known commercially as "rubber hams," the shape being almost identical with that of a good Yorkshire. Germany has commandeered nearly the whole of the rubber business, and the big German companies control the shipment of rubber in nearly every part of the world. The first thing, when a rubber ham comes to a factory, is to split it open. Natives have a wily trick of "stuffing" the ham with stones or metal to increase its weight. A sea voyage causes the rubber to lose weight, and the man who deals in the raw material has to make good the loss resulting from exposure to air. After the ham is cut and inspected, it is put into a crusher and ground out of all recognition. The next evolutionary stage is the washer, where all dirt, stray leaves, and impurity are cleaned out. It emerges from the washer in knobby rough sheets. The length of time it remains in the drying room depends entirely on the use to which it is to be put. "Compounding" is the next stage, sulphur being used to cure the rubber.

Immense care and skill is necessary in the compounding of rubber for tyres. Pure rubber would tear into ribbons with the wear and tear of the roads. When the necessary "compound" is decided upon, and the ingredients added, the whole is put in the mixing rolls. One roll runs quicker than the other, so that the twisting thus caused thoroughly mixes the compound with the rubber that is to form the tyre.—*Motoring Illustrated*.

PLUMBAGO MINING IN KALUTARA
DISTRICT.(From *Administration Report for 1901*.)

The price of plumbago, which fell heavily early in 1900, remained low in 1901 but rose slightly towards the end of the year. Few pits were opened; many were closed. In October only 36 pits were being worked, as compared with 94 a year before. They were distributed as follows:—Pasdun Korale East 27, Pasdun Korale West 6, Rayigam Korale 3.—Total 36. Of this total 31 are situated on land alienated by the Crown, 3 on land leased by the Crown, and 2 on paraveni land. By the end of the year 14 out of the 27 pits in Pasdun korale east had been closed. The number of mining declarations received at the Kacheheri fell from 204 in 1900 to 45 in 1901, of which 35 were for land in Pasdun korale east.

Messrs. Skrine & Co., on behalf of Messrs. Reckitt & Sons, Limited, were working during the year the three mines situated on land leased by the Government, viz., Humbuluwa at Liniyawa and Kokkumbura and Nakaulketiya at Migahattenna. By the courtesy of Messrs. Skrine & Co. I am able to append the following observations made by Mr Gill, the Manager of the Mines, on their operations:—

The work of developing the mines has progressed steadily during the year, and satisfactory results have been obtained. No new shafts have been sunk, but those already in existence have been considerably deepened. The system of work carried on under the previous management has been abandoned, and all operations are carried on in accordance with modern European methods. The native workmen have, on the whole, taken kindly to the system adopted, and a number of them are becoming expert in the English methods of sinking, driving, stopping, and timbering. The system of twelve hours' work instead of twenty-four introduced during the previous year has been adhered to, better work being got out of the men in the twelve hours' shift system. During the past few months, by the order of the directors, only necessary work, such as timbering, has been done

during the day shift on Sunday. The plant of the mines has been considerably augmented during the year, and hand labour for raising plumbago, *debris*, or water entirely superseded by steam machinery. Winding plants are working at Kokkumbura and Nakaulketiya; a new winding engine is in course of erection at Humbuluwa, and the mines are kept free of water by five powerful steam pumping engines. A light tramway has been laid down at Kokkumbura and another at the Nakaulketiya mine for the removal of *debris*. The timber for the workings is obtained locally, alabo and hora having been decided on as the most suitable woods. A dynamite store has been constructed in accordance with the published regulations, new cooly lines put up, and a good bungalow erected at Kokkumbura. A freedom from accidents of a serious nature has been enjoyed, and the labour force of about 200 men resident on the mines is contented and fairly stationary. The speed at which the mining operations are carried out is steadily increasing, and considerable new developments are projected for the immediate future.

INDIARUBBER IN NEW GUINEA.

Melbourne, July 18.—A discovery, which may lead to the more rapid development of British New Guinea, has been reported to the Acting Prime Minister. The British Ambassador at Berlin has advertised Rp. Deakin, through the Colonial Office, that guttapercha and Indiarubber have been found near to Stephensort, in German New Guinea, by Capt. Schlechter, who has just returned from an exploring expedition. It has long been thought that guttapercha is to be found in British territory, and now that the Germans have discovered its presence on their division of the island, more attention is likely to be given to the establishment of an export trade of the commodities named by the English settlers.—*Adelaide Observer*.

A RUBBER SUBSTITUTE.

New York, July 19.—As the results of a series of tests which have been made for several months, it has been found possible to manufacture from Beaumont oil a perfect substitute for high grade rubber. A company has been formed with a capital of £200,000 to use the discovery commercially.—*Laffan*.

TEA: THE WORLD'S PRODUCTION AND CONSUMPTION.

The two special points which strike us in the diagram circular of Messrs. Gow, Wilson & Stanton, which we issued with our last issue of the *T.A.*, are the danger pointed out of China common teas coming back into competition with British-grown teas; and the advantage of and necessity for making as much of green tea as is possible both in Ceylon and India. The diagrams and letterpress are otherwise both interesting and instructive. We send them to all who get our blue tea circular. Another striking fact as shown in the diagram on the last page of the circular is how tea consumption in the United States has gone back from a total of 117 million lb. in 1895 to only 108 millions in 1900; while Russia and Germany have advanced in the same period from 98 to 132 millions. Clearly the latter, which still take 112 million lb. of China against only 20 of British-grown tea, are the countries to be specially exploited for the ousting of China. The progress made in the United States

with British-grown tea in the five years looks poor, compared with similar progress in Australasia, for instance; and the field for superseding "Chinas and Japans" is here also very considerable. Indeed the fact that China, Japan and Java should, in 1900, make no less than 253,695,914 lb. of the world's consumption, against 313,147,698 lb for India and Ceylon, shows that the "Far East" tea trade is by no means extinct and that not Over-production but *Supersession* must be the order of the day. To that end, the cheapness of British-grown teas at this time may be a blessing in disguise; for it ought surely to secure an increased demand for such teas on the Continent of Europe and North and South America. The last is not to be despised, for it takes over 4 millions of China tea; while Australasia still has 7 million of the same description, South Africa 1½ million and "Other Countries" 5½ million lb. Altogether there is plenty of room to fight the battle with China and Japan.

BOERS AND CEYLONESE IN EAST AFRICA.

A number of Boer families have been introduced into German East Africa, to pursue stock raising and Agriculture on the high plateaux. The "Berliner Tageblatt" states that about 30 Ceylonese families have also been introduced for rice-growing in the low-lying regions, while great effort are being made to extend the area of coffee-planting. Coffee, too, is making headway and there are about 50 miles of railway open.—*Globe*, July 25.

THE "PRICKLY PEAR" CACTUS—makes a good fence, and was formerly used for the purpose by the mission fathers of California. Rabbits and other burrowing animals also seek their protection for warrens. Many birds build in the same refuge from their enemies. The giant "candle cactus", resembling a huge candelabra and covered with spines, is perforated by the Gila woodpecker, which, after making a hollow in the pith from 12 to 30 feet above the ground, builds its nest there.—*Globe*, July 25.

AFRICAN COFFEE.—The coffee, known as the Highland Coffee of Sierra Leone, was introduced to the West Indies about six years ago, through the instrumentality of the Royal Gardens, Kew. It is quite distinct from either Arabian or Liberian coffee, and is admirably suited for cultivation from sea-level up to an elevation of about 800 feet. The botanical name (*Coffea stenophylla*), that is "narrowed-leaved coffee," is a good name, as by this character and its small, dark-purple berries, it is readily distinguished from all other coffee. "Stenophylla" coffee has nowhere been more successful than under Mr Hart's care at the Royal Botanic Gardens at Trinidad. It has grown there into tall, handsome bushes, ten to twelve feet high, loaded with berries. It is singular that it has shown a marked tendency to be cross-fertilised by Liberian coffee, so that in the second or third generation its original characters have almost entirely disappeared. If this coffee is desired to be kept distinct it must therefore be cultivated away from other coffee plants.—*Barbados Agricultural News*, July 1.

THE PEARL FISHERIES OF CEYLON :
 PROFESSOR HERDMAN'S REPORT :
 GOOD PROSPECT OF CONTINUOUS
 FISHERIES IF SCIENTIFICALLY
 TREATED :
 TWO DANGERS TO AVOID :—"OVER-
 CROWDING" AND "OVERFISHING."

No act of Governor Sir West Ridgeway is more likely to be fruitful in material advantage to this Colony, than the selection of Professor Herdman, F.R.S., to inspect and report on its Pearl Oysters and Fisheries. We had in 1896 seen something of Dr. Herdman's work in the Isle of Man where he had established a Marine Laboratory which was an object of much interest to the Zoological section of the British Association meeting that year in Liverpool—one that included a special scientific excursion to the neighbouring island which Sir West had administered until 1895 when he left for Ceylon. We felt sure the right man was coming to deal with the problem of our Pearl Fisheries as soon as we heard of Dr. Herdman's appointment. The result, to judge by the Report, which we issued as a special supplement last evening, more than justifies the most sanguine expectations. Indeed, the regret must now be that Professor Herdman was not called in ten years earlier. But the fact was that "science" had got discredited, both in official and unofficial circles in Ceylon, ever since the failure of Mr. Holdsworth's mission in the time of Sir Hercules Robinson. That energetic Governor, when he found that—instead of four or five successive annual fisheries beginning with 1863 as anticipated by the then Inspector (and Collector of Customs), the Hon. Geo. Vane—there were no oysters available after the first harvest (which yielded R510,000 of revenue), resolved to call in the aid of science to see what could be done. Mr. Holdsworth, a Fellow of the Zoological Society of some experience in connection with home fisheries, was selected, but he met with most unfortunate circumstances during his few years in Ceylon; for not only did he never see a fishery but there was no bank covered with young oysters for him to examine or experiment with. From 1863 to 1873 proved a complete blank in our Pearl Oyster annals and Mr. Holdsworth left us none the wiser, so far as any practical result was concerned, though his Reports in themselves afforded in their way interesting reading. Very different is Professor Herdman's experience. He came to us not immediately after a successful fishery (such as occurred in 1891, giving R963,749 of revenue) but at the close of another decade of blanks and just when our historic Banks had once again become covered with enormous deposits of oysters, estimated for one bank alone at over a hundred thousand million! And not only young oysters; but in the case of one or two Banks a great

many of an age that all past experience shows should be fished "next year," lest they may slip away or be lost—from one or other of the several causes which have disappointed our hopes in the past. In his Report Professor Herdman does not enter into the history or causes of past failures.—For the present at least, he wisely leaves alone a discussion of the reasons for the periodic succession of a series of years with fisheries alternating with a series of blanks. On that subject he may possibly enter later on. But while going at once to the work before him, and giving us the results of his observations and scientific knowledge, he indicates two dangers apparent to the biologist in connection with such Fisheries, which may very likely indicate the key to much that is mysterious in the past,—namely the dangers of *overcrowding* and *overfishing*. The former especially is very evident at the present time (as it was to Sir William Twynnam and Captain Donnan in 1862, in 1879 and in 1889); but—for the first time, we believe, in the whole history of Ceylon Pearl Fisheries—is a practical remedy proposed, namely that of *thinning out and transplanting the young oysters*. This, Professor Herdman assures us, can be easily and speedily done on a large scale by dredging from a steamer at the proper time of year, when the young oysters are at the best age for transplanting. Here is the one specially valuable result, so far, of Professor Herdman's Mission; and if he and his Scientific Assistant, Mr. Hornell, are enabled to carry out successfully the remedy herein proposed, we say they will most amply justify Governor Ridgeway's step in securing their appointment and be the means of conferring an immense advantage on the island by turning its Pearl Oyster Fisheries from an entirely uncertain, intermittent source, to a comparatively permanent source of revenue. Of the other work, of the two scientists, we need only notice the selection of Galle Harbour as the site of a Marine Biological Laboratory, and here the necessary experiments are now being carried on by Mr. Hornell, which are to determine the best size of oyster to transplant, the right season of the year (October or March) for the operation, and whether only oysters attached to movable objects can be depended on, or whether the *lyssus*, once dredged or torn away, can be replaced without injury to the oyster.

We must not, of course, be too sanguine as to the future. The warnings of the past, ever since Sir Henry Ward's day, are sufficient to teach caution. We must first see actual transplanting on a considerable scale successfully carried out, and still more a successful fishery from the bank so planted, as well as a proper harvest gathered from the bank relieved of the superfluous bivalves. In all this there will be a risk; but Professor Herdman's modest, albeit clear and practical, statements inspire confidence, and we hail his Report as both extremely satisfactory and encouraging to the Government and public of this Colony.

VIEWES OF A MANAOS RUBBER MERCHANT.

During a recent visit to New York of Mr N H Witt, a leading rubber merchant of Manáos, the rubber centre of the upper Amazon, he was asked by "The India Rubber World" for his views on the practicability of companies being organised to work on a large scale in the movement of rubber direct from the producing districts to the consuming markets.

"I do not believe that such a thing can be done as yet," said he. "The difficulty of the labour problem is an old story which continues to be repeated. In the Amazon valley all the labour must be imported, together with provisions.

"There are no European peoples who can stand working in the climate of the Amazon valley. Something might be done with coolies, but it is a difficult matter to arrange with the government of British India for their introduction into South America. There has been talk of importing Chinese, but they would likely all turn traders and desert the rubber camps.

"I am convinced, therefore, that for a good while to come the safest way to deal in rubber is through the establishment of trading houses at the principal centres, as at present, and buying such rubber as may reach the market, from whatever source."

In answer to a question as to whether the existing rubber fields on the Amazon were showing indications of becoming exhausted, Mr Witt said :

All the fields which yield rubber other than Caucho still seem to produce the usual output. It is probable, however, that in some districts on the lower Amazon the trees have ceased to yield, and the fact that more rubber has been shipped this season from the state of Pará than last season may be due to the fact that the rubber workers have gone into new territory. In some cases the men may have worked harder, as we call it, forced by the low rubber prices ruling now. The increasing total production of the Amazon valley is due, of course, to the general widening of the district gone over in the search for rubber.

"One thing which indicates that the trees in the districts which have longest been worked are becoming less productive is the fact that the rate of shrinkage in the Island's rubber received at Pará gradually becomes greater. I remember that in 1885 a shrinkage of 6 per cent. was expected in Islands rubber, and the rate has gradually increased until now a shrinkage of 14 per cent. or even more is not unusual. And meanwhile there has been no important improvement in means of transportation between the Islands districts and Pará. Evidently there is a smaller percentage of solid rubber in the milk than when the trees were fresher, and with the same amount of smoking as formerly more moisture is retained in the rubber to be lost during shipment. In other words, while the trees apparently yield as much milk as formerly, the real production of rubber per tree is less.

Mr Witt spoke of the rapid exhaustion of Caucho in all the districts where the Peruvians went in search of it, and it was his impression that the trade of Iquitos, largely based upon Caucho, was not, for this reason, showing any increase. There was a possibility, however, that with the total

exhaustion of Caucho on the upper Amazon—say within the next ten years—the Peruvians might turn their attention to gathering fine rubber, and thus replace in a measure the Caucho trade.—*The India Rubber World*, July 1.

TRINIDAD PRODUCE REPORT.

Trinidad, July 2nd, 1902.

Produce.—Cocoa.—Owing to a less active demand for European account, and also in consequence of slightly better receipts from the country during the earlier part of the fortnight under review, our local market has become somewhat easier and we quote today from \$13'25 to \$13'75 per fanega as in quality. The alternate dry and wet weather which we have been experiencing has had a beneficial effect on the cultivation and the outlook for the next crop appears to be rather hopeful at present. There have been further moderate arrivals from the Venezuelan coast and we quote for Good Ordinary grades from \$13'50 to \$13'60 per fanega.

Copra.—Receipts from the country are small and the price is firm from \$2'85 to \$3 per 100 lbs. Quality made is very ordinary on account of the difficulty of drying with the present rains.

"CAPITAL" ON THE INDIAN TEA CESS.

The writer of Current Coin in *Capital*, in the issue of August 7th, thus comments on the Indian Tea Cess:—"I do not anticipate that there will be any violent representations against the imposition of the Cess, though the unexpected not infrequently occurs. I am not at all sure that the proposed Cess will do more than lessen the returns to the shareholders; but as drowning men clutch at straws, so shareholders, who have not received any return on their capital for years, must be ready to clutch at any expedient, for it cannot put them in a worse position. I consider, however, that a Cess of one-fourth of a pie per pound on all Indian teas exported by sea from India is not at all a happy idea. The biddings at the auctions here advance by pies per lb. The tax is to be not more than one-fourth of a pie per lb. The question is—On whom is this tax to fall, on the consumer or the producer? The accepted doctrine is that all taxes fall upon the consumers, but this is not so when the supply is in excess of the demand. If the tax is to fall on the purchaser of teas at auction in Calcutta, he will surely protect himself by bidding one pie less, and consequently to obtain one-fourth of a pie for advertising purposes tea growers will give away three-fourths of a pie. Can anyone imagine a more wasteful scheme? Of course in the case of teas shipped direct by the gardens to London this argument does not obtain. But the effect of the Cess will be to encourage the direct shipment of teas to London by a bounty of three-fourths of a pie per pound. Is this intended? The right mode of levying the Cess would be by an octroi on all tea coming into Calcutta or Chittagong, and this could be as easily levied as an export duty. All tea comes by rail or river steamers, and the matter could be easily adjusted. The present idea is clumsy. I am not in favor of a compulsory cess but, if there is to be one, let it be levied on business principles. There is one thing that shareholders in Tea gardens should bear in mind, and that is that it is not in the interests of the managing agents to curtail the output of tea. There are so many little profits to be made out of the handling of the

chests that a reduction in output does not answer the agents' purpose at all. Hence gardens are often worked that are an absolute drag on the tea company, the agents apparently always hoping against hope that they will come round in time. Meantime all the little items of profit go merrily on. If the tea is shipped to London there is a commission on acceptance of bills, the various little commissions of the London house, the private wharf profit and the like; the shareholders do not see them but they are there. And this reminds me of a little story of a ship captain who used to trade to Calcutta in the good old days. In his accounts there duly appeared an item of "Buggy hire." The owner demurred. He objected to the Buggy hire and told the captain that he would not pass such a charge in future. On the next voyage the accounts were presented as usual, duly scrutinised and passed, the owner remarking that he was glad to see that the obnoxious charge no longer appeared. "Ah!" murmured the worthy skipper under his breath, 'you may not see it but it, is there all the same.'

ACETYLENE TO ENTICE INSECTS.

The current number of the *Acetylene Gas Journal* points out the advantages of this new illuminant for enticing night flying destructive insects to their doom in orchards and other places. The *Journal* says:—"By means of acetylene, for instance, it is possible to establish bright lights everywhere in the orchard or about the grounds in a way that is wholly out of the question with the electric arc. The expense of acetylene for such purposes is likewise very moderate. The manner of employing acetylene, for insect destruction, is by placing a low standard, surmounted by a burner of the gas, in a pan which holds a mixture of vinegar and molasses or of kerosine, the light being fed from a generator near by through a hose. The smallest kind of generator or any kind of a portable acetylene lamp, such as a bicycle, a miner's or a table lamp, is suited to this use, by placing the same in, or just over, a basin of the liquids named. It is well to have a receptacle of some size, as the idea is to drown the insects. In the month of July, 1901, in Beaujolais, France, more than 177,000 moths were thus killed in the space of 18 days. Twenty little lamps were employed for the purpose, the consumption of each costing 8 centimes per evening."

FORCED PLANTATIONS.

(From a Correspondent.)

Attention should be called to the practice adopted by gardeners and fruit merchants, more especially in recent years, to ripen plantains artificially for the market with a view to obtain a quick sale. The result is that the fruit is rendered soft and pulpy and the flavour destroyed. Plantains forced in this way become rotten and worthless very quickly, and therefore have not the same value to those who purchase them. Forced plantains may be known by the softness of the fruit, and by the greenness of the short stems by which they are attached to the stalk of the bunch. If allowed to ripen naturally, the stems ripen with the fruit into a pale straw colour and the fruit is ready to be eaten as soon as it can be removed from the stems without the slightest

effort. This is not so with artificially ripened fruit, as the short stem remains green and tough, so that it is difficult to remove it, while the rind appears to be ripe.

It may be interesting to relate what this artificial process is—a process which seems to be spreading extensively throughout South India. A large earthen pot is taken and a bunch of plantains with some leaves is put into it. Another pot of similar make but smaller in size is filled with straw, and its mouth placed on the mouth of the larger pot. The mouths are then sealed with cow-dung (that useful article to many people in this country) and occasionally with clay instead. A hole of about an inch in diameter is made in the bottom of the smaller pot, which is upside down, and a piece of glowing ember, or charcoal, is put through the hole and placed on the top of the straw. A current of air is then blown by the mouth through the hole for a few minutes. This fans the glowing ember inside, and smoke from the ignition of the straw is forced down into the vessel containing the fruit requiring ripening. After this the whole is sealed to prevent air from entering. This is done in the morning, and repeated in the evening, and also on the morning of the next day. If the plantains be wanted very soon, they are smoked a fourth time.

It is a pity that this forcing process was ever resorted to, as it will be abundantly evident that not much flavour can remain after it is over. Europeans should set their faces against it, and refuse to buy such artificially ripened fruit. If ladies would give strict orders to their cooks not to buy such plantains, but only those that have been allowed to ripen naturally, and if Hindus would do likewise, fruit merchants would soon stop such a practice. The plantain is a most wholesome and nutritious fruit, especially the *vastali* and the *pouvazhai*, which are among the best table plantains. When properly ripe and in good condition, and mashed up with a fork on a plate with a liberal supply of milk, plantains make an excellent dish and are easily digested. But in these days, when fruit merchants hasten to bring about a quick sale by the forcing process, one almost despairs of ever getting a good plantain possessing its natural and delicate flavour, so much prized by many people in this country,—*Madras Mail*, Aug. 10.

INFUSED TEA LEAVES AS MANURE.

(To the Editor, *Indian Gardening and Planting*.)

SIR,—Re your note on infused tea leaves as manure, I remember many years ago a friend of mine in Madras treating a small tea-rose plant with the remains of his tea pot. I have never yet seen a rose plant blossom as that did. It was for about two or three months one perpetual bloom, fresh flowers coming up as fast as others were cut off. My friend was going to France and he gave me the plant, which by that time had ceased flowering. It never flowered again. The tea infusion with the infused leaves must have been too forcing, and a few months after it withered and died. I was very sorry, because the flowers, though small, were every one of them perfect, and somehow I never could get another plant like it again, though I looked up a number of neighbours' gardens. This experience of mine might be of use to those who would try infused tea leaves as manure. W.
—*Indian Gardening and Planting*, Aug. 7.

RUBBER ACCORDING TO THE CONSULS.

CEARA.—Mr. Acting Consul Williams reports that the rubber exports of Ceara were small, owing to the high duty collected by the State on the rubber exported; part of what used to come to Ceara from the neighbouring States of Piahy and Rio Grande de Norte was exported from the States that produced it.

CONGO.—To the consular report of Mr Whitehead are added the following remarks:—Exportation of rubber has nearly trebled since 1898, and that commodity is by far the Congo's most important article of commerce. During the year under review the export of rubber amounted to £1,758,638 in special, and £1,807,327 in general commerce, out of totals of £2,019,536 and £2,160,302 respectively. The 'special' commerce thus differentiated from 'general' means the exportation from the Congo of products yielded within the territory of the State. Of the total 'special' export of rubber, amounting in value to £1,758,638, Belgium's proportion was £1,713,926, and the United Kingdom's only £188! Of the 'general' commerce in rubber, amounting in value to £1,807,327, Belgium's share was £1,747,323, and the United Kingdom's but £1,162. Little wonder that the importance of Antwerp as a mart for rubber has grown at a great rate since the Belgians set themselves to exploit the 'Independent' Congo State. From the report itself it would appear that the satisfactory development of the commerce of the Independent State of the Congo continues; that it is largely, though not entirely, owing to increased exports of indiarubber, and that this trade is almost entirely in Belgian hands.

COLOMBIA.—The Colombian Consul-General in London has made the following communication to Reuter's Agency:—"A contract has been secured from the Government for the navigation of the Caqueta and Putumayo rivers with their tributaries. The concessionaire (Mr. J Bidlake) is permitted the free introduction of boats and such machinery as he may require. He is to receive 1,250 acres of land for each vessel he puts upon the rivers. He has also the right to build wharves and necessary buildings on public domains. The contract is to continue in force for ten years. The territory covered embraces the larger portion of Southern Colombia, and includes a vast rubber forest, the extraction of the product being the main object of the enterprise."

PERU-BOLIVIA.—H.M. Consul-General at Callao remarks that the india-rubber industry is likely to progress, as, from all accounts, the forests of Peru contain innumerable rubber trees. From 1st July, 1900, to 30th July, 1901, grants amounting in the aggregate to 1,240,000 acres of forest land, said to contain valuable rubber trees, have been made by the Government. These lauds lie in the Departments of Huanaco and Cuzco. The periods of the grants are either five or ten years. The royalty claimed by the Government is 2s for every quintal of rubber which is exported. During the same period six other concessions were granted under somewhat different conditions. One of the grants comprised 4,942 acres and the others 1,235 acres each. These grants are divided into plots called 'estradas.' Each 'estrada' contains within its boundaries 150 rubber trees. The royalties levied in this case are 20 cents annually for each 'estrada' and 20 cents for each hectare of land which the estradas cover.—*India-rubber Trades' Journal*, July 7.

CAMPHOR MONOPOLY IN FUKIEN.

On the authority of the Japanese Foreign Office, it is now stated (says the *Kobe Chronicle*) that the Chinese Government has decided to establish a Camphor Monopoly Office in Fukien, placing the manufacture and sale of camphor under the control of the Japanese. It is not correct, however, to say that the monopoly right of the camphor trade is to be conceded to the Japanese Government. In future the Japanese may be a party to the camphor business by contributing a part of the expenses of monopoly, but no definite arrangements have yet been made.

POULTRY BREEDING IN RUSSIA.

Without any great exaggeration it can be said that there is no house, no family in Russia, where poultry is not bred. Peasants in their small izbas, big landlords on their estates, and even inhabitants of town breed poultry, mostly hens for laying and for supplying the market. Beside hens, other kinds of poultry are also kept, as geese, ducks, turkeys, guinea-fowls, peacocks, swans, and even certain species of non-domesticated birds—as partridges, turtle-doves, black-game, woodcock, etc. All possible species of hens can be found in Russian poultry yards, and amongst them those native to England and America—as Cochin China, Brahmapoetra, Jangshan, Plymouth Rock, Wyandote, Dorking, etc. But the thoroughbred hens are to be found mostly in poultry yards owned by amateurs. The average country inhabitant, however, does not possess any superior kind of poultry; he owns generally mongrels, and attaches more importance to the quantity of the birds than to their good qualities. But there exists in Russia two breeds of hens which are looked upon as national breeds. They are, firstly, the Orloff, and, secondly, the Paul species. Opinions are divided concerning their origin; some attribute it to Count Orloff-Tchernensky, and others to an Oriental stock from Persia, the Paul breed got its name from the village of Pavloff, where it was first obtained in Catherine II's reign. These two kinds of hens, bred in Russia for more than a century, are entirely unknown to the outer world, and they are so exclusively Russian as are the fighting cocks in England. The Orloff and Paul breeds are rather sportive than utility breeds, although they are not wholly lacking in the latter qualities. Goose breeding is widespread. It is probable that formerly it attracted amateurs, as there are still existing some special breeds peculiar to Russia alone, for instance the fighting geese of Toula, Arzamass, and Kholmogory. They have a round head, large forehead, and a very short but strong beak. Their flesh is savoury, they are very prolific, and easy to breed. The duck is equally widespread, but we seldom meet superior breeds, as Rouen, Aylesbury, Pekin, etc. The same can be said about turkeys; the better species, as the Cambridge or the American one, are principally to be found in amateur aviaries. The peacock is exclusively bred merely as an ornamental bird, and has no economical importance. The same may be said about the swan. Partridges, quails, woodcocks, and blackbirds are bred on big country properties for sporting purposes, and not for the market. Pheasants are bred more abundantly, and there are some well-known estates as, for instance, Luamenskoe, belonging to Their Imperial Highnesses the Grand Dukes Nicholas and Peter Nicolaevitch, and

Bialo-Tserkew, belonging to Count Bianicki, which can vie with the most perfectly kept covers of other countries. As Russian people do not eat pigeons as a rule, they are only bred by amateurs. There are, however, some national breeds, as Turman and Tchisty, and there exists also a charming little species with a top-knot, known as the Bukhara pigeon. In the last twenty years many bird-breeding societies, with wide ramifications, have been formed, constituted principally by amateurs, who organise Shows and contribute to elevate the level of poultry breeding. But we can say that until then there was no scientific poultry breeding in Russia. It occupied no place in rural economy, and as its production was not expensive, people were satisfied if they had enough poultry and eggs for their daily use. Things are different now, and the trade in this line has reached vast dimensions. Unhappily, we do not possess exact statistic data about Russia's production and its home consumption. We have, however, some indication about poultry export. In 1897 the export was valued at 35,000,000 roubles, and in 1898 at 40,000,000 roubles. Compared with other countries, Russian export occupies the first place. The principal item in the export is eggs. Of the 40,000,000 roubles in 1898, 32,000,000 roubles were for eggs, and the remaining 8,000,000 roubles for poultry proper. Its production is increasing by leaps and bounds, and will presently assume gigantic proportions. As the Russian climate, with the exception of the extreme north, is very favourable to poultry breeding, we may suppose, as foreign demand is constantly increasing, that the production will rise and that commercial companies will be started to organise the export in the best possible way.—*Russia*, July 19.

WOOD FUEL.

Mr D E Hutchins, whose valuable paper on 'Forestry,' read on November, 22nd, 1899, will be in the remembrance of those members who are interested in the subject raised in *Nature*, of the 10th July, a rather novel question in connection with the supply of timber. He suggests that it would be worth while to cultivate the wattle or eucalyptus vegetation in Anstralia or South Africa, with a view to its being used as fuel. He argues that eucalyptus planted on tropical mountains would produce wood fuel at the rate of 20 tons per acre per year in perpetuity, and points out that, by a calculation of Helmholtz, a eucalyptus plantation would store up about one per cent. of the solar energy received on the unit of area. Its dry timber, which weighs 60 pounds per cubic foot, as compared with coal weighing from 50 to 52 pounds, is said to have an equal or higher thermal power than coal. As these calculations were made from natural forests, Mr Hutchins argues that by selection and cultivation, even double the amount might be produced where there was a powerful sun, a heavy rainfall, and a very rapid forced growth. Very large districts of the world would supply the requisite conditions, and he looks forward to a yearly output of over 40,000 million tons, or even on an average forest yield of 20,000 million tons, the world's yearly output of coal being calculated as 663 million tons. The suggestion is certainly a novel one, but its merits and its practicability must be left to be discussed by experts on the subject.—*Journal of the Society of Arts* July 25.

MINING EXPLOITATION in the Dun is likely to receive a stimulus from the fact that Messrs Bird and Company of Calcutta have obtained from the Government of the United Provinces a license to prospect for minerals over an extensive area in that locality.—*Indian Agriculturist*, Aug. 1,

JOTTINGS FROM SUMATRA'S EAST COAST :

(*Coffee-planting by an ex-Ceylon Colonist.*)

"Hard times, alas! are with us still

The coffee-planter's lot—

Allowing him only just enough

To boil the daily pot."

—*Ancient MS.*

'Tis a bad sign in coffee here that some folks are beginning to reckon on 'next year,' that will o'-the-wisp which deluded with false hopes so many Ceylon men in the sad years between the decline of coffee and the rise of tea.

We have just had one of the most wonderful blossoms I have ever seen, so we are all right for 'next year.' But from all I hear there are some quaking hearts wondering if they can hang on till then. Last year, in addition to the plague of caterpillars, we had an abnormal and prolonged drought which was fatal to blossoming, and the consequent short crop which we are now taking in presses hardly on all. Twelve months ago we were working day and night with hand-pulpers to work off our coffee and sending our parchment to Singapore to be cured. Now we are all provided with grand establishments: put in the pig at one end, press the button and cured hams and sausages come out at the other. But pig *won't* get over the stile, and I fear me some of us *shan't* get home tonight.

I've just had

A RUN THROUGH THE DISTRICT,

Serdang I mean, and I never saw coffee looking in better heart. Rich, dark-green foliage and plenty of good wood, but everywhere the same; no crop, or only a very little. The caterpillar-stricken patches are different. They bear the mark of the beast most unmistakably, and it will be long before they recover their vigour.

Most men seem to think that the damage done by the caterpillars is confined to the denudation of the tree of its leaves. I am inclined to think that a further mischief is done by the caterpillar in imparting a poison to the sap of the trees. Of course, I can prove nothing; but I am very strongly of this opinion. Anybody coming over here now with a view to *speculative* investment, in the event of Brazil cutting its own throat, could certainly pick up a bargain or two. The statistical position is appalling: and if Brazil goes on for another two or three years at its present rate of increasing production, and can stand the racket, the East Indian

COFFEE PLANTER

will be as extinct as the dodo. If on the other hand Brazil, as is stated, has overdone it and must reduce its output by more than one-third, there is a good time coming for us. We shall be able to pay our debts and drink champagne on birthdays!

However, in view of considerably over a quarter of a century's experience in the East, I make it a rule to keep a stiff upper lip and be prepared for the worst; and when it comes, take it smiling; and if you can't take it smiling, take it as smiling as you can.

—Shut up you Pessimist.

Pessimist.—Go to the—inkpot you interfering—
It is always pleasant for

AN OLD CEYLON MAN

to hear his old country well spoken of. Some days ago I met a friend who was one of a special-train-party sent up a few months ago to Kandy—chiefly I think through the enterprise of the well-known Manager of the Queen's Hotel. My friend was full of praise of the country and all that therein is. The railway, the view from the railway, the mountains in the distance, the smiling terraced paddy-fields below—these, we thought, had exhausted his vocabulary. But no! Peradeniya was yet to come. My friend is a great amateur of all sorts of tropical botany, and it was surprising what an amount of detail he had been able to observe in what must of necessity have been more or less of a hurried scamper. His observations were sharp and to the point; his praise unstinted; his admiration unbounded. More was to come. But in few words:—'Kandy,' he began—there was a pause—'Kandy,' he began again and lay back in his chair: 'Kandy is the most beautiful place in the world!' And he lay back in his chair, puffing huge rings of smoke, through which I suppose he revisited 'the most beautiful place in the world,' for nothing more was to be got from him that night.

The same gentleman on his return the other day had only four hours to spend in Colombo, and these he spent in looking for seed-nuts of the king coconut, but without avail. He wants them sorely—not for trade purposes; but merely to add to his orchard which is a most comprehensive one; and if any lowcountry reader of these lines has a sympathetic heart and would like to profit

BY EXCHANGE OF FRUITS,

let him put a few seed-nuts of the king coconut variety into a gunny bag and send them to O. Puttifarenko, Lobo Pakam, O.K. Sumatra, and he will certainly get a good return in other Tropical fruits not common to Ceylon. Please, Mr Editor this is not an advertisement, but only an opportunity for gentlemen gardening for *pastime only* to exchange the 'fruits' of their experience.

But anybody sending such things to Sumatra's East Coast (O.K., Oost Kust, East Coast) should always ship by *North German Lloyds*. By other lines your parcel may go to Bali, Lombok, Macassar, even Samoa, or somewhere. *'It 'im over the 'ead with a 'ard 'eavy 'ammer and make in 'owl 'orrible.* It was not the Socratic one this time, but another little beast in his image—just as I thought I had him by the neck, he disappeared into the ink-pot again.

26th July, 1902.

W. T. McK.

PRODUCE AND PLANTING.

"CEYLON AND ITS PLANTING INDUSTRY,"

Mr J Ferguson writes: "The most notable fact revealed by the figures is the falling-off in the area of tea, the total in cultivation on plantations being 4,000 acres less than a year ago, or, including native gardens, a decrease of 6,000 acres, making a total of 386,000 in place of 392,000 acres. This must be due to the abandonment of non-paying fields and of some unprofitable gardens; for it is accompanied by an extension of the total extent in cultivation by 1,000 acres, although poor 'coffee' has gone down, being 3,200 acres less than a year ago. Cacao, on the other hand, is 500 acres more in planted extent; cardamoms are greater in area by 1,800 acres; cinchona shows an increase

of 1,000 acres; and India-rubber (chiefly the Para or Hevea variety) of nearly 1,000 acres—which must, however, be rather under the actual area planted during the year, our total extent planted being about 3,400 acres. In several minor products, too—camphor, nutmegs, crotons—there has been a good deal of planting, and still more have we had in the Kelani Valley and other low country estates, a planting out of coconut palms among the tea, just as Para rubber has been put in freely on the Kalutara tea estates. The check to tea, and the act that there are no clearings this year to plant ought to strengthen the hopes of those who believe in a future for our staple, so soon as consumption overtakes production. A year ago we anticipated that there would be 400,000 acres under tea at an early date in Ceylon; whereas now we are in reality back to 386,000, with no immediate prospect of extension. In our shipments of tea from Ceylon this year we are so far 5,000,000 lb. behind the same date last year for the United Kingdom, but shipments to Russia and America show an increase. Our coconut palm industry—chiefly in native hands—covering 600,000 acres with a crop of one thousand million coconuts (for oil copra, fibre, desiccating kernels, &c.)—is in a highly prosperous condition; while that in cinnamon bark and in plumbago mining continues fairly satisfactory. The Boer prisoners are making preparations against their return home—the first transport calling at Colombo shortly—and are likely to take a good deal of Ceylon tea with them."—*H and C Mail* August 1.

PLANTING NOTES.

BERMUDA ARROWROOT.—A report on Bermuda recently issued by the Colonial Office states that the cultivation and manufacture of arrowroot, which were at one time important industries in that colony, have, from various causes, greatly declined in recent years. The arrowroot produced in the colony by the latest improved methods is of an excellent quality, and there is a good opening for investment of limited capital in this industry.—*Chemist and Druggist*, July 26.

EUCALYPTS are freely referred to in Ednie-Brown's volume on the "Forests of Western Australia"; but he often gives no scientific name. We quote two sentences:—

TUART.—This is a handsome Eucalypt, and has a wonderfully bright and cheerful appearance in the forest. The bark is of a greyish-white colour, and is smoothly crinkled and persistent throughout. The trees are always clean and bright-looking. In the young stage the species forms a very ornamental tree, and is planted as such in some of the other Colonies. It is straight, well-clothed, and has a beautiful bright-green leaf, and in this respect is not unlike the Karri.

CRIMSON-FLOWERING GUM.—This is referred to here, not because of its value as a timber tree but simply as a gorgeous and remarkable specimen of the forest flowering trees of Western Australia. The subject is a very handsome, branchy, umbrageous, small tree; its foliage is dark-shining green with the leaves standing out more flat, and not edgewise, as is usual with the eucalyptus family generally. The specimens which I saw ranged from 20 to 40 feet in height, with stems averaging about a foot in diameter. The bark is rough and somewhat like the red gum; the wood is a dark, blood-like colour. These trees had their branches sweeping down to the ground amongst the ferns.

TO THE PLANTING WORLD.

Seeds & Plants of Commercial Products.

Hevea Brasiliensis.—Orders being booked for the coming crop August-September delivery 1902, booking necessary before the end of April, quantities of 100,000 and over at special low rates. Plants available all the year round, 100,000 and over at special low rates. A leading Rubber planter in Sumatra, who purchased 50,000 seeds in 1899, and 100,000 in 1900, writes us, under date 15th November, 1900:—"I received your letter of 20th October, from which I learn that you added another case of 5,000 seeds to replace the loss, &c. I am satisfied hereby, and even after this adding I am satisfied by the whole delivery of this year." Special offer, post free on application.

Castilloa Elastica.—True superior variety cultivated in Mexico, seeds from specially reserved old untapped trees. Orders booked for August-September delivery 1902, immediate booking necessary; large quantities on special terms; Plants in Wardian cases.

A foreign firm of Planters writes under date 11th October, 1901:—"We beg to enquire whether you would procure us 100,000 Castilloa seeds, in which month we might expect them, and what would be the average price." Special offer, post free on application.

Manihot Glaziovii.—Seeds and Plants available all the year round, 100,000 and over at special low rates. A Mexican planter in sending an order for this seed wrote on the 22nd August, 1900:—"If they arrive fresh and germinate easily I may send you larger orders, as they are for high ground where the Castilloa does not thrive."

Ficus Elastica.—Seeds available in May-June; booking necessary before the end of March; also plants.

Mimusops Globosa (Balata) wood of the tree is much sought for buildings, fruits sweet like a plum and eaten, oil from seeds, said to yield as much as 45 lbs. of dry rubber per tree per annum, the milk is drunk and when diluted with water used as cow's milk, grow from-sea-level up to 2,000 feet, orders being booked for seeds and plants, price on application.

Cinnamomum Zeylanicum (Cinnamon superior variety).—New crop of seed in April to June; booking necessary before the end of February, also plants.

Coffee Arabica, Liberian Hybrid and Maragogopie Hybrid.—New crop March-April; immediate booking necessary.

A foreign Agricultural Department writes dating 9th September, 1901:—"Please accept our order for 175 lbs. of Tea seed and for 2,000 Coffee beans. In regard to Coffee seed I would say that this will be the first importation made by this department, and we will leave the selection of the varieties to be sent to your judgment."

OUR DESCRIPTIVE PRICE LISTS.

The following six Descriptive Price Lists are now being forwarded with Circulars and special offer of Seeds and Plants of Rubber and other Economic Products:—

1. Tropical Seeds and Plants of Commercial Products, enlarged edition for 1902.
2. Seeds and Plants of Shade, Timber, Wind-Belts, Fuel and Ornamental Trees, Trees for Road-sides, Parks, Open Spaces, Pasture Lands, Avenues, Hedges, and for planting among crops (Tea, Coffee, Cacao, Cardamoms, &c.)

3. Seeds and Plants of Tropical Fruit Trees including Mango grafts.

4. Bulbs, Tubers and Yams.

5. Orchids—Ceylon and Indian.

6. Seeds and Plants of Palms, Calamus, Pandanus, Cycads, Tree and other Ferns, Crotons, Roses, Dracinas, Shrubs and Creepers.

Special Arrangements made with foreign Governments, Botanical and Agricultural Departments, Planters and others for supplying seeds and plants of Commercial Products in large quantities.

"SOUTH AFRICA."—The great authority on South African affairs of 25th March, 1899, says:—"An interesting Catalogue reaches us from the East. It is issued by WILLIAM BROTHERS, Tropical Seed Merchants of Henaratgoda, Ceylon, and schedules all the useful and beautiful plants which will thrive in tropical and semi-tropical regions. We fancy Messrs. Williams should do good business, for now that the great Powers have grabbed all the waste places of the earth, they must turn to and prove that they were worth the grabbing. We recommend the great Powers and Concessionaries under them to go to William Brothers."

Agents in London:—MESSRS. P. W. WOOLLEY & Co., 90, Lower Thames Street.

Agent in Colombo, Ceylon:—E. B. CREAMY, Esq.

Agent in British Central Africa:—T. H. LLOYD, Esq., Blantyre.

Telegraphic Address:

To the Editor.

GREEN TEAS AND ——— GREEN TEAS IN CEYLON.

Stagbrook, Peermaad, S. India.

SIR,—In your footnote to a letter signed "Willing to Learn," in yours of 18th July you refer to "Green Teas" as "*manufactured*" at Ambewatte Mills. I have again to point out to you and such of your readers as are as hazy on the subject of "Green Tea manufacture" as is "Willing to Learn," that "Green Teas are" *not manufactured* at Ambewatte Mills; but that manufactured Green Teas are coloured and restored there. There is no secret about the process. It is merely a matter of extra expense. "Willing to Learn" can see the process for himself as adopted in Japan on pages 12 and 27 of the Report of the British Vice-Consul at Yokohama upon the Japanese Tea Industry, printed at the *Observer* Printing Works. Machines can be bought for colouring large quantities quickly instead of using the Panning Process described in above report for about £375 f.o.b.; but probably after reading the article on Colouring of Tea on page 27, he will bide a wee before following Messrs. Finlay, Muir & Co.'s example. —I am, sir, yours faithfully,

H. DRUMMOND DEANE.

P.S.—If experts in colouring green teas are wanted, there are many men in India who have nothing to learn from the Japanese.

[It is very good of Mr. Drummond Deane to enlighten us; but we have yet to learn that he has been inside the Ambewatte Mills to see all the process. Here is what Mr. A. K. Muir said in England the other day:—

A factory has been erected in Colombo and equipped with the necessary machinery for making green teas in the Chinese and Japanese fashion. This factory is capable of turning out about 3,000,000 lb. of green tea per annum. About one-fourth of this quantity is at present being manufactured there, and if it proves that 3,000,000 lb. can readily be sold in the United States and Canada the output will be increased accordingly.

—ED. T.A.]

THE "MANUFACTURE" OF GREEN TEAS IN COLOMBO;

MR. DRUMMOND-DEANE EXPLAINS.

Stagbrook, Peermaad, S. India, Aug. 2.

SIR,—With reference to your footnote to my letter in your issue of 28th instant, it is not necessary for me or anyone else to go inside the Ambewatte Mills to know that any large quantity of green tea leaf could not be transported to Colombo and *manufactured* there. On the other hand manufactured leaf can of course be transported there and sorted or coloured in any way that is found paying, and I for one wish the enterprising firm in question every success,

though I doubt the desirability in the long run of colouring Ceylon and Indian Teas. Mr. A. K. Muir, when he spoke (in the speech you quote) of "making" green teas in the Chinese and Japanese fashion, was *not* talking to manufacturers but to consumers, and, if he had used the words "turning out" instead of the word "making," he would have been absolutely correct; or had he used the word "into" instead of "to" he would again be correct. Not that such a slip would matter at all to the general public, but here in India and Ceylon it is a different matter because many men are thinking of "manufacturing green tea" but reluctant to begin so long as from your editorial chair the fiat goes forth that to "manufacture" green teas on the best Japanese lines, intending manufacturers must either obtain an entry into the "Ambawatte" factory or be out in the cold. This is a fallacy. If any gentlemen wish to colour their green teas I have no doubt Mr C Judge of 47, Free School Street, Calcutta, will, for a small remuneration, give them every particular for doing so by hand. If they wish to do it by machinery it is a mere question of a very expensive machine. Two very large gardens in India are colouring their teas with great success as regards appearance, to my personal knowledge, though their teas are made on the system first introduced into Ceylon and India by myself.—Yours faithfully,

H. D. DEANE.

[The above letter, we take it, was written before Mr. Drummond Deane saw Mr. Leslie Rogers' report on Ambawatte samples? Our latest news is of a leading Ceylon planter who was, in confidence, taken through Ambawatte and who expressed himself as perfectly satisfied as to no extraneous substance being added to the teas. At the same time our correspondent is right about planters having to continue on his plan of turning out green teas.—ED. T.A.]

"THE CONSOLIDATED TEA AND LANDS" AND "AMALGAMATED TEA ESTATES" COMPANIES.

In re "COMMISSIONS"—AN EXAMPLE
TO BE FOLLOWED?

July 21.

DEAR SIR,—There is a *down* among some Ceylon tea planters on what are called the "Muir Companies"; but it seems to me, Sir, that much occurred at the Glasgow meetings of the "Consolidated" and "Amalgamated" Companies deserving of praise from outside planters. There are Planting Companies in Ceylon that pay no dividends; but the remission of fees and commissions is rare? Here is the Chairman's reference in Glasgow:—

"With a view to enabling the directors to make up the full sum drawn from the reserve account last year and thus place the company again in a dividend-paying position as soon as possible, the Calcutta and Colombo agents have agreed to give up to the company, for the benefit of the revenue account of 1901, the whole of their commissions for that year; the directors have returned one-half of their fees, and the London agents have also returned one-half of their commissions."

There are other passages in the proceedings that you ought to copy and emphasize.—Yours, etc.,

FAIR PLAY.

[We regret not having given the proceedings in full. Mr. A. K. Muir, who is a keen man of business—as we saw in Calcutta—made a capital Chairman; but he was inclined to be a little too sanguine—for instance, at the “Consolidated” meeting, he said:—

“There is no doubt, Gentlemen, that the tea industry has, for the last two years, been passing through very trying times, but the present position is not by any means so gloomy as might be imagined from the market quotation of tea shares. Without being unduly optimistic, I think there are some indications that the tea-growing industry will, before very long, again enjoy a period of prosperity. The remarks recently made by the Chancellor of the Exchequer may fairly be taken as equivalent to a promise of the early removal of the additional 2d per lb. on the duty on tea, which has been a serious burden on the industry, as it has undoubtedly been borne almost entirely by the producers. The consumption of Indian and Ceylon tea has been going on increasing satisfactorily, and if it continues at the same rate should before long overtake and pass the production. . . . The export of tea from China has been steadily declining. [Not so, for the present season.—Ed. C.O.] In Japan there has been a marked advance in the price of labour, so much so that it has become impossible in many districts to grow tea at a profit. In these districts, I am informed, the tea bushes have in many cases been pulled up and mulberry trees have been planted in their place. The exports from Japan have fallen off over 10,000,000 lb. and it will be difficult for them to make their exports up to the old figures. For the past few years both the Chinese and the Japanese have tried to off-set the advance in labour and the lower prices in the United States by putting less labour on their tea. I refer now to the rolling. The result has been that the quality has fallen off very considerably.”

Later on, he stated:—

“As regards finding other fresh outlets, I may remind you that the Australian markets are now free and that the American tax will be removed next year. Progress in America has, so far, been disappointing, and Indian and Ceylon producers are beginning to realise that if they are to make headway there they must set themselves to turn out the class of tea which the Americans want. There is a market for over 60,000,000 lb. of green tea in America, which sells at from 7d to 1s 6d per lb., the average price of green tea in America being about 8½d to 9d per lb. These teas are made in China and Japan, and it seems reasonable to suppose that if we are to produce an article suited to the American taste we must study the methods of China and Japan. With his object in view the Anglo-American Direct Tea Trading Company, Limited, have during the past year had a representative in Japan, studying the system of manufacture adopted there. A factory has been erected in Colombo and equipped with the necessary machinery for making green teas in the Chinese and Japanese fashion. This factory is capable of turning out about 3,000,000 lb. of green tea per annum. About one-fourth of this quantity is at present being manufactured there, and if it proves that 3,000,000 lb. can readily be sold in the United States and Canada the output will be increased accordingly.”

Mr. Wm. Mackenzie made some remarks worth quoting:—

Mr W Mackenzie, after referring to some items in the accounts, and the necessity for economical work, said he hoped commissions on results would continue to be paid to estate managers. Personally, he thought the reserve fund, which now stands at £85,000, should be applied in wiping out such nominal assets

as debenture expenses and preliminary expenses, and in reducing block account, to which he noticed interest continues to be charged. He also thought it would not be fair to use present valuations as a test per acre. We went in at a high value, and things have fallen a bit, and therefore we cannot be too mathematical, but must consider the circumstances, and what is good for practical protection.

At the meeting of the “Amalgamated,” the Chairman said:—

As mentioned in the report, the Calcutta and Colombo agents have, in view of the disappointing results of last season's working, voluntarily agreed to give up to the company for the benefit of revenue account the whole of their commissions for the year. The London agents have also agreed to give up one-half of their commissions, and the accounts have been framed on that basis. As regards the future, you will no doubt also appreciate the offer made by the Calcutta and Colombo agents to accept lower remuneration than they are entitled to under their agreement while the depression in tea continues. The planted area of the company's properties is now 13,49½ acres. The estimated yield of tea for the current season is 3,175,230 lb. As stated in the report the increase expected is mainly from the company's young estates in Assam, which are now coming into bearing, and which, having been planted with a high-class lot of tea, should help to improve the average price of the company's produce. . . . The company's coconut estates in Ceylon, aggregating about 1,000 acres, continue to make satisfactory progress, and the growth of the palms generally is reported, according to latest advices, to be excellent. While this is so, these properties cannot be expected to contribute to the profits of the company for two or three years owing to the long period this product takes to mature.

Mr. Alex. Mann, the Company's Visiting Agent, made an important statement, the closing sentence especially being noticeable:—

This company has the great advantage of having most of its properties in the two best tea districts in India, viz., in Assam and Darjeeling, and it is rather unfortunate that these are the two districts that have suffered more than others last year in quality of manufacture.

It may be pointed out that there is practically no more land suitable for tea to be had in the Darjeeling district, so the over-supply too often heard of in connection with tea generally should not apply to teas from this hill district.

—ED. C.O.]

CACAO—AND ITS FERMENTATION.

July 22.

DEAR SIR,—Your appeal to Cacao planters to give their experience in the way of fermenting and washing (in connection with Mr. Renton's valuable information) will, I am afraid, not be responded to. Is it shyness or egotism?—the latter I think. If it is the latter, it is a mistake; for I dare assert that the produce of the individual planter will not receive much attention in the market if the country is thought to produce an inferior article.

Much is to be learnt about fermentation, that mysterious operation. It wants a specialist, and it has to differ for every variety.

Coincidence—this is what I wrote on June 16th to my London agents;—“Our cacao is not appreciated in Germany on account of its sour smell, it is said, which is due to the washing. To obtain the red colour outside, appreciated by London buyers, it is necessary to wash after a day's fermentation, dry slowly, give another night's fermentation, dry slowly, give another night's fermentation, dry slowly. This way of fer-

ménting leaves the bean devoid of the chocolate taste, when a longer continuous fermentation, taking care not to overheat, brings it out but darkens the skin. To dry the bean without washing gives it a dirty appearance and renders it more liable to mildew. It is the reason, I think, for which in some parts of Central America they earth the cacao (Puerto Cabello, the highest priced, is earthed).—Yours truly,

CACAO PLANTER.

CEYLON TEA CHESTS AND TEAS FOR THE CANADIAN MARKET.

July 27.

DEAR SIR,—In view of the recent official correspondence published by the Tea Traders' Association *re* Ceylon-made chests, the enclosed letter will interest all your planting readers, especially as it refers to Ceylon "greens." The writer, as you will see, is a Japanese tea importer in Montreal and should know what best suits the trade generally. It may also be as well to point out that pine chests were only imported by local merchants when Momis could not be obtained. We don't think many are coming forward now.—Yours faithfully,

MERCHANT.

Montreal, March 12.

In reply to your inquiry *re* the prospect of Ceylon and Indian teas with the Canadian market, I may tell you my own opinion, which is that they have a good prospect in blacks as much as Japan has in its greens. They try quite hard to compete with us in green tea recently, but unless they make still further improvements, I do not think they can ever displace us from the market. There are many defects on their part if I point out, but it is needless to say to you about its make, etc., except something wherewith you are interested directly. It may be interesting to you to know (as you are exporting Momi Tea chests) that I have seen many packages of Ceylon tea which are not of (our) Momi wood, but of pine; the latter, in my opinion, is not from Japan and resembles very much Chinese pine. As you have some idea of tea, you should know that boxes for tea, made out of pine wood either from Japan or elsewhere, cannot be good for tea; and I am greatly surprised to see the Ceylon merchants (who are so earnest in pushing their tea and effecting all kinds of improvements) use boxes made of pine. The boxes that I saw at your mills are very good and very suitable. Don't you supply large quantities? Perhaps China pine is cheaper, but cheap things always come out dearer in the end and I shall not be at all surprised if this is found out and pine boxes avoided altogether. I have also seen some boxes which, I fancy, cannot be made in China or Japan, as the wood appears to me to be from some very cold country in the North part of Europe as far as my knowledge of lumber tells me; you may perhaps know where they come from. Without anything further interest,—I remain, yours truly.

A GOOD TREE FOR TEA ESTATES.

August 5.

DEAR SIR,—The tree referred to by a Dimbula Manager in your issue of the 30th July should be *Ailantus*: I think it appears in

the Peradeniya Gardens Catalogue as *A. malabaricus*. It was planted in the south of France about thirty years ago as a food for one of the new species of silk-worms then introduced, and on a small scale in English gardens on account of its ornamental appearance.—Yours faithfully,

B.

["*Ailantus Malabarica*"]—is no doubt the tree and here is Trimen's information:—

"Low country of the moist region; rather rare. Seven Korales; Colombo; Heneratgoda. Fl. Jan.; white. The bark is tonic and febrifuge. A brown fragrant, resinous exudation is given by the inner bark, and is used in dysentery as well as material for incense. Wood very light, soft and spongy. *Ailantus* is from 'Ailanto,' said to be native name of *A glandulosa* in the Moluccas."

From the "Treasury of Botany" we further quote:—

"*AILANTUS*. The *Vernis du Japon* of the French, *A. glandulosa* of botanists, is in its native countries, China and India, where it is called Ailanto, a tree of large size and handsome appearance, bearing numerous pinnate leaves from one to two feet long or more, and clusters of greenish flowers of a disagreeable odour. It is of rapid growth, making, when favourably situated, annual shoots from three to six feet in length. Its German name, Gotterbaum, 'tree of the gods,' is said to be a translation of *Ailanto*. French arboriculturists recommended that its lateral branches should be annually lopped off, when the main trunk will ascend perpendicularly and sustain a symmetrical spreading canopy. In France and Italy, it is much valued as a tree for shading public walks, and is planted for that purpose along with the tulip-tree, horse-chestnut, plane, &c. Its leaves are not liable to be attacked by insects, which is a great recommendation; nevertheless they are the favourite food of the silk moth, *Bombyx Cynthia*; and they continue on the tree and retain their green colour till the first frosts of November, when the leaflets suddenly drop off, the leaf-stalks remaining on often a week or two longer. The wood is yellowish-white, satiny, and well suited for the purposes of the cabinet-maker. There are specimens, both in England and of the Continent, exceeding sixty feet in height. The name 'Japan varnish' seems to have been applied to it through some mistake. The genus belongs to the *Simarabaceae*."

[Probably the *Dimbula* trees are from imported seed of *Ailantus glandulosa*.—ED. T.A.]

TREES FOR TEA ESTATES.

Glasgow, Agrapatana, Aug. 9.

DEAR SIR,—The trees growing on this estate, of which mention has recently been made in your columns, answer the description of *Ailantus Glandulosa* given in your issue of the 8th inst.

A small quantity of the seed was got by Mr. A L Cross, but I have no record of it, and he was unable to give me any information when I applied to him a few years ago. They are deciduous trees, shedding their leaves about the month of September, so far none of them have flowered. The growth compares very favourably with grevilleas of the same age. Some trees on this estate ten and eleven years old are about 50 feet high. They are handsome, healthy

looking trees, and I do not know anything better for growing amongst tea. I am taking steps towards having any doubt as to their identity removed.—I am, yours faithfully,
ROBT. WATKINS KERR.

JAK FRUIT IN INDIA AND CEYLON.
Aug. 7th.

DEAR SIR,—I learn on good authority that in India the largest and best jak fruits are borne on the roots of old trees, *i.e.*, on such roots as come above the soil, which they often do in the case of very old trees. I have seen regular patriarchs of jak trees in Ceylon, with huge fruits hanging from all parts of the trunk down almost to the surface of the ground; but I cannot say that I have ever seen fruits produced on the roots. I should like to know whether the experience of any of your lowcountry readers agrees with my own or with that recorded in India.
—Yours faithfully,

INTERESTED.

THE BRITISH NORTH BORNEO COMPANY.

Kandy, 11th August.

DEAR SIR,—I have just received the Report issued by the British North Borneo Company's Court of Directors for 1902, in which the following items, which may interest your readers, appear:—

Receipts in 1901 were	..	\$655,569 02
Revenue 1900 do	..	\$587,226 81
Increase of Revenue		.. \$68,342 21
Disbursements 1901	...	\$431,219 82
1900	..	\$492,858 63
Increased Expenditure		... \$28,361 19
Imports value 1901	...	\$3,262,763 70
Do. 1900	..	\$3,178,929 20
Increase		.. \$83,834 50
Exports value 1901	..	\$3,382,387 64
Do. 1900	..	\$3,326,621 39
Increase		.. \$55,766 25

The Court of Directors propose declaring a dividend to Shareholders of 2 per cent on Shareholders' capital of £741,130, beside paying 5 per cent on debentures, £200,000.—Yours faithfully,

W. D. GIBBON, Agent.

JAK FRUIT BORNE ON ROOTS: A REPLY.

Galkissa, August 13.

SIR,—In reply to your correspondent "Interested", anent jak fruit in India and Ceylon, I have not seen a single jak tree in Ceylon the fruits of which are borne on the roots, but there are, as your correspondent is aware, trees with huge fruits hanging from the trunk and touching the surface of the ground. The former kind too is found wild in Parute, a place on the South Indian Railway line near Ponlicherry, noted for fruits produced on the root, which are considered very delicious,
M. P. C.

TEA OVER-PRODUCTION: A NEW SCHEME? : IS IT WITHIN "PRACTICAL POLITICS"?

Gammaduwa Group, Gammaduwa, Aug. 15.

DEAR SIR,—I trust the following will commend itself to the careful consideration and support of your readers. For a sum of £20,000 (twenty thousand pounds sterling) the output of Ceylon tea can be reduced by 7,500,000 lb. (seven million five hundred thousand pounds) being the yield of 30,000 acres of tea at the very moderate estimate of 250 lb. per acre. This can be accomplished provided the money can be found, and, handed to the Committee of the Planters' Association of Ceylon, who would, I presume, appoint trustees for the disbursement of the Fund. My proposal is that all Proprietors of tea estates, resident, non-resident or Companies, who find it impossible to cultivate tea at a paying figure, be invited to enter into a contract for one year with the Trustees of the Fund.

They must agree to bind themselves to cease plucking, from an area of their own choosing, of not less than 25 acres of tea, now in bearing, for a period of one year from 1st January, 1903, on condition they receive from the Fund the sum of 80 cents per acre per mensem, to enable them to weed the tea which they shall have ceased to pluck, and bound themselves not to pluck for that period.

Example: A Proprietor or Company having say 300 acres of tea in bearing (the youngest tea over four years old,) on agreeing to cease plucking 100 acres from the 1st January, 1903, would receive from the fund R960 during 1903. This sum would enable the Manager, to keep the 100 acres free from weeds during that time. Without attempting to go into details, I think a few of the advantages of the scheme are:—estates do not in any way suffer, rather the opposite; mortgagees would not interfere, they should rather approve, as the tea on the 100 acres would have improved by the rest. Buildings would cost no more to keep up; and a smaller labour force will be sufficient for the crop and maintenance of the other fields. Neighbouring estates, proprietors and managers would have no cause to complain of the condition of the abandoned tea, as it will, or ought to be easier weeded than the fields which are regularly plucked.

The objection may be raised that it will be impossible to check the Superintendent or the coolies should they pluck the tea on the fields set apart for the year, and that the tea would be sure to be plucked by some, though not in every case. I do not believe this could be carried on to any extent if at all without being discovered, as non-plucked tea fields are not so difficult to verify, but to help to guard against this the fund has still R12,000 from which Inspectors might be employed to make surprise visits to contracting estates.

I commend the above to my brother Planters in the full assurance that they will give it their careful consideration. The only difficulty, which presents itself, is, How are we to raise the money? The "Thirty Committee" requires all the Cess and more, were it available, and this lessening of production can scarcely come under the Ordinance which empowers that Committee to carry on its work.—Yours faithfully,

JAMES WESTLAND.

JAK FRUITS.

Trincomalee, Aug. 14th.

DEAR SIR,—“Interested,” in your issue of the 12th instant, makes enquiries of jak fruits borne on the roots of trees. I hear on reliable authority that in 1889 at Sampelton, a village in the North, a tree in the garden of one Mutar Kadramer, produced a ripe fruit on the root, 6 feet off the tree, under soil not deep, and it was traced by the smell and a crack on the surface earth. Those who ate it tell me that the pulp was delicious. Yours faithfully. J. B. C.

NIYANGALA AND VEGETABLE POISONS.

DEAR SIR,—With reference to the account of “deadly poisoning” as the result of eating a tuber of *Gloriosa Superba*, I think you will find that the use of the tuber “as an abortive for criminal purposes” (as Dr. Watt puts it) is by no means uncommon among the Tamils of the North.

The properties of such vegetable poisons and the means of detecting them, have yet to be studied by medical and scientific men who at present are. I believe, quite ignorant on these points: and there is little doubt that many a death from “unknown causes” or “dysentery” must be attributed to the effects of vegetable poisons—the study of which should furnish congenial work for our local scientific celebrities.—Yours truly,

ÆSCULAPIUS.

[What do the local Medical Association and Dr. Chalmers say to this?—ED. T.A.]

TROUT.

August 19.

DEAR SIR,—Referring to a cutting from an Aberdeen paper in your issue of the 18th re “Marked trout caught in Deveron,” I hope the Provost and the Inspector of Fisheries will excuse me when I say, “Steady old boys,” as I can only swallow that trout *cum grano*. A trout is a trout (yclept *salmo fario*, if an ordinary brown one) and if he ever attains the size of 6 lb. in the old country, my experience is that he’s a very old trout, indeed, but no doubt there are exceptions to the general rule. Was that trout really a brown trout, a sea trout, a grilse or a young whale? The statement would not be at all a surprising one for Ceylon, where the climate and abundant food seem far more conducive to rapid growth than home conditions.

I have a well-authenticated case of a trout having increased from 1 lb. to 3½ lb. here in 6 months, but perhaps better not tell this to the Lord Provost or Mr. Inspector, as it might lead to a terrible waste of salt and strong language.—Yours faithfully,

PISCATOR.

THE “AGRICULTURAL LEDGER”—1902—No. I.—Indian Tanning Materials. A list of the raw stuffs of India which contain tannin, with notes on their composition and the preparation of extracts, by Mr D Hooper, F C S.

THE KANAN DEVAN HILLS PRODUCE COMPANY, LIMITED.

The report of the directors for the year ending 30th November, 1901, to be submitted to the fifth annual meeting to be held at 22, West Nile Street, Glasgow, on Friday, the 18th July, 1902, at noon.

The Directors beg to submit their report for the year ending 30th November, 1901.

The tea crop obtained from the Company’s Estates amounted to 2,031,235 lb. compared with 1,444,695 lb. in 1900. While larger crops were gathered at both the Northern and Southern Indian properties than in the previous year, the yield from the latter, owing to unfavourable weather, was considerably short of the estimate. Latest reports as to the condition of the young plants are satisfactory, and point to the Estates as they come into full bearing giving a large average yield per acre. The price realised was 7.23d per lb. which is disappointing, but a distinct improvement in quality is expected by the local management as the Estates generally mature. The yield of Coffee was 1,495 cwt., and the Cinchona Crop amounted to 251,537 lb.

For some considerable time past, in view of the adverse circumstances affecting the tea-growing industry, the Directors have had under consideration the terms of the Agreement between the Company and its managing agents. While it was recognised that at the time the agreement was entered into its terms were reasonable, the agents, on being approached, expressed themselves as perfectly willing to consider a re-arrangement, and they voluntarily offered in future, during the continuance of the present depression in tea, and, while reserving their rights under the agreement, to restrict their charges as agents of this Company to their actual outlay, plus a Commission of 3 per cent on the net profits. The managing agents have also, in view of the disappointing results of last season’s working, voluntarily agreed to give up to the Company, for the benefit of the revenue account of 1901, the whole of their Commission for that year; and the London Agents have also agreed to return one-half of their Commission.

Given effect to the concessions referred to in the preceding paragraph, the accounts show a balance at credit of profit and loss account of £15,989-4-5. Against this sum are chargeable:—Commission on profits to estate managers and Secretaries, interest, discount on bills, &c., and interim dividend at the rate of 6 per cent. per annum for the six months ended 31st May, 1901, paid to the preference shareholders on 15th June, 1901, which total £11,661-1-3, leaving a balance of £4,328-3-2. Out of this the Directors propose to pay a dividend at the rate of 6 per cent. per annum on the preference shares for the 6 months ended 30th November, 1901, payable on Monday, 28th July, 1902, which will absorb £3,000 and leave a balance of £1,328-3-2 to be carried forward to the following year.

No new tea or coffee extensions are in progress or contemplated, but the planting of Cinchona is being continued through the existing cultivation in Travancore, and a few acres of specially suitable fresh land will be put out in 1902. The area of the Company’s estates, which have now been practically all surveyed, aggregates 15,861 acres.

The estimates of crop for the current year are 2,962,480 lb of tea, 1,587 cwt. of coffee, and 239,500 lb of cinchona.

Efforts continue to be made to increase the consumption of Indian and Ceylon Teas elsewhere than in the United Kingdom, and more particularly in America and Russia, for both of which countries the Directors believe the teas produced by this Company’s Travancore Estates are specially suitable. Producers in India have started an organisation for increasing tea-drinking amongst the native population, and it is hoped that in time an appreciable quantity will be consumed there. This scheme receives the support of the Directors, who are glad to report that some progress has already been made.

Owing to its former inaccessibility, and to the heavy expenditure which has had to be incurred in opening up communications, the development of the Company's large Concession in the Kanan Devan Hills, Travancore, has cost more than was originally expected. It was understood at the time planting operations were commenced in these Hills that the Government of His Highness the Maharajah of Travancore would construct a cart-road from the High Range to the plains, and thus afford direct communication to the port of Cochin which is about 86 miles from the Company's headquarters at Munaar. After protracted negotiation, however, the Travancore Government declined for the present to proceed with the construction of the proposed cart-road to the west, owing to the cost being estimated by their chief engineer at so high a figure as £112,000. The Company was, in the circumstances, obliged to make its own arrangements for opening up communications, and this was done by the construction of a main cart-road and tramway for over 30 miles through the Concession to its eastern extremity, and by the erection of an aerial ropeway from that point (6,000 feet above sea-level) to a place called Kotagudi in the plains. From Kotagudi a cart-road 10 miles long was made to Bodinaikanur, one-third of the cost of which was contributed by the Government of Madras. There is a Government road from Bodinaikanur to Anmanaikanur Station on the South Indian Railway, connecting with Tuticorin, from which port the Company's produce is shipped. The Directors are glad, however, to be able to state that the Government of Travancore, although unwilling meantime to proceed with the western outlet, have agreed to contribute up to R400,000, or about £26,500 for the construction of a cart-road to the north to connect with the Madras Presidency road-system, and an agreement has been entered into whereby the Company has undertaken to make this road at a cost not exceeding the figure named. This road will be of great advantage in making the Concession more accessible and cheapening the cost of rice and other foodstuffs there.

The shareholders will notice from the accounts that the paid-up capital of the Company, as at 30th November last, was £360,000, and that the Block cost of the properties, which includes, of course, the expenditure by the Company on communications referred to in the preceding paragraph, amounted, as at that date, to £844,895 8s 9d. It is estimated that a further sum of about £120,000 will be required to bring the existing young cultivation to maturity, and to complete the equipment of the properties with factories, machinery, &c. The Directors, therefore, decided to issue the balance of the authorised Capital of the Company, namely, 15,000 Preference Shares and 10,000 Ordinary Shares. This fresh issue of Capital will, of course, be offered in the first place to the Shareholders of this Company, but the Directors are glad to be able to state that Messrs. James Finlay & Co. are prepared to take up, at par, whatever portion of the issue may not be subscribed for by other Shareholders, and to apply, so far as required, their cash advance to the Company, which exceeds £300,000, in meeting the amount due on the shares which may be allotted to them. To the extent of their cash advance so applied Messrs. James Finlay & Co. will take the position of shareholders instead of creditors of the Company.

The Directors propose to make a call of £2 per share on the ordinary shares already issued, of which due notice will be given. On the fresh issue of ordinary shares it is proposed that £3 per share should be payable on application and £3 per share on allotment, making the new issue also paid up to the extent of £6 per share.

The Directors regret to state that Sir John Muir, who has acted as Chairman of the Company since its formation, has been obliged to resign as member of the Board on account of the state of his health.

They hope that after a time he may be able to again preside at their meetings. In the meantime Mr A K Muir, who was offered and accepted a seat on the Board, has agreed to act as Chairman. Mr Muir has been in India for the last eleven years, latterly as Senior Manager of the Calcutta Agents' firm, and has been connected with the management of the Company's estates since planting operations were commenced in Travancore.

In terms of the articles of Association, one of the Directors, Mr A B Murray, retires at this time. The Directors regret that Mr Murray, although eligible for re-election, finds it necessary to retire on account of ill-health, and they have considered the question of filling his place. They approached Mr D M Mannay, of Messrs Kelly & Co., Exchange Square, Glasgow, and he has expressed his willingness to be nominated for a seat on the Board.

The Auditors, Messrs Alexander Sloan & Co., C.A., retire, and offer themselves for re-election.

DUMONT COFFEE COMPANY, LIMITED.

DIRECTORS' REPORT.

The Directors submit the general balance sheet and profit and loss account for the year ending 31st December, 1901.

The gross profit for the year, exclusive	£.	s.	d.
of £10,263 15s 7d brought forward from			
previous year, amounted to	73,693	4	10
And the London charges were	3,314	11	7
	<hr/>		
Leaving a net profit of	70,378	13	3
Amount brought forward from 1900	10,263	15	7
	<hr/>		
	80,642	8	10

Interest at 5½ per cent per annum inclusive of income tax has been paid on the Debentures amounting to £21,989. A payment of 2½ per cent inclusive of income tax was made on 1st Feb, 1902, on account of arrears of dividend on the preference shares £10,000. Ditto, ditto, was made on 1st July, 1902, on account of arrears ditto £10,000

	41,989	0	0
	<hr/>		
Total	38,653	8	10

It is proposed to set aside for buildings and machinery the sum of

5,000	0	0
-------	---	---

And to carry forward a balance of 33,653 8 10 At a later date, when more of the crop has been sold, the Directors hope to be in a position to pay a further dividend on account of arrears of the preference shares out of this balance.

The crop for 1901 has amounted to 143,395 cwts., which is equivalent to the large yield of over 12 cwts. per acre of the coffee lands in yielding.

Of this quantity 103,615 cwts. were sold in London. 14,645 do do in Santos. 4,819 do do in New York. 21,316 do were unsold at date of making up this account.

Total .. cwt. 143,395. The gross average price for the whole crop (including the portion unsold, which has been taken in the accounts at 30/ per cwt.), is equivalent to 38/8½ per cwt. landed in London, as against 40/2 per cwt. the previous year. The average price realised for the Company's pulped coffee, of which there were 39,362 cwt., was 37/5½, and for the Company's nupulped coffee 32/3½.

The exchange rate for the milreis was again adverse to the Company's business, being 117-16 as against 10-44 the previous year; but, notwithstanding this, the coffee was laid down in London at 2/6½ per cwt. less cost than in 1900.

The coffee crop from Brazil for the year under review was the largest on record, being 15,500,000

bags, as against 10,900,000 bags the previous year; and this, together with the crops from other countries, proving largely in excess of the world's requirements, caused a heavy fall in prices.

The Brazilian crop for the current season is expected to be considerably less than that of the past year, and the Company's estate manager estimates the yield from the Dumont property at about half that of the previous year.

The heavy crop that had to be dealt with necessitated the purchase of additional railway rolling-stock, and also an increase in the buildings on the Company's property, the expenditure on which has been charged to capital account.

Mr P R Buchanan, owing to prolonged absence in India, has ceased to be a Director of the Company and the Board has elected Mr H K Rutherford to the vacant office of chairman.

It is with extreme regret the directors have to record the death of their colleague, the Hon H A Lawrence, who took the deepest interest in the affairs of the Company.

Mr H K Rutherford and Mr Stratton Boulnois retire on this occasion from the Board, and being eligible offer themselves for re-election.

The auditors, Messrs Jackson, Pirley, Browning, Husey & Co., also retire, and again offer themselves for re-election.

TEA COMPANY'S REPORT.

Empire of India and Ceylon Tea.—The directors, in presenting the accounts made up to December 31 last, state that the rainfall during 1901 was, in Assam, very short in the early months, and the weather was, on the whole, rather unfavourable for quality and output. In the Dooars it was favourable. In Ceylon the weather was generally unfavourable. The company's gardens in Assam obtained an average price of 7'87d. against an average price of 8'76d for the Assam Valley. Its gardens in the Dooars obtained 6'25d, as against an average for the district of 6'65d. The gardens in Ceylon secured 6'06, as against 6'15d for the district. Although one property in Assam was highly successful, on the whole results were disappointing, except in the Dooars group. On the Dooars gardens expenditure shows an increase due to the whole outlay on Tasati being charged to revenue. This garden is by no means in full bearing, and left a loss on the year of nearly £2,400, but it is confidently expected that it will be able to give a good account of itself henceforward. In Assam and Ceylon substantial savings were effected, but not sufficient to compensate for the fall in the price of tea. The Ceylon crop was short, and the board has again to record a loss on the working of the gardens. In the autumn of 1901 radical changes were made in the management, and while it was too late to expect good results in 1901 as a consequence of those changes, the board is fairly confident that 1902 will make a better record. So far the year shows an increase in output and a reduction in cost. The present low range of price, is likely to promote the sale of Indian tea in markets outside the United Kingdom. The profit and loss account shows a balance of £9,292, to which must be added £5,536 brought forward from last year. The half-year's dividend on the preference shares held over from 1900 was paid in December, 1901, and the directors now recommend the payment of half the preference dividend due for 1901, £5,475, and that the balance of £3,879 be carried forward.—*H and O Mail*, Aug 1

SPANISH COCONUT OIL.—The *Gaceta de Madrid* of July 9th contains an order authorising the temporary admission of coconut or coprah for use in the manufacture of coconut oil, which must be exported within a maximum period of one year, through the Custom House of Barcelona, for the firm of Garcia and Co. of Sans. There will be a rebate of sixty per cent of the duty paid on coprah on importation.—*Chemist and Druggist*, August 2.

PLANTING NOTES.

CINNAMON.—The third quarterly auctions took place in Mincing Lane on Monday last when 800 bales were offered and 500 sold. The sale is reported to have passed off with fair competition. Notwithstanding this, however, unworked firsts and seconds are said to have fetched prices from 1d to 2d lower than in last sale.

SERICULTURE IN SIAM.—Siam is evidently intent upon improving her sericulture. Yesterday six Japanese men and two women, all experts, recommended to the Siamese by the Japanese Government, arrived by the ss. "Kawachi Maru" en route for Bangkok, having been engaged for a term of years. Certain districts of Siam are extremely favourable for the cultivation of the silkworm, the rearing of which would seem to be an employment well suited to the lethargic habits of the Siamese.—*Straits Times*, Aug. 4.

SHOOTING IN CEYLON: A GOOD BAG.—Ceylon is not yet by any means depleted of the big game necessary to provide a good day's hunting such as was enjoyed in the old days when the planter "led a glorious life of a pioneer hunter on the threshold of paradise." Messrs. Tranchell and Dickson's experiences at Panawa, in the wilds of the Batticaloa district, prove this to be the case. Mr. Dickson has had a unique and exciting experience, but apart from that little affair of his with a wounded and infuriated bear; the sport was excellent and the bag obtained sufficient to turn other Ceylon hunters green with envy. Such bag should be the means of attracting sportsmen to the Island, especially in view of the failure of the grouse prospects on the Scottish Moors!

OLD KING COFFEE.—In view of the frequent mention of coffee in our columns recently, in connection with the affairs of the Dumont Company in which Ceylon men hold large shares, and with the enterprise carried into the Far Eastern Colonies also by Ceylon planters, it will be of interest to read what is said of the prospects of our old staple nearer home. Not a few of our old planters have found a home in Southern India, where the outlook seemed bright at one time. There has been, unhappily, a change for the worse; and this is what an Indian paper of recent date says:—

"The decline in the Indian coffee industry is strikingly shown by the latest published figures. The average production of the last five years was under 20 million pounds, as compared with 34 million pounds in the preceding five years, and the quantity produced last year was less than half the quantity produced ten years ago. The cause of this decadence is the severe competition of Brazilian coffee, and the absence of a domestic market. The exports, apparently, exceeded the production during the past ten years, but this discrepancy is explained by the greater accuracy with which the export statistics are kept. The United Kingdom and France take between them considerably more than half of the total output of Indian coffee; and the state of the industry may be judged from the fact that, since 1897, the London prices have decreased more than fifty per cent. In view of these figures, observes the Lahore paper, there seems no escape from the conclusion that coffee is a doomed industry in this country."

THE TEA INDUSTRY IN CEYLON AND
THE SUPPLY OF FUEL :
A SERIOUS PROBLEM OF THE NEAR
FUTURE SOLVED BY THE SUCCESS
OF FUEL OIL.

In not a few districts in Ceylon there is no more serious question facing the planter than his future supply of fuel. Scarcity and high prices have already made themselves felt severely in not a few cases, and practical men have been shaking their heads over the prospect, more especially where fuel for "power"—for the steam engine furnace—has to be provided as well as for the tea dryers. We are aware that in one or two instances, at rare intervals, oil for steam engine fuel has been used on plantations, just as it is at the electric works in Kandy and in most of the Railway workshops upcountry. But it was a much more delicate matter to experiment, and decide, on the fitness of the fuel oil for tea-drying purposes. The "Shell Company" and their local Agents, Messrs, Delmege, Forsyth & Co. (who have long been considering the question from a business point of view) deserve credit for going to work after a very practical fashion to secure the necessary solution. An Engineer of the Company—an expert in all that concerns the use of oil fuel—has for some time been making a series of experiments at the Galaha Factory along with the capable Manager, Mr. W. M. Hall, and we are now informed that these have been crowned with success, as may be judged from the following statement which has been placed at our disposal:—

FUEL OIL FOR TEA DRYERS.

It is a well-known fact that in certain districts, Ceylon Tea Growers have almost exhausted their supply of firewood, and in the near future will find it a difficult matter to keep their dryers running on account of an insufficient and inferior supply, with eventually a total lack of firewood. Comparatively few are, however, aware that liquid fuel can be used in lieu of firewood, and it is said even at less cost, and Tea Planters will certainly be glad to learn that extensive experiments in the burning of fuel oil in Jackson's Tea Dryers have been carried on at the Galaha Factory during the last two months with very gratifying results. The steam jet system is that used; while absolutely no alteration is required in the furnace. The burner is placed on the front of the furnace on trunnions, and can be swung out of position at a moment's notice when the furnace is again ready for solid fuel. The oil tank can be placed at any convenient place in or near the Factory. One man only is required to work the whole arrangement. After testing several burners, that of "Rusden and Eeles No. 00" has proved to be the most economical and suitable for this class of work. The fuel used was Borneo oil supplied by the "Shell" Transport and Trading Co., and the amount of fuel consumed on an average of a long series of tests was rather less than six gallons per hour, actual tea drying being carried on during the whole of the experiments. The manager of the Galaha Factory, W. M. Hall, Esq., will be pleased to show the burning of the fuel oil at the Factory to any interested in it, if due notice is given. In anticipation of a great demand

for fuel oil, Messrs. Delmege, Forsyth & Co., the Agents, are erecting storage tanks at several of the centres.

As to the cost, Mr. Hall estimates that with firewood costing R2 per cubic yard, his tea-drying costs 75 cents per lb., and he feels sure that with the fuel oil he can do the work as, if not more, cheaply. This is extremely satisfactory, because the delivery of the fuel can be made more economically to estates close to a railway station, say for instance at Hatton, Kotagala and Talawakele—three centres where we believe fuel to be scarce—than at Galaha with the many miles of cartage involved. Tanks are at once to be erected at convenient centres and portable iron cases are to be substituted, for wooden casks so apt to leak, for the transport by rail, with a suitable package to carry on coolies' heads where there are no cart roads available. Another great advantage of the new system is the equality of temperature for drying that can be maintained; whereas with firewood as the teamakers know, this is a very difficult matter. Altogether, then, it must be confessed we are here face to face with a very notable improvement and advance in connection with tea factories, and we may well prophesy that no long period will elapse, before the use of fuel-oil for tea-dryers will become almost universal in the hill-country of Ceylon; while, in many cases, it will also be used for the furnaces of plantation steam engines. It must be remembered that the Galaha experiments only apply to Jackson's dryers; and in this connection it may be noted that Mr. Jackson himself has invented an air-injector for oil-fuel, which is necessary where there is no steam used. But we have no doubt that the makers of other dryers—of the Siroccos and Brown's Desiccators—will be keenly alive to the application of the new fuel to their inventions. Planters, after satisfying themselves of the wisdom of the change, must, of course, apply to their engineering advisers to get the needful adaptations made, whatever be their style of dryer, and a start in this direction need not be delayed from any fear that the fuel-oil required, will not be available, as there is always an ample stock for all requirements in Colombo.

MR. HART AND THE TRINIDAD ROYAL
BOTANIC GARDENS:

NEW KINDS OF RUBBER; GRAFTING
CACAO.

As usual, Mr. Hart's Annual Report (from April, 1901, to 31st March, 1902) is both full and very interesting. We have marked all that is of most value to planters and horticulturists in full, and meantime would say that an experiment in Bee-keeping (Italian Queens being introduced) is likely to prove very successful and generally useful. We cannot understand why an attempt at bee-keeping is not made in the Henaratgoda Gardens: there are two Ceylon honey-making bees worthy of attention. We dare say Gangarooka will first show an experiment. Mr. Hart has a good deal to say about Rubber. His Castilleos are seeding freely, and the seed is good, but it has "a very fugitive vitality, and even with the best packing it is very difficult to send it long

distances in good order." Seeds from Para Rubber trees, growing far and high up in the interior (possibly a new variety), is attracting attention. West African "Silk rubber," *Funtumia elastica*, trees are making splendid growth. Trees not four years old are over 20 feet high with stems 12 inches in circumference. Landolphins (creepers) are grown against the Indian rain tree, *Pithecolobium Saman*, and give excellent rubber fluids which easily coagulated. Mr. Hart is succeeding with the camphor tree, citronella grass, various fibre plants, peppers, vanilla, clove, cinnamon, ginger, kola, &c. He is strong on the value of *Erythrina* (Immortelle) as shade for cacao, and the flowers are said to have a high nitrogenous value. With various fruits—mangoes, oranges, mango-steens, lemons, plantains, &c.—Mr. Hart is experimenting with more or less success. His coffee hybrids are turning out well and are favourably reported on from Mincing Lane; but nothing is said as to their being proof against the fungus, *hemileia vastatrix*. Mr. Hart pays special attention to his cacao section, and new varieties—one from Venezuela and *Theobroma pentagona*—are doing well. He is a strong believer in the value of grafting cacao of the best kinds and feels sure this will result in samples of fruit far superior to any now seen. So Mr. Herbert Wright will have to hurry on at Ganguroowa and show how a plot of grafted cacaos of the best kinds—from strong, large trees with heavy crops and large beans—are to do in Ceylon. For fuller information of valuable experiments in Trinidad we can only refer to September's *Tropical Agriculturist*.

HORTICULTURE IN NUWARA ELIYA.

A VISIT TO MR. JOHN COTTON'S ORCHARD.

The pride of Mr. Cotton's orchard just now is the single apple (of the size of an orange) known as the Kentish Fill Basket, on a tree about 7 feet high, which Mr. Cotton a few years back got from Mr. A. J. Kellow of Albion, Nuwara Eliya, and planted about his orchard till at last it seems to have got placed in proper soil and is now rapidly growing into a big tree. Mr. Cotton has just imported plants of the Beauty of Stoke, Boston, Russet, and Emperor Alexander; these have all been set about two weeks last Friday, and to all appearances have started to grow. Mr. Cotton hopes soon to have plants of all the varieties to sell.

CHERRIES.—The latest varieties have been imported and set during July, among them Purple Jean, Waterloo, Florence and the Verdus (black variety) all striking new buds famously. Mr. Cotton's experience with imported cherry plants is wide.

PLUMS.—The success which has attended the Red Heart Plum of which several hundred fruits weighed down the many trees both last year and this year, and the propagation of cuttings being alike successful and easy—the result has encouraged Mr. Cotton to experiment with the Golden Drop, Diamond, General Hand, Orleans, General Sago, and the Golden Heart. The orchard has just now in bearing the Ootacamund and Kelsey beside the Golden Heart. The sale of the Red Heart Plum plants has been a big one and the demand continues to increase. He would strongly recommend to every land-owner to plant out the Red Heart

Plum—those in the writer's yard, barely two years, are just now in flower and grown without much fussing or care.

ENGLISH GOOSEBERRIES.—Of these there are the green, red, white and yellow varieties growing in the orchard, and Mr. Cotton was kind enough to mention that this was his first attempt with Gooseberries, and he was quite certain that the plants, which were looking healthy and in fair growth for the short period they have been put down, were for the first time experimented with in Nuwara Eliya.

CURRENTS.—Red and white; these plants put down during the middle of last season came to fruit early this year and had a few springs on them, much to Mr. Cotton's delight. The plants are now coming on rapidly, and Mr. Cotton expects to be able in a few months' time to graft cuttings of all the above varieties for anybody wanting to plant out these fruits about their homes.

ORRANGES.—The imported plants of last year are doing well and young plants from these will be available by the end of October. Just now a few plants are on hand, which await booking. That further success may attend Mr. Cotton is the wish we express heartily; for, he is a resident worthy of the clime he has decided to live in for so many years past.—*Cor.*

A DISEASED OR DIRTY "GARDEN'S" ACT FOR CEYLON.

Ever since in 1869 we saw farm fields in Tasmania, nicely enclosed by stone walls or dykes, but in some cases, bearing one continuous crop of thistles, from wall to wall, and learned that a Thistle Act had to be passed in the Colony to deal with such cases, we have, from time to time, pointed out the need of a similar Ordinance in Ceylon. At one time "white weed" on coffee estates was the great trouble—one neglected dirty property imperilling its neighbours and causing heavy expense; but who hears much of "white weed" now. Other weeds have in many districts superseded it, just as lantana is so freely losing ground upcountry. Now a-days, it is the cacao planter who specially wants protection, and that very much from native neighbours who will not deal with, or destroy, their diseased trees, from which the fungi or other enemies freely spread. Most applicable, too, would such an Ordinance be to the case of neglected coconut gardens. We have had expensive personal experience in this direction. The owner of a well-tended garden of palms, dies; it falls into as indifferent hands, gets quite neglected, and becomes a regular breeding-place for beetles which, of course, fly over into the adjoining gardens. In such a case a law giving adjacent owners the power, after due intimation, of entering and destroying beetle-infested palms, or corners full of illuk-grass, the expense to be a first charge on the property, would seem to be equitable. The same applies exactly to the case of diseased and neglected cacao gardens; and in both cases, there could be an official inspection and report—Mr. Carruthers, Mycologist, and Mr. Green, Entomologist, being available—before due notice was given, and failing redress, action taken at the expense of the owner.

PLANTING FORTY YEARS AGO.*

A FEW REMINISCENCES BY ED. T.A.

Our first inspection of a coffee estate was of Aliwētenatenne in the Mellemahauwara district; that was in 1861. The owner—a Mr. Turner—had died suddenly, and being in Kandy, Mr. Richard Rudd invited us to a drive to Teldeniya and a ride thence up to the far-famed Gap in the Eastern mountain range, near the spot where the last King of Kandy was captured in 1815. *En route* we were stopped by cherry “Ned Mortimer”—then in his prime—who shouted “Come and see 15 cwt. of coffee (cherries) per acre on Rajuwella No. 2” At our journey’s end we were met by Mr. Richard Burke (then quite a young planter) who begged the owner to come and inspect the finest coffee clearing in the island on Angruwella in Rangalla district.

The following week we accompanied “Abercromby Swan” to “Vicarton” and “the Borders”—to inspect his line coffee, clean estates and crops of “Sepoy Coolies” in West Matale. “A rupee for every weed you pick up in my fields” was his triumphant challenge to visitors. James Grant (John had begun pioneering in Travancore) Donald Bain and John and Charles Forbes were neighbours;—(but we are merely giving a skeleton sketch; details and incidents must await the future Autobiography?) We rode across to Elkaduwa, up by Syvakande where we encountered Edward Young, riding down from Kellebokka on a big horse which threatened to kick our pony into the ditch; looked in on D. Watson on Dambulgalla; had a grand afternoon outlook over the Valley (a picture of green framed by the everlasting hills), got to D. Weibster on Wuttekelly; and then made the round of the Knuckles and Rangalla. Heigho! what grand shows of coffee everywhere; and what bright ardent spirits among the

KNUCKLES BRICKS!

Is there any one of them left in the island now—save Mr. Channing Esdaile who is revisiting his Madulima property?

Next year 1865 found us in the wake of Sir Hercules Robinson on his memorable tour through Uva and Sabaragamuwa, the veteran Major Skinner piloting the new Governor and bidding farewell himself to scenes with which he had been familiar since 1825! Who can forget the delight of the veteran head of the Public Works Department with the Farewell Address which the Haputale planters, headed by “clever Henry Don” presented to him (the best expressed Address he declared, he had ever read and he wished to know who was the writer:—“a feather”, as we told the old Major ten years afterwards in England, “in the cap of the young Sub-Editor and Reporter” who had been asked to draw it up!) Who remain of all who met Sir Hercules Robinson at Kalupahane in 1865, save R. E. Pineo (Colombo Club) A. Macphail, W. H. Wright and ourselves?

Next year (1866) brought a

* The hypercritical will say, that means 1862 and Ed. “T.A.” though he arrived in 1861, never saw Kandy or a coffee estate till 1864! It was Dr. Johnson who retorted on the old lady—who found fault with his saying a certain pear-tree was “loaded with fruits,” because she had counted and there were only 40 pears—“Od’s Madam would you have us swear to the truth of a song!”

BLACK FRIDAY

in London Overend Gurney & Co. down) and great depression in Colombo; so that £500 could not be raised in the Fort to buy an estate which a few years after sold for £5,000; and bushels of coffee were exchanged for as many bushels of rice to keep coolies from starvation.

Hard work was the order of the day during 1865-78; and our next trip upcountry was to visit “Logie Elphinstone” on Westhall and Macleod on Kulienna, early in 1869. Aild what a delightful ride we all three had into

DIMBULA FELIX

as it was called—for, the Wilderners of the Peak was, comparatively, still *terra incognita*—Logie and Belgravia were then the farthest estates, with a 50-acre clearing in Matakelle as an excuse for sport; and all the region beyond up to the Gorges and the foot of the Bopats was “Sporting Reserve” never to be cultivated! Dimbula now counts 50,000 acres in cultivation out of 55,000 in private hands. In 1869, only 8,000 acres were opened—much of it newly burnt off as we saw it—and only 20,000 acres in all had been taken up. Forest, forest everywhere: our ride through forest from Forest-creek to New Valley, Dikoya, was declared to have its risks—bad fords, or rotten wooden attempts at bridges, perhaps a prowling elephant, or the chance of getting bogged in a morass in some of the gullies below Kotagala. But our chief enemy proved to be heavy persistent rain. [This was again the case on crossing from Dimbula to Dikoya, in 1872, when we were glad to accept Mr. Stepford Sackville’s hospitality at Drayton and pass a pleasant forenoon with him, the late Walter Campbell, one of the Camerons and John Buchanan now in Brazil.] In 1869 Dikoya and Maskeliya (the latter with four blocks sold) had only 6,000 acres cleared: S. Le Cocq and T. R. Dobree were chucking at the foolish rush into the region beyond; they had had enough of rain] and were soon after off to select land, the one in Morawakkorle and the other Nitre Cave!

The land was all before them

Where to choose,—

and they left behind them Bogawantalawa, the Agras and the best of Maskeiya, to fix on two of the poorest spots in our hill-country. But then the old Demerara coffee planter Sir Wm. Reid (who for himself in 1840, selected Spring Valley, the finest block in Uva) after passing through and rejecting Haputale, fixed on a corner of Rakwana for his nephew Charles Shand’s future coffee plantations!

Where are the Dikoya men of 69—James Mac Donald, the cheetah-slayer, L. H. Kelly, Sillery, Mackinnon, Davidson, MacLellan of the bagpipes, Reid? Two only remain in Ceylon, we believe, Giles F. Walker who was superintendent on Del Rey, and D. W. H. Skrine who managed his own compact Warleigh property of 120 acres planted, a perfect “gold mine” in coffee. And yet poor Dobree and Lecocq with all their Dikoya experience, would not touch, but rather an away from such land! As for Maskeliya, there were only four blocks taken up in 1863, the pioneer being Tom Gray with Banyan and Oroca. Time and space fail us to record here any of the many planting adventures of those early days before roads and bridges came into existence. There were

scapes by flood and field,—

and there were actual fatalities—deaths by drowning in trying to cross the Dikoya river in monsoon

floods; while "Pedigree" Banner got his name after a narrow squeak of a raft capsizing with himself and two companions and because one of them risked his life to recover a valuable paper in an overcoat pocket, which turned out to be (not a title-deed but) a copy of the "Liverpool Mercury" with the pedigree of his family. The disgust of the rescuer may be imagined! Then there was poor old Noad, Chief Surveyor, under Colonel Myers, S. V. G., nearly starved under Adam's Peak living on the coolies' rice for weeks together, while his supplies were stopped by three rivers all in flood, and rendered impassable. Well may the present generation of planters between Adam's Peak and Great Western (is there anyone left who was in the same region in 1869, besides the two named above?) be told by us:—

If you had seen these roads
Before they were made,
You'd have held up your hands
And blessed General Wade!

It was in 1869 that we collected, for the first time, the planted acreage of each estate: Meddecumbra with its thousand acres of coffee was the biggest by far in the young districts: Del-rey had 290, Kirkoswald 287, Warleigh and Newton each 120; Bearwell was a forest; Palmerston and Belgravia each 100 acres and so on.

Our next big planting trip was in 1872. Starting from Galle for the newly-opened Morawak-korale district to visit Le Cocq and his sinne dnrais, A. E. Scovell and A. T. Rettie; across Gongalla through Rakwane, riding from Palnadulla right through Haputale, Badulla and Passara districts; back to New Galway and Nuwara Eliya and thence by the Kikkimaana bridle road through the forest to Upper Dimbula, represented chiefly by Lousa and Scalpa. Of the country as it then appeared, of incidents and adventures, much might be said (we pencilled the draft of the Memorial that started the agitation for railway Extension from Nawalapitiya to Nanuoya and Haputale, while lying on the patna in front of the old Bandarawella rest-house, on this trip); but we must not tire our readers and have said enough for today.

Trusting to our memory—which is probably with advancing years, not so good as it once was—we find we made several omissions of importance in our instalment of Reminiscences published on Friday last. One is simply unpardonable; for it was to the hospitable bungalow of Mr. and Mrs. W. D. Gibbon at Hoolankande that we turned our pony, when we first entered the Kellebokka valley in 1864; and it was then, if we recollect aright, that we accompanied Mr. Gibbon and Mr. Charles Catto on a very notable jungle expedition across the Knuckles range to take stock of a new experiment in planting on the Eastern spurs and slopes—an experiment which it would have been well for Mr. Gibbon if he had never touched. (But of how many more can that be said as to planting on the Lagalla side:—Poor Ted Hope and Wingate, Thomas Mackie, Borron and many more who lost much money in vainly trying to make plantations pay in wind-blown districts.) Another visit to the same veteran planter, when he became Manager of Oodoowella, first made us acquainted with

THE HANTANNE DISTRICT.

The romantic history of the first estates planted; the tragedies connected with the deaths of Henderson, Urquhart and Falconer; and the

still more harrowing murder by Sinhalese villagers of the young Welshman, Morgan, when riding with the monthly bag of rupees through a bit of jungle before bursting out on the patnas of Kitooolamoola, would fill up much more than a column if space and time permitted. A. C. Mortimer as Manager for Sir John Cheape's group of estates was the great gun of the district, and he was succeeded by Wm. Cameron and James Beaton. Old Gottelier on Peradeniya and Paul de Chermont—with the grand old giant rose-tree on Ooroogalla—were characters in their way; and altogether there are many pleasant reminiscences of Hantanne in the early days, as there is respecting the

HEWAHETTES

which we first entered by the old road from the top of the Kandy Lake to get to Kirrimettia, Bowlane, Bopitia, Patiagama, etc.—the ground being nearly everywhere strewn with coffee-bumper crops and scarcity of coolies accounting for much cherry lost. Then Dr. Dodsworth, proprietor of Kirrimettia, who dated from "the forties," rode down with us to pay our first (but by no means last) visit to the

PATRIARCH OF DUMBARA,

the late Robert Boyd Tytler, regarding whom and his work as Pioneer of Coffee and Cacao how much could be told!

We regretted at this time not to be able to visit

DOLOSACIE

and look up Mr. Wm. Rollo (who had just—1864—got a young Assistant in Mr. C. W. Horsfall, now our neighbour in Baillie Street); while his planting neighbours then included Messrs. John Stephens, J. A. Bell, Henry Saunders, W. C. Whitham, R. B. Downall, Blacklaw, Inray, James Blackett, G. M. Ballardie, R. Porter Wm. Taylor, etc. We had to wait some years before we saw one corner of the district with Mr. T. Smith at Barnagalla.

Still another early trip that should not be forgotten was that with Mr. Andrew Cross from Nuwara Eliya into Maturata to be the guest of Mr. J. H. Renton and thence to ride back into Udapussellawa and visit our old friend Mr. G. A. Dick on Ragalla, then being opened. Still earlier, of course, was our acquaintance with Mr. Dick when Manager of Nayapane in

PUSSELLAWA,

while Maurice Worms ruled over Rothschild; F. R. Sabonadiere was a little King at Delta, and had for genial neighbours, such good men and excellent planters as old George Shireff on Helbobde, John Lewis Gordon on Wavendon (afterwards and still partner in Messrs. Geo. Stenart & Co.), John Martin on Sir Horace Rumbold's estate of Melfort, W. Sabonadiere on Glenloch, Northmore on Whyddon, Sweeting on Kallugalla, Capt. Donald Graham on Mahavilla (to be succeeded later by Wm. Mackenzie), and the Bowden Smiths in

NILAMBE.

To that district we made a most pleasant trip with Old Colonist when he was doing double duty as V. A. for Messrs. Geo. Steuart & Co. as well as for Lee Helges & Co. when (as Price and Boustead's Agents) they held a long list of estates in Agency. Of the Wariagallas under Henderson and Arthur Davidson, and of E. S. Grigson, as a young planter opening his first clearing of 100 acres of beautiful young coffee on Nilambe estate, we have most pleasant recollections; as also of C. S. Armstrong on Morahena. But we must close what is after all little more than a preliminary sketch.

THE AGRICULTURAL MAGAZINE, COLOMBO.

Added as a Supplement Monthly to the "TROPICAL AGRICULTURIST."

The following pages include the Contents of the *Agricultural Magazine* for September :—

Vol. XIV.]

SEPTEMBER, 1902.

[No. 3.

KURAKKAN.

SOME months ago we read some remarks of a Government Agent to the effect that Kurakkan is a palatable and nutritious food when properly prepared as a porridge, though only fit to be utilised for gun wads if turned out in the shape of the indigestible cakes so much affected by the village housewives of the North-Central Province.

We make this reference to show that even in Ceylon there are among the more enlightened population those who see some good in this much-maligned article of diet:

In our last issue we quoted under the head of "Three Chena Crops" the remarks of an African authority on the subject of native diet. The author of these remarks proposes submitting samples of Kurakkan (with other grains) to the authorities at the Imperial Institute, with a view to settling certain points relating the possibilities of Kurakkan, such as whether by careful and continuous selection, the hard husk of the grain can be reduced (as has been done with wheat and maize) to a minimum, and whether the grain could be harvested and cleaned, husked and milled on a commercial scale.

To give another instance of the good opinions that are gathering round this "pariah" among cultivated grains, we may mention that the Agricultural Explorer, the United States Government, on the occasion of his last visit to Ceylon, procured through us a quantity of the two cultivated varieties of Kurakkan seed for experimental purposes, with a view to testing its suitability for the warm arid regions of America, together with other drought-resisting plants (from the region of the Persian Gulf and India) which he was giving his attention at the time.

Kurakkan (well known as "ragi" in India) is scientifically known as *Eleusine coracana*, and is a cultivated variety of *E. indica*, a common weed. In the Madras Presidency the crop occupies no less than 1,551,000 acres, and in Bombay 802,000 acres. These are the returns for these Presidencies for 1887-8, but the plant is largely cultivated in other parts of India as well. In Mysore *ragi* constitutes the diet of four-fifths of the people.

Professor Church's analysis of the grain is as follows:—

	Husked.	Unhusked.
Water	... 13·2	12·5
Albuminoids	... 7·5	5·9
Starch	... 73·2	74·6
Oil	... 1·5	0·8
Fibre	... 2·5	3·6
Ash	... 2·3	2·6

The nutrient ratio is given as 1 : 13, and the nutrient value 84. Phosphoric acid exists in the whole grain to the extent of 4 per cent. As a food Kurakkan is looked upon as indigestible, but it is the defective cleaning and preparation of the grain that causes indigestion and other stomach disorders. From a dietetic point of view it is a suitable food for the working man.

OCCASIONAL NOTES.

Mr. J. B. Carruthers, the Government Cryptogamist, is reported to be working at the "betel disease" with a view to discovering a remedy. The "disease" is due to a fungus and causes much loss to cultivators of this remunerative product. The application of lime to the soil has been known to check the attack, and Bordeaux solution is about to be tried in some of the infected School Gardens.

An article on Tapeworm in the Dog appearing in the June number of the *Agricultural Journal of Victoria*, the following recommendations are made under the head of treatment:—"To expel tapeworms from dogs no remedy succeeds as

well as arecanut. The dog should be kept off food for about 12 hours, and then from 15 to 60 grains of powdered arecanut should be given in a little milk. A dose of 30 grains will suffice for a dog weighing 25 lbs., and 60 grains may be given to a very large dog, and 15 grains to a little one. About a couple of hours after the administration of the arecanut a dose of castor-oil should be given and the dejecta watched for the segments or joints, which may be seen to be crawling about, and these should be burnt before they get a chance to burst and scatter the eggs which they contain.

We have to acknowledge with thanks the following publications:—

Journal of Agriculture of Victoria.
Agricultural Gazette of New South Wales.
Queensland Agricultural Journal.
Journal of the Department of Agriculture, W. Australia.
Station, Farm and Dairy, Sydney.
The Indian Agriculturist.
The Indian Agricultural Ledger Series.
The Agricultural Journal of Cape Colony.
The Capricornian, Rockhampton.
The Sunday Times, Perth.
The Journal of the Imperial Department of Agriculture, West Indies.
The Veterinary Journal.
The Proceedings of the Royal Agricultural Society, England.
The Proceedings of the Highland and Agricultural Society, Scotland.
Nearly all these come as exchanges for our own Magazine, and they constitute an excellent nucleus for an Agricultural Reading Room.

Greatest amount of rainfall registered in 24 hours on the 20th August, 1902, 1·10 inches.

Recorded by ALEX. PERERA.

A NEW EDIBLE TUBER.

The *Agricultural Gazette of New South Wales* for July contains an article (from which we cull the following information) on the New Edible Tuber, *Coleus (Plectranthus) coppini*, said to be cultivated and used in the French tropical colonies. From past experiments it would appear that the plant will thrive in the southern districts of France, and that, going on the analysis of the tuber, it is desirable to encourage its cultivation as a vegetable.

Successive analyses gave the following results:—

Fatty matter	2·50	per cent.
Glucose	16·68	"
Saccharine	1·67	"
Not defined	4·35	"
Gum and Pectic matter	16·05	"
Albuminous substances	5·78	"
Starch	14·00	"
Ash	4·26	"
Cellulose, ligneous matter	40·71	"
and loss	"

100·00

The ashes are said to consist of sulphates, phosphates and carbonates; the weight of the potash 2·49, and of soda 1·34 per cent. "The tuber," says Mr. Heckel, the author of the article, "containing fatty substances, is rich in starch, glucose and saccharine. It certainly contains but little albuminous matter, but is, nevertheless, a perfect food."

The taste of the tubers, when cooked, are said to be agreeable and somewhat like salsify, while richer in alimentary equivalents. Fresh, the tubers contain 80 per cent water, but they dry and shivel up in a few days when they show about 75 per cent.

This esculent would be a close relative to our "innala," sometimes spoken of as "country potato" (*Coleus parviflorus* before *Plectranthus tuberosus*) locally considered to be a very wholesome vegetable.

A MANUAL ON BEE-KEEPING.

Bee-keeping in the West Indies is the title of a useful little pamphlet issued by the Imperial Department of Agriculture for the West Indies. The author of the manual is Mr. W. K. Morrison who, writing in a popular style, gives the reader a deal of useful information on the subject. He recommends bee-keeping as particularly well suited to schoolmasters, and if only our village pedagogues will occupy their spare time in the manner suggested, we shall before long have springing up a rural industry—eminently suited to the tastes of the easygoing villager, and affording the cultivator's family (and himself between sowing and reaping) a remunerative means of livelihood.

Mr. Morrison settles the question of the variety of hive by saying "the Langstroth is an all round hive suited to any purpose."

As regards variety of bee the author tells us, "The Cyprian is likely to do well in the

West Indies, as also is the Syrian or Palestine bee which is closely related to the former. The latter can seldom be obtained in a pure state, and the choice of a race for the West Indies is practically limited to the Italian, which is also the one best suited to local conditions." And again, "A dash of Cyprian blood in the Italian makes an excellent strain of bees for work in a hot climate."

At present, however, it will be enough if the "mee-messa" (*Apis indica*), the only satisfactory honey bee of Ceylon and one capable of domestication, is taken in hand and kept in frame hives, and the hints given in the West Indian pamphlet followed as to procedure.

In previous numbers of the Magazine we have given a complete account of what has been done in the past in the way of bee-keeping, describing the different varieties of honey-makers and their characteristics.

An experiment in apiculture has been carried on at the School of Agriculture since 1900, with a view to "educating" the Ceylon honey bee; and the Director of the Museum and Government Entomologist have shown interest in the experiment.

We must not omit to mention that Mr. Charles André, of Kuruwagala, has kept bees for many years, and planned a special hive on the lines of the Langstroth hive, specially suited to the Ceylon bee.

BETEL CULTIVATION IN INDIA.

(Continued.)

In Bengal three varieties are cultivated, one of which (difficult to grow) is known as 'sweet betel,' and has a fine flavour and odour like camphor. There it would appear that the vines are grown on 'pandals,' but before being allowed to creep over them the creeping stem is pulled down repeatedly, and a portion is made to rest on the ground in a soil which is covered with a little earth, a few leaves being plucked each time. Pond-mud and other good mould is used for occasionally earthing-up.

In Orissa, we read, the plant reaches maturity in 12 or 15 months and yields leaves for 50 or 60 years. An acre is said to yield from £88 to £100 gross or a net profit of from £25 to £35.

In Ahmednagar betel begins to yield from the third year, and picking is carried on at intervals of 8 to 10 days. The vine is cut to the ground once a year, after which new shoots spring up and are trained on to the live supports—*Erythrina indica* (erabodu) or *Moringa-pteriosperma* (murunga).

In Kandesh the leaves are plucked with the aid of sharp-edged thimble-like plates which nip the leaves clean off without wrenching the plant. Then the leaves retail at 1 to 2 annas per 100.

In Poona where it is well-manured the vines last from 15 to 20 years. Every year the upper half of the vine is cut, while the lower half is coiled and buried under fresh red earth and manure.

In Nashik the acre yield is said to be worth Rs. 150 to Rs. 750 annually, but from Rs. 400 to Rs. 600 are often spent before the crop yields any return. Stunted shoots are said to give the best leaves, soft, smooth and full of flavour, while those on luxuriant shoots are coarse. Two kinds of vines are distinguished, one yielding quick returns, the other better and larger crops.

In Dharwar the vines are planted in the open on quick-growing trees, 2,000 to the acre, the crop last for from 4 to 7 years. Then the vines are dug up and the leaves of the supports are used as manure and the wood for fuel. After a catch crop of sugar cane for which the land is well prepared betel follows on.

In Kanara betel is allowed to run up mango trees.

In Thana the vines are started in pits 1½ ft. apart, and when established are given 5 oz. of oil cake (generally mustard as castor is found unsuitable) and a second dose of ½ lb. being given at a later stage.

In Kolaba the vines are manured with fish and yield a crop in the first year.

The ordinary fertilisers used in India are dried and powdered cowdung or dry soil from ponds.

POULTRY PICKINGS.

Considerable vitality has lately been exhibited in poultry-fanciers' circles. We have long known that there are amongst us a few poultry enthusiasts, and the names of Messrs. T. Sanmugam, Chapman Dias, and Dr. VanRoyen are well known among Ceylonese bird fanciers, who have for some time been devoting time and attention to the subject of the improvement of poultry. Now, however, the number of private individuals who are interested in this home industry is larger, and we know of one Government officer who is taking up the matter of improving the poultry of his province from his official standpoint. Under these circumstances it is not unreasonable to expect that some real benefit will accrue to the country.

The following is a resumé of the results of the Poultry Show held on the 13th August taken from the *Ceylon Observer*:—

The Brahmas exhibited were considered no quality at all and cocks and cockerels received no prize. Langshans also failed to come up to expectations. The four Leghorn imported hens exhibited were capital specimens and there was keen competition between Mrs. F. C. Loos (jr.) and Mrs. M. J. Cary, the former being awarded the prize. There was a fair lot of country-bred Leghorns. Mr. Geo. John, who was the chief competitor, carrying off the prize for hens and Mrs. Cary for cockerels. Dr. Thomas exhibited a very fine imported Minorca cock which carried away the prize from two others. Mrs. Loos and Mrs. Bowie divided honours for hens in this class. Mr. Seale got first prize for c. b. Minorca cocks with an animal which showed good quality, as also did the hens amongst which Mrs. Bowie's bird got the prize. The

cockerels and pullets in this class were very difficult to decide upon for prizes as they were a fine level lot. Amongst Plymouth Rocks the imported and country-bred hens were judged together owing to the paucity of entries in the former class and, of course, the two imported hens carried away first and second prizes. They were fine specimens of the breed, the country-breds also showing comparatively good quality. The cockerels and pullets exhibited included some fine imported birds which secured three prizes for Mrs. Bowie, Mrs. Haslop getting third prize amongst pullets. A showy Orpington cockerel exhibited by Miss Kendal Watson was considered a very fine country-bred bird and was awarded the prize in its class, while the same lady carried away the prize in the next class as well. There was a very fine class of Indian game fowls which were acknowledged to be of even better quality than those shown at the last show at "Temple Trees." The Maha Mudaliyar's prize for the best Indian cock was awarded to Dr. VanRooyen's exhibit which was considered to be one of the best bred birds hitherto shown. This bird was erroneously entered on the list as belonging to Mr. Jeffery. Mr. Serasinghe's exhibit won the special prize offered by Major Firminger for the best Malabar cock in the Show. Mr. Henderson won the Cup presented by Mr. A. Y. Daniel for the best Indian game hen with a fine specimen of its kind, Mr. Jeffery coming second. The pure-bred Indian game pullets and cross-bred cocks and cockerels were of a very poor quality and got no prizes. In class 39 there was a fine specimen of the Plymouth Rock in a sturdy cock, but no prize was awarded, as there was hardly any competition. There were two pairs of Bantams, but they were not in condition, although the spotted black and white pair were indeed a pretty set. The prize in this Class (41) was, therefore, awarded to two white silkies which were curiosities in their way. There was quite a number of curlies exhibited. No guinea fowls were exhibited, and the few ducks on view were of a very poor quality. This was amply compensated for by the exceedingly fine collection of geese, Mr. Jeffery getting the prize for a very shapely trio and Mr. A. Y. Daniel coming a close second with a pretty pair, one white and one dun. The pigeons shown were all in very good condition, including a pair of rare White Barbs which many considered should have got at least second prize instead of the Brown English. Mr. Daniel's pair of Maltese were a fine large pair, one white and one light brown.

Miss Kendal Watson's fine black Orpington cock was awarded the Championship prize offered by the Lieut.-Governor, the bird being from eggs supplied by Mrs. Bowie, whose imported Plymouth Rock ran it close. Mrs. Bowie got the prize for the best hen in the Show with a fine Plymouth Rock.

Our local poultry fanciers are, however, not to be satisfied with occasional Shows, but have established a Society and are going to have a Journal, both which we sincerely trust will be well supported and together be a power for good.

It is only by combined action of this kind that any real work can be established, and it is a pity

that the various Committees appointed in connection with Cattle, Poultry and similar Shows cannot unite to form an Agricultural Society which is sadly wanted in the Island.

Eggs for hatching which have travelled, should always be placed on their large ends in bran or chaff, and allowed to rest for 24 or 30 hours before placing under a hen. When valuable hens are in question, use two hens and place half the eggs under each. Never overcrowd a broody hen with eggs; give her rather a less number than she can cover.—*Journal of Agriculture, South Australia.*

Where birds come from a distance the following rules should be strictly observed:—

(1.) Place in a warm, well-ventilated coop, and keep for, say a week till the bird has settled down and seems quite well.

(2.) Give water sparingly, and even then it should be boiled and allowed to get cold. A change of water is often provocative of disease.

(3.) For a few days feed on bread soaked in boiled milk. If milk is scarce make a sop of stale bread and boiling water; then squeeze out the surplus water and add a little hot boiled milk. Gradually feed ordinary food.—(*Ibid.*)

A USEFUL DISCOVERY.

According to the *Station, Farm and Dairy*, Dr. Anderson, of Minnesota, has made a discovery which promises to revolutionise the preparation of staple food stuffs. The starting point of the discovery was the peculiar action of Indian-corn under the influence of heat, resulting in the parched grain known commonly as pop-corn. Already he has succeeded in adding something like sixty different kinds of starchy foods, by popping not only Indian-corn and rice but also potatoes and other starchy food-stuffs. Having found that popping was due to the expansion of moisture inside the corn, he concluded that he had only to secure three factors—heat, pressure, and a sudden release of the pressure. The next step was to construct a steel cylinder to represent the envelope of the grain. Having placed a piece of raw potato in the cylinder, the receptacle was closed and submerged to an interior pressure of three or four atmospheres. Heat above 220° F. was applied for a time, and then the pressure was suddenly released, with the result that there gushed up from the cylinder a mass of snow white "popped" potato as light as pith. This product can be compressed for transport and restored by soaking to prepare it for consumption. The treated stuffs are found to embody many advantages lacking in the original products, being delicate, soluble, digestible, and nutritious. Flour and water treated in the same way popped into "full-fledged biscuits" as light as feathers and free from fermented leavening so objectionable to weak digestion.

This so-called discovery proves what observation and thought can do. Popped corn, rice and potatoes steamed in their jackets are all familiar enough, but so long no one has seriously observed the conditions under which these delicate and digestible products were produced and the possibility of acting upon other starchy food stuffs—free from an enclosing membrane or jacket under similar conditions.

A word as to the value of popped Indian-corn and other grains. Medical men have by experience found that such products are digestible and nutritious, and prescribed them as a suitable diet for children, just as they would prescribe extract of malt, possibly owing to the fact that the change resulting from "popping" were similar from a chemical point of view to malting. In a lecture on Native Food Stuff of Africa by Mr. Open, administering the Agricultural Department, Rhodesia (we quoted from his lecture in our last issue), the peculiar sustaining power of popped Kaffir corn or sorghum is referred to and instances given of its value as a diet under trying circumstances. Mr. Open there says, "I am sure there is considerable chemical change in the parched and burst grain, and that analysis would easily show the reason of its nutritiousness." We have no doubt that with the developments in the direction of preparing starchy foods similar to popping grain, the chemistry of the process will be soon made clear.

NATURE STUDY LESSONS.

FIRST COURSE IN THE STUDY OF PLANT LIFE.

(Continued from August Number.)

THE LEAF.

Leaves differ greatly in size, shape and other characters, but most leaves agree in having a more or less thin, flat green portion called the blade. This blade is in some plants connected to the stem by means of a stalk as in the croton; in others the leaf stalk is absent as in screw-pine (*Wetakeya*). In addition to these parts some leaves bear at the point where they join the stem a pair of leafy structures which may be very small as in the shoe-flower (*Sapatamal*), or large and leathery as in the bread fruit which drops them as the leaves expand. These are called stipules, and their function is considered to be the protection of the leaf buds or young leaves before expansion. Notice in the plantain tree how the young leaves are for protection rolled up in the hollow stalks of older leaves. The protection of leaf buds by scaly leaves is seen in the grape vine (*Mudarapalam*), and in the underground stem of ginger (*inguru*). Some leaves are thick and fleshy as bowstring hemp (*Neyanda*). An onion bulb consists of a mass of succulent leaves closely packed round a tiny central stem. Here we have an instance of leaves storing food for the future use of the plant, as the swollen stem of the potato and the thickened roots of radish do.

On the surface of leaves are certain markings due to the presence of tougher structures running through the leaves. These are called veins, but unlike the veins in our body, which are hollow structures for the conveyance of blood, the veins of a leaf are solid. The principal vein which generally intersects the leaf into two equal parts is called the midrib. When this midrib is elongated or developed as in the mango, we get leaves of the pinnate or feather type, with veins branching out from it. When the midrib is contracted or undeveloped we get leaves of the palmate or hand type, as in the papaw (*pepol*), in which the veins seem to spread out like the fingers of the hand. There is a large class of plants in which the veins branch to form a kind of net work, as in the orange (*puuidodan*), and another large class of plants in which the veins run parallel to one another as in the plantain. In some plants—ferus (*meemana*)—there is a peculiar forked arrangement of the veins. These arrangements of the veins help us to classify plants.

Notice in *Glorioso superba* (*Niyagala*) how the midrib of the leaf is extended to form a hooked structure which enables the plant to support itself; this being another of the special arrangements for helping the plant to grow upwards.

The surface of a leaf may be hairy as in *Coleus aromaticus* (*Kappra walliya*), and sometimes these hairs are of a stinging nature owing to an irritating fluid they contain, as in *Laportea cremulata* (*Ma-ussa*). There are also smooth leaves as those of *domba*.*

We have leaves of almost every shape—compare the heart-shaped leaf of *Colocasia* (*Gahala*), the kidney-shaped leaf of *Hydrocotyle* (*Gotukoia*), the needle-like leaf of the whip tree (*Casugas*) the round leaf of the lotus (*Olu*) and so on. But leaves vary also according to the extent and the manner in which they have been cut into. Compare the entire leaf of the jak with the irregularly cut leaf of the bread fruit or papaw. Note that a leaf which consists of one blade, no matter how much it has been cut into, is a simple leaf. But leaf which has been divided up into distinct parts (leaflets), each of which constitutes a secondary leaf (bearing the same relation to the midrib, as the leaf does to the branch) is a compound leaf. Take a rose leaf and see how it consists of distinct leaflets. Examine a tamarind (*Siyambala*) leaf and see what you can learn from it in this connection.

A very strange form assumed by the leaf is the pitcher-like structure in the pitcher plant (*bandurawel*), but of this and other insect-eating plants such as the *Drosera* (*wata-essa*) I shall have more to say in another lesson.

You will also learn something of "seed leaves" when I come to speak of seeds.

THE FLOWER

I have told you that everything borne by the stem is a leaf or a modification of a leaf. Now the parts of the flower, you may be surprised to hear, are also modifications of leaves.

* In this connection notice the prickles on the surface of the leaves of the wild brinjal (*Katuwalbatu*.)

A perfect flower, that is one which has all its parts, such as the shoe-flower, may be said to consist of four distinct kinds of leaves. The outermost and lowest of the flower leaves form the calyx, which consist of small green structures (the sepals) like little leaves. Sometimes, as in the shoe-flower, we find an extra growth outside the calyx; this is called the *epi-calyx*, which is not commonly found. The flower leaves next to the calyx are the petals, which together constitute the corolla, the coloured and showy part of the flower. The calyx and corolla together may be called the protective organs of the flower since they protect the more important and essential parts of the flower which are within them.

The third series of flower leaves found next to the petals are the stamens in which you will still be able—as in the case of the calyx and corolla—to trace the original outlines of leaves. The stamens consist of delicate stalks supporting a two-lobed structure corresponding to the blade of a leaf. Inside the two lobed structure or anther is a yellow powder—which is shed when the anther is ripe—called pollen. You will see later on that this yellow powder is of the greatest importance in the formation of seeds.

The last and innermost series of the flower structure is the pistil. It is not easy to recognise the leaf here, but with a little trouble you will be able to do so. The pistil consists of a more or less hollow structure below, containing what may be called seed buds or ovules which afterwards become seeds. Alone, it consists of a style or a delicate stalk holding up the stigma, or the part on which pollen is shed. The stigma is generally either sticky or hairy in order to catch the pollen grains.

There, you have a general idea of the flower, and what you should now do is to examine as many flowers as you come across, and see if you could pick out the different parts you have been told about.

Remember that all flowers are not perfect. There are flowers that have only one of the protective organs, as you will see if you examine the tube roses in your garden. Some flowers have stamens and no pistil, as you will find in some of the flowers borne by your bitter gourd (*Karavila*) or *Luffa* (*Vetakolu*) creepers. Again some flowers have only the pistil without stamens, as in the large-flowered papaw. As minor points note that the stalks of the stamens may be missing as in temple-flowers (*araliya*), or the style may be wanting as in the papaw flower referred to above.

I must tell you of another leaf-like structure which is sometimes found on the stalk that bears the flowers. This is the bract, which is sometimes green, but more often brightly coloured or white. When large and enclosing a collection of flowers it is spoken of as a spathe. Carefully examine the coloured bracts of *Poinsettia* and *Bougainvillea*, for which there are no vernacular names; but they are common enough in gardens. The spathe of the coconut and arecanut palms are familiar enough, while some of you may have seen the white spathe of the garden caladium and the large showy spathe of the arum lily which grows upcountry.

THE FRUIT.

In speaking about the various parts of the flower I made mention of the ovary. True fruits are formed by the development of the ovary, and when mature they contain one or more seeds which are nothing more than the ovules that have undergone certain important changes to be referred to later on.

You can watch the growth of the ovary into the fruit in your own garden in the bandakka or brinjil plant, and note the changes that take place.

Observe that some fruits are more or less dry and others are succulent. When the bean is mature it is dry, but a ripe orange or mango is quite succulent.

Some fruits are of a very simple structure. In the bean, for instance, you can distinctly trace the leaf structure. The pod may be said to consist of a leaf with its margins united, so forming a hollow body in which are contained the seeds. In the mango we can distinguish three layers in the structure which contains the seed: (1) the skin, (2) the pulp, and (3) the hard portion wrongly called the seed. The true seed of the mango is what is contained inside this so-called seed. The orange is not so simple in structure; it consists of a number of chambers, each of which has a few seeds imbedded in the succulent matter that is the portion that is eaten. The pineapple is still more complex in structure; it is called a compound fruit because it results not from one but many flowers. You should notice the pineapple when it is in flower and see how a large number of flowers take part in the formation of the fruit. But the pineapple is a very strange fruit, for the stalk which bears the flowers and parts of the flowers beside the ovary, also help in the formation of the fruit, and what is most peculiar is that there is a crown of leaves borne on the flower-stalk where it comes out at the top. The jak and the breadfruit are also compound fruits of somewhat similar structure to the pineapple.

The coconut resembles the mango in structure though not in shape, size, &c. Instead of a succulent outer covering we have a mass of fibre, but like the mango we have an inner shell. The edible portion of the coconut is therefore the seed. Paddy is a very simple fruit with a dry scaly covering, and rice is the seed.

You should notice that some fruits spring from below the flowers, while others spring from above it. In the guava the fruit is formed below, in the orange above the flower. Thus we speak of inferior and superior fruits.

Some fruits when quite mature split open, so that the seeds may fall, this is seen in beans. Others, like the mango, do not split. Most dry fruits split open while succulent fruits do not, but in the nutmeg you have a more or less succulent fruit which splits open.

There is still more for you to learn about fruits later on.

THE SEED.

You have some idea now of what is a seed. You know that it is formed from the ovules found within the ovary, but you will naturally

ask what makes the difference between an ovule and a seed? The chief difference is that the seed contains a minute plant called the embryo, and the ovule does not. This minute plant is formed in the ovule as the result of a process known as fertilisation, that is the influence of the pollen of the stamens upon the ovary of the flower and the ovules within it, resulting in the ovary and its ovules being transformed into fruit and seeds.

A seed may be said to consist of the following part:—(1) a seed coat, inside which are contained (2) the embryo or minute plant with a very minute stem and root and one or two seed leaves called cotyledons, with (3) a store of nutriment for the development of the young plant in the earliest stages of growth and until it can supply food for itself. A seed may be compared to an egg, which also has a shell, a little embryo, which develops into a chicken, and a store of nutriment consisting of the red and white parts of the egg.

When the seed is put into the ground, under favourable conditions, it develops a young plant, just as an egg by the process of "hatching" produces a chicken, both having developed from an embryo nourished by the store of nutriment supplied to them. Some seeds are large as in the coconut, others are small as in paddy or mustard. Seeds vary much in colour and are sometimes mottled as in the castor oil. Seeds are smooth as in bandakka or hairy as in cotton. But all these differences you can observe for yourselves, and it would be very interesting to make a collection of seeds and note how they differ. The store of nutriment provided for the nourishment of the embryo is what gives value to all cereals as food, (just as it gives value to the egg as an article of diet) whether it be wheat, oat, barley, paddy, Indian-corn, beans or other kind of seeds. This nourishing portion is what has been provided for the development of the young plant, but which man appropriates for his own use.

TANNING MATERIALS.

Ceylon, like India, is rich in tan-producing trees, and Mr. D. Hooper's list of Raw Stuffs containing tannin with notes on their composition, &c., (*Agricultural Ledger*, No. 1 of 1902) deals with many trees common to both countries. The notes contain valuable information, and we therefore reproduce those of special interest from a local point of view. Allowance has, of course, to be made for different localities, for it is well-known that the proportion of tannin varies considerably in samples obtained from different places. Still the information given is a fair indication of the utility of local tan-producing trees.

In the following table the highest percentages obtained in examination by analysis of tanning materials is given:—

Terminalia chebula	Wood	28.6
Rhizophora mucronata	"	26.9
Cerlops Cndolleana	"	26.2
Cassia an ricalata	"	23.0
Cerlops Roxburghiana...	...	"	19.2

Acacia dealbata	Wood	17.8
,, arabica	"	16.7
,, leucophlea	"	16.2
Brugnicra gymnorhiza...	...	"	16.2
Bridelia retusa	"	15.9
Kandelia Rheedii	"	12.2
Casuarina equisetifolia	"	11.1
Cassia fistula	"	9.5
Acacia catechu	"	6.8
Pterocarpus marsupium	Bark	5.4

Terminalia chebula (Sin. Aralu).—The fruits of this tree, well-known as chebulic myrobalans, are a valuable tanning agent. They are collected largely and exported to Europe. The dried fruits are extremely rich in gallotannic acid and require no preparation except powdering or crushing in a mill. Some recent (1900) analyses by Dr. Leather of samples from different parts of India indicate that the tannin present varies from 31 to 43.74 per cent.

The fruits should be collected before maturity, otherwise there is apt to be variation in their strength. The oblong pointed solid fruits are much superior to the round and inflated ones. The astringent principle lies in the outer pulp of the fruit, the stone-like kernel containing hardly any. (This is a fact that does not appear to be recognised locally.) The fruits are not liable to deterioration, so that it is more economical to export them in their natural condition. The extract (varying from 57.87 to 59.47) made in open pans tends to absorb moisture and to ferment when exposed to the air. It would therefore not be satisfactory to prepare a tannin extract from myrobalans, unless made with skilled appliances. (The preparation of such extracts will be described later.) A factory with vacuum pans has lately been established in India.

The bark, too, provides a valuable tan. In young trees the proportion of tan is about 33.0, not much inferior than in average samples of myrobalans.

The true galls found on the leaves and twigs are used in the preparation of ink.

Terminalia belerica (Sin. Bulu).—The fruit is a commercial article under the name of Beleric myrobalans, but it is inferior to the chebulic variety. Examination of different samples showed that the percentage of tannin varied from 5 to 17.4. The nuts are used in the adulteration of ground chebulic myrobalans.

Terminalia catappa (Sin. Kotamba).—The bark of leaves of the country almond give a black dye with salts of iron. Wardle in 1887 separated 9 per cent of tannin from Madras bark. (We find no reference made to the highly astringent character of the "husk" round the fruits.)

Terminalia Arjuna or glabra (Sin. Kumbuk).—The bark is astringent and is occasionally used for dyeing and tanning. Specimens examined yielded from 8.6 to 16 per cent tannin, giving a blue-black colour with ferric salts. The tannin in the fruits would seem to be very variable, ranging from 1.38 to 9.6 per cent.

Terminalia tomentosa.—The percentage of tannin varied from 5.7 to 13.6; that in the fruit from 4 to 5.9 per cent. The extract is said to be

too dark necessitating decolouration before condensation in a vacuum.

Anogeissus latifolia (Sin. Dawu).—The leaves and bark of this tree are astringent, a specimen of Madras bark yielding 32.5 per cent, and of leaves 15.5 per cent of tannin. The sale of dried and powdered leaves has been suggested.

(To be continued.)

THE PACKING OF FRUITS AND SEEDS.

BY J. H. HART, F.L.S.,

Superintendent, Royal Botanic Gardens, Trinidad.

(Concluded.)

(2.) SEEDS.

Some people are under the impression that the Botanic stations maintain seed shops, where any kind of tropical seed can be purchased in the same way as from seedsmen in temperate climates. It is not so. There are very few tropical seeds indeed, which can be safely kept for more than a month, a great many which cannot be kept more than a week, and not a few whose vitality is destroyed in one or two days if not properly cared for. Thus, a seed shop under European conditions for tropical seed is impossible.

Tropical seeds possess for the most part a very fugitive vitality, and are easily destroyed by an excess of either drought or moisture; but more quickly by the former. Even if left exposed to air, the humidity of which is generally high, they suffer largely, but if in a position where the alternations of dryness and humidity can affect them, they are destroyed in a very short time.

Proper methods have therefore to be devised to keep them in a suitable state until they reach their destination.

Such seeds as mango, cashew, nicker beans, some palms &c., can stand a large amount of hardship and will keep for a long time, and may be packed in bags or boxes for transit. It is quite a different matter, however, with seeds of *Artocarpus*, *Brosimum*, *Amherstia*, *Castilloa*, *Hevea*, *Cynometra*, &c., &c. Such seeds must be preserved in a suitable medium to keep them in good condition and preserve them for any length of time either in hand or on a journey. The best medium found so far, is the fine dust or short fibre from the interior of the coconut, commonly called coconut refuse. This material is the lightest that can be employed and answers well for almost any kind of seeds. It is especially suitable for packing in tins for transmission by post.

Another material which has been successfully used is weathered charcoal dust. New or unweathered charcoal dust is just as bad for packing seed as weathered dust is suitable, on account of its caustic character and the amount of moisture it will absorb from seeds packed in it. A danger with both materials is, that spores of certain fungi get into them and destroy the seeds they cover.

Packing for delicate seeds should not be too dry or too wet, but a happy medium between the two, just sufficient to prevent the seed losing moisture and insufficient to start it rapidly into growth. On the whole it is better that seeds should germinate on the way than be kept too dry, provided the process of growth does not reach beyond a certain stage.

Experience teaches that greater success is met with if seeds are started on their journey as soon after harvesting as possible, and not kept a day longer than is necessary. If only required for home use, they are best sown as soon as possible after being gathered.

There is another danger to which even the hardiest of our seeds are subject, and that is, the attacks made upon them by ants, weevils, and other small insects. Seeds which have suffered in this way are often to all appearance perfectly sound, but a close examination will generally show that the germ or growing part has been entirely destroyed. The seed is therefore useless.

Persons living in temperate climates, with no experience of the tropics, can hardly believe that seeds cannot be dealt with in the tropics as in temperate climates, viz., gathered, cleaned and placed in a "dry drawer" until required. Proof that imported seeds will not keep is to be found in the universal complaints of the bad quality of the seeds which are on sale. Many trials of freshly imported seeds have been made at Trinidad. As a rule, they have been found to be good on arrival, and to lose vitality exactly in proportion to the time allowed to elapse since they were imported.

Peas, which on first arrival showed a germination of 98 per cent, kept for one month in a dry drawer will have their vitality reduced to 40 per cent, and in three months' time not 10 per cent will germinate. Other kinds of seeds are affected in a similar way. If the period of test, however, happens to be in the dry season, vitality will be found to be more persistent.

These facts were recognised many years ago and have been met, by ordering periodical supplies at frequent intervals. Seeds can be kept for a greater length of time if they are imported in packages which have been sealed in dry air in the temperate zone and only unsealed as required. The best packages for seeds are small tins opening readily with a thumb piece, like Huntley and Palmer's biscuit tins, or the tins used for packing Capstan tobacco.

Continental seedsmen adopt new methods quicker than English traders. The latter do not appear to exert themselves to keep the West Indian trade.

The transport of seeds should always be made by the quickest route and by parcel post, where possible. Consequently they should be put up in light and handy packings.

SWEET POTATOES.

The West Indian Department of Agriculture are giving some attention to the growing and preserving of Sweet Potatoes. We feel sure that a good deal can be done to develop and

encourage the cultivation of this useful tuber in Ceylon. Most people associate the sweet potato with the Southern Province, where it is extensively and successfully grown; but few are aware that the tuber reaches the height of perfection in the Hanguranketa district. On a recent visit to this part of the country—eminently suited for vegetable and fruit culture—we had an opportunity of seeing for ourselves how the "batala" grows there. Two vines dug up at our request but quite at random, gave two potatoes which together weighed 10 lbs., or approximately 5 lbs. each, but we were informed on reliable authority that 8 lbs. as the weight of one yam was by no means uncommon. What is a noteworthy fact is that these boulder-like masses are on cooking as soft and mealy as could be wished, and practically contain none of the fibrous matter that so often spoils the flavoured tubers of the South. On the spot the price during the season is only one cent a pound, so that here is an opportunity for any one with an eye to business working on the lines adopted in Antigua for preserving the sweet potato in some form for future use. Mr. Spooner of that town is reported to have made many tons of meal, preparing it by slicing the potatoes in a chaff-cutter and drying them in the sun (as is done in Japan) on wire-netting—the drying being completed in about 8 hours. One ton of potatoes of this method yielded 910 lbs. meal at the cost of about £4 10s. per ton of meal produced. Dr. Voelcker, who analysed the product, found it had the following composition:—

Moisture	..	11.99	per cent.
Nitrogenous matter	..	5.12	..
Oil	...	1.19	..
Sugar	...	9.90	..
Starch and Carbohydrates	..	67.01	..
Woody fibre	...	1.89	..
Mineral matter	...	2.90	..

As regards the keeping qualities of the meal, we read that it was stored in tins for twelve months, after which time it was found to be quite good. We understand that another use to which sweet potatoes are put is for making spirit, which is shipped to Portugal for fortifying wines. As regards meal, we fancy that the cost of production would be much less in Ceylon if the poorer Kandyan families can take up the preparation which, so far as we know, is not known among them, though Cassava and other meals are commonly prepared.

A good deal has been written about a banana meal industry for Ceylon, but though a sample, prepared by Mr. Chas. Stouter of Anuradhapura, gained a Gold Medal award at the Paris Exhibition of 1900, we understand that the price offered for the meal by probable dealers in Ceylon if the poorer Kandyan families can take up the preparation which, so far as we know, is not known among them, though Cassava and other meals are commonly prepared. A good deal has been written about a banana meal industry for Ceylon, but though a sample, prepared by Mr. Chas. Stouter of Anuradhapura, gained a Gold Medal award at the Paris Exhibition of 1900, we understand that the price offered for the meal by probable dealers to whom samples were submitted both in Paris and London, was by no means encouraging. An analyses of Mr. Stouter's Plantain Meal has been given by us in a previous issue. The interest in the question of commercially manufacturing this product has evidently not altogether abated, as we learn that an enterprising gentleman is giving it his serious thought. To him we

would commend for his consideration the cognate question of profitably manufacturing Sweet Potato Meal, than which we cannot think of a more suitable diet for children. An excellent way of preparing the potato for the table is first to boil, then slice and toast.

We hardly think there is room for improvement in the Hewaheta potatoes referred to above. Some time ago we imported tubers of what was described as one of the finest table varieties of America, but the product of their cultivation was by no means superior to the local article.

◆

DIRECTIONS FOR HARVESTING THE TOBACCO CROP.

Tobacco plants are usually twenty-two weeks in maturing from the time of transplanting; and for four to six weeks after topping, when ready for cutting, the leaves become thick and brittle, and will crack when doubled between the finger and thumb. They also exhibit mottled yellow spots.

It is always wise to allow the plant to ripen thoroughly, as the quality is much improved by so doing and the weight much greater; the colour also is better and more uniform. The process of cutting is performed by splitting the stalk with a tobacco-knife down the centre to within 8 or 10 inches from the bottom, without cutting off the leaves.

The stalk is then severed close to the ground. The plant is better left with the butt up in the sun for an hour or two, according to the heat of the sun, when it becomes toughened or wilted, and can be handled without fear of breaking or bruising. Tobacco should never be cut directly after rain, or when it is wet from any cause. After heavy rain it is wise to allow at least one fine day to intervene before harvesting, to allow the nicotine to again accumulate. After tobacco has been well wilted, it can be placed in piles of five or ten plants, one directly above the other, until the cart is ready to take it to the scaffold or shed. In good fair weather the better plan is to hang the plants on the scaffold, first putting them on small sticks about four feet in length by opening the split stalk and hanging the plant across them. It is a mistake to put the plants too closely on the stick, the best guide as to distance being to allow the breadth of the hand between the butts at the top of the stick. The stick, containing eight or fourteen plants according to size, is then hung on the scaffold, allowing about ten inches of space to separate them. When the tobacco begins to colour a nice yellow or light brown, which usually occurs in this climate in seventeen or eighteen days, it should be removed to the shed. If the tobacco is to be cured by open fires, close your sheds up as soon as all the leaf begins to colour well, and keep your fires going in pits in the floor, keeping a low degree of heat, say 70 to 80 degrees, after which raise the heat slowly until at the end of two days you have reached 125 degrees, after which you can safely go to 125 degrees. The tobacco must be carefully watched until the midrib of the leaf is dry two-thirds of the way down, then the fires can be withdrawn and the shed will

cool. The tobacco will then absorb a certain amount of moisture and become soft, and the colour will become regular. If wet weather should come after this process is finished keep small fires in the shed to maintain an even temperature. More tobacco is spoiled by too fast airing than too slow, and care should be taken to see that the tobacco does not get wet or poleburn while the drying process is going on. If such should occur, open up the shed at once to allow free circulation of air, and when the sweating stops go on with the fires. The system generally followed by growers in Victoria is that for air curing is open sheds with the aid of little firing. The shed is covered round with hessian, which is rolled up during fine weather, and the air allowed to get through the tobacco.

Directly wet weather ensues the hessian is dropped, the shed closed as close as possible, and small fires lighted in pits to keep out an excess of moisture.—*Victoria Agricultural Journal*.

GENERAL ITEMS.

In Germany the regulations of the Meat Inspection Act of 1900 are of the strictest, and prohibit the use of boracic acid and its salts, formaldehyde or formalin, salicylic acid and its compounds and other less known substances; but in England the Committee of the Local Government Board have allowed the use of boracic acid and its compounds in fresh and cured meat, butter, &c., (equivalent to 5 per cent boracic acid) and one grain per lb. or pint of salicylic acid except for milk, cream, and butter and infants' food. The presence of salicylic acid where used must be declared and the use of formalin is condemned.

A Mr. Swinle is reported (by the *Chicago American*) to have produced (and to be able to reproduce always) water melons up to 20 lbs. weight, which do not contain a single seed.

The Arseuite of Soda, the *Queensland Agricultural Journal* states, that the Principal of Hawkesbury Agricultural College has found a solution of one lb. of the chemical to eight quarts of cold water very effective, the spray killing every living plant on the ground, on which nothing was able to grow for quite a month. So that for keeping garden walks, tennis courts, &c. clear of weeds, nothing could be better,

The *Journal of the Jamaica Agricultural Society* refers to the "Lawton Process" of fruit preserving as a decided success, and states that

delicate fruit (such as bananas) could now be carried from the ends of the earth to London with safety.

Here are some useful hints for thrifty housewives:—

(1.) *Ink Stains*.—Ink stains are very easily removed if put immediately in milk and slightly rubbed for a few minutes. If allowed to dry, they are not so easily removed, but can be by a little more effort.

(2.) *Blood Stains*.—Blood stains can be removed from an article that you do not care to wash by applying a thick paste made of starch and cold water. Place in the sun, and rub off in a couple of hours. If the stain is not entirely removed, repeat the process, and soon it disappears.

(3.) *To remove Mildew*.—Soak and wash the spots in sour milk and you will have no trouble in removing the same.

(4.) *Fruit Stains*.—Hold the goods stained over a vessel in such a way that pouring boiling water on the opposite goods, and in a short time the stain will be seen to disappear.

(5.) *Iron Rust*.—Place a bright tin, pour over a kettle steaming with boiling water, moisten the goods with water and hold the iron rust spots closely to the tin and rub them with oxalic acid. As soon as you see the rust disappear rinse in cold water to remove the acid, as it tends to rot the goods, but if the process is performed quickly there is no danger of this.—*Queensland Agricultural Journal*.

The following facts from the *Sunday Times* are calculated to make one pause and think a little about the complexity of that wonderful machine, the human body:—"Every time the heart beats a small tumblerful of blood is passed from one of the chambers of the heart towards the lungs to be purified; at the same time another tumblerful of purified blood leaves the heart to travel through the system. As the heart beats 72 times a minute, it thus deals with about 3 gallons of blood in that brief space. The body contains roughly 70,000,000 pores which are always giving out moisture, though this may not appear as beads of perspiration. During hot weather or when laborious work is being done, the moisture given out varies between a pint and a quart a day. Every square inch of the body bears a pressure of 14 lbs., or a total of about 29,000 lbs. on the entire body. Every meal we eat traverses a journey during digestion and assimilation of about five times the height of the human body. This fact should be sufficient to persuade against over-feeding and over-taxing the digestive organs.

COLOMBO, OCTOBER 1st, 1902.

No. 4.

PLAIN TALK TO SMALL OWNERS IN WEST INDIAN ISLANDS.*

By His Honour F. H. Watkins, Commis-
sioner of Montserrat.)

It is my intention this afternoon to speak on one or two matters of interest to those connected with agriculture, and especially to small owners and those engaged in the development of what are called 'minor industries.'

I cannot speak with deep practical experience, but there are points which must strike anyone who moves about Montserrat with his eyes open and who reads what is passing in the outside world of agriculture. My address will therefore be composed largely of notes prepared from the valuable publications of the Imperial Department of Agriculture for the West Indies, the United States Department of Agriculture, the Department of Public Gardens and Plantations in Jamaica, and other reliable sources, confirmed by personal experience and observation.

IMPORTANCE OF GOOD SEED.—While many of the dangers to crops cannot altogether be avoided, it may be possible, with care and foresight, to keep clear of some which are commonly unnoticed. One of the most important considerations at the outset is to secure reliable seed of good varieties of plants. As I have often said, and inferior variety requires, as a rule, more care and attention than a better and more vigorous variety, while the difference in the sale of produce of the two means, in many cases, the difference between profit and loss. Good seed is absolutely essential to successful cultivation. Efforts should, moreover, be made gradually to improve your crops, by careful selection. A Canadian farmer, by careful selection extending over a number of years, has gained a world-wide reputation for the quality of his seed and is able to dispose, at fancy prices, of a large crop for seed pur-

poses alone. On the other hand, a leading planter in Antigua, by having inferior onion seed sent him by mistake lately suffered a large loss. *Be sure to ask for the best seeds and varieties, and insist upon obtaining them.*

VALUE OF THE SOIL.—Every farseeing landowner bears in mind that his land is so much capital. Every crop taken from the land removes certain substances from the soil. If you desire to continue to derive full benefit from the land, you must feed and replenish the soil, otherwise you will be living on, and eating up, your capital. Too little importance is attached to this essential matter especially by those working provision grounds. 'Natre,' as has been wisely said, 'is a strict accountant; and if you demand of her, in one direction, more than she is prepared to lay out, she balances the account by making the deduction elsewhere.' You must, therefore, feed, or, in other words, manure and fertilize the land.

CLASS OF MANURE.—Manures may be divided into two classes:—

(a) Complete manures, which contain everything which the crop requires.

(b) Incomplete manures, containing certain ingredients and constituents required by particular crops and soils.

Here, the nutritive requirements of the different crops and soils have to be considered, and the small owner would do well to obtain the advice of those with experience of manures.

Estate Yard Manure.—Of complete manures by far the best is ordinary estate yard manure. Nothing better can be wished for when it is properly made and can be obtained in sufficient quantity. Not only does it contain the ingredients required by every crop, but also a large quantity of valuable organic matter, which in addition to its value as plant food improves the general condition of the land, opening up stiff soils to admit air, and helping to conserve moisture in light soils.

Green manuring.—Peas, beans, and other leguminous plants have the power, which most plants have not, of taking in the nitrogen of the air and building it up into substances of great value to plant life. When

* (From Imperial Department of Agriculture for the West Indies.)

such plants are dug in they decay and add this nitrogenous matter to the soil, and thus to future crops. This is one of the cheapest ways of enriching the soil. Many people having stock, turn the cattle into the field when the green dressing is ready and apply, with advantage, the manure thus obtained to the land.

Value of Lime in Manuring.—Although I have advised you, in the case of incomplete manures, to obtain expert knowledge as to their application, a few words on the use of lime in agriculture may be in place. Lime is of value directly and indirectly. Directly, it supplies a necessary element of plant food in soils deficient in lime; indirectly, it unlocks the unavailible potash, nitrogen, etc., in the soil. It also exerts influence on the mechanical condition of soils, rendering heavy soils loose and binding together loose soils. Care should, however, be taken in its application, for, used alone, lime, in most cases is rather a stimulant than a fertilizer. There are two old sayings, 'Lime makes rich fathers but poor sons,' and 'The use of lime without manure makes both farm and farmer poor.' It should always be used together with other necessary manures and fertilizers, and infrequently applied small quantities rather than in large quantities at long intervals. About 3 cwt. per acre every year would be sufficient as a rule in Montserrat.

CROPS.—Commercially considered, crops may be divided into two classes:

(a) Those for home consumption which do away with the necessity of importing food. These may be termed our 'Agricultural Defence Force,' for they enable the labourer and, in fact, everyone, to save money.

(b) Those for export, constituting our 'Attacking Force' which will enable the island to make money.

FOODSTUFFS FOR HOME CONSUMPTION.

Avoiding unnecessary expenditure is one of the ways of increasing capital. Sufficient consideration has not been paid during the past, in Montserrat, to growing foodstuffs for home consumption. In a valuable paper by the Hon. F. Watts upon the food supplies of the Leeward Islands, (*West Indian Bulletin*, Vol. 1, pp. 270-280), it is pointed out that the value of foods, exclusive of liquors imported into the Colony in 1898 was £132,728, an amount larger than the revenue of the whole of these islands.

It is admitted that a quarter of these imported foods might reasonably be replaced by home-grown produce. It is well worth while to turn some attention to those vegetables and foodstuffs which can be stored and put to use at times when both employment and provisions are scarce and when we have to rely upon articles of food imported from other lands. Among those which will keep I shall deal with yams, farine, and corn.

YAMS.—The Government has recently introduced from Antigua and Barbados good varieties of yams. Last year about a quarter of an acre (between two and three 'tasks') was planted in yams at the Chateau or Hospital Garden. Nearly 27 barrelsful were reaped, containing about 130 lb. each, or 3,510 lb. in all which at $\frac{1}{2}$ d. per lb. means a gross return of £28 per acre. The land had been carefully dressed and manured and was rich. When reaped they should be kept dry with plenty of air passing around them. A dusting of slacked lime is at times useful. A ready market is found for yams in Trinidad and elsewhere, but even if they are not sold, they are useful in the months of scarcity and want of employment. Care should be taken to plant the different varieties apart, especially the long thin yams which are more suitable for baking. Several barrels of white eddoes and tannias, which are highly appreciated in Barbados, have also been obtained for distribution.

'FARINE.'—Efforts have been made to teach people how to make farine from the root of the cassava plant because it can be stored—a property not belonging to cassava roots. Farine will keep for months or years, and in Dominica and St. Vincent nearly every labourer has his barrel of farine which comes in useful about the middle of the year. There are numerous

ways in which this valuable meal can be used as a food. All that is required for its manufacture is a small pan or copper, one of which has recently been erected at the Hospital Garden. Instruction to about fifty people in the manufacture of farine has been given at the Experiment Station at the Grove and elsewhere during the past year.

MAIZE.—Many persons grow maize or what is called native corn. Recently I bought 7 barrels of corn, on the husk, for 21 shillings. When shelled they gave 65 gallons, or rather more than 8 bushels, equal to 4 bags of American corn which is now selling at 10s. a bag. I thus saved more than 20s. besides retaining the cob, which, ground with the grain in a suitable mill, adds largely to its nutritive and digestive properties. The great objection raised by people to the more extensive cultivation of native corn is that it will not keep. I am of opinion, however, that with care and attention native corn may be preserved much longer than is usual in Montserrat. One or two hints may be of use.

(a.) Never pick corn on a wet day nor, if possible, until after the sun has shone upon it some hours.

(b.) The common practice of gathering and storing corn with the husks still enclosing the ear is advocated by many from a belief that the husks serve to protect the grain from the attacks of insects. The insects most destructive to stored corn are the grain moth and several weevils, and, as the corn may be infested by these insects while still in the field, there is little to support the idea that the husk serves as a protection. It is like shutting the stable door after the horse has been stolen. The husks add to the bulk of stored corn, afford little protection from insects, and provide the best of hiding places for rats and mice. Most of the corn has to be husked before it can be used. Husking can be done more rapidly while the corn is being gathered than at any other time, and, under ordinary circumstances, it is the best time for doing the work.

(c.) When it has been gathered and husked, it should be put into boxes or barrels of which the bottoms and sides are perfectly tight or hermetically sealed, and treated with bisulphide of carbon to kill the insects. If thoroughly dry, when brought in from the field, it may be thus packed for several days without fear of heating and moulding, and if treated with bisulphide of carbon it will be secure from insects for some months. One to three pounds of the liquid will be found sufficient for 100 bushels or 50 bags, and it costs about 1s. per lb. The process is to pour the liquid over the grain and to cover all over closely with tarpaulin or sacks. Special care should be taken not to allow lamps or lights of any kind near the building where it is used, until the odour has disappeared, which will be from 3 to 6 days after the application. Seed corn should not be treated for longer than 24 hours; the box should then be opened and the vapour allowed to pass off. I have already spoken to you of the importance of carefully selecting the seed. The usual custom is to sell the best cobs, reserving the worst for seed purposes. Carefully go through your corn and select the largest and most vigorous cobs, and a great difference in the yield of your future crops will be the result. Opinions differ as to whether the best and most vigorous seed is to be found at the top or bottom at the cob. It would be an interesting experiment if you were to cut some cobs in two, separating the seeds at the bottom from those at the top, to plant them in two plots of equal size and notice the difference in yield, if any. It would be well for the small owners of a district to combine and purchase a corn sheller and also a corn mill. A corn mill would cost about £1 5. 0. to £1 10. 0. landed, as would also a corn sheller.

FOODSTUFFS FOR EXPORT.

With regard to our attacking force, or articles of food for export, there is no reason why small owners should not make Montserrat the kitchen or market garden for the neighbouring islands. The chief of

these vegetables and foodstuffs to call for our attention are; onions, potatoes and other table vegetables, cacao, ginger and honey.

ONIONS.—Last year seed was obtained from Teneriffe, but a sufficient quantity was not available to meet the demand. Many of those engaged in the industry lost their first sowings owing to the heavy rains of September and October. All, however, who have reaped and are reaping have every cause to be fully satisfied with the results, both as regards quality and quantity. When establishing their onion industry Bermuda had for many years to struggle against far more adverse circumstances than those experienced in this island, and we have the advantage of starting strengthened by the experience of others as to the best methods of cultivation on which I venture to give a few hints.

Onions require a light, friable, well drained, and well manured soil. When planted, they should be carefully weeded and watered, and when pulled they should be carefully laid out on the floor, for 10 to 14 days, away from the sun and rain, both of which are likely to injure the bulbs. Crates for shipping the onions are obtained from Halifax by the Canadian boats. (a) The size of the crates is:—Ends, 16 in. long, 7 in. wide, $\frac{3}{4}$ inch thick, planed one side, 8 ends to a crate; slats $2\frac{1}{2}$ in. wide, 3-8 in. thick, planed one side 14 slats to a crate, One bundle of ends and 2 bundles of slats will make ten crates complete. (b) Cost: \$8.00 (£1. 5) per 100, free on board. Freight: \$3.00 (12/6) per 100. With regard to onions, a merchant in New York writes advising shipping as soon as possible in December. "That is the right time to start if you can possibly do so, so as to have everything marketed before Bermuda starts. When she starts, prices are apt to drop very suddenly. This drop usually occurs in April, about the middle of the month. Do not forget to have your onions packed immediately before the sailing of the vessel bringing them; always have them freshly packed and the crates tightly filled. They always lose considerably in transit, consequently every care must be taken to ensure their arrival in good condition—everything depends on this." Thus it is a case of the early bird getting the worm. I should like some of you to experiment in keeping onions. From July to the end of the year, onions at times command what may be called fancy prices in these islands. The seed should be obtained direct from Teneriffe, for it is cheaper, costing about 4s. per lb. landed here, and is more reliable. Six pounds of seed are sufficient for an acre.

ENGLISH POTATOES.—From the experience of those who have grown English potatoes within the last two years, it seems to be difficult to obtain reliable results except at an elevation of 800 to 1,000 feet. Excellent potatoes have been obtained at low elevation but the results are by no means so certain as in the case of onions. Further experiments are being made and it is hoped soon that we shall be better qualified to speak on this vegetable and offer recommendations of a practical character.

OTHER VEGETABLES.—A large number of Boer prisoners are shortly to arrive in Antigua, and this may afford an opportunity for a temporary market for the disposal of green and other vegetables. It is not to be expected that any of the usual articles of consumption, such as meat, will be directly obtained from these islands, but there is a likelihood of a demand for vegetables and ground provisions which could be grown in Montserrat. In selecting the kind of vegetable to be planted, it must be borne in mind that Montserrat is without telegraphic communication and that steam and other opportunities are rare and uncertain. Only such vegetables as will keep for, at least, a week after being gathered should be planted. Lettuce, for instance, may be regarded as out of the question. Among those to be selected should be squashes, carrots, turnips, khol-rahi, radishes, egg-plant, pumpkins, melons, beetroot and, of course, onions and potatoes. The following hints as to the cultivation of each of the plants named have been taken

from reliable sources of information. On the cultivation of such plants as ochros, pigeon peas sweet potatoes, etc., I need hardly speak. As a general rule pulbous vegetables should be sown in the open ground at once, but non-pulbous plants should first be sown in boxes and then transplanted in showery weather or after rain.

Squashes.—A light, rich soil deeply worked is best. Plenty of stable manure will be repaid by increased yields. They should be planted in hills 4 feet wide and covered to a depth of 1 to 3 inches. One ounce of seed will plant 25 hills. Weeds should be kept down and the hoe used as soon as the vines begin to run. As a rule, the squash may be gathered in 50 days. Some of the scalloped or 'pattypan' varieties are excellent and snitable for shipping.

Carrots.—Carrots require rich, deep soil of a friable character. They should be grown in rows 1 foot apart. The seed should be covered lightly and pressed down firmly. If radish seed be sown in the same row it will break the surface and mark the rows so that relief will be given in case the ground should hake. Thin out to 4 inches in the row. One ounce will plant a row of 100 feet long and may be gathered in 70 to 120 days. Carrots are best eaten when young.

Tomatoes.—A clayey soil is liked by some, sandy by others. The land should be deeply dug, and plenty of manure will make good tomatoes on almost any soil. Sow the seed in boxes, and when the plants are two to three inches high transplant 3 feet apart in rows $3\frac{1}{2}$ feet apart. Thorough cultivation, loosening the soil, and killing the weeds will be required until the plants begin to cover the ground. The soil should be mounded up 3 to 4 inches. Some support, trellis-work or sticks, is necessary to keep the fruit off the ground. One ounce of seed will produce 1,500 plants and they take 3 to 4 months to come to perfection. Great care should be taken in preparing the fruit for the market. It should be fully grown but still green, if to be shipped. It should not be bruised, and each fruit must be wrapped in paper.

Turnips.—Rich and finely powdered, sandy or gravelly soil is best. Turnips are sown in drills 1 foot and $\frac{1}{2}$ inch deep. Water freely, and cover with straw to prevent them being scorched. The plants should stand at least 3 inches apart. When gathered, the tops may be cut off and sold separately for greens. One ounce of seed is enough for 150 feet of drill, and turnips mature in about two months. If kept too long they become pithy and hot.

Khol-Rabi.—This vegetable, as its name implies, is apparently a cross between a cabbage and a turnip. It is usual to sow the seed thinly in boxes or nursery beds and, when sufficiently strong, to transplant the seedlings into well manured ground 9 inches apart in rows 18 inches distant. At the 'Meadow' it has been treated as a turnip with successful results. It comes to maturity in two to three months.

Radishes.—Radishes require little space, should be grown on a nice rich soil and sown thinly on a bed, the drills being 12 inches apart, and the plants 3 inches in the drill covered 1 inch deep. The plants should be thinned promptly, watered well and covered with litter if exposed too much to the sun. Radishes should be eaten young; otherwise they become tough and indigestible. The young leaves make an excellent salad. One ounce of seed will sow 100 feet of drill. They are ready for use in 20 to 40 days according to the kind.

Cucumbers.—The great thing to be guarded against in growing cucumbers is the attack of grubs and insects. As a rule cucumbers and squashes do best on newly dug land, that is, where no crop has recently been planted. The seed should be sown $\frac{1}{2}$ inches deep in a warm, light, sandy soil, in a mixture of cow manure and wood ashes, on hills a foot high, 4 to 5 feet wide, and 6 to 8 feet apart, which have been thoroughly prepared by digging, raking and mixing with stable manure. There is a tendency to an excess of leaf to the detriment of the fruit by the

use of improper fertilizers. The plants when young must be carefully weeded, great care being required not to move or injure the cucumbers. One or two ounces of seed will plant 100 hills and the cucumbers may be picked in 50 to 75 days.

Melons.—The cultivation of melons is very similar to that of cucumbers, but more heat, light and air are necessary, and not so much moisture. The vines may be pinched back if they run too far. Musk melons require 2 ounces to 100 hills, water melons 4 ounces, Musk melons ripen in about 100 days; water melons in 120 days.

Egg-plant or the French Aubergine.—This plant will thrive in any good soil. The seed is sown in boxes or beds, and when about an inch or two high, planted out in beds 3 feet apart in rows 3 feet apart. They require shelter and much water. Thinning out improves the size of the fruit. It is a good plan to graft the egg-plants on the common shushumber. This method may be learnt on application to Mr. Jordan at the Grove Experiment Station.

Pumpkins.—Can be planted like squashes, but at double or treble the distance, and only one plant to a hill.

Beet Root.—Should be sown from July to January, at intervals, so as to secure a succession, in a sandy soil in drills 15 inches apart. The young plants are thinned out to allow 9 inches. The seed might be soaked in lukewarm water for some hours and, while still moist sown 1½ to 2 inches deep.

A valuable pamphlet (No 8) entitled *Cultivation of Vegetables in Barbados* published by the Imperial Department of Agriculture should be in the hands of every small owner. It costs only 2d and is obtainable in this island, with other publications of the Department, from Mr. W. Llewellyn Wall, Plymouth: and elsewhere from the Local Agents of the Department.

(To be Continued.)

ON SOME NEW SPECIES OF EUCALYPTUS.

By R. T. BAKER, F. L. S., CURATOR, TECHNOLOGICAL MUSEUM, SYDNEY.

[From the Proceedings of the Linnean Society of New South Wales, 1900, Part 4, October 31st.]

E. INTERMEDIA, sp. nov.

"BLOODWOOD" OR "BASTARD BLOODWOOD,"

(Plate xlvii, fig. 1.)

A medium-sized tree with a light brown fibrous bark. Leaves lanceolate, acuminate, about 6 inches long, and 1-1½ inches wide or more, pale on the underside; lateral veins oblique, fine, numerous, parallel; intermarginal vein quite close to the edge.

Flowers mostly in large terminal corymbs. Calyx turbinate, 4 lines in diameter, 3 lines long, on a pedicel of about 4 lines. Ovary flat-topped. Stamens all fertile; anthers parallel, opening by longitudinal slits.

Fruits urceolate, about 6 lines long, 4-5 lines in diameter, contracted at the orifice to some times 2 lines; rim thin, capsule sunken.

Hab.—Ballina (W. Bauerlen); Richmond and Clarence Rivers (Rev. Dr. Woolls); Barney's Wharf, Cambewarra (W. Bauerlen, P. Macpherson).

A tree closely allied to both *E. corymbosa*, Sm., and *E. excimia*, Schau. It has, however, always been considered as the northern form of the former species, but in botanical characters it more nearly resembles the latter, and especially *E. maculata*, Hook. The chemical constituents and optical features place it midway between the two former. It differs from *Ecorymbosa* in the nature of the timber, bark, oil and fruits which have not the marked recurved rim of that species.

From *E. excimia*, it differs in having pedicellate fruits, a stringy flaky bark, a pinkish timber, and in its chemical constituents.

Dr. Wolls was cognisant of the differences existing between these species, for in his "Flora of Australia" (p. 238) he states:—"At the Clarence and Richmond Rivers the 'Bloodwood' prevails to a great extent, and the workmen reckon two kinds—the one with smooth and the other with rough bark. . . . It seems probable that the Mountain 'Bloodwood' (*E. excimia*), which overhangs the valley of the Grose, is different from the Bloodwood of the north." As stated above, other botanist have always regarded the northern "Bloodwood" as identical with the Sydney and southern "Bloodwood"; but Dr. Wolls is the only one who connected it (the northern one) with *E. excimia*, Schau., and recent observations also show it to have affinities with that species.

Its physical characters, however, are so evenly balanced between the two that it is decided to give it specific rank.

It differs from *E. terminalis*, F. v. M., the "Bloodwood" of the interior, in its bark, timber and oil; and from *E. trachyphloia* in its larger fruits, bark and chemical constituents.

Its fruits are exactly identical in size and shape with those of *E. maculata*, but it resembles this spotted gum in no other characters.

This tree is constant throughout an extensive range, as it was found many years ago at Barney's Wharf, Cambewarra, by W. Bauerlen, who forwarded specimens to the late Baron von Mueller, who considered it a hybrid between *E. corymbosa*, and *E. maculata*, but of course he only had dried material upon which to base his opinion.

The timber of both the southern and northern trees is similar in colour, hardness and other characters, and the chemical constituents of the oil show no variation.

TIMBER.—A pale-coloured timber, hard, straight-grained, and easy to work. It is much closer in texture than the Sydney Bloodwood, *E. corymbosa*, Sm. The figure is occasionally not unlike that of *E. maculata*, Hook. Gum veins are not infrequent. It is considered a good, durable timber, and superior to that of *E. corymbosa*, Sm. It has quite a metallic ring when the fractured edges of a piece are rubbed together.

OIL.—The yield from this oil is .125 per cent. It consists very largely of pinene, 58 per cent. of the oil distilling below 170° C.; only a trace of eucalyptol could be detected. The specific gravity of the crude oil @ 15° C. = .8829. The specific rotation of the crude oil [α] D = + 11.2°. This oil differs from the oil of the Bloodwood of the Sydney district, inasmuch as the latter is laevo-rotatory to about the same extent. The rotation of the oils from *E. corymbosa*, Sm., and *E. excimia*, Schau., and this species varies in about equal proportions, that of the oil of this species being about half-way between those of *E. corymbosa*, and *E. excimia*, although the constituents of the oils of the three species differ but slightly, being largely pinene.

E. ANGOPHORODES, sp. nov.

"APPLE-TOP BOX."

(Syn. *E. Bridgesiana*, Baker, *partim*.)

(Plate xlvii, figs. 4a, 4b, 4c.)

A medium-sized tree with a white box bark persistent to the ultimate branchlets.

Stem leaves ovate-acuminate, cordate, shortly petiolate, glaucous, variable in size from 1 to 3 or 4 inches long, and 1 to 3 inches broad; venation indistinct on both sides. Leaves of mature trees narrow-lanceolate, about 6 inches long, acuminate, not shining, of the same colour on both sides; venation finely marked, oblique, spreading; intramarginal vein removed from the edge. Oil glands numerous.

Peduncles axillary, 3 to 4 lines long, slightly compressed, bearing a few flowers. Calyx hemispherical.

to payriform, 1 line long; pedicle about 1 line long. Operculum hemispherical, shortly acuminate. Ovary domed. Stamens all fertile; anthers parallel, opening by longitudinal slits.

Fruits hemispherical to slightly pear-shaped, 2 lines in diameter and under 4 lines long; rim thick, sloping outwards—a ring just below the edge; valves generally 4, exerted under 1 line.

Hab.—Colombo, N. S. W. (W. Bauerlen); Towrang N. S. W. (R. T. Baker).

The herbarium material of this species is so similar to that of *E. Bridgesiana*, that on my first examination it was included under that species (Proc. Linn. Soc. N. S. W., 1896.)

My field observations since that date, and the acquisition of further material such as timber and oil, have convinced me that two trees are quite different, and should not be included under the same name. Mr. W. Bauerlen, indeed, who has known the trees for very many years, has always held that the two were different in specific characters.

E. Bridgesiana is known vernacularly as "Apple" and "Woolly-butt," but this tree as "Apple-top Box." As stated above, the foliage, fruits and flowers certainly resemble those of the former species, but there the similarity ends. The bark is a true box-bark, but the timber is quite unlike that of a box.

It differs from *E. Cambagei*, Deane & Maiden, in the superiority of its timber and the inferiority of its oil, and the shape of its fruits; and from *E. nova-anglica*, Dean & Maiden, in the bark, colour of timber, and oil.

It has little affinity with such Boxes as *E. hemiphloia*, F. v. M., *E. Woolfsianz*, Baker, *E. conica*, Dean & Maiden, *E. pendula*, A. Cunn., (*E. largiflorens*, F. v. M.) although it appears to be a connecting link with these and what are known as *Bastard Boxes* such as *E. Cambagei*, Dean & Maiden, and *E. bicolor*, A. Cunn.

It is quite limited in its distribution, and presents no difficulty of determination in the field.

The bark has not an essential oil as pertains to *E. nova-anglica*, and *E. bridgesiana*.

Although it has a regular light-coloured grey box bark, yet the appearance of the tree is more like that of an "Apple tree" (*Angophora*), hence the local name of "Apple-Top Box."

TIMBER.—A pale-coloured, soft specifically light timber, open in the grain, and perhaps to be regarded as porous. It has not the broad sapwood of *E. Bridgesiana*, Baker. It seasons well, and is suited for cabinet work, as it closely resembles in colour, weight and texture the timber of *Angophora intermedia*, DC. It is much superior to that of *E. Bridgesiana*.

OIL.—The yield of oil from this species is 185 per cent. A large quantity of phellandrene is present, also some pinene, and 26 per cent. of eucalyptol was found in the rectified oil (fraction representing 70 per cent. of the crude oil). The specific gravity of the crude oil at 15° C. was .9049; the specific rotation of the crude oil = [α]_D = -12.7, the levorotation being due to the phellandrene. The constituents of this tree differ greatly from those obtained for *E. Bridgesiana*, Baker, a species which in appearance it somewhat resembles. The oil of *E. Bridgesiana* is of excellent quality, while that of this species is of little commercial value, irrespective of the small yield (H. G. Smith).

E. WILKINSONIANA, sp. nov.

(Syn. *E. hamastoma*, var., F. v. M., Eucalyptographia, Dec. ii.; *E. levopinea*, var. *minor*, Baker).

(Plate xlvii, fig. 2)

A medium-sized tree with a thin compressed stringy-bark—not furrowed.

Sucker leaves lanceolate, falcate, generally under 3 inches long and under 6 lines wide, oblique, thin; venation oblique, parallel, distant; marginal vein removed from the edge. Leaves of mature trees similar to sucker-leaves, only larger.

Flowers in axillary peduncles of about 6 lines long. Calyx small, 1 line long, 2 lines in diameter pedicle about 1 line. Operculum small, hemispherical, acuminate. Outer stems apparently sterile; anthers kidney-shaped. Ovary flat-topped

Fruits hemispherical, 5 lines in diameter, rim thick, red; valves slightly exerted, acute.

Hab.—Dromedary Mountain (C. S. Wilkinson, F. G. S.); Colombo (W. Bauerlen); Barber's Creek (H. Rumsay); Sutton Forest (R. T. Baker).

This is the "Stringbark" variety of *E. hamastoma* Sm., mentioned by Baron von Mueller in his Eucalyptographia under that species.

It was first observed in this colony by the late Government Geologist, Mr. C. S. Wilkinson, F. G. S., at Dromedary Mountain at an elevation of 1,500 ft. above sea level, and named for him by Mueller as stated above

It differs, however, from *E. hamastoma*, Sm., in the nature of the timber, texture and venation of leaves, bark and chemical constituents of the oil and kino; and it is on these differences that it is now raised to specific rank.

The bark and timber ally it to *E. eugenioides*, "White Stringybark," and in botanical sequence it is placed next to that species.

The oil resembles that of *E. levopinea*, Baker, but on other characters connect it with that species.

The fruits, and particularly the oil, differentiate it from the other "Stringybark" such as *E. capitellata*, Sm., *E. macrorhyncha*, F. v. M., *E. eugenioides*, Sieb., *E. E. dextropinea*, Baker.

The red rim of the fruits has evidently been the cause of the misplacing of this species, but it is well known now that this is a character common to a number of Eucalyptus.

It is a feature quite absent from *E. levopinea*, Baker. In fact the fruits of the two species are so very different that the trees could not be synonymised with any degree of correctness in specific naming. The bark, leaves, venation and timber of these trees also differ.

E. levopinea, Baker, has a hard compact bark right ont to the branchlets, whilst this tree has a light-coloured, loose stringy bark, not extending out to the limbs.

It is quite distinct in specific characters from the two stringybarks described in this paper, viz., *E. nigra* and *E. umbra*.

TIMBER.—Pale-coloured, very hard, close-grained, heavy. In transverse and compression test, it stands higher than that of any of the other Stringybarks above enumerated. It is evidently an excellent timber, and is strongly recommended for forest conservation.

OIL.—The yield of oil from this species averages about 9 per cent. It consists very largely of levopinene. A small quantity of eucalyptol is present in the oil at sometime of the year, and a small quantity of phellandrene at others. This terpene alters much, occurring in small quantities in many Eucalyptus oils at certain seasons of the year, whilst at other times it is absent. The specific gravity of the crude oil was .894 at 15° C.

The specific rotation of the crude oil = D = -23.9; no phellandrene was detected in the January oils.

No less than 86 per cent. of the oil distilled below 170° C. The levorotation of this oil is due to the levopinene present. The odour of the oil after saponification of the small quantity of ester present is exactly that of oil of turpentine (H. G. Smith.)

E. OVALIFOLIA, sp. nov.

"RED BOX."

(Plate xlvii, figs. 6a 6b.)

A medium-sized tree with a smooth bark, decorticate at the base of trunk, producing a roughish appearance.

Leaves small, of light yellowish colour, sometimes glaucous, oval or ovate, shortly acuminate, mostly 2 inches long and ¾ inch wide, rarely 3 inches long;

venation faintly marked, lateral veins distant oblique, spreading, the marginal vein removed from the edge, producing at the base of the leaf a trinervate appearance. Petiole slender, under 1 inch long.

Flowers in axillary or terminal panicles, 6-8 in the head. Calyx under 2 lines long, 1 line in diameter, tapering into a slender pedicel. Operculum hemispherical, depressed, very shortly acuminate. Ovary flat-topped. Outer stamens sterile. Anthers parallel, opening by pores at the truncate end.

Fruits small, 2 lines long and $1\frac{1}{2}$ lines in diameter, rim thin, contracted slightly at the orifice, valves not exerted.

Hab.—Bathurst, Rylstone and Camboon (R. T. Baker); Hargraves (A. A. Sutor); Gerogery (L. Mann)

A medium-sized or rather stunted tree growing in poor, sandy, rocky soil. The bark can hardly be said to be smooth, and neither is it altogether a box-bark such as that of *E. albens*, Miq., or *E. hemiphloia*, but rather between a box and a smooth bark. The upper parts of the trunk and limbs are quite smooth.

It is allied to *E. melliodora* in the shape and venation of the leaves, and perhaps in the exterior character of the bark, but it has not the yellow satin on the inner surface of the bark such as obtains in *Emelliodora*. It differs, however, from that species in the shape of the fruits, colour of timber, and chemical constituents of its oil.

It differs from the typical *E. polyanthema*, Sch., of Victoria, which has a persistent box-bark right out to the branchlets, larger and obicular-shaped leaves, and larger fruits. The oils of the two species are not at all identical, but there is a resemblance in their timbers.

It differs from *E. conica*, Deane & Maiden, in having a smoothish bark, and in the shape of the leaves and fruits, and chemical constituents of the oil; nor can it be confounded with *E. pendula*, A. Cunn., (*E. largiflorens*, F. v. M.) which has a box-bark, and fruits and leaves quite different from this a species.

The timber, leaves and bark differentiate it from the *Lignum-vitæ*, *E. Fletcheri*, Baker, of St. Mary's and Thirlmere.

In botanical sequence it is placed next to *E. Dawsoni* Baker, as it approaches this tree in the colour of its timber, and occasionally in the shape of the leaves, but differs in every other respect.

There appears to be no reference to this tree in the writings of Dr. Wools and Mr. A. G. Hamilton, both of whom wrote on the *Mudgee Flora* so that it must have escaped their observations, as it occurs at Hargrave, mid-way between Mudgee and Wellington.

Timber—When growing on poor ironstone ridges the tree becomes rather stunted and the stem has a tendency to barrel, so that it yields only small specimens of timber. It is red-coloured, hard, close and straight-grained, and very durable in the ground. It is suitable for all kinds of heavy work.

Oil.—The yield of oil from this species is 27 per cent. It contains much phellandrene and but a minute quantity of eucalyptol at time of distillation. It is not, however, a commercial oil. It is distinctly different from *E. polyanthema*, Sch., of the south, which gives a commercial oil rich in eucalyptol.

The specific gravity of the crude oil at 15° C. is .9053. The specific rotation of crude oil [a] D—993°

There is very little difference in the constituents of this oil and that of *E. Fletcheri*, Baker, the "*Lignum-vitæ*" or Black Box at St. Mary's, as they both contain the same constituents in practically the same amount (H. G. Smith).

E. FLETCHERI, sp. nov.

"*LIGNUM-VITÆ*," "Box."

(Plate xlv.)

A medium-sized tree with a box-bark on the trunk, branches smooth, branchlets glaucous,

Leaves from orbicular to ovate-acuminate in shape sometimes oblique, cuneate or rounded at the base from 1 inch to 3 or 4 in diameter, thin, not shining; venation faintly marked, lateral veins oblique spreading; intramarginal vein removed from the edge, more pronounced at the base, giving a trinervate appearance to the leaf. Oil glands very numerous; flowers numerous in axillary or terminal panicles peduncles short, 2-3 lines long.

Buds about 5 lines long. Calyx conical, with scarcely any pedicel. Operculum hemispherical, very shortly acuminate or obtuse.

Ovary flat-topped. Outer stamens sterile. Anthers parallel, opening by terminal pores.

Fruits conical, about 4 lines long, 3 lines broad; rim thin, and mostly in mature fruits with a notch; capsule sunk.

Hab.—South Creek, St. Mary's (R. T. Baker and N. V. Fletcher); banks of the Nepean River (Rev. Dr. Wools); Thirlmere (W. Cambage).

It is named after the late Norman Fletcher, B. A., a promising young botanist much interested in Eucalypts, who, in Company with the author, some years ago discovered trees of this species at South Creek, St. Mary's near the railway bridge. A tree apparently restricted in its geographical distribution to the watershed of the Nepean River of this colony.

The late Dr. Wools was very probably the first to collect material of this tree for botanical determination, and he forwarded it to Mueller under the local name of "*Lignum-vitæ*" (*Eucalyptographia*, Dec. iii). This latter author, working on morphological grounds, confounded it with the Victorian 'Red Box', *E. polyanthema*, Sohau. The dried specimens of the two species are very much alike in the shape of the leaves and fruits, but the trees differ considerably in other characters. For instance, the Victorian 'Red Box' has a persistent box-bark right out to the branchlets, and a dark red timber, while its leaves are larger than those of this species. The New South Wales tree has thick, rough, flaky bark, and the wood which is of a brown colour towards the centre, is very hard and tough as recorded by Dr. Wools (Fl. Aus. p. 236). The two timbers alone are sufficient to differentiate the trees, whilst their essential oils possess quite distinct chemical constituents.

This is another example showing how essential it is that field observations are required in order to determine correctly the specific rank of Eucalypts.

It generally occurs on the banks of rivers and creeks, growing along with *E. bicolor*, Cunn., but this latter species, although having a somewhat similar bark and timber, is quite different in the fruits leaves, venation and oil.

In colour of timber and bark it appears to stand apart from the western "Boxes," such as *E. Woolsiana*, *E. conica*, Deane & Maiden, *E. albens*, Miq. but in fruit and shape of leaves it resembles *E. populifolia* and *E. polyanthema*, Schan. whilst it only approaches *E. conica* in the shape of the fruit.

The leaves are thinner than those of *E. populifolia* and have not the lustre so distinctive of that species.

It differs also from this latter species in the shape of its fruits, and in its timber and oil.

E. quadrangulata, Deane & Maiden has a lighter coloured timber, sessile fruits with extended valves and lanceolate leaves.

Timber.—It is well described by Dr. Wools (*loc. cit.*). No doubt owing to its good qualities it has been extensively cut by timber-getters as it is quite rare now in its original habitat (Nepean), but is more plentiful at Thirlmere. It is worthy of propagation

Oil.—The yield of oil from this species is 294 per cent. It contains much phellandrene and but a minute quantity of eucalyptol. In constituents and characters this oil differs but little from that obtained from "Red Box," *E. ovalifolia*, Baker, of Rylstone. The specific gravity of the crude oil at 15° C. is .8905

Specific rotation of crude oil [a]_D = -14.2°. The laevo-rotation is due to phellandrene. It is not a commercial oil. The amount of ester and free acid are small in this oil, consequently the crude oil is not very dark-coloured, the red colour of crude eucalyptus oils being due to the presence of a minute quantity of iron from the stills being dissolved in the free acid occurring in the oils. The colour is removed by agitating with potash.

(To be continued).

THE IMMORTELE AS A SHADE TREE FOR CACAO.

BY PROF. CARMODY, F.I.C., F.C.S., & Mr. J. VERTEUIL, F.C.S.

(Read before The Trinidad Society 10th June, 1902.)

Last year in Agricultural Society paper, No. 155, it was shown that Immortelle flowers were particularly rich in Nitrogen, and it was estimated that they contributed to the soil a larger amount of this substance than was permanently withdrawn by the cacao bean. This year the investigation has been continued, and through the kind co-operation of Mr. J. G. de Gannes we are able to give a more accurate estimate of the Nitrogen supply from these flowers. Mr. de Gannes' valuable report is attached.

This year we have not found any of the samples to contain more than 4.03% of Nitrogen which is considerably less than the 6% found in last year's samples.

Taking Mr. de Gannes' figures and ours (reduced to 3% to be within safe limits) the following calculation is made:—

50 immortelles = 800 lb. dry flowers
at 3% of Nitrogen = 24 lb. $\frac{1}{2}$ acre.

250 Cacao trees = 500 lb. cured cacao
at 2½% of Nitrogen = 12½ lb. per acre.

and shows an excess of about 12 lb. of Nitrogen per acre.

Apart from the question of the retention of the Immortelle as a shade tree, which we submit these figures fully justify, the results of this investigation suggest that flowering trees may be utilized to keep the Nitrogen of the soil in circulation and to conserve it by bringing it from lower depths in a soluble form and periodically spreading it in a less soluble but easily decomposable form on the surface of the soil.

It will be remembered that last year it was stated that the amount of Nitrogen in the flowers rapidly diminishes. We now find that this depends on the methods of storing the samples; and that if the flowers are spread out thinly, instead of in heaps, that there is no loss of Nitrogen even when freely exposed for several days to the air.

We now wish to bring to the notice of the members of the Society another point which appears to us to be in favour of the retention of the Immortelle in preference to other shade trees. It has long been observed that the Immortelle drops its leaves during the dry season, and it has been stated to its discredit that it ceases to give the necessary shade at the time when the Cacao trees most require it. It should not be overlooked that one of the functions of the leaf is to evaporate water in large quantities, and in the absence of leaf there must be absence of evaporation. The water evaporated is drawn from the soil by means of the roots, and it follows as a natural consequence that a leafless Immortelle tree does not absorb from the soil that large amount of water which its leaves, if present, would have evaporated, and that this water remains available for the cacao trees which are never entirely leafless. The value of this self-denial on the part of the Immortelle during the dry season when four or five months the rainfall is very low has, we think, not been fully appreciated.

With reference to the previous paper on this subject Professor Carmody has been reminded that he cannot claim to be the first to point to the flower as the special and most valuable feature of the Immortelle as a Cacao shade tree. At the time of writing the paper he believed he was alone in giving expression to such advanced opinion; but he is glad to find that one of the most astute observers among our Cacao planters, viz: Mr J. P. Bain, has long held and expressed the same view.

LA CHANCE, ARIMA,

7th April, 1902.

DEAR PROF. CARMODY,

The Immortelle tree—Anauca—from which I collected the flowers, the flowers, is an isolated tree and was profusely laden with healthy flowers at the time but its size is rather below the average full grown trees. I must here remark that the "Anauca" does not thrive its best in the Vegas. I had underneath the tree properly cleaned, and the flowers were collected carefully and weighed twice a day. The quantity collected amounted to 130 lbs. but a good many were blown away by the wind outside of the area cleaned, and I think by adding 30 lb. to the quantity collected making 160 lb. would be as nearly as possible correct. I regret I did not collect flowers from the "Bocare," it escaped my memory to do so when the trees are flowering, but it is my impression that as they do not bear so profusely as the "Anauca" the weight per tree is less notwithstanding the size of the flowers being larger.

J. G. DE GANNES.

GRAPE GROWING IN JAMAICA.

(THE GLENFARG VINES.)

I was first induced to take an interest in grapes culture, by my having attended a series of lectures given at King's House, by the then Superintendent of the Gardens there, Mr. W. J. Thompson, now of Castleton, and so far, I have never had cause to regret it,—and I have never ceased to take a lively interest in all things appertaining to grape culture. During the course of these lectures, I discovered that it was Mr. Thompson's belief that we should not permit our vines to fruit before they were five years old, and that very nearly disgusted me of trying to plant any, as I was entirely against waiting for so long a period on any crop. However I was able to procure a few cuttings, and several people who saw me with them, informed me that I would have to wait ten years for a crop. I soon discovered that like many other well known fables, this was untrue in practice, as I was able to produce fine grapes in two years.

Having planted my vines, and after seeing them grow for three months, I was so pleased, that I thought I would go one better. I got an American flower catalogue, and after having read up all the wonderful descriptions given of the Concord, Brighton Eaton, etc., I sent off for \$10 worth, and they reached me in good condition, they were planted out and that was all; in nine months they had in some cases put on three or four leaves, and in one case I got one bunch of grapes, which had on five of the sourest grapes one could ever desire to taste. I dug them up, and against American vines I wrote failure and disappointment. In the mean time my other ones had come on nicely, and I now had the opportunity to attend a series of lectures and demonstrations given by Mr. Cradwick here, (in the Hope Gardens) as the vines were now removed from King's House. These demonstrations were very helpful to me, and fully brought out the fact that reading to me was one thing, and ocular demonstration another. I learned sufficient, to my way of thinking, to prune or rather cut back my vines in that year, and in the early part of the next I pruned off for fruit. The white variety I planted fruited heavily, but all

the nursing could not bring them to perfection, as they began ripening they began splitting and nothing could save them. These vines are what are known as Posters Seedlings, and so far as my experience goes, they are utterly worthless for a tropical country—though they are far ahead of any other white varieties as a heavy copper. The black varieties—Barbarossa or Black William, and another, Lombardy, did well, and are still doing well. The Black William is certainly the most profitable grape for culture in the plains of Kingston and St. Andrew. This vine here covered a sloping arbour 150 feet long and 21 feet wide before it was four years old, and having been pruned in February of one year, it was never without fruit in all stages for the next eighteen months. At one time it had on over a hundred large bunches. I had the pleasure of sending one to the Director of Public Gardens, and another to Sir Henry Blake. The former sent me a very complimentary letter, and the latter took his to Montego Bay and exhibited it in the Court House there. During the year just passed this vine has excelled all its previous records. On the 2nd February it was pruned by Mr. Greenless and my brother and it received a liberal supply of goats manure, (four cart loads,) and later on six loads of fresh manure from cow stables, with periodical forking and watering it produced the largest crop. At one time it had on 250 bunches of good grapes, and it was the wonder of all who saw it. We sold Five Pounds Ten Shillings and Sixpence of grapes off this crop alone and gave away quite as much again, besides winning the first prize at the Kingston Flower Show. Acting under the advice of the Botanical Staff I pruned in August, the vine cropped fairly well, but the unusually heavy seasons which followed completely spoil the crop. I have now planted out twenty of the Muscat of Alexandria and Shafston, Muscat generously given to me by Laurence Tate, Esq., of Shafston, and fifty of the Black William. I have also through the courtesy of the Director of Public Gardens, six fine plants of the Great Hampton Court vine. The soil here is what is described as a sandy loam; the deeper you dig the more sand you get, and this seems to suit grape growing admirably. The climate is warm during the day and moderately cool at nights. The district is very dry, and here let me say that growing at stake is unsuitable to this country. The vines so treated failed entirely, and common sense shows that if a vine will cover a great area and produce good fruit it ought to be allowed to do so. We have no winter here to check continuous growth. All the vines are on wire arbours and have the full benefit of the sea breeze. That apostle of grape culture, the Revd. Wm. Griffiths, says the reason that black grapes are not liked is that every old woman knows when a white grape is ripe, but nobody knows when the black grape is. As soon as the latter turns purple they are gathered as ripe, and as a result they are sour, and the grape gets a bad name—when every grape turns black the bunch can be permitted to remain on for two weeks, and then they will be as sweet as any white grape, but of course lacking the flavour of the Muscat. Grapes can be grown profitably and easily, and there is lasting fame awaiting the agriculturist with a scientific and experimental turn of mind, when he succeeds in producing a hardy white variety out of the Black William, by cross fertilizing or grafting, which will retain the vigour of the parent stock whilst retaining the delicate Muscat flavour. In conclusion, I must here record my thanks to the Botanical Department for the able assistance always readily given me at all times. Messrs. Cradwick and T. J. Harris have personally visited and given instructions on these vines, and I have never failed to get valuable assistance from the subordinate staff, and to them is due the praise which the success of these vines merit.

W. RAMSAY THOMAS.

Kingston, 31st March, 1901.

P.S.—I might be pardoned for mentioning the following circumstance. In 1900 the Director of Public

Gardens and Plantations was on leave in England. I wrote asking him to try and obtain a few cuttings of the famous Hampton Court Vine; in reply to my letter he said he would try, in due course he returned to Jamaica fetching several cuttings and a fine picture of the vine with a book recording its history. I planted six of these cuttings myself, and gave two a neighbour. They have done remarkably well my neighbour's vines started fruiting when a little over nine months before they had the first pruning, and at present they have seven or eight bunches on them.—W.R.T., 8th April, 1902.—*Journal of the Jamaica Agricultural Society.*

PLANTING NOTES.

A SEQUOIA "COMBINE."—All lovers of the grandly beautiful in Nature—numbering among them the readers of this Journal—will be glad to learn that an effort is being made to induce the Government of the United States to purchase and preserve the giant trees of California, now threatened by the lumberer—only the Mariposa Grove being the property of the State, the remainder being in the hands of private individuals which spells lumberer. It would be an eternal disgrace to all concerned if these magnificent specimens of an old time variety were to be cut down and converted into furniture, &c. It is affirmed that they adorned the present landscape thousands of years since, and one of those now interested in their preservation affirms that as far as may be, the giants of the Gold State may be considered as immortal? for they are growing now, some of them. But in these days of "combines"—of "trust"—why appeal to Government when a few of the so-called "millionaires" could between them sign a cheque which would save all brother or explosion of sentiment, and render the donors famous for ever—even at the expense of conferring upon the rescued giants the names of all the members of their respective families. A State so rich as is California—rich in the products of the soil and the metals—could we imagine, easily settle the whole business in a very few days.—*Gardeners' Chronicle.*

COUCH GRASS.—You have given your correspondent Pan-Adam (see *Gardeners' Chronicle*, p. 331), a laborious task in advising him to trench his land 2 feet deep or more to get rid of Couch grass. About 1 acre of orchard ground here was overrun with this weed, also Mare's Tail, Docks, Nettles, and woodbine, the latter running up the stems of the Apple and Pear-trees besides half smothering some old Currant bushes. Instead of trenching and picking them out, I planted Rhubarb in the worst places, sufficiently close to surround the stems of the trees, but the Currant trees were destroyed as soon as others were raised to take their place, and Rhubarb was planted. The Rhubarb was lifted the third year for forcing, and fresh plantations made each spring, so we have always two or three batches going. The crops that follow the Rhubarb are Jerusalem Artichokes, Scotch Kale, Winter Greens, and Potatoes, where open space admits of it. I have destroyed the weeds profitably, and in a way that no other known method would have done so effectually, and I would strongly advise Pan-Adam to give my plan a trial. I think the Mare's Tail a most determined grower, and when once it gets a hold on the land or of gravel walks, it defies every means for its destruction. When present in gravel walks I assume that the roots were present in the soil when these were made; at any rate, weed-killers have been applied which destroys the tops, but after a year or two it comes up as vigorously as ever. *W. P. Roberts, Cueden Hall Gardens, Preston.* [Not every gardener wants large quantities of Rhubarb, or to crop his orchard with Kale, &c. Ed.].—*Ibid.*

PLANT SANITATION.

The advantages gained by sanitation, or preventive medicine in preserving human life and making it more vigorous are universally recognised facts and hardly needed to be supported by data to prove them. Two hundred years ago the mortality in London was 80 per 1,000; it is now about 20; and this has been brought about, not by the possession of knowledge of disease and the means of combating it, but by continually putting such knowledge into practice.

The introduction of sanitary methods is comparatively recent. The first Public Health Act was promulgated in 1813, though local efforts had been made earlier. Since then the tendency of such legislation has been to place the regulation in the hands of the local authorities, subject to a general superintendence by a Government department. Still later has come the adoption of measures in Britain to protect animals from disease. Until comparatively recently lung disease (contagious pleuro-pneumonia) and foot-and-mouth disease caused large and frequent losses of cattle, estimated at nearly 2,000,000 per annum—a loss of perhaps £3,000,000 each year. Foot-and-mouth disease has been almost exterminated. Glanders, which was responsible for the loss of large numbers of cavalry horses, is now rare both in the Army and in private stables. Rabies will no doubt be at no distant date recorded in the category of extinct diseases in Britain, if preventive measures are continuously and thoroughly carried out.

Sanitation for mankind was probably induced to some extent by fear; for animals partly from motives of benevolence, but mainly for economic reasons. Plant sanitation also must be considered for economic reasons. Increase of population necessitates larger food supplies. The fight of the farmer in Britain and the planter in Greater Britain must become more strenuous as competition, cheapness of transport, and the opening up of new countries go on. Yet while many means of producing larger crops and improved varieties have been devised and made use of, no means for keeping cultivated plants in health, or preventing the spread of epidemics, have been to any extent practised in Britain or encouraged by the State.

That great loss of wealth has been suffered from diseases to plants, figures have been frequently adduced to prove. The potato disease in Ireland caused immense losses and a disastrous famine. The phylloxera on the vines of France reduced the yield of wine by 90 per cent., and spread to and affected other Continental vine-growing countries. Estimates have been carefully made to show that in Australia wheat rust causes a loss of nearly £1,000,000 annually. In 1882 the hop-aphis lost to Kent and Sussex alone about as much. In India the annual loss by wheat-rust has been calculated at not less than £91,000,000. In America in 1882, before any steps were taken to mitigate these evils, the Agricultural Commissioner estimated the enormous sum of from £40,000,000 to £80,000,000 as the amount of waste due to insect diseases alone. Ceylon suffered to the extent of probably over £15,000,000 by the coffee leaf disease, which

led to the ruin of the industry in that island. All these estimates must from the nature of the data be only approximate; but even if they err on the side of exaggeration it is plain that vast losses have occurred through diseases to cultivated plants.

Can these losses be reduced or to any extent avoided? The answer to this question is found in other lands more than in our country, though in some cases in Britain diseases have been treated with success, and the cultivator has benefited by his intelligent action. Germany and America are in the van in proving the value of knowledge gained and put into practical form in the use of sanitary measures for plants. The vine industry in France, Italy, Germany, Madeira and other grape-growing countries was almost ruined by the phylloxera, until means were found to minimise the attacks, and varieties of the plants were discovered in other countries which were immune from the ravages of this destructive insect. The vines were still suffering from phylloxera when a mildew or blight, due to a fungus, began to do serious damage to crops. Through a fortunate accident—the spraying of vines by the roadside with blue stone to prevent plifering of fruit—a fungicide was found for this disease, which prevented the extinction of the vine, and is still recognised as the most important substance for spraying in leaf diseases. In America, among other industries orange growing and vine culture have been relieved from various diseases, and organised campaigns have kept the many insect and fungal enemies of these important cultivations in check; and in many wheat-producing countries sterilisation of reed-corn before sowing has done much to exterminate smut-diseases.

The large bodies of workers in these countries are to a great extent helped and encouraged by the fact that the people for whom they are working have an intelligent knowledge of the methods and results of plant pathology and therapeutics. In America—where money's worth is required for money—£600,000 per annum is spent in supporting a large staff of experts whose efforts are directed to the improvement of agricultural methods, crops and stock, the introduction of new plants, and the prevention and cure of epidemic diseases.

It is true that there are cases of plant disease which have not been to any extent lessened or prevented by science. But even in the much older science of human medicine failures might be mentioned, and yet these still unsolved problems of the doctor do not in any degree shake the faith of thinking men in the value of medicine and surgery. The plant doctor has frequently to submit to the halfhearted carrying out of preventive methods, or the refusal to do anything at all to interfere with the progress of a disease. I myself, when advising the proved and practicable remedies for a certain disease, have been met with the remark: "Don't you think that if I got rid 'of this disease in my trees I should only get some other?" The mixture of ignorance, apathy and fatalism shown in this reply is, to say the least, not encouraging. Further, the plant therapist does not possess one of the chief weapons of the doctor and the "vet" against contagious and infectious diseases— isolation. Where it is possible in the case of a rusted wheatfield, a cankered larch plantation, or a blighted potato crop to isolate the diseased plants and prevent them from contaminating their neighbours, the plant doctor and the farmer would have a far easier battle against these diseases. The agriculturist is wont to complain that the number of diseases by which his crops are affected is so great; but comparing any species of cultivated plants with man, the horse, the dog, or other domestic animal, we do not find that the diseases suffered by them are less in number than those we deplore in our plants. Plant diseases are on the increase—for very evident reasons. In the economy of Nature the intermingling of species of plants with others differing in structure, habits and inherent characters hinders the progress

and endangers the existence of the organisms which cause the largest proportion of our epidemics. The spread of such diseases among human beings, sparsely scattered over a wide area, is low. In closely-packed populations the prosperity of the organism causing the evil is most marked. But the multiplication of large areas of plants of the same kind destroys the natural equilibrium and increases the danger of epidemics. This danger calls for corresponding precautionary measures. A hundred years ago the conditions favourable to the rapid spread of a disease caused by insect, fungus or bacterium were very much less than at the present day. But our weapons for an intelligent fight against the attacks of these organisms were then of little use, and were wielded without confidence. We have now, as in human therapeutics, got past the "bleeding for all evils" stage, and our weapons are of no mean order. Man's power over the organisms which injure cultivated plants is immeasurably greater than it ever was before, and his knowledge of the plants themselves is equally extensive. Indeed in many ways the knowledge of plant pathology and therapeutics will bear comparison with that of human and veterinary medicine.

All efficient measures for the preservation of health whether carried out by individuals or communities rest upon exact knowledge of the causes of diseases and the effects they produce in their victims. It is a matter for congratulation that there are a host of instances of the accurate tracing, by observation, of the causes of many diseases of plants. This has been accompanied by experiment, and it needs no argument to convince anyone in the least acquainted with inductive science that experiment is as essential as observation. The science of plant pathology and therapeutics has its giants, whose brilliant work has gained valuable positions in the advance of knowledge. Medicine has its leaders like Hunter, Pasteur, Simpson, Lister; and De Bary, Hartig, Tubeuf, Frank and others will be remembered as the pioneers in a science the importance of which, from an economic point of view, will by-and-by be as fully recognised as medicine or veterinary science. During the past fifteen years the discoveries made in combating insects and fungi which are parasitic on plants have made almost a revolution in agriculture, though this has not been so much felt in Britain as in other countries. The conservatism of the British farmer is a very marked character and leads to great delay in accepting the lessons learnt outside his own sphere.

The general laws of sanitation in plants do not differ very much from those laid down for preventive medicine in man or animals. They include the removal and destruction by burning of dead plants, or dead parts of plants, suffering from communicable diseases, as soon as the outbreak is noticed and before it has widely spread; the prevention of conditions which favour infection; the isolation by means of trenches of plants whose roots are diseased; and the exclusion or quarantining of plants from infected countries. These are but examples of sanitary methods which should commend themselves to every practical man, and have been used with great success in numerous cases. They are, however, almost useless without an intelligent watching for the appearance of disease, such as every careful mother or shepherd exercises in the family or flock. It is not unusual to find a lack of observation in noticing the appearance of blights on crops, so that the evil is not considered until the fields are most markedly devastated. Observation, too does not always lead to intelligent action. The farmer who seelug "smut" in his wheat takes no measures, and attributes it to the prevalence of "the mild plant," is not a myth and may still be found in Britain. It is necessary, when sanitary laws are announced, that they should receive the support of those they are intended to benefit, and a belief in such rules must be inculcated in those engaged in cultivating plants.

The machinery for technical instruction in rural districts in Edgland exists, and could be used (as it has been to a slight extent) for disseminating such doctrines. But the farmer will learn more by his eyes than by his ears. His own knowledge, which gives him what success he has in his art, has been gained by the use of his eyes, rarely by reading books or attending lectures. Demonstrations of the methods and results of plant sanitation, to which all agriculturists and horticulturists should be invited, should be carried out at local agricultural shows, at weekly markets and fairs, and at Colleges of agriculture. The interest the bee-keeping, dairy management and other demonstrations evoke at agricultural shows points to the fact that farmers are not averse to taking advantage of this, the best method of instruction. Landowners might arrange that demonstrations of spraying, fumigating, isolating by trenches and other operations should be shown at convenient places, where their tenants and others could come and see these things for themselves.

The science of plant pathology and physiology has opened a new epoch in agriculture, and British farmers should be alive to this fact. Let them not allow their competitors in other countries to profit at their expense by knowledge which they also might possess and which would enable them to get in advance of others by obtaining more from the soil, with less expenditure of time and money. It is difficult for those interested in these questions to avoid a tendency to "make the flesh creep" by exaggerating the probable results of supineness in the matter, but it is unwise, because the Britisher—and the agriculturist not less than other classes—directly he hears any suspicion of the shriek of the enthusiast, assumes an antagonism without relation to the gospel of the preacher.

The conversion of the agriculturist and horticulturist to these beliefs is not an easy matter, even as the agitation against small pox, vaccination and muzzling for rabies shows to be the case with human and veterinary sanitation. A shorter and perhaps better way would be for those who control such affairs in the State to satisfy themselves—as has been done by foreign governments—of the importance of plant sanitation and of the confidence to be placed in means already used, and then to enforce their practice. The history of sanitation shows that the existence of knowledge and the promulgation of methods were of little use till the force of the law was called into make the carrying out of these methods obligatory. The mortality in human beings and domesticated animals would be far higher in Britain if the laws with regard to notification and treatment of cases of fevers, small-pox, pleuro-pneumonia in cattle, swine fever, etc., were not enforced. There is little doubt that if the Board of Agriculture initiated similar measures to protect crops, in a short time those benefited would recognise their value, just as has occurred in other countries. In America the National Government exercises a supervision and control in matters of quarantine and prevention of disease in plants, and expects each State to provide for the proper and timely application of the most approved remedial and preventive treatment when found necessary. The actual laws as to the suppression of diseases among cultivated plants are enacted and carried out by each State. These laws vary to some extent in the different States, but they are all accompanied by penalties—both fine and imprisonment—for neglect of orders to carry out the prescribed treatment. In Michigan any person who neglects to remove and destroy a diseased tree or fruit, after such examination and notification as is provided by the law, is guilty of a misdemeanour, and punished by a fine not exceeding one hundred dollars, or by imprisonment in the country jail for not exceeding three months, or both.

Such legislation in America has been in existence for nearly 20 years, and is extending with the exact

knowledge of the method of spread of parasitic diseases and with progress in agriculture. A permanent legislative committee was appointed some few years ago to watch over and control matters relating to plant diseases, and this committee is in touch with the various local authorities. This was the result of a "National Convention for the suppression of insect pests and plant diseases by Legislation," held at Washington in 1897, and attended by some fifty agricultural and scientific experts.

In Germany official notice is annually given of examination for particular parasites, and these orders are carried out through the police authorities. In some of our own colonies, notably Australia and Canada, equally strict laws exist. Queensland has fully recognised the value of State aid to agriculture by giving it the best scientific advice, and by the "Diseases of Plants Act, 1896," of that Colony after enacting that certain importations of plants from places where diseases of these plants are prevalent are prohibited, every nursery is required to be registered and regularly inspected by an officer duly authorised by the Minister for Agriculture. In the event of the nursery being diseased, the officer notifies the nurseryman to take the necessary measures for the eradication of the disease, specifying the required measures in clear and easily intelligible language. For example in the case of fruit-fly disease the instructions are:—"All fallen fruit of whatever kind, whether harbouring insects or not, shall be gathered at noon of each day, and all pest-infected fruit shall be submitted to the process of boiling or be buried beneath not less than 1 foot 6 inches of solid earth. The trees shall be sprayed with one of the following mixtures." (The methods of preparing the mixture and the number of and interval between the applications are given.) That in countries where personal freedom is so carefully guarded such laws should be passed and carried out without friction shows that the planters of these countries are awake to the value of these legal enactments.

There are difficulties in carrying out such laws, and it may be urged that the inspection would be costly and hard to carry out efficiently; but these difficulties have been met with and overcome in human and veterinary sanitation, and even in plant sanitation they are not proving at all insuperable in countries where the system has been in force for some years. It is said that in Britain we are not yet ripe for this kind of legislation, and that popular opinion would disapprove of measures interfering with the freedom of tea cultivator. But history shows us that such arguments have been advanced against sanitary reform in men and animals. The effective carrying out of health regulations and the economic benefits which result have been the best answer to these objections. The Board of Agriculture could by means of existing data easily satisfy itself and others that the cost of the introduction and administration of sanitary laws for plants was money well spent. A series of epidemics, causing great losses to farm crops and other plants, would no doubt produce a different feeling in the matter, but would it not be wiser to learn by experience already gained, and not wait for further lessons from this expensive though effective teacher?

Looked at from the point of view of insurance against possible losses, or as an investment which will ensure greater profits, plant sanitation should commend itself to the business man. It is the duty of those whose interests are at all affected by the prosperity of agriculture—a fairly extensive class—carefully to weigh the evidence in other countries and at home in favour of sanitary methods for plants, and having convinced themselves as to their practical value, to lose no opportunity of furthering the cause of *Planta sana in plantario sano*, by inculcating the aims and methods of plant sanitation, and where advisable taking means to obtain the support of the State.

J. B. CARRUTHERS,

—Contemporary Review for May, 1902.

MODERN METHODS IN TOBACCO CULTURE.

BY A. M. HOWELL.

Perhaps I can entertain and assist the farmers of Victoria, in the columns of "The Australasian," by briefly outlining my experiences in the culture of tobacco. It may be proper that I should state, by way of introduction, that my training in the arts of growing and curing tobacco-leaf was acquired on the farm, in the Southern States of America, where I was born and reared, and where the choicest of "bright" aromatic tobaccos are grown. It may be added that in later years I have given close attention and study to the principles involved in both growing and curing—the really scientific principles that come within the easy grasp of the common run of intelligent farmers, and this means no more nor less than the application of good commonsense, once you see the how and the why. These principles are few in number, but they are not to be trifled with if the grower is aiming at tobacco of good quality, that will bring the highest market price, wherever he may sell it. There are just a few important—it may be said absolutely important—points to be strictly and rigidly adhered to, and these are:—

THE MAIN QUESTIONS INVOLVED.

1. The selection of a suitable soil for the type of tobacco desired to be produced.
2. The selection of a suitable variety or varieties of tobacco, looking likewise to the class and type desired.
3. The cultivation of the crop, including the work of the plough and hoe, the prompt and diligent pruning of the plants, the extermination of insect pests, and all else that can be done to promote the fullest expansion of the leaf.
4. Preparations for curing and the harvesting of the crop at the proper stage of ripeness, looking to a uniform yield of ripe, mature leaf and to desirable colours.
5. The curing processes—the ultimate tulle of the tobacco-grower—how to produce bright and beautiful colours that at once captivate the tobacco manufacturer and command the highest market prices, and pay the producer a good round profit.
6. The care of the leaf after it is cured, which means its preservation in sound condition, and the fixing of the colour, which may be lost or faded or deepened into other shades by improper management.
7. Packing and marketing—in the local home market or abroad—with extreme care as to content of moisture and the possibility of dangerous absorption of moisture in the hold of the ship.

SUITABLE TOBACCO SOILS.

In growing tobacco there is nothing more important than the selection of a suitable soil. This matter is co-important with curing the leaf. With the most skillful curing that can be done the influences of the soil are inevitably present. Proper curing will, of course, make the best that is possible of any leaf, grown upon any soil, but upon the character of the soil the grower must depend for the raw material out of which to turn out excellent cured leaf, of any given class or type. To grow the cigarette leaf, for instance, upon a dark, rich soil is impossible. Such leaf is produced on a sandy soil of only very moderate fertility, and cannot be produced upon any other with any degree of certainty. With a good season—a year of satisfactory rainfall—the certainty would be the reverse way—that fine cigarette goods would not be the yield from a very fertile soil. Granville county, in the state of North Carolina, is famous for its production of the finest types of bright tobacco, and they are grown upon poor sandy soils, so poor, indeed, that, to use an expression common in the vernacular of that region, they will barely "sprout cow peas." Soils of only medium fertility, containing a predominance of sand, are unquestionably best for

that general class of leaf required in Australia for pipe-smoking—classified in America as “manufacturing leaf.” Well-handled leaf from such soils will contain a deficiency of nicotine, will be of mediumly fine texture, will burn with freedom and with good flavour and aroma.

AVOID COMPACTED CLAYS

A hard, compacted, or tight, waxy clay subsoil should be avoided, especially if the top-soil or soil proper is shallow. Examine the roots of plants grown in such a soil, and it will be found that they have not reached any considerable depth, but have branched out laterally or have rebounded, so to speak, and appear crimped and crumpled, with but little growth where they have come into contact with the impenetrable clay subsoil. It will be found also that such soils quickly dry out down to “hardpan” in seasons of drought. The hard subsoil may maintain a minimum of moisture, sufficient to keep the plants alive, but there will be poor growth, and the product small, short, ribby leaves. The reverse will be the case if the crop is grown in a fine, deep sand, or sandy loam and for reasons that are at once obvious to the practical farmer. Such soils hold moisture with greater tenacity. Water rises to the surface by capillary force much more slowly in such soils. Consequently, there is less evaporation from them. Such soils come nearer than any others to maintaining just the proper quantity or percentage of moisture that plants require. In seasons of drought they hold moisture longer than fine, impalpable clays or silts, and in season of excessive rain they quickly drain themselves to the proper limit, which is very important to the tobacco crop in the matter of texture of the leaf. Tobacco will not stand an excess of moisture to be of good texture and flavour. It will grow coarse, and heavy, and excessively gummy in a saturated soil, or one nearly so.

SOIL MOISTURE, AND SYMMETRICAL GROWTH

It is easy to see that in loose, friable soils, with subsoils of like texture, the roots of the plants easily reach to considerable depths and to the level of permanent moisture without encountering too much of it. Now just here we come to a question of supreme importance in growing good leaf, and that is the matter of continued uninterrupted growth. In the production of leaf of the best and uniform texture the growth of the plants must go on unchecked. In that case there is regularity and symmetry in cell growth and constant, measured expansion. The soil that is capable of storing and holding persistently a moderate percentage of water is the soil that will promote and maintain the regular growth just described. In such soil, with fairly good seasons, the soil being not very rich in nitrogen, but having a plentiful content of potash and lime, the leaf will reach a satisfactory width and length. In all cases, once a tobacco crop is planted, everything feasible should be done to accomplish the greatest possible expansion of the leaf. It may be noted here that the ribs and veins of a tobacco leaf never increase in number from the time it is first unfolded in the tiny plant in the bed, no matter to what size and length it may grow. Count them when the leaf is the size of a shilling coin, and again when it is 2ft. or 3ft. long, and it will be found that they are the same in number. Now the greater the expansion of the entire leaf the wider the spaces between the ribs, and the greater the proportion of parenchymatous matter—or ribless and veinless tobacco. In cigar tobacco, if of the proper texture, the greater will be the proportion of wrappers, as cigar wrappers must come from the web of the leaf occupying the space between two lateral ribs. This maximum expansion is best promoted by a soil that maintains a proper percentage of moisture—about 40 per cent. of its water holding capacity—and no soil serves this purpose better than a fine, deep sand, or a sandy loam, with a friable, workable subsoil. In the American states the soils generally adopted by the most successful growers of fine tobacco are those above described, containing from 60 to 90 per cent. of fine sand. They are, in many cases, what geolo-

gists term transported soils or drift soils. Where the land is really too poor to produce leaf of sufficient size for the type wanted, manure or stable manure well rotted, is sparingly used, or, in its stead, commercial fertilisers, containing rather high proportions of the mineral elements such as potash and phosphate of lime. It is perhaps rare in Australia to find soils too poor in plant food to grow excellent tobacco. At least, I have found this to be the case in New South Wales, where I have had several years' experience in growing the weed.

DARK RICH SOILS UNUITABLE.

The main objections to dark, rich soils, such as the silty, humic flats along the rivers and creeks, is that in season of generally satisfactory rainfall they overdo what the intelligent, ambitious tobacco-grower requires. They produce what may be termed “too much of a good thing”—coarse, heavy leaf, with enormous ribs and veins, with too much gum, too much nicotine, rank, strong stuff, that is devoid of that delicacy of flavour and aroma that pleases the average smoker; and such tobacco has to be very considerably steamed and manipulated to get it to burn well in pipe or cigar if, indeed, it can be used at all for the later form of smoking goods. These dark, rich soils contain too much nitrogenous matter and that kind of plant foods tends to coarseness to large growth which however desirable in maize and some other farm crops, is modifiedly the reverse of what is wanted in a crop of tobacco.

REARING TOBACCO PLANTS.

As the season is at hand for sowing seed, perhaps a fitting conclusion to this contribution would be some suggestions on the production of plants. Tobacco seed should be sprouted before sowing. Fold the seed up in a dark wollen cloth, about three-ply, to compactly with twine, and soak the packet in warm water for 12 or 15 hours. Sprout a well-rounded teaspoonful of seed for every ten square yards of bed which should produce a sufficient number of plants for two acres. When the packed seed has been soaked in warm water for the time stated, put it in a closed tin or other similar vessel, and place in a warm situation, as near the kitchen stove, and keep warm and moist until the seeds show general sprouting. The bulk of seed should show quite a speckled or grey appearance with germinated seed before sowing. Have the bed ready—a rich, black soil is best for producing plants. To prepare the bed, dig and pulverise to the finest tilth to the depth of 12 in. to 18 in. use no manure. After the bed is fined and levelled, pile wood upon it plentifully, and burn it well, so that the soil is well cooked to the depth of 12 in. or 3 in. This process destroys all vestiges of insects, and the seeds of noxious grasses and weeds and improves the texture of the soil. Again rake the bed well, and clean it of rubbish. The seed being ready, as above described, mix thoroughly with about half a bushel of moderately dry fine, sifted soil, adding sufficient ashes or cornmeal, or other white material to give the mass a bright appearance, so that it can be seen in contrast with the soil of the bed. Make sure that the seed and soil are very thoroughly mixed, by sifting through a fine sieve a number of times. Sow by hand lightly and evenly, never allowing handfuls to fall in a place. Make three or four sowings instead of sowing all at one going over. In this way an even and regular distribution of the seed will be accomplished. Sweep the bed very lightly with an ordinary house broom, dragging the broom rather than brushing. Water the bed freely at once with a fine-rosed sprinkler, slowly so that the water does not run on the surface and float the seed into heaps. Now cover the bed with the cloth called bessian, the cheaper, open quality, laying the cloth, flat upon the bed in contact with its entire surface, and pin it down securely on all sides. All future waterings, until the plants are well up, must be done upon this cloth, which takes the water readily and prevents it from flowing on the bed's surface and washing the seeds out of place. The seeds will “come up” better under this cloth, and more evenly,

than in the open air, especially if there is any wind. The tiny seedlings will appear in from two to four days, and the hessian may remain lying upon them for two or three days longer, or until the plants show signs of stretching—their stems lengthening out as they reach upward for more light. Stretching must not be permitted, as it greatly weakens the plants. The hessian must be raised about 3 in. or 4 in., resting on poles or cross-sticks for support. From this period on the bed of young plants should have a plenty of light and moisture, and should be covered only at night for protection from cold and frost, and during the heat of the day for protection from a very hot sun. To nourish and hasten the growth of plants liquid manure should be used—a very weak solution at first when the plants are young and tender, and of greater and greater strength as they grow larger and become more hardy. Very strong liquid manure should never be used, however. The beginner is apt to make it too strong. Good barnyard or stable manure, well rotted, is the proper material. Soak it in water, strain and dilute with water with judgment, being careful to err, if at all on the safe side by making the solution too weak rather than too strong.

PROTECT THE PLANTS.

Beds of tobacco plants should by all means be protected from the wind, especially dry, hot winds. So, protected they will grow much more rapidly and perfectly, and should become sufficiently developed for transplanting in about eight weeks from the time the seed is sown. For avoiding the wind there is no better plan than hoxing in the bed with boards, and it is not a bad plan to have the bed in a pit its top about 12 in. or 18 in. below the surface, in which case care must be taken that water does not flow into it during heavy rains. In the woods far removed from the fields of cultivation, near a river or creek, is the best place for the plant-beds, looking to the avoidance of fungus diseases and destructive insects that may infest the farm premises, and to a constant supply of water.—*Australian.*

THE FORMOSA TEA INDUSTRY.

Memorandum on the Tea Industry of the Island of Formosa.

BY THE BRITISH CONSUL AT AMOY.

The following notes have been drawn up from personal knowledge supplemented by information furnished by the Japanese authorities. Attached hereto will be found a pamphlet* issued by the Formosa Government which will be of interest, and will, it is hoped, assist to a clear understanding of the tea industry.

* The pamphlet may be seen by those interested at the Chamber of Commerce.

With regard to the Export of tea from this Island, the "season" does not coincide with the twelve months' returns from January to December of the Customs tables, and an extract has therefore been made (see below) for the sake of comparison from both the Customs returns and the Consular reports on the season's yield for the last five years and seasons, dating from 1897, when the Island was still suffering from the effects of disturbances consequent on the Japanese annexation.

Export of Tea, 1897-1901, extracted from the Japanese Customs Returns.

YEAR.	OOLONG.		PONCHONG.		TOTAL
	Quantity.	Value.	Quantity.	Value.	
	lb.	£	lb.	£	
1897 ...	17,857,438	651,583	2,145,152	46,794	701,377
1898 ...	17,422,631	569,684	2,704,185	52,673	£22,357
1899 ...	—	549,834	2,918,277	60,812	610,646

1897-1898 ...	484,061	—	484,061
1898-1899 ...	424,271	—	424,271
1899-1900 ...	377,848	32,502	410,350
1900-1901 ...	359,000	39,000	3,8,000
1901-1902 ...	338,500	64,500	403,000

Especially worthy of notice, apart from the steady decrease, up to last year, in quantity and value of this Export, is the growing trade via Kelung to Kobe for further shipment to the United States at the expense of the Amoy trade during the last three seasons. The inclination of the Japanese authorities is naturally all for the development of the Export of this staple to their own country, and it receives every encouragement from them in that direction, in respect of harbour development at Kelung and by means of preferential duties or harbour dues. The Oolong teas are the final quality of teas produced here and are destined for the American and London markets, whilst the Ponchong tea, which is, both as regards manufacture and export, in Native Chinese hands, is sent for consumption to the mainland and the Straits Settlements. This latter tea is highly scented by means of the blossoms of certain fragrant flowers—among them being those of the gardenia, the Tehn-lan (*aglaia odorata*, Lour.) and Magni (*Jasminum Sambac*), but the Oolong teas are not dependent on any adventitious aid for their aroma. The following notes on the preparation of tea have to do solely with Oolong leaf. It will be understood that the leaf goes through two courses of preparation, one at the hands of the cultivator or planter, and the other by the tea-merchant at Twaentia (Jap. Daidotei) the local tea market and export centre, where the leaf purchased from the planter or broker undergoes another firing, and, after sorting, is put up in chests for shipment to Amoy or Kobo. It will be noticed that no kind of machinery is used in the manufacture, the entire process being carried out by hand with the aid of very primitive utensils, made principally of split bamboo in different forms, which, however, seem admirably adapted to the end desired. The wood used for chests is imported from the mainland ready cut into small pieces of standard size suitable for building up the boxes. The lead foil with which the boxes are lined is made by hand, being pressed when in a molten state between large tiles, and then cut to measure locally, the lead use for the purpose being imported in pig form from Australia. The districts under tea cultivation in this Island lie between Lat. 24°N. and Lat. 25°10'N., extending from Taichin and Shoka in the South, and Keung and Kimpooi in the North; the intervening country being almost continuous stretch of hill and uplands. The parts most famous for tea are the hills and uplands on both banks of the Tokoham and Kelung rivers, whilst of these tracts the locality which yields the choicest leaf of the whole Island is Paichipo, the upland country around the eastern extremity of the Tokoham river.

The table below gives the names of the principal producing centres and the respective areas under tea-cultivation:—

Prices of all commodities and consequently of labour have risen year by year since the annexation of the Island to Japan. Rice in particular has gone up in value to an extraordinary degree, and great distress has generally been felt in consequence. The expense of such industries as the manufacture of tea have experienced an increase of fully 60 per cent in ten years, or an average of 6 per cent per annum. The following is an estimate of the expense entailed in the preliminary manufacture of tea for delivery to the tea-merchant; taking 100 catties of tea as the unit (1 catty = 133 lb.)

RENT (say)	£. s. d.
Note.—Rent of one "Ko" (1956 sq. yds.) is gold yen 30, or £3 2s. 6d. A "Ko" bears 10,000 plants and produces 600 cattiees of raw tea	0 10 5
CULTIVATION (say)	0 6 0

Note.—The tea-gardens are tilled four times a year, in spring, Summer, Autumn and winter. For one "Ko" of garden 43 coolies are employed, their wages being 40 sen (10d a day including food, making a total of £ 1 15s.

PREPARATION OF TEA (say)	1 8 4
Note.—Subdivided as follows:—	£. s. d.
Picking	0 12 6
Fuel	0 1 6
Charcoal	0 1 10
Labourers	0 4 6
Do, food	0 8 0

Total...£2 4 9

Over 100,000 persons are engaged in the production of tea in this Island, and it is said that in Tawatutia alone those occupied in the business number over 10,000 males and females. Labourers in the districts given up to the cultivation of tea-gardens are all natives of Formosa, and in the intervals of tending the tea are all engaged in farming and agriculture.

With regard to the labour engaged in the final preparation of the tea, the sorters are all natives of this Island, but the remainder immigrate temporarily from the mainland of China as occasion requires. This custom is of long standing, and intending employers have to engage their men in advance, making the re-engagement at the close of each season when their employes returns to China. Their passage money is advanced to them, half the wages of the season is paid to them on account, and the balance is handed to them when they leave the Island. Rates ruling for labour are approximate as follows, when calculated by the month:—

	s. d.
Tea-coolies in Tawatutia	14 7
Tea-sorters (women and gir's)	9 5
Tea-garden labourers	15 8
Tea-cultivators	18 9

Wages paid to coolies by tea-merchants and farmers vary, but the above is a fair average. Wages paid by the merchants in Tawatutia are given above as for the month, but they are as a rule estimated in the lump for the nine months or so of the season. Tea-sorters are paid by the day, and it is the general custom to supply coolies and sorters with food, at an average cost per head of about 6s. a month. Tea-gardens in Formosa are, as a rule, held by natives of the Island, who either rent uncultivated land from the owners, paying certain rates for fixed periods, and plant tea for their own profit; or rent a garden already planted. The former pay about 6s. a year for one "Ko" of untilled land, and the latter a rent of about £2 10s. the "Ko" per annum. As already stated there are two processes in the manufacture of tea; the preliminary preparation or curing by the planter and the final process carried out by the export-merchant. There are many methods practised by the cultivator in the first process, varying with the different districts, but the variation is unimportant. The successful production of Oolong tea depends greatly on the weather, and whether the season is favourable to the development of the leaf. The preliminary preparation of the leaf is, according to the season of the year, as follows:—

DISTRICT.	AREA. Acres.	NUMBER OF PLANTS.
Paichipo	274 81	6,300,000
Haiseoanpo	601 86	14,879 600
Bunsoanpo	757 74	22,500,000
Sekiteito	1,473 87	36,470,000
Tokampo	2,249 60	62,890,000
Aachirifumpo	1,114 14	6,080,000
TOTAL...	6,471 52	149,119,600

SPRING TEAS.—The fresh picked leaf is first spread on a cotton cloth (No. 3, plate 10, of the pamphlet), and dried in the sun until it curls up. This is to assist fermentation, and takes about 20 or 30 minutes, the workman in the meantime turning it over once every five or six minutes. The moment when this process is complete is recognized by the smell, and the tea is then taken under shelter to finish curling which is carried out as follows:—A small quantity (about 1½ lb. or 2 lb.) is laid on flat round trays, made of split bamboo, arranged on shelves (No. 4, plate 10, and see plate 11), and the leaf is turned over at intervals of four or five minutes to let the air circulate freely, whilst it is rubbed between the hands to promote fermentation. Fine dry weather is required for this part of the process, as damp weather destroys the aroma. After the preparatory indoor drying has gone on for about two hours the leaf is emptied into larger trays (No. 6, plate 10, and see plate 11) holding some 30 to 40 lb. and turned over by hand for another two hours or so at intervals of about ten minutes or a quarter of an hour, the process being considered complete when the leaf shows reddish brown at the edges, and gives out a fragrant scent in place of the raw smell of the green leaf. It then undergoes a first firing. About 2½ lb. to 3 lb. or more of the leaf is placed in a shallow iron pan over a fire (No. 7, plate 10), after three or four minutes the leaf softens owing to the evaporation of its moisture, when it is removed to another pan and fired for another two or three minutes. (Some prefer to fire the tea for six or seven minutes in one pan only.) After this it is transferred to small split bamboo trays which are placed on the "hai-i" or rubbing-table, where the leaf is rubbed and pressed by hand for two or three minutes. The second firing, is much the same as the first, the only difference being that in the latter case the fire is not so hot as in the other. After the second firing, the leaf is poured out into a "toppin" or bamboo mat (No. 9, plate 10) and rubbed and pressed between the hands for some seven or eight minutes until the moisture comes out of it, which is a sign that this process is finished. The compressed leaf is then well separated by hand, and is put to the first drying, the method of which is as follows:—5 lb. or 6 lb. of live charcoal are put into the fire places (plate 12), and after the fumes have dissipated a "poelan" or bottomless round bamboo cylinder (plate 12) is set on the top, and on this rests a fine mesh sieve (No. 10, plate 10), holding about ½ lb. of the leaf at a time, where it is dried for one or two minutes. For the second drying the process is repeated. The leaf is then subjected to a third drying to complete the entire process before delivery to the merchant. In this last drying it is necessary to keep up a slow fire, and the fire is therefore banked up with ashes, the frame over it, and some 6½ lb. of tea in the sieve which surmounts it; the leaf being turned over once in 10 minutes for 2½ to 3 hours. Owing to the cooler weather, raw leaf prepared for spring teas, takes a very long time in curling—and the liquor, appearance and aroma being all inferior the tea commands a low price.

SUMMER TEAS.—The process of preparation is identical with the foregoing, but owing to the difference of the temperature the time occupied in curling is shorter (see table below). The leaf prepared at this season is of the very best quality.

AUTUMN TEAS.—For time occupied in process of preparation see table. These teas are only inferior to the summer teas, with a good aroma, and find a ready market.

WINTER TEAS.—For time occupied in process of preparation see table. Tea prepared at this season is, for climatic reasons, inferior in aroma, and can be classed with the spring teas.

The table below gives the times for the steps of the preliminary preparation at the four different seasons of the year:—

	Spring Teas.		Summer Teas.		Autumn Teas.		Winter Teas.	
	h. m.	h. m.	h. m.	h. m.	h. m.	h. m.	h. m.	h. m.

Questions addressed to tea planters with regard to variation in quality of teas elicited the opinion that this depended greatly on the care and attention given to the four steps of turning over, drying, rubbing and firing. If the turning over is carried on for too long a period, the leaf becomes soft and loses its aroma. Especial care must also be taken that the leaf be turned over uniformly. If the pan-firing process is too quick it leaves a raw smell in the leaf, and if it is too slow it dissipates the aroma. It is important that every part of the leaf should be brought into contact with the pan. If it is subjected to an insufficient rubbing the leaf will not curl. It is better to rub too much rather than too little as the rubbing and rolling have a great effect in producing a good scent. If the leaf is insufficiently fire-dried it will not yield a good aroma, and owing to the moisture remaining in it will easily deteriorate in quality afterwards. On the other hand if the fire-drying is too prolonged or the leaf is exposed to too much leaf heat, a poor aroma is the result. Great care has to be exercised therefore to insure a properly graduated drying. Four catties (533 lb.) of raw leaf yield one catty of rough prepared tea; therefore, as 10,000 plants give 20 piculs (1 picul = 100 catties) of raw leaf, the same number of plants will yield five piculs or 665 lb. of prepared tea. The final firing of the tea in the godowns of the merchant reduces the weight by another 10 or 15 per cent. The last process consists of sorting the tea by hand and sieve (see plates 13 and 14), when it is fired for some 12 hours, with an interval of cooling for one or two hours after 7, 8, or 6 hours' firing, and is then packed for shipment. The merchants are of opinion that the final firing is the crucial step of the whole process.

AN ACCOUNT OF THE CULTIVATION AND MANUFACTURE OF FORMOSA TEA, PUBLISHED BY THE DEPARTMENT OF AGRICULTURE AND COMMERCE OF THE GOVERNMENT OF FORMOSA.

(Translated from the French.)

FORMOSA TEA.

In the North of Formosa between 20° and 25° 10' North Latitude, there stretches a district of from 160 to 170 kilometers in length and 80 to 120 kilometers in breadth, intersected everywhere by chains of mountains which occupy two-thirds of its surface. This tract of land, which is entirely cleared, is the centre of the production of the tea called "Oolong" whose quality is renowned. The numerous villages, which cover the valleys there, are inhabited by Tea Planters. For the most part these plantations are in terraces on clayey slopes which facilitate drainage; this advantageous position joined to a climate particularly favourable gives them a solid prosperity. The temperature does not rise above 28° centigrade (82° Fahrenheit) in the highest summer heat, never falling below 10° (55° Fahrenheit) in the depth of winter. The yearly rainfall is, 2000 m/m. The plantations are therefore exempted from an intense

heat and a vigorous cold, which would both be injurious to their fertility. In this region, so privileged by nature, the cultivation of tea has succeeded in reaching an extraordinary extension, so much so, that the slopes and the valleys are entirely covered with this luxuriant vegetation. Of all the plantations the best known are those of Tokanpo, Haisoanpo, Chutenpo, Paichipo and Bunsanpo situated on the upper course of the River Tamsui, in the valleys of Toakoham, Keelung and Shintiam.

The origin of tea cultivation in Formosa is obscure, but it is believed that the tea plant was imported thither from China, about 100 years ago.

At the commencement, the cultivation was limited only to a few unimportant plantations started on the outskirts of Taipei by some private individuals for their personal use; but from 1855, it began to develop, and from that date steadily extended year by year. At the same time, owing to the choice of varieties of tea and to the improvement in the process of preparation, the yield and the quality of the product did not cease to improve, so that to-day the north of Formosa is endowed with an abundant wealth. Eight varieties of tea have been introduced there according to the soils that suit each of them. The different varieties cultivated reach a height varying between 0 meters, 4 and 0 meters 7 or 8.

Generally the plants are obtained by sprigs. Transplanted, they begin to yield after 4 years, and from the 13th to the 16th year which follows their transplantation, they undergo a stump cutting. The picking of the leaves takes place 6 or 7 times during the year, from April to November. They pick only the young terminal leaves which are plucked by the hand, three at a time with the greatest care. The teas are known according to the season of the picking. There are the Spring, Summer, Autumn and Winter crops. The extent of the plantations varies from 100 square metres (about 1/40th acre) to 300 square kilometres (71,114 acres). Their output is about 1,200 kilogrammes (2645 lbs.) of green leaf per 10,000 square metres (2471 acres) = 1070 lb. per acre. The cultivation is simple and easy, the soil naturally fertile claims only four tillages during the year and it does not require any manure which, far from being useful, would deprive the tea of its characteristic flavour, as has been proved by experience. The tea of Formosa is prepared in two different methods, according to which it is either called "Tea Oolong" or "Tea Pawchong." "Oolong" Tea is of long standing in Formosa, but the production of Pawchong tea is rather recent. We shall now sum up briefly the Processes of Preparation of the two above-mentioned kinds of Tea.

OO LONG TEA.

The preparation is two-fold. The first which is but temporary is made at the Tea maker's. The second which is the final one, on the premises of the Tea merchant.

A. TEMPORARY PREPARATION.

As the work is done by men's hands only and without any machinery, the result depends on cleverness, which is acquired only after years of practice; in fact it is a question of real art which is grasped by workmen of experience, who reach a perfection absolutely inimitable, and which entirely depends on the individual himself. This is the process of the Temporary Preparation of Tea:—The picked leaves are spread on a cloth called "Moa-po-tia" and put out to dry in the sun, in order to obtain a first softening. Then they are stored in a room, where they undergo a second softening, heaped up in "kalei," (a sort of frame or round board made out of bamboo strips interwoven) placed one over the other. Poured back into vases called "kamwo," they are submitted to a third and last softening, before being warmed in pots. The softening, having for its object to perfume the tea by the fermentation that it produces, is a delicate and important operation which requires from the workmen great cleverness. In order to obtain a good result from the three suc-

cessive operations, it is necessary to constantly observe the state of the weather and to take note of it. The heating in pots (a la marmite) is made at two different times. In this operation the difficulty is to get the necessary degree of heat. When out of the pots (marmite), the tea is dried at three different times in vases called "Poelan" with a fire carefully regulated. These are the different operations necessary to the temporary preparation of tea. It is said that this process requires altogether 7 h. 50 in Spring, 5 h. 54 in Summer, 7 h. 33 in Autumn, and 7 h. 13 in Winter. What is essential in the preparation of "Oolong tea" is to give it first its perfume, then its flavour and colour which is seen when decocted. Its appearance, when dry, is a matter of less consideration. The preparation of "Oolong" tea consists then:—1. In a scrupulous care to be used in the softening and the desiccation. 2 In a careful examination of the prepared tea which is obtained through the proper and correct tests which every tea-planter and cultivator possess.

The ratio of the weight of the green leaf to that to which the preparation called "temporary" reduces it being 4 to 1, it follows that a plantation of 10,000 square meters will produce 300 kilogrammes of tea of "temporary preparation," if its yield in green leaf is 1,200 kilogrammes. The tea of "temporary preparation" if its yield in green leaf is 1200 kilogrammes. The tea of "temporary preparation" is called "tea in bag," because the producers carry the same and deliver it in bags of the capacity of about 34 kilogrammes.

B. FINAL PREPARATION.

The tea merchants of Toa-Ko-Ham buy from the cultivators the temporarily prepared tea which then undergoes a second and last process in the manner following:—The leaf is passed through a perforated framework, being then thrashed with a winnow called "Shokalei." In this manner only the finest leaf remains. This is then put for 7 or 8 hours in an oven and warmed to the right temperature. This work finished, the tea is packed in cases. The second preparation reduces from 10 per cent to 15 per cent. the original quantity of tea which has been so treated, and the tea cases are of a square shape, in wood, fitting exactly to a doubt case in tin. The wood used for the manufacture of the outside case reminds one of "Cryptomeria," but it is harder and less elastic. Every year it is imported from Amoy. The dimensions of the cases are not uniform; some can contain 20 to 33 cattles (27 to 44 lb.), others from 7½ to 15 cattles (10 lb. to 20 to lb). The large size is called a "half-chest" and the small a "box." Outside, all the cases are wrapped up with paper upon which are designed flowers, birds or personages, and which bear also the name of the tea merchants. Tea, after its second process, is commonly called "tea in case." "Oolong tea" holds the mean between black and green tea, from which it is distinguished by its delicious perfume and agreeable flavour. It has both refreshing and stimulating properties. It bears different marks which are generally used in the markets of Amoy and America as distinguishing the qualities:—

1st. Choicest.	5h. Superior.
2nd. Choice.	6 h. Good.
3rd. Finest.	7th. Fair.
4th. Fine.	8h. Common.

Although known in China since the olden times, the method of preparation of "Pawchong tea" was introduced into Formosa only 19 years ago. Its preparation consists of heaping up in a closed room "Oolong tea" mixed with fragrant flowers which impart to it their perfume. This heap is then dried and the flowers are finally removed. Tea so prepared yields a sweet taste and a peculiar smell. The flowers intended for this use are of four different kinds which give their name to the tea which they

perfume. Pawchong tea is wrapped up in separate paper packets and packed in a case whose partitions are covered with tin foil just as in the case of Oolong tea. The outside is wrapped up with paper which bears a description of the contents, and the whole is covered with a bamboo mat. The cases are described as being of 1 nin (= 37 grammes and ¼ of silver), of 2 nin or of 4 nin according to the quality of the merchandise they contain, although the capacity is equal to 20 cattles (27 lbs.) for all the cases.

The export trade of Formosa tea owed its source to an attempt made by the Englishman J. Dodd, 31 years ago, with 5,000 lb. of tea which he forwarded to Amoy, and from there to the United States through the English firm of Messrs Tait & Co. From that date this branch of commerce made very quick progress. Formosa tea has surpassed in reputation all similar products of the Far East imported into the American market. It has attained the first rank amongst the articles of commerce in the Island, and its export has now reached the value of 6,000,000 yen per annum. The United States of North America are the most important buyers of Oolong tea. Nine-tenths of the whole export of Formosa tea go to their markets. A small quantity is exported to Canada and to England.

The cargoes intended for America come down the river Tamsui and arrive at the port of the same name, where they are transhipped aboard steamers and sent to Amoy and from there to New York via the Suez Canal. Eight or nine-tenths of Pawchong tea are forwarded to Java Borneo Sumatra and Australia: the remainder is sent to Annam Siam Singapore and to other parts of the Straits Settlements. The shipments intended for Australia go via Amoy and those for Annam and Singapore via Hongkong.

DESTRUCTION OF INSECTS.

We have received from the *Academie des Sciences*, a brochure by M. M. Vermoral and Gastine on their latest experiments for the destruction of the *Pyrale*. Finding any pulverisations with liquid insecticides, soapy emulsions of nicotine petroleum, or pyrethrum, etc., useless, as these do not reach the insects wrapped up in the tender leaves by means of a web they weave for themselves, they tried arsenical solutions, salts of baryum, etc., in order to poison the leaves. But the wise creatures avoided these. Finally they had recourse to gas and toxic vapours, operating under conical metal bells, inside which increasing doses of gas were let out. But even these were unsatisfactory in their results. So they made an entirely new experiment with heated air. The pyrales, exposed to a hot vapour of a temperature of 48 to 50° centigrade, died in 3 or 4 minutes. They are killed at a much lower temperature (45 C.) if exposed for 10 minutes. Towards 40° C., they struggle and come out of their retreats, and the tender foliage is not destroyed at that temperature. The method of operation is further described. Metal bells were used and flexible tubes conveying watery vapour.

PLANTING AND PROGRESS IN THE
FEDERATED MALAY STATES.
EXTRACTS FROM ANNUAL REPORT FOR
THE YEAR 1901

By the Resident-General W. H. Treacher,
C.M.G.

MINING.—As regards the chief industry, tin mining, while the average price of the metal for the year was lower than in 1900—\$67.56 per pikul of 133½ lb (£108.15 per ton) against \$74.15 (£132 per ton)—the output was:—

	Pikuls.	Tons.	Value.	
1900 ..	713,000	42,440	\$52,800,000	£5,500,000
1901 ..	789,000	46,960	53,600,000	5,240,000

The out-turn approximated to that of 1896, which ranks next to 1895, in which year the largest record for the Federated Malay States was obtained, pikuls 825,000, the sterling price being £62 per ton only, or \$32 a pikul. The labour force is returned, approximately, at 170,000 against 168,000 in 1900.

Tapioca cultivation is extending in Negri Sembilan and a condition attached to the alienation of fresh land for this product is that the planter must introduce some "permanent" form of cultivation, such as coconuts or rubber. Tapioca cultivation has been commenced in Pahang and will be encouraged. In Perak, especially, a considerable area of native-owned land is planted up with fruit trees. There is a ready sale for fruit to the miners, the trees require or receive little attention, and this fact indisposes the native to the more arduous labour of paddy cultivation.

The total forest revenue for the year under review was \$287,542 and the expenditure \$97,789. For 1899 the receipts were \$212,730, and for 1900 \$242,936. The estimated revenue for the present year is \$260,000. It must be recollected that since the commencement of 1901 the collection of gnta percha *Palaquium* has been prohibited. The department is now *inter alia* energetically engaged in continuing to search for and reserve tracts known to contain palaquium trees, in planting up and supplying from nurseries, and in facilitating the growth of

self-planted trees in the palaquium reserves. It has been found necessary to close, to a great extent, the mangrove (fire-wood producing) forests in Perak, which prove to have been over-exploited. These forests are being examined, surveyed and reserved. In due course working plans will be framed and the forests will be worked and become a source of considerable revenue.

GOVERNMENT RAILWAYS.—Open Lines.—The mileage open for traffic at the end of the year was 244½ miles (Perak 147, Selangor 97) as compared with 234 miles in the previous year. The nett revenue was \$1,079,118, showing an increase of \$43,750 over the results of the year 1900. The gross earnings were \$2,240,822, and the gross expenditure \$1,261,704. The proportion of working expenses to gross receipts was 53.99 per cent, as compared with 50.41 per cent. The worst percentages were shown by the new Province Wellesley section 91.77 and the new Larut and Krian section 91.94.

The Railway capital account of open lines is given as:—

Perak	\$10,637,387
Selangor	7,896,624
	<hr/>
	\$18,534,011

and the return earned thereon during the year was 5.82 per cent, being for Perak 4.72 and for Selangor 7.30 per cent. The average cost per mile of construction and equipment of open lines to the close of 1901 is reported to have been \$75,754—this includes the cost of constructing wharves, piers, buildings, sidings and the purchase of land at six ports, the expenditure at Port Swettenham alone amounting to \$1,108,791. The new rates and fares referred to in my last report came into force during the year. The present rates are said to compare favourably with those charged on the Ceylon Government Railway, though the cost of maintenance and working is higher than in that Colony. The figures of capital account above given do not include the large sums assigned for the extensions in hand.

CONSTRUCTION.—The estimate for the cost of the 179 miles of extension, the construction of which was commenced in 1896, put by the revised estimates of December, 1900, at \$16,472,982 has been raised by \$389,778 so that the estimated cost per mile is \$100,380. Of these 179 miles there were open to traffic at the end of the year 82 miles. The total expenditure on the extensions up to 31st December, 1901, is given at \$14,103,743, all furnished by current revenue of the States.

Towards the close of the year arrangements were made for the engagement of a party of surveyors from Australia for the survey of the proposed extension from Seremban (Negri Sembilan) through Kuala Pilah to Kuala Gemas, on the Johore boundary—some 54 miles. A provision of \$87,000 has been made for this survey, which is now in hand. With the completion of the extension to Kuala Gemas there will remain only the State of Johore to be traversed say 120 miles, to complete the line from Penang to Singapore. From Kuala Pilah will probably be the most accessible route for railway extension from the main west coast line into Pahang.

ADMINISTRATION.—A General Manager of the Federated Malay States Railways was appointed during the year—a long-needed step in the right direction. The appointment was conferred upon Mr C Edwin Spooner, lately State Engineer, Selangor, from whose annual report I have gathered the information summarised in these pages. Mr Spooner was transferred to the service of Selangor from that of Ceylon in 1891, and among other works carried out the Kuala Lumpur Water Supply, erected the admirable block of Government Offices, Kuala Lumpur, and engineered the fine road over the Semaugko Pass from Selangor into Pahang.

PUBLIC WORKS.—The total expenditure on Public Works, exclusive of the cost of establishments was \$3,600,000.

IRRIGATION : KRIAN (PERAK).—This scheme was commenced in 1899. Owing to difficulties experienced in procuring labour and to the unhealthy nature of the work, the scheme is not likely to be completed before the close of 1904. Approximately 100 square miles of paddy land will be served by the works. The headworks will impound some 7,256,000,000 gallons of water in a sheet of water covering 10 square miles. The main canal is 15 miles in length and there will be 20 miles of branch canals, and, in addition, a large number of distributaries. The main canal will be capable of carrying 650 cubic feet of water per second. The scheme will supply water for domestic purposes as well as for crop irrigation and will act as a complete system of drainage in seasons when the rainfall may be excessive. The estimated cost is over \$900,000.

THE CAUVERY FALLS ELECTRIC POWER INSTALLATION.

Despite a hitch in the line arrangements, leading to a breakdown at the start, the Cauvery Falls scheme promises well. The Falls are ninety miles from the Kolar Gold-Field, on which not only is coal dear, but the scanty supply of water is another difficulty. Although not the longest electric transmission line in the world, there being one of 135 miles length in the United States, the successful operation of the plant is a very important and interesting event. The contract with the Mysore Government provides for the supply of 4,000 horse-power to the various mines under Messrs John Taylor and Sons' management with the option of additional power to the same extent later. It was estimated that the first 4,000 horse-power would cost the Mysore Government £300,000 to provide, while the provision for doubling the power if required by the mines, as no doubt it will be eventually, will entail the duplication of the plant, involving altogether a cost of some half-million sterling. The agreement with Government is for ten years, for the first of which £29 per horse-power is to be charged per annum to the companies; for the second, third and fourth years £18 per annum and for the fifth year not exceeding £24 per annum. By that time it is estimated that the Mysore Government will have recouped a good part of the expense it has been put to and for the remaining five years of the contracts the companies are only to be charged £10 per horse-power per annum. The Chairman of the Mysore Gold Mine, rather more than a year ago, gave the average cost of working by steam as £30 per horse power per annum, so that the advantage to the mining industry, apart from the important question of saving water, is obvious.—*Railways*, Aug. 13.

"IMPERIAL DEPARTMENT OF AGRICULTURE" FOR THE WEST INDIES.

From Dr. Morris we have received copies of: Reports on the Botanic Station, Agricultural School and Land Settlement Scheme, St. Vincent, 1901. Report on the Experiment Stations at Monserrat, 1900-1901. Reports on the Botanic Stations and Agricultural School, Dominica, 1900-1901. The Reports shew that good work is being done, especially in Dominica. Here are two interesting paragraphs referring to the last-mentioned Colony:—

African Rubber (*Funtumia elastica*): The trees continue to make progress. Should the yield and

quality of rubber prove good under the condition in which the plants are growing, this tree will have proved itself hardy and worthy of cultivation in the West Indies.

Central American Rubber (*Castilloa elastica*):—Five of the largest trees (over eight years old) are now ready for tapping experiments. A second batch of these plants are growing well in another part of the station. When young this plant requires as much shade and attention as cacao. At this stage it is also liable to attacks of a 'white blight.' In Tobago this tree is being used experimentally as shade for cacao. That it may be cultivated side by side with cacao may be seen at this station where cacao trees, within a few feet of it and under its shade, continue in health and bear good crops.

THE RUBBER FAMINE.

To the Editor of the *India-Rubber and Gutta-Percha Journal*.

Dear Sir,—Your correspondent who writes about "The Rubber Famine" appears to have as much knowledge of the subject as a cow has of playing the flute. How can any sane man talk about a "famine," whilst the imports into Liverpool alone are about six thousand tons yearly, to say nothing of the supplies received in Hamburg, Antwerp, and elsewhere? The supply is practically as inexhaustible as the sands on the seashore, and even if millions of rubber trees are ruthlessly slaughtered, others go on growing behind them as rapidly as the weeds in the back garden. There are, of course, fluctuations in the supply from certain districts, and difficulties in the way of collection and transport, but the supply is unlimited, and exports will certainly increase just as they have done steadily from Para, whence the output when I first knew the trade was only eight thousand tons yearly, but has now increased from 21,640 tons in 1896 to 27,730 tons last season.

NIVLOC.
—*India-Rubber and Gutta-Percha Trades' Journal*, July 21.

A PROPOSED NEW INDUSTRY IN NEW ZEALAND: PAPER.

The Government has sent to London a number of samples of New Zealand timber, in order that these may be thoroughly tested, with the view of having it decided whether it is possible to start the paper-making industry in this colony. Sir J G Ward, in mentioning this circumstance to the saw-millers' deputation on Monday, said that one of the daily newspapers in Australia required as much paper in twelve months as could be made from timber dealt with by any sawmill in this colony in that period; and if an industry of that kind could be started here, it would result in great benefit generally.—*New Zealand Mail*, July 16.

DEATH BY POISONING.

EATING A TUBER OF "GLORIOSA SUPERBA."

A Dolosbage correspondent writing on August 19th, reports:—

"The *Gloriosa Superba* is in full blossom just now, and an inquest was held this morning on a Kangany's wife at Pen-y-lan who tasted one of its deadly tubers."

Trimen says nothing about poison:—

"G. *superba*, Niyangala, S Karttikaikilanku, Ventonti, T. Rootstock of arched, solid, fleshy, white,

cylindric corms, 6—12 in. long, and 1—1½ in. diam., pointed at each end, bifurcately branched (or V-shaped), producing a new joint at the end of each branch; Low country, in bushy places; common. Fl. Sept.-Jan.; at first greenish, passing through yellow, orange, and scarlet to crimson from base to apex. Throughout India and in Burma, Malay, Cochin-China, and Trop. Africa. The character of the corms given above is from a note by Dr. Trimen, who further says that they are slightly acid."

But Dr. Geo. Watt gives fuller information:—

HABITAT.—A large scandent herb, grasping by the tips of its leaves; found in the forest of India, Burma, and Ceylon, ascending to 6,000 feet. It produces a large and very handsome flower, during the rain.

"MEDICINE.—The root is supposed by Hindu and Muhammadan physicians to have valuable medicinal properties. Dutt writes, 'It constituted one of the seven minor poisons of Sanskrit writers and had for one of its synonyms '*garbhaqhatni*,' or 'the Drug that causes abortion,' but I am not aware of its being used as an abortive for criminal purposes. The tuberous root, powdered and reduced to a paste, is applied to the navel, suprapubic region, and vagina, with the object of promoting labour. In retained placenta a paste of the root is applied to the palms and soles, while powdered *Nigella* seeds and long pepper are given internally with wine.' Early English writers on Indian botany and materia medica speak of it as a violent poison, but none furnish satisfactory details of a case in which marked ill-effects were produced by its use. It seems highly probable that these ill-effects have been greatly over-estimated, an assumption which is confirmed by experiments recently conducted by Moodeen Sherif. In a special opinion kindly furnished to the editor he writes: 'The root is not so poisonous as is generally supposed. I have taken it myself in small quantities, gradually increasing the dose to 15 grains. There were no bad effects, but on the contrary my appetite improved, and I felt distinctly more active and stronger. I have been using it in my practice during the last sixteen or seventeen years, and consider it to be a pretty good tonic and stomachic. Dose from 5 to 12 grains three times daily.' In Bombay it is supposed to be an anthelmintic, and is accordingly frequently administered to cattle affected by worms. In Madras it is believed to be specific against the bites of poisonous snakes, and the stings of scorpions, and is also used as an external application in parasitical affections of the skin. Surgeon-Major Thomson, C.I.E., has kindly furnished the following information regarding its utilisation in Madras:—'There are two varieties of this plant. The root of one plant divides dichotomously, that of the other does not divide at all but appears as a single piece shooting into the ground. The former is supposed by the natives to be the male plant, the latter the female. The male root is gathered during the flowering season, cut up in thin slices and soaked in butter-milk to which a little salt is added. In this composition it is soaked by night and dried by day for four or five days. It is eventually dried well and preserved. By this process its poisonous properties are said to be removed. When so prepared, and administered by giving apiece or two internally in a case of cobra bite, it is said to be an effectual antidote in cobra poisoning. It is called in Tamil '*Katharum cheddy*.' In scorpion and centipede stings and bites relief is obtained from the pain by applying a paste of the root rubbed up with cold water and then warming the part affected over the fire. This paste is applied also for parasitical affections of the skin."

"Notwithstanding its characteristic appearance, the tuber is occasionally employed by natives as an adulterant of the roots of *Aconitum ferox*, to which, indeed, they believe it to be closely allied in therapeutical properties.

"PHYSICAL CHARACTERS AND CHEMICAL COMPOSITION.
—The root flattened or cylindrical, sometimes much

pointed at both ends, sometimes consisting of two tubers uniting at right angles. On the upper surface may be seen a circular scar marking the point of origin of the stem, and on the under-surface beneath this another mark to which thin small rootlets are frequently left attached. Covering the tubers is a thin loose, and wrinkled epidermis of a brownish-gray or pale-brown colour and on removing this skin, a brown or dark-brown surface is exposed. On cutting the tuber it is found to be dull-white and farinaceous internally. The taste is faintly bitter, the odour slightly acid. A chemical examination by Dr. Warden resulted in the separation of two resins and a bitter principle, *superbina*, which the analyst considered closely allied to, if not identical with, that of *Scilla maritima* (*Dymock*)."

The case of this death in Dolosbage should be made the occasion of a careful enquiry and report for future guidance and protection.

CURING TOBACCO LEAF.

Some twenty years ago Mr. Cabanis, who had had experience in Cuba in planting tobacco, took exception, as a correspondent writing to us from Fort Stedman does, to the faulty methods adopted by the people of the country in curing their tobacco. He pointed out that sun-dried tobacco is never so palatable to smokers as that dried under cover. No doubt the latter method is not so easy nor so speedy as simply putting the leaf in the sun. The Shans apparently leave their tobacco alternately in the sun's heat and the night's dews with a result the reverse of pleasing. The correspondent says they are quite willing to learn a new method if there were only someone to teach them. Perhaps if the railway were made through the Shan States and the Shans were certain of securing a good price for all they can grow over and above their own requirements, there would be an improvement. The best tobacco-growing lands at present are at places distant from the railway, and perhaps that is one reason that so little care or trouble is taken by the cultivators in the important part of curing the leaf.—*Rangoon Gazette*, Aug 11.

RUBBER IN LOWER BURMA.

In the India rubber plantation at Mergui which is progressing favourably, the Government will in a few years have a highly remunerative return on the capital invested, beside the advantage to be derived from having introduced a new industry into Lower Burma. The extraction of rubber is said to be one of the simplest crafts in the world, which can be easily learned by the most ignorant. Kachins work it in the wild country between Upper Burma and India and equally wild and savage Indians in the Bolivian and Peruvian forests. A workman in the latter country usually taps from 75 to 159 trees a day, depending on his industry and the nature of the ground. A small incision is made in the bark and a tin cup attached to catch the sap. This is smoked and coagulated in the evening over a wooden fire which makes it hard, cured rubber. A collector gets from seven to twenty-one pounds of this rubber daily. The cost there comes to about 1s 4d per pound whilst the London price is from 4s to 4s 6d. The demand for rubber is increasing yearly, so that there would seem to be a bright future before the rubber industry in Lower Burma.—*Rangoon Gazette*, Aug 11,

REALIZATION OF FLOWERS.

TO THE EDITOR OF THE "TIMES."

Sir,—In *The Times* of Friday, July 11, you broach a subject of quite as much interest to agriculturists as to botanists, in reviewing "The Primrose and Darwinism." Whilst botanists are quibbling over small matters, fortunately for agriculturists there are men, who have no learned degrees, who for years have devoted their time to the subject of cross-fertilization, and turned it to practical account for the benefit of others. The Laxtons with the pea and the strawberry; Findlay in the development of the potato; and Garton in the cross-breeding of almost all farm plants, have done more good to British farming than has ever been effected by narrow laboratory tests, carried out without a definite object of practical utility. Whilst it has been generally accepted that grass such as the rye-grass and fescues could not be made to interbreed, Mr Garton has broken down the non-affinity of these varieties, and in his experimental grounds at Newton-le-Willows a large number of new cross-breeds of these may be seen growing at the present time. Oats which rarely produce more than two or three grains in a spikelet, except in a Chinese weed oat-grass which produces five, have been made to produce seventeen and any number from that down to two, and all with permanently fixed character. The kohl-rabi has been successfully crossed with the common swede; in fact, as a result of twenty years' unremitting work in cross-breeding, in the experimental grounds, there are at this moment tens of thousands of plants which shew variation to permit selection to establish a new and distinct breed from any one of them. As they are open to inspection this can be put to proof by any one interested.

In respect to insect-pollination, Mr Garton's observations go to show that Darwin far overstated the case. He has found that fertilisation occurs, at any rate among farm plants, at a much earlier period than is usually supposed, and certainly earlier than text-books suggest. So early is this performed that when insects enter self-pollinating plants, attracted by the colour or in search of nectar, fertilisation is completed; and his inference is that nectar is an after-product of fertilisation just as he has shown by his micro-photographs that an immediate result of fertilisation is the filling of the lodicules with moisture to ever open the glumes (at the base of which they are placed) to allow of the exit of the anthers, which, having performed their part of shedding pollen on the stigmatic surface, are no longer required. At this season, when the cereals are "in flower," an opportunity is afforded to anyone to test what he has so definitely shown, that when the anthers appear outside the glumes fertilisation has occurred some days.

Health has not permitted Mr Garton to publish a scientific account of his work, but when it does many of the points raised in your review will be cleared up. I have troubled you with this because, just at this season, the experimental grounds at Newton-le-Willows give too many proofs which botanists should not fail to see; and from the courtesy with which Mr Garton has shown his micro photographs to me and to others, I feel sure he would extend the same privilege to any who may be deeply interested in one of the most

important matters relating to agricultural prosperity.

I am, Sir, your obedient servant,
W J MALDEN, Principal, the Colonial College,
Hollisley Bay.—London *Times*, July 25.

ARTIFICIAL RIPENING OF PLANTAINS.

The forcing to ripen of this delectable article of the table, to which a correspondent lately drew attention in your columns, is a practice for which the grower, and not the dealer, of the commodity is primarily responsible. In the Pulneys, where an enormous trade in plantains is carried on with the plains, the Hill ryot depends mainly, if not entirely, for his bare sustenance, on the sale of his fruit at the weekly markets in the lowcountry, and therefore it is not surprising he should resort to artificial methods for bringing the fruit to maturity. Beyond robbing the fruit of its freshness and flavour (for who has not relished a plantain ripened on the tree?) this "blowing" of the half green fruit, as the practice is termed among the fruiterers, has not been discovered to produce deleterious effects on the consumers. That the trade in plantains has, of late years, assumed vast proportions in the Lower Pulney Hills, will be patent even to a casual observer. After the wholesale destruction of the coffee, as the result of disease, the Hill ryots planted up the lands lately occupied by coffee, with plantains; and, in the long run, they found the latter more paying. The result is that almost every new grant, under the Darkast Assignment Rules, is cultivated with plantains. The comparative ease and rapidity with which this crop is grown in an eminently fertile soil, and the permanency of a crop once sown, added to the luxuriant yield in all seasons of the year, make the plantain the backbone as it were of the Hill population, who, but for that, would be reduced to dire straits. In fact, it is the growing of plantains that alone enables them to keep the pot boiling, and to meet their Government dues. Coffee and cardamoms do not pay, except the very large investors, owing to the depression in these industries of late. It is therefore but fair to say that any restrictions placed on the hitherto free grants of Government lands, under the Dharkast Rules, would be productive of incalculable harm to the smaller ryot, as it would be literally taking away the food from his mouth. No one, who has some acquaintance of the conditions of the Hill ryot and his humble aspirations, will accuse him of land-grabbing. His lot is already a hard one, and it will be made infinitely worse if undue restrictions are introduced on the easy and inexpensive methods, heretofore in vogue, of acquiring land on permanent *putta*. Of the numerous variety of Hill plantains and degree of excellence of each, a good deal may be written; but the most delicious and, at the same time, least harmful is the tiny *Navaram*, a fruit about 2½ to 3 inches in length, with a thin rind, and of a most delicate flavour and sweetness. The Hill people attribute curative qualities to this species of plantain. The huge red plantain, which attains perfection on the Hills and is noted for its succulence and richness, is the largest of the Hill plantains one would suffice for a meal.

C. J. STRACEY,

—*M. Mail*, Aug. 20.

ARTESIAN SPRINGS AND THE AUSTRALIAN DROUGHT.

With regard to the phenomenal outbreak of springs in various parts of New South Wales during the drought, Professor David, of the Sydney University, explains that it is due to the fact that after long spells of drought water-bearing rocks become very much desiccated, so that they contract, and in the process of contraction cracks are formed, which admit of subterranean water, which was previously hermetically sealed, finding an outlet for itself at the surface. The water coming from them, he states, might flow for weeks or months, but it was not likely they would prove such a lasting source of supply as do artesian wells, for, if the water was present in such a large volume, it would in all probability force a much bigger outlet for itself. Then rain comes, the earth is soaked, and the cracks close again; so the springs, he adds, cease to flow. The outbreak of such springs after a long drought are by no means rare.—*Melbourne Leader*, June 14.

BOTANIC STATION, TOBACCO.

This station was started in June 1899 at Dealfair, a valley situated opposite the landing place at Scarborough. The site was selected in 1898 by the Imperial Commissioner of Agriculture and the Superintendent of the Royal Botanic Gardens of Trinidad. The soil is fairly good and there is a regular supply of water from a small spring on the land. The first year's work consisted of clearing and preparing the land, making roads, paths and drains, and starting a nursery. The latter in 1899 contained 1,600 economic plants. In 1899 and 1900 the laying out of the Station was greatly advanced. In the latter year the nursery was increased to 7,500 economic plants, of which 2,157 were sold, bringing in an income of £15 7s 3d. A large number of cacao and other plants were distributed free to settlers on Crown lands and others. Latterly, a house for the Curator, an office and a shelter for visitors have been provided. Also a new entrance rendering the Gardens accessible from the landing place.

Attached to the Station is a travelling Agricultural Instructor whose chief duty it is to visit the holdings on Crown lands, and advise and assist the settlers. About five hundred acres are estimated to be now in course of being planted by cacao trees. The Agricultural Instructor also assists generally in promoting industries in the land.

The Station is mainly supported from the funds of the Imperial Department of Agriculture but the grant is supplemented, to some extent, by the Government of Trinidad. The Curator and the Agricultural Instructor are departmentally under the Superintendent of the Royal Botanic Gardens at Trinidad. The Station is occasionally visited and inspected by the Imperial Commissioner of Agriculture.—*Barbados Agricultural News*.

PLANTING IN COORG.

A beginning has been made in growing crops other than coffee. In two cases sugarcane has

been grown, and ginger and saffron also in another, while elsewhere some attention has been paid to the cultivation of vanilla. The flowers of this plant, as is well-known, have to be artificially fertilised. This has been successfully accomplished in the case referred to with the aid of the humble Kurumber who has shown himself a very apt pupil and works most intelligently at the operation.—*Madras Mail*, Aug. 18.

PRODUCTS OF PARAGUAY.

The present important industries of Paraguay are the growing of Paraguay tea, maize, tobacco, oranges, beans and mandioc. The cattle industry is very large and exports of beef and hides extensive. Paraguay has immense forests of hard and soft timber, and an abundance of iron, marble, pyrites, copper and kaolin. The decree does not specify the amount, but authorises the necessary expenses for a proper exhibit of the country's resources and industries.—*Official*.

PLANTING AND R. B. GARDENS ON THE NILGIRIS.

From the Annual Administration Report (190-12) of the Government Botanic Gardens and Parks, the Nilgiris by R L Proudlock, Curator, we make the following extracts:—

Strobilanthes gossypinus, T Anders, flowered at the end of 1901, and it was a beautiful sight to see this shrub when it was in full flower, covered with bluish purple flowers; it is now ripening its seeds. The Curator has never seen this species in flower before. Most of the species of *Strobilanthes* flowers, as a rule, only once and then die.

The oldest tree of *Araucaria Bidwillii*, Hook, which is situated immediately below, and in front of the quarters of His Excellency the Governor's Medical officer, in the gardens, produced matured seeds during the year for the first time. Eleven seeds were sown on the 8th July 1901, and they have all germinated. The seedlings are still small, but are healthy and promising. This tree was planted in or about 1867—*vide* paragraph 38 of the garden report for 1878-9.

A good deal of planting was done during the monsoon as usual. A number of plants of *Widdringtonia Whytei* Rendle, were planted in a ravine above the overseer's quarters, and also on the side of the ravine above Government House.

Seeds of a fine species of Phoenix (*Phoenix Canariensis*, Hort. were received from Sir George King, K.C.I.E., San Remo, Italy, on the 14th May 1901, and a good number of seedlings has been raised from them. Sir George King states that this is a very ornamental species of Phoenix which is commonly seen in gardens on the Riviera, and he thinks it would be likely to grow in Ootacamund and Coonoor.

A one-ounce packet of seed of *Paspalum dilatatum*, Poir, a grass which has received much praise in the newspapers during the last few years as a drought-resisting fodder plant, was received from Mr John Cameron, F.L.S., Superintendent, Government Gardens and Parks in Mysore, on the 23rd July 1901. The seed was sown on the 25th idem and germinated well. The seedlings were planted in trial plots at Ootacamund, at Sims' Park on the 25th October, and at Burliar on the 17th December 1901. The plants are dwarf in Ootacamund, while at Coonoor and Burliar they have grown well, flowered and seeded.

The following are a few notes on, and measurements taken of, a few of the species of economic importance recently planted in Burliar:—

Name of species.	Height.	Girth at 4 feet from the ground.
The Durian	6 ft 10 in	Not taken.
Durrio zibethinus Murr	10 „ 9½ „	4½ in
Camphor	7 „ 9 „	Not taken.
Cinnamon Camphora,		
Nees and Eberm <i>b</i>	12 „ 4 „	6 in.
Avocado Pear	15 „ 10 „	8 „
Persea gratissima,		
Gaertn <i>c</i>		
Para rubber	18 „ 8 „	Not taken.
Hevea brasiliensis,		
Muell. Arg <i>d</i>	21 „ 9 „	8½ in.
Do do <i>e</i>	29 „ 0 „	6½ „
Central American rubber	12 „ 0 „	Not taken.
Castilloa elastica,		
Cervy <i>f</i>	18 „ 10 „	1 ft 5½ in
Kickxia Africana,	8 „ 10 „	Not taken.
Benth <i>g</i>	17 „ 10 „	0 ft 7½ in
Kallar variety of Ceara Rubber	22 „ 6 „	0 „ 9½ „
Manihot Glaziovii,		
Muell. Arg <i>h</i>	23 „ 5 „	1 „ 4 in

In order to give effect to the proposal and suggestion made in paragraph 50 of last year's report, to collect and plant in order in Burliar or elsewhere the progeny of the best rubber-yielding trees which are discovered in other plantations from time to time with a view to comparing their relative merits, nine pits, 26½ feet, apart in one line, parallel to, and 30 feet distant from, the last line of Castilloa were planted with cuttings on the 9th February 1902 and with seeds on the 6th March 1902, taken from the best rubber-yielding tree yet found at Bekki Kolley, Wynaad. It may be mentioned that this particular tree, which girthed 3 feet 3 inches at 2½ feet from the ground, yielded 14 ounces of dry rubber after one tapping, which was made on the 30th Jan. 1902. Adjacent to the line planted with the Bekki Kolley variety is a line of eight pits, 26½ feet apart, planted on the 23rd February 1902, with both seeds and cuttings of the Kullar variety. The yield of rubber from the parent tree (now dead) was never accurately determined, but it was known to be good.

Mr H G Parsons of Beechlands, Polibetta South Coorg, in his letter, dated 25th January 1902, to the Curator, states that he possesses a Ceara rubber tree "20

a Raised from seed received on the 26th August 1898. The plants are doing well.

b Planted 1st December 1899. The plants are growing vigorously, and are rather bushy in appearance.

c Planted 26th August 1898. The plants are growing well, but have not fruited yet.

d Planted in November 1893: The plants are growing vigorously, and after small trial tappings, they have yielded rubber of good quality. They are, however, too young yet to be profitably tapped.

e This is the tallest tree in the 1898 plantation and is of the same age as the above.

f Raised from seed collected in April 1897, and planted in September 1898*. The plants are making fine growth and flowered in March 1902, for the first time. Hitherto, in small trial tappings, these young trees have yielded a somewhat gummy substance possessing scarcely any elasticity and resiliency and therefore destitute of the properties of true rubber. Observations are being continued periodically so that definite information may be obtained as to when these particular trees will yield good rubber of marketable value.

g Raised from seed sown in April 1899, and planted in December 1899—*vide* paragraphs 11 and 18 of report for 1899—1900. The plants are doing well.

h This young tree, which has grown from a cutting put in on the 17th January 1900, now seeds freely and yields rubber of excellent quality.

years old, that is yielding 10 lb of rubber per annum," and he further states, "I have no other trees that in any way come near such a yield and some give next to no latex." Mr Parsons has quite recently sent here a few seeds from his best tree and has also promised to send a few cuttings of it. The seeds have been sown, and should they germinate it is intended to plant a third line at Burliyar with the seedlings. Should this variety prove in due course to be a better rubber-yielder than the Bekki Kolley and Kullar varieties, a distinct advance will have been made in the work of selection which has been undertaken.

On the cleared area which is free of mahoganies the following species of rubber-yielding plants have been planted, 30 feet by 30 feet, in lines:—

FIRST LINE.—Eight pits planted in February 1902 with the Bekki Kolley variety of the Ceara rubber tree.

SECOND LINE.—Eight pits planted in February 1902 with the Kullar variety of the Ceara rubber tree.

THIRD LINE.—Pits vacant—to be planted with Beechlands variety—*vide* paragraph 49 *supra*.

The following species of rubber trees were planted on Bekki Kolley on the 3rd, 4th and 5th February 1902, with a view to seeing whether they will succeed or not in that part of South-East Wynaad, viz.:—

11 Hevea brasiliensis at 25 feet apart, planted 3rd February 1902.

12 Kickxia Africana at 25 feet apart, planted 4th February 1902.

12 Castilloa elastica at 20 feet apart, planted 4th February 1902.

10 Manihot Glaziovii (from the best latex-yielding tree on Bekki Kolley), planted on the 5th February 1902, at 24 feet 4 inches apart.

6 Ficus elastica at 100 feet apart planted 5th February 1902.

ADAM'S PEAK IN CEYLON.

[The following paper in the *Scientific American* (July 5) is accompanied by four striking engravings entitled:—Adam's Footprint on Adam's Peak; Shadow of Adam's Peak at Sunrise, the Bible mountain in the background; Section of the ascent to Adam's Peak; Adam's Peak seen from the inn of Laxapana.—Ed. C.O.]

The followers of Buddha in India, Burma, Siam and Ceylon venerate Adam's Peak as their sacred mount; for, on the summit, which rises abruptly like a needle of rock from the mountains of middle Ceylon, there is to be seen, according to their belief, the imprint of a foot of the Buddha. Singularly, the Mohammedans consider this natural depression as a footmark of our common ancestor, Adam. So that Mohammedans as well as Buddhists come every year in crowds from the most distant parts of the country to testify their reverence for this holy relic like the Japanese in their regard for their sacred mount Fujiyama and the Chinese in a similar esteem for their Taishan in the heart of Shantung.

As, in the course of years, I have ascended these two mountains and published descriptions and photographic views, I undertook at the beginning of this year the same task with respect to Adam's Peak, less on account of the sacred footprint than those of the remarkable natural spectacle which has made this mount famous to Europeans; at sunrise Adam's Peak throws a sharply defined shadow, as deep as it is regular. This fact has been mentioned by various travellers, and it is even reported that the shadow has been seen from ships at sea, approaching the harbour of Colombo. But this is denied by the captains of the vessels plying regularly between Ceylon and the harbours of southern India. To some who have

been sailing in these waters for many years the precipitous top of the mount, which appears as sharp as a needle, affords a sign for steering their ships, but they have never observed the celebrated shadow from shipboard. I searched in vain in stores where Indian and Ceylon photographs are kept for views of the summit with the footprint and the temples built there, and decided to take the views myself.

Whoever gazes from below at the lofty peak, rising abruptly like an Indian Matterhorn from the towering masses of Ceylon, considers the ascent much more difficult than it really is. Not only do numerous pilgrims climb to the summit, but Europeans make the ascent every year; some of these, however, would hardly care to repeat it.

By dauntless enterprise a railway has been built in the mountains of Ceylon, and from Hatton, one of its stations, a convenient footpath leads, a distance of about 20 kilometres, to the inn in Maskeliya, which is situated in a valley at the foot of Adam's Peak. From here I started at midnight, accompanied by two guides and lantern bearers, and reached the Peak three hours later by gradual ascent. The climbing of the bare steep granite rock, which has a height of 2,260 metres, is less dangerous than fatiguing. In the upper part, in order to overcome the worst obstacles, series of steps have been cut in the naked rock and iron chains are strung along, similar to those on the Matterhorn.

At 6 o'clock in the morning we reached the summit. The plateau, which may have a circumference of one hundred steps, is inclosed by a wall breast high. Inside are a few low huts for the priests of Buddha and the pilgrims. From the centre of the plateau rises the granite rock 20 metres higher still, and on its very apex stands a small temple, open on all sides, in which the celebrated footprint is to be seen. This is here represented for the first time. (See illustration.) It requires a great deal of imagination to view this depression in the rock as the print of a human foot. The individual must have been of gigantic stature, for the length of the footprint, according to my measurement, amounts to 1.40 metres and the width 65 centimeters. On the south side stands a small altar on which the priests and pilgrims at sunrise deposit delicate white frangipani blossoms and grains of rice, afterwards kneeling with clasped hands and offering their prayers.

At 18 minutes past 6 o'clock a priest called my attention to the splendid disc of the sun, which appeared in the east in a saddle of the highest mountain of Ceylon, the Pedrotalagala. Opposite, on the west side, was seen the peculiar sharply defined shadow of Adam's Peak in magnificent grandeur. Like a dark pyramid of mist, it stood out from the gray background, which gradually became brighter. The higher the sun rose the lower the shadow sank, until finally it lay deep on the mountains at our feet. In two hours and a half after sunrise it faded away. This phenomenon is so peculiar and majestic that it keeps one from paying full attention to the splendid view presented from this lofty peak in every direction over this tropical island, so extraordinarily blessed. It was strange that half an hour after sunrise there appeared by the side of the principal shadow of the mount two others, paler, starting from the top and lower down

diverging in direction; these shadows disappeared gradually.

The descent under the scorching rays of the tropical sun proved very troublesome; here and there we passed over smooth granite walls, steep places of 65 deg. Yet the rare spectacle of natural beauty was so grand and unique that I can well recommend the ascent of Adam's Peak to every tourist. There is more occasion to visit this peak than the sacred mountain of the Japanese, the Fujiyama.—For our illustrations and the accompanying description we are indebted to "Illustrirte Zeitung,"

UPPER UVA, CEYLON, AS A STATION FOR BRITISH TROOPS.

BY ANOPHELES.

[In the "United Service Magazine."]

The transport by sea of a large body of troops after the experience of the South African War excites little comment and with our extensive mercantile marine now presents comparatively few difficulties, provided careful arrangements have been previously made. The ease and celerity with which the British troops were despatched from India to Natal was a momentous movement, the wide-reaching consequences of which are not yet, perhaps, fully appreciated. But it is well known in military circles that the Indian contingent prevented the Boers on the outbreak of hostilities from carrying their victorious arms to the Indian Ocean. At the same time it is fully recognised in the same circles that the Indian Government was reducing the number of white troops to an extent which would be dangerous or impracticable if an unruly native population or harassed frontier had been engaging its attention.

In the recent Chinese troubles (and further troubles in the near future are likely to again arise) the Indian Government was called upon for aid; thus in our last two campaigns India has on each occasion been called upon for troops, and on each occasion she has gallantly responded to the call. It is the opinion of all thoughtful men that to rely on India for troops in an emergency is a dangerous proceeding. More particularly at the present time when our restless Northern neighbour is pursuing his usual tactics in Manchuria and Thibet. From her geographical position India is admirably situated to deal with any crisis in the Oriental region; on the one hand she can strike rapidly to the west, and other equally rapidly to the east; but when by so doing she renders herself open to attack, and a staggering blow delivered to her would have such far-reaching consequences, it is a serious matter to weaken her unless the point at issue is one of vital moment. It is with diffidence that I, a non-batant, mention the word strategy or deal even in a cursory manner with questions of that military science; but I think even a layman can grasp the strategical importance of the geographical position of India when he considers that officers still on the active list have seen India sending troops to Persia, Cyprus, Egypt, the Sudan, the Cape and China more than once. Granted that she has done this with impunity in the past, it by no means follows that it would be a good policy to do so in the future. What would have been the condition of Natal, and indeed the state of affairs at the Cape at the

present moment, if India from internal causes had been prevented from sending a contingent to South Africa? The point I wish to bring to notice is this—that judging by our recent military history it is not only advisable, but perhaps vitally important to have ready at hand to send in any direction, and at the shortest possible moment, a well equipped, healthy body of men, complete in every detail, to those portions of the globe where hitherto India has been called upon to send her troops. Now, what are the conditions necessary to fulfil the above?

- 1—A favourable geographical position.
- 2—A country not liable to either external or internal attack.
- 3—Proximity to a good harbour with sufficient shipping.
- 4—Proximity to a railway.
- 5—An extensive country fit for military purposes.
- 6—Adequate local supplies, such as cattle, fodder, &c., &c.
- 7—A healthy climate for the troops.

The geographical position of Ceylon is practically the same as India. Colombo is the Clapham Junction of the East, where all the large Orient liners of the P & O, Orient, Clan, and other Companies call regularly, and where, consequently, the shipping necessary for the despatch of troops could be obtained and collected. The new breakwater and batteries now under construction will make Colombo secure from the elements and the enemy.

A glance at an atlas will, without argument, satisfy conditions 1 and 3.

Condition 2 is amply fulfilled. The insular position of Ceylon does not allow of its invasion as long as we command the sea, and the loyalty of the native population is such that the present governor, Sir West Ridgway, unhesitatingly offered the services of the only English regiment in the colony for duty at the Cape during the dark days of 1899.

The Ceylon Government Railway meets my fourth condition. It passes close to the country I am about to describe, and has stations at Diyatalawa and Bandaravella, in close proximity to ground in every way suited for a military camp, and within ten hours' journey of Colombo.

With regard to 5; Ceylon, to the majority of people, conveys the idea of a hot, moist, tropical country, enervating to a high degree, if not actually unhealthy. But the hill station of Nuwara Eliya at any rate is now becoming known, and it will not be strange to many to learn that other parts of the hill districts of Ceylon boast of an almost English climate; I may remark, parenthetically, in many respects a good deal better? I am not, however, advocating the claims of Nuwara Eliya. It is far too enclosed for the manœuvres of any but a very small body of troops, and even the open country in its near neighbourhood *(the Burrack and Moon Plains) is so studded with bogs and morasses that the movements even of a company would be largely confined to the high road. At the present some thirty or forty sickly men regain their stamina there, after the enervating climate of the low country. Hitherto the Sanatorium has been open from the middle of September till the burst of the south-west monsoon at

the end of May or beginning of June. Nuwara Eliya,* from a social point of view, with its race-course, golf links, club, and so forth, is a pleasant place enough in fine weather, but can scarcely become a station for practical, serious soldiering. In the neighbouring province of Uva can however, be found all the conditions necessary for the military training of 10,000 or more infantry in a healthy country, and with unrivalled climate. This appears such a startling statement that I propose to enter somewhat fully into the physical characteristics of the Province, its climate, and the health of the troops at present stationed there.

I cannot better describe the scenery of Upper Uva than by quotations from an account of a prolonged tour made through the Province in March, 1819, by Dr. John Davy (brother of the famous Sir Humphrey Davy), taken from his 'Account of Ceylon,' published in 1821. Dr. Davy was on the medical staff of the Army in Ceylon, with the title of Physician to the Forces. He travelled from Colombo to Uva *via* Ratnapura, and entered the Province from the Haputale (south) side, over the Idalgashena Pass, and from no point of view is the glorious scenery of Upper Uva seen to better advantage. * He says:—(Familiar to Ceylon readers.)

Dr. Davy visited Uva again later in the year 1819. His first tour was in March. On the second occasion he made his trip from the Nuwara Eliya side (about twenty miles north-west of Diyatalawa), and proceeded only as far as Fort MacDonalld six miles north of the camp.

The amphitheatre of hills surrounding the plain^s of Uva on the west and north effectually prevent the clouds and rain of the south-west monsoon from reaching them. Sir Samuel Baker, in his 'Eight Years in Ceylon,' gives the following account of this curious phenomenon seen during the south-west monsoon, when, while the western side of the island is enveloped in mist and rain, the wet weather terminates abruptly at Hakgalla, and the panorama of Uva is seen in all its beauty. He says:—(Familiar to Ceylon readers.)

I can do little more than refer to a very interesting paper on 'The Botany of the Ceylon Patanas,' by Mr Pearson, B.A., published in the proceedings of the Linnæan Society, vol. xxxiv. page 300, which will repay perusal. He enters very fully into the origin and present condition of this open country, and draws a somewhat close comparison between it and the savannahs of South America. He roughly estimates the extent of this patana, savannah or down country, as extending over 300 square miles, the far greater portion of which is in Upper Uva. He summarises his conclusions as follows:—

"An examination of such evidence as exists with regard to the origin of the patanas of Uva, and their western extensions up the slopes of the central ridge, leads to the following conclusions. On the Uva slopes below 4,500 feet (the lower limit of the Rhododendron) the peculiarities of the climate have co-operated with the periodically recurrent grass-fires to transform an open forest of low xerophytic trees with an undergrowth of grass (*i. e.* a savannah forest such as is still found on the eastern boundary of the plateau) into barren grassy plains. These plains, being almost completely denuded of soil, must be regarded as being

* Nuwara Eliya has a rainfall of 99·37 inches, and 2·2 rainy days; average of 26 7-12th years.

* The camp of the Boer prisoners at Diyatalawa is six miles from Haputale at the southern edge of the plateau.

of the nature of a permanent savannah, the natural re-forestation of the greater part of which is impossible under the present climatic conditions."

The above descriptions, written years ago by Davy and Baker, apply equally well to the present condition of the country. I may say that its general appearance is very similar to the South Downs of England, more particularly their steep escarpments in the neighbourhood of the well-known Berkshire White Horse. In place, however, of the elastic turf which makes those downs the finest galloping ground in the world, the hills are covered with a short, coarse grass which frequently grows in clumps, which makes progression on horseback somewhat difficult. In the convolutions of the hills where the ground is marshy, small clumps of trees and jungle grow thickly, preserved by the wet from the summer grassfires. These marshes, unless the country is well-known, likewise impede the horseman, who is liable to be badly bogged if he endeavours to ride over them. In spite of these difficulties and drawbacks a flourishing pack of foxhounds (the Errebotde hunt) holds its annual meets on these downs, and many a good gallop is enjoyed by the sporting planters in pursuit of the wily 'Jack.' The hills are composed of gneiss, for the most part unstratified, but in many places convoluted and distorted. Above this is the mica-schist, occasionally garnetiferous, in many sections on the hill sides it lies beautifully stratified directly on the underlying gneiss; in other places quartz is interposed, and its presence has no doubt given rise to speculation as to its being auriferous. Bands of iron pyrites are not uncommon. The soil is composed of these disintegrated rocks with outcrops of gneiss. It is a little difficult to say how far Government rights extend, for as far as I can gather no complete survey of the country has as yet been made. But the question of the destruction of crops by the movements of troops is one of no great moment as there is but little cultivation, and the few paddy fields in the folds of the hills are of limited extent, and can be easily avoided.

I am told by competent authority that the country cannot be surpassed for instructional purposes in scouting and outpost duties; if anything it is too difficult, owing to the irregular and confused character of the ground. I am informed that many parts of the surrounding amphitheatre of hills, with their rocky, steep and frequently precipitous sides, closely resemble the kopjes of South Africa. As a country for infantry, both mounted and dismounted, it is unrivalled, but owing to the absence of roads and other drawbacks it is at present not suited for artillery.

The climate is a decidedly good one, certainly for nine months out of the twelve. From October to January the north-east monsoon brings very wet weather with violent thunder storms; towards the end of January the weather clear and becomes fine and warm in the daytime and very cold at night, hoar frost being probably not unknown on the patanas. The burst of the south-west monsoon in May, which brings wet weather to the Colombo side of the island, only produces a few showers, but a persistent wind blows from this direction until September and the gradual setting in of the other monsoon. From the middle of June to the end of September men would take little harm from bivouacking in the open air, as the nights are perfect and not too cold. The maximum shade temperature in summer is probably not more than eighty-four degrees, and the minimum fifty degrees,

The rainfall is between fifty and sixty inches, * the far greater quantity falling in October, November and December. In such an ideal climate and situation, 4,000 feet above the level of the sea, at the present is the camp for the Boer prisoners at Diyatalawa in the Province of Uva. And in this camp some 6,000 men have lived a healthy but monotonous life for the last twelve months; monotonous because 5,000 of them are prisoners, and the remainder British soldiers occupied in the deadly monotonous duty of looking after them. If Diyatalawa can justify itself as one of the healthiest stations in the East when its occupants are prisoners and jailors, how much more is it likely to justify it were it occupied by men in the full enjoyment of their liberty?

By the time these lines are in print it is possible that the war will be over and the prisoners, or many of them, will be returning to their own country.

What is to become of Diyatalawa camp, with everything now ready for the occupation of some 6,000 troops? Will it be sold for old iron or be kept permanently as a station for British troops? It would be a real boon if only the English regiment in the island was stationed here instead of being broken up into fragments at Colombo, Kandy, Trincomalee and Nuwara Eliya, where the rout in duties of a garrison inevitably tend to mental stagnation and professional deterioration.

When dealing with the sanitation of an area, the most correct method of coming to a right conclusion regarding it is by enquiring into the diseases of the native population, and discriminating between the preventible diseases and those that are dependant on local conditions. This method should be followed in preference to that frequently adopted of judging of a locality by the health of those newly arrived in it. In this instance the latter method would be particularly fallacious, in as much as of the two British regiments stationed here, one came from the hardships of the investment of Ladysmith, and the other from the malarious district of Dum-Dum, after long service in India. In spite of these drawbacks, the medical officer in charge of the former of these regiments writes in most enthusiastic terms of the physique and healthiness of the men after they had four months' experience of the place, *i. e.* after they had got rid of the diseases they had brought with them or contracted from the Boers. The latter regiment has been here for nearly nine months, and was in a very sickly condition on arrival. Some seventy men have been either invalided home or sent away for change, but how far their complaints were due to local causes or were legacies from Dum-Dum and elsewhere it is difficult to say, but India has probably most to answer for. With regard to malaria, which was rife in the regiment on arrival, it is noteworthy that an examination in August of 600 men, which included a draft of 150 men direct from home, showed that only two men had an attack of malarial fever for the first time here. One of these was a man of the draft. It is interesting in this connection to note that only three specimens of the genus *Anopheles* have so far been captured here; one by Mr. Green, the Government Entomologist, and two by myself.

* Bandarawela three miles from Diyatalawa and with a similar climate has a rainfall of 64.89 inches; 40.81 of which falls in the north-east monsoon. It has 127 rainy days; average of twenty-five years, Compare Nuwara Eliya.

If the species had been abundant, many more of the fresh arrivals would surely have been infected with the malarial parasite, with such a large number of malarious cases open to the attacks of the mosquito.*

The native population is remarkably free from disease; the Colonial surgeon informs me that malarial fever is not endemic in the villages round Diyatalawa camp, but it is frequently introduced by the villagers who go on pilgrimages to such malarious places as Tissamaharama and Wellawaya. He also states that the last quarter is the most unhealthy time of the year. Cholera is occasionally imported from the low country, and venereal diseases are not uncommon.

A final word as regards supplies. The camp is about half a mile from the railway, from which supplies are sent into the camp by means of an aerial train. Wood in abundance is obtained from the neighbouring Government forests; the water is good, and can be obtained in reasonable quantity even in the dry weather. Slaughter cattle and vegetables can be obtained to a certain extent locally. The country is suitable for mounted infantry, but fodder is scarce, even the grass which springs up after the periodical burning is very coarse and lacks nourishment; it could be used for bedding, but some method would have to be found to rid it of the ticks of which there are a great number. To buy up the paddy fields and cultivate them with guinea grass (*P. maximum*) or Mauritius grass (*P. muticum*) would be a serious question. But a trial on an extensive scale on the hill sides should be made of *Paspalum dilatatum*, which grows well at Ootacamund and is a valuable grass for cattle. It is supposed by many to be of Ceylon origin and flourishes on any poor soil, provided it has plenty of water, and at a suitable elevation it will stand the extremes of heat and cold. It is thought very highly of by the farmers of Victoria and New South Wales.

Ceylon, Aug. 31, 1901.

PRODUCE AND PLANTING.

The news received by cable from Simla that the Indian Government intend levying a cess on exported tea at the rate of one-fourth of a pie per pound should stimulate the work of pushing Indian tea in foreign countries. The proceeds are estimated at three lakhs of rupees. Legislation will probably be undertaken in the winter.

The *Times* has the following on the Indian tea cess: "The decision of the Government of India to levy a cess on exported tea at the rate of one-fourth of a pie per pound has been taken in response to a memorial presented to the Viceroy in the spring of the present year by planters representing no less than 78.28 per cent of the capital invested in the industry, and owing 409,000 of the 520,000 acres devoted thereto. The memorial asked that the cess might be limited to five years, and that the proceeds should be devoted to promoting the consumption of Indian tea in India as well as in countries outside the United Kingdom, and otherwise in such manner as might be determined by a committee of planters to be approved by Government. The estimated proceeds of the cess, three lakhs of rupees, are about equal to the receipts from a similar charge levied in Ceylon on all ex-

ported tea. Owing to the excessive production in both countries in recent years, the supply to the United Kingdom has much exceeded the demand, and prices have continued to fall. Hence the memorialists urged that tea growing in India could only be continued on a remunerative basis by comprehensive measures being taken to open new markets. A voluntary cess has been in operation for some time, but has only yielded about half the amount that will be obtained when statutory authority for the impost has been given. The memorial pointed out that the proposal affected the tea industry alone, and its adoption could have no adverse influence upon any other trade or industry or on the community in general."

We reported in our issue of the 25th ult. Mr. Consul Playfair's views on the decline of the Chinese tea trade, and Mr. J. Scott, Acting Consul-General at

CANTON,

writing about the methods of the Chinese, says:—"The once important and lucrative tea industry has been almost ruined by Chinese apathy and neglect. The growers in the interior pay little or no attention to their plants, and do not trouble to renew the old bushes as they become decayed. The leaf is picked anyhow and at any time as prices appear favourable, with the result that, carelessly handled and fired, the tea, on reaching the London market, is frequently found affected or deficient in strength, body, and colour. It does not, therefore, come as a surprise to learn that the steady decrease in the tea trade has continued during the past year. Thirty years ago Canton exported to Europe some 13,000,000 lb of black tea, and nearly 2,000,000 lb. of green tea. Today Canton export is represented by less than 1,000,000 lb. consisting chiefly of Congou. The well-known scented capers for which Canton was famous, and of which some 7,000,000 lb. were exported in 1872, figure in the Customs returns for 1901 at an export of 5,790 lb. only. These figures do not, however, give an accurate return of the entire export, as many shipments are arranged in Hong Kong, to which port the tea is conveyed by junk, and does not, therefore, pass through the hands of the Imperial Maritime Customs. The following figures, for which I am indebted to an actual dealer, provides a comparison in the trade in scented capers during the past three years: 1899, 4,900,000 lb; 1900, 3,700,000; 1901, 3,000,000 lb. A further depressing feature is that the monthly returns of deliveries in London also mark a decline which would lead one to suppose that Canton scented capers are rapidly going out of consumption. The season now under review cannot be said to have been a favourable one as regards quality, nor was it remunerative either to foreign buyers or native sellers. Taken all round, the various crops during the season were of a fair average quality, but there was a considerable quantity of leaf left on the hands of natives from the previous season. This they had to work off by mixing it with the new season's leaf, a practice that no doubt had a detrimental effect, and which would have been accentuated had not scented flower been abnormally cheap and abundant, whereby it was possible for the teas to be scented above the average."

The Japanese seem greatly interested in the American tea-growing experiments. Sinko Hatto, a Wealthy Japanese now residing in New York, has been appointed by his Government to make a thorough study of tea growing conditions in South Carolina. Mr. Hatto says that his Government had been greatly interested in the published reports from the plantations in South Carolina and desired to get facts as gathered by a personal representative.

Coffee planters may well ask to be saved from the ingenious people who seek to produce adulterants to their product. In Austria they make a product called coffee of figs, which is supposed to be appreciated in Germany and Austria-Hungary. Nutritive power is claimed for it. It is obtained by drying fruit—especially figs—and mixing them with coffee. It acts

* In the month of August, with an average strength of 862, the average number of sick was twenty-seven, one-third of which were venereal cases. These figures tend to show that the sickness in the regiment was not due to local conditions.

as a colouring agent, and diminishes the excitant quality of the coffee and corrects its taste—save the mark! Several establishments in Algeria now manufacture fig-coffee, which is already used in Europe.—*H. and C. Mail*, August 8.

TEA IN PACKETS: COLOMBO THE MODEL.

Mr. H. Drummond, Deane writing from Peermaad, under date, 13th August, to the *Madras Mail*, says:—"I have read with interest the articles on the 'Tea Markets Expansion Commission' in your issue of the 15th instant, and I am at one with you in wishing all success to the enterprise of Messrs. Yule and Co. But it is to be deplored that the teas are not packed either in lead or at least damp-proof paper as made in China. Another fatal economy, peculiar to Calcutta merchants, is the want of firing machines for refiring teas before packing into packets. Contrast this with Colombo where I venture to state from experience no firm of any importance dealing in packet teas, or indeed acting as Agents for tea estates, is without some sort of firing machine, without which no repacked tea will maintain its flavour or aroma for any reasonable time. The consequence of this fatal parsimony will be that in damp weather within a month of distribution the teas will become mouldy and unfit for consumption. Yet the small dealer, as is well-known, will sell every packet if possible. Consequently, for every two packet of tea going into consumption and appreciated, the probability is that the moiety will cause disgust to the would-be convert. If it is found too expensive to put up one-pie packet in lead, at least give the tea a chance by packing it hot from a firing machine, and with every 100 packets supply an air-tight tin case with printed instructions urging the necessity on small dealers of keeping the tea free from damp. Any tea expert will bear me out in these remarks which apply to any teas sold in a climate such as Calcutta and Southern India. Possibly in the far North the climate, being drier, more resembles Europe where such precautions are not so necessary."

GREEN TEAS—AND GREEN TEAS.

We trust our readers will feel themselves enlightened by the "prodigious" correspondence with which Mr. Judge of Calcutta favours us today as Agent for the "Drummond-Deane green tea process." It is marvellous, however, how hard it is to get some people to give up misconceptions. For instance, in an editorial in "Indian Gardening and Planting" of August 21st, discussing Mr. Hart's letter which has set Mr. Judge to write, the editor says:—

A comparison of Mr Robert Hart's letter and our article, which it professes to set right, will show that Mr Hart and ourselves have been writing about different things, and that therefore his letter is no criticism of our article. In the first place, our article was called for by certain statements in the *Ceylon Observer* praising and advocating the artificially coloured teas produced at the Central Factory in Ceylon.

Mr. Judge himself too, uses the same term in this application. But surely he

and the editor have not still to learn that the teas produced at Ambewatte Mills are *not* "artificially coloured," and that this has been vouched for not only by local and American experts, but demonstrated to the satisfaction of leading Ceylon planters on the "Thirty Committee," who have been allowed to inspect the process? The sooner our contemporary, therefore, withdraws this allegation and apologises to the *Ceylon Observer*, the better. Even the local "Times" has been lately coming round to admit the superiority (including the purity) of Ambewatte-made teas. The sales in the London and American markets and the prices realised, have long ago shown where the superiority lay; but the drawback is in the comparatively costly means of preparing these teas as compared with the easy and economical Drummond-Deane process. Were it not for this, Ceylon planters and agents would probably ere now have freely followed the example set them in the Ambawatte Mills. As matters stand, we can only wish well to both processes; for we want to see a greatly increased quantity of green tea made before the end of this year, and although the Ambawatte Factory was stated to be equal to turning out 3,000,000 lb. per annum, we fear it is not going to do much more than one-half of this quantity for 1902; although it is expected to turn out 250,000 lb. a month from now up to the end of the year and will no doubt continue at that rate during 1903.

REDUCTION OF OUTPUT: AND TEA FROM LOW AND MEDIUM ESTATES; THE DUTY, &c.

It is pointed out that without any combination the proprietors and managers of estates at a low elevation, to a great extent, control the situation as to the quantity and quality of teas that may be turned out. If they pluck carefully and fine, to make good tea, estates higher up must go one better in order to secure proper value for their teas; and the result will be careful plucking all round and a considerable restriction of output. This, of course, would quite meet the proposal of Mr. E. J. Moss, of Foochow; and so long as there was a satisfactory demand—as at present—for good and fine teas, to study quality rather than quantity should be the more profitable policy. But, unfortunately, there are apt to be swings of the pendulum even in Mincing Lane, and when one of these occurs, there is a great temptation again to go in for the manufacture of common teas.

THE MANGOSTEEN ON THE NILGIRIS—*is now well established, and yielded a fairly good crop at Burliyar. It will surprise many people to learn that "the first two fruits of the season were received on 25th June 1901, but the main crop did not ripen until October and November: "an interval of five months between the first ripening and the main crop!—Indian Gardening and Planting, Aug. 21.*

TOBAGO AND THE WEST INDIES OVER 200 YEARS AGO.

(By Old Colonist)

I have been favoured with a copy of a very interesting old book entitled, "The present prospects of the famous and fertile Island of Tobago, with a description of the situation, growth, fertility and manufacture of the said Island," by Captain John Poyntz, first published in 1683, exactly two years after the work of our own Captain Knox on Ceylon. Tobago, as all readers of the *Tropical Agriculturist* know, is a very tiny island, 26 miles long by 6 or 7 broad, lying within 18 miles of Trinidad, to the Government of which it was annexed only 12 years ago, after rather a chequered history. It is only about 1-15th the extent of Trinidad and both together would only make 1-13th of the area of Ceylon. Yet, there is a certain interest attached to anything published 220 years ago, and the minute details of the product of this little Gem of the West might have been intensely interesting to the *Tropical Agriculturist* of today, had the descriptions been a little less exaggerated.

The literary style of Mr Poyntz, like that of good Mr Robt. Knox, is quaint in the extreme:—"The courteous reader is here presented with the present prospect of the Island of Tobago, about 40 leagues distant from Barbadoes; but far excelling that Island or indeed any other of the Caribee Islands in the fertility and richness of the soil. Yet exempted from those affrighting and destructive hurricanes that have been often fatal to the rest of the Caribee Islands. I am persuaded there is no island in America that can afford more ample subjects to contemplate the bounty of the Great Creator than this of Tobago, and I speak not by hearsay, or as one who has lived always at home; but as one who has had experience in the world and seen almost all His Majesty's *Foreign* plantations, and after having viewed them all, have chosen this Island to take up my *quietus est* in."

The "courteous reader" is now introduced to an array of plants, fruits, birds, beasts, and fishes rarely before heard of from one island, and some of which to this day are unrecognisable. I doubt for instance his plethora of luscious grapes as I have never found such in a *moist* tropical climate.

TEA, also, he says: "grows naturally and plentifully here, meaning such tea as is frequently sold in English coffee-houses." Poor Poyntz had probably seen the Paraguayan article, but *Thea Sinensis* not at all likely. It might here be observed that tea and grapes are never produced commercially in the same country, the conditions which favour the one being the opposite of what would suit the other. Pineapple, he confesses, "is a fruit of that excellency that I want *Rhetorick and Oratory* to express it." The *papaw* and *mammee* are grateful and appetising.

"The plantain of all fruits the Negro loves best. A sovereign wholesome food, some eat them raw when nature has ripened them; others boil them green, Now to roast them

they are bread, to boil them they are sauce or marmalade, but to barbecue or dry them in the sun they may rub them to a flour." (Curious to note the idea of desiccating the plantain, never yet commercially carried out.*)

"The coconut the Indians idolize it, and call it God's tree: because it gives both meat, drink and cloth. It is true beyond dispute that the nut of itself is sweet beyond the sweetest almond and the liquor to my liking beyond *Florens* or *Frontinack*. Of the prodigious pumpkins, I blush to express their magnitude!" The book altogether is more curious than instructive, I have already stated that the date of publication almost coincides with that of Robt. Knox's Ceylon, and is written in the same quaint style. But here the similarity ends. Robt. Knox had no special axe to grind, was a man of inflexible honesty who studied and wrote from the sheer love of acquiring and imparting reliable information.

Captain Poyntz was evidently a man of quite another type. Had he lived today he would have unquestionably been a great success as a Company promoter: a scrupulous veracity being by no means his strong point, and the whole object of his glowing description crops out in the concluding chapter:—"Showing that he had acquired from the *Duke of Courland* 120,000 acres of land on the said island for a Joynt Stock Co. for subscriptions of any persons who are willing to be adventurers in the same."

The little island, since that day, has seen many vicissitudes, now British, now Dutch, French and Spanish, but finally conceded to Britain. And, small though it be, it is worthy of more attention by trained tropical planters than it has hitherto obtained. Being beyond the zone of eruptions and hurricanes, with good soil in a healthy, forcing climate, it offers excellent prospects for the planter and fruit-grower.

No leaf blight there. No frost to frighten the orange-grower. Investors of recent years are, I know, well satisfied with their returns.

THE SEASON UP COUNTRY this year is what would be described twenty-five to forty years ago as "a perfect coffee-blossoming season." Indeed, where a little coffee is still found, as in Dumbara, there has been a wonderful blossoming display; but then the rain is wanting to bring the pin-point beans to maturity, and in place of many thousands, probably, only as many hundreds of bushels will be gathered. In respect of "tea," a sign of the season is the great extent to which the bushes are flowering—not so much as yet in the higher as in the medium and lower districts, and this, of course, means a check to flush. In some cases, coolies may have to be put on to strip off the flowers.

* Surely it has: plantain or banana flour is made in Jamaica and Queensland and desiccated plantains are sent from Singapore, we believe?—
ED. T.A.

A NEW WEED CUTTING MACHINE.

On a recent broiling, sunny day, I journeyed up through the beautiful Thames valley, branching off at Oxford to the staid and picturesque old town of Woodstock, to see a new machine with which Mr Angus, the Duke of Marlborough's agent, is more than delighted, for it has rid him of one of his greatest annual worries. Every spring the famous Blenheim lake yields a vast crop of tangled masses of weeds, which give it the appearance of a green field, and effectually puts a stop to boating and sailing, and to a lesser extent fishing, during the summer months. The clearance of these weeds has hitherto been a great undertaking, not only tedious and laborious, but costly. Now, thanks to the new invention, the work is carried out speedily and at a comparatively small cost. I should explain at once that this is not a machine intended to drag up the weeds by the roots or to dredge a lake of mud, but a weed cutter pure and simple, working on the principle of the reapers now used by every farmer except in mountainous districts, a boat taking the place of the iron wheels used on land, while the horse is represented by an oil motor or a steam engine.

It was a short walk from the entrance gates where Mr. Angus met me, down the sloping bank to a narrow backwater, where the remarkable little vessel was waiting us, steam up, and apparently fizzing over with anxiety to begin its arduous work of cutting a 10ft. channel through the weeds. As originally designed by Mr. Hall, it was intended to be worked by an oil engine, but the intricacies of these are somewhat beyond the knowledge of the ordinary estate hand, and Mr Angus decided to dispense with the oil motor in favour of a 6-h.p. steam engine, which does its work very efficiently, and is certainly the very thing for a large expanse of water such as exists at Blenheim or for keeping open the navigation of canals, sluggish rivers, and the like. In the larger illustration will be noticed two huge levers standing up diagonally from the sides of the boat. At the other end of these are to all appearance ordinary reaping knives. Those are under water in the photograph, but their position will be understood by a reference to the diagram of a small set of apparatus having one knife only. By raising the lever the knives sink in the water to a depth which can be regulated, and may be anything down to about 4ft. When there is no weed cutting to be done, and the boat is simply required to travel, then the levers are depressed level with the gunwale of the boat and the reapers rise up just above the surface. It will be seen that the boat is propelled by two stern paddles. Between them is the rudder, and as the rudder is moved to port or starboard, the paddles have a lateral movement with it and help considerably in steering which is a decided advantage when dense masses of weeds are being cut. The two sets of reaping knives do not quite meet under the stern, but there are guiding rods which carry the weeds, passing exactly down the centre of the boat on to the knives and very few escape.

I had not been on board five minutes before we were steaming through a terrible looking bank of weeds at a pace of between two and three miles an hour. The machine worked smoothly, and without the slightest hitch. The power of the knives must be enormous. A very intelligent man who was steering the boat told me that on one occasion they accidentally came on a piece of wire cable, which some men who had been working a steam plough or other piece of agricultural machinery had thrown into the lake. The knives cut it through instantly but the mechanism of the little launch was none the better for the accident. It will be understood, however, that knives which can cut through steel cable may be relied upon to sever anything in the way of weeds.

Leaving this end of the lake, and going through the fine bridge which divides the upper and lower waters, we next attacked a bed of water lilies,

and here again the machine was as effective as ever. When travelling in open water it steamed at from four to five miles an hour, so far as I could judge. Mr Angus kindly favours me with the following notes concerning the particular machine he uses. It will be seen that the Blenheim weed-cutter is a somewhat expensive one. In the printed particulars of the invention I note that what is recommended by Mr Hall is a standard size, having knives five feet wide to work four feet or less under the water. In these particulars it is said that the machine can be clamped to the gunwale of any boat or punt, and that it can be worked by hand or engine power. Where worked by hand power, one man would have to row the punt while another turned the wheel which works the knives. The particular machine which I saw at Blenheim is, however, undoubtedly the most economical in the long run where large areas of water have to be dealt with. It will be seen from the smaller illustration that in the cheap machine to be fixed to the purchaser's boat the cutter bar extends on one side only. But to come to Mr Angus's notes. He writes:

This machine, invented and patented by Mr Charles P Hall (His Grace the Duke of Bedford's agent), Estates Office Woburn Beds, is in my opinion one of the most valuable inventions for weed cutting on the market. Here at Blenheim where we have two sheets of water measuring close on 120 acres, it has been in use for the last three weeks with most satisfactory results. The lakes have been partially cleared of weeds each year by sec-sawing shackled scythes from a punt. This method was most expensive and inefficient; the weeds were cut in crescents, those near the ends of the scythes being only topped.

By means of this steam weed cutter we can cut from 1 ft to 4 ft below the surface of the water, and take a breadth of 10 ft 4 in. In my opinion if the work is commenced early in April or the last week in March no weeds will ever see daylight. If this is so the enormous work of bringing to shore thousands of tons of matter will be avoided and the weeds will no doubt become weaker every year. The weeds which are our greatest bane are the *Callitriche stagnalis* (the water star wort), and the *Hippuris vulgaris*—the mare's tail. Both are easily cut with the machine in question. The flat-bottomed little vessel which carries the machinery is 27 ft 6 in long, 5 ft 3 in broad, and draws about 1 ft of water when two men and the necessary coals, &c. are aboard. The boiler is 6 h.p and this drives a vertical reversible engine which not only works the propellers—stern paddles—but the two separate reaper knives. 2½ cwt of coal a day are used, and a man and a boy are the only hands required. The price of the machine in the form I describe is £225. Cutters worked by petrol engines or electric ones are no doubt cheaper, but for reliability and simplicity I cannot but think a steam driven one is best.

In the case of the Duke of Beaufort's Woburn estate, the machine resulted in a saving of about 75 per cent as compared with the expense of weed cutting by the old method. So far as I was able to judge, the machine used at Blenheim does its work as efficiently as any machine of the kind which is likely to be made. The less powerful and smaller machines will, of course, do their work more slowly; of them I have no experience. The machine does not clear away the weeds, but merely cuts them. The removal of the weeds from the lake has to be done afterwards from the bank. A rope is generally run out and surrounds a mass of cut-weeds, draws them ashore, and they are lifted out by means of rakes. It should not be very difficult to devise a machine which would lift weeds from the water and deposit them in a flat bottomed craft of some kind, but this would only be of advantage in large sheets of water.

It would be very interesting to know what view the fish take on weed cutting machinery. Those who desire to preserve fish should certainly cut their weeds with the greatest possible discretion, leaving patches here and there for shelter to the fish from

the light. It is a point of the greatest importance that care should be taken not to cut the weeds in the spring until after coarse fish have spawned, and the fry have become large enough to "flee away" on the approach of the knives and paddle wheels—the latter, I think, more disturbing than the former. The makers of the machine, I notice, recommend the cutting of weeds just before they reach the surface, and to cut them again and again throughout the season in order that the leaves may never breathe, asserting that if this is done they will become so weakened that they will gradually die out. This process, however, may mean the almost total destruction of one year's brood of coarse fish. Land agents and others who have the management of these matters should certainly make themselves acquainted with the times at which the various fish in the waters on their estate spawn, and watch the hatching of the eggs and growth of fry in order to ascertain when the weed cutting may be carried out without injury to the fishery. JOHN BICKERDYKE,
—*Field*, July 26.

PISCICULTURE.

Now that interest is taken in the East ament the importation of trout ova from Home with a view to the introduction of that game fish to Ceylon, the Doon, the Neilgherries, and Kashmir, it may not be out of place or devoid of interest for us to give a short resume of the necessary process and period of incubation. This we are enable to do through the courtesy of a friend, an expert, who has furnished us with a lengthy communication regarding the aquarium and exhibit of hatching apparatus at the International Exhibition now being held at Cork. From this letter we are enabled to produce the following article:—

"As most people are probably aware salmon or trout designed to supply ova for artificial propagation are caught some little time before the breeding season, and impounded in small enclosures where they can be kept under observation. The males, which can easily be distinguished by the colour of their bodies and the shape of the lower jaw, are separated from the females, and the latter are divided according to the time which appears likely to elapse before they are ripe. While ripening, the spawn is held in the tissue of the roe or ovary, but when thoroughly ripe the ova becomes detached and are loose in the general body cavity. This process completely alters the appearance of the fish. A hen fish with spawn not yet ripe is of compact form and firm to the touch, but once the ova are ripe and detached, if the fish be held up by the tail, the ova falling away to the front end of the abdomen cause the shape of the fish to "bag" in most unmistakable manner. The hen fish is now ready for "stripping." The operator holds her tail downwards, over a pail or can, and very gently presses the lower side of the body. After a few kicks by way of protest, not unnatural under the circumstances, she begins to yield her eggs in a continuous stream, her quota being about eight hundred to every pound of her weight.

Once "stripped" she goes back to the water none the worse for having been artificially relieved of all family cares. It is then the turn of the male, and when enough of his contribution has been poured on to the eggs, the latter are stirred round and round with the hands, and then covered with water. Fertilization is rapidly effected, and after an interval the eggs are washed and laid in the hatching trays. With reasonable care and gentle

treatment absolutely no harm is done to the parent fish; but artificial propagation is only too often brought into disrepute by ignorant and clumsy operators, who wrench the spawn from the bowels of the fish without knowing or caring whether it is ripe or not. A big fish, even if quite ripe, is not too easy to handle, and in such cases resort may be had to the "straight waistcoat" exhibited at Cork. It is used by Mr. Fitzherbert in his hatchery (perhaps the best appointed in Ireland) on the Boyne, in which a million and a quarter salmon fry were hatched last season.

Around the walls of the Irish Exhibition building is arranged a series of hatching-boxes as used at the principal salmon hatcheries in European and America. A number of these are fitted with water-supply and drain, but, of course, contain no ova, as no salmon or trout could be induced to postpone their family arrangements for the convenience of visitors to the Exhibition. Indeed, the few thousand rainbow ova which were hatched in the watercourse of the trout-farming exhibit in the grounds were probably the very last clutch of the season. At Cork the apparatus, although entirely practical in installation, is displayed in such a manner that all the details can be seen. In addition to those from other nurseries, incubating and hatching boxes are exhibited from Herr Jaffe's hatchery at Sandfort in Hanover. The incubating box, filled with boat-shaped trays of wood and coarse perforated zinc, will accommodate 24,000 ova, until the eye of the embryo can be seen. The coarse zinc of the trays does away with the necessity for a filter, and as the sediment can readily be shaken through to the bottom of the box, where it does no harm. When the eggs are "eyed"—(that is when the eyes of the embryo can be seen through the shell)—they are best transferred to the "hatching-box," with narrower trays fitted with finer zinc; or the coarse trays in the "incubating-box" may be replaced by others of the same size fitted with No 9 zinc: but Herr Jaffe prefers the narrow box on account of the greater concentration of water. The "incubating-box," although certainly desirable is not absolutely indispensable, as the "hatching-box" can be used for the whole process. Once "eyed," the ova are so hardy that the trays can be lifted bodily out of the water and all sediment washed away by the use of a garden syringe. Hatching takes place about twelve weeks after fertilization in the case of salmon, which spawn mostly in December and much sooner with rainbow trout which as a rule do not spawn much before March. In the case of salmon fry, much trouble and expense can be saved by using the "floating redd," another of Herr Jaffe's devices. One of them (in which the young rainbows were hatched) can be seen in the watercourse. It is simply a floating box with zinc sides and accommodation for the trays. The "redd" for practical purposes would be moored in the natural stream in which it was intended to ultimately liberate the fry. Eggs, taken from the "incubating-box" as soon as "eyed," are placed on the trays of the "redd." Here in due course they hatch, and when the babies are about six weeks old they are allowed to escape through the door at one end of the "redd," and seek their own way to fame and fortune.

Trout intended for farming purpose are hatched at Herr Jaffe's establishment in "hatching-boxes," and transferred when about ten days old

to a "floating nursery." One of these latter may be seen, stocked with babies, in the watercourse. The youngsters are fed four times a day with finely grated liver, and in about a month's time will be transferred to one of the ponds.

Among the other patterns of "hatching-boxes" exhibited are those from Scorton (Lancashire) and from Dumfries, N.B. In both of these patterns the eggs are accommodated on glass grills. In the boxes from the Dee Fishery, and from the Surrey Trout Farm, the trays are of perforated zinc. Both have partitions in the lower parts of the box for even distribution of the water. In the Midland Fishery box the trays rest on wires, and oscillate, for the purpose of shaking out the silt, to a touch of the hand. America is represented by boxes from Craig Nook on the Atlantic, and Battle Creek on the Pacific side.

Of the different forms of apparatus shown, it may briefly be said that all are equally efficient in skilful hands. The palm must, therefore, go to the kind that best combines economy of construction with simplicity of management. On this account little difficulty will perhaps be felt in selecting the Sandfort pattern.

In India there is no possibility of establishing a Salmon Fishery. Trout-farming, however, is a most profitable industry, and we hope to see it in time firmly established in Kashmir, where the authorities, the climate, and the natural features of the country and mountain streams are favourable to the venture. In Germany it has proved capable of acclimatization; and we trust that the results of recent importation of ova to the East will be such as to encourage private enterprise in the future, if not State; for the public importance of such fisheries is now well enough understood all over the civilized world, and its prospective value to Kashmir and other favourable localities in, or bordering on, our Indian Empire cannot be overestimated.—*Indian Field*, Aug. 21

CHINESE TEA.

To the Editor of the "Home and Colonial Mail."

SIR,—I noticed a paragraph in your issue of last week in which you commented on the report that there was a large demand for China tea in the tea-room of the House of Commons, which you supposed was an indication of the spread of the Imperialist idea. Has it occurred to you, Sir, in reading the reports of the various Consuls in China, that it might easily be believed, if one judged by these reports alone, that China was a portion of the British Empire? It is quite necessary that the British Consuls at the Treaty Ports should record facts about the tea trade, but it seems strange to find them actually pointing out the excellence of Chinese tea, and depreciating Indian and Ceylon tea. I have frequently noticed that in these Consular reports it is assumed that the falling-off of the trade in China tea is a circumstance to be deplored. This may be, for aught I know, perfectly legitimate on the part of a Consul at a Chinese port; but when we consider that British-grown tea has taken the place of China tea in most of the markets of the world, there should be nothing very depressing in the fact to a British subject, even if he be a Consul in China.

The British Consul at Fu-Chan in his last report, which has been printed in several of the leading home journals, describes the tea trade of China as a vanishing industry, and attributes the decline to the Indian and Ceylon competition, and to the obstinacy of the Chinese tea grower, who refuses to reform his method, as well as to excessive export duty as regards the neglect of the grower to use due care in the mani-

pulation of the leaf when growing and being picked, as well as in the preparation for export. The Consul says: "The means of ensuring this has been repeatedly indicated to him and put within his reach, but with no result. He has been in turns implored, scolded, and lectured, but all to no purpose. Some years ago a circular was issued by Sir Robert Hart, warning tea growers that, owing to the superior methods prevailing in India, the trade was slipping away from China. It was recognised by Europeans interested that the progress made by India and Ceylon had been secured by the substitution of machinery for hand labour. Machinery was accordingly imported. While Formosa was still Chinese the Governor imported into the north of the island, not only the machinery considered desirable, but even an expert from Assam. But neither in Formosa nor in Fu-Chan have those devices proved of any avail. Next there is the change which has come over the public taste in Europe. When Assam and Ceylon entered into the competition with China it was soon apparent that the liking for their products was increasing rapidly, and China tea was in no long time hopelessly distanced."

Now there is nothing to complain of here, but note what follows. "It is likely that, as regards delicacy of flavour and aroma, the teas of China are still assured of the suffrages of the cultivated few. Teas from the nearer East are admittedly coarser of taste and contain a larger percentage of tannin, on which account they are condemned by medical men as prejudicial to digestion. But they make an attractively dark brew and are economical. Thirdly, the trade in Indian and Ceylon teas has been fostered by judicious and persistent advertising, to which the Chinese merchants will not resort. Lastly, the trade is crushed by an excessive export duty."

The Chinese tea growers, if they do not advertise, as the Consul points out, are at least fortunate in the fact that they practically receive free advertisements of the excellence of their tea from the officials of a country whose sons are actually competing with them in the growing of the product, and who have to trust to their own enterprise in the competition for the tea markets of the world.—I am, Sir, yours, &c.,

AN INQUIRING PLANTER.

—*H and C Mail*, Aug. 8.

PLANTING NOTES.

THE ONCE IMPORTANT AND LUCRATIVE CHINESE TEA INDUSTRY—(writes the British Consul-General at Canton) has been almost ruined by Chinese apathy and neglect. The growers in the interior pay little or no attention to their plants, and do not trouble to renew the old bushes as they become decayed. The leaf is picked anyhow and at any time as prices appear favourable, with the result that, carelessly handled and fired, the tea, on reaching the London Market, is frequently found affected or deficient in strength, body, and colour. Thirty years ago Canton exported to Europe some 13 million pounds of black tea and nearly two million pounds of green tea. Last year's export was less than one million pounds, consisting chiefly of Congou. The monthly returns of deliveries in London also mark a decline, which would lead one to suppose that the well-known scented papers for which Canton was famous are rapidly going out of consumption. The recent decision of the Chinese Government to lower the export duty on tea to 5 per cent *ad valorem* may have some beneficial effect upon the trade, and will enable low-priced Chinese teas to compete more favourably with those of India and Ceylon.

GOVERNMENT ANALYST, TRINIDAD.—We have from time to time noticed and quoted the good work done by Professor Carmody, F.L.C., F.C.S., in Trinidad. We have now secured a copy of his annual report for 1901-2 showing in detail the work done. Of samples analysed the number was 2,210 against 1,747 in the previous year. Not only agricultural and industrial, but Customs, criminal and miscellaneous samples are detailed. Altogether a notable record of work.

THE COCONUT CRAB.—The following paragraph occurs in *Nature*, 24th July:—

To the *Notes* from the Leyden Museum Dr R Horst contributes some remarks on the habits of the coconut-crab, based upon observations made on captive specimens at Batavia and living examples near Bantam by Mr C P Sluiter. Recently some doubts have been expressed as to whether it is in the habit of ascending palm-trees. Mr Sluiter has, however, seen these crabs climb to the top of mangrove-trees and palms fully 60 feet in height. What they did when at the top he was unable to ascertain, but from observations made on captive specimens, he considers it probable that they were engaged in opening young coconuts and devouring their contents. Whether they have the power of opening ripe coconuts could not be determined, the specimens under observation merely fumbling such as were given them without attempting to penetrate the shell.

Can any one tell us of crabs being found on coconut palms in Ceylon? They are not once mentioned in our *Manual of the Coconut palm*.

INFUSED TEA LEAVES AS MANURE FOR ROSES.—In the proceedings of the Agri-Horticultural Society of India, which we publish in another column, will be found an enquiry from Messrs. Andrew Yule and Company, the Indian Tea Expansion Commissioners, as to whether infused tea leaves make a good manure for roses. It may be well to state the case fully for the benefit of our readers. The leaves of the tea plant, when plucked for the manufacture of the tea of commerce, are first withered or wilted, then passed through a rolling machine by which the cells in the leaves are broken up. This mass is then "fermented," and lastly dried by hot air in the tea dryers. The infusion of the tea in boiling water liberates the theine, or active principle, a large proportion of the tannic acid, and the essential oil. It is these organic substances that go to form the infusion of tea which we value so much. The organic matter, *i.e.*, the tissues, as well as some of the mineral constituents of the leaf, are left, and it is this that Messrs. A. Yule and Company wish to utilise as manure for rose bushes. If the infused leaves are treated in the same way as other leaves for the production of leaf-mould, *i.e.*, by rotting, there is no reason why they should not make a good manure for roses or any other plants. But to apply the infused leaves, *without* putting them through the process of decomposition, would be to court disaster for the rose bushes. If Messrs. A. Yule and Company desire to realise some revenue from the infused tea leaves, they should sell to native nurserymen, or "charawallahs," or to any one else who grows roses and garden plants. There is, however, one purpose for which infused tea leaves are largely used at home, and that is, for cleaning carpets in dwelling houses. The damp leaves gather up the dust, and thus render the housemaid's work easy.—*Indian Gardening and Planting*.

MANURE FOR ROSES.—Artificial manures, say a German contemporary, if properly chosen and applied, are the most useful, as by their use vigorous growth and fine flowers are obtained. Raw bone-meal, in point of usefulness, is preferable to manures containing phosphoric acid; but the manure most to be recommended is potash, and two dressings afforded during the summer have all the favourable results which one can desire from a manure.—*Indian Gardening and Planting*, Aug. 21.

TEA IN CEYLON IN 1802.—We are indebted to an upcountry correspondent for the following "cutting" from the *London Observer* of July 27th, 1902, reproducing what appeared in the same paper, one hundred years earlier or in July 1802:—

"A late attempt has been made by a naturalist of eminence to cultivate the tea plant in the island of Ceylon, but notwithstanding almost all the trees, plants and flowers of this part of the globe seem collected there the experiment has totally failed."

The second attempt made with tea was well-nigh 50 years later by the Messrs. Worms on Condegalle, also without success.

ECONOMIC PRODUCTS IN TRINIDAD.—Mr J L Hart, Superintendent of the Trinidad Botanical Gardens, in his annual report for the year ending March 31st, 1902, states that ginger can be very successfully cultivated in Trinidad, as the plant grows well and rhizomes are of excellent size. A plot devoted to this product yielded at the rate of ten tons per acre of the undried rhizomes. Kola grows fairly well, but as it takes some years to come into bearing no results have yet been obtained. A plot of turmeric has yielded at the rate of two tons per acre of green tubers. Cloves are found very difficult to rear through the early stages, but grow well when established. The section devoted to black pepper has made fair progress, but the plants have not yet reached their fruiting stage. The camphor-tree grows rapidly in Trinidad, but never attains a large size. Camphor and camphor oil, both of good quality, have been produced, and it is intended to grow a plot with a view to testing the feasibility of growing it on a commercial scale.—*Chemist and Druggist*, August 2.

THE LATE MR. OLIVER COLLETT.—*Nature* of July 31st has the following:—

Natural science in Ceylon has sustained a severe loss by the untimely death of Mr. Oliver Collett, F.R.M.S., who, while carrying on actively his vocation as a tea planter, found time for excellent original work both in the field and laboratory. He devoted himself especially to the Mollusca; and a genus and several species of land shells bear his name. As a member of the Ceylon branch of the Royal Asiatic Society he contributed various papers on zoological questions. He also brought his scientific knowledge to bear on some economic questions in connection with the cultivation of tea, and was much esteemed by his fellow planters, being at the time of his death Chairman of the local Planters' Association. Mr. Collett, who was thirty-five years of age, possessed a very attractive personality, and many, both at home and in Ceylon, who were brought into contact with him by common interests, deplore the loss of a charming friend and an enthusiastic naturalist. He died on June 13th, somewhat suddenly, at Colombo from an attack of dysentery.

TRADE FOR FIRST HALF OF 1902.

TEA EXPORTS.—Quantity.—The total output for the six months was 78,291,151 lb against 79,019,338 for the same period last year. Of this, 56,320,866 lb were shipped to the United Kingdom against 59,113,131, a decrease of 2,792,265 lb, while shipments to Russia, China, America and Africa show an increase of about 3½ millions and to Australia a decrease of about one million. The quantity of Tea offered in public sale in Colombo was 28,805,342 lb against 26,620,270 lb for the same period last year. Quality.—The quality though not as good as last year, has been up to the usual average.

Prices.—The average prices at the Colombo Sales have been better than those that obtained for the same months in 1901.

Average 90	31.52
" 1902	33.81

During the earlier part of the year prices ruled from 33 cents to 37 cents against 27 to 35 cents, but the position was reversed for two Sales at end of March and early April, but resumed the higher range during April and May, falling 1 to 2 cents in June below 1901. The price of Common "Leaf" Teas has been fairly well maintained all through the half-year, but Medium Teas have suffered in consequence, and have shown exceptionally good value to buyers, particularly during the months of May and June. Fine Teas have commanded good prices all along. One of the chief features of the Sales has been the price of Dust, which during the latter part of the half-year rose to 26 and 27 cents, having been bought by Russian Firms for shipment to China, to be manufactured into "Brick" Tea.

Green Tea.—There has been a material increase in the quantity manufactured, viz., as per Thirty Committee returns 1,414,391 lb against 677,887 in 1901. The prices for this class of Tea have fallen from the good rates ruling early in the year, but the demand at present quotations is good, having apparently been stimulated by the reduction in price.

Plumbago opened the new year with a sharp recovery in value, and a considerable amount of business was transacted at these higher prices, chiefly in the direction of the United States of America, which have taken about 3,000 tons more than during the same period in 1901. The advance has since been lost to a great extent, except for best kinds; these seem to be scarce and are fairly, firmly held for price. Exports amounted to cwt. 264,804 in 1902, against cwt. 187,437 in 1901, and nearly reached the record figure established in 1899. Evidently mining operations are stimulated by higher prices, as the increased quantities exported could have hardly all come out of local stocks.

CINNAMON.—This trade has been dragging. Values have kept fairly steady and are practically unchanged.

The exports during the six months amount to:—

Quills 749,059 lb	against 789,822 lb	in 1901.
Chips 742,618 "	"	649,845 "

Products of the coconut palm show the following exports:—

	1902.	901,
Coconut Oil	cwt. 168,148	cwt. 155,810
Copra	" 115,119	" 135,940
Dessicated Coconuts	lb. 5,565,364	lb. 6,907,531
Poonac	cwt. 67,505	cwt. 51,937
Coconuts	nuts 7,542,186	nuts. 9,170,807

COCONUT OIL.—The United Kingdom and India continue to take the bulk of our production, but lately an increased export has again sprung up for the United States of America.

COPRA exports have slightly fallen behind.

Prices have been very high all through the six months for both oil and copra, and although they have dropped somewhat, they must still be considered highly satisfactory to those that have invested in coconuts.

POONAC exports are higher, in sympathy with the increased export of oil.

Cocoa keeps about up to last year's quantity shipped:—

1902	cwt. 26,020	} first six months.
1901	" 28,532	

Prices have experienced a drop and the business in this article seems to have been dull.

Mr. Renton, the Tea Commissioner for the Continent, has suggested a different mode of preparation for the Continental Markets, and if this hint is being acted upon by planters, it may lead towards our product coming more into favour there and ensuring a better price.

CARDAMOM shipments are considerably ahead of last year;

314,138 lb. against 248,252 lb.

and prices have suffered a considerable drop since the commencement of 1902.

The shipping visiting this port is apparently still steadily on the increase and approximately 10 per cent more than in 1901.

FREIGHTS.—Merchants were startled during the course of the period under review by a combination of the British Ship Owners interested in the business of this Port being formed in England. At first this move was viewed with little favour, local shippers fearing it would naturally lead to an enhancement of freights. However, so far, their apprehensions have not been realised; the combination has been at work now several months and freights are practically what were before.

COTTON GOODS.—Cotton has fluctuated greatly during the period under review, Upland Middling opening at 4 17-32d in January against 5 17-32d at the beginning of 1901, 5½d being recorded at the end of April this year and 4 31-32 at the end of June. Futures are quoted steadily lower as far as March-April next, a record American crop being expected. Exports of cloth to Ceylon from the United Kingdom during the six months ended 30th June show a very large falling-off, costs apparently varying much in relation to cotton prices, while local values have been much as they were at the beginning of the year, lines in short-supply doing slightly better, others showing a somewhat weaker tendency.

RICE.—Prices opening in January with R3'45-R3'86 for Soolye receded slowly to R3'10-R3'70 in February, recovered slightly in March and closed firm at the end of June R3'28-R3'50.

The total importation for the six months was:—

1902	1,459,957 bags.
1901	1,343,440 do.

The local market has been very firm during the past half-year, and this has led to the introduction of inferior qualities to suit the demand for cheap rice for the planting districts.

COAL.—Imports have received a check and have fallen behind last year's quantity.

Cardiff	180,029 tons.
Indian	137,229 "
Others	476 "

Total... 317,734 "

against 342,625 tons in 1901. With lower prices ruling Cardiff coal has pushed a certain amount of Indian coal out of the market, as steamers are taking by preference the comparatively dearer article and thereby ensuring better quality, saving of labour, &c., which compensates for the difference in price.

EXCHANGE.—The year opened with six months sight credit bills quoted at 1/4 13-32, and Bank demand drafts 1/4 1-32. A temporary advance of 1-32nd took place about the middle of January, but was of short duration, and rates reverted to the former figure and remained steady till toward the end of February, when 1/4 7-16 was again touched for six months' credits. During March-April rates steadily gave way, and six months' credits were freely bought at 1/4 9-32. This

was practically the rate up to the end of June, although at times $1/4\frac{1}{2}$ was touched. Closing rates were:—

6 months' credits $1/4$ 9-32
Bank demand $1/3$ 15-16

The six months' discount rate in London at the commencement of the year was $3/3$ 16 per cent, and this was the highest quotation during the half-year. It fell to 3 per cent during January, and shortly afterwards reached $2\frac{1}{2}$ per cent, the closing quotation being $2/9$ 16 per cent, the lowest point touched.

CHAIRMAN.—It will be necessary to appoint a Chairman, Mr. Stanley Bois' term of office having expired.

COMMITTEE.—It will also be necessary to elect two members of Committee in place of Messrs. W. Shakespeare and F. O. Allen who retire by rotation.

ACCOUNTS.—The accounts of this Chamber for the past half-year, duly audited, are laid on the table.

MEMBERSHIP.—The number of members of this Chamber is 71, as against 69 in the previous half-year.

AMAZONIAN RUBBER.

TRAMWAY CONCESSION IN PARA.

From Mr Consul Churchill's brief report from Para we learn that the total exports of Amazonian rubber, including that from the States of Para and Amazonas and the Republics of Bolivia and Peru, during the year 1901, stating qualities, quantities and their destinations, were as follows:—

	Europe, Tons.	United States, Tons.	Total, Tons.
Fine	7,949	8,052	16,001
Medium	1,562	1,890	3,452
Coarse	2,557	4,284	6,841
" Caucho "	2,723	1,322	4,045
Total ...	14,791	15,548	30,339
" 1900...	—	—	25,807

Of the rubber exports of Para, amounting to 12,040 tons, valued at £2,659,160, we find that the United Kingdom took 4,609 tons, valued at £1,118,209, and the United States, 6,679 tons, valued at £1,361,553.

Mr Churchill's report also contains the information that concessions have been, and are about to be, granted for various purposes; such as improvements to the port and sewerage, but the concession holders must find their own capital. The port will require an expenditure of at least £2,000,000.

Capital will also be required for the conversion of the present tramway system from animal to electric traction. It is understood that the change will take place within the next two or three years. Tramways are very extensively used in Para, and the enterprise should be lucrative.

EDIBLE TUBERS.

With reference to the description of an edible tuber, which we reproduce on our seventh page today and which we had previously referred to Mr. Nock of Hakgalla as one of the most practical authorities on the subject in the island, that gentleman writes to us:—"The edible tuber, *Coleus Copsini*, is a plant I do not know, but from the description it appears to be very much like the 'Innala' or 'country potato' of the Sinhalese, *Coleus parviflorus*, of Botanists, and is a vegetable that I don't think ever likely to be much cared for by the European population. It is, however, a product that should be introduced to the Garden here, and if it should prove distinct

from the 'Innala' would add one more vegetable for native gardens. Since writing the above I have looked into the last *Tropical Agriculturist* and find on p. 78 a paragraph on *Plectranthus* as a vegetable. *Plectranthus* is only another name for *Coleus* and the very specimen, named in the accompanying slip, is called *P. Coppini*, so my view at first still stands good. We should have it, but I have not much faith in its ever becoming a favourite or taking the place of the potato."

A NEW EDIBLE TUBER.

COLEUS. COPSINI.

[By Edward Heekel, in the "Agricultural Gazette of New South Wales."]

A good deal has been written lately on the Ousounifing and its tubers, the use and cultivation of which are steadily increasing in the French tropical colonies. It has been incorrectly called *Plectranthus Copsini*; but, judging by the structure of the stamen, it is really a *coleus*. Being a new species, it is as well to give it definitely the name of *Coleus Copsini*. Some deficiency still exists in the history and knowledge of this plant and its tubers, particularly as regards the chemical analysis of the latter. I have thought that it might be of interest to give the results of the researches made by my friend, Professor Schlagdenhauffen, of Nancy, at my request, using the tubers from the last crop, of November, 1901, raised in the Colonial Botanical Garden at Marseilles. It is a very remarkable fact that this Soudanese plant will pass through all its stages of development in our short summer season of about four months.

From this fact, and also because it has not a name indigenous to the Soudan, I am persuaded that it originates in Abyssinia, like a great many more edible tubers belonging to the same class, *Coleus*. Beside this it resists very well the cold of the early part of November, and the first tubers introduced from the Soudan flowered early in October in Marseilles in the open air, producing fine heads of blue flowers, which only the cold of the end of November withered before they had turned into fruit; but each year I have obtained from eighteen to twenty stems, six to seven tubers per stem. These were heavier and larger in 1900. It would thus appear that cultivation favours the improvement and development of these tubers, and I intend to continue my experiment with the view of cultivating the plant in the southern districts of France. Another reason for this is that the results of the chemical analyses and culinary uses made by professor Schlagdenhauffen of the tuber encourage its introduction as human food—for cultivation, at any rate, in our southern districts.

We shall see from the analysis that the tuber contains fatty substances, is rich in starch, glucose and saccharose. It certainly contains but little albuminous matter, but is, nevertheless, a perfect food.

Its taste when cooked is very agreeable, resembling that of Japan Croue, or salsify, while it is richer in alimentary equivalents than either of these legumes.

In a somewhat dry lot of 30 tubers were found five or six weighing 0.015 lb; eight about 0.012 lb; three to two 0.007 lb; and the remainder about 0.005 lb (This would amount to, say, 66 to 250 to the lb.)

The largest were $1\frac{1}{8}$ inch long by $\frac{1}{8}$ inch thick; the average were between $1\frac{1}{16}$ inch long by $\frac{1}{16}$ inch thick, and the smallest were $\frac{1}{2}$ inch long by $\frac{1}{16}$ inch thick.

In a fresh state they contain nearly 80 per cent of water. They dry very quickly, and after being exposed to the air for some days they shrivel, and only show about 75 per cent of moisture.

When the dark brown or black skin is removed, they are white at first, but darken in a few moments;

moreover, the knife used turns black, which is an evident proof of the presence of a good deal of tannin, not only in the skin, but also in the body of the tuber. This, when stripped of the skin and thoroughly dried, has the appearance of a chocolate-coloured and very hard substance, which can be reduced to a fine powder by a pestle. This powder is submitted to the action of ether, of petrole, chloroform, alcohol and water, then the residue is calcined to ascertain the weight of the ashes, and the percentage of cellulose and ligneous matter can then be calculated.

Successive analyses gave the following results as to the composition of these tubers:—

	Per Cent.
Fatty matter	2.50
Glucose	0.68
Saccharine	4.67
Not defined	3.35
Gum and pectic matter	65.05
Albuminous substances	7.8
Starch	4.90
Ashes	4.26
Cellulose, ligneous matter and loss	40.71
	100.00

The ashes consist of sulphates, phosphates and carbonates.

The weight of the potash is 2.49 per cent, and of the soda 1.34 per cent.

These tubers, as is well known, replace in French tropical colonies the potato, which does not produce any tubers, but grows all into leaf. In the Soudan they are very much appreciated even by Europeans. When the tubers are scraped in the fresh state their odour is very much like that of potatoes. A very simple way of cooking them is to immerse them in nearly boiling water for 20 minutes, when the black skin can be easily removed, and the fleshy part which remains is white. Add a little chopped parsley, butter and seasoning and serve hot. Prepared thus, they have a most agreeable taste, resembling that of Crose of Japan, or salsify.

Note.—This appears to be a plant worthy of trial in Australia. As M. Heckel points out it is probable that with cultivation the tubers may be greatly increased in size. In some of the arid western districts potatoes can only be grown with difficulty, and this tuber may in time prove a good substitute for them. As a crop for pigs also there should be a future for it.

THE KLANG COFFEE CULTIVATION COMPANY.

PARA RUBBER GROWING SUCCESSFULLY.

The yearly meeting of the Klang Coffee Cultivation Company was held yesterday afternoon at the office of the Company, Weld Quay. The Directors consider the past year's working satisfactory, and the future prospects certainly favourable. It has been decided to plant up the whole Estate with Para rubber, but this will not interfere with the coffee for at least four years, when it can be decided which product it will pay best to continue cultivating. The Para and Rambong trees previously planted are growing strongly, and an experiment was made about four months ago in tapping three Para trees three years old, which yielded some $\frac{3}{4}$ lbs. good rubber valued in England at 3s 2d per lb.—*Penang Gazette*, Aug. 19.

THE OLDEST PARA RUBBER TREE IN PENANG.

Mr C Curtis, F.L.S., has been writing on "The Penang Gardens Rubber Tree." The tree in question is one of about two dozen young Para rubber plants

which were received from the Singapore Botanic Gardens towards the end of 1895 and planted out in the early part of 1896. It so happened that the tree in question was planted in poor gravelly soil on sloping ground, which, by the subsequent cutting of a road, converted the site into a dry bank. Hence the tree cannot be said to have grown up under the most favourable conditions. When the tree was some ten years old, the question of the best method of extracting coagulating rubber, and the probable yield, commenced to interest the planting community, and this tree, as being the largest in the Penang Gardens, was selected for experiments which have been carried on from time to time. In June 1897, when the tree was approximately twelve years old, it was thirty-six inches in circumference at three feet from the ground, and yielded one pound of dry rubber. In November-December of the next year the yield was three pounds; April-May, 1899, two pounds, eight ounces; November-December, 1899, three pounds, four ounces; October-November, 1900, three pounds, twelve ounces; and in August-September, 1901, when the circumference of the tree was sixty-six inches and its height about fifty-five feet, the yield was two pounds, two ounces. Mr Curtis points out that the interest in this particular tree lies in the fact that it has been tapped successively six times, from the eleventh to the fifteenth year of its age, that it shows no signs of deterioration and that the incisions made are all healed up. Since December, 1900, its growth has been slow, the present circumference of the main stem being only sixty eight inches; that is an increase of only two inches in a year and a half. Mr Curtis is of opinion that probably, under existing circumstances, this tree has almost attained its maximum size. He also states that one hundred such trees could be grown to the acre without being too crowded. It will thus be seen that the average yield per tapping amounted to two pounds eight ounces, so that at this estimate, and taking the price of rubber at three shilling per pound, an acre should produce a crop valued at thirty-seven pounds ten shillings at each tapping.—*Penang Gazette*, August 20.

COCONUT PLANTING IN THE STRAITS.

"Spero," writing in the *Straits Times* of August 21st, says:—May I ask if any of your readers can inform me whether or not coconut cultivation is considered to be on the increase in the Native States? One seems to hear more about it than one did, but perhaps it is not so much of the coconut tree itself, as of its enemies. My attention was drawn to this subject by an old friend of mine at home, who read in a recent issue of your paper the following statement—(copied, he said, from a Report of the Federated States United Planters' Association):—"Coconut planting does not increase in favour owing to the ravages of the beetle and the cost of keeping the trees clean". The above statement, as quoted, implies that the expenses entailed have been found to hardly warrant much attention being given to the cultivation, and, if this be the case, it must be very disappointing to those of the planters who, under the impression that coconuts had stood the test of hundreds of years, and had always been considered a sound investment, chose this form of agriculture in preference to those more speculative. My correspondent goes on to say, "surely trees which are scrupulously kept clean, and under constant supervision are in less danger than others;" there would seem to be a good deal in this argument. I am told that the Government is trying hard to enforce the Coconut Enactment as regards the holders of native plantations where a great part of the trouble must surely lie. But it is not on the

results from native holdings that the Planters' Association are likely to frame their reports. Thus it would be interesting from the would-be investor's point of view, if from no other, to ascertain the extent to which European cultivation has suffered by the "ravages of the beetle" to warrant the Planters' Association taking such a gloomy view of the situation. It must occur to the least observant that the prominence of such statements without more detail is hardly calculated to bring the cultivation in question into further favour, and in the Native States there must be many who have a large interest at stake.

"FORCED" PLANTAINS.

Mr. C J Stracey, in your issue of the 20th inst., refers to the statements of "A Correspondent" on "forced" plantains which appeared in your columns a short time ago, and says the practice of artificially ripening the half-green fruit "has not been discovered to produce deleterious effects on the consumers." He admits that this process robs fruit of its freshness and flavour, but he thinks that the practice is defensible so far as the ryots on the Lower Pulney Hills are concerned, owing to the desire they have to get a quick and regular sale for the fruit they so extensively grow. The question is not whether the plantain ripened by an artificial process is deleterious to the consumer but whether it is really worth spending money on it in its deteriorated condition. If this process destroys the freshness and flavour of the fruit there can be no real pleasure in buying and consuming it. Europeans are chary of eating the soft, pulpy, flavourless, artificially-ripened plantains sold and are greatly provoked when such are placed before them on the table for consumption. The people of India are not so careful and often eat fruit in a semi-decayed state, which may sometimes be the cause of "bowel" complaints. The article on "forced" plantains has already taken effect. I know of several Europeans who have taken action since they read it and ordered their cooks not to bring artificially ripened plantains any more. I have heard of complaints made by consumers about the unsatisfactory nature of the plantains put nowadays on the Madras market. They cannot understand, they say, why plantains have such an altered taste. My article has now enlightened them as to the cause of this. Plantains come from various parts of South India to the City for sale, I understand. My counsel is that, if Madras purchasers would sternly resist such an indefensible method of ripening them and refuse to buy them, the growers and the retail dealers would soon be brought to their senses and put only naturally ripened plantains on the market. This would set an example to the whole of South India, and to the fruit-growers on the Lower Pulneys in particular, who evidently are much to blame in openly carrying on the practice. A great future lies before the plantain, not only because of its fruit but because of the fibre which can be extracted from the stalk and made into ropes. Some of the finest and strongest

ropes can be made from certain species of plantains, which, if cultivated for fibre as well as for fruit, might become a source of wealth to the ryots of the Presidency. Thousands of plantain stems are cut down and thrown away as worthless, if they cannot be utilised as leaf-plates. The waste in fibre by this action, and the consequent loss in rupees must be very great. If plantain growers were taught how valuable the plantain stalk is in fibre, and if they would avail themselves of the fibre-extracting appliances which can be procured cheaply, they would benefit themselves to a large extent. They might grow the *Musa textilis*, which is the plantain so extensively grown in the Philippines. This plantain is well-known in India. It is called in Tamil *Peyan vazhai*, or the "demon plantain."—*Madras Mail*, Aug. 25.

FRUIT PULPING.

An account is given in the Annual Report on the Saharanpur and Mussoorie Botanical Gardens of some experiments made in the new Californian industry known as fruit-pulping. The idea is to boil down the fruit until it has assumed a semi-solid condition and then evaporate the remaining moisture, so that the pulp can be wrapped in oiled tissue and packed in an ordinary deal box. Experiments were made with peaches and mangoes, but the result was not encouraging. One hundred and fifty peaches, weighing 19½ lb produced 2 lb of dry pulp, costing 12 annas per lb, without counting the cost of stoning the fruit, boiling, straining, evaporating, putting up the bricks in an attractive form for sale, etc. Thus the cost of producing peach-pulp bricks is at least Re 1 per lb; and as the better class of peaches sell readily Rs 2 to Rs 3 per 100 and second-rate fruit at Re 1 per 100, it would not be worth the time and trouble of growers to adopt the pulping system. Moreover, it was found that the pulp-bricks would not remain hard and solid for more than a few days in the moist climate of the rains.—*Madras Mail*, Aug. 25.

THE COCONUT PEST IN THE STRAITS

Mr E V Carey writes from Klang to the *Malay Mail* as follows:—As instancing the danger of having any sort of rubbish lying about an estate, or in private compounds, the following little anecdote may be of interest. Some four months ago I had to discard a number of old sacks; these were thrown in a heap on the ground, covering a space just six feet square, and left there. Last week I have happened to notice them, and stood by whilst they were being removed. From this one little heap no less than 201 larvae of the rhinoceros beetle were collected. I am sorry for the one, but this is a true story, so I can't very well leave him out. Moral let every one keep his grounds scrupulously clean, and have even the insignificant and harmless-looking collections of rubbish promptly burned.

THE USES OF CASSAVA.

In the *Cosmopolitan*, Mr. Packard points out the astonishing agricultural possibilities of cassava, better known as tapioca. It is a bushy shrub growing to about five or six feet in tropical and sub-tropical climates,

and its roots produce more starch per acre than any other vegetable or grain. In South Alabama, Mississippi, Georgia and Florida its cultivation is spreading with great rapidity. It thrives best in the light sandy soil which before was thought not of much worth. The average yield of the roots gives eight tons to the acre. The starch from these roots costs only 2½d per lb., and it is said to be far superior to wheat starch at 3d per lb. The gain in using cassava for fattening animals, as compared with the old methods, is stated to be about 30 per cent on a seventy-day test. Hitherto artificial fertilisers have been used for cassava in America, but now it is found that several kinds of beans and peas growing freely in the regions where it is cultivated form perfect natural fertilisers for it. Tapioca is cultivated in the Straits Settlements, and would no doubt thrive equally well in many parts of India.

GEM-MINING IN QUEENSLAND.

has latterly attracted considerable attention, and with the view of obtaining some accurate information respecting the condition and prospects of this branch of the industry, it was considered desirable that an examination of the Queensland sapphire and opal fields should be made by persons specially qualified for the task. Accordingly Mr B Dunstan, Assistant Government Geologist, was deputed to visit the sapphire fields at Anakie in the Clermont district, and to Mr Jackson, also of the geological survey staff, was assigned the duty of inspecting the opal centres of the State from Cuumamulla to Winton. With respect to sapphire-mining at Anakie Mr Dunstan says that only a small portion of the extensive tract of sapphire-bearing country has been explored, the principal camps being confined to an area not exceeding 10 square miles. The sapphire deposits are found in much the same manner as shallow alluvial gold or tin, and vary in thickness from a few inches to several feet. The stones are blue, yellow and green, of numerous tints and shades, the green and yellow being the most beautiful. The yellow stones are rare, and the blue are of so dark a shade as to appear almost black, and cannot compare with the brilliantly tinted stones of Siam, Burmah, or Ceylon. Green stones, uncommon in other parts of the world, are found in abundance at Anakie, and their comparative rarity and frequently great beauty have created a growing demand for them. Amongst other stones found at Anakie is the hyacinth which, when cut, forms a richly coloured gem of a deep blood-red colour, and the Oriental cat's-eye, rejected as valueless until the skill of the lapidary disclosed the peculiar lustre that is occasionally very marked and effective. More important, perhaps, was the discovery that the sapphire deposits are also diamentiferous, and one diamond weighing 1½ carats, and absolutely colourless, was purchased by Mr Dunstan, and is now to be seen in the Geological Museum.

Mr Dunstan estimates the number of persons engaged in gem-mining at Anakie at the time of his visit to be 200, and the warden sets down the value of last year's output from the field at 6,090l.

The production of opal in 1901 was estimated at 7,400l.—*Board of Trade Journal*, August 7.

PRODUCTS AND TRADE OF JAVA FOR 1901.

The year 1901 can scarcely be regarded as prosperous for the Island of Java. Against a large sugar crop, there was a falling-off in the production of coffee, rice and coprah, while the import trade left much to be desired.

THE COFFEE CROP was very small. On the eastern side of the island the trees suffered a good deal from the effects of the eruption of the Kloet. The mu-

streams destroyed a few estates, and others were injured by falling stones and ash, and the blossom, then very nearly coming out, was more or less ruined. Government have abolished the export duty, which amounted to about 10d per 112 lb., and this may assist in resuscitating the culture. The production of the coffee crop from private estates in Java last year was 175,000 piculs Java and 118,250 piculs Liberia, while next crop is estimated at 389,500 piculs Java and 93,600 piculs Liberia. The Government crop was again small, amounting to 78,200 piculs Java and 30,417 piculs Liberia coffee.

QUININE.—Notwithstanding the increased monthly shipment of cinchona bark from Java to Holland during 1901 prices realised were satisfactory. The quantity of sulphate of quinine produced by the Bandung factory and sold at auction in Batavia during 1901 was 1,014,000 ozs. (English). The average price paid was 1-1-10thd. per oz, the equivalent of 17-10thd. per unit. The bulk of the quinine was shipped to the United States and London.

TEA.—The season's production exceeded any of its predecessors. The export has almost entirely been shipped to Holland and London, though regular small parcels of specially-prepared tea have been forwarded to ports in the Persian Gulf. Attempts are being made by Java planters to prepare their tea in tabloid form, which is considered in some quarters to be most suitable for the markets in Russia.

THE COPRA crop was much interfered with by rain, and was consequently below either of the two preceding years as regards quantity. Prices have been unprecedentedly good.

FERTILISERS.—Large quantities of sulphate of ammonia and blood manures from the United Kingdom and the colonies continue to be used all over the island. Groundnut-cake from the Madras coast and bean-cake from China also find much favour, and the imports of all kinds are increasing.

OIL.—The prospects of an increased business being done in liquid fuel have not so far been realised, but a considerable number of local industrial undertakings use this fuel in preference to coal.

CONSUL DAVIDS.

MICA PRODUCTION IN 1901.

In the *Iron Age* (New York) of the 17th ult. it is stated that the United States' Geological Survey has completed the report upon the production of mica in the United States in 1901, from which it appears that the total output of sheet mica during that year was 360,060 lb, valued at 98,859 dols, and of scrap mica 2,171 tons (of 2,000 lb), valued at 19,719 dols. In 1900 the production of sheet mica was 456,283 lb, valued at 92,758 dols, and of scrap mica 5,497 tons, valued at 55,502 dols. Mica has been found in many of the States, but in 1901 was produced only in New Hampshire, New Mexico, North Carolina, and South Dakota, by far the larger amount being obtained from North Carolina.

The production of mica in 1901 in detail was as follows:—New Hampshire, 65,800 lb of sheet mica and 255 tons of scrap mica; New Mexico, 3,100 lb of sheet mica and 140 tons of scrap mica; North Carolina, 266,160 lb of sheet mica and 1,775 tons of scrap mica; and South Dakota, 25,000 lb sheet mica; total, 360,060 lb of sheet mica and 2,172 tons of scrap mica. Idaho, Maine, Nevada, Rhode Island, and Virginia, which were producers of mica in 1900, had no production during 1901, and of the other States, with the exception of North Carolina, there has been a very noticeable falling-off in the production. In North Carolina there was a decided increase in the production of plate mica, but a large falling-off in the production of scrap mica.—*Board of Trade Journal*, August 7.

COLOURED AND UNCOLOURED GREEN TEAS.

(TO THE EDITOR OF THE "HOME AND COLONIAL MAIL.")

SIR,—I notice in your issue of July 18th that you have published a letter to me, from my old friend, Mr Hart, on the subject of finished and unfinished green teas. He is of opinion that the Canadian buyers will consult their best interests by using at once the teas he recommends, the finished article. My reply, copy of which is attached, states the case for Canada, and explains why the finished teas cannot be used at present)—Yours faithfully,
ROSS W. HAYTER,
50, Front Street East, Toronto, July 28, 1902.

Robert Hart, Esq.,

Sir,—Thanks for your letter on the subject of finished and unfinished Greens from India and Ceylon. We are not in a position yet to go into questions of the relative merit and quality of the "finished" article, as it is only during the last month that any samples of finished Greens from India have been shown. It may be, as you say, that they are superior and will fetch higher prices. This may happen when they become known and have been well advertised, like uncoloured green Ceylons have been. At present the Ceylon and Indian Greens that are wanted in Canada (I speak for Canada only) are the "unfinished" (to adopt the proper title) Ceylon Greens, and have been extensively advertised as such, as distinct from the coloured teas of Japan and China. They have got a firm hold of the public taste here. The reason is quite evident. When Mr Larkin and Mr Mackenzie undertook to push Ceylon Greens, the "finished" teas you are now making were unknown here, all the Ceylon and Indian Greens being of the "mamuna" type, and some of them excellent in both style and cup, brisk and pungent, and better than the finest Japans that can be bought here, and with plenty of the character that is wanted in Canada, which is, after all, the main point. In fact they have proved to be quite suitable. These are the teas that at a tremendous expenditure of energy and money on the part of Mr Larkin have got established, and, unless the supply of the "unfinished" type falls off, as you seem to think it I may, I predict that it will hold its own for some time to come. The public here have been educated up to the appearance, and are shy of a Ceylon Green that looks green, suspecting colouring matter. The keeping qualities, too, are all right. I have some that I have had nearly a year, and they are perfectly sound whereas a black tea would have gone off.

The motives you attribute to buyers here for using these teas is hardly a fair one. They had to use them or none, as there were no "finished" teas available when they commenced to push them, and the great point in advertising these teas is that they were natural uncoloured teas. You will understand, therefore, that Mr. Larkin takes but a small interest in these "finished" greens, so far as his own business is concerned, although he takes interest in them from another point. He can get gardens in Ceylon to make as much of the sort he requires—or as much as Canada requires—without much trouble, and also at the prices Mr. Larkin and others are prepared to pay.

There will no doubt be a market for both sorts as time goes on, but it will be some time before they get in here and displace the unfinished type, which has got a three years' start. I don't wish you to think that I am extolling the merits of "unfinished" greens as against the "finished," for I have had no opportunity yet of forming an opinion; what I want to make clear is that for Canada at present (for the reasons before stated) the unfinished teas are what

as wanted both as regards appearance, cup quality and price. They beat the Japans used in Canada on all points, prices not being the least important.—Yours faithfully,
ROSS W. HAYTER,
50, Front Street East, Toronto, July 28, 1902.

NOBODY'S BUSINESS.

(To the Editor of The Home and Colonial Mail.)

SIR,—It is satisfactory to see that some interest is being aroused in the extension of the use of China tea among those who are prepared to pay the highest prices—in the tea-room of the House of Commons and also among our richest consumers. Imperialism only interests itself in those who protect themselves, i.e., self governing colonies. Regarding reversion to China teas the cause is not far to seek. The blenders catering for the masses provide an article in which strength, more than ever, is the chief consideration. What those who are prepared to pay highly require is a good flavouring tea with most of this pungent character eliminated; substituting in its stead a brisk, light, flavoury tea. The masses will for the present stand by the stronger compound; unless they, as is so often the case, imitate their betters. Nor am I sure that 80 per cent of the public really care for strength in preference to delicacy of flavour. Fifteen years ago, when Ceylon teas so successfully and exclusively won the markets, they were thin and flavoury; and I well remember going round dealers' tasting rooms and being assured that, notwithstanding the public approval, they and some Indians were fetching far above the value put upon them by specialists. Having both Ceylon and Indian investments, I am writing in the interests of both, and am convinced that a delicate, light, brisk; pleasant tea of flavour can be blended from British-grown teas, as acceptable to delicate palates and as satisfactory to the doctors as anything China can produce. It would also be able, strength for strength, equally to bear with China tea the test in the laboratory. The one great evil of the ordinary pungent blend of commerce is that it is inclined to be "leathery", if drunk weak. Darjeelings, Ceylons, and some Doonars, and many other gardens from various districts could, by lighter rolling and brisker firing, produce an article which would please a finer taste and reassure the doctors. If this question were as fully advertised as Ceylon teas were fifteen years ago it would, as then, soon become the fashion now, as it became then.—I am, Sir, yours, &c.,
W. FORBES LAURIE.

—H. and C. Mail, Aug. 15.

MANURING TEA.

Mr Henry M Alley, the Ceylon planter to whom we owe a new system of plucking, which has been very largely adopted to the advantage of Ceylon gardens, favours us in this issue with his views on manuring, a subject which Indian planters would do well to study, as it is the backbone of the industry in many parts of Ceylon. Mr Alley pins his faith to manuring for quality, and we may state here that he has applied in India and Ceylon for patent rights in a new mixture of this own composition, with which he claims to effect the object of improving quality in tea manufactured.—*Indian Gardening and Planting*, August 28.

PAPER BUILDINGS.—The *Paper-makers' Monthly Journal* reports that a Russian nobleman has upon his estate at Savinowka in Podolia a paper house of sixteen rooms, built in New York, at a cost of 80,000 roubles, and its architect declares that it will last longer than a stone building. Bergen, in Norway, has a church built of paper capable of seating a thousand people.

PLANTING NOTES.

THE "TRUE GREEN TEA."—Messrs. Wm. Jas. and Hy. Thompson's tea circular, dated 31st July, has the following:—

"It has now been proved possible to make in India and Ceylon, without artificially colouring the leaf, the true "Green tea" of commerce, with pure and delicate flavour, and also the distinct variety called "Uncoloured tea," each so attractive in quality as to almost ensure a market provided a regular, abundant and uniform supply of equal value can be guaranteed. We entirely confirm what we wrote on this subject in our annual review."

RUBBER EXPLOITING IN PERU.—A report by the United States secretary of legation at Lima, Peru, in regard to the formation of two rubber exploiting companies was referred to in *The India Rubber World* of June 1 [page 280.] It has been learnt that the company with £26,000 capital, to operate in the province of Sandia, department of Puno, Peru, is the Tambopata Gum Co., organized by Señor Pedro D. Gallagher, of Lima. The new company to take possession of 50,000 acres of rubber lands near Marcapata, in the department of Cuzco, and east of the city of that name, was organized by Don Manuel Elguera, also of Lima, and a brother of the mayor of that city. It was Señor Elguera, by the way, who secured the concession in the Beni country, in Bolivia, now being exploited by the Andes Co., of Baltimore, Maryland.—*India Rubber World*, Aug. 1.

SEEDS FOR INDIGO PLANTERS.—In the *Natal Mercury* of July 4th it is stated that a possible new industry of considerable interest is in front of Natal. Mr A M Baily, accredited by the Government of India, and also by the indigo-planters in that country is at present in the colony making inquiries in regard to the indigenous indigo-plants of Natal, with a view to obtaining a large supply of indigo-seed for the use of Indian planters. It is probable that some hundreds of tons of the seeds will be required every year. It is suggested that this would be a valuable crop to grow in Natal, for seed purposes if for no other. The yield of seed for plants growing six feet apart is stated to be about one pound per plant, or 1,210 pounds per acre. The present price for the seed is 1s 6d per lb.—*Chemist and Druggist*, August 16.

MOZAMBIQUE.—There is a considerable falling-off in the value of the exports during the past year. These consist of groundnuts, copra and a small quantity of ivory and calumba root. Formerly india-rubber was despatched in important quantities to Hamburg and elsewhere; but the export of this valuable commodity was stopped in the early part of this year, the authorities stating that, owing to the admixture with the rubber of foreign bodies for the purpose of increasing its weight, it was acquiring a bad reputation on the European markets, and that until such time as the collectors of the juice could find means to procure a rubber calculated to create a demand for produce of this country, no more should be despatched. Naturally, this somewhat arbitrary order had a disastrous result, for many of the traders, who had accumulated large stocks, found themselves unable to put their produce on the market. The Governor-General has now withdrawn this prohibition.—*Cutta-Percha Trades' Journal*, August 4.

PERU.—The india-rubber industry is likely to progress, as from all accounts the forests of Peru contain innumerable rubber trees. From July 1st, 1900, to July 30th 1901, grants amounting in the aggregate to 1,240,000 acres of forest land, said to contain valuable rubber trees, have been made by the Government. These lands lie in the Departments of Huanuco and Cuzco. The periods of grants are either five or ten years. The royalty claimed by the Government is 2s for every quintal of rubber which is exported. During the same period six other concessions were granted under somewhat different conditions. One of the grants comprised 4,942 acres and others 1,235 acres each. These grants are divided into plots called "estradas." Each "estrada" contains within its boundaries 150 rubber trees. The royalties levied in this case are 20c annually for each "estrada" and 20c for each hectare of land which the estradas cover.—*Cutta-Percha Trades' Journal*, August 4.

TEA IN INDIA AND CEYLON.—Says "*Indian Gardening and Planting*," September 4th:—"In respect of the acreage figures it should be remembered that the procedure of the planters in the two countries is different. In India when land gets worn out, it is customary to extend and plant fresh land. This has been somewhat contemptuously styled a *jhuming* policy. But so it is; the old land produces little, still it is often kept up and swells the nominal total of acreage in cultivation. In Ceylon the practice is to make the most of existing cultivation, by forcing manure, which keeps up the output when the soil flags. Yet not content with thus forcing output of tea from old land, the Ceylon planters have gone ahead faster than the Indian in the typical Indian system of extension, for which the *Ceylon Observer* seeks to blame us." [Not so, we maintain, India in four years planted 17,000 acres more than Ceylon; and there has been no planting here at all for two years; while nearly all Indian Tea Company Reports up to this date, speak of "extensions."]

CACAO-PLANTING IN DOMINICA.—Mr. G. W. Penrice writes to *The Times* in a very cheery way of this island. He says:—

It is very probable that newcomers landing at Dominica will be told that the Crown lands are no good, and may be advised to buy ready-made places on the coast, where the labour of clearing and preparing the land for planting will be avoided, but this advice should be ignored, for although the land on many of the coast estates is still very fertile, it is not to be compared to the virgin land in the interior. Some of the cocoa trees which I planted 13 months ago on my property are quite equal in size to many trees that I saw on some of the plantations on the coast, and which I was told had been planted three years. Of course, the taking up of Crown land entails a certain amount of roughing it during the first year, as it takes some time to erect dwelling-houses, &c., but these discomforts become things of the past and are soon forgotten. It is not advisable for any one to go to Dominica with the intention of planting unless possessed of at least £2,000, but given this sum, together with the exercise of some tact in the management of the natives, success must follow.

INDIA RUBBER.—The India Rubber Industry is one of the most remunerative in Russia, and is conducted by wealthy companies. British dealers in the product should bear this in mind and afford every facility to purchasers of the commodity in question.—*Board of Trade Journal*, Aug. 14.

RUBBER IN THE STRAITS.—We are much indebted to Mr. F Pears for his letter in correction of our estimate of the area under rubber in Johore, which he would raise from 200 to at least 1,000 acres. We had less information about Johore than any other division of the Straits; but we would like to hear from residents in the other States as to our figures, which ran as high as 2,926 acres for Selangor.

TEA GROWING IN AMERICA.—America persists in her attempts to grow tea. According to the *American Grocer* of the 30th July "Texas is to have a tea farm at Port Lavaca. A start has been made with 500 plants. This is in line with similar experiments made fifty years ago." In the same journal we read the following:—"Sinko Hatto, on behalf of Japan's tea interest, has been appointed by his Government to make a thorough study of the tea-growing conditions in South Carolina."

THE MUNGPO CINCHONA PLANTATION.—Dr. Stuhlmann, Director of Agriculture in German East Africa, has reported upon various Indian products; among others upon Cinchona. As he says, the bark is chiefly cultivated by the Government. He deals specially with the Mungpo plantation, near Darjeeling, where an area of 40,000 acres is reserved. About 200 acres are planted with cinchona every year, so that about 1,500 acres are always occupied by this product, the trees being only maintained for about eight years, then rooted out and the ground left to rest. One plot has, says Dr. Stuhlmann, been resting for 15 years after producing a crop of *Cinchona succirubra*, and it will still be necessary to manure with bone dust before planting *Ledgeriana*. Wherever the soil is suitable *Calisaya*, var. *Ledgeriana*, is preferred but it requires good drainage. *Officinalis* does not succeed at Mungpo.—*Planting Opinion*, Aug. 23.

BANANAS—are now-a-days quite common objects of merchandise, and to a certain extent the banana peel has ousted the no less dangerous orange peel as a trap for the unwary in the London streets, but now the fruit will probably become even more common, for an agreement of considerable importance to Jamaica has just been entered into between Messrs. Elder, Dempster & Co. (Imperial West India Mail Service) and the United Fruit Company of Boston. The Direct Mail Company are under contract with the Government to run a fortnightly service of steamers, and to bring over from Jamaica 20,000 bunches of bananas by every steamer. Sir Alfred Jones has all along been anxious to make the service a weekly one, but the supply of fruit on the south side of the island was insufficient. This difficulty has been overcome by the agreement with the United Fruit Company, which does most of its own fruit farming, and undertakes to supply the extra steamers of the British line, which are to run from the northern side of the island to Manchester.—*Grocers' Journal*, August 2.

A NEW WEED-CUTTING MACHINE.—A Ceylon official is good enough to send us the extract from *The Field* on this subject which we reproduce elsewhere and to ask:—"Would not this be worth trying on the Colombo Lake?"—We commend the extract to the attention of the Chairman and Members of the Colombo and Kandy Municipal Councils—and also of the Local Board, Nuwara Eliya, where Lake Gregory is being steadily encroached on by vegetable growth, weeds, rushes, &c.

JAVA TEA.—As foreshadowed in the British Consular report for 1900 the season's production of Java tea in 1901 exceeded any of its predecessors. The bulk was almost entirely shipped to Holland and London, though regular small parcels of specially prepared tea were forwarded to ports in the Persian Gulf. Attempts are being made by Java planters to prepare their tea in tabloid form, which is considered in some quarters to be most suitable for the markets in Russia. Statistics of Exports for the last four years are as follows:—

1898	..	12,110,724 lb.
1899	..	12,841,702 lb.
1900	...	15,406,984 lb.
1901	...	16,750,872 lb.

Planting Opinion, Aug. 23.

DESTRUCTION OF PESTS.—There has just been issued from the Agricultural Department at Ottawa a valuable pamphlet whose title runs thus:—"Agricultural College, Bulletin No. 122. Spray Calendar—directions for treatment of insect pests and plant diseases. By W Lockhead, Professor of Biology and Geology, Orleans Agricultural College, Guelph. 1. Thorough intelligent spraying pays; 2. Spraying is a insurance; 3. Clear up refuse, gather up fallen leaves and fruit in the fall and burn them; 4. Protect birds and beneficial insects. Published by the Ontario Department of Agriculture, Toronto." There are a large number of recipes for "extirpation," with instructions of the mixing of ingredients, and notes as to how and when to apply them to the affected trees, vegetables; &c. Altogether it is a little work of great value to the market gardener and private grower. Such a work must spare the "Inquiry Department" at Ottawa much work and save much time just when a loss would be of importance. For such a work a large sale might be guaranteed in this country.—*Gardeners' Chronicle*.

IMPROVEMENT IN COCONUT CULTURE.—An old resident writes:—

"It would seem that the coconut does not admit of exploitation to any great extent—being indigenous and apparently unimprovable by pruning and grafting. "Selection" of seed, or "fertilizing" flowers to that end, might do something, but life is short—and a coconut tree is not a gooseberry bush!"

Careful selection of fully-grown, ripe nuts from a good district for the nursery is the only precaution we have heard of. It might be well to experiment in Ceylon with seed-nuts from the Straits or Java. Decandolle puts the Eastern Archipelago, extending up to Sumatra, as the original habitat of the coconut palm, from whence the nuts floated away both to Eastern and Western shores. Experiments in fertilising flowers ought to be tried in the Heneratgoda Gardens, if deemed of sufficient importance. What do Messrs. Lamont, Jardine and W H Wright say to this idea?—ED. T.A.]

A GUTTA-PERCHA EXPEDITION TO THE SOUTH SEA.

The Committee has sent Herr Schlechter to German New Guinea to explore this possession for Gutta-percha. The expedition was a complete success, Herr Schlechter having discovered at the foot of the Bismark Mountains, and elsewhere gutta trees and vines giving an excellent quality of gutta, equivalent to "guttamerah" and other finer sorts. Samples sent to Germany are now undergoing a detailed technical examination, but we may now feel sure that our cable industry can be provided with gutta-percha from the German colonies. This discovery is the more important as the supply from Northern Borneo and other gutta countries is rapidly declining, at least, for the better sorts. For this reason a Bremen merchant, Herr Oldemeyer, had promised a prize of £150 to the explorer who should find in a German Colony a wild-growing gutta plant giving a good latex. Of course, the prize is due to Herr Schlechter. West Africa is concerned in this discovery. Herr Schlechter has sent to the Botanical Gardens at Berlin cases of young plants from seeds of the newly discovered gutta trees and vines, and these plants are now being submitted to a trial of the West African climate, in the Botanical Gardens of Victoria (Kamerun) and Togo. These countries being nearer to Europe and better suited for plantation than the far-off and ill-developed islands of the South Sea, it would be a great gain if the gutta plants could thrive there.—*Gutta-Percha Trades' Journal*, August 4.

GOLD IN BRITISH GUIANA.

Reuter's agent, writing on July 31st, makes the following remarks:—

Although a British possession with undeveloped wealth of greater magnitude almost than that of the newly acquired colonies of South Africa, it is being left almost entirely to American and Continental capital to exploit it. The conviction has been firmly implanted in the British mind that British Guiana, or Demerara, is a sugar-cane growing country and nothing more, but the mistake of this must be evident when it is mentioned that only a fringe of the vast territory of 109,000 square miles is under sugar-cane—about 150 altogether being cultivated—and the greater part of the interior is as unknown as is the centre of Africa. The United States have just resolved to send parties to explore the interior of Brazil, the neighbouring country, and it is not improbable that this will be followed by a similar expedition to British Guiana. Gold, diamonds and balata are riches which the interior possesses and which at present are being worked with spasmodic efforts. In the case of the first-named industry little real attempt has been made at development, but a German company, known as the Omai Syndicate, have just completed the erection of a large plant to work the gold on up-to-date principles. Negotiations have also been entered into with a Dutch company with a proposed capital of £250,000 to take over and work gold claims in the Barima district. With regard

to the diamond industry, American capital is for the greater part, invested, and splendid returns have been received.—*London Times*, Aug. 15.

COCOA AND OTHER PRODUCTS IN TRINIDAD.

Trinidad, July 30th, 1902.

WEATHER.—We continue to have very favourable weather for all growing cultivation.

PRODUCE.—Cocoa.—The weather has been favourable for the prospects of the December crop. Receipts from the country continue to diminish daily, but, owing to a much less active enquiry, prices locally have declined to a rate more in keeping with prices in European markets and we quote today \$12.90 to \$13.10 for ordinary, and \$13.40 to \$13.50 for good estates grade.

COPRAH.—Some lots have been offered lately, the price still holding at 3c. per lb., which does not correspond with London quotations, the market there being weaker.

BALATA GUM.—London quotations at 1s 8½d. and 1s 9d. per lb. C & F do not encourage local buyers as this article here fetches 1s 9d. per lb. for other markets.—*Trinidad Semi-Monthly Market Report*.

MOSQUITOES, MALARIA AND YELLOW FEVER.

We are indebted to a scientific friend for the translation respecting "mosquitoes and yellow fever in Cuba", which appears in our daily and *T.A.* It is the most striking testimony we have yet seen to the vital importance and utmost practical value of the discovery made by Dr. Ronald Ross. We are all proud that a British surgeon should have been the first to demonstrate the connection between the "wee sconrels" (of the teased tropical Scot) and fever; but it reflects on our national enterprise that, apparently, our American cousins should be the first, in Cuba, to demonstrate the great and absolute saving of life from putting in practice the lesson taught by the discovery. We know from reports received by us, but not yet read, that Sir Wm. Macgregor, who is M.D., as well as Governor, has not been idle in Lagos, West Africa; but we do not think results like those reported from Cuba have been attained, or we should certainly have seen much made of them in the London press. To have saved 291 lives in six months in Cuba (a hotbed of yellow fever) is a most notable result; and how it has been done can be seen elsewhere. Surely, effective steps should be taken to get rid of mosquito-breeding stagnant pools and drains in several roads of this city in the interests of public health? But still more ought steps to be taken by Government to conquer and kill out mosquitoes in malarial districts where Surveyors, Irrigation and Railway Officers—apart from the natives—suffer so much from fever. After the example shown in Cuba it will be a disgrace if the Indian and Ceylon authorities, to delay any longer to engage in an anti-mosquito campaign.

MADRAS AND WEST AFRICAN PEANUTS.

A CONSUL-GENERAL'S REPORT.

In course of a report on French methods of peanuts crushing, the United States Consul-General at Marseilles gives some interesting particulars regarding Madras and West African nuts. The yield of oil from decorticated peanuts from the Madras coast, which constitute the largest import for the Marseilles soap trade, is from 39 to 40 per cent of their weight. The resultant cake contains from 7 to 9 per cent of oil. The price of the oil depends largely upon the purpose for which it is intended. Oil from Madras decorticated nuts, utilised by soap manufacturers, brings 58 francs per 100 kilograms (\$11.19 per 220 pounds) naked, first pressure, delivered at buyers' stores. The finest edible oils are obtained from nuts imported in the shell, these coming from the West Coast of Africa, chiefly from Ruffisque and Gambia. Oils from these nuts are worth from 75 to 80 francs per 100 kilograms (\$14.47 to \$15.44 per 220 pounds), naked, first pressure. Hand decorticated Mozambique nuts give an oil now worth from 74 to 75 francs (\$84.28 to \$14.47). The second pressure oil from Ruffisque, Mozambique, and Gambia nuts, which is suitable for illuminating purposes, is worth from 68 to 70 francs per 100 kilograms (\$13.12 to \$13.51 per 220 pounds). Ground-nut cake brings from 12.75 to 13 francs (\$2.46 to \$2.50) per 100 kilograms at mills, or 13.25 to 13.50 francs (2.55 to \$2.60) delivered f o b Marseilles in bulk, that is to say, without bags. There is usually a difference of 3 francs per 100 kilograms (58 cents per 220 pounds) in this market in favour of ground-nut cakes over cotton seed cakes. The latter are worth delinted, 10 francs (\$1.93) per 100 kilograms at mills. Marseilles oil cakes are sold most conclusively for cattle food. The soap mills of Marseilles consume on an average 3,000 to 3,500 tons of ground-nut and other seed oil per month, and about the same quantity of copra and palm-kernel oil.—*M. Mail*, Aug. 27.

MOSQUITOES AND YELLOW FEVER IN CUBA.

(Translated for the "Ceylon Observer.")

It has long been a matter of general knowledge that the mosquito is the principal agent in the dissemination of yellow fever and malaria. Since the beginning of 1901 a determined attempt has been made by the Americans to rid Havana (in Cuba) of these noxious insects. Two methods have been used for exterminating them:—first, every house in which there is a case of yellow fever, and the three or four houses in its immediate neighbourhood, are thoroughly fumigated, thus destroying the mosquitoes within them; secondly, and as a general measure, all standing pools throughout the town and suburbs are either drained or filled up. These pools are well-known to be the favourite breeding ground of the mosquito, the larvæ of which develop in still water from the eggs laid on its surface, and live in that element until their transformation into perfect insects. Sheets of water, which cannot be got rid of in that way, receive a layer of petroleum on their surface. When the larvæ come up to breathe, the petroleum clogs their breathing passages and speedily kills them by asphyxia.

In Havana there is now a staff of 100 men, whose sole business is the destruction of mosquitoes. Already excellent results have been obtained by

their agency. Before 1901 yellow fever was permanent throughout the summer. In January there had been 23 cases and 7 deaths. The war on mosquitoes began in February; and in that month there were 8 cases and 5 deaths, in March 2 cases, in May 4 cases, in June none. In September there were 2 deaths against an average of 70 previously. At the same time cases of malaria have sensibly declined in number, which is not to be wondered at, since mosquitoes are the main factors in propagating that disease. In September there were 11 deaths from malaria against an average of 32 up to that month.

In short from April 1st to October 1st, 1901, there were only 5 deaths from yellow fever, instead of 296 [a saving of 291 lives in 6 months!] These figures are eloquent enough in themselves to render comment unnecessary, on our part, upon the good work of the Americans through their vigorous action in Cuba. It is earnestly to be hoped that the example they have set may be followed everywhere.—*From the "Revue Scientifique," April 19th, 1902.*

A CEYLON VIEW OF THE CASE FOR MANURING.

I notice in your editorial of 24th July that you advocate the adoption by India of the manuring systems in vogue in Ceylon in preference to the Indian methods of extension so much practised hitherto. It is unquestionably true that continued extension of a garden to compensate for declining yield merely means increased cost of production per lb. Yet the other system, which, if carried out on certain lines, will give largely increased crops and at the same time often reduce the cost of production per pound of tea, is not without its disadvantages which are becoming more apparent every day under the increased area operated upon within the last few years. In the first place overproduction is unquestionably increased, and, in estimating the financial return, allowance is hardly ever made for the effects on the market, that immediately result from the adoption of such schemes by any reasonable number of estates—and in tea, where each company knows what its neighbour is doing, such new methods of cultivation cannot be confined to one or two individuals, but are quickly taken up by many others who often look upon the figures shown them as their only salvation.

If an apology were needed for the action of Ceylon in this matter, it is to be found in the fact that with our poor soils the necessity for costly artificial manures is imperative, if estates are not to deteriorate.

It is with present prices impossible to provide the necessary money for such increased expenditure, so that proprietors are driven to employ such quantities and qualities of artificial stimulants as will greatly increase the total yield, often by 50 per cent or more and thereby in the cheaper harvesting off the same acreage permit the cost per lb. of made tea to remain at the same figure, or under certain circumstances to be reduced.

Yet there is a nemesis that invariably follows such action: firstly in the drop in value of the teas owing to overproduction; and secondly and more seriously in the slow but steady decline in quality of the crops grown by such means.

This decline in quality so not at first noticeable but in the second and third year generally

becomes very perceptible. It is due to the exhaustion of the soil as regards its available mineral and organic matter by the very much increased network of root growth formed to support the bush stimulated by large soluble supplies of Nitrogen, Phosphoric Acid and Potash manures.

There are other technical reasons, dependent on the character of the measures used, that add to this tendency. As such, however, come under certain discoveries as regards manuring for quality, that will shortly be brought before the industry as soon as protection for the invention is secured, they may for the present be passed over.

If, however, India generally is as fortunately situated as Assam, there is no need for the adoption of Ceylon systems of "forcing" or "thorough" cultivation as they are called by those who oppose or who practise these methods of tea culture.

Mr Mann in his report to the Indian Tea Association has treated the question in a most thorough manner. His recommendations, if followed, will insure that the fields are preserved in a first-class state of vigour by the use of natural manures, which, though according to the new discoveries they may not directly improve quality, will yet certainly not cause any deterioration therein. The cost of such treatment is also almost negligible and, if similar methods were possible on the steep estates of Ceylon, they would be far and away preferable to any systems of cultivation at present in vogue.

Unfortunately such is not the case. The character of the land and soil in Ceylon is entirely different from the flat alluvial of Assam, while natural manures, except in small quantities on a very few favoured estates, are conspicuous by their absence. That the last word has been said as regards Ceylon methods of manuring is not the case. No industry in these days of competition can afford to remain stationary, and it is almost a matter of certainty that the next few years will see the adoption by Ceylon, and it is hoped by India, of the improved methods of manuring for quality, in contradistinction to quantity, that will shortly be brought within the reach of those desirous of increasing their yearly profits at other than their neighbours' expense.

That it is also still possible for the tea industry to reduce cost of production is clearly shown by the success of the new system of plucking that I am responsible for and by the attention it is attracting throughout Ceylon, where the experience of plucking goes back for over twenty-five years but is yet found capable of improvement.

HENRY M. ALLEYN.

Ceylon, 18th Aug., 1902.

—*Indian Gardening and Planting*, Aug. 23.

QUININE MONOPOLY IN JAVA.

It is stated that an agitation has arisen among the cinchona growers of Java to induce the Dutch Government to take over the quinine manufacture, and to convert it into a State monopoly. The planters are under the impression that, as Java is the principal source of production of cinchona bark, the Dutch Government by monopolising the industry would have it in their power to adjust the price of quinine in the world's markets to almost any height they thought fit. The attitude of the

Dutch Ministry towards this scheme is not known, but it is significant that the Governor-General of the Dutch East Indies has empowered the officially-appointed Director of the Government Experimental Institute for cinchona cultivation to take over the management of the Bandung quinine factory, retaining meanwhile his directorship of the Institute. Should the monopoly be carried out, the first effect would be the prohibition of all export of cinchona barks from Java. It is believed, however, the *Sud. d. Ap. Ztg.* says, that the Dutch are too cute business men to enter upon a course of action which might lead to a profitable industry slipping out of their hands through the stimulus to cinchona growing that would naturally be excited elsewhere—in Ceylon, for instance. —*British and Colonial Druggist*, Aug. 15.

PLANT TREES

What do we do when we plant the tree?

We plant the ship which will cross the sea:

We plant the masts to carry the sails,

We plant the plank to stem the gales,

The keel and keelson, beam and knee:

We plant the ship when we plant the tree.

What do we plant when we plant the tree?

We plant the houses for you and me,

We plant the rafters, the shingles, the floors,

We plant the studding, the laths, the doors,

The beams, the siding, all parts that be,

We plant the house when we plant the tree.

What do we plant when we plant the tree?

A thousand things that we daily see,

We plant the spire that out-towers the crag,

We plant the staff for our country's flag,

We plant the shade, from the hot sun free,

We plant all these things when we plant the tree

HENRY ABBEY.

—*Agricultural Journal*, Natal.

YIELD OF RUBBER.

To the Editor of *India-Rubber and Gutta-Percha Trades' Journal*.

Dear Sir,—Some time ago you asked for some further particulars about two cultivated rubber trees, nineteen years old, having yielded twenty five pounds of rubber each, as per the following paragraph:—"From the *Penang Gazette* we learn that upon reliable information two cultivated rubber trees of nineteen years old have recently been tapped, and gave 25 lb of rubber each. At least ten of such trees could be grown to the acre, and the result would be 250 lb of rubber per acre in nineteen years, as against 9½ lb in Assam in twenty-six years. Our contemporary does not state what species the trees belong to, and we rather question whether any trees have been cultivated for so long as nineteen years. Perhaps some of our readers in this locality can give us some further information." The two trees referred to are situated in Kwala Kangsar, Perak, and *Ficus elastica*. Mr R Derry, Superintendent of Government Plantations, Perak, in his report for the year 1900, says: "The largest tree at Kwala Kangsar is about ninety feet high, and eighty-eight feet at three feet from the ground. Measuring all round the aerial roots the branches extend to 36 paces, and the largest leaves obtained 13 in. x 7 in.; its age is nineteen years." Again he says: "From the latter (referring to the two nineteen-year-old trees) 25 lb of rubber has been got from each tree and the tapping was far from being exhaustive."

Our returns here from *Ficus Elastica* are likely to be far in excess of those officially recorded by the Government Plantation in Assam, which, indeed, so far, do not offer much inducement for private enterprise in this direction.—I remain, dear Sir, yours faithfully,

FRANCIS PEARS.

Lanadron Estate, Muar, Straits Settlements,
June, 27th 1902.

RUBBER TREES AND WHITE ANTS.

Replying to a correspondent of our contemporary, Mr E E Green gives some useful information:—"Your correspondent 'Rubber' does not say whether the 'white ants' are attacking the outside or inside of his trees. There are many different species of termites (white ants) in Ceylon. Most of them confine their ravages to dead wood; but others certainly do attack living plants, though it is usually the more functionless parts of the plant that attract them. For instance, one species eats away the heartwood of tea plants; but leaves the outer-growing parts (cambium layer, &c) untouched. I should be glad to receive specimens of the termites that are damaging the rubber trees, together with exact particulars of the nature of the injury. If the point of attack is external, an application of 'Gondal Fluid' (invented by Dr. Geo. Watt) might be tried. It should be painted on the base of the stems. A band of some sticky compound might prove useful. The ants would find great difficulty in crossing this. An Indian paper (*Indian Gardening and Planting*, September 20th, 1900, p. 190) gives an account of successful experiments conducted by the Agricultural Society of India, with a compound called "Atlas Preservative A." This mixture was applied both to dead wood and living plants, with satisfactory results in every case. The termites refused to touch the plants that had been so treated. Unfortunately the paper does not give the name of the maker, or tell us where the preservative can be procured. But, if these termites are internal feeders, nothing can be done beyond the destruction of their nests when found. The difficulty is to be sure that you have found the nest of the actual species that is doing the damage. In the case of the species that hollows out the stems of tea plants in Ceylon, I have never been able to trace any definite nest."

EUCALYPTUS COCCIFERA.

With reference to Mr Divers' letter on Eucalyptus at p. 140 of your issue of March 1, I desire to say that in my opinion there is no doubt that Eucalyptus coccifera is a good species and quite distinct from *E. amygdalina*. The former is a shrub or small tree, chiefly found near the summit of Mount Wellington, Hobart, Tasmania; the latter is usually a fairly large tree, widely diffused in Tasmania and Australia, and known as Peppermint. *E. coccifera* does best in England, because it never grows naturally except in cold localities. *E. resinifera* is the "Forest Mahogany" of New South Wales and grows naturally in rather warm situations, i.e., at no great elevation above the sea-level. Of course, like many other species, it can be gradually acclimatised into somewhat colder places. *E. ficifolia* is a small Western Australian species with beautiful masses of flowers, varying from pink to scarlet. It grows well about Melbourne (Sydney is too warm for it, except in

exceptional circumstances), and seed can be purchased from any good Melbourne firm. It is apt to die off at the collar if the situation be too moist.—*J. H. Maiden, Sydney.*

RUBBER CULTURE IN THE CAMEROONS.

According to private information to the *Tropenpflanzer* the rubber culture in that province makes further progress. At the Moline plantation the growth of the *Kickxia* trees is very favourable and also this year's plants developed well. Dr. Preuss, the director of the botanical gardens at Victoria-Cameroons, writes, even in March, that the *Kickxia* is the only rubber tree that may have a future in the Cameroons, for already very young trees give good rubber. On one tree, which had three fruits one month ago, there are now blossoms and fruits of all sizes. This year he has distributed 115,000 *Kickxia* seeds. The trees do not give much shade. One would therefore do best to plant them thickly between the cocoa trees, provided this does not damage the cocoa trees. Mr Preuss is now planting a big ground with *Kickxias* at various distances from one another. Regarding *Castilloa Elastica*, the trees which have not been attacked by caterpillars are getting on all right at the Moline plantation and Mr Eigen thinks there is little to be feared during the rains. Mr Preuss is sure that, with some attention, the greater part of these caterpillars can be removed. As a rule they do not sit in the bark itself, but just underneath the outer skin and can hardly be noticed from the outside, but can easily be found by passing the fingers along the soft parts undermined by them. The bark has then to be removed quickly and no time must be given to the larvæ to retreat into the interior of the stem. Mr Eigen tried to protect the *Castilloas* against the beetles by putting lime and clay on the stems, but this had no effect during the rainy season, as it was washed off by the rains. Sticky girdles are, of course, quite useless as the beetle flies into the trees. The only effective remedy during the rainy time seems to be the painting of the stems with tar. Dr. Preuss discovered the caterpillar also in the *Kickxias*, where it had made passages in the bark but could not enter the wood. It has now disappeared.—*Gutta-Percha Trades' Journal*, August 4,

LIFE IN THE WILDS OF BRAZIL: A RUBBER INSPECTOR'S TRIALS.

RUBBER ESTATES OF PARA v. F S CLARK.—Before Mr Justice Darling and a special jury an interesting case was heard on July 23rd, in which a vivid description of life in the wilds of Brazil was given. Mr Clark went out to Para in 1899 as an inspector in the employ of the Rubber Estates of Para, Limited. He fell ill, and in consequence his agreement was cancelled and he returned home. Subsequently proceedings were instituted to recover from him the balance of an account for goods supplied from the Company's stores. Mr Clark counter-claimed for wrongful dismissal and breach of agreement "to provide properly furnished house and accommodation" and "all necessary medical stores." His Lordship intimated that there was no wrongful dismissal and that the breach of agreement was the only matter that required investigation.

Mr Clark described his accommodation at Cunhanton as a long shed, part of which was a house and part of which was a store, the whole covered with a roof of corrugated iron. The sleeping accommodation consisted of a small room in which seven or eight officials hung up their hammocks. The only alternative was to sleep on the verandah. As for furniture, there was only one or two chairs, and scarcely anything else. They had to use soap boxes instead. The food was mostly third-rate tinned stuff, and as a delicacy was added dried cod fish. In reply to his Lordship, Mr. Clark stated that there was no chance of shooting any game, a parrot being about the most that could be obtained. At another station where he was sent to the accommodation was even worse, the roof leaking badly. When they arrived at first the room was full of sick natives suffering from fever, dropsy, bad throats, and so on. They had to turn them out, and as a consequence about a half of them died. There was no doctor, and when he fell ill the only attendance he could get was a chemist's assistant who used to come up to practise on the natives. As he did not like the looks of this assistant he did not undergo treatment.

Ultimately Mr Clarke was sent to Para, where he received notice of dismissal. His health had been bad ever since. In cross-examination Mr Clarke stated that, as they could not drink the water, they had to drink beer.

On behalf of the Company it was stated that the accommodation was only temporary and as good as could be expected under the circumstances. The Company's manager at Para said that no complaints had been made, otherwise he would have done all in his power to mitigate matters. Judgment was given for the Company with costs.—*India Rubber Trades' Journal*, August 4.

EXPERIMENTS WITH LIQUID FUEL

The question of liquid fuel is receiving my general attention from planters in Ceylon. When it is mentioned that it has been estimated, by a competent authority that planters have spent for oil to date this year R60,000, and that to produce the same result with liquid fuel R30,000 only would be required, it will be seen that consideration of the subject is profitable to the planter. An up-country correspondent writes to us:—"I have just returned from Nawalapitiya where I went to see a Hornsby Ackroyd Engine, 9½ actual horse-power, tested with liquid fuel. Messrs. Brown & Co. have been driving their workshops there with a 9½ horse-power Trusty Engine, but to test the liquid fuel at the instance of Messrs. Delmege Forsyth & Co. they put a 9½ horse-power Hornsby Ackroyd Engine alongside of the other and the 9½ horse-power Trusty Engine used 30 of a gallon per hour to drive the workshop while they used only 75 of a gallon per hour working with liquid fuel in the Hornsby. They tested the Hornsby for an hour to 9½ actual horse-power working with liquid fuel and it used 84 of a pint per horse-power per hour. No alteration is required in the engine and it was worked as easily with liquid fuel as with bulk oil and the one or other could be turned on or off at will and the engine continued to give the same result. This is a very great matter for the planting community as it reduces the cost of power to under half of what it was before. Liquid fuel at Nawalapitiya costs 20 cents per gallon getting it in casks; Bulk oil less rebate 45 cents. If

Bulk installations are arranged for the liquid fuel the cost of freight will be much reduced. The cost of liquid fuel in Colombo is 12 cents; freight and sending it in casks is 8 cents per gallon."

SOLUBLE TEA SYNDICATE, LTD.

The memorandum and articles of association of this new Company are given in the *Gazette*. The objects for which the Company is established are, among others:—

(1) To purchase or otherwise acquire in Ceylon or elsewhere any patents, *brevets d'invention*, licences, concessions, and the like conferring an exclusive or non-exclusive or limited right to use, or any secret or other information as to any invention in relation to the manufacture of soluble tea and in the processes by which the same is effected, and any improvement in such manufacture, and any advantages and benefits incident to or be derived from the same.

(2) To enter into any agreement or agreements for effecting such purchase, and in particular into an agreement with Montagu Kelway Bamber and John Roger for the purchase of their inventions and patents in connection with the manufacture of soluble tea and in the processes for effecting the same and any improvements thereon for a sum of One thousand Pounds (£1,000) sterling in cash and Sixty-one thousand Rupees in ordinary shares of this Company, and a further sum of Three thousand (£3,000) sterling and Six thousand (£6,000) sterling to be paid to them out of the profits earned by the Company during five years from the incorporation of the Company, or out of the profits to accrue to the Company from the sale of the business thereof within such period of five years, as provided in the said agreement with the said Montagu Kelway Bamber and John Roger, and subject to the conditions therein contained.

The nominal capital of the Company is R500,000 divided into 5,000 shares of R100 each with power to increase or reduce. The signatories to the memorandum and articles of association are:—Messrs John Spicer, E Ernest Green, John Roger, M Kelway Bamber, J A Henderson, W T Highton and G W Suhren each—taking a share. The first Directors are to be as follows:—Messrs John Spicer, Frank Liesching, Montagu Kelway Bamber, and Francis Theophilus Turpin.

CONTRACTS AND COCONUTS IN

CEYLON.

[BY A SETTLER.]

We were partners, Jack Ohren and I, and had lost rupees and time in many wild schemes by way of making a fortune in Ceylon. Our latest venture was a coconut estate. We had secured a Government contract for the supply of wood as fuel on the railway engines running between Colombo and Nanu Oya. It was necessary to live near the railroad and in a district where this fuel should be easily procurable. We pitched upon a village close by Veyangoda, about forty miles up the line from Colombo. Plenty of jungle lay around, and the station was within a mile. We experienced some difficulty in discovering a habitation; the only one available was an old house standing in about 100 acres of coconut land. It appeared to have been untenanted for years; there were no doors, the verandah was broken down, and great vines thrust their way from floor to roof. As for the plantation, it had returned to its original state of jungle. However,

We concluded that the place would have to do. The landlord had notice of our coming; he was an old Cingalese gentleman of venerable appearance, and received us with much ceremony.

A PALAVER FOR A LEASE.

Two wooden chairs were placed for us under a banyan tree and some bottles of beer procured from somewhere brought forward for our refreshment; but as these had stood for some time in a temperature of over 100 degree the beverage was flat, warm, and undrinkable. We accepted some arrack, guaranteed to be sixty years old; it was a liquor resembling curacao with an aftertaste of coconut. Grouped behind our host stood the grey-beards from the village; all the male population of the neighbourhood squatted round in a wide half-circle; the females were not *en evidence*, but a sustained giggling in the bushes, and the occasional glimpse of a bright-coloured garment, revealed their presence.

Proceedings opened with a speech from our prospective landlord who began by asking a favour. His nephew, educated at a mission school, desired a post as clerk in the Kacheheri (Government offices). The young man was brought forward and salaamed profoundly. I promised to use my influence in this direction, and referred to the object of our visit; we wanted a lease of the land and dwelling-house for a term of years—how much? At this there was quite an outcry; the day was young, and tomorrow would bring another day. Why hurry? It surely would be an honour and blessing to the village if the Mahatmayas took the place; they could live there for ever and a day without fee or payment; but the owner was a poor man, what would we offer? It was good land, the best in the island, and the house walls were so thick that an elephant, or a drove of elephants for that matter, could not push them down—such mangoes and bananas were never grown elsewhere. These remarks were not addressed directly to us, but shouted from one to the other with much noise and gesticulation. Some individual made an assertion, and this would be taken up and repeated in chorus all round the circle. A wild-looking man, with hair tangled to his shoulders, jumped about like a marionette, relating, amid much excitement, a story about his cow. It appeared that the animal had strayed into this Garden of Eden about which we were in treaty and was lost for some days. It returned to the bosom of his family so fat that no one could recognize it. Two of this man's comrades beat their naked breasts and tore their hair, declaring that their friend spoke the truth. The cow was wellnigh bursting its hide with fatness. At this juncture I rose to a point of order and suggested that the meeting should now disperse, leaving the landowner, two of his friends, and ourselves as a Committee to determine the point at issue. This brought the crowd up with a sharp turn, the noise was hushed, and they departed.

METHODS OF COMPUTING RENTAL.

The native method of estimating rental of coconut land is somewhat primitive. Records of the estate for the past hundred years were produced written in Cingalese characters on palm leaves, and the number of nuts averaged; it was then cheerfully proposed that we should pay an annual rent equal to double that value. It was no easy task to persuade them that this demand was unreasonable; in letting the place they

would be at no expense in collecting crop and so on. We offered half the rent. After another visit a few days later we got a lease on this basis, and entered into occupation.

First of all the bungalow was made habitable with a new roof and a clean cowd-ung floor; the fallen trees were useful in propping up the verandah; two camp beds, some furniture, and a few kitchen utensils bought in Colombo completed our household equipment. We then turned out attention to the plantation. All jungle growth was cut down, the land irrigated and manured, and fresh saplings planted in place of those coconut trees which had fallen. We calculated that the yield of nuts would be increased fourfold in a few years. Then agreements for supplies of wood were negotiated with neighbouring owners of forest land; we bought some bullocks and waggons, and engaged a gang of coolies; the wood was carted each day, cut in lengths, corded, sent to the depot, and piled in the yard, ready to be put on board the railway engines. Then a bright idea occurred to me. It was ever thus. I was always brimming over with bright ideas, which when tried in the balance, were generally found wanting, so far as pecuniary advantage to ourselves was concerned. Many passenger boats called at Colombo—P. & O., British India, Orient, and Messageries Maritimes; occasionally two or three would be lying in the harbour at the same time. We would raise chickens and sell them on board. Two incubators were purchased; it was easy to keep up the required temperature during the day in the sweltering heat of Veyangoda; at night the lamps wanted a little care.

OUR POULTRY YARD.

Our bungalow had soon so large a feathered population that there was scarcely room to turn. Turkeys, geese, ducks, and chickens, we reared them all and they roosted all over the place. Having raised our fowls, the next step was to dispose of them, and this part of the business proved more difficult than I had expected. The chief stewards on board the ships willingly accepted our hospitality in the shape of tiffin, or dinner, at the Grand Oriental Hotel. Champagne is expensive; it takes off the profit on a small deal, and they were not liberal with orders. We had scarcely taken into account the ice chambers with which all these big liners are provided. My first sight of one of these was a revelation, rows and rows of ptarmigan, larks, ortolans—everything was there, to say nothing of tons of beef and mutton. On my last visit I bought two English pheasants from the steward of a P. & O. boat. I gave a good price for these, and took two men home with me to help eat them. The pheasants were delivered to the appu (head servant) with many injunctions as to careful cooking and so forth. We sat down to dinner expectant—"Shot in old England, my boy"; soup was served, then an entrée. Our cook was a dab on entrées, but it was well not to inquire too closely into their composition, and then came beef, the same tough old beef. "Appu," I said, "where are those birds I gave you this afternoon?" "Master had birds I bring in just now; master eat plenty, and say very good." It was too true: the cook had cut the pheasants into small pieces, and served them up as "salmi" of jungle-fowl. In connection with our poultry-raising experiment, an aunt of mine in Somersetshire forwarded us a

crate of English fowls, Orpingtons and Minorcas ; these arrived in good condition, but after a time they one by one sickened and died ; the cobras accounted for some, others succumbed to heat apoplexy. Altogether they did not take kindly to the climate. I had not the heart to write and tell the old lady about this, but some elephants' tails that Jack had in his possession came in handy. I got these mounted and framed in a case, with an inscription to the effect that it was presented to me as first prize for an exhibit in the Trincomalee Poultry Show. It occurs to some people even now, who see the case hung up in the old home, that it is a somewhat incongruous prize for a poultry show ; but my relative explains that Ceylon is such a queer country.

A SERIOUS CONSPIRACY.

In the meantime the timber business was prospering ; we had settled down to a pastoral life and were happy. Then the blow fell. Our men returned one day with empty waggons, and reported that the proprietor of the place where they had been working had met with a domestic misfortune ; his mother and grandmother had suddenly died, and no timber could be removed on that account. On sending to three land-owners the coolies came back empty-handed with the same tale. We were liable to a penalty of a thousand rupees for breach of contract with the Government. We started off at once, provisioned for a week. If these people could not let us have wood, we must go further afield and make fresh arrangements. A Winchester repeater was taken along and revolvers. It was not contemplated to use these seriously, but the villagers in the interior bore a very bad character ; a display of force might be necessary. We also carried a gun for snipe and hare. Something in the way of game must be shot each day for food. Tinned meat gets monotonous. As our procession approached the forest belonging to that orphan who had first refused to supply, there was an ominous tom-tom beating and blowing of horns. The wood lay stacked under the trees in corded bundles, and our frightened coolies proceeded to put it in the carts. This was the signal ; they were instantly surrounded by a horde of naked savages, all carrying knives and screaming like demons possessed. Our appearance from under the waggon tilt, and a rifle-shot fired in the air, caused a general stampede, although they did not run far. I inquired for the landowner ; he could not be seen, but the Aratchi (headman of the village) was dragged forth much against his will. It was then we learned the true inwardness of all this trouble. Our landlord's nephew, thanks to the letter I had written for him, had obtained a billet as clerk in the Kachcheri ; he had ferreted out the particulars of our contract, and then communicated to these people the astounding fact that we were receiving more money for wood than we paid for it. The result had been that each native owning a strip of jungle immediately sent in a tender for the supply of fuel for the Government locomotives ; they had no thought of keeping faith with us. I showed the headman my repeating rifle and partially explained its mechanism, assuring him that from a distance of twenty miles, more or less, it must hit the mark every time, and would fire a thousand shots without a reload. He was much interested, and no doubt made up his mind to steal it if an opportunity occurred. After seeing the carts loaded and despatched we set out to call upon the native chief of the district (the Adigar),

with the intention of lodging a complaint as to the unruly conduct of his people, and making some agreement with him for the regular supply of wood. It was three days' journey to this gentleman's residence, and we never got there.

IRREMIEDIABLE DISASTER.

On the evening of the second day we halted under some palms by a well, lighted a fire that the smoke should keep off the mosquitoes, and prepared to encamp. I noticed a man hiding behind some bushes near by, and reached for a revolver, not doubting that our friend, the Aratchi, had sent some one to annex that rifle. But it was not so. I fired a shot in his direction, when the man broke cover and came rushing frantically towards us. It was our Tamil timekeeper ; he could have come up before, but had taken a short cut across country, and waited here in order to make his entrance with proper dramatic effect. The poor fellow threw himself flat on the ground, moaning piteously. He was covered with blood, and presented a most woeful appearance. Many of these sanguinary stains were artistically smeared on his body quite recently, but his tale was bad enough for anything. Disaster has indeed overtaken us. Our coolies, in attempting to remove another load of wood, had been attacked and severely beaten, two of them tied up and tortured, bamboo splinters put down their finger nails ; the bullocks were also shamefully maltreated. This was not all : the mob had looted our bungalow and burned the store of wood. We held a council of war. It would be worse than useless organizing a punitive expedition to the offending village ; no one would be there, while we might do some damage and get into legal difficulty. It remained only to return home as quickly as possible, and this we did, to find desolation ; everything portable was stolen or destroyed, and the coolies had run away not to return for many days. The most extraordinary feature of the whole affair to an Englishman unacquainted with Eastern ways was the fact that everyone at Veyangodda professed to know nothing whatever of the outrage ; they had neither seen nor heard any disturbance. This occasioned some delay, as the rioters had to be identified, and it is impossible to say if the real culprits were eventually caught or not. The native police are not particular, so long as they get someone ; but about a score of men were found for the next assizes. I saw them in the dock, and a sorry-looking lot they were. — *Pall Mall Gazette*, Aug. 12.

PLANTING NOTES.

RUBBER.—The attention of the Committee of the Liverpool Chamber of Commerce had been drawn to the desirability of urging the Colonial Government to instruct the natives, in a systematic way, in the best methods of preparing rubber of different kinds for European markets. It was pointed out that the market price for rubber is at present so low that it would be well to encourage the natives to attend to the production of and to prepare the best qualities of rubber only ; that when the heavy portage on the coast is taken into account it is essential to get the highest qualities of rubber, free from water, in order to be able economically to work at greater distance from the coast ; and lastly that so long as there is free competition amongst the coast merchants the native may rest assured that he will get the full market value for his produce at the shipping port. It was resolved again to press the matter upon the attention of His Majesty's Government. — "Liverpool Chamber of Commerce."

THE EXTRACTION OF SARSAPARILLA is free to every inhabitant of the Republic of Guatemala who obeys the necessary rules. A written request for a licence, drawn up on stamped paper, must be presented to the political chief of the district, stating the locality where he proposes to work, the number of workmen employed, the length of time for which the licence is desired, &c. The person holding such licence may put up houses, huts or any necessary workshops under the condition that, on the expiration of his licence, such improvements remain the property of the Municipality or Departmental Government. One indispensable condition is that at least two roots be left on each plant, so that it may grow again, and, of course, persons holding licences for the extraction of sarsaparilla are expressly forbidden to engage in the extraction of rubber or any other substance than that named in the said licence. A minimum duty of one dollar (currency) must be paid on every one hundred pounds of sarsaparilla obtained, and the offices where the duty is to be paid are specified in the regulations. The licence is withdrawn if it is proved that the person holding it has destroyed all the roots of one or more plants, or has broken any other of the rules laid down.—*B. and C. Druggist*, August 22.

ELECTRIC POWER PLANTS IN THE PACIFIC STATES OF AMERICA.—In a paper recently read before the New York Electrical Society, by Dr. F. A. C. Perrine, a full account is given of the progress made in utilising the waterfalls and rivers along the Pacific slopes of the Rocky Mountains for the development of electric energy and its transmission over long distances for use in town lighting, and for motive power in the mining and manufacturing districts of the Pacific States. Power is transmitted for distances rising from 50 to 80, to 150 and even 218 miles! After this, how long is it to be before the Colombo Electric Company utilise the great waterfalls from Maskeliya to the Kelani Valley? Here is a case in the Far West, or very nearly the Far East from Ceylon:—

"One of the most remarkable installations is that at the Snoqualmie Falls, Washington State. These Falls are situated in the Cascade Mountains, amidst most beautiful surroundings of river, gorge, and magnificent spruce forests. To provide the power-house here, the startling plan was adopted of excavating a cavern within the very rock over which the Falls plunge. This was rendered necessary owing to the spray from the Falls, which made it impracticable for any power-house to be established at their foot, and to have gone further down the river to a suitable site would have involved greater expense than the present work. To reach the cavern in which the power house is situated entrance is made by a little cabin near the fore bay to a shaft in which an elevator works, and which also contains the penstock, and 250 feet below the surface the machine-room is reached, in which are located six 1,500 kilowatt generators. This plant was one of the first in which aluminium was used for its transmission lines. The lines are carried over difficult mountains, and through continuous forests of dense spruce and fir, which have been carefully cleared along the route to prevent the trees falling and interrupting the service. Current is transmitted at 60 cycles to the cities of Seattle and Tacoma, where it is employed for lighting and for operating the railways. In Seattle the current is transformed by rotary converters, but in Tacoma motor generators are used for this purpose and regulation obtained by a combination of synchronous and induction motors."

JAPANESE CAMPHOR.—The Nippon Camphor Company (Limited), of Kobé, has been taken over by the Monopoly Bureau of the Formosan Government, and is carrying on the business as hitherto under the name of the Kobé Branch of the Monopoly Bureau of the Formosan Government, at No. 4 Fukiai, Kumoidori, Kobe Japan.—*Chemist and Druggist*, August, 30.

OIL OF THE ATLAS CEDAR.—The essential oil of the Atlas cedar, which has recently been strongly recommended as a remedy for venereal diseases equal to sandalwood oil, has been chemically examined by Boisse (*Bull. Comm. 1902, 291*). The most important point which this examination brings out is that the oil contains sixteen per cent of a sesquiterpene alcohol. As is well-known, ordinary cedarwood oil only contains about two per cent of such alcohols, whilst it is to the presence of a large amount of such bodies that sandalwood oil owes its efficiency.—*Chemist and Druggist*, August 9.

PISCICULTURE!—The disciples of Izaak Walton in Ceylon will, we are sure, appreciate the article we reproduce from the *Indian Field* on this subject. (See page 252.) The article is published by our contemporary in view of the interest now "taken in the East anent the importation of trout ova from Home with a view to the introduction of that game fish to Ceylon, the Doon, the Neilgherries, and Kashmir" and consists of a lengthy communication regarding the aquarium and exhibit of hatching apparatus at the International Exhibition now being held at Cork which gives a short resumé of the necessary process and period of incubation.

"CEYLON TEA ABSOLUTELY REPULSIVE"—Such is the courteous expression of personal opinion used in a letter to the press by Mr. Arthur Stanhope Aldrich, H.I. Japanese Majesty's Consul at Wellington (Palmerston North?), a copy of which he sends us with his compliments. It is considerate of Mr. Aldrich to do so; and in return we are not only replying to some of his statements at once; but are sending him a copy of our little pamphlet on Ceylon tea, showing the wide appreciation of its good qualities, by the best judges of tea in the world—in the United Kingdom, Russia and Australia. The people of North America are far behind as tea-drinkers and have to be educated up to the standard of the best teas. It is all very well for Mr. Aldrich to stand up for the country he represents; but his "absolutely repulsive," as applied to Ceylon tea, is too much and very unjustifiable altogether and he has to be told that Canton merchants, dealing with the finest and most delicate of China teas, have confessed the very high qualities of our teas which can be got of as delicate a flavour as any from China. Of course, there is such a thing as bad tea to be got under the name of "Ceylon," but not nearly in the same proportion as there comes from China and even Japan, where Prussian blue and other deleterious substances are used to colour the tea. Mr. Aldrich has evidently much to learn about Ceylon tea, as well as about the doings of the Chinese and Japanese in regard to much of their teas.

Correspondence.

To the Editor.

LIVE STOCK AND SINHALESE CATTLE IN TRINIDAD.

Government Farm, Trinidad, B.W.I., Aug. 13.

DEAR SIR,—May I ask you to again kindly accept the Annual Report on the working of the Trinidad Government Farm?

The Farm is placed in a new situation and greatly enlarged, and I trust that its usefulness to the Colony will be increased.—Yours truly,
C. W. MEADEN, Manager.

[We quote at once the parts referring to the Sinhalese cattle:—

THE HERD.

PURE BRED ZEBUS.—This section of the herd has been increased by the addition of seven heifers. A bull and two cows are on their way out from India. Thus augmented, the Zebu section will be in a position superior to any in its history, in number, stature and general form.

MILCH HERD has been increased to 147 breeding cows all in good profit, these will be steadily increased and with the help of the Tobago branch a sufficient number of cows will be established so as to furnish from them the animals required to supply beef for the institutions. In three to four years' time we should be in a position to do this, and the cost of doing so will be covered by the annual revenue or without additional expenditure.

CINGALESE.—There is nothing worthy of remark concerning these; two calves were born, one being deformed had to be destroyed. The general health of the herd has been good, a few acute cases of mammitis occurred amongst the cows, but yielded to iodine treatment. Six adult animals died from injury, four caused by falling into deep open drains and breaking their backs before help arrived. This will occur until the drains are ploughed in. Two deaths occurred from injury inflicted by other cows. Ten calves died from various causes, chiefly dysentery.

114 calves were born of the following breeds:—

Bulls.	Heifers	
2	4	Pure bred Zebu.
39	36	Half do
4	2	Crossbred Red Poll.
8	6	Crossbred Guernsey.
8	5	Crossbred Zebu.
2	...	Cingalese.

The bulls in the public pastures are in good condition; a cross-bred Red Poll and a Guernsey are at San Fernando; others in the Queen's Park, Arima and St. Augustin are well bred Zebus. A new pasture was opened at St. Augustin and upwards of a hundred cows have been entered. This is mentioned to show that if good bulls and accommodation is provided an increase of stock soon is evident. Arrangement is being made to place a pure Zebu bull at Mayaro and others in different districts if places can be provided.

The sale was not so successful as in former years and in justice to the Farm should not have been held owing to the unsettled condition of the place; but as the sale is a fixture looked forward to with considerable interest both locally and in neighbouring islands, it would not have been desirable to omit it.

	Dollars.
One heifer, Zebu	... 67
One pure Zebu Bull	... 150
Five ½ Zebu Bulls	... 33 00
Five ¼ Zebu Bulls	... 25 40

Of the animals sold the Zebu bull went to Berbice.

The report is a very full and useful one dealing with a variety of cattle, an Agricultural Show, Butter-making, the Stud, Pigs, Poultry, Milk Analyses, List of Stock, Sale of Artificial food.—ED. T.A.]

SEYCHELLES GUANO.

London, E.C., Aug. 13.

DEAR SIR,—In the *Overland Observer* received this week some interesting "notes from the Seychelles" are published, and, it is stated, that the exports of guano are steadily increasing. You may have forgotten that some two years ago I called attention to this deposit of guano which, though poor in ammonia was specially rich in phosphate of lime, containing from 58 to 61 per cent of this valuable manuring constituent in a form admirably adapted for tea, coffee and sugarcane, when mixed with crushed cake such as castor or rape in order to supply the necessary nitrogen, and assisted by the admixture of sulphate of potash for the supply of the dominant element of the mineral portion of the above crops.—Yours,
JOHN HUGHES.

PECULIAR STONE FROM WATTEGAMA.

Aug. 15.

DEAR SIR,—I have sent by this train a small parcel containing a peculiar iron-stone which on breaking showed some different growth inside. Perhaps you can get an opinion on it.—Truly yours,
J. H.

[We sent it to Mr. Kelway Banber who kindly writes:—"I am afraid I am not geologist enough to give the correct name for the piece of rock you have sent me, but it is very similar to some gneisses, and the colouring is evidently due to the weathering, combined with an irregular infiltration of water and air, which oxidises the iron compounds in the rock, with the production of the brown colour, in the immediate neighbourhood of the infiltration."—ED. T.A.]

RUBBER IN JOHORE.

Muar, via Singapore, Aug. 22.

DEAR SIR,—Referring to your rough approximation of the area under rubber in the Malay Peninsula, I can assure you that Johore at a very low estimate can account for one thousand acres. I can give no exact figures, as no returns are published; but I know what the few Europeans in the territory are doing, to which must be added the Malay and Chinese efforts in this direction. I must say also that these latter seem to be awakening to the fact that it is a good thing to go in for, judging from the enquiries I get for plants.—Yours faithfully,

FRANCIS PEARS.

RUBBER CULTIVATION IN THE MATALE DISTRICT.

Keppitigalla, Matale, Aug. 22.

DEAR SIR.—Having read the article under the above heading in the *Tropical Agriculturist* for August, 1902, from which it is inferred

that Para Rubber is unsuitable for this district, and that Castilloa is preferable—which deductions are mainly based upon *experiments* made with a few trees, and most probably growing in a favoured locality, viz., near a river—

1. do not think such figures can be used as an estimate over a large area; not that I for one moment doubt them, but as they are acknowledged experiments, they cannot have the same weight as the actual results gained over a large number of trees.

2. Prices quoted for samples cannot be depended upon, especially when the brokers know there is no bulk behind them. A sample of Para Rubber sent from this estate, when I first started tapping, was valued at 4s. 1½d. per lb.; but when the first *lot* was despatched, which was every bit as good as sample, it sold for 3s. 6d. This proves that a price quoted for a sample is not given when the article is sent in bulk, especially for a new product.

Therefore I now give you a few figures of the actual results of tapping, for the first five months of this year, January to May, 1902, and trust the figures will be of interest to all concerned, as I believe they are the first published from any estate in Ceylon; and as Para Rubber is still in the experimental stage these figures would provide some data to work upon.

I have had the actual results from one or two of the Kalutara estates given me; but I must admit that I cannot hope, at any rate at present, to compete with them, in either the quantity per tree of dry rubber or the low rate per lb. of gathering the latex; or it appears the trees in Kalutara are capable of yielding nearly twice the quantity of rubber obtained here. But in prices Matale can quite hold its own. At the last sales in London four boxes of Keppitigalla rubber was sold at 3s. 6½d per lb. against about seven cases of Kalutara at 3s. 6d.

Much higher prices than these have been gained by the latter mark at previous sales. The trees growing on this estate are about 8 miles from Matale town, as the crow flies, at an elevation of about 600 feet to 1,400 feet, ages of trees from 8 to 11 years; the largest girth one foot above the ground is 47 inches. Temperature in shade 77 to 92 degrees highest recorded in April. Average rainfall 70 to 80 inches. The trees are not inclined to spread, and grow straight up, with few side branches, and make an excellent light shade for cacao planted 12 feet apart in line, and 24 feet from line to line, thus giving about 150 trees to an acre. Tapping proceeds throughout the year, and each tree has two series of tappings lasting about two months.

Now we come to results:—Number of trees tapped once 3,903:—Since October 1901, and dry rubber from first tapping 2,128 lb. or just over half lb. per tree. Some of these trees were tapped again in June-July, and gave equal results, thus making 1 lb. rubber per tree per year. By the above figures, it will

not be too much to estimate three-quarter lb dry rubber per tree all round, having 150 trees to the acre. The best results are not always gained from the largest trees, as many of the smaller trees yield twice as much.

An experienced person can tell fairly well by the appearance of the bark whether a tree will yield well or not. A tree with a greyish, and hard-looking outer bark very seldom yields well, while on the other hand a softish-looking bark, almost flesh-coloured, is sure to give a good yield.

The proportion of scrap rubber to best quality is very small indeed, about 4 per cent only.

Number of pounds dry rubber gathered from January to May, 1902, 1,362 lb.

Best quality	1,302 lb.
Scrap rubber	60 lb.

Total	1,362 lb.
-------	-----	-----	-----------

Cost of tapping and curing 1,362 lb dry rubber	R 570 63
Transport, rail fare, boxes, &c.			R 31 13
Cost for the year: 1,600 collecting tins	R 48 00
Cost for the year: 1 doz. tapping knives	R 30 30
48 coagulating tins	R 9 60

Total cost accessories for 12 months	R 87 90
Jan. to May 5 months 'share of accessories	R 36 60

Total cost in Colombo for 1,362 lb. rubber	R 638 36
--	-----	-----	----------

or cents 46.86. per lb.

Most of the rubber was sold at 3s 6d per lb., and the scrap rubber at 2s.

From the above facts it remains for your readers to judge whether Para Rubber is suited to the Matale district or not.—I am, sir, yours faithfully,

FRANCIS J. HOLLOWAY.

Samples of rubber sent.

[Which can be seen by any one interested, at the *Observer* Office.—Ed. T.A.]

TROUT FISHING IN CEYLON.

Aug. 26.

DEAR SIR,—This sport has so far been more or less in its infancy, though I have had many a pleasant day's fishing during the past few years; but there's a real good time coming in the near future and I hope all interested in this most healthful, pleasurable pastime will now join the Club and so help to make things hum generally. I had occasion to be in Nuwara Eliya yesterday and, of course, made it convenient to have a couple of hours' fishing from 2 to 4 p.m. During that time I landed 28 fish. One a brown of just under 1 lb., I kept and the other 27, all locally-bred rainbows and real little beauties, ranging from 3 to 8 or 9 inches, I safely transferred from the Nuwara Eliya stream to the Nanuoya at Blackpool.

Had it not been that the capacity of the carrier had to be considered I have no doubt I could have transferred 100 at least before dusk for the stream simply swarms with young trout and I fished only a few hundred yards of by no means the best of it.

I have had better sport than this in Old Scotland, but I've often had much worse; and, though I did not succeed in landing two trout at one cast, with a couple of flies on, I had frequent double rises and might have done it had I used more suitable flies for such work.

I think the Club should present a few of those little fishes to all members of the Club within a reasonable distance of Nuwara Eliya, provided they have suitable ponds or streams which they will endeavour to protect from the rapacious curry-pot of our friend, Ramasamy.

This would help to start the general distribution of these fish, which is much to be desired, I think.—Yours faithfully,

JOHN FRASER.

PAPAIN OR PEPSINE.

August 1902.

DEAR SIR,—In your *T. A.* number of 1st Oct., 1898, page 236, I found an article about Papain. It is said:—"Out of many fruits you will only be able to obtain but a few ounces, whereas from the trunk of the tree and other parts of the plant you can obtain several pounds." I am intending to make a trial with Papain producing, but not knowing how to obtain it from the trunk I should be very thankful to anyone with experience for information,—Yours truly,

A DELI (SUMATRA) PLANTER.

[Who has had experience of Papain extracting or collecting in Ceylon? We should advise our Deli friend to make experiments on his own account and judge by the result and the report of his European Agents.—*ED. T.A.*]

THE SUPPLY OF COCONUTS FOR LOCAL WANTS AND EXPORT.

August 26.

SIR,—In reply to "*Cocos Nucifera*" in your issue of August 22nd, I would be inclined to say that local consumption of coconut products has increased prodigiously within the past 20 years, perhaps even to an extent beyond the supply made by extended cultivation. When I first came to Ceylon the use of coconuts was confined to householders in town and well-to-do owners of country gardens. But now-a-days coconuts for sale are a feature in every village bazaar throughout the hill as well as low country, and poor indeed is the Sinhalese who does not make use of the ubiquitous palm nut. However high the price offered by export dealers, native families, I believe, will not now forego their usual share of coconuts, so that in reality the supply for foreign trade comes from the large plantations rather than the small gardens.—Yours, etc.,

TRADER.

[Our calculation used to be 350 to 400 million coconuts to supply the export trade

and as many more for local food purposes. For the latter estimate, say, we have, 700,000 households using on an average 1 to 2 nuts daily—and take 1½ nut a day which will be 383 million nuts a year. In this way we may make up an estimate of 800 million nuts as a year's crop in Ceylon; but one estimate went as high for a good season as a thousand million of nuts.—*ED. T.A.*]

WATER BOTTLES AND FIRE—TESTED.

Aug. 27.

DEAR SIR,—I noticed in your issue of the 23rd instant a statement by a "Mr. Percy Burd of Cheltenham" on "Watter Bottles and Fires" which struck me at the time as rather tall and I thought it would be rather interesting to test its probability.

In the first instance it is a matter of some considerable difficulty to get a candle alight with a lens even in this country. The wax melts freely and the wick gets charred and glowing, but the candle does not burst into flame, at least in my experience.

Secondly, I have never seen carriage lamps fitted with burning glasses. They are generally made with plane glasses, the light being concentrated by means of silvered reflectors at the back and sides, which would make the feat still more difficult.

Thirdly, it is not difficult to compute from the data what the elevation of the sun was at the time and place mentioned. It is easy to see that the altitude of the sun must have been equal to the gradient of the road, for the sun's heat to have produced its maximum effect. The following table gives the elevation of the sun above the horizon at Canterbury at the beginning, middle and end of October, between 2 30 p.m. and 3-30 p.m., and the corresponding gradient

	At beginning of October.		At middle.		At end of October.	
	Elevation.	Gradient.	Elevation.	Gradient.	Elevation.	Gradient.
At 2-30 p.m.	27°	1 in 2	22°	1 in 2½	17°	in 3½
3. 0 p.m.	24°	1 in 2½	18°	1 in 3	13°	in 4½
3-30 p.m.	20°	1 in 2¾	15°	1 in 3¾	10°	in 5¾

So that, even if the two first objections were waived, the writer was apparently travelling along a road about two and a half times as steep as the steepest carriage track allowed in England (1 in 15). If his carriage candles did get alight, it is improbable that the sun's heat was the cause.—Truly yours,
F. R. H. S.

USEFUL TREES FOR THE HILL COUNTRY.

Abbotsford, Aug. 29.

DEAR SIR,—If the tree on Glasgow Estate is *Acrocarpus fraxinifolius* it isn't in it with *Acrocarpus grandis*. I have both of these here and the latter is far and away the finer tree of the two; but trees vary so in different situations and conditions that one oughtn't to dogmatise. The seed of the

former I got from William Brothers about 11 years ago and the seed of the latter came from Java at about the same time.

The *A. Grandis* will, I think, be a magnificent tree ultimately, but at 5,000 and 6,000 feet, trees do not grow as quickly as most of us would like them to.

The *Gmelina Arborea* mentioned in *Indian Gardening and Planting* of 14th August sounds very promising for our higher elevations, but what about our local varieties, *G. Rheedii* and *Asiatica*? Are they large trees and at what elevation do they grow? Where can one get seed of this *G. Arborea* and Northern Indian tree seeds generally nowadays?

Mr. Gammie used to be most obliging in the olden times; but he, I hope and believe, is now enjoying his *otium cum lig* on the retired list, so please advise as to where one should apply.—Yours faithfully,

JOHN FRASER.

[Our correspondent must try the "Himalaya Seed Stores" whose full-page advertisement he will find in our *Tropical Agriculturist*. As to the trees referred to, here is what Trimen says of "Gmelina's":—

G. arborea, (Et-demata, Sinhalese) (*G Rheedii*.)

A large spreading tree, bark a greyish-yellow, rather rough, thick, branchlets and young parts covered with a very fine, white mealy pubescence.

Moist region up to 5000 feet; rather common, but often cultivated. Fl. March, 4 upper lobes dull orange-pink, lower one lemon-yellow. Also in India, Burma, Malaya, and Philippine Islands. The Flower suggest a Bignoniaceous plant. They appear along with the young foliage, the tree being deciduous. Wood yellowish-white even-grained, light, strong, tough, and durable; an excellent timber. The bark and the fruit are employed as medicine in bilious fevers.

(*G asiatica*.) (Demata, Sinhalese, Kumil; Tamil). A much-branched bush, bark yellowish-white, smooth, branchlets horizontal, rigid, often compressed puberulous, frequently much shortened and spinous at the end.

Open places in low country up to 2000 feet; common. Fl. September; bright sulphur-yellow. Also in South India. The bark and roots are used in medicine. The fruits are eaten.

Dr. Watt chiefly dwells on their medicinal uses: save that in respect of the wood of "*Arborea*" he writes:—

STRUCTURE OF THE WOOD—Yellowish, greyish or reddish-white, with a glossy lustre, close and even-grained, soft, strong, does not warp or crack in seasoning, weight from 28 to 35 lb per cubic foot, breaking weight of a bar, 6 feet x 2 inch x 2 inch, 580 lb (according to Baker). It is light, has a good surface, is very durable, is easily worked, and takes paint and varnish readily, and is, therefore, highly esteemed for planking, furniture, carriages, boat-decks, panelling and ornamental work of all kinds (*Gamble*). Mason states that it is largely employed by the Karens for canoes, and by the Burmans for clogs. Owing to its extreme durability, it has been recommended as an excellent timber for making tea boxes, and has also attracted much attention as a very suitable wood for furniture, picture-frames, and similar work in which shrinking and warping have to be avoided. Buchanan states in his *Statistics of Dinajpur* that "it is much employed by the natives for making their instruments of music." The excellence of this timber for many purposes

appears to have been first noticed and described by Roxburgh, who subjected it to various experiments which he describes as follows: "One of the experiments, and the most interesting, was made by placing part of an outside plank in the river, a little above low water mark, exactly where the worm is thought to exert its greatest powers. After remaining three years in this situation, though examined from time to time, the piece was cut, with the view of carrying a specimen of it to England, and to my great joy, I found it as sound and in every way as perfect throughout, as it was when first put into the river. Amongst other things, a valuable flood door was made of it, to keep the tides out of the Botanic Garden. It is now seven years and a half since the door (which is 4 feet square) was made, and though much exposed to the sun and water, yet it remains good; while similar doors, though much smaller, made of teak, were so much decayed a year ago, as to render it necessary to replace them." Since the date of the publication of the above experiments, the wood has come permanently into notice and is in considerable demand in Calcutta for furniture-making.

As for "*Acrocarpus grandis*," we find no mention whatever of "*grandis*" by Dr. Watt, or any other authority at our command. In fact Watt says the genus "*Acrocarpus*" contains but the one species "*fraxinifolius*."—Ed. T.A.]

WATER-BOTTLES AND FIRE.

Stubton, Rakwana, Ang. 30.

DEAR SIR,—I have read several letters in your correspondence columns on the subject of "water bottles and fire." You may be interested to hear our experience. At 8-30 one morning, when standing on our back verandah, we noticed smoke rising from a table on which were placed three caraffes or bedroom table bottles, which had been cleaned and were to be refilled and placed in each room. We concluded from the distance that the smoke was steam only, rising from the damp table; but when we approached we found the smoke arose from one spot only and the table was quite dry. The heat from this spot was so great that it burnt our fingers. The table was charred. We then realized it was the effect of the sun's rays passing through the bottle; but as there were three and the sun fell full on each, we marvelled at the others remaining untouched; so, we changed their position. To our surprise no smoke or heat emanated from the other two, although removed to the same spot as the smoke originated from: but in a few seconds the wood was burning hot and smoke ascended from the first bottle although placed at the extreme end of the table on the other side. The bottles were all in shape globular; but the glass thicker of the one that attracted the sun and flatter at the base. Why were not the others, when placed in the same position, worked upon in the same way by the sun's rays? We can quite understand that the sun's rays passing through a bottle standing in a window-sill could set light to curtains.—Yours truly,

M. BARTRUM.

P.S.—The bottles were empty.

[We referred this interesting experience to our scientific correspondent, "F. R.

A. S., "who writes:—"I have read your correspondent's letter. There can be but one explanation of the facts. The bottles were all empty and only one burnt the table. The inference is that this particular one had sides thicker in the middle than at the neck or bottom, thus forming a meniscus lens, or burning glass, which would collect the parallel rays of the sun to a focus on the table. The large majority of caraffes are like the two others your correspondent mentions, with sides of equal thickness throughout: these would have no more effect upon the sun's rays than an ordinary pane of glass. It is curious to note that there would probably have been no burning of the table an hour or so later, as the rays would not then be concentrated enough for the heating effect to have been apparent. This can easily be tried if the bottle is still in existence."—ED. T.A.]

THE USES OF "GLORIOSA SUPERBA AND POISONING THEREBY—AND ANTIDOTES.

Indian Museum, 1, Sudder Street, Calcutta, Sept. 1.

DEAR MR. EDITOR,—I acknowledge with many thanks the receipt of copy of your paper for 20th August, 1902, containing notice of death of poisoning through eating a *Gloriosa superba* tuber.

I agree with you that the subject deserves further inquiry. Under the title of poisonous plants of Bombay (Journ. Bombay Natural History Society, VII. No. 4, 1893, p. 489) Major K. R. Kirtikar gives an interesting account of the plant which is illustrated by a coloured plate. He states that very few cases of poisoning are on record. The plant is known all over the country as a virulent poison; it is also said to be useful in fevers as an antiperiodic.

In a paper on "Poison Lore of the Hindus," read before the Indian Medical Congress, December 1894, by Dr. N. Subramanya Aiyar (Indian Medical Gazette XXXI, 1896, p. 5) we are told that *ginger decoction* is an antidote for "*Gloriosa*" poisoning. This writer also adds that the root divested of deleterious constituents is reported to be a great remedy for ascites.—I am, yours sincerely,

J. HENRY BURKITT.

BRITISH NORTH BORNEO :

Audi alteram partem.

SIR,—Your contemporary seems determined to hang British North Borneo. I do not know what actuates this desire, but certain it is he does not seem to mind whose opinions he takes. One day he publishes an account which the next day he has to correct. I look to see Mr Graydon's revised before long.

The Consular Reports show that by a Census taken in 1891 the population of Labuan was 5,853 and of Sandakan 6,350 (including respectively 25 and 127 Europeans).

The shipping (including native, with the neighbouring islands, Sulu, Palawan, &c.) of Sandakan is returned as follows:—

1886	..	115	ships	..	29,213	tons	} Entries
1890	..	198	do	..	64,210	do	
1898	..	651	do	..	93,181	do	

The trade of British North Borneo amounted in thousands to:—

	Imports	Exports
	\$	\$
1885	648	401
1890	2,018	901
1898	2,419	2,881
*1900	3,178	3,336

(* According to Whitaker.)

To show the principal trades embodied in the above figures, the following statistics, showing a steady advance of prosperity—are entertaining:—

	1886.	1890.	1898.
Value in	\$	\$	\$
Tobacco	1,618	396,314	1,358,666
Timber	27,626	44,584	214,343
Guttapercha	34,747	54,448	125,280
Sago	53,417	36,950	118,602
Rattans	67,100	64,961	80,315
India Rubber	8,535	21,581	79,600
Provisions	—	—	77,724
Birds' Nests	27,953	44,864	47,160
Camphor	8,711	14,193	37,047
Coffee	—	—	28,620
Salt Fish	—	—	26,777
Trepang	—	—	26,053
Damar	11,365	5,287	25,590
Hemp	—	—	24,590
Seed Pearls	—	—	23,795
Rice	7,933	6,321	14,248

I mention rice as it is an industry in which Ceylon is interested and one likely to be developed. The infinitesimal Fruit Trade referred to by Mr Fyers amounted to \$5,412 in 1898.

The average rainfall might be put down at 100 inches for the whole country. Chena cultivation was generally in vogue.

I take the following extracts from the Consular Report of 1899:—"As regards openings in N. B. there is ample room for encouragement. . . Payable minerals will doubtless advance the prosperity of the country, but I look upon agricultural products as the backbone of B. N. B. . . The Government offer a limited number of free grants of land of 500 acres to young men with a capital of £2,000 or upwards for the cultivation of tea, coffee, &c. . . The mineral resources of the country cannot be said to have been fully investigated and much remains to be done in this direction. . . The climate is not unhealthy, but, of course, varies in different districts of this large country. . . Compared with other countries (I do not mean Singapore or Hongkong, which are collecting centres of trade) the tariff, as regards imports is very low indeed." From the same report I gather the highest rate of duty was 10 per cent—generally imposed. On a good many articles, (cloth, leather, metals, &c) 5 per cent. Building materials, food-stuffs, metals, &c. were on the free list. . . There was considerable trade with the neighbouring islands, but great room for development with a settled Government (over them *sic*). There were three engineering shops in Sandakan and about 200 Europeans in the whole territory. Readers are referred to the Straits and Singapore Directory for further information. The concluding words of the first part of the report are, "In my opinion North Borneo has a promising future." Up to the

date my information takes me, there are only signs of a steadily increasing prosperity, there is nothing to suggest a retrograde movement. I am anxious to know what has happened since then. Messrs. Fyers and Graydon agree about the railway "going nowhere in particular." They seem to have lost sight of its object, if they ever knew it, like a good many non-observant men have done. Consul Arthur Keyser in his 1899 Report, after saying that the development of the country as yet is only in its infancy, goes on to say "at Beaufort" (where the railway runs) "and for many miles round, the country is unpopulated and the land is without cultivation. Beyond the present cutting of the Railway lie vast ranges as far as the eye can reach. On the further side of these hills is the country which it is proposed to open up. . . . This splendid stretch of country is full of possibilities of development, and the railway is apparently being constructed in order to afford capitalists opportunity to investigate them. There is no road, only a jungle path." He points out that the cost is likely to be considerable and the engineering difficulties great.

In conclusion, I may say, I have no connection whatsoever with British North Borneo, nor with anyone connected with it and that I have not even the pleasure of knowing Mr W D Gibbon. I merely place the knowledge I have gathered together at your disposal for the benefit of your readers, lest they should be led away by your contemporary's remarks without a careful investigation of the case. As I am only quoting, what I have said will lose none of its value if I do not sign my name.--I am, Sir, yours faithfully,

A.

[Consular Reports should certainly be reliable; but British Consuls are not only men of honour, but strictly responsible for what they report. Here is what the "Statesman's Year Book" for 1902 states:--

"About 1,000,000 acres have been alienated by the Government on leases of 999 years for tobacco planting, pepper, coffee, and jungle products. There are 12 estates planting tobacco, 43 coffee and coconuts, 3 Manilla hemp, 3 pepper and gambier.

	1898.	1899.	1900.
	Dollars.	Dollars.	Dollars.
Revenue proper	505,369	546,129	588,026
Expenditure	633,051	568,347	1,366,955
Exports	2,881,851	3,439,560	3,336,621
Imports	2,419,087	2,456,998	3,178,929

The revenue includes sums realised by land sales' and the expenditure includes payments on account of railways, telegraphs, and other public works, amounting for the year 1900 to 983,186 dollars.

Most of the trade is carried on through Singapore with Great Britain and the colonies. The chief products are timber, sago, rice, gums, coffee, pepper, gambier, gutta-percha, tapioca, sweet potatoes, and tobacco which is being planted on a large scale. Coal and gold have been found. The exports comprise mostly jungle and sea produce, wax, birds'-nests (edible), coco-nuts, gutta-percha, sago, tobacco, rattans, india-rubber, seed pearls, beche-de-mer, &c. A flourishing timber trade is stated to have been opened with China. Exports of leaf tobacco in 1900, 8,625 bales, valued at 92,000L. Shipping entered 1900, 110,908 tons; cleared, 111,385 tons; nearly all British. Borneo is now connected by cable with the outer world by a branch of the cable between Labuan and Singapore. A telegraph line has been constructed from Menumbok, where the cable reaches land, to Sandakan, where there is also a telephone exchange. A railway is in course of construction from Brunei Bay into the interior, and from there

to Jesselton in Gaza Bay. It is expected that the whole length of 110 miles will be open for traffic before the middle of the year 1902."

—Ed. T.A.]

FIRST SNIPE OF THE SEASON.

Kurunegala, Sept. 7.

DEAR EDITOR,—May I, again this year, claim the honour of having shot the first snipe of the season? I got one this morning at 7.30.—Yours, etc.

A. W. WARBURTON-GRAY.

[This is very early; has a snipe ever been shot in Ceylon before the end of August?—Ed. T.A.]

THE PRODUCTION OF THE COCONUT PALM.

Sept. 8.

DEAR SIR,—I was much interested in "Traders' letter on the above subject. I agree with him that the local consumption of coconuts has grown enormously during the last quarter of a century; but I doubt if that alone explains the inelasticity of the exports of the products of the coconut palm. There never has been a year since the British occupation in which hundreds, and even thousands, of coconut plants have not been put down by villagers and small proprietors; and during the last 30 to 40 years the acreage under coconuts must have quite doubled. I am afraid the deficiency in fruit is due to backwardness in cultivation. Only the trees immediately round the villager's hut bear heavily: his garden is neglected. Even headmen, and proprietors of tens and hundreds of acres, do little in the way of cultivation. The trees look after themselves; they are unmanured; and their crops decrease or stand stationary. It is the exception, and not the rule, to plough coconut land, to weed round the trees, to manure them at regular intervals. Hence, I believe, the disappointing outturn, as exhibited in the export tables you publish.

COCOS NUCIFERA.

[Again, in many cases of small native gardens, the planting is so close, that if half the palms were cut down, the crops would be larger.—Ed. T.A.]

PLANTING POTS.

Sept. 12.

DEAR SIR,—I have just seen "Planter's" query *re* planting pots. They are on the same principle as a flower pot, only narrower and have no bottom. These are laid down like planting baskets in nurseries for coffee, filled with earth and seeds put in. At planting they are carried to the field, earth and plant emptied out and placed in the hole, while the plot was taken away and kept for future use.

They are expensive to make and cost a great deal in transport and I should strongly advise "Planter" to use baskets as cheaper and more satisfactory generally.—Yours faithfully,

B. H. J.

THE JUNGLE CROW.

Abbotsford, Sept. 15th.

SIR,—I was very pleased and proud when some five or six years ago a couple of jungle crows settled down here as they are really handsome birds when on the wing.

They now swarm all over Upper Diambula ; but as I feel quite certain they have either killed or frightened away large numbers of our small insectivorous birds, I have shot some six or eight of them during the past few months ; and I hope all who can hold a gun straight will join in exterminating the thieves and so help to safeguard our little, feathered friends. One crow actually attempted to enter a pigeon-cot in my kitchen verandah the other day, so like all crows they have cheek for anything.—Yours faithfully, J. F.

P.S.—Here is what "The Indian Field" of 4th inst. says of them under "The Game Destroyers of India":—

Crows.—An arrant egg thief and chick destroyer is *The Jungle crow*. Found throughout India and ascending to considerable elevations in the Himalayas capable of enduring heat and cold, it is one of the ever-present sources of game bird destruction. In portions of the hilly tracts it is so numerous that it is a wonder the black partridge, chukor, etc.; ever succeed in hatching out their eggs. *The carrion crow* also is answerable for the absence of many a young brood of chukor, but is not found in any numbers except in Kashmir and the neighbouring hills. The delinquencies of the jungle crow (*Corvus macrorhynchus*) were brought to our notice not many years ago in a forcible manner. We were in camp at about 6,000 feet in some hills which were evidently popular breeding grounds for chukor. A prolonged halt enabled us to look for nests. One we discovered in a corn field contained 16 eggs of the chukor, whilst on the edge of the scrub jungle were other chukors' nests with varying numbers of eggs, none of these were at all carefully concealed; in nearly every instance the jungle crows found them out. Near the camp were three or four large clumps of high trees and there the crows were breeding. Most of the young crows were hatched out, for the jungle crow breeds about April in the hills, and often somewhat earlier in the plains. We saw the parent birds flying with egg shells in their bills and on walking round found as we have said most of the chukors' nests were rifled. We wiped out that colony of crows, and thus did a good turn to the chukor as a small return for the harm we have so often done them.

PLANTING NOTES.

CEYLON TEA IN WESTERN AMERICA.—From Mitcham, Surrey, under date 18th July, Mr. Fairhurst sends us a copy of an advertisement of Ceylon Tea, cut from *The Santa Cruz* (California) "Surf"—which he says will shew "that the exploitation of the tea is not quite so unknown [in America?] as a letter in your paper lately would make it appear." The advertisement is certainly striking (2½ inches by 4) half of it showing a doughty warrior on horseback, the "Pride of Ceylon." While below it we read "Finest Hill-Grown Tea—Registered Trade Mark." The rest of the letterpress is:—

Try "Pride of Ceylon" Tea, packed in Ceylon. One teaspoonful will make one quart—5 to 8 cups. Blue Wrapper, 50c per lb.; Red Wrapper, 75c per lb.; White Wrapper, \$1.00 per lb.; F. A. Peterson and Co., Direct Importers. 136 Pacific Ave., Santa Cruz. Also sold by:—Hinkle's Cash Store, 2 Pacific Ave; F. D. McPherson, 180, Pacific Ave; W. A. Husband, Seabright. Sold only in the original hermetically sealed packets,

COTTON SEED OIL.—In a circular which has just been issued to the shareholders of the Cottonseed Company (Limited), the directors state that a mill of commercial capacity has been erected on the company's riverside premises in London, and that in a trial run all that is claimed for the company's process in the treatment of cottonseed was fully established. A larger building is now being adapted to receive another mill of greater capacity, which, together with further mills of varying sizes, is now well under construction.—*Chemist and Druggist*, August 30.

THE ORANGE.—The Orange is of comparatively modern introduction in horticulture. It is not mentioned in the Scriptures, nor by Herodotus, who lived five centuries before Christ, and who wrote a list of fruits then known, nor by Virgil, who wrote much about such matters one hundred years before the Christian era. The Orange came originally from the south of China, Barmah and India. It is found growing wild in the jungles in various parts of India. The Arabs introduced the Orange to their country, and thence it got to Syria and Southern Europe. This was probably the Bitter Orange. The sweet variety was brought to Europe about the fourteenth century by merchants of Genoa or Portugal. Thence the tree was passed by the Spaniards and Portuguese to the Azores and other parts of the "New World," and found congenial conditions. Mexico, Florida, California, proved to be highly suitable. The St. Michael Orange originated in the Azores; the Pernambuco and Bahia (or Navel), were both named after provinces in Brazil. The Orange is now found growing in nearly every country where there is enough sunlight and absence of severe frosts.—*Journal of Horticulture and Cottage Gardener*, August 14.

CEYLON "GUANO."—We recall a very interesting account by a sportsman in the "Days of Old" of a visit to certain "caves" in the backwoods of the Kalutara district whence the Sinhalese paddy cultivators were in the habit of excavating guano—the droppings of birds and especially bats—and conveying the same for use in their paddy fields, having fully realised the value of such manure. We mentioned this fact to Mr. Kelway Bamber who expressed a wish to see a sample. We hope still to get one of the Kalutara article; but the first to reach us were two samples from a Hanwella resident of guano used by the cultivators in that neighbourhood. These are not "the real Simon Pure", being mixed with earth and poor in quality as Mr. Kelway Bamber kindly reports:—

"I tested those two samples of guano you kindly sent me some time ago, but they turned out of little value as they contained extraneous matter including earth, small stones, &c., especially No. 2. The following was their composition:—

	No. 1.	No. 2.
	Dark	Light
	coloured.	coloured.
Nitrogen...	2.80 per cent	1.12 per cent
Phosphoric Acid	1.76 "	trace
Potash19 "	.19 per cent

The first might be of value for application to local gardens, but would not stand freight charges."

THE FUTURE OF GREEN TEAS.—From a letter of Mr. Drummond Deane under date, Sept. 12th, we quote an opinion which may be of interest to green-tea makers, though each will no doubt judge for himself on the question raised:—

"I believe that for a time the coloured pure teas made by Ambawatte and Baraora, may through a closer resemblance in appearance to the colour 'Chinese' teas, help to open the doors of the American market, which is desirable; but I cannot lose sight of the fact that to the ordinary consumer the 'pure pan-coloured,' and the impure 'Japanese' or 'Chinese coloured' teas will in appearance resemble each other, which to my idea is not desirable. While as to the statement of Mr. Hart and, I believe, Mr. Galt, that only these 'pan fired' teas will keep and give full flavour, we have the report above mentioned on page 16, and also Mr. Hayter's letter from Toronto in reply to Mr. Hart which both go to prove that the panning process subsequent to steaming, is not necessary for *flavour* or for 'keeping qualities' of green teas. And I very much doubt if there is more profit in a coloured tea coloured by machinery panning and selling at say 7½ annas than in ordinary green teas selling at 5½ to 6½ annas in Calcutta or Colombo."

GREEN TEAS FOR AMERICA.—The Editor of the *Indian Planters' Gazette* has the following satisfactory note on Mr. Judge's letter:—

"We are much obliged to Mr Judge for his letter, although he has been labouring under a misapprehension. Mr Hart's contention is that greens which have not undergone the final (long and expensive) process of panning,—which puts a hard greenish greyish appearance on them naturally (without the aid of deleterious foreign substances such as the Chinese use)—are not "true" or finished greens. The assertion is one of purely personal opinion on which parties can well afford to differ, for it is of no material consequence at the moment. After reading Mr Judge's letter, we are inclined to think that, in this matter, there will be found to exist a satisfactory demand and a good market for both unfinished and finished greens. In our notes, in our last issue, to which Mr Judge refers, we assumed that Mr Hart's dictum was in the main correct, for the simple reason that the United States, on the whole, prefer coloured greens, and the American market is the one we specially desire to capture, as it will eventually take the bulk of the green teas which British-growers will manufacture.

It was on this score that we wrote:—"What is wanted (i.e., of course according to the gospel preached by Mr Hart,) is that the manufactured green teas shall in their finished state wear a greenish hue, *without being coloured by foreign substances.* This can only be obtained (by which we mean of course, on a commercial scale) by using the latest Deane-Judge machine, which the Baraora Tea Company have alone got in use at present, and (we were careful to add) a certain amount of panning." We should perhaps, have italicised the last five words, for we never for a moment intended it to be understood that the Deane-Judge machine *itself* put the hard greenish greyish appearance on the dry tea, being fully aware that the process of repeated panning could alone effect this. Mr Judge clearly defines the work done by the latest improved Deane-Judge machines and the Drummond Deane System of green tea manufacture.

GREEN TEAS—AND GREEN TEAS.—There is a current belief that low-country leaf makes as good green tea as high-grown. This is true, we believe, as regards "raw" or unfinished greens; but it is not so in the teas made according to the process used at Ambawatte. In teas so prepared, the superiority of high-grown leaf is readily realised. It remains to be seen how far the latest processes shortly to come into use, will succeed in turning out as good greens from low-grown as from high-grown tea.

PARA RUBBER AT THE STRAITS.—From an extract given on page 257 it will be seen that a Para rubber tree at Penang, about 17 years, old, has been tapped six times between the 11th and 15th year without suffering any harm giving 2½ lb. rubber each time on an average. Its size now (probable maximum) is 68 inches circumference main stem at 3 feet up. Probably 100 such trees per acre would do well, and if a price of 3s per lb. could be counted on, a return of £37 10s at each tapping, per acre, would be very good. The *India Rubber World* which has been decrying Straits rubber is said to be published in American interests. Can this be true? We doubt it.

AN EFFECTIVE BIRD-SCARE.—At this place it has been our study to preserve all birds by encouraging nest-building in every way possible, and in this blackbirds and thrushes have not been slow in taking advantage of the privilege afforded them. All this was very well so long as the birds fed themselves and their young upon worms and such-like; but when the Strawberry season came on, and the weather became hot and dry, and fewer worms were about, they turned their attention to the Strawberry-beds; nor in this were they in the least shy, for, until we endeavoured to let them know that Strawberries were to them forbidden fruit, they naturally appeared to have an idea that the garden and its fruit were all their own. The usual guys, &c., were set up, the scaring effect of which lasted only for the usual day or two, if indeed even for so long. Having in the house a couple of very talkative parrots, some of our people suggested trying the effect of placing these birds out upon the Strawberry-beds. One of them, a grey bird from the West Coast of Africa, talks fluently and his words are well pronounced; some of his speeches run thus: "Three cheers for the King; hip, hip, hip, hurrah! that is my loyalty;" "Elizabeth's got the blues; nothing new in that;" these and similar speeches alternative with splendidly whistled tunes, such as "Rory o' More," "Pop goes the weasel," The Campbells are coming," and similar other little ditties, with great force, finishing up always at the end of each speech or tune with a well pronounced "What do you think of that?" putting great emphasis on the word "that." No. 2, a green bird from Cuba, has not such a full vocabulary as the African, but in its Spanish vernacular it made some queer noises; so that between the two blackbirds and thrushes evidently thought it best to give the immediate surroundings of these birds a wide berth, and our Strawberries were by these means very much preserved!—W miller, Berksw. —*Gardeners' Chronicle*. Aug. 16

TO THE PLANTING WORLD.

Seeds & Plants of Commercial Products.

Hevea Brasiliensis.—Orders being booked for the coming crop August-September delivery 1902, booking necessary before the end of April, quantities of 100,000 and over at special low rates. Plants available all the year round, 100,000 and over at special low rates. A leading Rubber planter in Sumatra, who purchased 50,000 seeds in 1899, and 100,000 in 1900, writes us, under date 15th November, 1900 :—“ I received your letter of 20th October, from which I learn that you added another case of 5,000 seeds to replace the loss, &c. I am satisfied hereby, and even after this adding I am satisfied by the whole delivery of this year.” Special offer, post free on application.

Castilloa Elastica.—True superior variety cultivated in Mexico, seeds from specially reserved old untapped trees. Orders booked for August-September delivery 1902, immediate booking necessary; large quantities on special terms; Plants in Wardian cases.

A foreign firm of Planters writes under date 11th October, 1901 :—“ We beg to enquire whether you would procure us 100,000 Castilloa seeds, in which month we might expect them, and what would be the average price.” Special offer, post free on application.

Manihot Glaziovii.—Seeds and Plants available all the year round, 100,000 and over at special low rates. A Mexican planter in sending an order for this seed wrote on the 22nd August, 1900 :—“ If they arrive fresh and germinate easily I may send you larger orders, as they are for high ground where the Castilloa does not thrive.”

Ficus Elastica.—Seeds available in May-June; booking necessary before the end of March; also plants.

Mimusops Globosa (Balata) wood of the tree is much sought for buildings, fruits sweet like a plum and eaten, oil from seeds, said to yield as much as 45 lbs. of dry rubber per tree per annum, the milk is drunk and when diluted with water used as cow's milk, grow from-sea-level up to 2,000 feet, orders being booked for seeds and plants, price on application.

Cinnamomum Zeylanicum (Cinnamon superior variety).—New crop of seed in April to June; booking necessary before the end of February, also plants.

Coffee Arabica, Liberian Hybrid and Maragogopie Hybrid.—New crop March-April; immediate booking necessary.

A foreign Agricultural Department writes dating 9th September, 1901 :—“ Please accept our order for 175 lbs. of Tea seed and for 2,000 Coffee beans. In regard to Coffee seed I would say that this will be the first importation made by this department, and we will leave the selection of the varieties to be sent to your judgment.”

OUR DESCRIPTIVE PRICE LISTS.

The following six Descriptive Price Lists are now being forwarded with Circulars and special offer of Seeds and Plants of Rubber and other Economic Products :—

1. Tropical Seeds and Plants of Commercial Products, enlarged edition for 1902.
2. Seeds and Plants of Shade, Timber, Wind-Belts, Fuel and Ornamental Trees, Trees for Road-sides, Parks, Open Spaces, Pasture Lands, Avenues, Hedges, and for planting among crops (Tea, Coffee, Cacao, Cardamoms, &c.)
3. Seeds and Plants of Tropical Fruit Trees including Mango grafts.
4. Bulbs, Tubers and Yams.
5. Orchids—Ceylon and Indian.
6. Seeds and Plants of Palms, Calamus, Pandanus, Cycads, Tree and other Ferns, Crotons, Rosos, Dracinas, Shrubs and Creepers.

Special Arrangements made with foreign Governments, Botanical and Agricultural Departments, Planters and others for supplying seeds and plants of Commercial Products in large quantities.

“ SOUTH AFRICA.”—The great authority on South African affairs of 25th March, 1899, says :—“ An interesting Catalogue reaches us from the East. It is issued by WILLIAM BROTHERS, Tropical Seed Merchants of Henaratgoda, Ceylon, and schedules all the useful and beautiful plants which will thrive in tropical and semi-tropical regions. We fancy Messrs. Williams should do good business, for now that the great Powers have grabbed all the waste places of the earth, they must turn to and prove that they were worth the grabbing. We recommend the great Powers and Concessionaries under them to go to William Brothers.”

Agents in London :—MESSRS. P. W. WOOLLEY & Co., 90, Lower Thames Street.

Agent in Colombo, Ceylon :—E. B. CREASY, Esq.

Agent in British Central Africa :—T. H. LLOYD, Esq., Blantyre.

ST. HELIER'S TEA COMPANY, LTD.

ANNUAL REPORT.

ACREAGE.

250 acres in bearing.
29 do planted in 1886.
34 do planted in 1898.

313 acres.
114 acres Jungle, &c.

Total 427 acres.

The Directors have now the pleasure to submit their Tenth Annual Report to the 30th June last, from which it will be seen that the debit balance of R1,776.41, being loss on last year's working, has been wiped out and a small credit balance of R99.19 remains in hand to be carried forward.

The crop, which was originally estimated at 105,000 lb. of made tea, has turned out only 97,288 lb., realising an average price of 34.66 per lb., as against 33.03 last year.

The cost of tea in Colombo, exclusive of the sum of R1,453.06 expended on capital account, works out at 24.43 cents per lb., as against 28.05 cents per lb. last season.

With reference to the loan of £3,000 on the security of the Company's estate, the mortgagees having decided to call this up on 15th October next, and the Company not being in a position from a financial point of view to meet the same, steps are being taken to replace the mortgage; and it is not anticipated that there will be any difficulty in so doing.

Mr H G Bois retires from the Board by rotation; but, being eligible, offers himself for re-election.

The shareholders will have to elect an Auditor for season 1902-03.—By order,

BOIS BROTHER & CO., Agents and Secretaries

WANARAJAH TEA COMPANY OF CEYLON, LTD.

REPORT OF THE DIRECTORS.

Acreage.

Tea in bearing	1,028 acres
Planted in 1896	12 do
Do 1898	20 do
	1,060 acres in tea.
Timber Trees	.. 20 do.
Forest	.. 27 do.
Grass not available	.. 27 do.
Total	.. 1,134 acres.

The Directors have the pleasure of presenting to the shareholders the report, balance sheet and profit and loss account for the year ending 30th June, 1902.

The crop harvested amounted to 442,887 lb., against an estimate of 440,000 lb. The crop for 1901 was 436,945 lb.

351,617 lb. have been sold at an average of 44.70 cents.

MANURE.—The estimate provided for 370 acres. The acreage completed was 389, at a cost of R10,077.23.

FACTORY AND MACHINERY.—During the past season the Factory has been extended, and the Machinery increased at a cost of R12,907.32, which amount is debited to capital account.

After paying off an interim dividend of 5 per cent, and allowing 5 per cent depreciation on buildings and 10 per cent on machinery, there remains the sum of R75,884.03, including the balance

brought forward, R36,087.77, which the Directors recommended to be applied as follows:—

To a final dividend of 10 per cent, making a total of 15 per cent for the year	R37,800.00
To be carried forward	.. 38,084.03

The estimated crop for season 1902-1903 is 450,000 lb. of made tea.

The Visiting Agent's reports can be seen by shareholders at the Company's Offices.

Mr J W Vanderstraaten retires from the Board by rotation, but is eligible for re-election.

The election of an Auditor for the current season rests with the shareholders.—By order of the Board, BAKER & HALL, Agents and Secretaries.

CLUNES ESTATES CO. OF CEYLON, LTD.

REPORT OF THE DIRECTORS.

CLUNES DIVISION.

Superintendent:—R. O. De Saram, Esq.	
Tea in bearing	.. 390 acres.
Forest	.. 174 do.

Total .. 564 acres.

ERRACHT DIVISION.

Superintendent:—B. Alleyn, Esq.	
Tea in bearing	.. 501 acres.
Forest and Waste land	.. 244 do.

Total .. 745 acres.

Grand total ... 1,339 acres

The Directors now submit to the shareholders the accounts and balance sheet of the Company for the year ending 30th June, 1902.

The total quantity of crop secured amounted to 364,941 lb. of tea a very disappointing result, being 88,059 lb. short of the estimate. The shortage was mainly due to the unfavourable flushing weather experienced in the first six months of the financial year. In spite of the smaller yield the cost of production compares well with most other estates in the District *i. e.* 21.17 cents per lb., whilst the nett average price realised was 29.03 cents per lb., against 25.60 cents per lb. obtained last year.

Capital Expenditure was incurred to the extent of R5,346.83 in providing increased withering accommodation on Erracht estate.

Depreciation of buildings and machinery is allowed for on the usual scale, and the Directors consider it advisable to put aside a sum of R1,500 against doubtful Coast advances.

After making the provisions alluded to above the result of the year's working shews a nett profit of R14,804.09. To this must be added the balance brought forward from last year, bringing the total to credit of Profit and Loss Account to R19,175.10.

In view of the present uncertainty regarding the immediate future of the Tea Market, and taking into consideration a rather sharp attack of helioptelis from which Clunes estates is at present suffering, the Directors consider it advisable to transfer R15,000 to Extension Fund, (thus obviating the necessity of borrowing money on capital account) and to carry forward the balance *i. e.* R4,175.10 to current year's account.

No Capital Expenditure is anticipated for this year, and the crop is estimated at 417,400 lb. of tea against a Working Expenditure of 82,918.37.

In terms of the articles of Association Mr V A Julius now retires from the Board but is eligible for re-election.

The appointment of an Auditor for the current year will rest with the meeting.—By order of the Directors, WHITTALL & Co., Agents and Secretaries

THE PENRHOS ESTATES COMPANY OF CEYLON, LIMITED.

REPORT OF THE DIRECTORS.

DIRECTORS:—E M Shattock, Esq and G W Suhren, Esq. The Directors have pleasure in laying before the Shareholders their Report and Accounts for the year ended 30th June, 1902, duly audited.

The amount of Tea secured was 237,229 lb.—210,120 lb on Estate account as against an Estimate of 207,000 lb, showing an increase over last season of 10,977 lb, and 27,109 lb manufactured from bought leaf, a decrease as compared with last season of 7,919 lb.

The Comparative Table of the Estate Tea for the past six seasons is appended, and will doubtless be found of interest:—

Crop in lb.	Cost laid down in Colombo.	Or without Manure.	Net Av. Price.	
1896-1897	155,625	27.52	26.31	36.42
1897-1898	145,250	26.23	25.65	39.12
1898-1899	158,106	25.41	24.05	41.03
1899-1900	196,554	23.74	22.32	37.46
1900-1901	199,143	26.29	23.88	34.89
1901-1902	210,120	22.39	21.50	32.94

The total Crop secured cost, inclusive of Manure, 22.72 cents per lb. laid down in Colombo, and realised a net average price of 32.30 cents. Included in the Expenditure is a sum of R536.18, which has been spent in re-draining a further portion of the Estate. This work is being steadily proceeded with, some 199 acres having been treated up to date, and the improvement in the appearance of the bushes on those fields where the work has been carried on is already most marked. A sum of R933.09 has also been spent during the year on the upkeep of young clearings.

After payment of the Interest on Debentures, viz: R3,030.00, the nett Profit for the year comes to R16,727.52, or slightly over 11 per cent on the Capital of the Company. To this must be added the amount brought forward from the previous season, viz: R1,142.38, making the total amount available for distribution R17,869.90.

The Directors recommended that this be apportioned as follows:—

	R.
By payment of a dividend of 7 per cent	10,500.00
By payment of a bonus to Superintendent	1,250.00
By placing to Reserve Fund	2,000.00
By carrying forward to next account	4,119.90
	<u>17,869.90</u>

The acreage of the Company's estates is as follows:—

Old Tea	..	548½	Acres.
Tea under 4 years	..	7½	do
Tea under 2 years	..	44	do
		<u>600</u>	Acres.
Forest	..	42	do
Chena &c.	..	296	do
		<u>738</u>	Acres.

Mr E M Shattock retires by rotation from the Board of Directors but, being eligible, offers himself for re-election.

It will also be necessary to appoint an Auditor for season 1902-3.—By order of the Directors, LEE HEDGES & Co., Agents and Secretaries.

Colombo, August 18th, 1902.

HAPUGAHALANDE TEA COMPANY, LTD.

Report of the Directors presented to the eighth annual ordinary general meeting of shareholders held on Saturday, 30th August, 1902, at 12.30 p.m.

Your Directors beg to submit their Annual Report and Accounts for the twelve months ending 30th June, 1902.

The quantity of Tea manufactured for the season (including estate and brought leaf, but exclusive of that manufactured for other estates) was 135,150 lb as compared with 181,020 lb in 1900-1901. The serious falling-off in crop was due to the abnormally unfavourable weather experienced during the first few months of the period under review.

Estimating the unsold tea at a safe valuation, the amount realised for this product has been R41,392.98, equal to an average of 30.63 cents per lb.

After setting aside R3,293.58 for depreciation on buildings and Machinery, the sum available for distribution (including R5,492.13 brought forward from last account) is R14,658.96. From this sum the Directors recommended payment of a dividend of 5 per cent, absorbing R8,5000 and leaving R5,153.96 to be carried forward.

In terms of the Articles of Association Mr Keith Rollo retires from the Board of Directors and is eligible for re-election.

The appointment of an Auditor for the current season will rest with the meeting.

LEWIS BROWN & CO.,
Agents and Secretaries.

EILA TEA COMPANY.

DIRECTORS' REPORT.

Messrs. G F Walker, S Bois and H G Bois. The Directors herewith submit their report and accounts for the year ending 30th June, 1902.

The following figures show the result of the year's working on the Company's estates:—

	Estimated Crop.	Crop realised in Colombo.	Cost per lb.	Price realised.
Eila	252,550	237,175	19.50 cts.	27.22 cts
Kanangama	114,500	86,585	24.73 "	28.44 "
	<u>367,050</u>	<u>323,760</u>	<u>20.90 cts.</u>	<u>27.54 cts</u>

from which it will be seen that there was a shortfall in crop of 43,290 lb, but the cost of production was only 20.90 cents against an estimated cost of 21.46 cents for which much credit is due to the Superintendent. The shortfall on Kanangama estate was to a great extent due to the severe attacks of helopeltis and partly to an insufficient labour force and steps have since been taken to put this latter on a more satisfactory footing. At the end of the season helopeltis was very bad on Kanangama and it is to be hoped that the measures employed by the Superintendent to cope with this pest will be successful. The visiting agent in his last report stated that the general appearance of the tea on both estates was satisfactory.

During the year a further instalment of £500 was paid to the Standard Assurance Company, in reduction of their loan per £7,000. The amount now outstanding is £5,000.

The net profit for the season after providing for 10 per cent depreciation on buildings and machinery is R7,676.83 out of which the Directors propose to pay a bonus to Mr. Dawkin which will absorb R 500.00 to pass the Reserve Account.. .. 6,500.00 to carry forward to next season! 676.83

R7,676.83

The estate of the Company now consist of:—

Eila	..	716 acres	Tea 5 years old and upwards
		240 do	Forest.
		<u>956</u>	acres.
Knangama		215 acres	Tea 5 years old and upwards
		103 do	Forest.
		<u>323</u>	acres.

The estimates for the current season provide for a crop of 375,180 lb. Tea at a cost of R33,935.65.

Mr S Bois retires in accordance with the Articles of Association, but being eligible offers himself for re-election. It will be necessary to appoint an Auditor for season 1902-3.—By order of the Directors, J. M. ROBERTSON, & CO., Agents and Secretaries. Colombo, 8th September, 1902.

THE TEA CORPORATION, LIMITED.

ANNUAL REPORT.

The following is the report issued for 18 months ending December 31st :—

Alfred Bull, Cyril Gurney, E H Hancock, T J Lawrence, R R G Norman and V H Smith :—Directors.

Frederick Tatham :—Managing Director in Ceylon. Antony Gibbs & Sons :—London Agents.

Report of the Directors and Accounts for the eighteen months ending 31st December, 1901, to be submitted to the annual general meeting of Shareholders on the 21st July, 1902.

The Directors beg to submit herewith the accounts of the Corporation for the eighteen months ending 31st December, 1901, and they regret to have to report that the conditions prevalent in the Tea Industry during the greater part of that period have led to very serious results, especially in the case of estates such as those of this Company, which in the main produce medium to low-grade tea. As Shareholders are well aware, prices were unprecedentedly low during most of the period in which this last year and a half's tea has been sold. Indeed, they were, generally speaking, fully 1d per lb. below those of the previous year, and even then the market was below normal. The restriction of production which was very generally practised—in view of the accumulation of stocks and the relations of supply and demand—involved an increase in cost, which naturally follows a reduction in crop.

The following figures indicate the results during the past three years :—

	Crop lb.	Cost of Pro- duction.	Average Sale Price Net.
	1897-98	1,112,606	31 cts. per lb 5d
	1898-99	1,234,442	26.10 do 5 15-16d
	1899-1900	1,276,139	25.60 do 5 3-16d
	1900-01	1,164,435	27.62 do 4½d
(6 months only)	1901	366,816	36.98 do 5 3-8d

From these figures it will be seen that the year's crop up to 30th June was reduced by over 110,000 lb, instead of showing the expected increase; that it cost 2 cents per lb more to produce, owing to this shortage and that the prices obtained for the tea average a figure which barely covers the cost. The prices for the succeeding six months showed a marked improvement, but owing to the usual comparatively small crop, and the extra expenses which are always incurred during that period, the cost per lb is nearly 10 cents higher. It is expected that the crop for the full year will not fall far short of that for 1900-01 and the cost should be reduced to about 26 cents. The falling-off in shipments from India and Ceylon did not immediately produce any effect on prices owing to the large stocks of Tea in London, but an improvement was shown in the late autumn, which has unfortunately not been maintained.

The loss on the Estates for the eighteen months is £318 6s 8d. After adding Debenture Interest, London Expenses, &c., there is a loss of £7,331 12s 5d, after deduction of Balance brought forward.

The expenditure on the work done at the Plumbago pits has been heavy owing to a large inflow of water. The amount of Plumbago won was about 60 Tons, but unfortunately prices ruling were low. In the last few months a considerable amount has been secured, a good vein having been discovered, which, when realised, should considerably reduce the Exploiting

Account. The workings are at present let to Natives on satisfactory terms, involving no risk to the Company.

As soon as the accounts for the last financial year were complete, the Directors invited all the largest Shareholders to meet and confer with them on the financial position, and in consultation it was agreed that accounts should in future be made up to 31st December; hence the reason that the present accounts cover eighteen months. The Directors before the issue of this Report again met some of the larger Shareholders and consulted with them as to the financial position of the Company. The general feeling was that it was imperative to raise money to strengthen the position of the Company, and that after the matter had been considered at the Annual Meeting some action should be taken.

The Directors retiring in rotation are Mr Vivian Hugh Smith and Mr Reginald R G Norman, who, being eligible, offer themselves for re-election.

The Auditors, Messrs Broads, Paterson & Co, also retire and offer themselves for re-election.—By order of the Board, E. T. BARTLETT,

15. Bishopsgate Street Within, E.C. Secretary.
Dated 8th July, 1902.

PLANTING NOTES.

COTTON SEED—is, of course, known locally, and has been known for generations, as excellent food for cattle. Poonac is nowhere in competition with cotton seed, in the estimation of cart and milch cattle, as any one who has watched them make a rush for the milky morsel must know. But it would appear that only her immediate neighbours have been the chief customers of India for this product. Europe has now awakened to the fact that what was long considered a worthless residue in cotton-cleaning, is useful for man, as well as beast! An Indian contemporary reports that :—

"A remarkable feature of the trade of the past year has been the development of traffic in cotton seed, of which 150,000 tons have been shipped from Bombay in the fifteen months ending last June, compared with only 1,800 tons in 1893-99. The whole has been sent to the United Kingdom, where a brisk demand has sprung up for this previously almost worthless bye-product of cotton industry for such productions, as the manufacture of oil and margarine."

NORTH BORNEO AND PLANTING, &c.—are not treated after a flattering fashion by Mr. H. A. B. Fyers, Surveyor, in an interview with our contemporary. Here is the material part :—

"How far have the maritime parts of the country been developed?" "Well—they have a railway there, and it is the funniest railway you ever saw or heard of. It was constructed before cart-roads were made, and the railway does not seem to have any approach roads at all; and for sixteen miles it runs through a mangrove swamp and into which it almost disappears! That is the Jesselton-Beaufort railway, and Jesselton is now the capital." "What of the agricultural activities and possibilities of the country? Have you come across many plantations?" "Precious few: there is some amount of tobacco cultivation round Darvel Bay—that is the North-east corner of the island—but only this year three or four estates there had their crops destroyed through floods." "Who are the planters?" "The majority of them are English and Dutch men. The chief centres for the tobacco are Darvel Bay and the valley of the Kinabatangau River." "Is there any other agricultural industry?" "Not to speak of. The Chinamen grow vegetables, which are all consumed in the country, and there is some fruit culture at Kudat, right to the extreme north of the island."

THE AGRICULTURAL MAGAZINE, COLOMBO.

Added as a Supplement Monthly to the "TROPICAL AGRICULTURIST."

The following pages include the Contents of the *Agricultural Magazine* for October :—

Vol. XIV.]

OCTOBER, 1902.

[No. 4.

THE TAMARISK.

THE Tamarisk (*Tamarix gallica*), known to the Tamils as *kiri*, is described by Trimen as a large shrub or tree with slender branches occurring on the sea coast chiefly on the North-West, between Chilaw and Jaffna. It is one of the few forms of vegetation which are suitable for planting in exposed situations along the sea border, with the special object of arresting drifting sands.

In an article appearing in the August number of the *Agricultural Gazette of New South Wales*, some interesting facts relating to this Ceylon plant are given by the writer, Mr. W. S. Campbell. We read here of the Tamarisk being planted in the most exposed situations on the coast, at the mercy of severe gales and strong winds with constant encroachment of sand, and yet growing from the start. Under favourable conditions the plant is said to grow into an ornamental and shapely tree attaining sometimes a height of 20 to 25 feet. Another name for it is the "flowering cypress."

In Dr. Hedin's book "Through Asia" the Tamarisk is referred to as the plant which encroached furthest into the awful desert regions traversed by the traveller.

The specific name *gallica* indicates the fact that the plant produces galls which are sometimes used in medicine and as deying agents where astrigency is wanted. In medicine it is employed as a tonic, while it is a substitute for hops in making beer in Denmark. The ashes of the plant, when found growing near the sea, are found to contain a large pro-

portion of sulphate of soda, to obtain which it may be profitably burnt. The abundance of this salt is said to explain the use of the plant as a diuretic agent.

Mr. Campbell mentions the curious fact that the Tamarisk produces a kind of manna when punctured by an insect known as *Coccus manniparus*, but distinguishes this from the manna of the Old Testament which is traced to a lichen.

The Tamarisk is mentioned by Homer and other ancient poets, and has been long held to be a celebrated medical plant by the Arabians.

It is interesting to note the plants used in New South Wales for planting along the sea coast with the double object of serving as wind belts and arresting shifting sand. There are marram and spinifex grass (planted on the sandy bank along the beach) and (higher up) *Pinus maritima*, *Ficus macrophylla*, *Metrosideros tomentosa*, *Lagunaria Pattersonia*, *Arundo donax*, *Pampas grass*, &c.

Seeds of marram grass were not long ago distributed by the Botanical Department for trial. *Arundo donax* is familiar enough as an introduced plant, while *spinifex squarrosus* sometimes called "water-pink" is that quaint form of vegetation which rejoices in the quaint native name of "Maha-rawanarewula" meaning "the great beard of Ravena or Rama."

CURE FOR TAPE WORM.

(To the Editor, "Agricultural Magazine.")

Ratnapura, 30th Sept., 1902.

SIR,—For the benefit of your readers I give you a better cure for tape worm in dogs than arecanut, which often harms the dog. I got the recipe from Dr. Carberry. It is powdered pumpkin seed. Give a teaspoonful or more with every meal, and have patience. It is tasteless and harmless. Watch for the head of the worm.—Yours faithfully,

G. S. SAXTON.

[We are glad to learn of this very simple and safe remedy.—Ed. A.M.]

Mean36

Greatest amount of rainfall registered in 24 hours on the 4th September, 1902, 2.37 inches.

Recorded by ALEX. PERERA.

OCCASIONAL NOTES.

In the *Farmer's Bulletin*, No. 78, issued by the United States Department of Agriculture, is described the process of manufacture of a new fungicide, named *Sar*, said to be very effective. It is made as follows:—"Place 15 lbs. of flower of sulphur in a barrel, mix thoroughly with $\frac{1}{2}$ lb. of finely-powdered resin, stir well with 3 quarts of water, which should make a thick paste. The paste must not be thin and watery, nor so dry as to crumble to powder when stirred. Then add 10 lbs. of caustic soda and stir well. After from three to fifteen minutes the mass turns a reddish brown and boils violently, and must be stirred well, preferably with a broad paddle to prevent it from running over. After it has ceased boiling, add slowly about two gallons of water hot if possible, but cold will do, and then carefully pour off into another vessel marked to hold 6 gallons, and add hot water till the six-gallon-mark is reached. This gives a stock solution, which must be kept in tightly corked jars or in closed barrels or kegs, since it spoils if it comes into contact with the air. It is also decomposed if it touches metals." Of this stock solution $1\frac{1}{2}$ pints to 50 gallons of water is recommended for treating seed oats for loose smut, the seed to be soaked for 24 hours. A stronger solution, one gallon in 50 of water, can also be employed, in which case two hours will be sufficient for soaking.

Since referring to *Spinifex squarrosus* in our General Items column, we have discovered a curious error in the note on this grass which occurs in Trimen's *Flora*, Vol. V., on page 174. All who live by the sea are no doubt familiar with the plant, called "water pink," probably

owing to the resemblance of the ashy green foliage to the common pink of our gardens. The peculiar crackling noise produced when the dry plant is thrown into the fire, has, we feel sure, often served as a substitute for the bursting of the Christmas cracker to the fisherman's child, while the flying ball of the flower head is supposed to illustrate "the rolling things before the wind" and "the wheel before the wind" mentioned in the Bible. The curious error we have referred to above is the translation of the Sinhalese name Maha-Ravana-Rewula into the great *bund* of Ravana" instead of (as Ferguson correctly puts it) "the great beard of Ravana." One can understand the simple mind of the native seeing a resemblance in the coarse hard grass to the grisly beard of the hairy Bakshia hero, but where does the word *bund* come in at all?

Regarding the well-known Mauritius or water grass (*Panicum muticum*, *P. Barbinode*, but not referred to as *P. Molle*, though this is the name given in Trimen's "Catalogue"), we read in the "Ceylon Flora" that "It is singular that neither Thwaites, Trimen or Ferguson give a Sinhalese or Tamil name for it." But on turning to Trimen's Catalogue it will be found that he gives the common enough Sinhalese name *Diyatanakola*. Its omission from Watts' Dictionary (so stated in the 'Flora') is due to the fact that the grass was practically unknown in India, where our other cultivated fodder grass *Panicum maximum*, Guinea grass (whose native name is, by the way, given in the "Flora" as *Ratejana* instead of *Ratatana*) is common enough. About ten years ago the then Superintendent of the Government Dairy (Mr. C. Driberg) supplied the Poona Farm with the grass for planting at Poona where it was not heard of before.

Imperata arundinacea, or "Illuk" grass, is figured in the July number of the Journal of the Department of Agriculture of Victoria, where it is also known as the Lalang or Blady grass. The following notes are supplied: "The Lalang grass is a native of all the Australian Colonies . . . and is very conspicuous in a paddock on account of its large white flower spike. It is by no means a good fodder on account of its hardness, though stock will eat in a young state, and especially after a bush fire. It is often used with advantage for thatching. It is also useful for binding sand in moist localities." So that there is a good word for even such a pest as "Illuk," which some one facetiously remarked was a corruption of "Ill-luk" which it certainly brings to the unfortunate planter upon whose land it encroaches!

CASTOR OIL.

Some time ago we referred to the recommendation of an Agricultural expert that all backward parts of estates should be put under the Castor Oil plant, as the oil is a marketable product, while the refuse cake (ponac) is a

valuable manure. We have been collecting a small quantity of seed of the large fruited variety of the Castor from plants grown in the Colombo stock, and will be glad to give these away to any one desiring to have seeds. The variety is a fairly high shrub and rather a good shade tree.

In the *Queensland Agricultural Journal* for July we are told that 2s. 9d. per gallon is the price the oil may be expected to bring in Australia, though buyers would probably be willing to pay 3s. to local manufacturers, as the loss by leakage in tins from Europe is very considerable. The quotation is for lubricating not medicinal oil.

The following note about the extracting of the oil (from the *Queensland Agricultural Gazette* for June last) will be of interest:—Briefly the operations of oil extraction are by expression, by boiling with water, or by the agency of alcohol. A comparatively simple process can be tried by any one interested, and a good oil should result if the seed is of the right variety.

First, cleanse the seeds from fragments of the husk and from dust, and submit them to a gentle heat, but not greater than can be borne by the hand, which process makes the oil more fluid and more easily expressed. A whitish oily fluid is thus obtained, which is boiled with a large quantity of water, and all impurities are skimmed off as they rise to the surface; the water dissolves the mucilage and starch, and the albumen is coagulated by the heat, thus forming a layer between the oil and the water; the clear oil is then removed and boiled with a small quantity of water until aqueous vapour ceases to rise and a small quantity taken out in a phial remains perfectly transparent. The effect of this is to clarify the oil and rid it of volatile acid matter. Care is necessary not to carry the heat too far, as the oil would acquire a brownish colour and an acid taste.

In India the seed is first shelled and then crushed between rollers, placed in hempen cloths and pressed. The oil is afterwards heated with water in a tin boiler until the water boils. This serves to separate the mucilage and albumen, the product being then strained through flannel and put into canisters. Any oil-press would suffice for extracting oil for ordinary purposes, and by decantation and some process of filtration it could be purified. Cheap wooden rollers would serve the purpose, and these could be driven by a horse-gear, after the fashion of driving the old horse-mills for crushing sugar-cane.

We should very much like to see Castor oil cultivation given a fair trial on a few acres of land that are found unsuitable for the regular crops of the country, so as to prove the value of the produce, both oil and poonac, per acre.

THE BULRUSH MILLET.

Pennisetum Typhoidum, as the plant is scientifically named, is also known as the

Bulrush Millet, Cumboo or spiked millet, and in many parts of India as Bajri or Bajra. In the Bombay Presidency the area occupied by it is considerably over 4 million acres, and in many parts forms the staple food of the people. In the Madras Presidency the area under Kambu (as it is there called) is nearly 2½ million acres. In the North-Western Provinces and other parts of the Indian Peninsula it is also grown to a large extent.

The following are the uses of the plant as enumerated by Dr. Watt, Reporter on Economic Products to the Government of India:—

Food.—The grain is chiefly used by the lower classes, and in many parts of India it is their principal food. It is supposed to be heating, and is, therefore, in Northern India consumed mostly in the cold weather. The flour, made into bread or cakes with butter milk is the staple food of many, and is more nutritious than rice. In Khandesh it is often eaten with butter and various condiments by the well-to-do. The following is the composition of a sample of the unhusked grain according to an analysis made by Professor Church:—

Water	11.3	%
Albuminoids	10.4	"
Starch	71.5	"
Oil	3.3	"
Fibre	1.5	"
Ash	2.0	"

The nutrient ratio being 1: 7.6, and the nutrient value 89½. The grain contains 4.2 per cent of potash and .68 per cent of phosphoric acid.

Fodder.—It is occasionally grown for green fodder, but the stalks, after the grain has ripened, are more or less utilized as fodder in various parts of India. Sometimes the straw is carefully stacked and preserved to be chopped up and given to cattle with green fodder.

In an interesting report on South Indian Fodders, with analyses by Dr. Van Geyzel, M.B., C.M., F.C.S., F.I.C., Chemical Examiner, Madras, the following is given as the composition of Cumboo straw: Moisture, 7.07; Ash, 8.04; Fibre, 37.63; Fat, 1.34; Carbohydrates, 43.65; Albuminoids 1.94; Nitrogen in non-albuminoid compounds, .33; Albuminoid ratio, 1.44. If the nitrogen found in the non-albuminoid compounds be calculated in the usual way as albuminoids and the nutritive relation worked out, the result shows that Cumboo contains 4.02 albuminoids and its albuminoid ratio will be 1.21. In Trimen's Flora we read that Cumboo is cultivated in the hot region. He describes it as a widely cultivated millet in the old world from Italy to China, especially in Africa, and records the interesting fact that the grain, like Canary seed, was used for feeding the carrier pigeons which were employed before the introduction of the telegraph in carrying news from Galle to Colombo.

POULTRY NOTES.

We have received a copy (September) of the *Indian Fowl Fancier and Farmers' Journal* edited by H. E. Abbott. It is a useful publication which supplies a decided want, and is neatly got up.

The September number of the above is largely taken up with Ceylon news and notes, dealing chiefly with the Shows that took place last August. The idea of the Ceylon Poultry Club adopting the *Indian Fowl Fancier* (with pages devoted to Ceylon) as its official organ is an excellent idea. It is no easy matter to run a monthly magazine with anything like success.

The *Adelaide Observer* has the following amusing note about the poultry tick and bug:—

As there is some diversity of opinion with reference to the poultry tick and bug, some holding that they are different, while others agree that they are the same thing, it was thought an opportune time to discuss the matter from a scientific point of view at a meeting of practical poultry men recently held in Adelaide, and a well-known scientific man was asked to give his opinion upon the matter. He stated by explaining that the big mother tick was the bug, but he got no further as he was unable—owing to the sounds of laughter—to proceed even to tell what was his opinion of the father tick.

Fowls like newly-cut grass; give them all they want of it. The clippings from a lawn-mower are just the thing for them. Dry chillies broken up may be fed to poultry in moderate quantities with good results, but do not make their food too strong with it. Thorough fumigation of poultry houses can be carried out by wetting sulphur with kerosene and setting fire. The poultry should of course be out of the way and the house well secured and so left for about two hours.—*Sunday Times* (Perth).

For egg production crushed bones, plenty of lime and clean gravel must be always at hand. Cooked coarse meat chopped up might be given twice a week, and an occasional allowance of green food especially if birds are kept in confinement. A box or barrel of oyster shells, broken up small enough for the hens to swallow should be on hand. A pound weight sprinkled every day will be found none too little for 20 or 25 hens.—*Ibid.*

Here is a recipe for chicken cholera:—2 oz. pulverised capsicum; 2 oz. pulverised asafetida; 1 oz. pulverised rhubarb; 6 oz. spanish brown; 2 oz. flowers of sulphur. Mix thoroughly and keep in an air-tight can. For use take a teaspoonful and mix with the mashed food, and feed twice a day till all symptoms of the disease disappear.

A remedy for scurvy legs is to apply, at the earliest possible stage, a mixture of sulphur and lard, allow it to remain 24 hours and wash thoroughly with strong suds made with carbolic soap.

It is interesting to read an account of the laying competition organised by the *Daily Telegraph* and conducted at Haukesbury Agricultural College, under the supervision of Mr. D. S. Thompson, the Poultry Expert. We can only summarize the results by saying that the Silver Wyandottes led all through, except for a day or two when they were passed by the white Wyandottes at the beginning and by the Buff Orpingtons towards the end.

Mr. T. J. McCue, the Poultry Editor of *Station, Farm and Dairy*, in answer to a correspondent who enquires what is the best breed for a small run for eggs and table purposes, replies: I would recommend Wyandottes or Orpingtons. Both are good layers of a fairly-sized egg, and the chicks grow fast if cared for properly.

TANNING MATERIALS.

(Continued.)

In our last issue we considered the tan-producing trees belonging to the order Combretaceæ.

Another order which is characterised by tan-producing trees is Rhizophoraceæ or the Mangrove family. Of these we have a number occurring in Ceylon, and these we shall proceed to consider:—

Rhizophora mucronata (Sin. Kadal).—This tree occurs in most of the salt-water estuaries and backwaters round the whole coast. Analyses of the bark give rather a variable composition, showing how important it is to secure standard qualities. Thus, Prof. Dunstan found as little as 4.13 per cent of tannin in the dry bark, and Mr. Hooper as much as 29.50 under similar circumstances. Dr. Busse found in the dried inner bark of East Africa 47.99 per cent of extract, consisting of tannin and brown colouring matter. Extracts of bark gave on examination from 33.5 to 75.94 per cent tannin in the dry substance. The extract from the bark of this tree is considered better than of other mangroves for the purposes of the cotton dyer, but Prof. Hummel considers it far from being equal to the best catechu sold for that purpose. Bark is exported to some extent from Ceylon to India.

Rhizophora mangle (*Candelaia*).—This tree, also known as *Kadal* in Ceylon, occurs though less commonly with *R. mucronata*. A sample of Trinidad bark examined by Messrs. Hunt and Mackay of Leeds gave tannin (by hide powder) 25.10; while the extract or concentrated juice was found to contain 58.30 tannin (by hide powder). The bark of this is also exported from Ceylon to India.

Bruguiera gymnorhiza.—This is one of the species common in the mangrove forests all round the coast. In French Cochin China an extract is made from the bark, and this is sent into the market as a substitute for catechu under the name of *Cay Day*. Dr. Busse obtained 44.71 to 53.12 per cent of tanning extract from samples of this bark from East Africa. Analyses of bark by Prof. Dunstan gave 12.77 of tannin in dry bark; by Mr. Hooper 15.90 tannin and (in dry bark) 15.50; by Dr. Leather 14.81 tannin. While analyses of

extracts by Mr. Hooper gave 57 tannin or 71.7 (in dry bark); and by Dr. Leather 53.42 to 56.33 tannin and (in dry bark) 64.2 to 60.7.

The wood yields a poorer extract, for while bark prepared at Dehra Dun extracts yielded 33, 46, and 51 per cent by Lowenthal's process, two samples of wood extract gave only 13 and 16 per cent tannin. Bark exported to some extent from Ceylon to India.

Cerriops Candolleana. (Tamil Chirukandel) — This tree is also common in the coastal mangrove forests, as at Negombo and Chilaw. There is said to be a steady demand for the bark in the Calcutta market, where 10,000 to 12,000 maunds are sold annually. The bark gives a considerable large amount of tannin, and gives a deep red colour—with water. From samples of bark examined the percentages of tannin in certain samples from Bengal reached 27.24, equivalent to 31.56 tannin in dry bark. Mr. Hooper also found as much as 26.20 of tannin or 30.20 in the dry bark. The extracts from the bark of this tree have been for some time in the London market. The percentage of tannin in the exact (taken from analyses by Prof. Dunstan, Mr. Hooper and Dr. Leather) is found to rise up to 63.83 and (in dry bark) to 86.95, while extract prepared at Dehra Dun shewed a percentage of 90 of tannin.

Extracts are, as a rule, made by evaporation in the ordinary still, but we are told that "in Singapore, Borneo and Ceylon, factories have been erected for the purpose of preparing cutch substitutes." In Ceylon a special concession was made by Government to a company working in the Eastern Province, but as far as we know the operations there have now been suspended.

Cerriops Roxburghiana.—This tree differs little from the last in habit and foliage. The bark is usually found in the market in the form of reddish-brown quills, and its decoction gives a deep reddish colour and astringent reaction. The ordinary bark examined by Mr. Hooper showed 19.20 per cent tannin. The tannin in the dry bark was found by Mr. Hooper to be 21.10 and by Prof. Dunstan 23.54. A sample of extract from the first mentioned showed 53.5 tannin and (from dry bark) 62.1 percent. Mr. Gamble of Dehra Dun writes that in practice the barks of *C. Candolleana* and *C. Roxburghiana* could probably be used indiscriminately.

Kandelia Rheedii.—The bark of this tree was found to contain by Prof. Dunstan 11.99 tannin in dry bark, by Mr. Hooper 12.20 tannin and (in dry bark) 13.40, by Dr. Leather 14.54 tannin, but instances have been known of a percentage of 20 and even 27 per cent of tannin occurring. The extracts on the whole are said to be less satisfactory than these from *Cerriops* bark, and yield about half their weight of tannin calculated in the dry substance.

Carallia integerrima. (Sin. Dawata).—This is a common tree about the sandy lands in the northern part of Colombo. The tree shows its relationship to the mangroves by the large tufts of aerial roots it sends forth from the trunk and branches.

A specimen of the bark received in 1897 from Pegu afforded only 1.5 per cent of tannin. The bark was about half an inch thick and the ash

content amounted to 15.2 per cent. It would thus appear that Dawata bark is of poor quality for tanning.

(To be continued.)

NATURE STUDY.

At a recent meeting in London the Duke of Devonshire said:—It is frequently said, and I am afraid with a certain amount of truth, that education as at present conducted is not so fully appreciated in rural districts as I am happy to say it is in towns. If this be so, we have in nature study the means of bringing rural education into the same relation to rural life as to the industries of urban localities. If at present the village labourer takes interest in his children's education, I am afraid it is only too often with the object of enabling them to escape from the drudgery of his own existence, and to exchange it for the more exciting atmosphere of the towns. And if that feeling has its effect on the agricultural labourer, we cannot wonder very much if some country gentlemen and many of the farming class have not hitherto viewed education with any great enthusiasm. At the Board of Education we have long been conscious of this difficulty, and have been most anxious to find some means by which elementary instruction should be brought into closer relation with rural life, and that all classes connected with the cultivation of land should come to feel that education was not antagonistic, but, on the contrary, conducive to the interests of agriculture. To attain this end we could not do much without external assistance. That external assistance has come in this new departure. An influential committee has been formed, including a large number of members of Parliament and county councillors, with the object of drawing up proposals to improve the character of the instruction given in rural districts. The resolutions drawn up were presented to the board, and were accepted with great pleasure and satisfaction by Sir John Gorst and myself. (Cheers.) We have also endeavoured to take some practical steps in the direction of this change. But one difficulty was to find teachers sufficiently conversant with natural science and the objects of country life to impart this new form of instruction. The department now requires that nature study, in its practical and experimental form, shall be taken as one of the subjects of the teacher's certificate examination. In that we have been most cordially assisted by the great majority of training colleges and by many of the county councils. We hope that this new departure may do something to increase the interest felt in schools in rural districts. It must not, however, be supposed that nature study is to be exclusively confined to country schools. I conceive the idea which underlies this movement is that, while there is much to be learned from books, and it would be foolish to neglect those stores of knowledge acquired by those who have gone before us, there is also much to be learnt, not from books, but from the facts of nature; and while the study of books is often only an exercise of the faculty of memory, and may leave almost untouched other faculties of the mind, on the other hand, the intelli-

gent study of nature necessitates observation, and provides a mental discipline that cannot fail to develop those powers of the intellect which it is the object of true education to discover, to cultivate, and to strengthen. (Loud cheers.)

NATURE STUDY LESSONS.

SECOND COURSE IN THE STUDY OF PLANT LIFE.

THE STEM.

From the position of the stem it would strike you that it is a means of communication between the roots and the leaves of plants (the branches large and small being divisions and subdivisions of the stem). But—you might well ask—what is the nature of this communication, and how is it carried on? Before answering this question, however, I must tell you something about the structure of the stem. Now I do not mean to explain to you its ultimate or minute structure, for if I tried to do that I would probably perplex you, and that is just what I want to avoid doing. The study of minute structure in plants (or animals) is a special study known as Histology, a knowledge of which is not necessary for you to understand the functions of the stem. Indeed, I do not want you to acquire a special knowledge of Botany, but to know enough of the plant and the functions of its various parts or organs to enable you to understand its wants so as to be in a position to supply those wants.

The stem—and in fact every part of a plant—is made up of minute *cells* which differ in size, shape and other characters, and these cells combine in various ways to form what are called *tissues* or cell masses, which of course differ according to the character of the cells that go to form them. There are also associated with tissues, *vessels* which you might think of as minute tubes each formed out of two or more cells.

The structure of the stem is characterised by a more or less definite arrangement. Let us take the stem of the mango as representing a very large class of plants. If you examine the stem of the mango, cut right across, you will be able to distinguish the *bark* on the outside, next to it the *wood* occupying much the larger space, and, generally, in the centre, the *pith*. But between the bark and the wood is a very thin but very important layer of cells forming what is known as the *cambium* or growing layer, which has the power of forming wood on the one side and bark on the other, and so enabling the tree to grow in thickness. Similar active growing tissue occurs at the ends or growing points of stems and branches enabling them to develop in length or height.

See if you could distinguish in a cross section of a mango or rose stem a number of radiating lines running from the pith to the cambium. These are the *medullary rays* which serve as a means of communication between the various parts,

The stem of the coconut as representing another large class of plants is rather different in structure. Here the tissues do not go to form successive layers of bark, cambium, wood and pith, but, when examined on the cross cut, shows a ground work of soft tissue through which the harder portions are irregularly scattered. The so-called bark is really of the same character, but contains a very much larger proportion of the hard tissue.

It is the hard or woody parts of a stem that perform the function of conveying fluids (and all plant food must be in the fluid condition as I will explain later on) from the roots to the leaves. You have all, no doubt, heard the expression "sap-wood," and can probably distinguish the sap-wood from the "heart-wood." Well, it is the sap-wood or fresh outer wood that carries on the work of conveying fluid matter upwards. The inner harder dried wood is what affords us timber.

You must know that there is a good deal of water passing out in the form of vapour through the leaves. (I will tell you more about this when we come to speak of leaves.) Now the constant evaporation from the leaves tends to bring about an upward current of fluid through the stem. This general explanation is, I think, sufficient for you to understand one of the important functions performed by the stem, viz., the conveying upwards of liquid plant food from the roots to the leaves.

Now, I have no doubt, you are ready to put me another question, and that is—what happens to the food materials that are conveyed to the leaves? To fully explain this I shall have to tell you a great deal about the functions of leaves, concerning which I have yet to speak to you. But this much I will tell you now—the plant food taken up by the roots and passed up by the stem is prepared, or made fit for the use of the plant in the leaves.

So far as we know, therefore, the course which the ascending sap, as it is called, takes is through the cells forming the younger layers of wood, the vessels assisting when the current is rapid; while the prepared sap is generally believed to descend and circulate through the inner layers of the bark. [The bark I should tell you consists really of three layers which can be well seen in the "shoe-flower" stem as (1) an outer "skinny" layer, (2) a middle greenish layer, and (3) an inner fibrous layer.] If the above facts be true, then if you remove a ring of bark from the stem of, say a mango or orange tree, or bind the stem very tightly with a strong hoop, no increase of wood should take place below the ring or hoop, while a thickening should occur immediately above it,—for the reason that while the unprepared fluid sap travels upward through the wood cells, the prepared sap cannot descend below a certain point where active growth results from excessive nutriment. This is an experiment worth trying, and you should try it.

I have already told you that certain underground stems become swollen and store up

nutriment for the future use of the plant. This reserve food chiefly consists of starch, and as you know such tubers are used as food by man. As examples of such farinaceous tubers, I may mention the potato (arthapal), yams (kondol and various kinds of "ala"), arrowroot (hulankiriya), and edible canna (but-sarana). But the stems of certain large trees also store up farinaceous matter, as, for instance, the sago palm (sow) and the kitul, sometimes called the "Bastard Sago" palm, the flour (piti) of which you are no doubt familiar with.

We may now consider for a little the uses of the parts of the stem. I have already referred to the value of the wood of certain plants as timber. We have, as you know, many excellent timbers in Ceylon, some particularly valuable and used for ornamental furniture, such as ebony (karuwala) and calamander (kalumederiya); others useful for building purposes such as jak (kos) and teak (Tékka). I need not here refer to the different uses of wood for fuel, paper-making, &c.

The bark of trees which yield tan are used for tanning or the preparation of leather; the "Patana oak" (kahata) and the common country mangrove (kadol) are instances of such trees.

Some woods yield dyes, e.g., jak (kos) yields a yellow dye, and sapan (patangi) a red dye.

Many important drugs are got from the stems of plants. It is sufficient to mention one, viz., quinine, which is obtained from the bark of the Cinchona.

Some trees such as the Hal yield a valuable resin, others like the Dorana yield oil, others again (e.g., Caju) yield gum. Another class of trees, to which the Indian rubber tree belongs, yield rubber.

Many trees, such as Sunhemp (Hana) are valued for the fibre they yield.

Exceptionally we find very soft and spongy stems as in the pith plant (mahadiya siyambala).

The soft succulent stems of certain herbaceous plants such as amaranthus (tampala), and Lassia (kohila) serve as vegetables.

Another very useful substance obtained from the stem is cork, but almost the whole of the cork of commerce is got from one species of oak which is found in Spain, South Italy and North Africa.

I have told you a good deal about the uses of the stem in order to interest you, but what I want you to remember is the important functions performed by the stem, as well as something of its structure; and to take advantage of every available opportunity to examine and compare the stems of plants and to study their structure and peculiarities.

C. D.

RINDERPEST.

Mr. D. Hutcheon, the Colonial Veterinary Surgeon at the Cape, where he has had better opportunities of studying this fell disease among cattle, is about to publish a pamphlet on the

subject. The *Agricultural Journal of Cape Colony*, which we are indebted for the following extracts from an advance proof, says with reference to the diagnosis of the disease—often rendered difficult owing to the absence of what are generally considered characteristic symptoms, especially in the earlier stages. The temperature is usually an excellent guide, but this cannot always be relied upon, as we often get a high temperature in other diseases involving the digestive organs. For example, there are many cases of Rinderpest in which the flow of tears is not very marked, and the discharge from the nose barely discernible. There is invariably more or less of a dribbling of saliva from the mouth, but we get that associated with Redwater, also congestion of the liver, and other derangements of the digestive organs; while a violent diarrhoea, the fœces being mixed with blood and mucus, is often the accompaniment of the bowels, caused by cattle eating certain irritant bulbous plants, such as tulip. Numerous cases of acute catarrh are met with also, which simulate the symptoms of Rinderpest very closely, but the discharges from the eyes and nostrils are more viscid than in Rinderpest, while there is no flow of saliva from the mouth, and the fœces are usually normal. In all outbreaks, therefore, in which only one or two animals are affected, it is necessary to make a postmortem examination, and even then, unless the case is sufficiently advanced, the typical appearances—the yellowish-grey exudate of the mucus membranes, and the ulcerous erosions of the fourth stomach and bowels—may not be sufficiently developed to lead to a decided opinion on the case, and unless there is evidence of contagion, further developments must be awaited.

The following are the extracts we are permitted to give from the Journal referred to:—

"On viewing the carcass of an animal that has died of Rinderpest, the body is generally much emaciated, and the natural orifices are soiled with a dirty discharge, and the carcass exhales a peculiar foetid odour. The principal and pathognomonic lesions of Rinderpest have their seat in the mucous membranes of the digestive tract, the respiratory passages, and the urinary apparatus. The mucous lining of the mouth is congested, and covered over with a slimy mucus. It presents a bright salmon colour, but if the beast has been killed and bled before examination, this bright pinkish colour disappears. The epithelium is frequently found detached in places, leaving small ulcerated-looking spots. These are met with most frequently on the under surface of the tongue, inner surface of the lips, and on the dental p.d. The mucous membrane of the fauces and pharynx is the seat of catarrhal inflammation, and covered with thickened mucus—sometimes purulent. The nasal mucous membrane is likewise the seat of catarrhal inflammation, its surface being covered with purulent mucus, and towards the openings of the nostrils, small ulcers or abrasions are frequently met with. After passing the pharynx and larynx, there is very little change to be observed in either

the trachea or œsophagus. Slight catarrhal inflammation is sometimes met with in the bronchial tubes, with collapse of some of the smaller lobules. Pulmonary emphysema may also be present, but, as Williams remarks, this is due to the formation of gases in the areolæ of the connecting tissue. But the changes in the lungs are neither constant nor pathognomonic, and are secondary as a rule. There is sometimes ecchymotic patches on the endocardium of the heart, and similar spots are met with, occasionally, on the epicardium, with a little fluid in the pericardial sac. On opening the abdomen, the peritoneum is congested and very frequently spotted, and there is a variable quantity of a yellow serous fluid in the peritoneal cavity. It is comparatively rare to find any pathological changes in the first and second stomachs, although a little serous infiltration is sometimes met with under the epithelial lining.

"The third stomach is generally hard, and the food between the leaves dry and caked. But very frequently, more especially if the sick animal has been allowed to drink large quantities of water, the contents of the third stomach are found quite fluid.

"It is in the abomasum or fourth stomach, and the intestines, where the most marked and characteristic changes are met with. The mucous membrane of this stomach is the seat of acute catarrhal inflammation, the sub-mucous tissue is swollen, and infiltrated with a serous effusion, especially on the rugæ or folds. The mucous membrane is also swollen, and its epithelium detached—desquamated—in patches of various sizes, leaving ulcerated sores, more particularly near the pylorus or bowel, and, where these ulcers present the appearance of dark eroded sores, with the yellow degenerated tissue resting in their centres, small petechial spots are often found studded all over the congested area.

"In the small intestines we find congestion and inflammation of varying degrees of intensity, with a muco-purulent greyish yellow exudation, in some cases covering innumerable small spots scattered all over the mucous membrane of the bowels; in other cases this exudation is found covering almost the whole surface of the mucous membrane. In more severe cases this presents the appearance of a thick croupous-looking exudate, which—in parts—forms a complete cast of the bowels.

"In such cases the epithelium is thickened, softened, and is found detached over large patches throughout the small intestines, leaving the membrane red and granular looking. Peyers glands or patches are generally inflamed, swollen, and denuded of epithelium. The changes in the large intestines are not usually so well marked or so uniform. In many cases the inflammation is more in patches, and in the rectum the mucous membrane is often intensely inflamed, and presents a blood-streaked appearance. The epithelium is swollen, and covered over with a muco-purulent exudate, while there is more or less infiltration of the sub-mucous tissue. In many severe cases, however, the

large intestines are just as seriously affected as the small, with numerous small patches of desquamated epithelium. It is a very curious fact also that many of the cases which manifest the most severe external symptoms do not show the most characteristic *post-mortem* lesions.

"The liver very often appears congested, and presents a yellowish colour of varying tints. In many of the cases, however, the liver is perfectly normal in character and appearance, and the gall perfectly healthy. The mucous lining of the gall-bladder is sometimes inflamed, especially about the base of the sac, and studded all over with blood spots. The gall presents varying shades of colour, from a deep green to almost blood red, and is often thick and curdy looking. The mucous lining of the urinary bladder is sometimes affected also in patches with a little sub-mucous infiltration, and similar appearances present themselves in the vagina of the female. It is not my intention to go minutely into all the *post-mortem* changes which may be observed in individual cases. The most marked and pathognomonic *post-mortem* appearances are those seen in the mouth and upper air passages, and in the fourth stomach and intestines.

"The medicinal treatment of Rinderpest is seldom followed by any satisfactory results. A large number of medicinal remedies were tried, such as germicides, anodynes, astringents and laxatives, alone and in various combinations. Some of these appeared to exercise a beneficial effect, but I am strongly of opinion that the varying success which attended the administration of these several remedies depended more upon the mild or severe nature of the particular outbreak, than upon any specific action exercised by the medicine. In its usual virulent form, ten per cent. of recoveries was considered a very fair average, but in some outbreaks fifteen, twenty and up to thirty per cent. of recoveries were recorded, more particularly during the hot dry summer weather.

"In India they have had the same experience. Pease says:—The disease in some parts of India, and notably those parts which are naturally hot and arid, where the temperature of the air rises very high, is frequently noticed to be of a far milder type than is the case more particularly in the hills, and it has appeared probable that desiccation of the virus by the great heat and dryness influences its virulence to a considerable extent—60 to 65 per cent. of recoveries may sometimes be observed in the hot districts of the plain.

"I think there can be little doubt that dry heat does exercise a modifying influence on the virulence of the disease, but it does not altogether account for the exceptionally mild form that the disease assumes on individual farms here and there in a district where the climatic and other conditions are similar to those on other farms adjoining, where the disease presents its usual virulent character."

Be that as it may, I am of opinion that if careful statistics could be collected, it would be shown that, where the affected cattle could be properly

attended to, comfortably sheltered from the hot sun in summer, and from the cold in winter, kept away from an unlimited supply of water, and given nourishing gruel to drink, that a higher average of recoveries would follow than where a large number of different medicines are used. I do not mean to infer that medicine is useless in Rinderpest; some may modify the symptoms and alleviate the suffering, but none of the medicinal remedies that I have tried, or heard of being used, appeared to exercise any very marked influence on the course or character of the disease. The Indian Cattle Plague Commission agreed that mild laxatives in the early stages of the disease did good, and Veterinary Surgeon Thacker, who is reported to have treated 2,541 cases of the disease with great success, always gave three ounces of finely divided sulphur in two quarts of gruel morning and evening, until some slight laxative effect was produced.

"The principal methods of inoculation against Rinderpest practised in South Africa are bile and serum. The former is used both fresh and glycerinated, and the latter in the form of preserved serum, and as blood freshly drawn from a recovered animal.

"Inoculation with pure bile, either obtained from an animal affected with Rinderpest immediately after death, unless the duration of the disease has been unduly prolonged, or from an affected animal killed while in the last stage of collapse, which is usually about the sixth or seventh day of the fever, or the tenth or twelfth day after artificial infection. This is Koch's method. The dose recommended is 10 c.c., injected into the cellular tissue under the loose skin of the dewlap, and well rubbed in.

"Koch's instructions were to use biles of a dark green colour with a white froth, and it is generally acknowledged that these are the best, but experience has shown that biles of all shades of colour, except those which are red from the presence of blood, and those which are very thin and of a light yellow colour, may be used so long as they are clear and free from any putrid smell. 'Animals which were injected with brownish green gall containing the Simpson bacillus in pure culture, and gall of a brown colour, containing both bacteria and streptococci, became immune without the occurrence of any accidents such as abscesses.' (Kohlstock.)

"As the bile obtained from different animals may vary considerably in strength and immunising properties, all the galls extracted at one time, after being kept separate for twelve hours to see whether they remain all right, should be mixed together, so as to render them as uniform in strength and character as possible. If practicable bile should be used within from eighteen to thirty-six hours after it is drawn, unless it can be kept in ice, when it will keep sweet and effective for a much longer period; but even under such conditions, it should not be kept over four days, as its immunising properties are liable to become modified when kept beyond that period.

"Further experience indicates that the bile obtained from cattle which contracted the disease spontaneously, and is extracted immediately after death, is generally more reliable than bile obtained

from cattle which are given the disease artificially, by the subcutaneous injection of virulent blood. Hence smearing the muzzle and nostrils with infective material was considered a more satisfactory method of infecting animals for bile production.

"In connection with this subject Dr. Eddington says in his Annual Report for 1897, page 67:—'That according to the recent researches of Fraser, the bile of all animals has peculiar antitoxic virtues, and he suggests that the ingress of poison by the alimentary tract is attempted to be met with, and antagonised by the bile secretion, so that the giving of Rinderpest to animals by the natural channel may—and I think probably does—stimulate bile production. Further, where infection is made through the gastro-intestinal tract, the poison must, in the first instance, act through the portal vein; while in subcutaneous infection the virus must be carried to the liver, for the most part along the branches of the hepatic artery, a most important difference, seeing that in the one case the action proceeds with regard to the hepatic lobules centripetally, while in the other case it proceeds centrifugally.'

GENERAL ITEMS.

In the account of a new edible tuber in the *Agricultural Gazette of New South Wales* occurs the following passage:—"Its taste, when cooked, is very agreeable, resembling that of Japanese Crosuej or salsify, while it is richer in alimentary equivalents than either of these legumes." Whether the word Japanese qualifies the term salsify, and if so, whether the plant is a legume, we cannot tell, but the vegetable ordinarily known as salsify (*Tragopogon porrifolius*) belongs to the order Compositacæ.

As soon as tomato plants show signs of disease, they should be at once sprayed with Bordeaux mixture made up as follows:—Dissolve 4 lbs. bluestone (sulphate of copper) in water (hot water if possible) after "powdering" the bluestone, and mix thoroughly 4 to 6 lbs. of fresh quicklime with water: then mix the two and add 40 gallons of water to bring to the proper strength.

The most commonly used colouring matter for dairy produce (cheese and butter) is the vegetable extract from *Bixa orellana*, known as "annatto," which was so successfully manufactured in Ceylon by the late Messrs. Borron and VanStarrex of Crystal Hill Estate, Matale. Referring to annatto the *Journal of the Board of Agriculture* says:—"This and other yellow colouring matters of vegetable origin, turmeric, saffron, &c., have generally been considered harmless in the quantities employed, but they are being gradually superseded by coal tar yellows, the action of which on the human system is not fully known. Butter from Holland, Australia and the United States is very frequently coloured with coal tar yellows. A large number of margarines are also so coloured. The coal tar yellow most frequently employed for dairy produce and margarines is

known commercially as "butter yellow" (*Dimethylamido-azo-benzene*) and is generally supplied ready dissolved in oil, either cotton seed, rape, linseed or sesame (gingelly) oil. Tropæolines, derived from coal tar, are also coming into use.

400 lbs. weight of fowl manure is equal in value to 2,400 lbs. farmyard manure. In one ton of the former analysis showed 48.60 lbs. phosphoric acid, 48 lbs. potash and 67 lbs. nitrogen; while farmyard manure contained only 6 lbs. phosphoric acid, 10 lbs. potash and 11 lbs. nitrogen in a ton.

Rice-paper, says the *Weekly Scotsman*, is not made from rice, but from the membranes of the bread-fruit tree. This is certainly news. The rice-paper tree is well known to be *Fatsia papyrifera*, the paper being manufactured out of the pith. The famous papyrus used as paper by the ancient Egyptians, was, however, prepared from the pith-like tissue of the tall stems of a sedge (*Cyperus*).

In sowing cow peas, 10 lbs. will suffice for an acre if sown in drills, and 40 lbs. if sown broadcast (which is not to be recommended). The fattening value of the cow pea will, it is expected, bring it into the near future into general cultivation.

Other names for the common gram used as a horse food with paddy (known in the vernacular as "kadala") are Bengal gram, chick pea, rams' horn, and coffee pea. The plant is said to be a native of Armenia, and has been cultivated as a human food for over 3000 years. Next to cereals it forms the largest part of food in Spain, India, and Africa. The presence of oxalic acid in the clammy oxidation on the leaves makes them unsuitable for fodder. The crop ripens in about 4 months, and the yield of seed is sometimes as high as 100 bushels per acre.

Tagassrte (*Cytisus proliferus albus*), so much written about as a fodder plant, is a shrubby perennial legume. The seeds are slow in germinating and need soaking for about 24 hours. At the end of about the third year cattle or sheep may be turned into the field, and the crop will require no further attention except occasional cutting back to prevent too high growth. The leaves and twigs are said to be very nutritious, and the plant worth a trial in dry hot districts, for when once established it is practically unaffected by draught.

The vines of the sweet potato are in some places used to make an excellent hay; while in India *Crotolaria juncea* (Sin. Hana) is grown to feed milch cows.

"What does my land require?" is a question we have been told many a struggling farmer would like to have answered, but it is not easy to give an answer. It may be obtained most readily, it has been thought, by analysis of the soil. That it is obvious must be unsatisfactory unless there is a considerable area of the soil evidently all alike in its component parts. Where the land is so mixed as it is on most parts of our coast country, any analysis can only be useful for a limited area. It has been urged that cheap analyses would be a boon to farmers; but to be useful they would have to be numerous, and would thus run away with money. Soil analysis, like mill testing, is good as far as it goes; but as the dairyman looks to his churn for proof of excellence, so the arable farmer must look to his crops for proof of the quality of the soil.

A correspondent to the *Queensland Agricultural Journal* says that warts on a cows' teat could be cured by the application of molasses twice a day.

* The TROPICAL AGRICULTURIST *

◇ MONTHLY. ◇

COLOMBO, NOVEMBER 1st, 1902.

No. 5.

FOLIAR PERIODICITY IN CEYLON.

BY HERBERT WRIGHT, A.R.C.S., F.L.S.

Paper read before the British Association for the Advancement of Science, Belfast, September, 1902. Reprinted by "Tropical Agriculturist," Nov. 1902.

THE subject of foliar periodicity in the tropics is of especial interest (a) in virtue of the assistance it gives to the study of the histological differentiation of the secondary xylem, (b) in consequence of the plants having less resistance than in temperate zones, and (c) because erroneous conceptions of the scarcity of deciduous tropical trees exist in the minds of many botanists.

The high temperature and humidity of the air in most parts of Ceylon is such as to allow nearly continuous growth of the arborescent vegetation. In consequence of this, there is no period analogous to the winter of a temperate zone when almost every species becomes leafless and remains so until the spring time arrives. The majority of the trees in Ceylon are of an evergreen nature, and even in the deciduous forms there is considerable irregularity in the periodicity of leaf fall and production.

DECIDUOUS TREES.—In Ceylon, there is no relationship between deciduous and allied species. The same genus may or may not contain deciduous species, or as in the genera *Terminalia*, *Ficus*, *Sterculia*, *Stereospermum*, and many others, there may be a very large percentage of the species deciduous. Some natural orders, as for instance the *Sapotaceæ* and *Ebenaceæ*, are peculiar in that only one or two species are other than evergreen, and not a single natural order can be quoted which has a high percentage of deciduous species. Nevertheless, though this investigation is quite young, I have obtained nearly 200 species of Ceylon trees which pass through a deciduous phase at recurring periods of time. It is worthy of note that though different specimens of the same species show every variability in the

period of time at which they drop their leaves and produce new foliage, yet the same tree passes through this phase at exactly corresponding times from year to year.

In studying the behaviour of our deciduous trees the most usual conclusion is that no law and order prevails, and any tree drops its leaves how and when it chooses. There are, however, certain features which point to a climatic response, and others which indicate that the personal or interval forces are the chief agencies at work. It can be definitely stated that the majority of our deciduous species show a response to climate, in so far that they do, in climates similar to that prevailing at Peradeniya, drop all their leaves and remain leafless during our hottest and driest season. This hot dry period extends from January to April or May, and the leafless trees of *Bombax malabaricum*, D.C., *Eriodendron anfractuosum*, D.C., *Spondias mangifera*, Willd., *Stereospermum cheleoides*, D.C., *Ficus Arnottiana*, Mig., *Derris robusta*, Benth., *Careya arborea*, Gaertn., *Ficus religiosa*, L., *Catappa Roxburghii*, Br., and very many other species, give a characteristic barren appearance to the arborescent vegetation. Very many species undergo defoliation, and this does not occur during the dry part of each monsoon but only during the time stated. The deciduous trees seem, therefore, only to recognise one hot dry period of three to four months as against the alternating dry and wet months of the remainder of the year. Further, every tree of *Terminalia Catappa* undergoes a complete change, of leaf during the dry part of each monsoon, and other species, I suspect, undergo foliar repletion twice every year. In addition to these we have some species, not native, which though they drop all their leaves and regain complete foliage at one time of the year, also suffer partial falls and productions at other times of the year. *Pithecolobium Saman*, Benth.; *Stereospermum cheleoides*.

Instances of acclimatisation are well known, but there are also some species which do not appear capable of readily accommodating themselves and

drop and produce leaf during any month of the year. This is characteristic of *Cedrela Toona*, Roxb., planted in the upcountry and a native of Australia.

There are some species which though in the Peradeniya districts are quite deciduous, yet in the more equable climate of Java are quite evergreen.

That the climate of Ceylon has a decided influence on the periodicity of the deciduous species is obvious if one leaves the Peradeniya district in May and proceeds to the Northern parts of the Island where there is very little rain in the S. W. monsoon, and where the weather from January to October is relatively dry and hot. The defoliation and foliar repletion has been considerably delayed in the Vavuniya and Mannar districts compared with Peradeniya, the species common to all districts dropping their leaves at times which differ by many weeks and months. In the northern districts so long as the plant drops its leaves during any of the eight or nine months, the same climatic advantages, if any, will accrue.

It may therefore be concluded that the variation which occurs in the temperature and humidity of the air in Ceylon is so great that it exerts a decided influence on the phenomenon of defoliation of many of our species. The climatic conditions in Ceylon are not equable enough to allow the plants to continue their development along a chance line, and botanists desirous of studying the personal equation of plants should select a more equable area.

PERSONAL EQUATION.—Though the climatic effects are obvious on many of our species, there are several trees which behave in a manner indicative of personal or interval factors being at work.

Many species drop their leaves and regain full foliage at a time which appears decidedly disadvantageous. Many retain full possession of their foliage or put forth the whole of the young tender leaves at a time when the physical conditions favour maximum transpiration. These species may be less plastic to the climatic forces, or it may be that they can achieve their ends in opposition to still more severe external forces.

If one selects trees of *Lagerstrœmia flosregina*, Retz; *Bridelia retusa*, Spreng; or species of *Canarium* or *Palaquium*, he will find that though they exist alongside each other under conditions which are physically identical, yet the time of fall of old leaf, production of new leaf and of flowers differs considerably in specimens of the same species. In the first mentioned species, the variation is a question of months, and to see members on the same plot, dropping their leaves when others are quite bare, others in full old leaf, and others in full new leaf and flower impresses one with the significance of the internal forces.

Again there are species which undergo defoliation at approximately the same time of the year though they are under very dissimilar climates, and one is led to infer that foliar periodicity is inherent and asserts itself no matter what external forces are at work. Many species drop their leaves and remain bare during a period of wet cool weather when the transpiration is probably at a minimum. This occurs at Peradeniya with trees of *Albizia procera*, Benth., and *Pterocarpus echinatus*, Pers.; during the dull moist months of June and July. The periodicity would here appear to be inherent, though there is the possibility that these plants have, in the migration of species, found themselves at a place where the climate is not in harmony with their original periodicity.

The feature which impresses a resident in Peradeniya is undoubtedly the great irregularity in the foliar periodicity of the different trees. It would be very difficult to draw general conclusions as every tree has its own peculiarities. There is not a month in the year when all the trees are in full foliage, and this can only be explained when we possess a better knowledge of the internal forces at work in every species.

The most important point, however, rests in the fact that many of our markedly deciduous tree at Peradeniya and still more so in the northern districts of Ceylon, remain bare only for a part of the hot dry season, and perhaps when the temperature and dryness of the air is at the maximum they burst out into full tender foliage. The output of leaves at any time necessarily occasions increased transpiration, but when this occurs at our hottest and driest time the transpiration is probably at the maximum. It is therefore very difficult to correlate the deciduous phase with the theory of checking transpiration in every instance, and in these cases we must look for other forces which are probably internal, e.g., *Stereospermum suaveolens* D.C., *Spondias mangifera*, Willd., and *Azadirachta indica*, A. Juss. We will now proceed to discuss the significance of foliar periodicity and the assistance it gives towards a true interpretation of the histological differentiation of the secondary xylem.

Complete defoliation and foliar repletion usually results in the differentiation of rings of growth in the wood of the stem. In temperate zones the phenomenon is annual, and when such is the case, each ring of growth represents one year of time.

In Ceylon and the tropics generally the fall of leaf and production of new foliage is often more than once per year, and is further subject to variations according to the internal requirements of the particular plants. It is therefore obvious that at least a knowledge of the exact periodicity of every species must be at hand before we can interpret the time value of the rings of growth.

For convenience we may first describe the periodicities of trees belonging to the *deciduous* class.

The sapling stage, often including the first few years of the plant's life, is reported to be of continuous growth, but in many species, notably *Eriodendron aufractuosum*, defoliation occurs during the first year and a ring of growth is presented in the stem. In species where there is no such differentiation the central wood must represent an unknown number of years. In most of our mature trees the foliar repletion occurs once per year, but in others such as *Terminalia Catappa*, *Stereospermum chelonoides*, *Pithecolobium Saman*, it occurs oftener, and each period of foliar activity must needs be represented in the stem. Many trees undergo foliar depletion at irregular intervals of time, probably as a result of successive years of drought or purely personal reasons, and in each case a complete knowledge of the life history of the plant is necessary before the differentiations in the xylem can be explained.

Then again I have seen *Portlandia grandiflora* completely defoliated by an insect as soon as it came into new leaf, and several weeks were required for a complete renewal to be effected. If my information is correct that this tree undergoes this cycle every year, the rings of growth should be double those of an undisturbed tree of the same species.

Similar to these are certain trees of *Bombax malabaricum* at Peradeniya which are completely defoliated by the ravages of the flying foxes which annually visit the district. These animals appear after the trees have completed their annual output of leaves and remain until all the foliage has been devoured; by this time the other trees of this species are just beginning to drop their leaves and a curious sight is then presented. Those trees which have been defoliated by the flying foxes now burst out into new leaf for a second time that year, and as they go on from year to year, a comparison of the rings of growth in the stems of such trees with those which are never thus defoliated should prove highly interesting. Probably many other trees suffer defoliation from like causes and it is obvious that a knowledge of the life history of each plant necessary before the time-value of each ring of growth can be determined.

Now consider the *evergreen* trees. For our purposes an evergreen tree may be defined as one which never becomes even partially bare so long as it is free from disease. There can be no sharp line between trees belonging to the evergreen or deciduous classes.

The evergreen trees are continually putting on new leaf, and though the older leaves gradually fall off, the net result is usually an increase of foliage from year to year.

The young trees usually put on new leaves at a successively increasing rate from year to year, but when mature a regularity in output often asserts itself. In a large number of our species the foliage is added at one or more times every year, and in such *e.g.* *Mangifera indica*, L., definite rings of growth are produced every year. The output of new foliage leads to an increased transpiration, and this may or may not lead to the differentiation of a ring of growth. The trees which show an annual output of leaves at a particular time are invariably mature and flowers follow in the axils of the new leaves. In young, non-flowering evergreens, however, the foliage is often added in two parts, one in the N.E. and the other in the S.W. monsoon. Evergreens characterised by such a bi-annual foliar periodicity are comparable to the deciduous *Terminalia Catappa* trees, and the rings of growth in them probably number more than one per year. There are, however, a very large number of evergreen trees which have no fixed foliage periodicity but put on new leaf every week or month of the year. Among these we have several species of *Eugenia*, *Artocarpus* and *Cinnamomum*, and numerous others, the rings of growth of which, when present, require a deal of consideration before a correct elucidation can be given.

Finally, there are evergreen trees which though they produce a large number of leaves at a particular time each year, are continually putting forth new leaf buds during the remaining months of the year. It is further conceivable under equable physical conditions, for the same tree to change its mode of leaf production from time to time, in which case a knowledge of the personal equation of the plant would be of the utmost importance.

The point which we have to notice is, that, providing there is a special period at which the evergreen or deciduous trees put forward their leaf for the year, this will result in an especial amount of transpiration for that period. This is usually followed by the differentiation of large lumened thin walled tracheal elements, and each ring of growth thus established is a record of past foliar activity.

The tendency is to produce a very distinct ring of growth in those deciduous trees which are bare for very long periods, though this by no means prevents very slow growing evergreens from producing rings of varying significance. There are, however, many deciduous trees which show very poor rings of growth, and on the other hand evergreen trees with very pronounced rings in the secondary xylem.

This brings us to the other factors which determine the significance, and in some cases, perhaps, the actual formation of rings of growth in our tropical woods.

The factors are

- (1) Rate of cambial activity.
- (2) Independent effect of a hot dry climate.

RATE OF CAMBIAL ACTIVITY.

An erroneous popular notion exists that in Ceylon the deciduous trees are usually of more rapid growth than the evergreens. This probably has its origin in the fact that the deciduous trees which are most conspicuous are the plentifully distributed members of the *Malvaceæ* and *Euphoibiaceæ* which attain enormous dimensions.

No such relationship exists, however, and the rate of cambial activity is of great variation in trees of both classes.

On the one hand the quickest growing tree in Ceylon is *Albizia Mollucana*, an evergreen, while quick growing trees such as *Melia dubia* and *Bombax malabaricum* are markedly deciduous. On the other hand the *Sapotaceæ* and *Ebenaceæ* include some of our slowest growing trees and though the majority are evergreen, there are a few which are deciduous; similarly slow growing trees in the form of *Bridelia retusa*, and *Crataevæ Roxburghii* are decidedly deciduous. Hence no definite relationship exists in this connection.

Nevertheless the rate of cambial activity is an important factor in determining the significance of the rings of growth, and an active meristematic layer is probably the cause of the rings being more prominent in a quick growing evergreen than in a slow growing deciduous tree.

Consider first the rate of cambial activity in the deciduous plants. Here we will consider trees which are deciduous at approximately the same time of the year for about the same length of time. Our best examples of quick growing trees are *Bombax Malabaricum* and *Eriodendron aufractuosum*. In these species the rings of growth are very conspicuous and may measure several inches in diameter.

Crataevæ Roxburghii is a species characterised by a slow rate of cambial activity, and the stem does not attain a diameter of six inches in twenty years. The rings of growth are here very inconspicuous though the tree is bare for four to five months every year; in this species the leaf fall takes place at a remarkably slow rate, the discoloured leafless first beginning to drop on 26th August, though the tree does not become absolutely leafless until the middle of October each year. Similarly the output of new leaf proceeds at a very slow rate, and consequently the rings of growth are inconspicuous.

A complete list of plants can be quoted to show that the significance of the rings of growth in stems of deciduous trees is in proportion to the rate of activity of the vascular cambium, providing other conditions are the same.

Similarly with the evergreen trees which put on new leaf during the same months of the year, moderately quick growing trees such as *Mangifera indica*, show definite rings of growth; whereas our slow growing species *Palaquium* and *Diospyros* (trees which sometimes do not exceed a diameter of six inches in 60 years) the rings are very poorly defined.

The importance of the rate of cambial activity is best realised, however, if we compare the rings of a moderately quick growing evergreen and a slow growing deciduous tree, say *Mangifera indica* and *Crataevæ Roxburghii*; for though the latter is bare for so very many weeks every year, its insignificant rings cannot be compared with the broad bands in the wood of the former.

The independent effect of climate is very difficult to determine since the significance of the rings of growth is in part a consequence of additional factors, viz., rate of cambial activity and foliar periodicity, which it is impossible to eliminate. The ideal conditions would be, where a hot drought of three or four months is followed by continuous rain for the remaining eight or nine months, and evergreen trees having no seasonal periodicity or a deciduous tree undergoing complete defoliation and repletion in the middle of either period of drought and rain. Trees approximating to the former class are to be found in certain *Cinnamomum* species, and of the latter class in *Terminalia Catappa*, though neither of these nor the climate in Ceylon are in exact accord with the theoretical condition desired.

Nevertheless, an evergreen tree having no fixed periodicity but continually putting forth a regular supply of leaf when subject to such a climate would provide good material for determining the part which a strongly marked climate plays in the

significance of the rings of growth. In the deciduous trees which undergo foliar repletion in the middle of the drought and rainy seasons the rings of growth would probably be more enhanced when produced in the midst of the hot dry season when transpiration was at the maximum.

Allowing that the above results may be logically expected, a number of interesting points crop up for consideration.

In the first place we have to realise that perhaps a definite histological differentiation can be effected in the secondary xylem purely in consequence of the excessive transpiration occasioned by a period of excessive drought, which may be eccentric or recur constantly from year to year.

In the second place, if the time of foliar repletion for any tree coincides with the only hot dry period of the year, as it very often does, the excessive transpiration which will most probably occur will be met by the differentiation of tracheal elements of greater width than those produced during the rest of the year when transpiration is reduced. The reduced transpiration is a consequence of the air being cooler and more moist and the leaves becoming cuticularised. Hence the enhancement of the rings of growth in consequence of the above coincidence.

This has an important bearing on the relative significance of the histological differentiations according to the time when the plants undergo foliar depletion and renewal. If, for instance, *Pterocarpus echinatus*, instead of putting out its new leaves during the cool damp month of July, it had to do this in the middle of the hot dry month of March, the ring of growth would probably be considerably enhanced. Similarly the significance of the rings of growth would be reduced if those trees which now undergoes foliar repletion in March were to do so in July. Hence we are bound to conclude that the significance of the rings of growth of trees which put on their new leaf when the air at its maximum temperature and dryness is due in part to the increased transpiration then occurring.

There are other interesting branches of this subject such as (a) the relation of leaf to flower production, and (b) the order of defoliation to direct light when trees are under open or close canopy or under partial shade, but as we are here confined to the relation of foliar periodicity to the xylem differentiation they need not be here discussed.

The most valuable facts will be obtained by studying the behaviour of selected trees from year to year and examining the tissues which have been produced during the periods of observation. The study was commenced while I was engaged as Scientific Assistant to the Director, R. B. G., Peradeniya, and I take this opportunity of expressing my gratitude to the numerous friends who have, and are still assisting me in this work.

ANNUAL REVIEW OF RUBBER MARKET FOR 1901.

KRAMRISCH & Co's. (LIVERPOOL AND LONDON) ANNUAL REVIEW OF THE RUBBER MARKET FOR THE YEAR 1901.

During 1901 the Rubber Market has not been characterized by heavy or exceptional fluctuations; it was again not a particularly satisfactory one for holders and importers of the leading grades, and although trade remained exceedingly active throughout the year, the values of all grades of Rubber at the close are less than a year ago, and Fine Para shows a further recession of 3d. per lb. and other grades in proportion. The bulk of the stocks of Mediums has gradually been exhausted, although it must be admitted that the prices realised were exceptionally low and showed an enormous loss to the importers

or holders, and even the more recent imports were disposed of at prices which not alone showed no profit, but in most instances the prices realised show a considerable loss. The imports of important Medium grades have fallen off considerably, and as the enquiry has increased for same we do not anticipate a further appreciable decline in values, and one ought certainly to advocate the encouragement of a substantial increase in the imports.

As regards the quality of Para Rubber, considerable grievance was again cause by the want of care in the proper selection of these grades, especially from the Island districts, and this has led to numerous disputes amongst contracting parties. Trade in Great Britain and with leading Continental Rubber works was fairly good and the stocks of raw material at the factories are not large, and in spite of the fact that deliveries have been exceptionally heavy, the reported consumption of Fine Para exceeds that of previous years. The American market showed the position there not to be so strong except for the first few months, but generally speaking the Rubber trade has been busy and the only important speculative stocks are held by one leading American house, whose position at the close of the year was considered very precarious visible supply now of Para and Peruvian is 4,618 tons against 4,100 tons last year. This includes America with a stock of 2,005 tons against 1,200 tons last year.

Should the demand for Para Rubber continue good, the statistical position at the end of 1901 is certainly a very healthy one. The total for the year's crop (from July 1st to December 31st) amounts to 13,680 tons, this means an increase of 2,400 tons, while against this the total increase of the visible supply gives us only about 490 tons, thus about 1,920 more tons have gone into consumption, this despite the fact that it is well known that the "invisible" supply is exceptionally small. Although grave financial difficulties were experienced by many holders of Rubber, the position of the Rubber market is fairly sound, and with constantly increasing consumption, Rubber must be considered very reasonable at present quotations.

PARA KINDS.—At the beginning of the year we had to record a brisk enquiry for Para grades, and business on a large scale resulted, but, owing to continued "bear" operations, prices quickly exhibited an important recession, and while Hard Fine Para was quoted at the beginning of January at 3s. 10½d., Soft at 3s. 9d., Negroheads, Scrapy at 2s. 9½d., Island at 2s. 1½d., Cametas at 2s. 4d., Peruvian Ball at 2s. 7½d., and Slab at 2s. 2d., prices declined rapidly during the latter portion of the first month, and sales for forward delivery at a marked decline were done on a large scale, with the result that prices for Para grades receded about 3d. per lb. by the end of the first three months. In America Fine Para was then sold as low as 3s. 6d., Scrapies 2s. 6½d., Island 1s. 11d., Ball 2s. 4d., and Slab 1s. 11d. per lb. We then began to receive the first advices from Para of probable short receipts, and some important buyers partly relying upon these reports bought large quantities, thereby causing considerable briskness; this improvement was actively maintained for a few weeks, and as high as 3s. 10d. to 3s. 11d. was paid for Fine during the middle of April. Other sorts were 2d. to 3d. per lb. dearer. Soon afterwards, however, the market again showed signs of weakness, the demand being somewhat dragging, and in July Hard Fine was quoted at 3s. 8d., Soft 3s. 6d., but a temporary reaction in August resulted in quotations again reaching 3s. 10d. to 3s. 9d. We have then had irregular declines of 2d. per lb., and in November Hard Fine was as low as 3s. 5½d., Soft 3s. 3½d., the lowest of the year. Additional cable advices from Para of probable short receipts during the end of the year and the early months of 1902 brought about some recovery on less pressure to sell, and with very large deliveries and moderate receipts we

close the year firmly with quotations of Hard Fine at 3s. 6 $\frac{1}{2}$ d. and Soft at 3s. 5 $\frac{1}{2}$ d. Negroheads continue to remain very scarce, Scrappy being quoted at 2s. 9d., Island (of which the greater portion is being to America) 2s. 1 $\frac{1}{2}$ d., Cametas 2s. 2d., Ball, 2s. 6d., and Slab 2s. 0 $\frac{1}{2}$ d. The total amount of Rubber imported from Brazil shows a further increase of 3,200 tons, and the total quantity exported from the State of Amazonas, including Peruvian via Iquitos and Manaus, is 4,000 tons against 3,100 tons. The Peruvian Fine imported has we think been better as a whole, but owing to the Rubber having arrived in most cases uncut and unselected before shipment, new rules had to be adopted in order to provide for this altered mode of shipping this rubber. The Peruvian Ball imported has not been up to the expected quality, and at the end of the year the standard of fair average quality was considered lower, although some nice clean Hard Balls when received did realise fairly good, and in some cases exceptional prices. The slab continues to be of good serviceable quality, and the consumption of it is certainly spreading. Bolivian kinds have been very fair, but the imports were not as large as last year. Mollendo again showed a marked improvement in quality, and consequently sold exceedingly well. From Venezuela via Orinoco the supply was less than last year and the quality not very attractive.

Imports of Ceara Scrap are smaller, but of these grades only the best qualities could be sold easily, others are dragging. Of Manicoba kinds we received less, but quality was good, and prices realised were satisfactory. Pernambuco and Assaree qualities have somewhat improved, but owing to the general decline of the Rubber market, the values of these classes receded considerably. There were not very important arrivals of good Mangabeira and although the stocks are considerably going down and available supplies very small, the prices realised for ordinary quality show an enormous falling off in price. The imports of Mattogrosso, in sympathy with Para, showed similar fluctuations, although transactions were only spasmodic. Central America has again been conspicuous by a further considerable decline in its export of Rubber, probably owing to the continued political unrest existing in those parts, and the only rubber reaching us comes from the Columbia districts, but the quantities were very insignificant. The Equator and Guayaquil kinds sold readily, and the prices at the end of the year are only about a 1d. lower than they were a year ago. Of course this refers to good qualities only. Inferiors and mixed kinds are much cheaper. The imports from Honduras, Mexico and Panama were likewise very small.

AFRICANS.—As expected at the close of the previous year, the increase in imports of these descriptions was not only not maintained but showed a considerable and serious falling off, and we estimate the difference of imports from Africa to be about 2,000 tons below that of last year.

With the exception of slight spurts in April and again in August (in sympathy with Fine Para), the year 1901 has been characterised by an uninterrupted decline in African Rubber, the only exception being First Sierra Leone Niggers which are actually rather dearer than a year ago, while all other descriptions show a decline varying from 1d. to as much as 6d. per lb.

From Angola we received 250 tons less, made up in shipments from Benguela of 1,250 tons, as against 1,500 tons in 1900. Loanda 730 tons, against 678 tons (besides 200 thimbles). Quality has been hardly so good. The Congo has slightly increased, but the quality has seriously declined; about 5,300 tons, against 5,000 tons in 1900. The average price shows a very considerable fall because so much was of poor quality. The supply from Sierra Leone and French Guinea has again fallen off, partly owing to the prohibition by the French authorities of the exportation of dirty, wet, and inferior Rubber from

Conakry. The quality being thus reliable has caused consumers to look on this kind with favor, and their appreciation is reflected in the price which is unusually high compared with other Rubbers, both African and Brazilian.

Quite an extraordinary decline in supply of Gold Coast, Accra, Lagos, &c., and only moderate from Cameroons, Sierra Leone, Gaboon, &c., and small of Senegal. Prices of nice Hard only about 2d. lower, but Soft common and Lagos fully 4d. decline for the year. We no longer quote Strips and Biscuit, the pressing of Lump Rubbers being practically abandoned. Liverpool imports of West African 4,200 tons, against 5,140 tons in 1900, and 5,600 tons in 1899. The Congo Free State has given increased exports to Antwerp, but other kinds of African have gone there in reduced quantities, so that the total Antwerp imports show little change.

During January, African Rubber met with a disappointing demand at rather easier prices. February and March were very dull and prices declined for most sorts, closing with lower values all round. In April, fairly good trade was done at rather better prices, closing however somewhat quieter. A moderately large business was done in May at irregular prices. Good Sierra Leone sorts were then well in demand, showing however little, if any, change in price, whilst Lump descriptions were 1d. to 1d. per lb. lower. During June and July African Rubbers met with a moderate to poor demand at general lower rates, and only a comparatively small trade was done at barely steady prices. The demand was better in August, especially for parcels of good quality which arrived from Sierra Leone. This position of the market was not maintained, and we see a constant falling off in the demand, which remained disappointing with only small business passing at generally lower rates, until the end of November, when quite a steady trade was done at generally unaltered and in some instances slightly increased prices. The demand continued to improve during December for all the better grades, and rather higher rates were paid all round.

EAST COAST OF AFRICA (ZANZIBAR, &c.)—The supplies of these descriptions have continued to gradually fall off, and to this must be ascribed the fact that at the close red hard Rubber is only 1d. per lb. lower, but White and common Ball Rubber declined about 4d. per lb. **LAMU BALL (MOMBASA)**: The arrivals were not important although the quality was fair and good clean Rubber sold fairly well prices, however, showing a decline of 2d. for the year. **NYASSALAND** sent us very good Rubber, but the consignment were small, and when they reached, the market were bought up readily at fair to full prices. **MADAGASCAR** supplies were again on the decrease, and have only been about half of what they were last year, and values were consequently well maintained.

Imports from **CEYLON** were again insignificant, but whatever small quantity reached this market it proved very attractive, as the quality and condition continued to be excellent, and many buyers were anxious to secure even the small arrivals, owing to the specially clean condition of this Rubber. We confidently expect that if larger imports could be arranged a great circle of consumers would come in and pay full prices for these grades, especially if the quality be kept up. It would be advisable to encourage the planters and others interested in this product in giving particular attention to this most valuable Rubber. High prices were realised, and 3s. 9 $\frac{1}{2}$ d. was recently paid for Fine and 2s. 4d. for the Negroheads. It is, of course, known that this Rubber, should practically be of the same kind as the one coming from the State of Amazonas, being grown from Para seed.

RANGOON and PENANG has also been in much reduced supply. Of the latter description we practically received no further shipments this year, but in spite of

this, all the old stocks held were most difficult of sale, and what was disposed of showed an enormous decline and thus Rubber that was quoted at 3s 2d, a little more than a year ago sold at about 2s. 2d. to 2s. 5d. per lb. according to quality. If good quality of these descriptions could be imported to sell at present rates, it is certainly worth encouraging as with scarceness of Good red, Mozambique Ball, the demand for these Red Penang kind would again grow gradually.

Small quantities of ASSAM were shipped, but the quality was very poor and sandy, and consequently did not meet with any requirement or interest.

BORNEO.—Of this Rubber the supplies have not been excessive, but in sympathy with the general tendency of the market prices declined. These grades are still held for higher prices, and with a continuance of the lower quotations all round we must also look for much reduced values in these grades before one will be able to effect larger sales. PONTIANAK: Supplies were about the same as those of last year and sold readily prices showing very little change at the close of the year.

Rubber from FRENCH COCHIN-CHINA and from LOWER CHINA have continued to sell well, the quality and condition of nearly all arrivals were satisfactory and the small trade done must have been profitable to the importers.

JAVA Rubber and NEW GUINEA have been very scarce, but generally speaking these qualities were not in great demand, and quotations were only nominal.

BALATA.—We had reduced arrivals of these descriptions, and all the imports of these grades have met with a good demand, although at one time Block BALATA was as low 1s. 7d. The year closes with buyers at 2s and sellers at 2s. 1d. Nearly the whole of the stock in first and second hand has been cleared off and gone into consumption, and all new arrivals are selling very readily at full prices. SHEET BALATA.—Owing to the increased consumption the prices have also gradually gone up, and the market closes with buyers at 2s. 7d., showing 4d. per lb. advance for the year.

GUTTA-PERCHA.—The year opened with a very poor demand, and the market continued weak throughout almost the whole of the year. It was only during November that, owing to larger contracts for cables being placed, extensive buying orders appeared on the market, thus increasing values of GUTTA-PERCHA, and since then a fairly large business has been done. There seems to be every prospect of a continued good market, with fair prices being paid for good and desirable qualities of Gutta-Percha.

AGRICULTURAL CHEMISTRY.

The second edition of the comprehensive work of Professor DEHERAIN on the subject of agricultural chemistry* has lately been published, and brings up-to-date most of the more important investigations connected with the study of plants, and the cultivation of the soil. In his introduction, the author states that the plant is an "instrument of reduction," because within its cells are separated the element oxygen from carbonic acid (dioxide), which is a compound of carbon and the element oxygen; and from nitric acid, which is a chemical compound of nitrogen and oxygen. The plant further takes these separated gases and unites them with the elements of water, whereby in a series of rapid stages they become converted into such substances as sugar, starch, cellulose, oil, and albuminoids. Plants are the only organic things that make use of the forces of the sun to build up from these elementary substances products alike suitable for human and animal food. The chief object of the author in his voluminous work is to show how the double work of reduction and of reconstruction, or building up, is

carried on; also how we may obtain by the help of plants, a suitable climate, and a properly cultivated soil, such a quantity of vegetable products that its sale shall be remunerative.

One of the greatest of the practical problems presented for solution by agricultural chemistry is the conservation of plant food. With an abundance of plant food, and a favouring climate, it is difficult to place a limit to the power of the earth for supporting life. Should the cultivator succeed in raising the amount of food supply beyond that which his land would naturally yield, he is serving at once his own interests and those of the public generally, because both agricultural and horticultural prosperity are better secured by the increase of produce than by rise of prices.

The author commences his work with a description of the development of plants, including the germination of seeds, and the production and assimilation of plant food. The portion on growth and maturation has been considerably enlarged in the present volume. Next follows a full description of the importance of water; its circulation in the plant; the enormous evaporation excited by the sun's rays, which the plant can only maintain by constantly drawing upon the resources of the soil; should these fail, the plant languishes and dies.

The second part of the treatise treats of the study of arable land, which is described as a reservoir from which the roots of plants have to obtain their supply of water. It is only a properly cultivated soil that can fulfil its chief function of being a store-house of moisture. Water flows away over soil hardened by drought; it does not easily penetrate into a sun-baked surface; and hence, under such conditions, it remains in the top layers of soil, it soon evaporates and is lost. On the other hand, water penetrates into a well-worked soil, is held in suspension, and remains there until wanted. It descends into the lower layers where the more deeply penetrating plant-roots feed. The plant-food of the soil only has access to the absorbent organs of the plant when presented in a proper soluble or semi-soluble form in connection with water.

The study of soil ferments has been largely extended in this edition; the author shows how the organic matter of soils becomes oxidised, how ammonia is formed, and how nitrates are reduced.

The third and fourth portions of the work deal with the subject of manuring. Considerable stress is laid upon the importance of a suitable supply within the soil of soluble available mineral plant-food, such as potash, lime, and phosphoric acid. The question of green manuring, that is ploughing-in growing plants, and the cultivation of autumn catch-crops, is recommended, because they retain the nitrates formed in the soil during the summer months. Green manuring further promotes the production of vegetable organic matter (humus) within the soil, and prevents the nitrates from being washed away by winter rains. Nitrogen in the form of nitrates is generally regarded as the best kind of nitrogenous food for plants. Plants obtain their nitric acid by absorbing the nitrates that are already present in the soil, those that are carried down to the soil from the air in rain and snow, those that are applied artificially in fertilisers, and those that are formed in the soil from the nitrogen of other substances. As is explained, all the nitrogen that is applied to the soil for fertilising purposes, especially in farmyard manure and in green-manuring, is not in the form of nitrates. It must first undergo certain chemical changes before it becomes available to plants. These changes take place through the agency of micro-organisms or ferments; and that particular process in which the nitrogen of the ammonia-gas is changed into nitric acid, which is called nitrification. One of the most active periods of the production of nitrates in the soil is during the early spring months, when the rootlets of growing plants greedily lay hold of it as it is formed.

It is not only by hindering the loss of nitrogen that catch crops are useful, but they also increase the

* *Traité de Chimie Agricole*, 2nd edition, 1902, P. P. Deherain.

amount of humus in the soil. The function performed by humus was long misunderstood, but it is now known to be the soil's storehouse of nitrogen, and although not directly available to crops, it is rendered so by nitrification. Farmyard manure introduces into the soil these nitrifying organisms in large quantities, a quality not possessed by chemical fertilisers; a point of great importance, but which is sometimes overlooked.

The author goes on to show that the largest crops are to be obtained by a proper combination of farmyard manure and artificial fertilisers.

The end of the 19th century was marked by several great discoveries in agricultural chemistry. In 1876 Messrs. Schloesing and Muntz showed that the formation of nitrates in the soil is the work of special ferments. In 1885 M. Berthelot proved that the fixing of nitrogen in the soil takes place by means of micro-organisms; and in 1886 Messrs. Hellriegel and Wilfarth proved that Leguminous plants only make use of the free nitrogen of the atmosphere when they form on their roots nodules containing bacteria or microbes.

In order to promote nitrification, warmth, moisture and air must be present in suitable quantities and proportions. One of the objects of ploughing and digging should be to bring about the best conditions for nitrification, for if they are faulty this action may be feeble, or entirely arrested.

Nitrification is promoted either by long or short fallows (bare soil) conducted during the warmer months of the year, but if a super-abundance of rainfalls upon the land before growing crops have made use of the nitrogen rendered available by tillage, serious loss may accrue by drainage. This fact leads to the conclusion that fallow lands, and those which have received frequent tillage while producing a summer inter-tilled crop, should be fully occupied by plants before the autumn or winter rains occur.

Moderate rains may serve to carry the available nitrogen downward, but it tends to rise to or near the surface as soon as capillary action is restored. But if water drains through or passes over the surface of the land rich in soluble nitrogenous compounds, great loss of plant-food may take place. Nitrification is checked by the drying effect of growing crops; this can be obviated by the application of a dressing of nitrate of soda.

The author concludes his work by stating that much of the land of France is irrigated for market garden purposes. This practice is specially suited to lands broken up into small holdings. By persevering toil the gardeners of these districts are enabled to produce their early vegetables, cut flowers, and fruits, which are distributed all over Europe.

In these irrigated soils, enriched by copious manurings, micro-organisms and ferments multiply exceedingly, and push production to its maximum, because water is the first condition of fertility.

We can confidently recommend this valuable treatise to our readers, who will be fully repaid by a careful study of its contents.—*Gardeners' Chronicle*, Oct. 4.

FUTURE OF RHEA IN INDIA.

By J. KARPELES.

(Specially translated for *Planting Opinion*
from the *Journal d' Agriculture*
Tropicale.)

I wish to attract your attention to a new industry of British India, which I think is bound to play in a few years a very important part in the French textile markets especially against flax and hemp.

This is "rhea," whose cultivation has been so far in the experimental states in British India; the other countries in which rhea has been tried as a commercial enterprise are, however, not better off than British India. All the experiments made so far in

Algeria and the Far East have, after the first period of cultivation, come to an abrupt end through the impossibility of properly decorticating the fibre, no machine having been known to give any industrial results. The employment of chemicals to remove the skin from the fibre after decortication, *i.e.*, after the wood is removed cannot be considered as solving the problem of the industrial production of a fibre ready to be put on the spindles. The acids which we are bound to use affect the fibre, taking away part of its strength and consequently of its value. The decortication of the stems when dry, which I will not discuss on the point of the value of the fibre, cannot be carried out in countries where the rainfall and consequently the production of the plant, is enormous, like India, Indo-China, and Java: where the air is so saturated with humidity during 6 months of the year that it is impossible to dry the stems. These would surely ferment and become valueless, and it is precisely during the six months in question that the production is the greatest.

The decortication of the dry stems being put aside as impracticable and the chemical process as dangerous there only remains the decortication of the green stems. I have succeeded in getting hold of a machine of French production, which gives perfect results, *i.e.*, a beautiful fibre, entirely decorticated and without the least trace of skin or wood. Established in British India, at Calcutta and Madras, for thirty years I had occupied myself so far nearly exclusively with indigo. The rivalry of the synthetic produce has had the results of lowering the price of the natural indigo to such an extent, that it does not any longer pay many planters to continue their industry. The Government have been touched by the situation of the planters and have encouraged them, both privately and openly, to go in for new products. The cultivation of fire-bearing plants and of sugarcane were put forward at once. Since 1898 I have been persuaded that indigo planters, who, only in Bengal, represent 1st-class hands to the extent of 150,000 hectares, were ready to go in for rhea, provided it was possible to put before them some good and unquestionable results. Since 1899 I have had some small experiments made at three indigo plantations: at Dalsing Serai, (Durbungah), at Bungalow (Monghe), and at Pakabaree (Mocrshedabad). The plant grew splendidly and after one year, one root becoming 15 or 20 roots, we could extend the cultivation sufficiently to order several machines and find out the production per acre and per machine, *i.e.*, the nett cost of the fibre. In the meantime the 3 plantations above mentioned were regularly giving 4 to 5 crops (cuttings) per annum and produce per acre, which had been at the start 35,000 stems per acre is today between 80 and 100,000 stems per acre. This is the number of stems which grow generally in China, and I remember reading in the "Journal of the Jamaica Agricultural Society" that the crop gave even up to 200,000 stems per acre.

In 1901, the experiments with the decortication could be commenced, the rhea being 2 years old and giving regularly stems 2 m. to 2.50 m. of length. I had imported from one maker 4 different types of machines, of which I sent one each to Bungalow and Pakabaree and two to Dalsing Serai. The former two plantations were unable to show any industrial result, but their produce was identical and absolutely pure, barring the gum, which was found in proportions varying between 25 @ 28 % as in the China grass of commerce.

The fibre obtained was found to be about 3 1/2 % of the nett weight of the stems, *i. e.*, with their leaves stripped off. At Dalsing Serai, the machine being perfect we could treat 4 crops, which gave us the following results:—

Number of stems per acre	..	80,000
Weight of stems per acre	..	5,500 kilos.
Produce of absolutely dry fibre	190	"
Produce of 2 machines per hour	9	" of dry fibre,

The above figures taken as a basis and calculating the keeping in order and the amortization of the machines, the expenses of cultivation, the wages and the incidental expenses at the same rate as with indigo, we can produce rhea at about 350 francs per ton in India or about 450 francs c. i. f. French ports. This price is evidently only approximate, the eventuality of losing one or more crops not being impossible, but is low enough to have caused a great stir in Governmental circles and among the planters. The Lieutenant Governor of Bengal, Sir John Woodburn, asked me *proprio motu* to visit him and give him explanations about rhea, also the Minister of Finance and commerce, Sir Edward Law, who has been encouraging me for the last two years. Both these gentlemen took the trouble to go to Dalsing Serai, 12 hours journey from Calcutta, to see for themselves the results obtained, and to them may be added H. H. the Maharajah of Durbungah, a member of the Viceroy's Council and the biggest landholder of Bengal. This chieftain has ordered to be made, through the administration of his possessions, an agreement with me for the immediate putting under rhea of 500 acres. Many planters are going in for rhea and in 3 years there will be about 5,000 hectares under rhea, which will have absorbed several hundred machines. This will be a great success for the French mechanical industry. The use of rhea by the French spinners can be considered so far theoretical. The few Spinning Mills employing China grass at Entraignes, Malannay Billegarde, Amilly, and Lille are not important enough to constitute an industry, but it is evident that the day it will be possible to put on the market important quantities of rhea fibre at moderate figures, these mills will become larger and the 1500 tons maximum they consume now will speedily become 15000 tons. I have sent to Lille some samples of the produce of our plantations and I was told that the fibre as it is, without any degumming, can be used by hemp and flax spinners for their big and middling counts. There is an assured and big outlet for the middling and big counts; therefore direct competition with hemp. The spinners of China grass (rhea) use the fibre undegummed and don't want the produce to be delivered degummed, preferring to regulate the degumming themselves. The flax spinners will only be able to use rhea from India for their fine counts after degumming. As the spinners are not at present organised for such a process and to justify expenses for installations of this kind the net cost of the undegummed fibre should be very low or we should deliver a degummed article. The latter presents, however, such difficulties, as regards the risk of turning out an article insufficiently or too degummed, that the danger of competition with flax, to produce fine counts, rivalry that is bound to come some day, cannot be said to be so imminent as with hemp.

CULTIVATION OF PINEAPPLES.

By W. CRADWICK, TRAVELLING INSTRUCTOR.

SOIL.—The best soil for pineapples is a rich well-drained loam, they cannot be grown profitably on any other. The colour of the soil does not matter, but there must be at least fifteen inches of good sweet top soil on the land in which the pines are to be grown.

DRAINAGE.—The top soil must be thoroughly plowed and broken up. If below this, the soil is the least bit heavy, trenches to the depth of two feet must be dug to thoroughly drain it. If the lower layers of soil are clay, trenches three feet deep must be dug. If the level is so low that water lies at or near the surface, raised beds three feet high should be made on which to plant the suckers.

This plan has been very successful near Hope Bay. Pineapples must have the best drainage possible or they will get all sorts of "disease."

PREPARATION OF SOIL.—Next to drainage in importance is the thorough forking and breaking up of the soil. There is an old Creole proverb that a pineapple sucker "planted with one chop bears in one year, with two chops in two years, and so on." The origin of it in my opinion is that when planting in new rich soft land, when a hole big enough to receive the sucker was easily made with one chop of hoe or digger, the pine sucker invariably produced a fruit within the year. When planting in old hard land where it was necessary to make two or three chops in order to make a hole big enough to receive the sucker, the sucker for want of cultivation or soil naturally soft, took two years to fruit. This explains how necessary it is to cultivate the land thoroughly.

SELECTION OF SUCKERS.—Plant nothing but good strong, fresh, stout young suckers; the proper size is from twelve to fifteen inches. Anything bigger or smaller is a mistake. Thin weedy shade-grown suckers are dear at a gift. Overgrown plants are not suckers, and should only be used to grow suckers from. In purchasing suckers, see that they are pointed just as they are torn away from the parent plant; for old long suckers can readily be trimmed down to look as short as young suckers.

PLANTING SUCKERS.—As soon as the sucker is taken off the old plant, it should be planted. If it is a fresh healthy one, it wants nothing at all done to it. If it is not a good healthy one, burn it. If you plant a poor sucker it will be a trouble all the days of its life. Never let suckers lie about in heaps; never let them get wet.

Have your land properly prepared and when the suckers are taken off, plant them as quickly as possible. The land should be so soft that the suckers can be pushed down to the proper depth without having to use anything to make a hole with. Plant the suckers in beds not wider than can be weeded from the sides without having to step on them. Pineapples must have soft soil, and if the beds are walked on every time they are weeded, they soon get hard and stop the roots growing.

CULTIVATION.—Never allow the weeds to grow. Stir the soil often, using a Dutch or push hoe, this is much better than the draw hoe which is very liable to bruise and shake the suckers when trying to dig out weeds which grow close to them.

DISTANCE.—Different varieties can be planted at different distances: the Ripleys and Bullheads eighteen inches; Smooth Cayennes two feet to two feet six inches.

REPLANTING.—Replant every year, never trust to ratoons. It is only by replanting every year that the quality of the fruit can be kept up, and the fruit made to come in at the right time. Ratoons will nearly all come in at the time of year when pines are not wanted. Pineapples are worth very little after the May rains begin, and everybody should make experiments in planting so as to find out the right time to plant to make their fruit come in at the right time, that is from Christmas up to May. The time will be different in different places.—*Jamaica Bull. Planter's Monthly.*

THE SANDALWOOD TREE.—MR. BARBER, Government Botanist, Madras, has made the interesting discovery that the roots of this tree are parasitic in character, and puts forward a plea for a closer study of the natural history of the tree. "It appears to me," he writes, "sufficient attention has not been given in past attempts at artificial reproduction, and a careful study of the liking of the Sandalwood for its different hosts is sure to be productive of useful results."—*Gardeners' Chronicle.*

**THE INDIARUBBER TREE:
ITS LATEX-BEARING DUCTS.**

BY HENRI LECOMTE.*

The latex of the caoutchouc plants is contained in lactiferous channels, whose distribution varies with the nature of the plant and perhaps also with its biological conditions. It is evident that an exact knowledge of the distribution of the *laticifers* (the latex bearing ducts) is indispensable for fixing the regulations of methodical work. Unfortunately, this study has been neglected, so that the processes of extracting the latex are altogether empirical. My present intention is not to consider all the cases that may arise but simply to call attention to certain facts and considerations, which may enlighten experimenters in their researches.

For example in the *Landolphia Heudelotii*, which furnishes the larger part of the caoutchouc exported from the Senegal, and Guinea) (in west Africa,) it is easy to recognize from a cross section of the *liane* (climbing plant), that the laticifers are especially distributed in the middle portion of the bark but are almost altogether lacking in the enter portion, as well as in the zone nearest the wood.

To reach the laticifers, there is therefore need of penetrating through the bark. The laticifers of the *Landolphia Heudelotii* are long tubes, ramified and anastomozed, whose diameter varies from 30 to 45 thousandths of a millimeter. These laticifers extend principally along the stem, but, as I have said, they are ramified, and these ramifications take a direction more or less oblique.

A transverse section *a b* of determined length and depth, may, for example, encounter a number of laticifers and produce a proportionate number of orifices from which the latex will flow. A longitudinal incision *c. d.* of the same length and depth, will meet a much smaller number.

The inspection of the figure (1) will render further explanation superfluous; but it is not difficult to
