a b—Cross section meeting six laticifers.
c d—Longitudinal section meeting only one laticifer.

demonstrate the fact at least in the case of the *Landolphia Heudelotii*. It is known—and this is the point of departure of the processes of the extraction of the caoutchouc from dry bark—that the latex coagulates spontaneously in the laticifers of the bark when it dries, so that each laticifer of dry bark contains a very thin filament of rubber. If a piece of dry bark is broken and the two fragments separated carefully, they are seen to be united by a multitude of rubber filaments, the number being equal to that of the laticifers encountered by the section (Fig. 2.)

Let this section be made perpendicularly to the length of the stem, or parallel to this length; the filaments are still found in large number if the section is crosswise, but in small number only if it is longitudinal. Fig. 3 drawn

FIG. 2.

Two pieces of bark broken apart crosswise, but still connected by a large number of caoutchouc filaments.

FIG. 3.

Illustration exhibiting the caoutchouc filaments connecting two strips of bark.

Between *a* and *b*, the filaments proceeding from the transversal insculations.

Between *a b* on one side and *c* on the other, the filaments correspond to the laticifers encountered by a cross section.

which causes the longitudinal cracks, so characteristic, for example of the surface of the bark of an oak tree. If an annular cross band of bark is removed from the trunk of a tree, and the attempt afterwards made to replace it at the spot from which it was taken, the two extremities will not meet.

It is precisely this tension which causes the flow of the latex, which the capillarity would keep, in the absence of this intervention, in the interior of the laticiferous ducts. Inmaking a cross section, the tension of the tissues above and below this section is not modified. The result is that the latex will flow as freely as possible. A longitudinal section, somewhat extended, would, on the contrary, produce different

from nature, exhibits this clearly. A piece of bark of rectangular form was separated in to parts by a perpendicular section along the length of the stem; the two portions were still connected with numerous filaments of rubber. If one of these fragments was afterwards broken in two parts, by a section parallel with the axis of the stem, and the two parts *a* and *b* separated, as shown in Fig. 3, they were seen to be connected by a small number only of thin threads of rubber, cause such a section meets a much less number of laticifers than a cross section of the same extent.

We may, therefore, consider it demonstrated that two equal incisions made in the bark will encounter very different numbers of the laticiferous ducts, according as the section is longitudinal few laticifers or transverse many laticifers; it is not difficult to conclude that the cross section will cause a much greater quantity of the latex to flow than the longitudinal section. This is very easily shown on living climbing plants belonging to the genus *Landolphia*.

I have also verified the fact on a young *Castilleja elastica*, which was placed at my disposal by Messrs. de Vilmorin, Dr. Morris, in his Cantor lectures, published in the *Journal of the Society of Arts* London has stated that in the trees of the genus *Hevea*, cultivated in the Henarat goda garden in Ceylon other things being equal the oblique incisions, (45°) produced about twice as much as the vertical incisions.

The transverse incisions have another advantage with reference to the gathering of the latex. In consequence of the constant growth of the elastic cylinder surrounded by the bark the latter, not following this growth, is stretched more and more, like a too narrow garment, around too voluminous a body. It is this tension of the bark

*Translated from the *Journal d'Agriculture Tropicale* (Paris, April 30, 1902), for THE INDIA RUBBER WORLD. The suggestions contained in this article were presented in a popular lecture on "Caoutchouc and the Plants which Furnish It" delivered by this botanist at Paris, on March 4, under the auspices of the French Association for the Advancement of the Sciences.

results, for the two lips of the wound would tend to separate, and the tension would become feeble.*

As is seen, several causes contribute to render more efficacious the transverse incisions of the bark, with reference to the flow of the latex. But are these sections to be exclusively recommended? That is not my opinion: for the cultivator ought not merely to have the present harvest in view, but the possibility of future harvests. From this viewpoint, the transverse incisions may be disastrous, and the more so as they are the more extended.

Every wound made in a bark produces a scar more or less rapidly by the formation of new tissues, and from this fact the laticifers, at first continuous, are separated into portions, the shorter as the incisions are the nearer. It necessarily results that the future incisions meet only fragments of laticifers yielding only a small quantity of latex.

In my opinion, and for the reasons mentioned above it would be suitable, if transverse or oblique incisions are to be made in a shrub or tree, to first make a number of incisions at the same height—say 3 meters from the ground—then to commence afterward a little lower, and so on until the last incisions occur near the ground. Then on leaving the tree at repose for a sufficiently long period—at least a year—new tissues will be formed in the interior of the bark and in these new tissues prolongations of the original laticifers will penetrate. After this period employed by the tree in producing new tissues, containing laticiferous ducts, incisions can be made again, identical and in the same order.

In no case should completely annular incisions be made. This will prevent the circulation of the sap and compromise the life of the plant. Too wide incisions distance between the edges of the

*It is not correct to say as Bouysson, has in the *Revue Generale des Sciences* that the latex is a kind of ascending sap. I do not think that any proof whatever has been yet presented of the circulation of the latex in the ducts. The fact that the latex flows unequally at the lips of an incision is a direct consequence of the difference of tension of the tissues on the different sides of the incision and the flowing may naturally be greater at the upper lip of the section than at the lower. This I have verified with the *Landolphia florida* in the hothouses of the Museum. The fact that the incisions made near the ground (*Hevea* produce more latex than the same at a height of 2 or 3 meters scarcely he explained except by a difference of tension of the tissues at different heights;

incisions should also be avoided; for the healing of the wound is the longer and more difficult in proportion as the edges are further separated from each other.

It will not be difficult to fix upon the plan of a certain number of methodical experiments and observations which persons living in the tropical regions, and having at disposal rubber trees or plants, might undertake. The results of such an inquiry would be important with reference to the future of the plantations of caoutchouc which of late are coming into existence so generally in all the tropical regions of the globe—*India Rubber World*.

PLAIN TALK TO SMALL OWNERS IN WEST INDIAN ISLANDS.*

(By His Honour K. H. Watkins, Commissioner of Montserrat.)

(Concluded from page 226.)

TROPICAL PLANTS AND INDUSTRIES.

There are many small industries suitable for the tropics, but I will touch briefly on three—cacao, ginger, and bee-keeping.

CACAO.—It is true that in Montserrat there are no large areas suitable for cacao, but in every district suitable, small patches are found on which even a few trees could be grown with profit. Mr. Whitfield Smith, in an interesting report on cacao growing in Grenada, has shown what can be done on a small estate under seemingly disadvantageous conditions. From this small estate an average return of 7 hags of cacao to the acre was obtained. With cacao selling at only £3 per cwt., this would mean a return of over £30 per acre. For cacao select a sheltered spot, and plant even if he had a dozen or more trees. Bananas and ground provisions can be grown between the trees until they come to perfection. Look after your trees well as if they were pet children, and you are, in a few years, almost certain to make a profit. Choose your pods and seeds carefully. There are many varieties: the short smooth-skinned pods or Calabacillo cacao; the Forastero or Trinidad cacao with big heavy, straight pods; and the Criollo with long, curved pods, constricted at the upper end, tapering at the lower, with a deeply wrinkled skin. The last named should be chosen, for the Spanish or Calabacillo variety does not contain as many seeds in the pod, and they are smaller and flatter and slightly bitter. The consequence is that the crop is smaller and inferior.

GINGER.—The Consular reports of Central America have of late years been calling attention to the opportunities afforded, for making fair profits out of the cultivation of ginger. An excellent article on the subject appeared in a recent number of *Chambers' Journal*. According to this article the soil for this crop should be of a rich vegetable composition, loose and moist, yet well drained. Sandy or heavy soils should be avoided. It is advisable to select what are known as the more temperate, that is, hill regions of the tropics where the rainfall is more or less abundant. The soil should be loosened by the hoe when the ground has been furrowed. The soil is banked up in ridges small holes are made 3 inches deep and one foot apart. Then healthy roots, or rhizomes, are selected and carefully divided into short lengths, each fragment having at least one shoot attached. One of these pieces is placed in each hole and covered up with fine earth containing as much vegetable matter or manure as possible. Planting generally takes place about April or May, and the land is regularly weeded.

Four months after planting the plants will commence to bloom. Towards the end of the year both the flower-bearing and the leaf-bearing stems begin to

* Imperial Department of Agriculture for the West Indies.

FIG. 4.

This view not presented with M Lecomte's paper illustrates a prevalent method of cutting the rubber tree (*castilloa elastica*) in Mexico.

fade and then wither. The rhizomes, or roots, should then be harvested like potatoes, but care should be taken not to injure the 'races' or 'hands.' When the 'races' have been freed from the small fibrous roots, they are sent to the market either as green or cured ginger. The cured article may be either 'coated' or 'uncoated' ginger. The former, also known as 'black' ginger, consists of pieces of rhizomes, or roots, about four inches long which have been plunged into boiling water to kill them, and afterwards thoroughly dried. The drying is usually effected by spreading out and exposing the roots to the sun. During the process the ginger must be occasionally turned, while it is advisable to take it in every evening just as the sun goes down on account of its tendency to mildew. The 'uncoated' or 'white' ginger roots are well washed and *scraped* or *peeled*, and then put up to dry from 5 to 10 days in the sun, being sometimes bleached in a weak solution of chloride of lime. Provided they are kept from the sun, the roots may, if necessary, be kept for two or three days after digging before being scraped or peeled; but it is preferable to scrape or peel without delay. In some places the ginger, after drying is put into baskets and undergoes a 'bumping' operation for 2 or 3 hours daily for several days, which is believed to facilitate its 'keeping' properties but this process is not usual. The entire operation of curing could be done by women and children. Ginger, depending on the quality, fetches from £2 to £4 per cwt. .

Experiments at the Grove have recently shown that a patch of ginger yielded at the rate of 14,000 lb. of green ginger which shrunk, when dry, to 5,000 lb. per acre. The value of this when *well cured* would probably be about £40.

BEE-KEEPING.—Many of you may have heard the interesting lectures given by the Bee-Expert, recently employed by the Imperial Department of Agriculture who visited the island early last year. By that visit bee-keeping received a stimulus, and several persons have engaged in what may be made a most fascinating and profitable study and occupation. A few remarks based on the experience of those at present engaged may be of value and interest. First, as to the cost of starting in bee-keeping. It is as well to commence with only two hives so that your attention may be concentrated upon them. The initial cost for the two hives would probably be:

(1) Two hives, with one super (locally made)	s.	d
(2) Six additional supers —	14	0
(3) Two Italian Queens —	6	0
(4) Two swarms — —	12	6
(5) 250 Sections — —	9	0
	5	0
	<hr/>	
	£2	6 6

From these two hives the following annual results could reasonably be expected:

Honey in sections.....256
or Extracted honey...—160 bottles.

The present price (and I must give the warning that, as most of the neighbouring islands are gradually engaging in the industry, the prices will fall there) is from 6d. to 9d. a section, and from 6d. to 1s. for a bottle of extracted honey. This is a very fair return within twelve months with an original outlay of £2. 6. 6. After the first year there are fewer expenses, and consequently greater profits.

Montserrat honey has received high praise in the other islands. For fuller information about this subject, see the valuable, well illustrated pamphlet issued by the Imperial Department of Agriculture, called *Bee-keeping in the West Indies*. It can be obtained from the Local Agents of the Department price 4d.

REGULATION OF THE QUALITY OF EXPORTED FRUIT.

At the West Indian Agricultural Conference held last January, the Hon. S. Olivier, Colonial Secretary of Jamaica, read a paper on 'Regulating the

quality of Exported Fruit.' According to the official report of the proceedings, he pointed out how owing to the regrettable action of persons shipping immature or badly packed fruit there was a very real danger threatening the fruit trade of these Colonies. If such a course were pursued without check West Indian fruit would earn a bad name, and fail to command the confidence of the market. He stated that it was impossible to forbid absolutely the importation of any kind of fruit, however bad, or to give a Government guarantee after inspection to all fruit shipped.

He proposed a general scheme, the main features of which were:—

- (1.) The establishment of a complete register of all growers and packers, with a nominal licence for packing house.
- (2.) The marking of all packages with the name and address of the packer and his packing houses.
- (3.) The establishment of standard grades for size and quality of fruit throughout the West Indies.
- (4.) The inspection of the packing houses and packages, at any point before shipment, by proper inspectors.
- (5.) The presence of a responsible agent in the selling market.
- (6.) It was suggested that, to maintain a high standard of fruit exports, inspectors should have power to brand packages found to be improperly described.

You will thus understand the importance of placing a good, and at the same time a well graded quality of fruit or vegetables on the market. Two or three points are to be observed. Taking onion growing, for example, you have to ensure;—

- (1.) That a good quality is grown.
- (2.) That only the good onions are exported, and in boxes containing equal sizes.
- (3.) That onions of different varieties are kept separate.
- (4.) That each year the same kind of onions are sent under the same name.
- (5.) That you send to your market the onion that people want, not what you think they want, or should want. This persistent disregard of what the buyers require and attempts to force upon them articles which we suppose they ought to use, have done more than anything else to injure British commerce. People will often pay fancy prices for what they like, but absolutely refuse to look at what they do not want.
- (6.) That you always keep a good name in business transactions. A good name is a considerable asset in business, and you must resolutely set your face against any one attempting to injure the good name of any West Indian industry.

EXPERIMENT STATIONS.—Before concluding I beg to advise you to pay frequent visits to the Experiment Stations and Plots which have been established in this island by the Imperial Department of Agriculture. Here you will not fail to learn valuable lessons and gain information of the highest interest. I often walk through them myself and never leave without having gained both pleasure and profit.

CONCLUDING REMARKS.—Such is a brief sketch of of what has occurred to me with regard to what small owners might do to help themselves. Even if the sugar market were most favourable and the stern hand of compulsion were not pushing us onwards to seek other means of livelihood, profit and pleasure might be derived from the pursuit of these minor industries. In the times before us, that must in any case be fraught with anxiety, we need to induce every one to act vigorously, and to lead them to work industriously and intelligently. No work is worth doing badly; and he who puts his best effort into every task that comes to him will surely outstrip him who lazily awaits his opportunities.

ON SOME NEW SPECIES OF EUCALYPTUS.

By R. T. BAKER, F. L. S., CURATOR, TECHNOLOGICAL
MUSEUM, SYDNEY.

[From the Proceedings of the Linnean Society of New
South Wales, Part 4.]

(Concluded from page 229.)

EUCALYPTUS WOOLLSIANA, sp. nov.

"MALLEE BOX."

(Plate xliii.)

A large tree up to 80 feet high, and more than 3 feet in diameter. Bark persistent half-way or more than half-way up the trunk; smooth, chiefly of a rich brown, colour.

Sucker-leaves lanceolate, alternate, 2-3 inches long, $\frac{1}{2}$ to $\frac{3}{4}$ inch broad. Mature leaves under 6 inches long, on a petiole less than $\frac{1}{2}$ inch; narrow-lanceolate, tapering to a fine recurved point, mostly of a thin texture, of a light yellowish-green, sometimes slightly shining; venation obscured, impressed on the upper surface; lateral veins few, intramarginal vein removed from the edge.

Peduncles axillary, from 2-12 lines long. Flowers few. Calyx about 1 line in diameter, tapering into a short stalk. Operculum hemispherical, acuminate, and often shorter and more obtuse than shown in the plate. Ovary flat-topped. Stamens all fertile; anthers parallel; connective large and long, attached at base to the filaments.

Fruits small, 1 line in diameter, hemispherical to slightly pear-shaped; rim thin, slightly contracted, valves not exerted.

Hab.—Girilambone, Cobar and Trangie (W. Bauerlen); Nyngan and Murga (R. H. Cambage).

This tree is a half-barked "Box," and allied in bark and timber to *E. populifolia*, *E. albens* and other cognate box-trees.

Of all the box trees described this species has probably the narrowest leaves. The fruits are small, and some what approach in shape those of the Green Mallee, *E. viridis*, Baker; but the bark, timber, and chemical constituents of the kino and oil differentiate it from that species.

The leaves have a shining surface occasionally, as pertains to *E. populifolia*, F.v.M., or *E. Behriana*, F.v.M. It differs from *E. microtheca* in the valves of the fruit not being exerted, in the colour of the wood, and in the bark and chemical constituents.

From *E. hemiphloia* it differs in the nature of its timber, oil, buds, and leaves; from *E. pendula*, A. Cunn., in the venation and shape of the leaves, the shape of the fruits and constituents of the oil, and particularly in its timber, and it has a more erect habit than this species. *E. populifolia* has much wider leaves, but the bark of the species is very similar, but is not associated in any other respect with this species.

Mr. W. Bauerlen states "that it is usually associated with *E. populifolia*, the Green Mallee (*E. Evridis*, Baker), and the Grey Mallee (*E. Morrisii*, Baker), on which account it is called "Mallee Box." I have never seen it in mallee form, and as a result of my inquiries it appears that it does not grow in that form."

Of described species it is most closely allied to *E. hemiphloia* and other "Boxes" in oil, kino, and botanical characters.

It differs from *E. conica*, Deane & Maiden, in height, bark, timber, oil and fruits.

Although the two species are not easily separated on herbarium material, they are never confounded in the field.

TIMBER.—Hard, close-grained, interlocked, heavy, durable timber, of a brownish colour. Useful for bridge-decking, posts, railway sleepers, and general building purposes. It is in great request at the Cobar mines for shoring the roofs.

KINO.—Turbid in cold aqueous solution, but the turbidity is removed on boiling. The constituent present besides tannin is "endesmin" (H. G. Smith). The kino is plentiful even on trees not in any way injured (W. Bauerlen).

OIL.—The yield of oil from a large number of distillations was 495 per cent. The oil contains but a small quantity of eucalyptol, less than 5 per cent., and consequently is not a commercial oil. It contains the aromatic aldehyde previously known as cuminaldehyde, and which constituent appears to be characteristic of true "Boxes." It has now been described and named (aromadendral).

The specific gravity of the crude oil at 15° C. is .889. The specific rotation of the crude oil is $[\alpha]_D -13.7^\circ$.

The laevo-rotation of this oil is due to the presence of the aromatic aldehyde (aromadendra).

Phellandrene is not present in this oil (H. G. Smith)

E. UMBRA, sp. nov.

"STRINGYBARK" "BASTARD WHITE MAHOGANY."

(Plate xlii.)

A tall tree, attaining sometimes a height of 100 feet, with a dark-coloured stringy bark.

Sucker-leaves opposite, sessile, cordate, ovate, acuminate, thin, pale-coloured on underside; venation more pronounced on the underside; upper surface shining; over 3 inches broad and under 6 inches long. Mature leaves lanceolate, falcate, large, up to 9 inches long and 1 $\frac{1}{2}$ inches broad, pale-cured on both sides, coriaceous; venation very distinct; lateral veins distant, spreading, oblique; marginal vein removed from the edge.

Flowers in short axillary peduncles, 6-9 in the umbel. Calyx 1 line long, on a pedicel about 2 lines long. Operculum hemispherical, shortly acuminate. Ovary flat-topped. Anthers kidney-shaped.

Fruits in the early stage pilular and under 3 lines in diameter, and the rim thin and valves sunken, but in the mature stage inclined to be pear-shaped with a diameter of 5 lines, and a very thick red rim.

Hab.—Wardell, Dundoon, and Tumbulgum (W. Bauerlen); Peat's Ferry, Military Road (R. T. Baker); Tinonee (J. H. Maiden); Gosford (J. Martin); Cowan Creek and Milton (R. H. Cambage); Eastwood (R. T. Baker).

The early fruits of this species have a remarkable resemblance to those of *E. acmenoides*, Schau; in fact, so much so, that in herbarium material the two have very probably on this character been confounded in the past. The two species differ however, considerably in the shape, texture, colour and venation of the leaves, as well as in the mature fruits, which have a broad rim.

E. acmenoides, Schau; has thin leaves with a pale undersurface, the leaves undoubtedly resembling those of an *Acmena* (*Eugenia*, as now understood). But those of *E. umbra* are of a uniform colour on both sides, longer and broader, and with a very marked venation much like that of *E. patenteris*, Baker.

The sucker leaves are quite distinct from those of *E. acmenoides*, which also has a lighter-coloured bark, but a superior timber.

E. acmenoides is well figured by Mueller in his "Eucalyptographia," and this species can be from the above description easily distinguished from it, so that it is not considered necessary to give a drawing here.

In botanical sequence it should be placed it next to *E. acmenoides*, from which species, however it also differs in the chemical constituents of its oil, as well as in the nature of its timber and bark.

The broad sucker-leaves differentiate it from any described species of Stringybark, to which division of the Eucalypts it undoubtedly belongs; and, as stated above, this is one of the characters which separate it from *E. acmenoides*, Schau,

Mr. W. Bauerlen gives the following description of this tree as observed by him in the northern scrubs:— "Height 40-80 feet; diam. 2-4 feet. Bark stringy, used for bark. Timber usually pale coloured, much like that of *E. acmenoides*, which tree it resembles also in the bark and general appearance, but is easily distinguished from it by its broader and thicker leaves, with a more bluish colour; especially by the very broad young leaves, somewhat yellowish in colour and conspicuously veined, while those of *E. acmenoides*, are much smaller, narrower, thinner, and of a deeper green colour; in fact, much resembling those of *E. microcorys*, with which species both are associated, yet only *E. acmenoides*, penetrates with *E. microcorys*, into the rich scrub, while this species is only found in the poorer forest country. The two species being otherwise much alike in general appearance, they are readily distinguished by the timber-getters, who invariably prefer and select *E. acmenoides* for splitting into posts and rails, etc., for which purpose *E. acmenoides* bears an excellent name, whilst this species is somewhat inferior, and does not split quite so well."

TIMBER.—A dirty pale coloured timber, darker than White Mahogany, *E. acmenoides*, Schau. It is subject to the attacks of a borer, which, of course, deteriorates its quality as a marketable timber. It is hard and close-grained, but does not season well, and is altogether a much inferior timber to White Mahogany, *E. acmenoides*—a fact well known to the timber-getters.

OIL.—The yield of oil from this species is .155 per cent. No phellandrene was found, but much dextro-pinene was present. It contains but a minute quantity of eucalyptol.

The characteristic constituent of the oil from this species is an acetic acid ester. The specific gravity of the crude oil at 15° C. was .8963.

The specific rotation of the crude oil was [a] D +41.5.

The saponification figure for the ester was 35.8.

Another consignment of the leaves of this species were received a month later, and gave practically identical results, showing again the constancy of the constituents in the oils of the same species.

The yield of oil was .169 per cent.; specific gravity crude oil—.8961.

Specific rotation crude oil was [a] D +43.8, and the saponification figure for the ester was 35.3 (H. G. Smith, F.C.S.).

E. NIGRA, sp. nov.

"BLACK STRINGYBARK."

(Plate xlvii, fig. 3.)

A tall tree with a black stringybark.

Leaves lanceolate, scarcely falcate, occasionally oblique, mostly under 4 inches long and under 1 inch wide, of a dull green colour; venation only faintly marked on the upper surface, but very distinct on the lower; lateral veins oblique, distant; intramarginal vein removed from the edge.

Peduncles axillary, short, under 4 lines, bearing a cluster of from 8-12 small flowers. Calyx hemispherical under 2 lines in diameter, on a short pedicel. Operculum hemispherical, acuminate about 1½ lines long when mature. Ovary flat-topped. Anthers very small parallel, filaments very slender.

Fruits about 4 lines in diameter, hemispherical, to pillular, rim variable, thin, or truncate and even domed occasionally, valves slightly exerted.

Hab.—Richmond River District (W. Bauerlen); Cook's River Sydney (H. G. Smith).

From *E. Wilkinsoniana*, Baker, and *E. macrorhyncha*, F.v.M., it differs in fruits, timber and chemical constituents of the oil. From the stringybark, *E. umbra*, Baker, of this paper it differs in the shape of the sucker leaves and chemical constituents of the oil, although the immature fruits of these species are somewhat similar.

E. eugenioides, Sieb., and *E. capitellata*, Sm., approach each other very closely in morphological characters, and there often seems to be a gradation between the two, but, nevertheless, the two species are quite distinct; and so in this, although there also appears some similarity in the fruits of this species and *E. eugenioides*, yet the two differ in too many characters to be the same species.

The sucker-leaves are not unlike those of *E. capitellata*, whilst the buds are similar to those of *E. eugenioides*. The fruits approach somewhat in shape those of the latter species, with which it has probably been confounded in the past when determined on dried specimens.

If it were not for the distinctive character of the timber and oil I should certainly have made it a variety of *E. eugenioides*, but the former product is of too poor a character to be associated with so excellent a timber as that yielded by White Stringybark, *E. eugenioides*. The oil also differentiates it entirely from that species.

On the sum of the above differences it was decided to give the tree specific rank, and botanically it is placed next to *E. dextropinea*, Baker, from which it differs in the shape of the fruits, barks, leaves and chemical constituents. From *E. levapinea*, Baker, it differs in the shape of the fruits, quality of timber and constituents of the oil.

TIMBER.—of a dark brown colour (hence the specific name), much affected with borers and not valued for durability by timber-getters and others interested in the trade.

OIL.—Yield very small, only 3½ oz. from 534 lb. of leaves in fact too small to make a fractional distillation, It has thus the smallest yield of the stringybark, next to *E. capitellata* (H. G. Smith).

EUCALYPTUS LACTEA, sp. nov.

"SPOTTED GUM."

(Plate xlvii, fig. 5.)

A fair-sized tree with a dirty, flaky bark, which occasionally is smooth.

Sucker leaves ovate; leaves of mature trees lanceolate, up to 6 inches long and varying in breadth up to 9 lines, straight or falcate, not shining, of the same shade of green on both sides; petiole under 1 inch. Venation fairly well marked, veins oblique, spreading, the distinct intramarginal vein removed from the edge. Oil dots numerous.

Peduncles axillary, with few flowers (5 to 7) in the head, occasionally only 3. Calyx hemispherical. Operculum hemispherical, shortly acuminate. Ovary flat-topped. Stamens all fertile; anthers parallel, opening by longitudinal slits.

Fruits hemispherical to oblong; rim with valves domed and almost touching, thus leaving only a slight aperture to the ovary; or the rim thin and the valves exerted and widely distended.

Hab.—Mount Vincent, Ilford (R. T. Baker); Oberon Road, O'Connell (R. T. Baker, R. H. Cambage); Southern Road, Wingello (R. T. Baker, H. G. Smith); along the main Western Road, Blackheath, and Mt. Victoria (R. T. Baker).

In the field this tree might be confounded with *E. viminalis* or *E. hæmastoma* as both these Eucalyptus have a similar although variable bark.

The bark of this species, however, never has the horizontal "scribble" insect markings almost invariably occurring on *E. viminalis*, Labill., and *E. hæmastoma*. It has similarly shaped leaves in all its stages of growth, whilst the sucker-leaves of *E. viminalis*, are narrow, cordate-lanceolate, sessile.

The fruits differ from those of *E. viminalis* in shape, rim, and direction of valves. The trees too are not found near water, as pertain almost invariably with *E. viminalis*, but on dry, stony ridges. It differs also from that species in the constituents of its oil.

It resembles *E. maculosa*, Baker, in the shape of the fruits, but differs from it in the timber, bark and oil constituents. It differs from *E. hæmastoma*, Sm., in timber, fruits, leaves and chemical consti-

tnents of the oil; and from *E. aggregata*, Deane & Maiden, in bark, fruit oil and habitat.

Its specific characters differentiate it from any of the other smooth-barked species. Of the rough-barked Eucalypts its fruits are often not unlike those of *E. fastigata*, Deane & Maiden, and *E. Smithii*, Baker.

The specific name refers to the copious exudation of a milky substance from the stem when the tree is cut at certain seasons of the year.

TIMBER.—A very pale-coloured, whitish timber, fissile, only used for fuel, much softer than that of *E. hemstoma*.

OIL.—The yield of oil was '541. It is not a commercial oil at present, as it contains but a very small quantity of eucalyptol. No phellandrene is present.

The specific gravity of the crude oil was '8826 at 15° C.; of the rectified oil '8788.

The crude oil has no rotation, while the rectified oil had a rotation of 1° in a 100 mm. tube.

A sample of oil from this species, obtained from Charley's Forest Braidwood, was almost identical with that from Ilford in constituents and physical characters (H. G. Smith).

EUCALYPTUS POLYBRACTEA, sp. nov.

"BLUE MALLEE."

(Plate xlv., figs. 7-8)

A glaucous Mallee, with quadrangular branchlets. Leaves lanceolate (those on the early shoots lanceolate to oblanceolate), erect, rarely falcate, not oblique; narrow, under 6 lines broad, mostly 3 inches long, acuminate, often with a recurved point; midrib raised on the underside, giving a leaf strong resemblance to that of an *Olea* not shining; intramarginal vein removed from the edge, lateral veins oblique, spreading, finely marked, only occasionally distinctly pronounced; petiole about 3 lines long. Oil glands very numerous.

Peduncles axillary, short 2-3 lines long, angled, with from 8-12 flowers. Buds in the early stage of development angular, surrounded by numerous acuminate, glabrous, ribbed, whitish bracts, short, 1 to 1½ lines long, glaucous. Calyx conical, tapering into an exceedingly short pedicel. Operculum obtuse, or only very slightly acuminate, hemispherical. Ovary flat-topped. Stamens all fertile; anthers parallel, opening by longitudinal slits.

Fruits hemispherical to pear shaped, 2 lines in diameter, glaucous; rim thin, slightly contracted, valves deeply sutured, not exserted.

Hab.—West Wyalong (R. H. Cambage, L. S.).

This Eucalypt is one of the Mallees occurring between the Lachlan and Murrumbidgee Rivers, where it is known as "Blue Mallee," to distinguish it from its congeners.

The dried herbarium material is not easily separated from that of *E. viridis*, Baker, *E. Woolfsiana*, Baker, and *E. conica*, Deane & Maiden, as the fruits of all these species are almost, if not identical; but this Eucalypt differs principally from them in never attaining tree-form, and in respect of its floral bracts.

Other points of difference are the angular buds its glaucous character, shape of the leaves and quadrangular branchlet; whilst the most marked distinctive character of all its oil, the yield and chemistry of which place it amongst the most valuable of our trees famous for the medicinal qualities of their oils.

Amongst other Mallees, it differs (1) from *E. gracilis*, F. v. M., and *E. dumosa*, A. Cunn., in the shape of the fruits and leaves, and the constituents of the oil; (2) from *E. oleosa* in the absence of the long, well-exserted valves, leaves and chemical constituents.

In botanical sequence it is placed next to *E. viridis*, as the fruits and leaves mostly resemble that species.

E. Woolfsiana and *E. conica* have much broader leaves, and are classified amongst the "Box" group of Eucalypts.

OIL.—The oil obtained from this species is one of the best for Eucalyptus oil distillation growing in this colony. The yield of oil, obtained from material sent from Wyalong in the beginning of December, was 1'35 per cent. The crude oil was only slightly coloured, being of a lemon tint. The odour reminded one of eucalyptol, and volatile aldehydes are but present in minute quantities. Free acid and ester are also comparatively small. 91 per cent. of the crude oil was obtained boiling below 183° C., and this contained 57 per cent. eucalyptol; no phellandrene was present, but pinene was detected. The crude oil was slightly lævo-rotatory, due to the presence of aromadendral (the previously supposed, cuminaldehyde). The specific gravity of the crude oil at 15° C. was '9143, and of the rectified oil '9109, this comparatively low specific gravity being due to the presence of such a small amount of constituents having a high boiling point. The specific rotation of the crude oil was [α] D-2-13° (H. G. Smith).

HORTICULTURE AT NUWARA ELIYA.

A VISIT TO MR. JOHN COTTON'S ORCHARD.

Probably barely one in five hundred visitors to Nuwara Eliya are aware that at the back of Lake View, the residence of Mr. John Cotton, may be seen the finest orchard in the island for wealth of imported fruit trees. It was in splendid condition the other afternoon, when the writer inspected it with his proprietor.

"Never," said Mr. Cotton, "has my orchard so come up to the expectations I have all along had of it, as it has done this year."

Mr. Cotton's first attempt at growing English and Australian fruit trees was merely an experiment, but it has developed far beyond that stage now. Mr. Cotton began his cultivation with plums, and the parent tree of this species brought to Mr. Cotton from Australia by Mr. A. J. Kellow, of Albion estate, Nuwara Eliya, may now be seen in full growth and loaded with large and delicious-looking fruit, in clusters, the size of the well-matured fruit being about equal to that of the native lime. These plums are of a dark red colour when ripe.

THE MAJORITY OF THE TREES IN THE ORCHARD

ARE PLUMS,

some of them being from three to four years old, whilst a few are seven years old, and they are almost all of them in bearing and well grown. The Red Heart plum plants from Mr. Cotton's orchard were in great demand last year, and this year provision has been made to meet requirements by a large supply not only of the Red Heart plum plants but also of other varieties. The Burbank Plum, of which Mr. Cotton had a large crop last year, does not seem to have quite come up to its past reputation this year. The plants nevertheless are looking quite healthy, and Mr. Cotton thinks that in all probability the crop will come on later, as the plants were pruned and handled later than were the Red Heart. Mr. Cotton places his great hope in a yellow Japanese plum, which is now thriving very well, and a variety called the Kelsey Plum is also now in full bearing. Another blood red plum, (of a very large size, the largest plum in the orchard, as Mr. Cotton says) is just about to flower. Of other varieties of plum now being experimented with are the well-known Golden Drop, the Golden Heart, General Hand, General Sago, the Diamond and the Orleans. A few of these varieties are now being tried in the Nuwara Eliya Park. Mr. Cotton has in his nursery many one year old plants of the Red Heart and blood-red variety, both of which are specially recommended for easy cultivation and quick bearing.

APPLES, PEARS, CHERRIES AND PEACHES.

Mr. Cotton may well be proud of the brave show he has made this year with his apples. As with his other fruit experiments, Mr. Cotton's experiment in apple-growing was only a small one at the start. The first plant he put down was of the variety known as the Kentish Fillbasket, which was also brought to him from Australia by Mr. Kellow. The tree is now about 5 years old, with a growth of 6 feet, and it carries one single apple, ten inches in circumference, when measured in the presence of the writer. The fruit will in all probability be ripe in a fortnight more, and in all probability will be bigger than. Mr. Cotton says that this apple-tree took a long time to adapt itself to the soil, but now that it has done so it is rapidly growing up. Experiments are being made with other varieties of apples, viz., the Russet, the Emperor Alexander, the Beauty of Stoke and the Boston, and Mr. Cotton hopes soon to have plants of seven varieties for disposal to his *lentele*.

The fruiting season of the pear trees is not yet upon us, but the trees in the orchard are already covered with a profusion of white blossom. The pear, found everywhere almost in Nuwara Eliya, is what is known as the "cooking pear"; but Mr. Cotton has succeeded in growing and eating pear (Le Comte pear) which has at last borne a fruit, after a seven-years period of coaxing and attention.

THE AUSTRALIAN PEACH.

Mr. Cotton states that his experience with the Australian peach is that it grows very luxuriantly in Nuwara Eliya but bears unsatisfactorily. He seems to think that the peach bears better outside a radius of seven miles from Nuwara Eliya. His trees are getting on as well as he could make them. Of cherries Mr. Cotton has many varieties, chief among which are the Verdus (a black cherry), the Waterloo, the Florence, and the Purple Jean. Several of these plants were imported lately and are already looking very vigorous. There are many varieties of young orange plants in the orchard, which are doing very well. Of the most successful varieties are the Washington, the St. Michael's the Rio, the Siletta, the Emperor Mandarin, are now being tried in the Nuwara Eliya Park, and Mr. Cotton expects to have some plants ready for sale by the beginning of next year. There are also about three sorts of lemons doing well in the orchard. One seven-year-old tree was practically loaded with as many as forty large size fruits. This plant like several others was also imported by Mr. Kellow.

THE CAPE GOOSEBERRY.

Another experiment the grower is very proud of is his Cape Gooseberry, which is in full bearing now. He has several other varieties of gooseberries (viz., the purple, the green, the red, the yellow and the white), but Mr. Cotton thinks that the cultivation of the Cape variety was a happy experiment. This does not signify that the other varieties (which are essentially English) are not doing well in Mr. Cotton's orchard. They were put down lately only, and not enough time has elapsed to prove the success or failure of the experiment, which is, according to Mr. Cotton, unique in Ceylon.

Mr. Cotton also has three beds (60 feet x 30, 40 feet x 30, and 90 feet x 30) of straw berries in his orchard. The plants are in bearing at present, and as many as 20 pounds of fruit have been collected from these beds of a morning.

STRAWBERRY AND GOOSEBERRY JAM.

The writer was favoured with three samples of jam made by Mr. Cotton from his strawberries, gooseberries, and tree tomatoes respectively. The jams were well prepared and tasted every bit as good as the tinned variety ordinarily met with. Mr. Cotton states that there is a demand for these jams, which he provides for by always having the jam ready in glass jars, sealed for delivery.

In a separate enclosure, Mr. Cotton has experimented on currants. He has four bushes here, all doing well and one bearing a small bunch of clusters. In this same enclosure are two grape vines (Muscat of Alexandria) trailing along frames attached to brick walls. These vines are from grafts imported from Australia. Another small vine has just begun to trail; this was produced from seed from the ordinary market grape. An apple tree in this enclosure (which was raised from seed from imported fruit) is 6 years old, but has not yet come to any good although it looks vigorous and stands about 3 feet high.

APICULTURE.

Mr. Cotton is of opinion that much of the success of his orchard depends on the beehives he has in it, the little insects helping materially in fructifying the flowers. There are two hives (in ordinary earthen pots and well-protected) in the orchard one of which is quite full of comb now.

FISH BREEDING.

A description of Lake View orchard would not be complete, if the writer omitted to mention that in addition to the above, Mr. Cotton has three ponds (connected by a small running stream) in one of which he rears a few trout, two of which are about 4 lb. in weight each; in the second pond he has twenty-four trout fry, averaging 1½ inches, and all doing well; in the third he had carp, but he has taken the last of these out.

Mr. Cotton's achievements unmistakably what well directed exertion can do, and his future experiments in fruit culture will be watched with the keenest interest by a growing section of the public.—*Local Times*.

ORNAMENTAL SEEDS.

Under the term of minor industries it has been proposed by Dr. Morris, in *The Agricultural News* of Barbados, to introduce new commercial plants, natives of other countries, but adapted for cultivation in the West Indies. In a recent number, in a paragraph on ornamental seeds, the writer says that "the present age is one in which there is a great demand for curios, and the increasing number of winter visitors to these colonies, should enable aged people and those who are only able to follow light sedentary occupations, to establish quite a small industry in mounting and preparing the ornamental seeds of the West Indies." It is pointed out that there are in the islands numerous seeds of an ornamental character, and that they deserve to be more widely known. It is, indeed, somewhat surprising that many of these seeds have not come more generally into European use than they have done, for they have always figured prominently among the exhibits at the several International Exhibitions of London and Paris, but mostly as ornamental beads, simply strung on strings for use as necklaces or bracelets, or perhaps for ornamenting table mats. Many of them are specially adapted for such purposes, but there are others that might well be used in a superior class of jewellery, in connection with which the following may be noticed:—Horse-eye beans. These are the seeds of species of *Mucuna*, chiefly those of *M. urens*, and they get their common name from the fact of their appearance being similar to that of the eye of a horse, though somewhat smaller. They are the produce of climbing plants of the tropics, belonging to the order Leguminosae, and are well known to travellers, in consequence of the pods in which the seeds are contained being thickly clothed with sharp, stinging hairs, which are readily detached by the slightest shake. A familiar illustration of the annoyance caused by these hairs penetrating the skin is to be found in the allied species, *Mucuna pruriens*, which furnish the cowhage, or cowitch, of pharmacy, at one time much used as a vermifuge. The horse-eye bean,

when fully ripe, dries well and becomes quite hard. It has a brown, pitted, or rough surface, surrounded with a smooth, darker band. Divided in half, hollowed out; hinged and mounted with a gold or silver rim, these seeds make excellent appendages for watch-chains, or variously treated with similar mountings, they would form quite attractive bracelets. Similar results might be obtained with nicker beans (*Cesalpinia bonducella*). There are also the produce of a leguminous plant, two or three seeds being contained in each pod, which is of a chocolate-brown colour, and studded with stiff woody spines. The seeds are about the size of a large Barcelona nut, irregularly globular, very hard, with a shiny surface, mostly of a greyish-slate colour, but sometimes yellow, orange nearly black, or even white. They are commonly used by the natives for making necklaces, bracelets, and rosaries. In India, where the plant is common, the kernel of the seeds is said to possess medicinal properties. The smaller seeds of the nicker, properly mounted and provided with a shank, might well be made into waistcoat buttons or ornamental buttons for ladies' dresses, as was at one time done in England with the soap berry seed. These are the produce of *Sapindus saponaria*, a small tree, the fruits of which are fleshy and about the size of a cherry, containing one hard, intensely black seed. The pulpy portion of the fruit shrivels in drying and becomes horny; it contains a large proportion of saponin, which is readily extracted by soaking in water, and is thus much used by the people for washing fabrics, as a lather is very quickly produced. The hard, round seeds are used for making necklaces, bracelets, buttons, and rosaries, and it is said that many years ago buttons were made of them, and used in England, chiefly for waistcoats. The absence of any figure or colour in the seeds, being a dull uniform black, does not recommend them for general purposes, but with silver mounts they would be particularly suited for mourning use. The intensely hard seeds of the *Gru* *Grn* palms, for the name is applied to at least two distinct West Indian palms, namely *Acrocomia sclerocarpa* and *Astrocaryum vulgare* are like the soap berries, black. They grow, however to the size of a walnut, and the centre being occupied with soft oily seeds, they can readily be hollowed in the form of boxes, or cut into buttons of different shapes and sizes, and as they take a fine polish should find some general application.

Amongst the brighter coloured seeds which should find a use amongst jewellers may be mentioned crabs eyes, furnished by a common tropical climbing leguminous plant (*Abrus precatorius*). The seeds are abundantly produced in small pods, and are themselves quite small, of a bright scarlet colour, with a black spot. They are very uniform in size and weight, the average weight being 1.75 grains. Wherever the plant is grown these very ornamental seeds are used for necklaces, ear ornaments, and personal adornment of all kinds, as well as for rosaries, and for decorating boxes, baskets, &c. Dr. Watt says the plant with its open withered fruits exposing the scarlet seeds is twisted round leafy boughs to simulate the holly at Christmas time at English stations in India.

It may be worth while saying that the seeds in the fresh state contains a poisonous property which is dissipated by boiling. Experimenting with the seeds of *Abrus* Dr. Warden is reported to have found that half a seed rubbed down with a small quantity of water and injected into the thigh of a full grown cat produced fatal effects in twenty-four hours. A seed almost identical in appearance, namely a bright scarlet with a black blotch but much larger in size, is that known as the *Jumbi* and produced by an allied leguminous plant, *Ormosia dasycarpa*. These seeds might well be used as a substitute for coral especially for necklaces and for mounting in brooches, as might also those of the coral tree (*Erythrina*) which are of

coral red without the black spot. A still brighter seed also without the black mark is that furnished in India by *Adenanthera pavonina*, a large leguminous tree of Bengal, South India, and Burma. It is generally known as the Andaman redwood tree but sometimes as red sandal wood, in consequence of its use as a dye in substitution for the true red sandal wood or red sanders wood. The seeds are nearly half an inch in diameter somewhat lens shaped, that is convex on both sides and of the brightest shining red. In India they are often strung and made into necklaces, bracelets, and other articles of personal adornment. They are also used as weights in consequence of their uniformly weighing four grains. Their bright colour, hardens and uniform size caused them to attract the attention, a year or two ago, of a London West-end Jeweller, who contemplated using them for brooches, pins, rings, &c.

That many of the seeds here enumerated, as well as others, are capable of extended utilisation cannot be doubted. Job's tears, the seeds of *Coix lachrym-jobi*, are by no means uncommon in the windows of fancy jewellers, made up into chains or bracelets, and there is no reason why there should not be a much greater variety of vegetable curios to choose from. Even with the job's tears, there are several varieties used in India that are still unknown in English commerce, and are only seen on native dresses, being used by certain tribes on account of their ornamental character. So long ago as the Colonial and Indian Exhibition in 1886, these seeds attracted much attention; and Dr. Watt, referring to them in his "Dictionary of the Economic Products of India," says, "They seem to stand a good chance of coming into use in Europe in the construction of artificial flowers, laces, bugle trimmings, and other such purposes for which glass beads are now used, and possibly also in Catholic countries, for the manufacture of rosary beads. If found capable of being dyed a deep black [or even brighter colours] there might be an extensive demand for them, since they would be much more durable than glass" so far as we are aware this anticipation has not been fulfilled, so that there is still an opportunity to establish a trade with these and other seeds, as for instance the so-called velvet seeds of British Guiana, referred to in the West Indian *Agricultural News**, which would make a good and novel trimming for ladies' dresses. —*Journal of the Society of Arts.*

COFFEE.—"Fertilizers and Coffee Cultivation, Addresses delivered before the United Planters' Association of Southern India, by Dr. Adolf Lehmann, Agricultural Chemist to the Government of Mysore, 1899-1902"—is the title of a useful pamphlet to hand today, published by Messrs Higgenbotham & Co, Madras. Coffee is, of course, a thing of the past in Ceylon; but from India over 200,000 cwt are still exported.

FLAX IN IRELAND.—The Flax Supply Association report respecting 1901, that there was a substantial increase of one-sixth. The increased acreage under Flax in Ireland, as compared with 1900, is coupled with a very large yield of fibre per acre, the largest yield registered for forty-seven years, viz., very nearly 37 stone per acre. It appears that the Ulster returns were very satisfactory all round; whilst of Connaught it is stated that the 300 acres there grown gave the splendid crop of 49 9-10 stone per acre, larger than that of any foreign country. It is therefore to be hoped that the average may steadily increase from year to year. The total yield of the 55,000 acres under culture was close upon 13,000 tons, a larger produce than any of the previous five years, and about equal to that of 1895.—*Gardeners' Chronicle.*

* The London agents for the publications of the Imperial Department of Agriculture for the West Indies are Messrs. Dulan and Co., 37, Soho-square.

SCHOOL GARDENS IN CEYLON.

The proposal to establish School Gardens in this Colony, and to make them a feature of future educational life, is worthy of encouragement. Being somewhat out of the beaten track of everyday instruction—which in most minds is associated with books, black-boards and slates—the idea of each school being possessed of a special province of its own where nature herself is to be the instructress, and where tender minds are to be gently led to exercise their powers and learn her secrets direct, may be considered by some to be a "fad"; but it has, at least, about it a graciousness which is winsome. The School Garden, although a new importation to Ceylon, has already a history and literature of its own. It is an established fact in many lands; a prized institution on the Continent and in America; and those who know most of it, and have carefully noted its working and effects, are among the advanced number who highly prize it as an educator, and would recommend its adoption everywhere. The idea, therefore, comes to us not untried, but as one which has been tested by many peoples: has established its footing not by ousting the well-known and venerated methods, or hustling itself into their place; but by a steady quiet growth which has won for it, approval and acceptance. It has been found to be radiant with much promise.

In the educational number of last month's *New York Outlook* there is an article on "School Gardens, their Development and Functions," which deals with the subject in an interesting way. Eighty years ago, the School Garden was first established in Austria and Sweden; got official encouragement, and in both these countries it still flourishes. The Austrian Imperial School Law has this for its ideal in the matter:—"Where practicable a garden and place for agricultural experiments shall be established at every rural school." In 1898 there were over 18,000 School Gardens doing their work; while in some of the provinces in Austria there was not a school without a garden. In Belgium each school must have a garden of 39½ square rods. The Federal Government of Switzerland has begun to subsidise School Gardens, and to offer prizes for plans and essays on the subject. France has 28,000 primary Schools with Gardens attached. Germany has taken no official action; but in the different States the system is recognised and adopted. Russia numbers 8,000 School Gardens, and hatcheries of bees and silk-worms have been added. Neither Great Britain, America, nor the Netherlands have as yet done much; but America is moving, and, as the idea has "caught on," rapid advancement may be looked for and by the end of the present decade the United States School without a Garden will be the exception. In Scotland 45 years ago there was, at least, one famed educational establishment—The Dollar Institution—where School Gardens played their part and the Institution

had then the unique place in Scotland of being recognised by the Government as a training centre for Indian Civil Service Candidates. Only in London and Dublin at that time could this needed instruction be elsewhere secured. Today the gardens are no more, and the prestige of the Dollar Institution is not now what it was.

Now, what is it that is claimed for the School Garden? It is held that it keeps the children more in the open air; that it substitutes, where possible, nature study for book-learning; that, while it does not pretend to teach the business of farming or horticulture, it tries to inspire a love for country life by a study of its phenomena. It trains to habits of accurate observation and elevates the mind in many ways. The radius of its influence is wider than the school. A wise principle is laid down not to attempt too much at once, and, while some of the American Schools have a plot for each scholar, others begin with but a single bank of wild flowers and ferns, the joint property of the scholars. If School Gardens in Ceylon will but create a love of country life, what a gain that would be. Our educated youths are inclined to look down on rural work as beneath the dignity of their enlivened souls—law medicine, and Government service being the openings they crave for—with the result that, while at the top of the profession there is always plenty of room, the rank and file are so jostled and hustled that life becomes in many cases a joyless grind, and sordidness at length quenches all its natural brightness. The prosperity of our Colony is based on successful Agriculture; and to have the educated rising generation taking an intelligent interest in it, and adopting it as a career for life's most strenuous efforts would be a very great gain for the island. When the Government takes to the distribution of new economic plants—as from time to time it has done in the past—the success of the experiment would be assured, if the new importations were reared and tended by people who knew something of plant life and whom early training had bent their minds in that direction, rather than if they fell into the hands of the ignorant and untrained. The Russian addition of Bee-keeping might well be adopted, when feasible, as an adjunct to the School Garden; becoming a source of revenue as well as an object lesson. Doubtless there would at first be some difficulties, and experience might have to be bought at a stinging cost; for our Ceylon bees have not yet, we believe, been domesticated—unless by Mr. Frank Benton, Apiarian, America, from the specimens he collected and took away over 20 years ago,—nor does it "improve the shining hour" for man's benefit. Still there is much first-hand information on apiaries easily accessible, and Bee-cultivation has been reduced to an almost exact science, so that an intelligent teacher, who elected to supplement his School Garden with a bee-hive, would soon find his way about, and have in his School compound a theme intensely interesting to young people, redolent of life as well as teeming with valuable instruction.

A COMPRESSED (WHOLE LEAF) TEA SYNDICATE, LTD.

The above new Company has been registered in England, and we take the following from the *Investors' Guardian*, August 9:—

Compressed (Whole Leaf) Tea Syndicate Ltd, (74,493).—Registered July 29, with capital £1,000, in £1 shares, to adopt an agreement with W Gow and J H H Rolfe, to buy, sell and deal in tea and other products and substances, capable of being dealt with by the invention for an improvement in the manufacture of compressed tea, mentioned in such agreement, and to carry on any business incidental or auxiliary thereto. No initial public issue. Begg, Dunlop and Co., of London, are the managing agents. Registered Office, 138, Leadenhall St, E.C.

INDIAN PATENTS.

Applications for the under-specified inventions have been made:—

No. 267 of 1902—Rakhal Dass Khan, rice miller Ramkristopor, Howrah. A mill for husking rice finally so as to make it suitable for use as a food-grain.

No. 268—Rakhal Dass Khan, rice miller, Ramkristopor, Howrah. A paddy-boiling apparatus.

No. 269—Rakhal Dass Khan, rice miller, Ramkristopor, Howrah. A mill for drying paddy and other food-grains.

No. 271—Basrur Brothers & Company, merchants and agents, Hanawar, North Kanara district, Bombay presidency, British India. Manufacture of a new product from the Talipot palm.

No. 288—David James Young, plumber, of Patea in the provincial district of Taranaki, in the Colony of New Zealand. An improved portable shower bath.

No. 290—Henry Mathew Alleyn, tea planter of Meria Cotta, Maskeliya, Ceylon. An improved manurial mixture for tea cultivation.

No. 303—Edward Daw Mashiter Cooper, conservator of Forests, Madras. Improvements in the fastening of doors, windows and the like.—*Indian Engineer*, August.

A USEFUL TREE FOR THE HIGHER PLANTING DISTRICTS.

Mr Nock writes that he has had a specimen sent him of the tree growing on an Agras estate, Dimbula, supposed to be *Ailantus glandulosum*; but which he (Mr N) thinks is rather *Acrocarpus fraxinifolius*, a tree from India. Mr Nock has sent the specimen to Peradeniya to be verified, so the result will soon be known. Meantime here is Dr. Watt's account of the tree known as the red or pink cedar of tea planters, which we believe with Mr Nock must be the tree growing on Glasgow:—

ACROCARPUS FRAXINIFOLIUS, *Wright; Fl Br Ind, II, 292; Wright, Ic, t. 254.*

RED OR PINK CEDAR OF (tea-planters).

VERN.—*Mandama*, NEPAL; *Mad ing*, LEPCHA; *Malai-kone*, TENNEVELLEY, *Kalinji*, NILGHIRS, *Kilingi*, BURGHERS, *Hantinge*, *belanjahavulinge*, KAN.

HABITAT.—A lofty deciduous tree, found in the Eastern Himalaya and lower hills down to Chittagong, ascending to 4,000 feet, also in South India and Burma.

STRUCTURE OF THE WOOD.—Sapwood white, heartwood light red, moderately hard. Weight 39 lb per cubic foot.

Used by Planters in Darjiling for tea-boxes and planking, in the Wynaad for building and furniture, and in Coorg for shingles.

In the *Tropical Agriculturist* for May 1833, some interesting information is given regarding wood for tea-boxes. Mr Bruce writes: "I have used this timber more perhaps than any other for tea-boxes and tea-house furniture in general, and if it had been well seasoned it is as good a wood as could be procured for the purpose."

Dr. Watts' extract from the *T. A.* probably explains how Mr A L Cross came to introduce this tree. In the very early years of "tea" here, we had a very carefully written essay on tea culture, prepared for us and published in our daily and monthly by Mr Bruce, an experienced Nilgiri tea planter, and it was no doubt on seeing his recommendation as given above that Mr Cross first got seed of the tree in question. The wonder is that *Acrocarpus fraxinifolius* is not grown more freely upcountry.

LIQUID FUEL FOR STEAM ENGINES.

We are informed that the Steam Engines of Messrs. Clayton and Shuttleworth—for which Messrs. Walker and Greig are Agents—work equally well with all petroleum having flash points from 82° to 240°. The conditions of working with the heavier oils require that the engine be altered slightly to secure economy with the liquid fuel, but these alterations are not an expensive item. Messrs. Walker and Greig have at present a 7 horse-power engine at work with liquid fuel at their Glencairn Works, Dikoya. But before the firm can give any advice on the subject of driving under these circumstances, they intend running the engine for one month on the new fuel, in order to be able to judge of its merits or demerits on all points.

RAILWAY TRAFFIC IN PLANTAINS.—A morning business visit to the Railway Goods Department at the main station—the approach road to which by the way is in an atrocious state—will generally reveal half a-dozen bullock carts being loaded up with green plantains; and from the intelligent Goods Clerk we learn that on an average 10 loaded waggons, chiefly from Rambukkana, Polgahawela, Ambepussa and Mirigama, arrive daily. Each wagon has probably 500 bunches, and each bunch averages, perhaps, 30 large plantains—so that 150,000 plantains (or one for each inhabitant!) come into the city by this route alone. Probably if the supplies received from the Cotta, Negombo and other sides were added, the total would be very much increased. A traffic in fruit from native gardens between Colomb and Avissawella ought to form part of the Kelani Valley Railway traffic, and the cultivation should be extended to meet the demands of a ready market as the result of railway communication.—We have been told since by native authorities that there are more like 100 to 150 plantains on each normal bunch?

CINCHONA BARK AND QUININE :

JAVA SWAMPING THE MARKET.

(C M & C Woodhouse's Circular, 21st August.)

On the 16th instant the exports of Bark from Java for first half of August were cabled as 1,227,000 Amst. lb. ! As this quantity would have been considered heavy for the whole month, the question asked everywhere is, "What does it mean"? In the hopes of getting Planters in Java to keep the market supplied with moderation and to avoid excessive harvesting of Bark which must end disastrously to all concerned, we think the following statistics may be found useful as showing roughly the position at the end of last year:—

	1901. Eng. lb.	1900. Eng. lb.	1899. Eng. lb.
Imports of Bark into U.K. & Holland	18,208,000	15,770,000	16,321,000
Exports of Bark from U.K. & Holland	15,271,000	16,243,000	15,823,000
	+2,937,000	-473,000	+493,000
Estimated Bark consumed by English and Dutch Manufacturers	2,000,000	2,000,000	2,000,000
Estimated difference in Stocks of Bark in London and Holland	+937,000	-2,473,000	-1,507,000
Quinine equivalent at 4½ per cent.	Ozs. +675,000	Ozs. -1,781,000	Ozs. -1,085,000
Increase in Stocks of Quinine in London during the year	201,000	563,000	997,000

Estimated difference in Stocks of Bark and Quinine +876,000 -1,218,000 -88,000

From the above it appears that, owing to the increased supplies of Bark from Java, the Production was last year in excess of the Distribution, but this would not have mattered much in view of the large reduction in Stocks during two preceding years, if consumption had been maintained, but the feature for some months past has been the large falling-off in Imports of Bark and Quinine into United States. Estimating the Bark as containing 4½ per cent. Quinine on average, the Imports of Bark and Quinine into United States compare as follows, viz.:—

	1901/2. Ozs.	1900/1. Ozs.	1899/1900. Ozs.
1st July to 31st May	5,227,000	6,683,000	6,193,000

Now it is not likely that actual consumption has fallen off to anything like the above extent, but it is unfortunate that, when the market is suffering from a diminished trade, the exports from Java should show a tendency to increase. We trust that the Planters there will be warned in time, as the future is almost entirely in their hands.

QUININE.—During the earlier part of the month the market was steady at 10½d to 10¾d per oz., with a moderate business doing to the Trade. This week, however, after the heavy Bark shipments were known, prices gave way 1d to 1½d per oz., and considerable sales were made at 9½d to 9¾d per oz. on the spot. The further decline again brought in buyers and there has since been a firmer tone, the latest quotation being 9½d to 10d per oz.

MANURE COFFEE.

I have before me a pamphlet by Gustav Helmrich on experiments in manuring coffee in Guatemala. It shows the perseverance, determined effort and scientific attention of a coffee planter amidst difficulties such as hail and rain that measured 180 m. in 2 hours and resultant landslips that carried away fair-sized fields.

Besides various conclusions come to concerning green manuring, weeding, etc., he lays stress upon the necessity for a well-balanced, complete manure. He prefers for good soil, or for land where natural manures are employed, a fertiliser containing

Phosphoric acid	8
Potash	13
Nitrogen	4

which should be used, not for each tree but for the whole field. With green manuring a fair supply of cheap nitrogen is obtained, but phosphoric acid and potash are wanting and should be supplied. Phosphoric acid increases the yield, but when it is in an easily soluble form the greatest care must be taken, for, if given in quantities too great, it forces from the tree one or two large harvests only to rush it to certain death unless a heavy nitrogenous manure is employed as an antidote. Potash acts on the wood and leaves. The coffee plant stands greatly in need of potash. When this fertiliser is not used the want is immediately noticed in the tree. Nitrogen shows its effect in strong fleshy branches of fruit wood, dark leaves and slow ripening. Lime unites for a short time the action of potash and phosphorous, the stout, long woody appearance resembling the effect produced by potash while the disintegrating effect upon the soil and the early ripening produced resemble the action of phosphoric acid. The usual course in fertilising is to wait till the impoverishment of the soil is patent to the naked eye, generally after some years, when the coffee roots have penetrated to a soil that starves them. As to the manner of manuring I think the advice is sound, and the only rational one is to fertilise the field as a whole and not the single tree. If a part of the plantation is lost, and dying trees unfortunately show in different places, the point for decision is whether the whole must be given up or the whole maintained, and the only way to keep the vacant spaces from increasing year by year is to grow green manure on them and to keep the whole field equally well manured.

As far as I have seen, great faith is held in superphosphates and the quickly acting and as quickly lost saltpetre, but few planters resort to a steadily acting, well-balanced complete manure such as a mixture of bone meal and potash with stable manure or poonac.

Ranipet, 21st Aug.

JOHN KENNY.

—Madras Mail, Aug. 27.

COLOURED AND UNCOLOURED GREEN TEAS.

To the Editor "Home and Colonial Mail."

SIR.—Mr. Robert Hart's able letter in your issue of the 19th July should set at rest the many misconceptions that have grown up on this subject. It cannot be too widely known among British planters and Directors of Companies that green teas, on whatever system they are made, come out coloured, or uncoloured, according to the style of the final firing. If this is carried out on the ordinary hot-air drying machines, the tea will assume the olive colour that has misled some tea experts into calling the Ceylon green teas made in this manner "Oolongs" or "Nannas," which they cannot be, for these descriptions are semi-fermented, whereas the Ceylon green teas produced on Mr. Drummond Deane's well-known system are entirely unfermented, The

colour of these answers to the colour of the Japan basket-fired green teas, which are also dried by a current of hot air, and passed on to the consumer without any colouring or finishing process being attempted. On the other hand, if the firing or drying operation is finished on hot pans, they will assume the desired green grey colour in the dry leaf. The Far East tea finishers, generally handling the tea when it is old, are obliged to add colouring matter to obtain the desired colour. On Indian gardens where the tea is finished *in situ* it may be coloured pure, for it will take colour without colouring matter when it is fresh, but only when it is fresh.

The advantage which Mr Deane's system of green tea making has over all others lies in the facility with which large quantities of leaf may be rapidly handled. It is not too much to say that the company, to which Mr Hart alludes as making coloured teas by the aid of Mr Drummond Deane's machine and system, could never have taken up the contract to produce 200,000 lb. of coloured green tea for the Indian Tea Association, and now 160,000 lb. more at half bonus after experience of the cheapness of green tea production on this process, if they had not had Mr Deane's machine and process to rely upon to produce the green tea, from which, by a final firing, they make the coloured or finished article. Mr Drummond Deane by his invention has indeed introduced as great a revolution into green tea making as was effected by the first machine rollers and dryers in black tea. If we are now in a position to compete with China and Japan in the matter of green tea, as the experience of Mr Hart's company shows that we are, it is entirely due to Mr Drummond Deane; who has made it possible to produce the uncoloured green tea, from which the coloured tea is made by the finishing process, cheaply enough to give us a chance on the market. In later days the tea industry and its promoters will come to recognise the immense debt it owes to Mr Drummond Deane, who has rendered green tea, coloured or uncoloured, on a large scale possible in India and Ceylon.

At the same time there is something to be said in reply to Mr. Hart on the subject of uncoloured green teas. These, it is now admitted on all hands, are as truly "green" in character as the coloured variety. Indeed it would be absurd to contend to the contrary, for it is from these uncoloured greens that the others are made. Mr. Hart, however, contends that the colouring process adds quality, develops the liquors and matures them, and that the process is necessary to enable British growers to compete against the Far East teas. If the colouring process is so necessary, how is it that some of the best Japan teas are not coloured or finished in the manner described? I allude to the "basket-fired" teas of Japan, which are in great favour in America. These "basket-fired" teas are dried in an apparatus by a current of hot air, corresponding to the drying machine with which the uncoloured green teas of India and Ceylon are fired. Their colour in the dry leaf is an olive brown or green very similar to the colour of our uncoloured teas. I have not heard that the trade considers that these Japanese "basket-fired" green teas are not "true" greens or that they show any deficiency in liquor or that they require further "development" or "maturing." I understand that they are well thought of by dealers and consumers.

I do not hold a brief for uncoloured green teas, but I think it useful to suggest that there should

be no dictation to tea makers which kind of tea, coloured, or uncoloured they are to make. It is a well-established fact that uncoloured green teas are going ahead well in Canada and that the demand for them is increasing both there and in the States. It is immaterial if the States' buyers, as suggested, buy them for the purpose of colouring, so long as they *do* buy them. For that matter, they do the same with Japan teas at seaport towns of Japan, for the Japanese do not make coloured teas on their gardens; it all has to be coloured by the buyers after purchase. The point to be considered is that, the demand being in this manner assured, it is a matter of personal convenience with tea producers which style they shall go in for. The price obtainable for the coloured tea is certainly higher, but the process again is more costly and in many instances the margin between cost and price will not show to advantage compared with the margin between cost and price of uncoloured teas. Possibly in some cases it will be equal and in a few, where the manufacture is taken up on a large scale, the advantage may be on the side of the coloured greens. But most concerns will not care to pledge themselves to a very large output at first or incur the expense of installing more plant than absolutely necessary. It would therefore be a hindrance to the movement to rule out uncoloured green teas from the advantage of the Association's aid, especially as the demand for it is well sustained. Even if it is bought for the purpose of colouring, it is so much off the black tea market and so much more British-grown tea gone into consumption and so a clear gain.

This I write without prejudice to the movement to produce coloured greens, answering to Japan and China teas, which deserves all encouragement and support. Speaking from personal knowledge I may say that a good many of those who are now producing uncoloured teas on the Drummond Deane system are experimenting with a view to colouring their teas before they leave the factory and, if they find that they can economically carry out the process, will adopt it; but if any hasty action against the manufacture of the coloured teas is taken, they will probably drop green tea for good.

PERMANGANATE OF POTASH AND MOSQUITOES, &C.

Here is the exposure to which our Correspondent "E. E. G." recently referred:—

"Other substances have been experimented with. Two years ago many newspapers contained an item concerning the use of permanganate of potash. As this item was credited to the Public Health Journal it gained a great deal of credence, and was afterwards mentioned in an interesting article by Mr A C Weeks, in the Scientific American. The published note read as follows:—

Two and one-half hours are required for a mosquito to develop from its first stage, a speck resembling cholera bacteria, to its active and venomous maturity. The insect in all its phases may be instantly killed by contact with minute quantities of permanganate of potash. It is claimed that part of this substance in 1,500 of solution distributed in mosquito marshes will render the development of larvae impossible; that a handful of permanganate will oxidize a 10-acre swamp, kill its embryo insects, and keep it free from organic matter for thirty days, at a cost of 25 cents; that with care a whole State may be kept free of insect pests at

a small cost. An efficacious method is to scatter a few crystals widely apart. A single pinch of permanganate has killed all the germs in a 1,000-gallon tank.

"The item is so obviously ridiculous upon its face that it would hardly seem worth while to make any attempt to refute its statements. Nevertheless, it has been so widely read that definite experimentation seems necessary to set the matter at rest. The unknown author's ignorance of the life history of mosquitoes in the opening sentence need not necessarily imply that he would not know a good remedy if he found one. Careful experiments were undertaken by the writer in July, 1898, with various strengths of permanganate of potash in water containing mosquito larvæ from one to six days old. It was found that small amounts of the chemical had no effect whatever upon the larvæ, which were, however, killed by using amounts so large that, instead of using a "handful to a 10-acre swamp," at least a wagon load would have to be used to accomplish any result. Moreover, after the use of this large amount and after the larvæ were killed, the same water, twenty-four hours later, sustained freshly-hatched mosquito larvæ perfectly, so that even were a person to go to the prohibitive expense of killing mosquito larvæ in the swamp with permanganate of potash, the same task would have to be done over again two days later. The same conclusion was subsequently reached, after careful experiment, by Dr Lederle, of the New York health office, and by the Italians Celli and Casagrandi."

HOME-MADE JAMS IN INDIA.

(By a Mem-Sahib.)

Reading an article in a late Home paper on the subject of "Preservatives in Food," I saw in it these words: "Mr Blackwell, though he does not put preservatives in jam, allowed that it would be useful to do so, and the chemist to Messrs. Keiller said that the makers who use preservatives have a great pull over the rest."

Preservatives or not, it seems to me only too true that of late years *all* tinned jams have deteriorated so far as keeping qualities go, for nowadays a tin often ferments and has to be thrown away after being open for less than a week, and I have even opened a tin in which fermentation had already started. This, from my own experience, I attribute largely to the use of beet sugar, with which all markets are now flooded, thanks to the bounties of foreign Governments, and to our own policy of letting the products of our Colonies slide without any help, when their trades are killed by such unfair foreign competition.

I have been out here many years now, more than I care to think about, and have always been keen on my own jam-making, having been brought up in an old-fashioned way, and having been taught to be proud of making my own preserves when one can rely on the materials being what they profess to be, the sugar being cane, and no preservatives used, except the good old-fashioned ones of care and good boiling. I allow it takes time and trouble to see to things oneself, but out here most of us Mem-Sahibs have time and enough to spare, and we surely may still take pride in such things. For years one has known that the staple of most tinned jams is anything but the fruit of which the name on the label leads one to imagine one is eating; carrots, turnips, pumpkins, etc., are all requisitioned, and

quite lately I was told by a man in the trade that common figs are largely used in strawberry jam, to give the necessary seediness. In every trade recipe glucose, which is I believe a product of coal, etc., figures largely to give stickiness and sweetness, with the use of less sugar, and less wastage from long boiling. These things are all doubtless good in their way, and one would not complain were they sold under their true colours, but I, myself, very much prefer to know what I am eating, and as my products seem appreciated by my guests, to judge by the consumption of them, perhaps some of my treasured recipes may be useful to others.

Of fruit in this country we have ample store, and ridiculously cheap, as compared to Home prices cane sugar can easily be got by buying direct from one of the big cane mills, and servants are willing; so on the score of economy, too, home-made jams are to be recommended; but to ensure success, strict personal supervision is necessary, unless one is lucky enough to have a servant one can implicitly trust. I find there are two items specially in which they want looking after: they *will* put too much water to the fruit, because "Missis only liking plenty jam coming," quite ignoring the fact that the water has to be boiled away or the jam will go mouldy or ferment; the other is that they have not the ghost of an idea what "simmer" means. If left to them the jam will boil furiously whilst the maty is energetic enough to blow up the fire, but energy and fire soon die down, and then the jam goes almost cold. Either a good oil stove or "Primus" is far the best for this work, as then you can regulate the heat to the exact amount required. Bearing these two facts in mind, and also that the fruit must be sound, ripe and dry, and the sugar *cane*, I pass on to some recipes.

First comes Cape Gooseberry Jam, which I consider the king of Jams, bar none. Take the fruit out of the hulls; wipe carefully to free from dust, rejecting all green ones. Weigh; prick each two or three times with a silver fork, and put all into a preserving pan of which the bottom is *just* covered with water; this prevents the fruit from catching, which it is very apt to do. Set aside $\frac{1}{2}$ lb of sugar for every lb of fruit. Let the fruit come slowly to a boil alone, stirring it carefully and gently with a wooden spoon. When it boils slack it off: add half the sugar and let it come gently to a boil again; slack it off again; add the rest of the sugar, and the juice of two or three limes for each lb of fruit. This depends on individual taste. Simmer slowly, stirring all the time till the juice sets on a plate. If you care to boil it longer it will jelly, and you can turn out the jar as a pretty golden shape, when cold.

The juice, strained from skins and seeds, weighed and an equal quantity of sugar allowed boiled to a jelly makes a delightful preserve for children, with whom seeds in jam do not as a rule agree.

Guava Jelly. Pare and core any number of ripe guavas. Those with pink flesh make a prettier coloured jelly than the white, but the flavour is identical. Put in a preserving pan with enough cold filtered water just to cover the fruit completely. I advise you to see it put over yourself or the servants will put in far too much. Stew gently with the cover on the pan, for about 6 hours, or until the fruit is almost dissolved. Here again, if left to himself, Rana

swamy will gallop the pan with the cover off, and in consequence the fruit will not boil to a mash, and you lose a lot of the juice. When quite pulpy strain it through clean flannel, wrung out in boiling water, or a thick *gharun*; it must be left to drip and not be helped by stirring with a spoon. I usually leave mine in a safe place to drip all night. Weigh the juice; to every lb. allow 1 lb of best white cane sugar, and the juice of three limes. Let it simmer till it jellies, skimming carefully. One time when I failed I found my sugar was beet-root, as I did not then know its evil propensities.

Guava cheese, for dessert, is very good, made with the pulp, put through a sieve to free it from seeds, an equal weight of sugar allowed, and a tea cup of juice to every lb of pulp. It should set and turn out in a rich deep red cake.

On the Hills splendid sour oranges are to be had and there are quantities of recipes for marmalade. I have my two favourites, one of which is a clear jelly with the transparent chips set in it very good to look at and still more so to eat. Cut the fruit up raw very thin, white and all together, only taking out the pips. To each pint of fruit add 3 pints of cold water; let it stand for 24 hours. Then boil gently for some time till quite tender, so that a straw will pierce the chips quite easily. Leave it till next day. To every lb of boiled fruit liquor and all add $1\frac{1}{2}$ lb white cane sugar; bring it slowly to a boil and until the syrup jellies and the chips are transparent. Boil the pips with about two big cups of water till reduced to about half, and add with the sugar; they help jelly.

Another kind, not jellied. To each lb. of sour oranges put 2 quarts of water, and boil the whole fruit for two hours, or till quite tender. Then cut all up into thin slices, taking out the pips. To each lb. of cut up orange add 2 lb. of best white sugar, and 1 pint of the water in which the fruit was boiled. While you are cutting up the fruit pour the water on the sugar, and let it stand to dissolve in the preserving pan, off the fire. Add the fruit and boil all together briskly for half-an-hour, or till the juice gets syrupy.

Here we have a little fruit in our gardens, called "Mock Orange." The bush is small, with tiny dark green leaves like a miniature orange tree, and the blossom is white and has an orange blossom scent. The fruit is about as big as a small marble, a dull deep red when ripe, and is a funny flavoured pulp round a big stone. It makes rather a fascinating jam which has quite a distinct flavour to any other. Wash the fruit in hot water, take out the seeds, boil till tender, in enough water to cover it, and then pass through a sieve; to each lb. of sieved fruit allow $\frac{3}{4}$ lb. of sugar, and simmer together till it gets thick. It has an acid flavour, and some prefer an equal weight of fruit and sugar. A very little grated spice can be added if liked, but I dislike spice in jam myself. This a beautiful rich red-coloured jam and well worth trying.

Now we come to mangoes, the fruit, *par excellence*, of India. Jam and jelly made of ripe and green fruit are all excellent.

Green mango jelly. Common ones will do, *faute de mieux*, but good graft ones are best. Peel, cut and stone the fruit. Put each piece as cut into water slightly acidulated with lime juice, or it will discolour. When all is cut up fairly small, drain dry and put into a preserving pan, with just enough water to cover it. Put on the lid,

and let it simmer, as for guava jelly, but the fruit being green takes much longer to get soft and squasy. When quite pulpy let it drip through flannel, but do not squeeze it at all. Weigh the juice, allow $1\frac{1}{2}$ lb of sugar to every lb of juice and boil together till it jellies.

If made from ripe mangoes; only use $\frac{3}{4}$ lb of sugar to each 1 lb of juice, and the first boiling will not take very long. When cutting the ripe fruit, too, do so over the preserving pan, to save all the juice, and do not put the pieces into water until you are going to boil them.

Jam from green or ripe mangoes. These are made alike, only the green wants more sugar. Grate or cut up the fruit after peeling and stoning it. Boil gently till quite soft or pulpy, and all in a mash; if preferred it can be put through a sieve. Weigh, and to every 1 lb green mango pulp allow $1\frac{1}{4}$ lb sugar. If ripe fruit is used only $\frac{3}{4}$ of a lb. Simmer gently till thick.

We have another fruit, called "Bilimbi" in our part, something like a long, sweet water grape to look at, but very sour, and yet it makes a nice flavoured jam. I wash it carefully, as it gets very dusty; grate it on a grater, and allow $1\frac{1}{2}$ lb sugar to every lb of fruit; boil all together till stiff. It turns a dark brown and is very nice for a change.

What can be nicer than pineapple jam? This wants special looking after, or, in his zeal to please Missis with quantity, Ramaswamy will sacrifice quality by cutting up the hard cores and putting in all the eyes, to the great detriment of the jam. See that the fruit is ripe and quite sound. Peel, cut out all the eyes carefully, and discard the cores. Either cut up all very fine, or grate each slice on a big bread grater to the core. Weigh, allowing $\frac{3}{4}$ lb of sugar to every lb of fruit. Put a large breakfast cup of water in the pan, add the fruit and the juice of two or three limes to each lb. and simmer nicely till reduced; as it is very watery. Then add sugar and boil together till nice and thick. For children I make jelly by boiling the fruit till in a mash, then straining, and then boiling the juice with an equal weight of sugar till it jellied.

People who live on the Hills can make jam and jelly of any fruit they can get, on these lines, as a very little experience tells one what quantity of sugar to use.

Jam made from the edible passion fruit is excellent too, and a great institution at the Cape. Pick the fruit from when quite ripe and purple. Peel off the outside skin with a sharp knife; cut the fruit in halves, scoop out the insides and place them in a bowl. Stew the outsides with water just to cover them, over a slow fire, for about 12 hours or till tender; being woody they take a long time. Add the juice of two limes to every 12 fruits. Strain the insides from seeds and add to the stewed shells, allowing 12 insides to every 12 shells, and $\frac{1}{2}$ lb. sugar for this quantity. Boil together till very thick and syrupy. It is something like apricot jam and very much the same colour.

Plantain jam is much liked by children and is easy to make. The fruit soon softens with boiling I always sieve it. Add $\frac{1}{2}$ lb. sugar to every lb. of pulp and the juice of two limes. Boil together till firm; it often turns quite a pretty pink.

Plantain jelly, too, is nice. Take some large coarse very ripe plantains, about 30, wash them well; add 4 pints of water and boil for two hours, uncover, Strain, but do not squeeze. To eight

cups of the juice allow five cups of sugar and the juice of three limes; boil till it jellies. It is not clear, but a nice red colour. If a few guavas, about six big ones, are added to the plantains and all boiled and strained together, it makes a nice variety.

A savoury tomato jelly to eat with meat is not much known. To each lb. of tomatoes allow 2 oz. sugar. Melt the sugar, stirring all the time, taking care it does not burn. Into this put two or three Bombay onions cut up very fine, for each lb. of fruit, and boil up nicely. Add the tomatoes cut up fine, a little pepper and salt, and if liked, some spice. Boil all to a pulp, strain, and then boil up the juice till it jellies. Put into *small* pots, as it does not keep well when once opened.

Sweet loose jacket oranges make delicious marmalade too. Scrape the skin slightly and boil till very tender; cut up all, only taking out the pips and allow $\frac{1}{2}$ to $\frac{3}{4}$ lb. sugar to each lb. of fruit. Simmer till nice and thick. This is more like a jam, being sweet, as marmalade is always slightly acid.

Roselle jelly is too well-known to require any describing. This is a fascinating subject, but I have run on longer than I intended and yet have not added any recipes for preserves for dessert, of which I have several. They may do for another article.—*M. Mail*, Sept. 6.

PRODUCE AND PLANTING.

We remark on Mr George Seton's interesting table of the working of forty-five

INDIAN TEA COMPANIES

for the past season. It will be seen that about half of these companies show increased profits, as compared with the previous year, while the other half have had their profits reduced. Taken all round, the profits were larger than in the previous year, but the amount distributed in debenture interest and dividends was much smaller. The total net revenue works out at £319,000, as against £297,600 in the previous year, and the average rate of dividend, including debenture and preference interest, is 2.72, as against 3.90 per cent. This lower return, in spite of bigger takings, is not due altogether to increased capital on which distribution has to be made, but may be attributed to the more cautious policy of the directors in keeping larger sums in hand, so that whilst the aggregate capital has only grown 4 per cent, and is accounted for by the fresh issues of four concerns, the total sum placed to reserved and carried forward has expanded more than 15 per cent. The production per acre fell from 487 lb to 421 lb, but the profit per lb increased from 0.85d to 1.03d, and the sale price was nearly a third of a penny per lb better. The ratio of operating expenses to receipts was 86, as compared with 83 per cent, and the profit on the total capital employed is equal to 3.50, as against 3.20 per cent. The situation revealed by this carefully-compiled table is that each garden or group of gardens should be considered by itself, and that it is difficult to generalise on the whole industry from the results of any particular working.

The Government Laboratory report, states that COFFEE substitutes are admitted free provided they contain no coffee or chicory. Needless to say, there is no lack of such substitutes. Roasted figs, turnips, acorn and dandelion are the favourites. This must be particularly gratifying to coffee planters. It appears that molasses form an ingredient of soy, cattle foods, and blacking, and these are now charged a shilling per cwt in respect of the sweetening matter in them.—*H. & C. Mail*, Aug. 29,

FRENCH-GUINEA RUBBER.

Captain Cromie, His Majesty's Consul at Dakar, in his Report on the Trade of French-Guinea for 1899 and 1900, which was not received at the Foreign Office until July 21 last, deals with a subject of much interest to tropical Colonies—the collection of rubber. The fall in the price of rubber in 1900 was especially felt in French-Guinea, eight-tenths of whose exports consist of that article. And there were special reasons which caused the Colony to suffer. "Having been a rubber-producing country for many years," says the Consul, "the vines, owing to wasteful methods of tapping them, had become comparatively scarce, and in order to increase the quantity of rubber for sale, the natives adulterated it in various ways. The merchants, anxious to profit by the high market, accepted the bales without examination, with the result that the rubber bought from the natives during the season 1899-1900 contained as much as 25 per cent. of impurities. The home markets, who could obtain rubber of a much higher quality from other sources, refused to buy the Guinea rubber, which thus remained on the hands of the merchants, who, in many cases, were compelled to sell at a loss. In the meantime European goods were accumulating in the merchants' stores at Conakry, as they had given their orders before the fall in prices. But the natives, alarmed at the low prices they were offered for their rubber (50 per cent less than the year before), only sold enough to pay their taxes and to such European articles as had become indispensable to them. As they had long ceased to cultivate anything but rubber, the fall in that article found them with nothing to replace it. The Government has adopted several measures which, it hopes, will remedy this state of affairs, so as to improve the quality of Guinea rubber. A Decree was issued in May, 1900, forbidding the sale of rubber in unopened bales. This has already had a good effect, as the natives, finding they were certain of detection, ceased adding foreign matter; but as the method of coagulating the rubber in calabashes ordinarily employed by the natives made it difficult to detect adulteration with resins, a further Decree was issued to the effect that, dating from the wet season of 1901, the only rubber allowed to be exported would be that prepared by the Foulah method, in red filaments, which was found to be the only one which permitted the detection of resinous adulteration."—*London Times*.

CEYLON TEA IN AUSTRALIA.

(From an *ex-Ceylon Resident*.)

Melbourne, Sept. 3.

I advised you by last mail of the Regulations which must now guide Colombo Exports of Tea to the Commonwealth. I feel I must, however, send you a line by this, to show you how acute the situation has become between the Importers whose tea has been seized, their sympathisers and the Minister of Customs. Sir Malcolm McEachern, who has been very dissatisfied with the new regime at the Customs ever since the fuss over the breaking of ship's seals, has told his constituents, he can no longer be looked upon as a supporter of the Government. Though his interests are *shipping*, it was over some remarks of his that the House discussed the Tea difficulty the other night. In one of the recent issues of the *Observer* *apropos* to tea stealing, you make the very pertinent observation, that "if there were no receivers there would be no thieves." Now, I hope you will persevere on your text that, if there were no

EXPORTERS OF FAKED RUBBER from Colombo, there would be no importers in the Commonwealth of any article or grade bear-

ing the name of Ceylon. It is to be hoped, too, that ere long there will be some proper accredited supervision at your Customs. It is the only sure safeguard. Possibly the Regulations here may be over-stringent, but not without cause.

When the tariff was being debated the strongest argument used for the retention of some duty on tea was not so much the need of it for revenue, but that

FREE SYDNEY

had become a by-word as the dumping ground for all that was most abominable and dirty in the tea trade, the refuse being used for blending.

It was argued that the 3d duty made such imports financially prohibitive here; but predicted that the moment Melbourne became a free port it, too, would be flooded with the filth for blending. Today the Protectionist prophets are simply saying "I told you so." Fortunately for the consumer, the Board of Health has stepped in strongly.

Some of the Firms, which have just happened to be dropped on, are well-known Houses considered beyond reproach, who must make the best stand they can against the Government. As one, in special, comes in direct contact with the public, I shall be able to let you know details and how matters go in a week or two.

I was told yesterday that there are a lot of "Ceylons" among the condemned tea! "*Ceylon dusts*, I suppose, you mean" I replied, which, no doubt, it is; but—quoted by the man interested in "Chinas or Indians" depend upon it—it is simply "Ceylons." In the meantime it is hard on the patient planter doubling his Cess, and striving with tooth and nail to get his product back to something of its good old footing, to have the reputation of his teas' purity sullied by unscrupulous exporters. In fact, I think, it is shocking that he is not protected against such happenings. It is this sort of thing which disheartens and disgusts those who are doing their best to push Ceylon Tea and watching with anxiety for a return of prosperity to the planters of

LANKA.

TEA IN MELBOURNE.

SAMPLES OF CUSTOMS ANALYSES.

A Colombo merchant has favoured us with the following:—

(Copy.)

Custom House, Melbourne, 18-12-01.

To the Government Analyst, Melbourne.

SIR,—I beg to hand you the accompanying sample of Tea marked as per margin, with the request that you will analyse the same and furnish a reply to the following questions, viz:—

1. Is the sample really Tea? Yes.
2. Is it exhausted Tea within the meaning of Act No. 6 of 191 or mixed with other substances or with exhausted Tea? Yes, the total ash exceeds 8 per cent.
3. Is it fit for human food? According to Customs Act 1901 Reg. Sec. 54 it is unfit for human use.—I have the honor to be, Sir, your obedient servant,

(Signed) R. H. Dawson, *pro* Collector of Customs.

(Copy)

Commonwealth of Australia, Customs and Excise Office, Melbourne, 31-5-1902.

To the Government Analyst, Melbourne.—I beg to hand you the accompanying sample of tea marked as per margin, with the request that you will analyse the same and furnish replies to the following questions, viz:—

1. Is the sample wholly Tea? It is tea dust.
2. Is it exhausted Tea? No.

3. Is it adulterated with spurious leaf or with exhausted leaves? No.

4. Is it unfit for human use? According to Regulations 15, Section 54, it is.

5. Is it unwholesome? No.

6. Does the sample comply with Regulation 15 relating to Sub-section (c) of Section 54 of the Act? No.

7. Give result of analysis.—Total Aqueous Tea extract, 42.1 per cent.; Total Ash, 8.79; Soluble Ash, 3.79.

8. Is the tea in your opinion a "prohibited import" within the meaning of the Customs Act and Regulations? It does not comply with the regulations under the Customs Act, *i.e.*, it contains more than 8 per cent. of Ash.

(Signed), C. R. BLACKETT, Government Analyst.

AFRICAN OIL PALMS.

We are surprised to learn that nothing is being done with the fruits of the West African Palms planted at Udagama a good many years back. One report on the palms is:—"They are still growing, they have attained to considerable size, but I do not think the nuts are of any value. The nut is smaller than a walnut, covered with a very tenacious fibrous husk like an areca. It seems to me to be of no value."

This surprises us very much; has any attempt been made to crush the nuts and extract the oil? Let a native chekku-mill be used, and the result reported.

PLANTING NOTES.

COHUNE PALM NUTS.—In British Honduras the Cohune Palm grows over a large extent of territory without any care or attention, and it having been ascertained that the kernel yields a supply of first-class oil, it has been determined to place the nut on the market, provided a machine can be invented by means of which to crack the nut and so to secure the kernel uninjured and ready for the oil extractor. The Agricultural Society of Belize has the matter in hand, and a barrel of Cohune nuts is now on the way to Mr Currie of the Imperial Institute, and he, we believe, will see to the placing of the sample before the trade. Mr Currie, we are informed, has reported that the value of the nuts is about £17 per ton.—*Gardeners' Chronicle*, Aug. 23.

"CASTILLOA ELASTICA RUBBER DRIED IN THE SUN.—Senor Joaquin Jimenez, an extensive sugar and coffee planter of Tuxtepec (Oaxaca), Mexico, is interested also in the cultivation of his India-Rubber, having planted up to date some 10,000 trees, though, perhaps, this number is not now standing. Recently he permitted some of six and eight year old trees to be tapped by men sent to his place by a Vera Cruz trader, who extracted and cured about 700 pounds of rubber for which they paid 80 cents, Mexican. The trees tapped yielded an average of about one pound per tree. There are on the plantation half a dozen trees, planted fifteen or sixteen years ago, one of which is supposed to have yielded 11 pounds of rubber this season. The rubber here referred to was prepared without the addition of any coagulating agent, the latex having been poured over a coffee patio (drying floor) and dried in the sun.—*India Rubber World*, August 1.

COFFEE AND RUBBER.

A writer of Planting notes in the *Madras Mail* Sept. 15th says:—Advices from London as regards the state of the coffee market are meagre in the extreme. While stocks of course still remain high, deliveries in London are very much less than at the same time during the last few years. Meanwhile, the price for rubber is rising steadily and there is little doubt that there will be a great and increasing market for it for many years to come. The uses for rubber have increased so greatly in the last few years,—and the industries for which rubber is so indispensable are all those with great futures before them—that there is every probability that the demand will ere long exceed the supply. Rubber of one kind or another—and the name of rubber-yielding plants is legion—will thrive almost anywhere in the tropics. But, it may be alleged, the areas of indigenous rubber forests now in full bearing are so vast as to make one doubt if the supply from them could ever fail. There is certainly no denying that there are prodigious forests of these trees; but at the same time one must bear in mind that the methods of extraction in many of these places are most crude and destructive, and the methods employed leave the jungle a useless and barren waste. This reckless destruction is bound to tell before long, with the world's consumption increasing as rapidly as at present. On the other hand, there is a talk of artificial rubbers, not of one but of many, and with the example of the indigo planters before them coffee planters may well hesitate before running their heads into a similar noose. I have been led to make these remarks on rubber in connection with coffee owing to something I read in the Report for 1901 of the United Planters' Association of the Federated Malay States. This says that a good deal of coffee was planted in 1901 mostly *in conjunction with* Para rubber, and that the cultivation of it (the coffee) has been well maintained and the quality improved. This will be news indeed to planters in Southern India, both on the score that rubber growing among coffee does it no harm,—Para rubber, that is to say, for Gatta Rembong (*Ficus elastica*) is acknowledged to be prejudicial to coffee,—and secondly, that it even improves the quality of the coffee produced. Nor does this seem unreasonable when one considers how very much planters depend for their shade on the *ficus* species—the *atti* or *ficus glomerata* being the most favoured of all,—and that trees of the *ficus* tribe all produce milk from which rubber of a sort may be made. The *Hevea Brasiliensis* or Para rubber is expected to yield in four to five years about 6oz. of dry rubber per tree, and some six year old trees have yielded over 1lb. at their first tapping. This is in the Federated Malay States of Perak, Selangor and Negri Sembilan. And Para rubber is selling at Home now at 3s 4d per lb. From two 19 year old trees of *Ficus elastica* in Perak I learn that 25lb of rubber was extracted per tree in one year.

THE MADRAS GOVERNMENT CINCHONA PLANTATIONS.

The Report of the Administration of the Government Cinchona Department, together with the Government Order thereon, have just been published. Mr George Romilly, the officiating Director, in issuing the Report, recalls to mind

that he only took over charge of the Department five days before the end of the official year 1901-02, and that he was consequently in charge for that time only of the year under review. However, the Report has been prepared on the lines hitherto adopted and, in the words of the Government Order, is clear and concise. The year seems to have a successful and fortunate one in every way. Not only was the season favourable on all the estates—the rainfall being ample and well-distributed—but the quantity of quinine distributed was the largest on record, *viz.*, 11,978½ lb. The installation of new machinery was the feature of the year. By means of it the bark is dealt with by the shale oil process instead of with the fusel oil in use before. But it was soon found that the machinery was in some respects defective and the results unsatisfactory. It was not till steam coils had been inserted in the extractors for the purpose of heating the shale oil that the full return of alkaloids was obtained. The machinery itself was not in full working order until November, but from then till the end of the year work progressed steadily and satisfactorily. The bark worked up was, however, of an inferior quality, so that, as the Government Order says:—“In the circumstances, the year's work cannot either in point of quantity or of cost be taken as a criterion of the efficiency of the factory.” The total area under cultivation is 1,071½ acres, of which 831½ acres are old, the remainder being composed of three extensions. The expenditure on the upkeep of the total acreage, including the charges of the head office, works out at R47-10 per acre. The total expenditure was R1,30,051. Of plantations was R58,938-13-1, and the expenditure in the purchase of bark and on manufacturing and distributing charges was R71,102-9. Excepting on one estate—Hooker—where the trees died out in considerable numbers, the plantations thrived in the year under review. The year's crop amounted to 154,044 lb. of crown and hybrid bark, but the annual yield required from the existing plantations has been fixed for the present at 3,000 lb. of manufactured quinine, and this amount is represented by 85,750 lb. of bark of 3½ per cent. quality. This has led Government to state in its Order that it would be glad to have the Director's assurance that the plantations have not been overworked, and it draws attention to the importance of maintaining the plantations as a reserve against the contingency of the market price rising. Some important scientific experiments were made on the Doddabetta estate during the past year. Samples of bark were taken from 38 trees selected at random, but large and well-grown ones, and their bark was analysed. The results in some cases were extraordinary, some samples giving as much as 13.99 per cent. of sulphate of quinine—a percentage which is probably unequalled by *Cinchona officinalis* anywhere. At present rates the value of an acre of trees giving bark containing 10 per cent sulphate of quinine, would be approximately R18,750. Further experiments are to be continued in the coming year, and seed from these good-caste trees will be carefully selected, sown and their produce tested. If the descendants of the parent trees prove equally rich in quinine, and fields can be grown giving an average of this 10 per cent bark, the poorer barks can be gradually eliminated and neglected. The extreme richness of certain of these samples augurs well for the success on the Nilgiris of the system of propaga-

tion by seed from trees selected on the analysis on their bark. The quantity of quinine distributed was the largest on record, a considerable increase having taken place in the sale of pice packets through the Post Office, which system was extended to Mysore Province. Over 9,500 of these packets (each packet contains 102 five grain powders) were sold this year as compared with 8,792 sold in the previous year. The balance sheet shows a loss of R7,293-10 3, a fact which is due to the prices charged and realised during the year not being sufficient to cover working expenses. In the future, either the price must be raised or the cost of production must be materially reduced. In conclusion, the Government in its Order tenders its thanks to the staff, one and all, but to Mr Standen in particular, "for the attentive care and ready resource that finally assured the success of new machinery."—*M. Mail*, Sept. 16.

CEYLON SPICES IN THE LONDON MARKET.

The following extract from the "London Commercial Record" is worth reading, in connection with the remarks of a merchant which we append to it:—

"Dealers in Spices may congratulate themselves as being about the only people who could boast this week of something like activity and good business. Not only have Pepper and Ginger maintained their rising attitude, but Cinnamon owing to the holding of the Quarterly Sales, has craved their attention as well. These Cinnamon sales have long ceased to be of any great importance, the days when they caused a stir in the market are over, yet they form an interesting function and not altogether devoid of importance to a fairly large proportion of Spice dealers and brokers. Cinnamon, like many other articles, has ceased to look upon London as the distributing centre of the world. It finds its way from Ceylon direct to any place of consumption, be it ever so small and be the quantity ever so insignificant. Germany, which used to procure its requirements from London, is now importing direct, and may be looked upon as the principal buyer of the spice; U. K. comes next, while Spain and America are steadily increasing their imports. To look at the steadily decreasing stocks in London, and the ever diminishing quantities exposed for sale, one is tempted to believe that a substitute for the product had been found, and that it is gradually dying out of consumption. This is, however, far from being the case. As a matter of fact the consumption, at any rate of quills, has steadily increased, as is clearly demonstrated by the following figures:—

1899	...	2,515,091 lb. quills.
1900	...	2,678,111 "
1901	...	2,756,270 "
		and
1899	...	1,829,127 lb. chips.
1900	...	1,863,406 "
1901	...	1,516,033 "

America seems to cultivate an increasing taste for this delicious spice, for no less than 358,300 lb. were exported to that country during 1901, as against 259,425 lb. in the previous year. The greater part goes on to San Francisco, whence it is distributed over Central America. In spite of the apparent increasing demand prices have steadily declined, and we doubt very much whether anybody

has appreciably benefited by his operations in Cinnamon. We heard usual assortment had been sold recently at 8½d c.i.f., a price, to judge from the values ruling in Ceylon, clearly proving the anticipation of still lower figures. The same opinion as to the future seems to be ruling in our market as well, for we doubt if an offer even at 8d c.i.f. would find a buyer. The auctions passed off with a fair demand; of the 825 bales exposed for sale, 517 changed hands, but prices could not be maintained and holders had to agree to a decline of from ½d to 3d per lb. according to quality. Since the auctions extreme quietness has ruled supreme, and even Colombo has not thought it advisable to try our market with an offer of any sort. Now the sales are over. Dealers in spices can bestow their entire attention upon the more remunerative branch of the trade once more."

On this a local correspondent remarks:—

"In place of the value of Cinnamon having gone down in Ceylon since the last quarterly sales in London, prices of usual assortment have improved quite ½d to ¾d per lb. So much for the influence of the London sales on the Colombo Cinnamon Market. How have the mighty fallen!

"Some day it will be the same with Tea if the enormous dock charges in London are not reduced."

DUTY ON TEA IN RUSSIA.

The following letter from Mr Renton to the Chairman of the P. A. has been placed at our disposal:—

Berlin, August 28th, 1902.

DEAR MR. KINGSFORD.—The Moscow papers of August 8th old time and 19th new time quote from the "Official Messenger" an Imperial decree raising the Customs duty on black *flowery* (?) green and yellow (?) teas imported into Russia via the Son-rechensk, Steppe, Irkutsk and Amour general governorships from roubles 22-50 to 25-50 per pound. The Customs Authorities are to be informed by telegraph of the immediate enforcement of the above. The decree states the above increase is temporary pending consideration of this question by the State Council. It is due, continues the decree, to the considerable decrease of expenses incurred in the delivery into Russia of Chinese tea, thanks to the Manchurian and Siberian Railways, thus necessitating more conformity between cost of sea and overland freight. The section of the Tariff affected is section 20, para 2. This increase ought to help Ceylon teas all the more, I think.—Yours sincerely, (Signed) J. H. RENTON
A. C. Kingsford, Esq., Rookwood.

A NEW VARIETY OF PEPPER.—Pepper, being a comparatively high-priced commodity owing to the fact that it grows only in a few countries, is subject to much adulteration. For this reason a report recently made by Professor Moissan, of Paris, is of importance. This report states that a new variety of pepper has lately been imported from Kissi, in French West Africa, on the borders of Liberia, which has been called *Piper Femicioni*, Heekel, after two investigators, one an army surgeon, the other a botanist. Dr. Buillé, principal chemist to one of the Paris hospitals, has examined the seeds and found that they yield a highly aromatic reddish-brown powder, rich in essential oil, and with peculiar characteristics. He considers this variety of pepper an acquisition among the useful plants.—*Chemist and Druggist*, August 30.

COFFEE—CACAO—RUBBER, &c.

In an article from the pen of M. Paul Dreyfus in "L'Economiste Français", the future of the African Republic of Liberia is dealt with in an interesting manner. Of late years more and more attention has been directed to West Africa and to the commercial and industrial possibilities of Liberia. This Republic is governed by natives repatriated for the most part from the United States, and its legislation as well as the character of its inhabitants is somewhat antagonistic to Europeans and European trade; but it will in the near future be impossible for Liberia to avoid close contact with foreign capital and foreign manufactures, in view of the many European establishments already scattered throughout the neighbouring regions.

Information as to the economic condition of Liberia is by no means easy to obtain, inasmuch as no official statistics exist. A sort of quarterly return of trade with interior is drawn up by the Liberian Customs and transmitted to the Treasury, but the latter department does not communicate these documents to the representatives of foreign Powers. The ports open to foreigners are Cape Mount (Robertsport), Monrovia, Junk River (Marshall), Grand Bassa Buchanan, Edina River, (Grand Sestos), Sinoe (Greenville), Setta Kroor Harper, and Cavally. No foreigner is allowed to become resident in the interior of the country, but there is a "reform party" in the Liberian Congress, and it is believed that considerable modifications in the present legislation as to foreigners will shortly be proposed. There is no staple industry in Liberia, and agriculture is in a very primitive stage. There are, however, great possibilities for agriculture, if the legislation admitted the employment of foreign capital in the country. Water is everywhere found in abundance in the Republic, and nearly all tropical products can be cultivated most advantageously. Liberian coffee is excellent, having a much appreciated flavour which cannot be found elsewhere. The present price of coffee in bulk is 9d to 10d per English lb. The coffee plant grows in a wild state in the forest lands between the Manal River and Cape Palmas, and in the interior as far as the Mandique plateau. The coffee plant commences to produce in the fourth year of its growth, but it would be necessary to improve the present method of decoration or barking, which does not present the berry in a very advantageous manner. Ginger, too, grows well, and palm trees are extremely abundant, especially in the Cape Palmas district (hence the name). Cotton also grows easily, but its culture is neglected. Arrow-root is also a product which can be grown with profit in Liberia. Cocoa is grown, but only to a small extent. Maize, pepper, rice, millet, yams, tapioca, orange trees, lemons, bananas, and guava, grow abundantly. The forests contain plenty of mahogany, yellow wood, gum trees and camwood. There are numerous India-rubber trees, but the Liberian Rubber Syndicate has obtained a monopoly of the rubber concessions in Liberia.

It is believed that there are rich gold veins in the Republic and also extensive coalfields, but so far none of these have been prospected. England exports to the country tissues, salts, soap, beer, salt beef, rice, whisky, condensed milk, potted meats, galvanised iron, tin, made up articles, vinegar, biscuits, &c. Germany does a good trade in wearing apparel, ironmongery, tools, petroleum, hats, both straw and felt, food stuffs and galvanised iron. France does very little, her commerce with

Liberia being limited to a few liquids and tinned foodstuff, via Liverpool. Monrovia, the Capital, is also the business centre. It contains about 5,000 inhabitants, and is in frequent communication with Liverpool, Antwerp, Hamburg, Rotterdam and Marseilles. The population of Liberia has been estimated at various figures between 2,000,000 and 767,000. In 1894, the last year for which figures are available the expenditure was \$151,975 and the revenue \$153,861. The public debt in 1897 was £100,000 contracted on a 7 per cent loan in 1871. There were in that year £164,000 arrears or interest. In 1893 an arrangement was made for the settlement of the debt as follows: The interest to be reduced to 3 per cent for three years, rising $\frac{1}{2}$ per cent every three years to an maximum of 5 per cent. A sinking fund of 1 per cent will commence to operate in October 1904. The interest has been regularly paid since the arrangement. There is no army, but two brigades of militia, which may be called upon in time of war. There is no longer any navy.

Such is the somewhat vague information Europeans possess about Liberia, but it is to be hoped that the measures now submitted to the Senate and the Chamber will open up this apparently naturally rich country to foreign enterprise.—*Financial Times*.

HOW TO MAKE BARREN TREES FRUIT.

AN OPINION FROM AMERICA.

We receive many enquiries as to how to make barren fruit trees bear fruit. We have invariably recommended root-pruning and occasionally "ringing." The late Professor Goff of the University of Wisconsin, U S A, one of the highest authorities on fruit culture, and who made a special study of the root system of fruit trees, propounded the theory of renewal pruning or invigoration of fruit trees through the medium of what are called "water sprouts." These "water sprout" shoots are produced in the old age of the trees for the purpose of replacing the old and reproductive wood and thus extending the age and usefulness of the trees. They are due to extended root action and when they appear in young trees, should be removed at once, as they produce wood without fruit. Root-pruning will prevent this, and induce the trees to fruit.—*Madras Mail*, Oct. 9.

THE OIL WELLS OF TRINIDAD.

The current issue of the *Board of Trade Journal* calls attention to the exploitation of the oil wells of the Island of Trinidad. No great quantity has yet been brought to the surface, although expert opinion indicates a very large supply. Analytical reports, however, are highly favourable regarding the quality of the oil. The discovery is said to have great commercial importance in view of the approaching cutting of an Isthmian Canal, and the proximity of Trinidad to what will in consequence be a great trade route.—*Daily Chronicle*, Aug. 15.

RUBBER PREPARATION.—Says the Editor of the *India-Rubber and Gutta Percha Trades' Journal*, Sept. 1st:—a method of preparation on a par with scientific cultivation is eagerly desired. We take this occasion again of pointing out how emphatically useful will be the researches of Dr Weber who is at present investigating this very subject, not in the laboratory but on the spot in Para,

A NEW VARIETY OF PEPPER.

Pepper, being a comparatively high priced commodity owing to the fact that it grows only in a few countries, is subject to much adulteration. For this reason a report recently made by Professor Moissan, of Paris, is of importance. This report states that a new variety of pepper has lately been imported from Kissi, in French West Africa, on the borders of Liberia, which has been called *Piper Famechoni*, heckel, after two investigators, one an Army Surgeon, the other a botanist. Dr. Barille, principal chemist to one of the Paris hospitals, has examined the seeds and found that they yield a highly aromatic reddish-brown powder, rich in essential oil, and with very peculiar characteristics. He considers this variety of pepper an acquisition among the usual plants.—*M. Mail*, Sept. 17.

JAVA QUININE.

The report on the Government cinchona plantations in Java during the first quarter of 1902, has been just issued. In the nurseries there was a large stock of well-developed plants, of which several thousands were sold to private planters. Contrary to what had been the case in previous years, very little bark had been shipped at the end of the quarter, owing to lack of labour. This scarcity of labour is a very grave question, and if the conditions do not improve within a short time it may have a serious effect on the harvesting and the preparation of the soil, which again will injuriously react upon the crops of the next few years. Analyses made with hybrid-grafts during the quarter under review confirm previous observations, that the increase of the alkaloids content is greater in the second year's growth. The analyses showed a content of sulphate of quinine in the first year of 2.74 and 2.60 per cent; second year, 6 and 5.60 per cent; and third year, 7.73 and 8.04 per cent. A large number of grafts were taken during the quarter from *Cinchona robusta*. These could be removed from the nursery and planted in less than three months' time. Ledgeriana and hybrid grafts, on the other hand, require from four to five months. The total number of plants at the Government plantations at end of the quarter was as follows: in the nurseries, 1,245 Ledgeriana, 390,700 Succirubra, and 30,000 hybrid in the open ground, 1,943,500 Ledgeriana, 402,900 hybrid, 343,800 Succirubra, and 45,000 officinalis.—*Planting Opinion*, Sept. 13.

RUBBER ACCORDING TO THE CONSULS.

SENEGAL.—Exports of rubber during the years 1900-1 were as follows:—

Countries exported to	1900.		1901.	
	Quantity tons.	Value. £	Quantity tons.	Value. £
France	380	74,621	318	38,748
U. Kingdom	32	6,476	..	8
Germany	21	..	38	5,509
Belgium	..	4,365
Other countries	50

LIBERIA.—As regards rubber, the Liberian Rubber Syndicate have the whole of its export from the Republic. They pay at present (1902) 1s 1½d cash per lb. in the country. The export duty is 3d per lb.

FRENCH-GUINEA.—Having been a rubber-country for many years, the vines, owing to wasteful producing methods of tapping them, had become com-

paratively scarce, and in order to increase the quantity of rubber for sale, the natives adulterated it in various ways. The merchants anxious to profit by the high market accepted the bales without examination, with the result that the rubber bought from the natives during the season 1899-1900 contained as much as 25 per cent of impurities. The home markets, who could obtain rubber of a much higher quality from other sources, refused to buy the Guinea rubber which thus remained on the hands of the merchants, who, in many cases, were compelled to sell at a loss. The Government has adopted several measures which, it hopes, will remedy this state of affairs.—So as to improve the quality of Guinea rubber, a Decree was issued in May 1900, forbidding the sale of rubber in unopened bales. This has already had a good effect as the natives finding they were certain of detection ceased adding foreign matter, but as the method of coagulating the rubber in calabashes ordinarily employed by the natives made it difficult to detect adulteration with resins, a further Decree was issued to the effect that, dating from the wet season of 1901, the only rubber allowed to be exported would be that prepared by the Foulah method, in red filaments which was found to be the only one which permitted the detection of resinous adulteration.

Exports and destination of rubber in 1899 was as follows:—To France and Colonies £15,943, United Kingdom and Sierra Leone £213,746, Germany £43,622, other countries £6,432, total £279,743. In 1900 it was to France and Colonies £31,521, United Kingdom and Sierra Leone £137,641, Germany £67,384, other countries £16,319, total £252,865.

GUATEMALA.—In 1900 there was india-rubber to the value of £53,012 exported while last year the value only reached £49,510. The coast-lying districts are particularly well suited to this industry, and with a little perseverance and patience planters would reap year by year, more and better crops, and would become independent of the varying prices of the coffee market. The Consul adds:—The cultivation of the rubber tree and the export of the product is a growth entirely of the last few years, and it is undoubtedly an industry which is admirably suited to the coast districts of the Republic, and should more than make up for the apparently permanent falling-off in the coffee-growing industry. Coffee, it has now been found may be grown with ease in all countries where a certain temperature prevails, and the consumption does not increase in proportion to the supply; while on the other hand good rubber is as yet only obtainable in few parts of the world, and the demand increased every day, and this demand seems likely to go on increasing with every new invention and improvement in almost every branch of the manufacturing industries. It is, therefore, worth the while of those who are considering the advisability of a planter's life in tropical countries to enquire into the details of rubber planting, at any rate so far Central America is concerned, where concessions of land are easily obtainable at very cheap rates, and where the huge markets of the United States lie so close at hand. It must be remembered, of course, that the returns are considerably longer in coming in than in many crops for rubber takes 10 years to yield a full crop. A person thoroughly acquainted with these subjects recently explained to me that the method he would follow would be to plant a grove of, say 100,000 plants, which at the end of five years would yield certain crop, say one-third of what fully matured trees should yield. At the end of the fifth year, the plants should be thinned down to half their number, or 50,000, on these 50,000 trees of five years' old a handsome sum would be realised which would entirely repay the original outlay, the running expenses being paid by the cultivation of some such fruit as the banana thus leaving the planter at the end of five years with all his outlay paid, and a grove in his possession yielding a larger product every year, and the expenses of his plantation paid by the secondary crop of bananas.—*India Rubber Trades' Journal*, Aug. 18.

WASTE PRODUCTS :

ARE COIR DUST AND COCONUT WATER USELESS ?

The extent to which waste products regarded as useless a few years ago, are now utilised in a variety of ways, in each succeeding branch of industry, is nothing short of marvellous; and we are hopeful that every year will add to our knowledge of the latent possibilities of much that is even still being thrown away. Now that the Messrs. Böhringer are in the market for tea refuse, no part of the output of upcountry Factories need be thrown away—or, what is even worse, sold to a class of people who will bring it into competition with what is avowedly sold for human consumption, and of which, alas! the markets seem to have too much. But, it is in respect of the products of the Coconut Palm, notwithstanding their proverbial thousand uses, that there seems to be special room for the work of the inventive genius; and, with a staff of skilled scientific workers connected with the Botanic Gardens—the Agricultural Department of the Government—it should not be left to outsiders to show what can be done with our “waste products.” Analysis, for instance, has shown that the husk of the cocconut is rich in potash; and yet coir dust, the residue after the removal of the fibre of commerce from the husk, is regarded as useless, save as an absorbent or deodorizer, and is allowed to rise mountains high in the vicinity of Coir Mills where the dust occupies valuable space and must be a menace to public health. Is it of no manurial value? And can it not be made of value as a manure by the action of fire, or of chemicals? Our German cousins are, perhaps, ahead of any other nation in turning to practical use, their knowledge of chemistry; and, if all we read be true, they have sounded the death-knell of the indigo industry on the adjoining continent. As manure manufacturers they may be able to point the way in the direction we have indicated; but meanwhile we hear of an interesting experiment for the conversion of coir dust into fuel in the form of bricks by pressure. A two-fold possibility unfolds itself to our vision. Not only may the resulting ashes prove highly efficacious as a manure; but there is also the chance that high pressure may disclose more profitable uses than fuel for the brick, and lead to the adoption of the hardened block or building and manufacturing purposes?

Another waste product is the water of ripe coconuts which are split every year in Ceylon to the total of hundreds of millions for domestic use, for copra drying, and for desiccating purposes. The water of the young cocconut is a delicious and refreshing drink. When the nut is ripe, the water is sharper in taste and smacks of toddy. Is it absolutely useless for the distillation of spirits, for the manufacture of sugar and jaggery, and even as a manure? Analysis shows that it contains 1.64 per cent of sugar, .26 gum, .06 phosphate of lime, .10 chloruret of sodium, .33 acetate of lime and of potash

.08 pectic acid, .16 albumine. Are the constituents too small to be of any practical value, considering that the water might well be collected in hundreds of gallons every day? Not very long ago the ashes from Woolwich arsenal were used simply to fill up hollows; an observant neighbour was regarded as a public benefactor when he offered to take all the stuff at 3s 4d per ton. A policeman or a watcher, more alert than most Government servants, observed copper filings being removed from the heaps. He confided the secret to his superior officers who thought they might try the experiment of selling the refuse by auction or by tender. The result was £6 a ton! A big leap from 3s 4d and yielding £10,000 a year. It is estimated that official shortsightedness is responsible for the loss of quite a quarter million sterling at Woolwich through ashes alone. Returning to our own island, we are ready to forget and forgive past losses if only we are let into the secret of making a profitable use of Coir Dust and Coconut Water!

ORANGE CULTIVATION IN EGYPT.

There is no doubt but that the cultivation of oranges is a far too neglected branch of horticulture in Egypt, which has been especially recommended by experts as one of the best suited spots for the establishment of a garden for oranges and other fruits of its class. Although much progress has recently been made in its cultivation in this country, there is still room for much greater extension. At present the export of oranges only amounts to about one eleventh of the import, and, fortunately for those in the orange trade, the fruit comes in at the same time of the year as the annual influx of visitors, much to their mutual satisfaction. The “Yussuf Effendi” is the variety most extensively grown here. These are mostly sold locally or at neighbouring large towns at a fair price. Although a nicely flavoured and satisfactory fruit, it has been cultivated too exclusively. The small variety, sold in England as Tangeriness, fetch about the same price as the best Jaffas. They should prove very remunerative to growers here for export. Belonging to the same loose-skinned group are the “Nagpore” of Bombay and “Sylhet” of Calcutta. Both of these are grown very largely in India and are very much alike. The “Nagpore” tree is a spreading variety while the “Sylhet” is an upright tree, grows higher, and is only grown from seed. Both are excellent varieties for exportation. Two other varieties which should do well here are the “Santolah” and the “Keonla.” The former orange is very small but extremely sweet. It grows almost wild in the hot, humid part of India between the Himalayas and the Ganges. It should be suitable for those parts of Egypt or the Sudan which have a similar climate; but should, of course, be tried in any part which can be kept well supplied with water throughout the year. Naturally, it requires very little attention. As novelties are always acceptable in English markets, and as it is sweet almost before it is quite yellow, it promises well. The “Keonla,” another Indian orange, is to be greatly recommended on account of its lateness. On comparing one of these trees with the “Yussuf Effendi” one would imagine that as both oranges were of the same hue and size they would both be ripe. This, however, is not so. Long after the other oranges have been gathered the “Keonla” stays on the tree until at last its colour is a beautiful dark red, and not till then is it sweet. Of course, in Egypt, this should be ready for gathering just as the “Yussuf Effendi” is over and when the “Portugal” is dearest, at about the end of April. Many other varieties of the Santarah

group, grown in India, Ceylon, South China, the East Indies, and Australasia, might be tried. The Australians have for two or three years been sending oranges to England. They are mostly of the Portugal variety and have reddish skins. This is, of course, rather an attraction, and so they sell at about two or three times the prices of the ordinary ones. Considering that it takes three times as long for ships to reach England from Australia than from Egypt, this should greatly encourage growers here.

Belonging to the Portugal group there are many kinds which ought to be grown here with great success. Already Egypt has successfully reproduced the blood orange from seed—a feat apparently as yet unaccomplished in any other country. Other varieties have been grown well in private gardens. There should, therefore, be a great extension in the growth of the seedless, egg-shaped orange of Malta, the Jaffa seedless varieties, and the "Bisry," which is grown from seed, and is one of the best of Jaffa oranges. All of these are too well-known to need description. The great advantage of this class of orange is its keeping qualities. With careful packing it will keep for two or even three months. The British Chamber of Commerce in Egypt reports that the egg orange has been introduced into Florida, and has been so successfully cultivated that it is probably now more extensively planted there than any other kind. In Malta there is said to be also a nique orange of the same group which is never sour from beginning to end but sweet and juicy. It is there called "Loomi Larenj." Such an orange should be well worth cultivating and should always command a good price. Another orange sold in Bombay, the "Mussembi," is brought from Poona, and it is said that it can be kept on the trees for a whole year without deteriorating. The Chamber of Commerce rightly complain that the "Leimoun Hindi," often exhibited at our horticultural shows, is not properly cultivated. To obtain a really delicious fruit the trees must have, as nearly as possible, conditions of soil, heat, and humidity similar to what they have in the island of Labuan and at Amoy where they grow to perfection.

As regards the treatment of the orange tree, practical experience combined with logical reasoning is of far more value than theoretical book information. Nevertheless, it is both interesting and very useful to read of results of others' experiments and work, and to profit by their successes and failures. The number of trees per feddan should be, to obtain the best results, one hundred. At Jaffa, however, as many as six hundred per feddan are generally to be found. Abundance of irrigation water is the *sine qua non* of a plantation and the watering should be done continually. The fruit consisting of over 90 per cent water, it will be understood that without a sufficient supply the tree cannot possibly do well. The average of several analyses of the orange shows that there are four parts each of nitrogen, phosphoric acid and potash per thousand. Calculating from this, 1,000 kilos of oranges will contain 4 kilos of each of these three constituents. Growers generally fail to supply this amount again to the soil, and, consequently, it gets weaker and the produce of oranges less. To obtain theoretically this amount of each, the trees supplying the thousand kilos of fruit should receive $2\frac{1}{2}$, $2\frac{1}{2}$ and $\frac{1}{2}$ kilos respectively of nitrate soda, superphosphate of lime, and sulphate of potash in return, besides an additional quantity for their growth of wood and leaves. Manure is one of the absolute necessities of the orange tree if it is to produce well. Every piastre properly expended in well manuring the trees brings much over a piastre's worth of extra fruit, either numerically or in size, besides giving a better flavour to it. The soil of Egypt is admirably suited to the physical requirements of the orange tree. A perfect soil is a mixture of sand and a little clay and lime. The lightness of this soil allows the water to sink in easily and the roots to spread out well. Now, if there be added to this good food for the tree, it can, of course, do well. The Nile mud, like the "loess"

of China, is a typical fertiliser. But growers must remember that where the deposit is thin or absent cultivation cannot be carried on profitably without, abundance of artificial manures. Speaking in a simple way, nitrogen produces wood and leaves phosphates produce fecundity, and potash produces sweetness and flavour. Lime is absolutely necessary for the orange tree, which absorbs great quantities of it. If not present in the soil it should be supplied in the form of Gypsum. If too abundant the sap will not run freely but $\frac{1}{3}$ kilo of sulphate of iron for each thousand kilos of fruit produced will correct it. The Gypsum and iron sulphate also help to fix the fruit on the tree. Seeds should not be treated with mineral fertilisers but should be given plenty of organic food. Stable refuse is excellent for the seed beds, but it should be passed through a very coarse sieve and the big straws taken away. Most people in Egypt make the mistake of digging holes round their trees and filling these with water. Instead of a bole, in the middle of which stands the tree, a ring should be made so that neither fertiliser nor water will touch the trunk. One very successful orchard owner bores holes in the ground in a circle round the tree varying in the size, depth and distance from the stem according to the size of trees. These he frequently fills with liquid fertiliser so that the roots thus receive a greater benefit and the tree can better keep its upright position. The best time to apply the manure is about a month after the gathering of the crop and again when the fruit is about half-grown. Thus the first part will strengthen the tree for producing the fruit and the other part will supply the nourishment for the fruit when growing.

Lemons, limes, citrons, and other trees of the Citrus group require almost the same treatment. The lemon and citron need more nitrogenous manures than the orange to the extent of about 12 per cent, and the other sour fruits of about 10 per cent. Lemons in this country are smaller but more juicy than others, and limes are very inferior. Both would repay generously more liberal feeding. A few only of the best and most suitable kinds of oranges have been named. There are many others which might be grown to advantage. Young trees and picked seeds can generally be obtained from the nurserymen and horticulturists in the different countries. Those who are anxious to obtain them would, no doubt, be able to get information and help from their respective Consuls. It is to be hoped that orange-growers will take "Excelsior" as their motto, and that we shall soon see a great development in the orange trade. With a little experimenting and care, many new varieties should be well-established and both quality and quantity improved. Those who prefer to keep to their present variety should at any rate spend a little on improving it. One thing is certain, any expenditure the growers may make in doing either or both will prove a good investment.—*Egyptian Gazette*, September 2.

THE DIFFICULTIES OF SELANGOR COCONUT PLANTERS.

Mr. Tanner, of the Kempsey Estate, Kuala Selangor, has again been visited by elephants. They damaged over six acres of young coconut trees. Two Malays followed the herd and state that they wounded some of them. This is the third time that Mr. Tanner's Estate has been similarly patronised.

It is reported that the Inspectorship of Coconut Trees is to be a Federal appointment. Mr. Grieve, of Kapar, is making a collection of the various kinds of coconut beetles, which he will ultimately hand over to the officials.

There is a report that there is a particularly bad bit of coconut-beetle infested ground immediately adjoining a Malay school in the neighbourhood of Kuala Selangor.—*Straits Times*, Sept. 12.

PLANTING NOTES.

OLD TREE STUMPS.—To remove old stumps, a correspondent to the *Country Gentleman* gives the following:—'Get a 2 inch iron pipe, 8 ft. long; have a steel point wedged into one end of it. With a sledge hammer drive this under the stump as far as may be necessary. Drop half a stick of dynamite into the hole thus made, and tramp earth upon it until the hole is filled, then light the fuse. The stump will be lifted entirely out of the ground with no earth adhering to it, so that it may be burned the next day.'—*Agricultural News*.

INCREASED EXPORT OF RAMIE FIBRE FROM KIUKIANG.—In his recent report on the trade of Kiukiang for the year 1901, the Acting British Consul at that port states that there was a marked rise in the export of ramie fibre, from 95,689 ewts., valued at 87,596*l.* in 1900 to 116,294 ewts., valued at 114,164*l.* in 1901. This is explained by the success of the experimental shipments to Germany having led to a continuance of such shipments by German firms in Shanghai. The average price was also higher than in 1900, and the Consul is informed that the advance has continued, so that this fibre, which is produced in the neighbouring part of Hupei, now commands 13 or 14 taels a bale instead of 10 or 11 taels.—*Board of Trade Journal*, Aug. 28.

COTTON AND COTTON SEED INDUSTRIES.—According to the annual report for 1901 of the British Chamber of Commerce of Egypt, the cotton crop of Egypt this season will prove to be a large one about 6½ million cantar, [Cantar=99 pound-], but the quality of it has been considerably damaged by fogs and rain. The question of quality is being much more studied by intelligent cultivators, and efforts are being made towards a more careful selection of sowing seed. This attention is certainly necessary, as there has been a noticeable falling-off during the last two or three years in the quality of the Mit. Affili cotton, which is the main cotton of the country. Yannovich and Abassi qualities have again been cultivated with success, and some fine samples of each have been produced. Yannovich has especially found favour, the fineness, length and strength of its staple has made it a suitable for American Sea Island cotton, the crop of which has been short in the last year.—*Board of Trade Journal*, September 4.

SOIL ANALYSES.—Many people hold erroneous ideas as to the value of soil analyses, some speaking as though they only required to have the soil analysed to know what manures to apply to certain crops to obtain the best returns. This, however, is far from being so. In the first case, it would be nearly impossible to obtain a sample that would fairly represent even a ten-acre field. Besides this, an analysis will only show what the soil contains; it will not tell whether the plant food is in such a condition that the plants can make use of it, neither will it tell him what treatment the soil requires to make that plant food available. So many other things, such as the physical condition of the soil and subsoil, its ability to retain moisture or perhaps the reverse, have to be taken into consideration that (except to the scientist) a soil analysis is just as likely as not to prove misleading in dealing with the manures such a soil requires. The only guide is experience. Find out what others have done under similar conditions, and prove by experiment whether the treatment beneficial in their case is equally so in yours.—*The Planters' Monthly*.

GAMBIA.—The quantity of rubber exported in 1900 was 125,446 lb., in 1901 146,573 lb., being a decrease of £1,254 in value.—*India Rubber and Gutta Percha Trades' Journal*, Aug. 4.

INDIAN TEA COMPANIES FOR 1901-2.—Mr. George Seton shows that about half of these companies show increased profits, as compared with the previous year, while the other half have had their profits reduced. Taken all round the profits were larger than in the previous year, but the amount distributed in debenture interest and dividends was much smaller. The total net revenue works out at £319,000, as against £279,600 in the previous year, and the average rate of dividend, including debenture and preference interest, is 2·72, as against 3·90 per cent. This lower return, in spite of bigger takings, is not due altogether to increased capital on which distribution has to be made; but may be attributed to the more cautious policy of the directors in keeping larger sums in hand, so that whilst the aggregate capital has only grown 4 per cent, and is accounted for by the fresh issues of four concerns, the total sum placed to reserve and carried forward has expanded more than 15 per cent. The production per acre fell from 487 lb. to 421 lb., but the profit per lb. increased from 0·85*d.* to 1·03*d.*, and the sale price was nearly a third of a penny per lb. better. The ratio of operating expenses to receipts was 86 as compared with 83 per cent, and the profit on the total capital employed is equal to 3·50, as against 3·20 per cent. The situation revealed by this carefully compiled table is that each garden or group of gardens should be considered by itself, and that it is difficult to generalise on the whole industry from the results of any particular working.

WEST INDIAN ESSENTIAL OILS AND ALOES.—At the Agricultural Conference held recently at Bridgetown, Barbados, under the presidency of Dr. D. Morris, C.M.G., Imperial Commissioner of Agriculture for the West Indies, Mr. J. H. Hart (Trinidad) read a paper on "The Preparation of Essential Oils in the West Indies," an industry which in the past has mainly been connected with Dominica. Mr. Hart exhibited specimens of fifteen kinds of essential oils, which he had prepared from plants grown on the lands of the Botanic Department, Trinidad. He discussed the various oils, described their mode of manufacture, and suggested steps which might be taken to encourage the industry. Dr. H. A. Nicholls (Dominica) and Mr. W. Fawcett (Jamaica) discussed the paper, the latter exhibiting a specimen of the oil of *Cananga odorata*, which he had prepared. Mr. W. G. Freeman, technical assistant, Imperial Department of Agriculture, also read a paper on the "Aloe Industry of Barbados," which had now almost dwindled away. Mr. Freeman pointed out the former magnitude of the industry, the exports being sometimes of more than 7000*l.* per annum, described the soil, cultivation and manufacture, indicated the detective methods which led to the decay of the industry, and made some suggestions for the future. Living specimens of Curacao and aloe plants were exhibited. The paper was Barbados followed by a discussion, to which Prof. Harrison (British Guiana), Mr. Francis Watts Leeward Islands, Mr. W. D. Shepherd (Barbados), and the President contributed.—*Chemist and Druggist*, August 30.

IRRIGATION IN INDIA.—The scale on which irrigation works are provided in India is not, we fear, appreciated by those who denounce official neglect whenever a famine occurs. We learn from an Indian paper that the irrigation statistics for 1901-02 break the record. The previous maximum area under canal irrigation in one year was 18½ million acres. The area now under irrigation exceeds 19½ million acres.

CASSAVA.—An important Experiment.—Swift and Company and other Chicago packers, have begun experiments on a project for shipping stock to Florida and fattening it on cassava root. This project was broached about year ago by southern men and representatives of the Louisville & Nashville and an investigation was made. It was found that cassava would grow well in waste land in northern Florida and southern Alabama and was a splendid cattle feed. Investigation so far made it appears that it would be much cheaper to send stock to Florida to fatten than to the western ranges. It is said that 1,000,000 acres in the South are available, much of it government land, ready for homesteaders. The value of cassava as pig food and for making starch is being looked into. The project will be undertaken gradually, and ultimately may result in large and profitable changes to the packing industry.—“News Bureau,” Boston.—*Jamaica Agricultural Society*, August.

PLANTING MANICOBIA RUBBER IN SERGIPE.—In a report on the title state of Sergipe (Brazil), the coast line of which lies between the ports of Pernambuco and Bahia, the United States consul, Mr Henry W Furniss, mentions that in 1898 the state appointed a commission to report upon the introduction of the Ceará variety of rubber for cultivation, should improve advisable. The commission visited Ceará, where the Manicoba rubber trees were originally found wild and are now under extensive cultivation, and as a result of their investigation Manicoba has been planted in various parts of Sergipe. The consul has seen two plantations, one with about 17,000 trees and the other with more than 20,000 both three years of age and apparently in a flourishing condition. Manicoba is grown from seed, planted at the commencement of the rainy season, 12 to 15 feet apart, usually three seeds to a hill, the most vigorous resulting plant being left to stand. Some planters file one end of the hard seed—which much resembles the seed of the castor bean—to assist germination; others soak the seeds before planting, but generally the seed is planted without previous preparation. It is said that the plant will grow on rundown sugar lands. It is cultivated on the sandy soils of Ceará, but it doubtless will succeed best on good farming land. The tree requires little attention, in many places the soil receiving no cultivation, and reaches a height of from 12 to 36 feet in four to six years. It yields rubber at a very early age, the average stated at about 2½ years from planting, when from 7 to 35 ounces of rubber may be obtained in a season. Rubber is obtained by removing from the trunk a V-shaped piece of bark, to the lower angle of which a small vessel is placed to collect the latex. Coagulation is assisted by smoking, as in the case of Para rubber, though the latex will coagulate spontaneously in the air. The cost of planting and gathering the initial crop is stated to be less than in the case of coffee, sugar, or cotton, while the profit is greater, and the consul believes that the new industry will become important.—*India Rubber World*, Aug. 1.

GRAPHITE (PLUMBAGO).—In the State of Travancore there are four mines from which graphite was extracted in 1901-02 to the amount of 2,490 tons. No information has been given of the quality of the graphite. It is doubtless exported, but no particulars of the trade have been furnished, nor are the capabilities of the mines known.—*Indian Agriculturist*, Oct. 1.

PLANTING IN MYSORE.—At an extraordinary General Meeting of the South Mysore Planters Association held recently the subject of the Coffee Cess was discussed, and the proposal that the Agents should be asked to raise their rates by Rs 5 per ton to provide for the Coffee Cess met with very little support. As regards limitation of advances to coolies, it was unanimously agreed that advances should be limited to Rs 20 per head.—*Pioneer*, Oct. 9.

THE PEPPER TRADE OF SIAM appears to be improving, though not extending in area. Last year the exports amounted to 1,156 tons, and the prices varied from 8¼d to 9¼d in the London market. Prices have a tendency to rise each year. The latest account says that this year pepper is coming in rapidly, but the export will probably only amount to 70 per cent. of that of 1901. Prices have been steady for the new season's pepper, which began to come in at the end of March. Most of it comes to London.—*Globe*, Sept. 12.

CEYLON TEA FOR THE PHILIPPINES.—We direct the attention of the “Thirty Committee” to a letter of an American gentleman, Mr. Dunleary, written from Mindanao in the Philippines, which has been prompted by his reading in the *Tropical Agriculturist* of the efforts made by Ceylon planters to push their teas. He points out that there is an excellent field to be exploited in the Philippines—where inferior China tea is now chiefly used—and that the Americans who once got used to the flavour of Ceylon tea would carry the taste back with them to America and there demand the same tea. What surprises us in this connection is that an enterprising Ceylon man like Mr. Tom Stephens, the well-known Dentist, established for some time in Manila, has not put a tea merchant there up to importing from Colombo, or gone in for a trial shipment himself. He will in due course read Mr. Dunleary's letter and may have something to say about its contents. Meantime the “Thirty Committee” should pass a hearty vote of thanks, in the name of the whole body of our tea planters, to Mr. Frank J. Dunleary for the testimony he bears as to the repulsive nature of much that he himself has seen in connection with the preparation of China and Japan teas. This testimony ought to be reprinted in large type above Mr. Dunleary's name, for circulation all the world over, but especially in North America. Owing to some blundering at this end which we cannot understand, Mr. Dunleary's letter, which is dated May last, only reaches us now. He encloses a second letter for the “Planters' Association” in which he mentions a Manila Tea House as suitable for an Agency for Ceylon Tea. But Mr. Dunleary has to learn that the planters or their Association do not establish Agencies. That must be done by the merchants of Colombo in the regular course of business.

CINNAMON IN LONDON.

It is of interest, after our reference on the 19th Sept. to the *London Commercial Record*, to turn to the specific expert report on the last quarterly sales of cinnamon—the source from which we have chiefly quoted for many years past. From the report, which bears date the day after the auctions, we learn that the quantity offered was a fair average one of 825 bales—the offerings at the corresponding sale last year having been 853, and in May this year 433. Had London been our only market for the famous Ceylon spice, as it was practically until the opening of the Suez Canal, the smallness of the previous quarterly catalogue would have led to keen competition, and to an advance in prices; but, as the *Commercial Record* observed, the Continent is supplied direct through its own Ports, to which generally foreign merchants now ship produce direct from the producing country. As a matter of fact we sent to the United Kingdom less than one-third of our quilled cinnamon—812,280 lb. out of exports totalling over 2½ million lb.—and 239,000 lb. chips out of over a million and-a-half! Germany took almost thrice the quantity of chips and about 57,000 lb. quilled bark more than the United Kingdom; while Belgium, Italy, Spain and America, all ran into pretty high six figures. Though London no longer holds the proud position she did in the spice market, she doubtless has among her constituents in the spice trade some of the best of her old customers. While it must not be forgotten that the volume of trade has about trebled, so that London attracts perhaps as much as she ever did in ante-Suez Canal days; while it is also a fact that the highest priced cinnamon continues to go to London. In the report before us, for instance, First quality of worked cinnamon fetched up to 1s 8d; seconds up to 1s 7d; thirds up to 1s 5d and fourths up to 11½d. We doubt if even one bale of cinnamon has changed hands locally at anything approaching these prices. The prices paid in the Port for Firsts, we understand, are about the equivalent of what fourths from good gardens like Goluapokuna fetched at the London Quarterly Auctions. If the Continent of Europe and America draw almost all their supplies from Colombo direct, London still continues to monopolise our best marks, chiefly it is believed for old Spanish and Italian houses which ask for the finest quills the island can turn out; and if its prices no longer regulate local rates, yet London pays for what it likes, double the prices which are quoted in local Price Currents!

As we said, the prices which ruled at the last auctions did not advance as expected because of the smallness of the offerings at the previous sales; but such as they were, they leave no cause for dissatisfaction. Previous rates were generally maintained, and where there was a fall it was easily explained. Altogether, as has been remarked, the spice market was about the only one in which produce showed some animation last month;

but heavy shipments have gone forward since then; and we are not sure that the next sales will show as good an average. Any way, the stocks are not heavy; and there is hope in that. Elsewhere (see page 7) we give the usual London Report on last sales.

SALT IN THE SOIL IN INDIA AND CROPS.

The soil in some parts of the country is very salt and so is the water of many of the wells. As it is important to know how far this affects their value for agricultural purposes, Dr. Leather, Agricultural Chemist to the Government of India, has investigated the effect of the salt on crops. He has found cereals growing well in soil which contained 0.099 per cent of sodium carbonate, and 0.018 of sodium chloride in the Cawnpore District. In the Aligarh District, wheat grew well in one case in the presence of 0.044 per cent of carbonate plus 0.021 of chloride, and in another in the presence of 0.137 per cent of carbonate plus 0.062 of chloride. The crop failed, however, in the presence of 0.193 per cent of carbonate plus 0.01 of chloride in one plot, and of 0.251 per cent of carbonate plus 0.008 of chloride in another. It is remarkable that such a small difference should be found in the amount of salts present in the soil when the crop grew well in the one case and failed in the other, but this is confirmed by similar results obtained in California. Dr. Leather finds the explanation to lie in the respective amounts of rain-water which the several soils would allow to enter at the surface. The word 'drain,' he says, cannot here be properly used, because the presence of these salts is a proof that the drainage conditions are extremely imperfect. But one soil will allow more water to descend into the surface soil than another. This would produce more dilute solutions of the salts in the one case than in the other, and it would explain why considerable differences in the growth of crops may occur in soils which contain much about the same proportion of salts. It is, indeed, a question of concentration of solutions that must be considered rather than weight of these salts per hundred parts of soil.

The water of many saline wells is used for irrigation. For instance, in the Muttra District of the United Provinces the water of such wells is considered by the people in some cases to be fit for application to the land before sowing, while in others it is applied to growing crops. Dr. Leather finds that in the latter case there is often a considerable proportion of nitrates in the water. In Gujerat he has observed that when the amount of total salts is high, the water is mixed with that from less saline wells. When the water does not contain a good proportion of nitrates, it cannot be used for irrigation in the absence of a good rainfall. Used alone in dry weather, such water is practically fatal to crops. A distinct line cannot be drawn between waters which are fatal and those which are not, but Dr. Leather finds that the most that crops such as cereals will bear is a solution containing 0.5 per cent of salts.

More generally, Dr. Leather finds that crops may suffer in solutions of 0.3 per cent of total salts, those which are most easily affected being the *Leguminosae*. In order to compare this result with that showing the proportion of salts in soil, he says that it may be assumed that the proportion of water in soils varies, shortly after irrigation, from 30 per cent to 10 per cent according to the nature of the soil and the climatic conditions. A soil containing 0.1 per cent of salts and 30 per cent of water may thus be considered as holding a solution of 0.33 per cent of salts. Dr. Leather infers from the agricultural effects of well waters that such a proportion is as much as cereal crops can bear. He therefore considers that a soil containing so high a proportion as 0.1 per

cent of total salts could only be expected to bear good crops if the water supply were regular throughout the season.—*Madras College Magazine.*

THE SAPPHIRE MINES OF ANAKIE, QUEENSLAND.

During my recent visit in Central Queensland I was asked to visit the sapphire mines of Anakie, 200 miles west of Rockhampton by rail. From Anakie railway station to the nearest mines, on Retreat Creek, is nearly eight miles. The oldest and most extensive rock masses in the Anakie district are granite and its varieties, assumed to be of metamorphic origin. Gneisses, schists, and slates rest against the granites, and are everywhere found in contact with them. Intrusive rocks, acidic and basic, occur throughout. The former, consisting of pegmatite, felspar, porphyry, and felsites, are in great abundance, and traverse the granites and gneisses in all directions. The basic rocks are hornblende, and are either massive hornblende, or else diorite. There are also outcrops of massive epidote rock and garnet rock in places. There is a younger formation, making a break between the other rocks. This consists principally of shales, sandstones, and conglomerates. The remnants of the pre-existing formation consist of boulders of hard flinty quartzite, of general occurrence in Central Queensland, and designated "billy." It occurs exclusively as boulders in the alluvial sapphire deposits. The sapphires are distributed over a large area, but nearly all are confined to the granite country. The deposits occur on the banks of the creek, but very rarely are they found in the beds of the present streams. Sapphires are found in the basalt at an altitude of 500 feet above the highest alluvial deposit.

In addition to gems there are found black tourmaline in abundance, titanite, pleonaste, and magnetite. At Sheep Station Creek there is a small outcrop of schist, sections of which show it to be hornblende, quartz, and red garnet. Policeman Knob, close to Policeman Creek, is remarkable for the number of white and coloured zircons found in the alluvial deposit below the basalt, but so far no sapphires have been got from the deposit.

The thickness of the gem deposits varies from a few inches to several feet. The bottom is usually a reddish clay, and below this clay another and sometimes richer deposit has been found. The sapphire wash is frequently clayey, and requires "pudding" before the gems can be extracted, but much of the wash is loose and friable, the sapphires being obtained by "dry sieving." In several parts of the field the wash is of enormous thickness, but very little prospecting has yet been carried on.

THE SAPPHIRE FIELDS.

The field is divided into four camps; I found the wash varying greatly in thickness. The wash includes, in addition to several varieties of "billy," red and brown jasper quartz, fibrous hornblende, magnesite, tourmaline, topaz, pleonaste, rock crystal, and several varieties of chalcodony. Several rubies have been found, which, compared to the blue, green, and yellow sapphires, are exceedingly rare. Some very fine stones have been found on this field, amongst them two very fine yellow, weighing nearly 50 carats each. The blue stones found are, as a rule, dark, but the green stones, when free from flaws, are very fine gems. Some fine hyacinths, a variety of the zircon, are also found at times. On Hunt's claim, one of the

best on the field the stones found were large blue and others of a beautiful light yellowish green. Zircon, garnets, and amethysts have also been found. I saw a fine yellow sapphire weighing close on 80 carats, and some fine green stones. Crystallised corundum has been found on this claim. One of the most brilliant yellow stones ever obtained, and which after cutting weighed 33 carats, was got in this mine. The Policeman Creek camp is celebrated for a diamond weighing 1½ carat, found in M'Chrystal's claim. The miners thought it was a white sapphire, but during Mr. Dunstan's visit he set them to rights on that point. It is quite probable that others were found previously and sent away with parcels of stones, as two other diamonds have since been found on Retreat Creek. Large sapphires are found on Ignana Flat; but from there to the lower end of Policeman Creek there is a gradual diminution in the size of the stones, although the blues of Ignana Flat are not as good in colour as those on the creek. The green sapphires found on the Central Creek are often of a brilliant shade. The sapphire deposits are, however, most extensive on Tomahawk Creek. Mr. Dunstan says that in places they are a mile in width and several miles in length. Occasionally there is a break, but otherwise they wind about on both sides of Kosky's Creek. The total distance along which the deposits are found in this camp is about 15 miles.—*Sydney Mail*, Sept. 6.

CEYLON TEA ON THE CONTINENT OF EUROPE.

Mr. J. H. Renton sends us three pamphlets bearing on Ceylon Teas. One is in Russ very prettily got up with 20 fine illustrations showing all the operations of tea planting and manufacture and even of despatch by steamer, with appropriate letterpress. Another in French "Rapport sur le The de Ceylon" by Dr. Doorkevitz and a third in German, a translation of the latter. The Russian chemist who writes these is well-known in the scientific world and in 1890 he gave some lectures at St. Petersburg upon Tea, especially showing its alimentary value. Not only is tea valuable as a stimulant, but it serves to create the heat necessary for the functions of the body. A table follows shewing the amount of caloric required every twenty-four hours and the quantities of hydrates of carbon, of albumen and fat required for the production of so much heat or energy, by means of which the functions of the body are carried on. To understand the influence of tea as a factor in the alimentation, one must study the two tables given, drawn up by Messrs Franklaud and Pavey, shewing the relative value of each food for muscular work, also the weight of nourishment necessary and the quantity to maintain a working man. In the table we note that the energy created by the consumption of so much carrots and potatoes—or of a much smaller quantity of beef-fat is the same. It followed then that with the man who lives on carrots &c., a considerable amount of energy will have to go to digest the food and he will never have the activity he might have had, if he had taken a more substantial food, of less volume.

In order to understand the place of tea in alimentary economy, we must study its analysis which is fully given and it is explained how tannin oxydises the blood and by combining with the albuminous matter of the tissue of the body hinders their destruction. The theine is doubtless nerve tonic, say they, and acts in the same way as would alcohol.

All this will appeal to Continental readers in their own languages.

GARDENING ON TEA ESTATES.

(For "*Indian Gardening and Planting*")

In Indian Gardening and Planting of 17th July 1902, you ask, under the heading of "Gardening on Tea Estates," "Why should not every tea planter in India turn his attention to the cultivation of the beautiful in nature? . . . The tea planter has every facility for successful gardening ready to his hand."

The answer to this question is not far to seek; and it is this: Few men or women *have it in them* to take the trouble that successful gardening requires. A man who has it in him to do this, will teach himself gardening almost under any circumstances. There is no recognised institution in India to which a youth, who is intended for a planter, can be sent to acquire a love of plants, and the rudiments of the way that they should be dealt with, in order to make them respond to one's wishes. Most children are fond of flowers—some are passionately so—and would intelligently learn a good deal about them, if they are taken early in hand by some one who knows how to deal with children's brains, and to put in them the best and lasting notions. But this natural love of plants is allowed to be frittered away by all sorts of distracting notions; so that after a time the child begins to look upon the time and trouble of attending to plants as a bore and is always wanting to do something else; as the child grows into a boy, with all manner of distracting thoughts, it is hopeless in most cases to try and win him back to gardening.

As men get old they begin to lose interest in this, that and the other pursuit, but if in their childhood and youth they have had their love of plants fostered, and have acquired the rudiments of gardening, that pursuit they will *never* tire of. In their spare moments they will be always in some garden, or wild place prying into the ways of plants and flowers. It is doubtful whether a child or a boy will take to plants unless he has it naturally in *him*, and feel a pleasure in discovering their secrets, or at all events in learning something about their ways. Parents are a great deal responsible for not having children taught more about gardening than they do. For instance, what is the first thing a mother in London thinks of doing when her children return home for the Christmas holidays? The first thing she thinks of is to take her boys and girls to the Pantomime, to see what?—a regiment of pseudo-nude girls dancing in a ballet and a lot of imbecilities in the bargain. The boy probably has awakened in his brain convolutions something very different from gardening, when he beholds those troops of girls rigged up in imitation nudity—something to dream of for months while he is trying to read his books on returning to school. I once asked a little girl, who was with her mother for Christmas holidays, this question: How long does it take you to gather up your thoughts again for renewed school work, when the Christmas carnivals are over? She replied *about two months*. The boy probably takes longer. Mothers are mostly ignorant, and do not understand the automatic action of the human brain; and that when she puts the exciting glamour of a pantomime into a child's head it is difficult to put it out again; and most of these boys and girls are supposed to be in training for making their own way in

the world later on. I do not suppose that more than one per cent of mothers look upon the future lives of her children as a life of struggle for existence. Pantomimes don't appear to help one much in that direction. It is only today in one of the papers I read that in a certain technical school they find a difficulty in getting students to come to be taught! The youth's brains are stuffed with a craving for amusement. I know of an official in India who had a son in Loudon training for the Indian Civil Service. He failed. Then he was coached for the Army. He failed again, and finally he was turned into a tea-planter. Not improbably in his new function, whatever that may have been, after the day's work he wound up in some verandah with his legs on the long arms of those curious chairs, smoking and drinking whisky and soda. How could such a creature take to gardening, in spite of "every facility for successful gardening ready to his hand." Probably he never knew even, or had the sense of observing that plants had sexes like himself! It is true that great efforts are now being made to bring boys and girls face to face with the realities of nature in what are called "nature studies." But with the dreams of a pantomime in his head what can a boy care about beetles and nettles? If the boy has it in him, and his father intends him to become a planter, there are facilities for training him in a knowledge of plants and their ways both in the Royal Gardens at Kew, and in the Horticultural Gardens of India. But do they, or will they take advantage of these institutions? I was, on one occasion, in the principal hotel in Kandy for a month. Periodically bachelor planters used to come down to the hotel, have a "blow out," and get tipsy, and make a row. The ennui of life with such creatures must have been great, and they had no outlet for their energy beyond that of driving coolies. To such persons a love of gardening would have been a Godsend. LONDON, Aug. 22nd, 1902. E. BONAVIA, M.D.
—*Indian Gardening and Planting*, Sept. 18.

CEYLON GAME PROTECTION SOCIETY.

Copy of minutes of a general Committee Meeting of the Ceylon Game Protection Society, held at the Hill Club, Nuwara Eliya, on Saturday, September 20th.

Present:—Hon. Mr. H Wace, Chairman, Messrs. C H Bagot, P R Shand, C C Wilson, J Wickwar, M J Kennaway and T Farr, Honorary Secretary.

The minutes of last meeting were read and confirmed.

Messrs. C C Wilson and M J Kennaway were proposed as members of Committee and duly elected.

The Honorary Secretary submitted a letter from the Colonial Secretary (No. 09,092) of June 13th, 1902, explaining circumstances and correspondence antecedent thereto with amended form of licence proposed by him.

The amended form was approved by the Committee and the Honorary Secretary was authorised to submit the same to Government.

The Honorary Secretary submitted a question of retention of watchers on the Meda and Kadawata Korales, Sabaragamuwa. Resolved:—"That the G. A. Sabaragamuwa be requested to be good enough to inform the Secretary, how these watchers are employed, and under whose immediate supervision, and to give a return of all cases instituted under the Game Protection Ordinances with result of same."

The Honorary Secretary brought to notice of the Committee, the question of the altering of the close season of the Eastern Province appearing in the Government Gazette No. 5,838—of March 22nd, 1902. Resolved:—"That previous to the altering of close seasons in any Province, the

Government Agent be requested to kindly submit the proposal for the opinion of the Game Protection Society's Committee."

The Honorary Secretary read out the Proclamation by Government of June 30th, 1902, relative to the export of horns of sambar and spotted deer and proposed that the Game Protection Society desires to record its thanks and full appreciation of the act of Government in issuing the said Proclamation.

The Honorary Secretary submitted particulars of a case of hunting by coolies in Maturatta in Crown forest and his letter to the Hon. the Colonial Secretary on that subject. It was resolved:—"That no further action was advisable in the particular case reported."

A vote of thanks to the Chair terminated the meeting.

Before the business of the meeting had commenced Mr. P B Shand inquired whether the admission of the Press reporters was in order, as they were in Committee and it was unusual to discuss matters of a private nature before the said representatives. The Honorary Secretary expressed his desire that the meeting should be reported, as there would be several matters coming forward, which it would be desirable to make public through the medium of the press.

Mr. C H BAGOT expressed his regret that Haputale was not represented at the meeting and the Honorary Secretary stated that he had called the attention of Messrs. J R Barkley and W Ormiston to the meeting by post cards in addition to the usual notice in the newspapers. With regard to the first subject under discussion by the rule prohibiting shooting in the Hill Reserves above 4,000 feet the Honorary Secretary gave a sketch of the history of the subject from the date of its origin terminating it with the letter from the Hon. the Colonial Secretary of June 13th, 1902. That letter being the immediate cause of the present meeting. The facts of the case are briefly these. Some two years ago the shooting of sambar in the Hills round about Nuwara Eliya by Tamil coolies and other poaching rascals had become so prevalent that the C G P S appealed to Government to put a stop to it, in the interests of sports-men generally. Hence the rule was made. It was, however, too comprehensive in its scope, and some objections to it were raised by certain members of the Society resident in Uva. On October 17th, 1901 at a general meeting of the Society attended by representatives from Haputale, the matter was thoroughly discussed, and a resolution in the form of an amendment was carried unanimously as follows:—

"That where registered packs of hounds are kept the killing of sambar be confined to stalking with the rifle at any elevation and to killing with the knife and hound."

The Hony. Secretary on October 30th laid the matter before Government forwarding copy of the resolutions passed at the meeting and on November 20th received a reply which entirely failed to help matters at all. On April 2nd, 1902 at a General Meeting of Society the subject was again brought up and again a resolution was passed emphasising the amendment passed at the preceding meeting.

The Hony. Secretary drew the attention of Government to the proceedings of the two meetings and received a reply dated June 13th 1902,

"Requesting him to forward a draft of the license, which would meet the wishes of the G P Society as some difficulty was experienced in comprehending its precise wishes.

The above retrospect brings the question up to the proceedings of the meeting now under review, and the following draft of a license with amended conditions was submitted by the Hony. Secretary as meeting the wishes of the Hony. Secretary of the Haputale branch in accordance with the proceedings of the two general meetings of October 17th and April 2nd.

Conditions of License referred to:—

- I. Shooting at night and netting are prohibited.
- II. This license is not transferable and can only be used by the person named in it.
- III. Hunting by men in gangs carrying sticks or guns with or without dogs is prohibited.
- IV. "Shooting elk and spotted deer within the Hill Reserves above 4,000 feet is prohibited except with the permission of Government in writing. The only modes of killing elk and spotted deer allowed within such reserves is hunting with dogs to the knife or stalking with the rifle."

This form of license being unanimously adopted by the meeting. The Hon. Secretary was requested to forward a copy to Government for approval.

The Hon. Secretary then brought up the question of the retention of the two game watchers employed in the Meda and Kadawala Korales of the Sabaragamawa District, stating that he was dissatisfied with the lack of information from the Katemahatmaya of those Korales with regard to what had been done by them. He (the Hon. Secretary) submitted that the country, wherein these watchers were employed, was not in any sense a sporting country and he was doubtful whether the G. P. Society benefited in any way by their employment and remarked that they would be far more useful in the Province of Uva as it was very desirable that the game as it overflowed the boundaries of the Yala Sanctuary should receive immediate protection. The Hon. Secretary also mentioned that when passing through the very centre of the country supposed to be patrolled by these watchers he received numerous offers from the villagers to get up deer drives and this was in the close season. The Katemahatmaya, however, of the Korales referred to, has reported to the Hon. Secretary that much good has been and is being done by the watchers. Hence the resolution which was carried at the meeting.

In introducing the subject of hunting by coolies in Maturata District during the close season of this year the Hon. Secretary explained that he had received a complaint from Mr Thorpe, of Ellamulla estate, requesting the services of one of the game watchers of the Society to assist him in detecting a gang in the act of hunting. There appears to have been some mismanagement for instead of waiting until the gang was actually engaged in pursuing or attempting to capture sambar, they were seized in the Crown forest and their guns and dogs taken from them. The Hon. Secretary, pointed out that the charges of the guns which were drawn and examined, consisted of bullets, slugs and heavy charges of powder and that the men had undoubtedly entered the forest with the object of killing sambar.

Proceedings, however, were not instituted owing to their not being detected in the act of shooting at, or killing sambar,

The Hon. Secretary then drew attention to the amending Ordinances No. 11 of 1902, and quoted the following therefrom:—

Sec. 3 sub-Section (5) "a License to shoot at, kill, capture, pursue, or attempt to capture game, shall be subject to an annual stamp duty of R3'50.

Sec. 6 sub-Section (c). Any person who in contravention of this Ordinance or contrary to the tenor of any License issued to him shall shoot at, kill, capture, pursue, or attempt to capture game, shall on conviction be liable for such offence to a fine of R100 or to simple or rigorous imprisonment for a period not exceeding three months or to both.

In view of the lapse of time that had occurred since the alleged poaching it was thought inadvisable to re-open the question.

A TEA COMBINE IN JAPAN.

The question of a tea combine seems likely to be revived in Japan. This time the idea emanates from the tea growers of Fukuoka, Kumamoto and Nagasaki. So far the proposal is only in the initial stage, although a number of people are anxious to push the matter through. With this end in view representatives of various bodies interested in the tea business have been holding a conference at Nagasaki.—*Hongkong Weekly Press*, Sept. 8.

PRODUCE AND PLANTING.

"The value of TEA, COFFEE, and COCOA imported into the

UNITED STATES

in 1902 was \$87,426,000 as against \$146,275,000 in 1892, which is a great falling off," says "Tea, Coffee, and Sugar" of New York; "but the figures for the present year are the largest since 1897, when they were \$1,000,000,000. In view of the tremendous imports of coffee the figure is surprising for the year, but it demonstrates the lessening values of the staples from year to year. The coffee we now drink does not cost so much, nor the tea either. Their quality, too, is not so high as formerly. The value of the tea imported this year was little in excess of \$9,000,000, whereas in 1875 it was \$22,675,000. Since then the population of the country has grown from forty to eighty millions, but the quantitative value in dollars of tea has decreased almost two-thirds. An inference is that the tea trade since then cannot have grown, and this, too, despite the enormous expansion of trade in the country. Coffee has done better, but the imports in 1875 amounted to \$50,000,000, whereas the value of them for the fiscal year just closed was only \$70,000,000. In 1875 the amount of coffee imported was 317,879,000 lb, but during the year just closed it was 1,091,792,000 lb, for the first time the billion mark was crossed. Our consumption of coffee has increased threefold, whereas the population has only doubled itself. Of tea in 1875 we consumed 65,000,000 lb, and this year it was only 75,000,000 lb, which is a retrogression relative to the increase of population.

The scene of the

AUCTION SALES OF TEA

in MINCING LANE does not exactly represent an earthly paradise, and it is oftentimes suggested that there is room for improvement in the method of conducting the auctions. There are frequent complaints on this score, and quite recently a growl has been uttered because the buying brokers include in their lists of "bought-over" teas which they distribute among the trade those parcels for which selling brokers have accepted their bids. The *Grocer*, we

notice, says this complacency is ridiculed by the majority of the trade. It points out that "as it is quite at the option of the selling brokers whether they accept or refuse these bids, it seems unnecessary to raise an outcry against the practice." No buyer is prevented from offering more money for any teas for which bids have been made, though the original bidder has the first claim, provided, of course, he is prepared to pay the increased price. In the main the owner gets the fair market price for his tea, and no doubt will continue to do so unless there are philanthropists in the trade who are willing to bid above their fellow-operators in order to benefit the importer. With regard to crying off bids that have been made this has been an unpleasant and growing practice within recent years. The question, however, is one that rests entirely with the selling brokers, for if auctioneers would only show a little more backbone by firmly insisting on their decisions being carried out there would be better order than at present prevails in the conduct of the tea sales. Where auctioneers have hesitated and wavered in deciding who was the first bidder nothing but confusion and disorder have resulted. It would also be a good thing if the brokers were to bring pressure on the importers to allow the buyers a profit on the odd chests that are sometimes withheld from a break, being kept back either for the merchant's own use or else for a 'friend in the country.' Frequent protests have been made against this proceeding, and frequent promises made of the subject being brought before the importer, but the outcome so far has been nil. Again there are occasions when breaks of a hundred chests or so have been sold, although offers have been made of a farthing more and 'drop' on condition that the parcel was divided into two lines. This means more money for the importer, but the offer has not always been entertained, and it is a pity that some definite rule is not made upon the subject. Many invoices also contain duplicate breaks of the same description of tea that might be bulked together, thereby saving time and the trouble of tasting an excessive number of samples. The trade are continually complaining about all these matters, and if they were duly recognised and provided for the procedure at the auctions would be characterised by a greater smoothness and less uproar than at present characterises the tea sales.—*H and C Mail*, Sept. 12.

TEA STATISTICS AND PROSPECTS.

The introductory portion of Messrs. Wm. Jas. and Hy. Thompson's Tea Circular by a late mail deserves to be carefully noted:—

Although good business is now being done the market lacks animation, and the news of light shipments from India has not received the notice it deserves at a time when deliveries for home use and export are steadily growing larger. Some of the buyers seem to be more intent upon discussing what is passing at the moment than upon making provision for the future, with the result that bidding at Auction is brisk at one time and languid at another, while prices are subject to much irregularity.

The movement, however, towards a high level of value for fine teas, accompanied by easier rates for inferior kinds, continues: it is helped by the action of buyers abroad who show much discernment and bid freely for Indian and Ceylon tea of the best flavour and quality. Judging from our own information, they are probably right who buy fine tea when they see it and also recognize that when it is scarce the good teas next in order of merit become more valuable.

There are signs that business with America this season will be larger than hitherto and may reach considerable dimensions if suitable teas be made in sufficient quantity to convince American traders that we can produce "Green tea" with the flavour of Moyune and "Uncoloured tea"—or "Unfinished tea" as some in Canada name it—equal in delicacy to the best from Japan. Both descriptions should be made. Our friends Messrs J & J R Montgomery & Co., of New York, inform us that they estimate the importation in North America this season will be as follows:—

	1902-3.	1901-2.	1900-1.
From China and Formosa	51 mils. lb.	40 mils. lbs	54 mils lb.
" Japan	38 " "	36 " "	38 " "
Total ..	89	76	92

This is so far encouraging, and we notice that the London stock of Ceylon tea on 1st September was considerably less than at the same date last year; but unfortunately Indian tea was $3\frac{1}{2}$ million lb. in excess and China tea $4\frac{1}{2}$ million lb. above the stock of September, 1901. Finally from a Statistical sheet issued by Messrs. Ewart, Maccanghey & Co., Ltd., we quote the following, *quantum valet*:—

	CROPS OF THE WORLD.	
	1901-2. Millions.	1900-1. Millions
Indian	175 $\frac{1}{2}$	167 $\frac{1}{2}$
Ceylon	143	149
China and Japan (Exports from)	154 $\frac{1}{2}$	184 $\frac{1}{2}$
Java	18 $\frac{1}{2}$	17 $\frac{1}{2}$
	491 $\frac{1}{2}$	538 $\frac{1}{2}$

MESSRS. BROWN AND DAVIDSON'S TALAWAKELE WORKS.

EXPERIMENT WITH LIQUID FUEL.

So much has been recently written about the attempts made to utilise liquid fuel in oil engines as a motive power that having heard of an experiment at the well-known works of Messrs. Brown and Davidson, Talawakele we sent our Upcountry representative there to witness and report on the success of that firm's latest venture. Our representative was cordially received and shown the engine experimented with, which was a Priestman Hull oil engine, selected because it was not of date and had not been worked for several years. After Messrs. Brown and Davidson's chief engineer had removed all the complicated gear, he substituted a simple valve gear. The engine was put through successful tests. The engine is of small construction, but nevertheless it started readily and easily, and developed a little over 4 horse-power pressure on a continued brake test. Our representative was informed by Messrs. Brown and Davidson that far from being prohibitive the alteration necessary, on this old and obsolete type of engine—was effected at a low cost. But the firm while they are prepared to alter any engine at use at present to work by liquid fuel—they, at the same time, do not advocate it, as the result of what its motive power would be after two or three years of continued work has to be tried and tested for some little time before they would express their opinion

as to its proving the success which is now anticipated in very many quarters. Our representative was also taken to Middleton estate, owned by Mr. A V Renton, where within a few hours yesterday (Monday) Messrs. Brown and Davidson changed an oil engine of the latest pattern which had hitherto been

WORKED BY PETROLEUM TO WORK WITH LIQUID FUEL.

The engine was one of their own "Cundall's" and of 25 brake power, and had been working quite smoothly with liquid fuel for some hours. There our representative met Mr. T MacLachlan who has something to do with the management of that estate, and was told by that gentleman that it was his opinion that liquid fuel would supply a long-felt want upcountry where firewood was scarce, and had to be brought from distances by wire shoots which had to be erected for the purpose at much cost. Mr MacLachlan's view was that it would in time be largely used as it meant working factories at much less cost than before, as whatever may be the drawbacks of liquid fuel it really supplied a distinct advantage in cost of working and labour. Our representative, from another source learnt that engines worked with liquid fuel would want a deal of looking after and cleaning as the oil itself was dirty. The oil, it is said, is a refuse oil, and is distilled from the ground in a crude state. It is in fact an oil from which petrol, kerosine and more volatile oils had been extracted, but what it is going to do for estates remains yet to be seen, and the venture of Messrs. Delmese Forsyth & Co. to

ERECT A STORE AT TALAWAKELE TO STORE IT, in view of their opinion, that it will be extensively used before long, and Mr A Hamilton Harding, the Honorary Secretary of the Dimbula Planters' Association, expressing it as it been generally understood that its demand would in the near future increase rather than decrease, speaks for itself. In Colombo we would add that the cost of petroleum now so largely used in factory engines upcountry is approximately 43 cents. per gallon, while the liquid fuel is obtainable at 12 cents. per gallon. Whether the prices will in time fluctuate remains to be seen, as the lesser demand for petroleum may bring its price down; while the increased demand for liquid fuel should have a tendency to raise its price rather lower its present rate even though facilities for importing liquid fuel in bulk be arranged for, as has been suggested.

THE FAUNA OF BRITISH INDIA.

We have to acknowledge receipt from the publishers of a copy of the latest volume of the above work, which includes the Fauna of Ceylon and Burma; and is published under the authority of the Secretary of State for India in Council. Edited by W T Blanford. The present volume is on Rhynchota.—Vol. I. (Heteroptera) by W L Distant. The publishers are in London: Taylor and Francis, Red Lion Court, Fleet Street. Calcutta: Thacker, Spink and Co. Bombay: Thacker and Co., Limited. Berlin: B Friedländer and Sohn, 11, Carlstrasse, 1902. The whole series is a most valuable one and in the preface to the present volume Mr Blanford states:—

Other volumes on Indian Invertebrata are in preparation, and two are so far advanced that their

early publication may be expected. These two are a volume on Ants by Colonel C T Bingham, and another on Longicorn Coleoptera by Mr C J Gahan. A volume of Land-Mollusca is also in hand, and arrangements are being made for further additions to the general series.

CINCHONA IN BENGAL.

According to the annual report by Major Prain, Superintendent of Cinchona Cultivation in Bengal, 13,434 lb. of cinchona febrifuge were manufactured last year at the Government Cinchona plantation in Sikkim, an increase, as compared with the previous year, of 3,599 lb. This increased quantity included 2,663 Cinch sulphate, of quinine, and 936 lb. of cinchona febrifuge. The receipts for the year amounted to R1,91,922 as compared with R2,27,087 for the preceding year. —*Madras Mail*, Sept. 27.

"ON THE ORIGIN OF PEARLS."

Dr. H. Lyster Jameson, M.A., is good enough to send us a copy of his paper on this subject reproduced from the proceedings of the Zoological Society of London. It is accompanied by four full pages of illustrations and a list of literature on the subject. Dr. Jameson controverts the theory that the pearl is due to the intrusion of an irritating body (a grain of sand, &c.) which the oyster proceeds to coat with carbonate of lime, so elaborating the pearl. His investigations go to show that the intrusion is rather by a living parasite, a "trematode." Trematode larvæ cause sacs to develop and these lead to pearl formation; but one must read the paper very carefully, to appreciate the full importance of the investigation carried on by the author and scientist. The paper should be of great use to Professor Herdman and Mr. James Hornell.

RICE IN INDIA AND AMERICA.

We remember reading a short time ago a learned discussion, as to whether India is the poorer for the growing volume of her exports; and the issue specially turned on whether the rice which was exported from the country was surplus stock, in excess of its needs, or whether it represented the food of the people which they were too poor to purchase, and for the lack of which they died in thousands and, in bad years, in millions. In recent years at least—whatever may have been the case a century back, India is believed to have always had rice enough for the needs of all her population; and the reason why famines that is scarcity in particular tracts, proved disastrous was mainly, if not solely, through the difficulty of transporting food whither it was most needed. We are by no means sure that India would be any the richer for the non-exportation of rice; but if the successful growth of rice in particular States in America has not been exaggerated, as has been the cultivation of tea, India will cease to be regarded in the markets of the world, at any rate in those at a distance, as a necessary source of supply. When

that happens, may we expect Indian famines to cease to decimate the population, or will the growth of more remunerative crops take the place of rice? We quote as follows from an Indian paper, as a new proof of the almightiness of Yankeeedom:—

"Writing of the growth of rice cultivation in Louisiana, the *Louisiana Planter* says: Hundreds of thousands of acres of land are being prepared for rice culture, and unless some adverse conditions intervene, our rice crop should be doubled, or tripled, within the next ten years. The prairies of South-western Louisiana have produced rice in small quantities for a century; but it has only been of late years, that active efforts have been made there in the direction of the artificial irrigation of rice. In Louisiana and Eastern Texas there were produced last year some 3½ million bags of rice, equal to about 175,000 short tons of clean rice. This large production has been nearly all marketed, and the advent of the new rice crop on September 1st will find but little of the old crop remaining on hand, the distribution of the last crop, the largest ever produced, having been successfully made and at good prices. All this is leading to new efforts in every direction for the enlargement of the industry, and one of the most notable of these schemes is that of the Bradford Canal, which will be about 75 miles long and 250 feet wide, and will afford ample irrigation for from 500,000 to 700,000 acres of land through the district which it will traverse."

CEYLON PYTHONS GALORE.

With reference to the statement of a Galle correspondent that a python 10½ feet long was killed near that town while attacking a goat, a Kadugannawa planter writes:—

"It may interest you to hear that three pythons were killed in the tea on this estate during 1901: the largest measured 11ft. 6in. by 18 inches in girth and the other two about 10ft. 6in. and 10 feet respectively." Tennent's reference in his "Natural History" is as follows:—

The great python (the "boa," as it is commonly designated by Europeans, the "anaconda" of Eastern story), which is supposed to crush the bones of an elephant, and to swallow the tiger, is found, though not of such portentous dimensions, in the cinnamon gardens within a mile of the fort of Colombo,* where it feeds on hog deer, and other smaller animals. The natives occasionally take it alive, and securing it to a pole expose it for sale as a curiosity. One that was brought to me tied in this way measured seventeen feet with a proportionate thickness: but one more fully grown which crossed my path on a coffee estate on the Peacock Mountain at Pusilawa, considerably exceeded these dimensions. Another which I watched in the garden at Elie House, near Colombo, surprised me by the ease with which it erected itself almost perpendicularly in order to scale a wall upwards of ten feet high. The Singhalese assert that when it has swallowed a deer, or any animal of similarly inconvenient bulk, the python draws itself through the narrow aperture between two trees, in order to crush the bones and assist in the process of deglutition.

* [That was 40 to 50 years ago when jackals prowled nightly along Turret Road.—ED, T.A.]

COOLY TIN TICKETS.

[The following correspondence has been sent us for publication.—ED. T. A.]

My dear T.—The enclosed remarks, with reference to tin tickets, written by the G.A., Western Province, may be of interest to you:—

“The objections that are raised in some quarters to tin tickets being required at all times in order to secure cooly rates appear to me somewhat unreasonable. I do not think it can be disputed that the certificate system at present in force is greatly abused, and that a number of persons travel under the certificate at cooly rates who are not *bona fide* coolies. I do not mean to suggest that planters wilfully grant certificates to persons who are not entitled to them; but I think that it is not an uncommon practice to give a certificate to a kangany without knowing who will travel by it. The restriction of cooly rates to gangs of six and upwards has probably greatly contributed to this abuse of the system. If tin tickets are, as is proposed, accepted as proof of the status of an estate labourer, such restriction will no longer be necessary. A single cooly may travel at cooly rates on production of his tin ticket and certificate. As regards the legal point, the ordinance specifies no form of certificate, nor is the Railway authority required to accept such certificate if he has any doubt as to the status of any alleged cooly labourer. It may be said that tin tickets may be in the same way misused by kanganies, but the new form of certificate renders this unlikely, and it is hoped that no planter will issue a tin ticket to a person who is not a *bona fide* cooly. The new form of certificate entails a little additional trouble, but on the other hand, combined with the tin ticket system, it renders desertion and crimping far more difficult and easier of detection. Undoubtedly employers of labour who are ready to take any coolies they can get without asking questions will oppose the system in its entirety, but I hope that in a short time the number of unregistered estates will be very small and that the transfer of coolies between estates will be greatly simplified by the adoption of the tin ticket system.”

The tickets are R2/50 a hundred.—Yours sincerely,
A. C. KINGSFORD.

Rookwood, Hewaheta, 26th Sept. 1902.

Sir,—With reference to your letter of the 22nd July, 1902, I am directed to inform you that the restriction imposed by the Government Agent, Western Province, was imposed by him not as Government Agent, but as the originator of the tin ticket scheme and to state that the question of the restriction is under consideration and awaits the receipt of a further communication from the Planters' Association of Ceylon.—I am, &c.,

(Signed) A. G. CLAYTON,

for Colonial Secretary.

Colonial Secretary's Office, Colombe, 29th Sept. 1902.

TEA IN JAVA.

Mr. L. A. Wright, of Maskeliya, who has just returned from Java—where he and other members of his family own property in tea, cinchona and coffee—has a favourable account to give of tea, notwithstanding the low prices. The rich Java soil gives a better yield per acre by, perhaps, 25 per cent than Ceylon; the labour is cheap and

reliable, and planters are taking to all the modern improved machinery. He also mentioned to a representative of our contemporary that the telephone is in universal use, nearly all estates and bungalows being connected.

PLANTING NOTES.

THE DEANE-JUDGE STRAINER—so successfully tried in Calcutta the other day, is to be still further improved by the principal parts being made in steel in England. Meantime there is another “Richmond in the field” in Calcutta—a Ceylon-made Machine of which four have been already ordered, and a trial of which may be reported any day now.

THE CHOLERA MICROBE IN WELL WATER.—The Madras Government has approved of the suggestion of the Sanitary Commissioner (Madras) that District Medical and Sanitary Officers be requested to send to him specimens of well or other water believed to be contaminated with the cholera microbe before they add permanganate of potash, and another specimen twelve hours after having done so. The purpose of the investigation is to ascertain what is the actual result of using permanganate of potash under the methods at present pursued.—*Pioneer*, Oct. 10.

BAMBOO FOR PULP.—The Collector of Customs at Trinidad reports that enquiries have been made of the Government of Trinidad respecting the possibility of obtaining bamboo in quantities large enough to warrant the establishment of a factory in the Colony for the production of pulp. At present immense areas in Trinidad are occupied by the bamboo, and these could be almost indefinitely increased if the plant were in demand. There is no doubt whatever that if a factory were established in our near Port of Spain a practically unlimited supply could be obtained within a radius of five or six miles.—*Board of Trade Journal* for September.

A DRY CYCLE.—All over the world there has been scarcity of rainfall and the Nile is expected to be lower than within living memory; but fortunately the Assiout Barrage was closed early, is expected to save the agriculturists of Upper Egypt. According to one of the London correspondents in Cairo Egypt will be repaid the cost of the Assiout Barrage in the first year of its existence—a marvellous testimony to the value of Government enterprise and of wise expenditure on reproductive works. From the *London Speaker* we quote:—“It is perhaps not too much to say that throughout the world the rainfall during the last five years has been below the average. In many of the southern districts of England, for example, old springs have dried up, and it has been necessary to sink wells deeper. In India, as everyone knows, the famines have been abnormal, and Australia has suffered terribly from drought. It is to be feared that the rains reported during the last few weeks in Australia are partial, and in many districts insufficient to restore prosperity; but happily the danger of any renewal of the famine in the Bombay Presidency of India has been altogether dispelled,

TO THE PLANTING WORLD.

Seeds & Plants of Commercial Products.

Hevea Brasiliensis.—Orders being booked for the coming crop August-September delivery 1902, booking necessary before the end of April, quantities of 100,000 and over at special low rates. Plants available all the year round, 100,000 and over at special low rates. A leading Rubber planter in Sumatra, who purchased 50,000 seeds in 1899, and 100,000 in 1900, writes us, under date 15th November, 1900:—"I received your letter of 20th October, from which I learn that you added another case of 5,000 seeds to replace the loss, &c. I am satisfied hereby, and even after this adding I am satisfied by the whole delivery of this year." Special offer, post free on application.

Castilloa Elastica.—True superior variety cultivated in Mexico, seeds from specially reserved old untapped trees. Orders booked for August-September delivery 1902, immediate booking necessary; large quantities on special terms; Plants in Wardian cases.

A foreign firm of Planters writes under date 11th October, 1901:—"We beg to enquire whether you would procure us 100,000 Castilloa seeds, in which month we might expect them, and what would be the average price." Special offer, post free on application.

Manihot Glaziovii.—Seeds and Plants available all the year round, 100,000 and over at special low rates. A Mexican planter in sending an order for this seed wrote on the 22nd August, 1900:—"If they arrive fresh and germinate easily I may send you larger orders, as they are for high ground where the Castilloa does not thrive."

Ficus Elastica.—Seeds available in May-June; booking necessary before the end of March; also plants.

Mimusops Globosa (Balata) wood of the tree is much sought for buildings, fruits sweet like a plum and eaten, oil from seeds, said to yield as much as 45 lbs. of dry rubber per tree per annum, the milk is drunk and when diluted with water used as cow's milk, grow from sea-level up to 2,000 feet, orders being booked for seeds and plants, price on application.

Cinnamomum Zeylanicum (Cinnamon superior variety).—New crop of seed in April to June; booking necessary before the end of February, also plants.

Coffee Arabica, Liberian Hybrid and Maragogopie Hybrid.—New crop March-April; immediate booking necessary.

A foreign Agricultural Department writes dating 9th September, 1901:—"Please accept our order for 175 lbs. of Tea seed and for 2,000 Coffee beans. In regard to Coffee seed I would say that this will be the first importation made by this department, and we will leave the selection of the varieties to be sent to your judgment."

OUR DESCRIPTIVE PRICE LISTS.

The following six Descriptive Price Lists are now being forwarded with Circulars and special offer of Seeds and Plants of Rubber and other Economic Products:—

1. Tropical Seeds and Plants of Commercial Products, enlarged edition for 1902.
2. Seeds and Plants of Shade, Timber, Wind-Belts, Fuel and Ornamental Trees, Trees for Road-sides, Parks, Open Spaces, Pasture Lands, Avenues, Hedges, and for planting among crops (Tea, Coffee, Cacao, Cardamoms, &c.)
3. Seeds and Plants of Tropical Fruit Trees including Mango grafts.
4. Bulbs, Tubers and Yams.
5. Orchids—Ceylon and Indian.
6. Seeds and Plants of Palms, Calamus, Pandanus, Cycads, Tree and other Ferns, Crotons, Roses, Dracinas, Shrubs and Creepers.

Special Arrangements made with foreign Governments, Botanical and Agricultural Departments, Planters and others for supplying seeds and plants of Commercial Products in large quantities.

"SOUTH AFRICA."—The great authority on South African affairs of 25th March, 1899, says:—"An interesting Catalogue reaches us from the East. It is issued by WILLIAM BROTHERS, Tropical Seed Merchants of Henaratgoda, Ceylon, and schedules all the useful and beautiful plants which will thrive in tropical and semi-tropical regions. We fancy Messrs. Williams should do good business, for now that the great Powers have grabbed all the waste places of the earth, they must turn to and prove that they were worth the grabbing. We recommend the great Powers and Concessionaries under them to go to William Brothers."

Agents in London:—MESSRS. P. W. WOOLLEY & Co., 90, Lower Thames Street.

Agent in Colombo, Ceylon:—E. B. CREASY, Esq.

Agent in British Central Africa:—T. H. LLOYD, Esq., Blantyre.

Telegraphic Address:

ARTIFICIAL MANURING FOR TEA.

[Paper read, September 29th by Chairman Dimbula P.A. at General Meeting.]

It may be within the recollection of some of you that 15 or 16 years ago, I published the result of a series of manuring experiments on coffee as carried out on Yoxford estate. With the advent of green bug, coffee was wiped out and those experiments came to an end. Eight years ago I was able to commence a series of experiments on tea which have been in progress since, and which have given me some insight into the principles which should guide us in dealing with tea. This is my justification for addressing you today on the subject of manuring tea, which is I judge of interest to most of you, though probably some already know as much as I do myself and perhaps more. I must commence by making the admission that I cannot give accurate scientific proofs of all my deductions. With coffee it was a comparatively simple matter as the object was solely to find out how to produce the largest crop with the least injury to the tree, whereas with tea it is, at least, as important to find out how far the quality is affected by the manure. On this latter point I have only been able to draw my conclusions from my general experience. Mr. Allyn says, I understand, that he has been able to get to the bottom of the subject and has patented his information, which you will be able to buy from him shortly. He has been more fortunate than myself in being able to expend money on a large scale which is necessary for discovering how quality is best maintained or increased, along with the increase of leaf. We see frequent references to manuring in the papers. Many seem to think that all manures should be suppressed by legislation as tending to over-production which is not only impracticable, but shows how little the true principles of manuring have been grasped. It is quite impossible to distinguish between manures which are sustaining and manures which are forcing, the difference is one of degree and not of kind. There are two systems of manuring in vogue: the one is mainly *sustaining* the object being to restore the natural fertility of the soil; the other is *forcing*, in that it tends to raise the production of an estate beyond what would have been its normal yield under the most favourable conditions. I regret to see the latter system has found its way into Dimbula, because this district has undoubtedly a flavor and quality which I would wish to see it maintain and which, I believe, will be lost by the adoption of the forcing system. I believe it is quite possible to manure in such a way as to keep the tea at a normal level of production combined with good quality and that it will pay better in the long run to work on this system. Such at any rate are the conclusions I have arrived at after ten years' experience of manuring tea and eight years of careful experiment. My first experiments were conducted with the object of finding out the most important element required in a manure for tea and were so arranged as to compare the results of adjoining plots of the size of one-sixth of an acre, by leaving out one element in each plot on the plan of M. Ville. The important elements removed from the soil by the tea crop are nitrogen, phosphoric acid and potash, 1,000 lb. of tea removing 45 lb. of nitrogen; 8 lb. of phosphoric acid,

and 22 lb. of potash. My plots were laid out, therefore, as follows:—

No. 1 in manure; No. 2 nitrogen alone; No. 3 phosphate and potash; No. 4 nitrogen, phosphate and potash; No. 5 nitrogen and phosphate; No. 6 nitrogen in excess, phosphate and potash.

I was very soon convinced that the dominating element was nitrogen. That is to say that without nitrogen phosphoric acid and potash were almost inert. That for the best effect all 3 elements were required and more especially potash. That additional nitrogen meant an increased yield, but did not invariably pay owing to the great cost of nitrogen. My further experiments have been directed more to finding out the most profitable mixture to supply and have not been carried very far as yet. The great cost involved has prevented my experimenting in the direction of finding out the effect of different manures upon quality and I have to fall back upon general conclusions from the observations of manuring on estates under my own direction and that of others. My conclusions may not be considered at all convincing, but I give you them for what they are worth. The sources of *nitrogen* best known to us are sulphate of ammonia, nitrate of potash, castor cake, blood meal and fish manure of *phosphoric acid*, bones ground or steamed, basic slag and fish manure (super-phosphates are seldom used) of *potash*. Nitrate and sulphate of potash and kainit which contains about 25 per cent of sulphate of potash. I have used my combinations of these manures, but for figures as to results I would commend to your notice Mr. Joseph Fraser's published experiments which are by far the most complete of any I have heard of. As regards their effect upon quality I give the preference to castor cake or a mixture of castor cake and blood meal as the source of nitrogen, for the reason as it seems to me that the effect is lasting and not too forcing; blood meal alone is too forcing and quickly used up. Sulphate of ammonia has invariably appeared to me to be accompanied by a loss of quality, whether used by itself or in combination, though it may be only a coincidence. Fish manure I have only used once, and I confess that I have a dislike to it as being too stimulating in its effect and its use has seemed to me usually accompanied by a loss of quality. I imagine that its nitrogen comes into action more speedily than its phosphoric acid, though it is very rich in both elements. Nitrate of potash is, I think, useful as a source of nitrogen and potash, the nitrogen coming into action very quickly but being speedily washed out in wet weather. Basic slag I look upon as a very valuable source of phosphoric acid and I am inclined to endorse Messrs. Freudenberg and Co's. statement that it tends to maintain quality in the tea owing to the two oxides of iron which it contains. Bones either steamed or ground should, I think, form part of every manure mixture as the phosphoric acid contained in them comes into action gradually and is not too speedily used up. I give the preference to sulphate of potash as the source of potash as being retained in the soil better than the nitrate. Potash, I consider, is a most important constituent in a manure if quality is to be maintained. Potash is known to have great effect upon the carbohydrates of plants, that is to say upon their main structure and ever since the time when I commenced my coffee experiments I have noticed that potash improved the health of the trees to which it was applied. I

believe it is of great value in helping them to resist diseases of a fungoid nature. The manure, which is most commonly used by those who are not well up in manuring, is castor cake and bones, which is an incomplete manure as containing a negligible quantity of potash. A well-balanced manure such as your Agricultural Chemist supplies you with, has its constituents so arranged that each element comes into action gradually and simultaneously and the more this point has been considered the greater the value of the manure in tea cultivation. And ill-balanced manure will stimulate the bush at first and then leave it insufficiently supplied with nourishment and a ready prey for disease. You want to manure your tea, say, every three years, therefore, the manure must last for three years in its effect. The difference between a forcing and a sustaining manure lies in the amount of nitrogen contained in it, and the form in which it is supplied. Take the typical forcing manure now so generally used:—

Castor Cake	400 lbs.	} per acre
Fish	400 "	
Nitrate of Potash	100 "	
Sulphate of Ammonia	100 "	

and compare it with the manure generally supplied by the Agricultural Chemists. The mixture I have quoted contains 82 lbs of Nitrogen as against about 25–30 lbs in most of the manures supplied by Messrs Freudenberg and Co., Baur and Hughes. As to the effect of forcing manures which, of course, form part of a regular system of working for large yield, such as low pruning, &c. You are all capable of estimating the effect just as well as I am. The great increase in crop is undoubted and the great falling-off in prices equally evident. I have for instance in my eye an estate in my own neighbourhood where the normal yield would be about 550 lbs per acre and which has been worked up to about 850 lbs per acre, the prices for the teas at the same time having dropped about 3d per lb.

That it is quite possible to manure and yet maintain quality I am well assured. Over the only field which I have manured twice on Holmwood for instance, I have been able to detect a distinct improvement in the cup. The manure applied was low in Nitrogen and rich in Potash and phosphoric acid, Basic slag providing part of the Phosphoric acid. On another estate, which I visit where Mr Bamber's mixture on especial analysis was applied, the Superintendent reports that the quality is returning as the result of the manuring and higher pruning and the prices bear out his statement. At any rate I would ask you before you commit your estates to the system of working for large quantity to weigh well the evidence for and against. In my strong objection to forcing manures, I am, at any rate in good company; for you have only to read Mr Bamber's report on tea soils to see that he condemns them. From what I hear I am inclined to think that our leading authority on manuring is of much the same opinion also. Before concluding I would like to touch upon the subject of green manuring as I think it promises to economise greatly the future manuring of tea. As you know there are certain plants and trees which have the property of collecting the nitrogen of the air and storing it in their roots to be given up afterwards to the soil such as the Leguminosa the Peas, Beans, Lupins &c., and among our best-known trees

the Albizzias, Dađap and so on, Mr Bamber recommends the trial of *Crotolaria striata* which has been used to some extent, I believe, on a Matale estate though with what result I cannot say. It is very evident however that if all the necessary nitrogen can be supplied by the atmosphere by means of green manuring, half the expense would be saved as only the Phosphoric acid and Potash would have to be supplied to the soil. I have tried a small experiment myself with gram on Holmwood which made a profit of R15 per acre; but when I tried the same on Ancoombra in Matale the growth of the gram was a failure, owing no doubt to the soil having been previously exhausted of its Potash and Phosphoric acid by the heavy crops of coffee which had been taken off that land. To get the full benefit of green manuring Phosphoric acid and Potash should be supplied to the soil before the Leguminous plant is sown. In the low-country I have noticed that Albizzias improved the tea under them in a most marked degree.

I hope I have not wearied you with my address. It is not scientific and is open to any amount of criticism and is only to be taken as presenting some of the conclusions drawn from practical experience by one who has always taken an interest in Manuring problems and who has the interests of this District more especially at heart.

The address was received with rounds of applause and Mr Wilson Smith proposed that a vote of thanks be recorded to the Chairman for his interesting discourse on Manuring. Mr. G D Jamieson seconded. W. D. BOSANQUET.

TEA MARKETS IN SOUTH INDIA. A CENTRAL TRAVANCORE SCHEME.

An extraordinary General Meeting of the Central Travancore Planters Association, called for the purpose of discussing the "Tea Exploitation Scheme for S India," was held at Pambanar Bungalow on the 20th September.

Mr H M KNIGHT was after some preliminary business transacted asked by the Chairman to explain the above scheme. He began by reading the scheme, and explained the paras, not clearly understood by this and other Associations.

The maximum price of 4 annas per lb., he said, did not mean that this was the maximum price at which the teas were to be sold, but the maximum price to be returned to the contributors before any remuneration accrues to the exploiters. The remuneration to exploiters is contingent upon the account sales showing a better nett result than 4 annas per lb., after returning which, the exploiters and contributors divide the balance. For instance, if a lb. of tea, after being suitably packed, is sold for 8 annas per lb. the account would be as follows:—

Dr.	As.
To paid Contributor	.. 4
To expenses (say)	.. 2
Balance to be equally divided between contributor and exploiter	.. 2
	Total As. 8
Cr.	As.
By sale of 1 lb. Packet Tea	.. 8

The nett result therefore to the contributor would be 5 annas per lb. if sold at 8 annas. He then went on to say that he thought it absolutely necessary to pack the teas in lead. He produced a

sample of Tea packed in foil paper which had been kept for one month and the tea had deteriorated. He therefore proposed that we would go to the expense of using lead, and thought a Drier, for use in packing, essential to success and suggested that a Drier should at once be purchased for this purpose. Mr Knight read letters from men in South Travancore who approve of the scheme and are willing to subscribe to a Fund which he thought should be raised for the purchase of a Sirocco, and other incidental expenses necessary for the starting of the scheme, also a letter from the Honorary Secretary of the Wynaad Planters' Association asking for information. An attractive wrapper he thought was necessary. He also stated that 100 chests of tea of 90lb. each were now on their way to Madras, Messrs. Parry and Co., having written that they were quite ready to commence operations. This quantity had been readily contributed in the District. After some considerable discussion in Committee, the Chairman put the following Resolutions in open Meeting, which were unanimously adopted:—

1. That members of this Association do agree to contribute at the rate of 3 annas per acre (cultivated) to the "South Indian Tea Exploitation Scheme," and that growers not being members be invited to subscribe to the Fund so raised and participate in the benefits.
2. That this Association do instruct Mr Knight to purchase a No. 1 Sirocco for the proper working of the scheme.
3. That this Association do consider that the design for wrapper should be left to the Committee, and would suggest that a Brahmany Bull should be on one side and instructions for making Tea on the reverse in the Vernacular.
4. That the Honorary Secretary do write to the U.P.A.S.I., urging the necessity for expediting Election of Committee.

Resolved that a vote of thanks be tendered to Messrs Parry and Co.

With a vote of thanks to the Chair the Meeting ended.—*M. Mail*, Sept. 29.

CASTILLOA RUBBER SEED AND ITS VITALITY.

The period during which the seeds of various economic plants retain their vitality is being investigated at the Royal Botanic Gardens, Peradeniya; but the following figures, supplied to us by Mr. Carruthers, may be of interest to any who may wish to send the seeds of *Castilloa* to a distant place.

2,000 seeds were sent off from Paris to Peradeniya, packed in leaf mould in four small tin-boxes, each containing 500 seeds. Upon being opened at Peradeniya on September 26th, six weeks after packing, the seeds were found to be as follows:—

	Box 1.	2.	3.	4.	Total.
Fully germinated...	96	128	67	96	337
Split and beginning to germinate ...	30	55	20	63	168
Good hard seeds unsplit...	14	12	68	75	169
Bad seed—destroyed by bacteria, etc...	350	300	338	260	1,248

This gives a percentage of 37 good seeds (2) per cent fully germinated, 8 per cent starting germination and 9 per cent good

seeds unsplit), and 63 per cent destroyed by bacteria or otherwise killed. The packing in leaf mould which usually contains numerous bacteria, fungi and insects, is not to be recommended. Probably if sterilised sand had been used, the proportion of good hard seeds would have been very much greater.

This seed is an especially unsuitable one for travelling, as it possesses no protective coat which prevents the inroads of insects or bacteria.

The short time that various economic seeds are credited with retaining their germinating power is, undoubtedly, in many cases, due to the fact that no special precautions are taken to prevent the attack of insects, fungi and bacteria, which find a congenial home in nearly all seeds. Most of the seeds, which do not grow, are found by their appearance and odour to have lost their vitality by the presence of foreign organisms: When the experiments, with regard to the seeds of Para rubber, tea and other Ceylon economic plants, have been concluded, the matter will be dealt with in one of the Circulars of the Royal Botanic Gardens.

TROUT OVA FROM NEW ZEALAND. 5,000 RAINBOW TROUT OVA FOR THE C.F.C.

The Ceylon Fishing Club has previously tried, by way of experiment, the importation of trout ova for the Nuwara Eliya and other upcountry streams from New Zealand Hatcheries and the fact that another large batch of ova has just been imported appears to speak well for the first trial. Mr. H D Elhart, Curator of the Nuwara Eliya Hatchery, of the C.F.C., was down in Colombo last month to receive a consignment of 5,000 ova of the rainbow species which was brought out from New Zealand by the P. O. steamer "Oroya." The ova, so far as can be ascertained, has been well packed and has received good attention from those in charge of the consignment on board the steamers, but it still remains to be seen how they will hatch out at Nuwara Eliya. We heard recently that the stew-ponds at the Sanitarium were cleared out and the fry put out into the streams, so that the arrival of the present batch has been well provided for. With the interesting correspondence from local anglers which we have lately had showing that the "rainbow" is taking kindly to our streams and showing its appreciation of our streams by spawning freely. We are, perhaps, not far from the time when importation will cease—an event which will reflect much credit on the zealous efforts of the Ceylon Fishing Club.

HIGHLAND TEA CO., LTD.—It is satisfactory to learn that this Company has paid an interim dividend of two per cent. the same as they did in 1901, the full dividend for that year being four per cent.

COCONUT CULTIVATION IN THE STRAITS.

To the Editor of the "Straits Times."

DEAR SIR,—Your issue of 12th instant has just reached me, and therein I notice a letter on the above subject from the pen of Mr. W. Greig, of Kuala Langat. As I happen to be Mr. Greig's visiting agent, as well as at the same time, Chairman of the United Planters Association, I trust that I may be allowed to make a few remarks bearing upon the existence of the coconut beetle in the Federated Malay States as adversely affecting investment in this particular cultivation. Perak and Negri Sembilan it is well known suffer but little in comparison with Selangor, and visitors from these States have over and over again, especially of recent years, expressed their astonishment at the terrible havoc wrought by "beetle" upon the coconuts in the immediate neighbourhood of Kuala Lumpur. Many Ceylon men, whose names are as well known to Mr. Greig as they are to me, have visited estates where coconuts have been planted, have gone carefully into the expenditure connected with the destruction of the beetles, and have advised their friends that until the pest has been brought within proper control, the cultivation of coconuts must be attended within considerable risk. The Selangor Government were prepared to give me a very large concession of excellent land, on as easy terms as even I could wish, with the object of opening a large area in coconuts, but the fear of "beetle" blocked the way, and the necessary capital was not forthcoming. Mr. Thomas North Christie, a man whose judgment Ceylon planters have, for many years now, regarded as well nigh infallible, recently recommended that one of the finest clearings of 2-3 years' old coconuts in Selangor should be at once interplanted with rubber. I admit that our alluvial soil has had something to do with these adverse criticisms, and that the presence of more or less stiff clay comparatively close to the surface is not regarded with favour by our Ceylon visitors, but I know that the ravages of the beetle are considered to be of much greater significance. In face of the foregoing it is surprising that the Annual Report of the United Planters Association should state "that owing to the ravages of beetle, and the cost of keeping the trees clean, coconuts are not as much planted as their fine growth would lead one to suppose that they would be. . . . Your Committee are of opinion that the cultivation will always be a remunerative one as long as it remains possible to keep the beetles under, without incurring a prohibitive expenditure in doing so." Mr Greig prides himself on being unable to record the loss of a single tree from beetle. I may as well explain that it is the duty of managers of estates in beetle-infested districts to see that each coconut tree is examined at least once in every three days and every day if the insects are present in great numbers. According to Mr Ridley, there are two species of beetle which attack coconut trees, *Rhynchophorus Ferrugineus*, the Red Beetle, and *Oryctes Rhinoceros* or the Rhinoceros beetle. The former, which is by far the most dangerous is, as far

I am aware, very rarely met with in Selangor. According to the same authority the adult insect of this variety with its long ovipositor pushes its eggs "as deeply into the body of the tree as it can." "It is here not to the perfect insect but the grub that does the injuries" borrowing "tunnels through the soft growing portion of the palm." The Rhinoceros beetle, on the other hand, never deposits its eggs in coconut palms, unless the trees are "decaying" or in other words, dying if not dead. But the insect "makes its way to the base of a leaf stalk and burrows into the heart of the cabbage, making a large hole." From these quotations it is clear that whilst the red beetle, despite the most careful attention on the part of the management, may do an infinity of damage "it being by no means easy to find out when a palm is attacked by this insect," regular inspection of trees, if properly

carried out, renders it practically impossible for the Rhinoceros beetle to do any very great permanent harm. It seems to me therefore that, given labour and the funds necessary to permit a regular examination of his trees, no planter should lose a single specimen from the attacks of the Rhinoceros beetle. To quote Mr Ridley again "it would be easy enough in a clean-kept estate to keep down the beetles, but where there is an endless supply of them in an adjoining estate, the matter is of great difficulty" which means I take it, that under such conditions, the expenditure of large sums of money has to be incurred. It is not my purpose in writing this letter to attempt to throw cold water upon the cultivation of coconuts, or to suggest that as the rotting timber on new clearings disappears the pest in that particular locality will not grow eggs, for I firmly believe myself that there is a lot of money in the industry, and that on no estates, properly managed by Europeans, has the expenditure upon beetles been found to be prohibitive. But I do say that when thousands of coconut palms have been killed and rendered unproductive through the almost criminal negligence of their native owners in not keeping them clear of beetles, it is high time that the Planters' Association drew attention to the fact and recorded that investors are, as a consequence, shy of giving the cultivation of coconuts the support that their fine growth would seem otherwise to warrant, and I am altogether at issue with Mr. Greig, whose figures are in my hands, and others, who state the cost of keeping beetles under "is merely nominal considering the total acreage under cultivation." It is essential that the trees in all infested areas should be regularly examined at very short intervals, whether the beetles are there or not, and when it is considered what climbing and looking over a coconut palm means, it is the sheerest nonsense for any one to try and make out that the expense is "merely nominal." The evil is a very real one indeed, and it is now for the Government without any further loss of time, to see that the remedy, on the lines of Mr. Ridley's excellent memorandum, is vigorously applied.—I am, dear sir, yours faithfully,
E. V. CAREY.

—Straits Times, Sept. 22.

Klang, 15th Sept.

THE UNITED STATES TOBACCO INDUSTRY.

The total quantity of leaf tobacco produced:—

1890	488,256,646 lb.
1900	868,163,275 "

The total production of the United States in 1900 shows an increase of 379,906,629 lb, or 77·8 per cent over the crop of 1890. All the states and territories were represented except Colorado, District of Columbia, Nevada, Rhode Island, and Utah, but the cultivation of tobacco on a large scale was confined to comparatively few states. The crop of only eighteen states exceeded 1,000,000 lb each and that of thirteen states 5,000,000 lb each. Eight states produced more than 20,000,000 and three states more than 100,000,000 pounds each. Kentucky, North Carolina, Virginia, Ohio and Tennessee, in the order named, were the five greatest producers, whose combined crop was 679,791,000 lb, or 76·3 per cent of the entire production. Kentucky alone produced 36·2 per cent of the entire crop of the United States.—Board of Trade Journal, Sept. 4.

CEYLON PARA RUBBER.—Mr. R W Harrison reports Culloden Para Rubber at last London sales as averaging 3s 8½d; biscuit selling for 3s 10½d, and scrap for 2s 5d.

NEW TEA COMPANIES.

The following have been registered in England;—
BLIND TEA AGENCY, LTD., (74,781).—Registered Sept. 4th with capital £100, in £1 shares, to acquire the business carried on by F A Woollatt as The Blind Tea Agency, and to carry on the business of planters and growers, importers and blenders of and dealers in tea, coffee, cocoa and other Eastern and Colonial products, etc. No initial public issue. The No. of directors is not to be less than 3 nor more than 6; the first are F A Woollatt, E E Jex and R S Wells. Registered office, 5, Fen Court, Fenchurch St, E. C.
EMPRESS TEA STORES, LTD., (74 803).—Registered Sept. 6th with capital £15,000, in £1, shares (50 def.), to carry the business of wholesale and retail merchants, dealers, importers and manufacturers of tea, coffee and all kinds of foods, drinks, provisions, drugs, chemicals, confectionery, perfumery, soap, furniture, household goods, etc. The subscribers are:

	Shares.
G W Winter, 11 Plympton Avenue, Brondebury, N W, clerk	.. 1
W L Rowe, 55, Warham Road, Hornsey, N, clerk	.. 1
T C S St. John, 119, Canfield Gardens, N W gent	1
W H Lewis, 711, Underhill Road, Dulwich, S E, clerk	.. 1
C J Chapman, 57, Bramford Road, East Hill, Wandsworth, S W clerk	.. 1
C Jones, 24, Roupell St, clerk	.. 1
E H Hoare, 1, Seymour St. W, gent	.. 1

No initial public issue. The number of directors is not to be less than 3 nor more than 5; the first are to be appointed at the first general meeting; qualification £25. Registered by Neve & Co., 21, Lime St, E. C.—*Investors' Guardian*, Sept. 13.

A MOSQUITO EXPELLER.

Mr. William Stiell, representing Messrs. Leyshon and Carroll, of Durban, has been visiting Delagoa Bay, with an ingenious apparatus for driving mosquitoes and microbes of organic matter out of a room. It is in the form of a tin cylinder, with large wick inside. This wick is saturated with ozone, extracted from pine-wood, together with eucalyptus oil and other ingredients, and the fumes arising therefrom drive the obnoxious insects and microbes from any moderately-sized room.—*O Futuro*.

PINEAPPLE AS AN AID TO DIGESTION.

Under this head the *Agricultural News*, which is a Fortnightly Review of the Imperial Department of Agriculture for the West Indies, has a note which has an important bearing on the trade in tinned Pineapples. The flavour of these fruits and their price, as compared with that of the fresh grown fruit have gained for them a very wide reputation, and tinned Pineapples are not despised even on the tables of the upper classes, so that Pineapples in this form have become a very large article of import, both from the West Indies and from the Straits Settlements. The fact of their containing a digestive ferment, to which the *Agricultural News* draws attention, is another and a strong recommendation to their use as a desert fruit. For a long time the Papaw (*Carica papaya*) has been known to contain a valuable ferment known as papain, used as an aid to digestion, and the *Agricultural News* now refers to the fact bromelin, the ferment of the Pineapple is almost identical in its action with papain. Quoting from the *Lancet*, it is

stated that "the partaking of a slice of Pineapple after a meal is quite in accordance with physiological indications," Bromelin exerts a powerful action on proteids digesting 1,000 times its own weight within a few hours. Fibrin disappears entirely, the white of eggs is digested slowly, whilst albumen of meat is transformed first to a pulpy gelatinous mass to be completely dissolved later. Cooking destroys the activity of the ferment, but the *Lancet* is of opinion that unless the Pineapple is preserved by heat, there is no reason why the tinned fruit should not retain its digestive power. On this the *Agricultural News* says—"Unfortunately for this hope, Pineapples are sterilized by steam-heat during the process of canning, the ferment being almost certainly destroyed. Unlike pepsin the digestive principle of the Pineapple will operate in all acid, neutral, or even alkaloidal medium, according to the kind of proteid to which it is presented. It may therefore be assumed that the Pineapple enzyme would not only aid the work of digestion in the stomach but would continue that action in the intestinal tract. Pineapple, it may be added, contains much indigestible matter of the nature of woody fibre, but it is quite possible that the decidedly digestive properties of the juice compensates for this fact." With such important properties in the fresh fruit, it seems that there is an opening for some one to try his hand in preparing Pineapples for exportation without the aid of heat.—JOHN R. JACKSON, Claremont, Lymington, Devon.

RUBBER EXPORT FROM PARA.

A report, dated 7th July last, by the United States Consul at Para states that, according to the final returns, the shipments of rubber from the Amazon Valley this season amounted to 29,977 tons, or 2,317 tons more than in 1900 1901. In the season just begun, it is believed that an exceptionally good crop will be harvested. The rubber fields of the lower river, and especially on the islands, are slowly but surely failing, both in quantity and quality; but the decrease is more than made up by the development of new fields and the expansion of the old fields on the Upper Amazon. While all the more important of the Amazon are supplying their full quota of rubber, and even making a promising increase, interest will be centred in the now famous Acre territory and in South-eastern Ecuador. In the regions reached by the Purus (of which the Acre is a tributary), Jurua, Beni, Madre de Dios, Javari, Ucayali, Japura, and other great affluents of the Upper Amazon, which penetrate Peru, Bolivia and Ecuador, there are immitable rubber forests as yet unexplored, which will now be gradually developed. Many seringueiros, or rubber gatherers, are making their way to these regions, and it is reported that several syndicates are about to begin operations in new fields in Bolivia and Peru. Bolivia continues to offer inducements for the colonisation and development of her vast area of rich rubber and mining territory.

The Consul adds that he is informed that the Government of the State of Amazonas has granted the exclusive privilege of receiving, cutting and packing all the rubber produced in that State to one wharf company. The creation of this monopoly will injure the rubber trade of that region, but Peru Bolivia and Ecuador will be the gainers, as rubber growers and gatherers in Para are seeking to escape the new restrictions, which entail considerable expense and trouble upon exporters.—*Board of Trade Journal*, September 4.

MR. ALLEYN'S NEW PATENT.

Among the applications for patents for inventions in India appears the following entry:— John Grieve, Engineer of Hatton, Ceylon and Henry Mathew Alleyn, planter, of Meeria Cotta, Maskeliya, Ceylon improvements in apparatus for grading, sifting, polishing, and increasing the keeping qualities of green or oolong teas, and improvements in apparatus for polishing, grading, sifting, and increasing the keeping qualities of black or fermented teas.—*M. Mail.*

—*India Rubber World*, Sept. 1.

PLANTING IN NORTH TRAVANCORE.

It is 25 years since Mr. Wm. Hendry, who leaves for "home" by the ss. "Shropshire" on Sunday, first came to Ceylon. But he had a break in that period of 10 years on his farm of Cairnton, near Fordyce, which farm he keeps on, although he has now again been out a good many years as a Manager of tropical estates. Mr. Hendry's latest engagement has been for four years in charge of the Puluvasal division of the Great Kanan Devan Co.'s property in North Travancore, under the chief management of Mr. P. R. Buchanan who is as active as when he was tea planting in Assam many years back. Mr. Hendry has a wonderfully good account to give of the

COFFEE, CARDAMOMS AND CINCHONA.

He himself has had chiefly to do with coffee, and it is quite cheering to learn of the splendid crops—4,000 to 6,000 bushels from less than 200 acres of young coffee. Indeed, the coffee had to be stripped of a great show of berries at two years old and it gave 40 tons the following season while it is due for 60 tons now. There is the inevitable fungus about; but it does not seem to do harm above 4,800 feet. Cardamoms are growing well; but recognising the limited market, energy is now chiefly directed to planting

CINCHONA

of which there will be a magnificent show ere long. As regards tea, hitherto the manufacture has been mainly through one factory; but Mr. Buchanan seems to favour separate factories which will no doubt cause Superintendents to take a greater interest in how their teas turn out. The WIRE TRAMWAY continues to work most satisfactorily.

PLANTING IN JAVA AND EXPORTS.

In connection with the emigration of Javanese, referred to in my last letter, the necessity of it is argued from various sides on account of the strong increase of the population. In 1870 the population in Java was 16,000,000 souls, and at present it is 28,000,090, thus showing an increase of 12,000,000 in thirty years. How to find work and food for this great number, which will continue to augment? This is a question earnestly to be considered by all who have the interest of Java at heart. Various means are mentioned, such as improvement of agriculture by irrigation, restraint of the cattle plague, and of disease in the coffee plant, and support of the sugar cultivation, &c., and if more attention had been given to all these means in former years much of the misery from which the population now suffers would probably have been prevented. Fortunately the condition is not gloomy in all districts. In the Preangerlands the condition is improving, and this will also be the case in the east corner; but notwithstanding this, a remedy will have to be found against the overpopulation. For this reason the attention is directed to emigration to the other colonial possessions, and among other places also the Lampong districts in South Sumatra are mentioned, where the soil is excellently fit for the cultivation of coconuts, rice, sago, sugar, cotton and indigo.

Of the comparison of the statement of exports of 1901 with the last twenty years, the result is certainly surprising. The general exports increased from fl.154,000,000 to fl.230,000,000, among which are several articles in which the natives have a direct interest, such as wood, fl.700,000 more; cinchona bark, fl.3,600,000 more; coffee, fl.5,900,000 more; petroleum, fl.4,600,000 more; rice, fl.2,500,000 more; sugar, fl.1,800,000 more; tobacco, fl.15,200,000 more; tea, fl.2,400,000 more. The total is thus fl.36,700,000, of which fl.1,500,000 must be deducted for reduction in value of exported indigo; balance, fl.35,200,000; so that still fl.36,000,000 of the increase of fl.76,000,000 have to be explained. The export of coprah was in 1884, fl.113,831, and at present fl.10,300,000. Sundry kinds of rubber increased by fl.13,300,000, shells by fl.2,600,000, and the balance must be found in various articles.—*L and C Express*, Sept. 12.

VISIT TO A RUBBER, CACAO AND COFFEE PLANTATION IN COLUMBIA, CENTRAL AMERICA.

VARIETY AND YIELD OF CASTILLOA TREES.

Dr. C. O. Weber is contributing to the "India-rubber Trade Journal" an account of his journey, inspection and laboratory work on a large plantation in the isthmus of Columbia which includes some 70,000 rubber trees (*Castilloa elastica*) some of them 11 to 12 years of age, besides cacao and coffee. Dr. Weber mentions that of the rubber-yielding *Castilloa* (there are at least four species) the best is the one possessing a whitish bark: it yields plenty of excellent rubber. Another has a black bark with a rough, irregular surface, and this yields a rubber as good as the white bark kind, but the tree is rapidly exhausted. Then again there is a variety with reddish bark very thin and fragile, which yields very little latex, but the rubber produced is of good quality. Still further, there is a variety "*Castilloa* of Panama" distinguished by the enormous size of its leaves—some of them even on young trees being 20 inches long. Now Dr. Weber found that the trees on the plantation above mentioned have a bark neither yellow nor white, but of a delicate pale pinkish brown, and they are found to produce a good yield of an excellent quality of rubber. Dr. Weber's results from the tapping of the trees on the Columbia plantation are given as follows:—

Age of tree	Yield of latex.	Per cent of rubber in latex.	Yield of rubber.
6	1 lb 13 oz	26	7.5 oz
7	2 lb 5 oz	26	9.6 oz
8	3 lb 1 oz	29	14.2 oz
11	5 lb 3 oz	31	1 lb 9.7 oz

These figures are much better than those obtained by the late Dr. Trimen at Peradeniya, and it is further stated that Dr. Weber considers his figures rather below than above the mark; while as the trees in question can with perfect safety, be tapped twice a year, the annual rubber yield can be taken at double that in the last column as given above. All this may be considered fairly satisfactory to our *Castilloa* rubber planters—few and far between as we fear they are. To wait 6 and 7 years is a long time; but a crop then of a lb. of rubber per tree, rising year by year until at 11 years over 3 lb. can be harvested, should repay both labour and patience if prices only keep as good as there is every prospect of their doing.

THE CEYLON "HANDBOOK AND DIRECTORY."

(By a *Jungle Eremite*.)

"Got what agin," growled Bill; "what's the matter now?" "It's the jumps, Bill," gasped the other, "the 'orrors they've got me and no mistake!"

This from Anstey's "Vice Versa" almost portrays my state of mind on reading—

"The present is an *ad interim* edition of the 'CEYLON HANDBOOK AND DIRECTORY.'"

I was seriously disturbed about my mental balance. Here I am in the jungle, my nearest neighbour miles away. At last I be-thought me of my Chinese k'ane. "What are those two words?" I asked. "*Ad interim*, Sir." I drew a long sigh of satisfaction: my nerves were all right after all! Rashly enquiring, he pursued, "Please, Sir, what is an *ad interim*?"

The strain had been severe. Rising on tip-toe and grasping the Great Red Tome firmly in both hands, I brought it down with a mighty crash on to the cranium of the pig tailed one. "*That*," I exclaimed, "*th^as*," and thou baleful one, *that* is an *ad interim*!" And the wretched Confucian sank into the bowels of the earth.

"Can't you ever be serious?" says the Familiar. (I could write a chapter on Familiars. Socrates, like the writer, must have spent many lonely years in the jungle. This time the invisible one is evidently a female. A male would have said: "Can you never be serious?")—"Can't you ever be serious?" Yes, my dear, as serious as a graven image and as dry as a wooden god; which reminds me—Boy, bring light refreshments.

But what I want to know is, if this is an *ad interim*, what is the *final* to be like?

It is impossible to be serious while that impudent little Familiar is raving at me out of Stephens' best blue black. * * * *

I think the compiler is to be congratulated on his dedication: and the illustrious person thus honoured may well count it as another feather in his cap.

The military information, especially the full details of the local Volunteer force on pp. 305, 604 620, 735 and 1,015, is of interest to many who, perhaps, do not often make use of the Directory!

To add more would be to pile Ossa on Pelion (or should it be Pelion on Ossa?). If Mr. Ferguson is to be congratulated on his Directory, much more is the colony to be felicitated on having such a single-hearted public man, such an excellent and pains-taking compiler, and such an able and accomplished statistician.—*From Sumatra.*

COCONUT CULTIVATION IN THE STRAITS.—

We are aware that a good deal of Ceylon money put into "Coconuts" in the Straits, is considered to be as good as lost, except where rubber has been planted between the palms and is succeeding, so as to become the main staple. Our late friend Mr. A E Wright was very sanguine at first about his young coconut plantation in the peninsula; but his trustees were glad to get out of the place for a small sum comparatively. The explanation of a good deal is found in the correspondence given in the *Straits Times*. On page 341 Mr E V Carey replies to Mr Greig and throws a good deal of light on coconut planters' troubles.

* Up to June, 1902: Colombo, A. M. & J. Ferguson, 1902.

Correspondence.

To the Editor.

AGRICULTURAL INFORMATION: A CORRECTION.

Imperial Agricultural Department for the West Indies, Barbados, 21st August, 1902.

DEAR SIR,—In the *Tropical Agriculturist* for July 1902, p. 11, just to hand, I notice an original article on the "Preparation of Commercial Papain" with wood-cuts is reproduced from the "Agricultural News", the fortnightly review of this Department, without an acknowledgment as to the source whence it was obtained. I am always delighted when information, in respect of tropical products, published by this Department, is reprinted elsewhere; but, in the instance I have referred to, it deals rather hardly upon us as the article is, as far as I am aware, the first which has appeared exactly describing the preparation of papain on a commercial scale based on the experience of many years. I am quite sure it is due to an oversight and that it only requires to be brought under your notice to be put right.*

I am glad to say that the publications of this Department are being largely appreciated in these Colonies. Last year we distributed about 50,000 copies of Bulletins, Pamphlets, and Leaflets amongst all classes of the community.

I heartily congratulate you on the completion of the Twenty-fifth † Volume of the *Tropical Agriculturist*.—Yours truly,

D. MORRIS,

"CEYLON TEA CHESTS AND TEAS FOR THE CANADIAN MARKET."

Foochow, China, Sept. 15.

DEAR SIR,—Our attention has been called to a letter dated Montreal, 12th March last, which appeared in the Correspondence columns of your paper dated the 30th July, in which the writer stated that the interests of the Ceylon Planter are seriously endangered by the use of "pine boxes" whether from China or Japan, and goes on to say that such wood can have no other effect, but to injure the teas packed in it. He also implies that in order to land the teas in good condition it is necessary to pack them in packages made in Japan from Momi wood. The reason for this opinion is not hard to discover when we see that the writer is "A Japanese Tea Importer in Montreal."

We wish to refute the statement that ill-effects to the tea will be brought about owing to the use of "China Pine" boxes. To all those who know tea it is a recognised fact that if there is one tea more than another which is susceptible to damage from smell it is China tea, and yet, in spite of that fact, all these teas have in the past and are now being packed in boxes made from

the so-called "China Pine"!!! In addition to this, all the boxes used for the packing of the extremely delicate teas of Formosa are made in this Port of Foochow from the very wood which "Merchant" so censures as a packing material.

As tea box-makers we are fully alive to the fact that wood smelling of resin is not at all suited to the requirements of the tea exporter, but so-called "China Pine" does not smell of resin or anything else, but is a clean wood of attractive appearance and great toughness and, on account of this latter quality, is superior to the Momi.

We maintain and can prove by actual results that the "China Pine" package will land its contents in Montreal or any other place free from taint (due to the box wood used) in better condition than will the Momi package, and that in addition to this the Planter will be able to reduce his expenditure for packing material.

We do not follow "Merchant" 's argument when he says that the writer, (A Japanese Tea Importer in Montreal) should know best what suits the trade!! We think that the latter is prejudiced in favour of the produce of Japan, for reasons best known to himself, and is doing his best to help forward Japanese interests at the expense of the Ceylon planter. We are convinced that if once "China Pine" packages were used by "A Japanese Tea Importer" he would find that his teas were delivered on the consuming market free from all resinous taint and that the packages carried their contents better than any other package yet placed on the market. Asking you to be good enough to insert this reply.—We are, dear sir, yours faithfully,

FOOCHOW SAW MILLS, Co., DODWELL
& Co. LTD., per E J MOSS, General Manager.

THE FIRST SNIPE OF THE SEASON.

SIR,—Mr. A. W. Gray reported the first snipe of the season on 7th September. I recall one shot at Wilson's Bungalow some years ago on September 1st. Can this be beaten? Please reproduce the following lines to cheer up

SOME OF US.

THE FIRST SNIPE.

Oh say to the sportsman what sound more exciting
In the cool grey of morning, or shadows of eve
Than the chirp of the snipe from the rice swamp, in-
viting

Pursuit, which it scarcely can wish to receive!
Above the rank sedges, to note the gay twitting,
To fill up our cartridges, quaking with fear,
Lest Brown hearing too, be before us in greeting

The first snipe of the year!
We shout to our Boy, and we bid him be ready,
At first glimmer of dawu with a basket of "prog,"
Aid to hunt coolies up who are knowing and steady
At beating up game in each promising bog;
And we speak with affection, and anxious directing
Bidding mongrel pups, our instructious revere,
And tell them most wonderful legends respecting

The first snipe of the year.
By daybreak we've donned our most ancient of
trousers,

Boots and coat only fit for an old clothes man's
sack,
We whistle the "Tommies" and "Bullies" and
"Towers"

That form our remarkable nondescript pack,

* We regret extremely the carelessness of a foreman printer in the matter.—Ed. T.A.

† Not quite; the 21st is our last—attaining our majority!—Ed. T.A.

We mount our gay tat and give millions of orders,
To coolies, and beaters, then merrily steer
Through the mist to the swamp which we hope will
afford us

The first snipe of the year.

Then we eagerly pull out our gun from its cover
And round us our cartridge-belt carefully strap.
We scorn the seductions of plaintive-voiced plover.
For the jungle-cock's crowing we care not a rap.
Down we crush past the screw pines, and through
the thick sedges

And hope that the mist wreaths will presently clear,
Send Ninga and Carla to beat up round the edges

The first snipe of the year.

"To heel," all you puppies, no foolish skylarking,
Too serious this for mere skirmish and play."
Then our eager eyes strain where the coolies are
marking—

Ah! ha! something rises, it's coming this way!
Bang, bang, go both barrels, at once almost firing,
The dogs, spite of shouting, rush forth from the
rear,

Look sharp ere those juveniles spoil, past admiring,

The first snipe of the year.

We pick it up gently, was ere such a beauty?
Just look at its plumage, and length of its bill!
Then off tramp we once more, for we feel it our duty,
Ere we breakfast, at least one good gamebag to fill.
What is that?—Oh good gracious, another gun
popping!

Within us arises a terrible fear
Some one else with more luck than ourselves has
been dropping

The First Snipe of the Year.

With rage in our heart through the swamp we go
plodding

And wishing our rival were in it fast stuck,
Till we come on old Brown who is frantically nodding
And in stentorian tones is abusing his luck.
"Not a bird can I hit, though persistently blazing,
"Away in the brown"—Then we give a wild cheer.
And draw from our bag, to his view high upraising

The First Snipe of the Year!

Ah! well, it is sport, and who'd think of ill-feeling
We stump on together, and share all our fun,
Till we feel rather limp, and our noses are peeling,
For above us is shining a powerful sun.
So we think about breakfast, and soon we are eating
Like warriors Homeric: ere long we clear,
Every dish, then praise thy life beauteous but fleeting

First snipe of the year!

We uncork in thine honour a fresh foaming
bumper,

(For shooting produces a wonderful thirst)
Ah! our bags may contain others, sleeper,
plumper,

Or larger, what matter when thou wer'
the First.

To the puppies, who watch us with tremulous tails
We endeavour to make this great difference clear.

And with whinnies of joy each expressively hails
The first snipe of the year.

Then as we ride home, we think, how can we hinder,
Our cook, who is safe our best feelings to shock,
By reducing that snipe to a pitiful cinder

And serving him up upon toast like a rock!
Oh! dear little bird, what a brilliant example,
To our frail human nature, thine own doth appear.
In death as in life a most excellent sample—

First snipe of the year!

E.

LIQUID FUEL FOR OIL ENGINES.

Colombo, Sept. 20.

DEAR SIR,—Messrs. Brown & Co., Ltd.,
Nawalapitiya, write us under date 19th inst.,
as follows:—

"Our engine is still running perfectly with
the Liquid Fuel and we have not cleaned it
yet. It is exactly two weeks yesterday
since we started running it continuously."—
Yours faithfully,

DELMERGE, FORSYTH & Co.

PROPOSED INCREASED IN TEA CESS.

Rookwood, Hewaheta, 24th Sept.

DEAR SIR,—I enclose for publication copy of
letter sent to the Secretary, Ceylon Association
in London, with reference to the proposed increase
in the Tea Cess.—Yours faithfully,

A. C. KINGSFORD.

Rookwood, Hewaheta, 22nd Sept., 1902.

W. Martin Leake, Esq., Secretary, Ceylon Association
in London, 61 and 62, Gracechurch Street, London,
E. C.

Dear Sir,—At a meeting of the "Thirty Committee"
held on the 13th inst, next year's votes were fully
discussed and the following resolution unanimously
adopted. Resolved:—"That with the present Cess
Fund at the disposal of the Committee the following
estimate for 1903, marked A, be approved, but the
Committee strongly recommend that the Tea Cess be
increased to half-a-cent per pound, and on that basis
submits the appended alternative estimate, marked B,
for the support and approval first of the Ceylon Association
in London.

ESTIMATE FOR 1903 (A).

Green teas (7,000,000 lb at 4 cents) ..	R280,000
America	105,000
Continent of Europe	75,000
Administration, Contingencies, etc. ..	10,000

Total ... R470,000

ESTIMATE FOR 1903 (B).

Green teas (12,000,000 lb. at 5 cents)	R600,000
America	105,000
Continent of Europe	75,000
Administration, Contingencies and unvoted balances	20,000

Total ... R800,000

The meeting that passed the above resolution was
thoroughly representative, twenty-eight, including all
the Colombo members being present. I invite fuller
consideration of the votes as explained under the
separate headings below:—

GREEN TEA.—The manufacture of this continues to
show a steady increase. The bonus has been paid on
the following quantities:—

1898 ...	13,302 lb.	1901 ..	590,000 lb.
1899 ..	86,327 "	1902 ..	2,316,921 "
1900 ..	472,294 "		(to date)

Total 4,478,844 lb.

This figure does not quite represent all the green
tea made, as the bonus is only paid on a certain
proportion of dust and faunings and on tea up to a
standard. The supply of Ceylon green tea at present
is not equal to the demand, the price has
consequently risen lately three to four cents a pound,
but many factories are now commencing to manufacture
and it is hoped the output for the year will reach
4 millions for which a bonus at 5 cents, per lb. is
available. This amount could, no doubt, be continued
next year with little or no assistance in the form of a
bonus, but to double or treble this total, many other
estates must be induced to purchase the necessary

machinery to manufacture this class of tea, and for this purpose, it is essential that the bonus be continued. If a larger quantity is made the price, no doubt, will fall temporarily; therefore the bonus offered should be sufficiently large to prevent green tea manufacturers turning their attention to black tea, the moment the price of black tea rises slightly, or the green tea market falls. Many are considering the question of manufacturing green tea, and any reduction in the bonus just now, is, therefore, very undesirable. A normal increase during 1903 would show an output of "7 million lb. and on this quantity our funds permit of a bonus of 4 cts. per lb. only." But in view of the large quantity of faced teas now going forward, which appear to be competing favourably in the United States with Japan pan-fired teas, given sufficient funds, a considerably larger quantity than 7 millions might be made next year. The Committee feel they should be in a position to encourage to the fullest possible extent, any demand for green tea that may arise, and it is for this reason alone, that they ask the permission of proprietors to increase the Cess to half-a-cent. per lb. It is generally conceded, that in manufacturing a considerable proportion of our crop into green teas lies our surest chance of improving the present position of tea producers and the prospects of success in this direction are very promising. Wherever our green teas have been introduced, in Afghanistan, Russia, Canada or the United States, the superior cup qualities of our tea have been at once recognised. These markets consume about 100 million lbs. of green tea.

The United States tea duty is to be removed on the 1st January, and dealers are, in anticipation of this, doing a hand-to-mouth trade, carrying only short stocks. This fact combined with the scarcity of Japan greens should afford us a great opportunity, during the early months of next year, for placing Ceylon green tea on a sound and permanent basis.

CONTINENT OF EUROPE.—The progress made on the Continent (apart from Russia) is of necessity slow, as the majority of the people do not drink tea. The small amount consumed is chiefly China, the bulk of which is laid down at Hamburg or Bremen at prices too low for Ceylon to compete with; but it is hoped that by steady persistence in pushing our teas, their better quality will bring them into use, and the same success in displacing China tea be obtained as in the case of the United Kingdom, Australia and Canada. A Renter telegram, dated London Sept. 10, "The trade returns show that the use of tea is steadily increasing in France, is encouraging; the reduction of the duty on tea in Germany next year should assist also.

The Committee have apportioned Mr Renton £5,000, or R75,000, for his 1903 campaign.

AMERICA.—The following remarks and figures taken from one of Messrs Gow, Wilson & Stanton's circulars are instructive:—"Considering the condition of the Tea trade in the United States and the heavy falling-off which took place in imports of other Tea into that country, it is encouraging to note that a larger quantity of British grown Tea has been taken. Prospects should be better when the duty which was put on as a war tax is finally removed.

CEYLON TEA TAKEN IN THE UNITED STATES AND CANADA.

1895	1896	1897	1898	1899
3,744,736	4,364,510	5,698,596	7,636,995	8,289,376
		1900		
		9,176,684	12,239,918"	

During the same period Indian imports increased from four millions to seven millions. The above figures may be considered very satisfactory, shewing as they do a steady increase in the consumption of Ceylon tea, at a time when the total imports of tea into the United States were falling off, as a consequence of the war tax. With the early removal of this tax, the increasing amount of green tea to be introduced and the representation of Ceylon at the St.

Louis Exhibition in 1904, the Committee feel the efforts of our Commissioner cannot at this time be relaxed, and that the Campaign in America should be continued at least to the end of 1904. We have set aside £7,000, or say R105,000 to be spent in America next year. Mr Mackenzie is to be asked to break new ground, farther West, in the vicinity of Chicago and St Louis.

FINANCES.—Estimating the crop next year roughly at 160 million pounds, at the present rate of Cess this would yield R480,000 add probable balance in hand at end of 1902 R200,000

R500,000

of which R470,000 has been voted, as per estimate (A), leaving a balance unvoted of R30,000.

If the Cess was raised to half-a-cent per lb the Committee would be in a position to make provision for 12 millions of green tea at 5 cts per lb.

It may not be necessary to impose the full amount of the increase; all we desire is that the limit of the present Ordinance be raised from 30 cts to 50 per 100 lb and that the limit need only be enforced, if the money is actually required for assisting the green tea industry. The Cess was introduced in the year 1894, for the purpose of increasing the consumption of Ceylon Tea in foreign lands, and how far this object has been attained, the following figures will shew. I again quote from one of Messrs Gow, Wilson and Stanton's circulars:—

Ceylon tea taken in foreign markets.	lb.	percentage of crop. per cent.
1895	... 19,923,803	19
1896	... 23,465,733	22
1897	.. 29,131,021	25
1893	.. 36,066,888	30
1899	.. 33,438,509	30
1900	... 49,259,693	33
1901	.. 58,797,549	40

During the same period the Indian exports to foreign countries show only an increase from 17 million to 36 million pounds. "This opening of new outlets has practically saved the industry from ruin." Indian planters fully recognise the advantage we have derived from our Tea Cess, and their long agitation to obtain a similar levy, is likely to be shortly accomplished. Steps are being taken to bring about an understanding with the Indian Tea Association, regarding joint action between India and Ceylon wherever possible, and to thus avoid the wasting of funds, by working on contrary lines.

I shall be glad if you will kindly put the above-mentioned resolution and connected matter before your Association at an early date. I may mention that the Hon. Mr W H Figg will be in London shortly, and if there at the time of your meeting, he will be glad to explain matters still more fully, and give the resolution his support.—I am, Dear Sir, yours faithfully,

A. C. KINGSFORD,

Chairman, Planters' Association of Ceylon.

CARDAMOMS IN CEYLON AND IN MYSORE:

SUPERIORITY OF THE LATTER.

Sept. 21.

SIR,—I notice that certain brands from the Native State of Mysore are included in your list of sales of 'Ceylon Cardamoms.' I enclose cutting of the same. These were shipped per 'Clan Macintosh.' Please reprint these to show that Ceylon is a long way behind Mysore still:—

CEYLON CARDAMOMS.

'Clan Macintosh.'—CCC in estate mark, 8 cases sold at 2s 10d, 1 at 2s 11d, 11 at 2s 10d; CT in estate mark, 3 cases sold at 2s 9d, 2 at 2s 10d;

MMM in estate mark, 12 cases sold at 2s 9d; MG in estate mark, 1 case sold at 2s 8d, 2 at 2s 9d, 3 at 2s 10d.

Is the fact forgotten that the nomenclature of cardamoms in Ceylon is all wrong? Cardamoms, that are called 'Mysore' in Ceylon are really 'Malabars' or 'Alleppy.' Cardamoms that are called 'Malabars,' are really 'Mysore.' It is, I am afraid, too late to change this now. 'CCO' brand is Cadamony, 'MMM' brand is Münjanbulla, both being estates in Mysore. I do not think that, in the list of Ceylon sales, from which this cutting is clipped, any of the 'Ceylon's' have fetched over-2s.

LATE MYSORE PLANTER.

[Can our correspondent explain why the Mysore cardamoms should be so superior? Is it the better soil or drier climate—or both? Even then, some parts of Uva and Maturata should offer as favourable conditions?—ED. T.A.]

CARDAMOMS IN CEYLON AND MYSORE:

ALSO ABOUT PEPPER AND TEA

PRACTICAL HINTS.

Sept. 26.

SIR,—In answer to your query *re* Mysore cardamoms I may state that the pubescent cardamom of Mysore (called in Ceylon "Malabar") has a far finer sample than the robust cardamom of Alleppy (called in Ceylon "Mysore") which now has taken the place of the other variety in Ceylon. Not only that; but I consider the treatment adopted in Ceylon is not so conducive to preserve the aroma as that on the estates in Mysore. In Mysore the cardamoms are dried by artificial heat and never see the sun until the bleaching process is begun. I should advise Ceylon growers to dry hard (preserving the green colour) and then have the cardamoms soaked, sulphured and bleached in Colombo. But to insure success you want some one in Colombo who understands the delicate handling of cardamoms. They should be spread on white cloths instead of dirty jute-hessian. This is not only a cleaner method, but the stray seeds from broken capsules are more easily seen and gathered. The two brands, I mentioned in my last letter, have never been sulphured. They are entirely sun-bleached. The sulphur processes, I think, cheaper and quite effective enough; but I never cared for the Ceylon way of sulphuring the cardamoms in the green stage. This leads to premature exposure to the sun which not only causes the cardamom to split, but also robs the delicate spice of much of its precious aroma. More care should be taken in picking the fruit. Where I was, the gangs went round every eight days (like tea) and boys were put on behind the gangs to find any missed ripe fruit. For every missed fruit the boys demanded six fruits from the peccant picker. Thus there were no fruit over-ripe or under-ripe if the gangs were well supervised as on a tea estate. Thus the sample was even and good. (Do your Pepper-growers know the advantage of "boiling" the berries? It's a good tip.) I consider that severe pruning of tea is ruining your bushes and causing planters to fall back on manure. This is not healthy. Prune lightly, dig your land, and pluck lightly.

LATE MYSORE PLANTER,

SUPERIORITY OF PRODUCTS IN INDIA.

DEAR SIR,—You ask why are Mysore Cardamoms superior to those of Ceylon; but why I may also ask was "Cannon's Mysore Coffee" superior to the very finest Ceylon Plantation in its day; while again Cochin Copra and Coconut Oil are always quoted at a considerable advance over Ceylon; and finally nothing in Ceylon can touch Darjeeling Tea! So you islanders ought to

CRY SMA!

[Very true; but there are a few things in which we are unapproachable, at least by India:—Our Cacao, highest price in market; our Cinnamon, the only perfect spice(!); our Plumbago; and now our Rubber and, last not least, our Green Teas!—There is nothing like having "a gude conceit" of ourselves.—ED. T.A.]

COCONUT WATER.

DEAR SIR,—An English visitor to Colombo, who had been a wine merchant in London, casually mentioned to me that he thought a capital and suitable drink for Ceylon could be prepared out of coconut water. He said it was having his attention, but I have heard nothing more yet. I send you his name for your private information. As he well remarked, our aerated drinks, such as lemonade, &c., were not light enough for the climate.—Truly yours,

INTERESTED.

[We fear the gentleman named will never be well enough to continue his experiments. Some one else should take the matter up.—ED. T.A.]

NEW AND MINOR PRODUCTS IN THE LOWCOUNTRY OF CEYLON.

Sept. 24th.

DEAR SIR,—In the "Agricultural Magazine" for August, the first article is on Keppetiya and

BETEL.

Agriculture is sure to advance, if all Mudaliyars and chief headmen in the island were to take as great an interest in it as does Mr. George Weerakoon, Mudaliyar of the Wellaboda Pattu, Matara. His communications on various agricultural subjects very often find a place in the pages of this useful Magazine.* It is to be hoped that this progressive Mudaliyar inculcates his views on the people under his charge, through his subordinate headmen. Why should not every Mudaliyar and his equivalent in the other Provinces, and aye, every Kachecheri as well, have small model gardens as object lessons and for the distribution of seeds and plants? All villagers believe in the virtues of Keppetiya (*croton tacciferum*) as a manurial agent, and use it in betel and garden cultivation. All aromatic smelling leaves are said to be valuable as fertilizers. Besides acting as mulch, Keppetiya leaves decay rapidly and becomes available as manure.

In "Notes," reference is made to the believers and unbelievers in the encouragement of the growth of

* Which, it may be mentioned, is regularly incorporated with the *Tropical Agriculturist*.

MIMOSA ON COCONUT ESTATES,

as a means of utilising this plant to attract to the soil supplies of nitrogen from the atmosphere I have heard it stated that one enthusiastic believer in it, stated that by encouraging its growth, he found that he not only secured better crops, but the kernel of his nuts was thicker than before and yielded a larger proportion of oil. The mimos is spoken of as "modest." I will call it "aggressive" or "assertive." Once let it get into your estate and you will have a constant battle to get rid of it. It is as difficult to be got under subjection as the Boers were. I have noticed parts of coconut estates over-run with it, and the trees were, by no means, looking better than their neighbours. But, says the enthusiast, to derive benefit from the mimosa, you must turn it into the soil. Why attribute any improvement that takes place in the condition of the trees to mimosa alone, and give no credit to the tilling of the soil and the green manuring involved in the operation? The benefits of both are beyond question. In European agriculture, clover was long known to leave the soil richer in nitrogen after the crop than before. Yet it was not dug into the soil, but was removed for fodder. Experiments have established that all legumes have bacteria-infected nodules, which have the property of converting the free nitrogen of the atmosphere into combined nitrogen assimilable by vegetation. The modest "pilla" is a leguminous plant growing on coconut estates, whose leaves, both here and in India, are used as a manure. The growth of the plants might be encouraged round the stems of coconut trees, in preference to the "touch me not," more true as regards its aggressive thorns, than its shrinking sensitiveness.

FLORIDA BEANS are much used now as an article of consumption. The possession of a deleterious principle in the bean, which is said to induce colic, has been overcome by first boiling the beans in water mixed with turmeric and salt. The hairs are all rubbed off, they are then fried with onions and made into a curry. A tree has been discovered, the wood of which, when partly cut, emits a strong odour of iodoform. I have met with a red, clayey soil in the hills of the Morowakkorale emitting a decided odour of iodoform.

The sixth lecture on PLANT LIFE is very attractive, and is very instructive reading. The best soil for cultivation should contain:—

Sand	50 to 70	per cent.
Clay	20 to 30	,"
Humus	5 to 10	,"
Carbonate of lime	5 to 10	,"

Alluvial soils are fertile by reason of the action of running water mixing their constituent parts thoroughly. A soil composed entirely of sand is valueless agriculturally, as it is non-retentive of moisture and has no plant food. Clay alone is as unsatisfactory as sand. Its close texture renders it impermeable to water, it is cold and damp and will bake as hard as a brick in dry weather, and is of no value as plant food. As a soil constituent, sand renders a soil porous and permeable to air, moisture and warmth; while clay absorbs gases from the atmosphere, keeps a soil moist and cool and is retentive of plant food, which would otherwise be washed out of it. The impurities of clay and sand are potash, magnesia, lime, iron, &c., derived from the rocks which are the origin of soils; these are important constituents

of the mineral food of plants. Sand and clay form the bulk of soils. Lime is a plant food and decomposes organic matter which supplies the nitrogenous food of plants. Nitrogen is at its highest in a peaty soil and at its lowest in a sandy soil. Clay soils have most phosphoric acid and in sandy soils the least. Clayey soils are also rich in potash, and calcareous soils are rich in lime. Sandy soils are deficient in both.—Yours truly

SCIENCE AND PLANTING.

LIQUID FUEL INSTALLATION.

Colombo, Sept. 30.

DEAR SIR,—Messrs. Brown and Company, Limited, Nawalapitiya, write us under date 29th instant, as follows:—"Oil Engine. We cleaned our Hornsby Akroyd Oil Engine yesterday, not because it showed any signs of wanting to be cleaned, but because we were anxious to see in what condition it was in, to enable us to form an opinion as to how long it would be advisable to continue running it in future without cleaning."

"There was a small quantity of deposit at the back of the Vaporiser, but the front of the Vaporiser and the back part of the cylinder were quite clean. The piston was clean and bright, and the rings were quite loose. The engine had run 23 days without cleaning, so that in future we will not need to clean it more than once in 4 to 6 weeks. It was running as well at the end of the 23 days as it did on the day it was started."—Yours truly,

DELMEGE, FORSYTH & CO.

CEYLON PATENT OFFICE

DILATORINESS.

Stagbrook Estate, Peermaad, S, India,

Sept. 30.

Sir,—With reference to your para, in the issue of the 25th September, regarding the "Deane-Judge Patent Strainer" you hint at other "patents being before the public ere long." This may be the case, but all I can say is that it is ten months since we applied for our Ceylon Patent and we can't get a definite reply from the Ceylon Patent Office. Considering that at the present moment there is, as far as I am aware, only one patent in existence as regards green tea manufacturing appliances, and it has taken the Ceylon Patent Office ten months to search the records, what price a speedy issue of other patents? Meanwhile producers spend at least 10 per cent more on production than need be the case, and we are unable to advertise freely the exact nature of our improved machinery which will so greatly economise the manufacture of "Green Tea," and would probably mean that a 4 cent bonus would be more remunerative to Green Tea Producers than a 5 cent bonus is at present.—I am, Sir, yours faithfully,

H, DRUMMOND DEANE,

PARA RUBBER IN MATALE.

Kepitigalla Estate, Matale, Oct. 1.

DEAR SIR,—I think the following sale of three cases containing 336 lb. nett of Para rubber grown on Kepitigalla estate, would interest those concerned in rubber cultivation, and also show that high prices can be obtained for rubber grown in Matale district. The price of fine Para, at the same sale, early this month, was 3s 0½d and three cases Kepitigalla sold for 3s 10½d, a price 10d above best Para. I have just despatched another 13 cases, and shall let you know results of sale. You will notice that the fine price 3s 10½d has been obtained for a large quantity (for Ceylon) and not merely for a few lb. which could be specially cured.

I will also take this opportunity to reply to the "Critic" in the "Times of Ceylon" who wished to make out that this estate was not in the Matale district. Kepitigalla estate proper is in the Matale district, as I know, when I have had to deal with the Village Headmen and Government Agents. Your contemporary's "Critic" might just as well say Yatewatte is not in Matale, as a good portion is in Kurunegala, and even facing Messrs. Finlay, Muir & Co.'s Delwita estate. But why particularise as to our boundaries? The fact remains that Para rubber has been most successfully grown, and proved to be of commercial value, and yield handsome profits. As I have proved by figures in my last letter it has cost 47 cents in Colombo or, say, 50 cents in London, and practically yielded a clear profit of R2:38 per lb. I also notice in the *Tropical Agriculturist* for September an article on Vanilla in Ceylon, where, it is stated that 70 beans was considered good for a vine. I have vanilla growing on this estate, 60 to 80 feet in length, trained on poles, 4 feet above ground, with 300 to 350 well-developed beans 5 to 9 inches in length, mostly about 7 to 8 inches, and have many vines with 150 to 200. I shall be pleased to show any one interested in vanilla cultivation, over the part of estate where the vanilla is grown.—I am, Sir, yours faithfully,

FRANCIS J. HOLLOWAY.

CEYLON TEA FOR AMERICANS IN THE PHILIPPINES.

Mindanao, Philippines.

SIR,—The aggressive operations for disseminating knowledge concerning Ceylon teas and the amount of money and energy the Ceylon Planters are expending on the above, leads me to make a suggestion nearer home. You are making efforts to educate the United States people to drink and judge good tea. So why not try them in the Philippines where there are over 30,000 soldiers and about 5,000 American civilians. The U. S. Army calls for tenders in Manila to supply the soldiers with tea and, if your planters could furnish the tea to them at, say, even cost for a trial or two, it would be money well-invested in my opinion, for the reason that when these thousands learned to drink Ceylon tea they would, on returning to their homes all over the States, be an advertisement in themselves as well as being consumers of the tea. Think of the influence these people would have in pushing

your teas in their home districts which would embrace every State in the Union. I know locally the officers and their wives are enthusiastic on Ceylon tea. I always use it and everyone who drinks it in my house say: where did you get it?—procure some for me and I have been doing so though with difficulty I have to send to Borneo and the steamer connections with Sandakan are very poor. I have no hesitation in saying that your tea once introduced to Americans in the Philippines, they would carry the flavour home and want it there. At present the army is using China teas and are paying —* a lb. I was a buying agent for two years for a Manila firm of Government contractors and in that capacity travelled over Australia, China and Japan; the former for meat and produce and the latter for produce and tea, and after seeing the Chinese and Japanese coolies preparing the leaf, I never drunk tea from these countries. The rolling and roasting process of fire dried teas is especially disgusting, where the women, in an almost nude condition are bending over the fire-pans and rolling the tea around, while the filth and perspiration dropping off their warm bodies into the pans is a sight that once seen, needs no further persuasion to abandon drinking these teas. There are a great number of army ladies in the Philippines, and as all ladies like good tea, I am sure they would be staunch supporters of using Ceylon tea on economical grounds alone, as a good tea is a cheap tea.

FRANK J DUNLEARY.

THE OBNOXIOUS PREPARATIONS OF CHINA AND JAPAN TEAS:

MORE AUTHENTIC "COPY" FOR A P. A. PAMPHLET.

Degalessa, Yatiyantota, Oct. 12.

SIR,—I have read Frank J Dunleary's letter in the *Observer* of 10th inst., and I can corroborate every word he says on the rolling and roasting process of Chinese and Japanese teas, having seen the working of teas outside Foochow and near Hiogo or Kobe. The pan system is accurately described. I went through a tea making Factory at Kobe; the pans were copper or brass and set at an angle on "chullu" fires, and the workers at the pans were just as Frank J Dunleary describes; the heat was awful and exudation of perspiration great, the building itself was very dirty, and the tea chucked into a corner of the room when finished. Much the same process was in use at Foochow by the Chinese; the only difference was that the Chinese rolled the tea with their feet by holding on to a bar; the Japs rolled it by hand.—Yours truly,

WM. MITCHELL.

RAINBOW TROUT.

North Cove, Oct. 2.

SIR,—An impression seems to have got abroad amongst fishermen, especially in the neighbourhood of Nuwara Eliya, that rainbow trout as soon as they attain a weight about a pound, disappear—the presumption being that they drop downstream and seek deeper and larger pools in the lower waters. This may apply to the Nuwara

* A blank here in letter.—ED. T.A.

Eliya fish with the lake so handy to them, but my experience of them in the Horton Plains and Aldie patana stream hardly bears this out. The first rainbow trout turned down into the Horton Plains stream—some thirty or forty in number so far as I can recollect—were brought up in the stew-ponds there and turned down by me more than two years ago not far from the Rest-house. The year following I caught one or two of these fish of over a pound in weight near the top waterfall above the Ohiya short cut, and this season a fish of 2 lb was taken in the waterfall pool itself. These fish by their weight and size must have been some of the first lot turned down, and they must have travelled up stream some three miles or so. In addition to this evidence, I have seen many good fish of the rainbow species quite recently in the upper waters of the Horton Plains stream. My belief is that if they have a tendency to work down-stream in England (and tradition certainly ascribes it to them) here in Ceylon this tendency is checked by the numerous waterfalls they have to encounter. I don't say that some do not go over the falls, but many are in my opinion induced to head back up-stream as soon as they feel the vibration caused by the fall below them. I will also give the result of my observations of these fish on the Aldie patanaas. There were about 200 fry and all were turned down in one small pool about 20 feet in length and 15 feet wide—and about 150 yards above some small falls and broken water rushing through a rocky gorge. Six to nine months afterwards I counted over 20 well-grown fish in the pool and in the slack water above the falls. After this they seemed to scatter and a few months afterwards paired off, one pair remaining in the original pool where they may be seen to this day, splendid fish of nearly 2lb. in weight. Another pair have established themselves about 60 yards lower down and another pair close to these. Up stream, judging by the number of fry to be seen there, must be many more survivors of the original and *only* lot of rainbow trout ever introduced into this water. It may be well to mention that except to provide a specimen for the managing Committee of the Ceylon Fishing Club, not a single fish has ever been taken out of this stream. In view of the above, I think, it a little premature to conclude that all our rainbow trout are going to disappear and work down into the low-country, and that we should therefore stock with more brown trout. Personally, I look upon these latter as a source of great danger to the young fry now being hatched in our streams. My reason for this opinion is that where brown trout are most numerous on the Horton Plains, country-bred rainbows are few and far between. On the Aldie Patanas, where there are no brown trout, the water teems with country-bred rainbows, and below Baker's Falls on the Horton Plains, where brown trout were only once turned down in any numbers, and where very few now survive, the rainbow trout are very numerous. All this points, I think, to one conclusion that the brown trout are devouring the ova and fry of the rainbows. It may be of interest, to the fishermen to know that these rainbows breed in Ceylon, apparently, from June to December, if not all the year round. A few days ago I observed numbers of fry not more than $1\frac{1}{2}$ to 2 inches long, and shoals of others ranging between 3 and 10 inches. I would ask you to publish these notes for the information of those who may be interested in them, and who have not the same facilities I have had

for observing the habits of Rainbow Trout in Ceylon waters.—Yours, &c.,
THOS. FARR.

No. II.

Abbotsford, Oct. 7.

SIR,—Mr. Farr's letter on the above subject, in your issue of the 6th, is most interesting reading to all local fishermen; but he mustn't run away with the idea that because rainbows stick to the Horton Plains and Aldie Patana streams they are non-migratory fish.

He doubtless read the recent Report of the Australian Fishery Board in which it was stated: "Rainbows have done exceedingly well in some rivers and in all lakes and ponds; but they have most mysteriously disappeared from several of the rivers into which they were put."

That they disappear from the Nuwara Eliya stream when they attain a respectable size is undoubted; and not only do they descend into the lake, but they actually go over the spill as there is a well-authenticated case of a rainbow having been caught in the stream below by Mr. Pardon.

This fish had been feeding on minnows or young earp and yet rainbows are said to be non-cannibalistic fish, but I fear me they will lose their fair fame in this climate. All the Salmon tribe go up stream to spawn, but it doesn't follow that they'll stay there. Why blame the browns for the paucity of local bred rainbows in the upper stretches of the Horton's stream, seeing only 30 to 40 fish were originally put into miles of it only some two years ago? I killed a couple of them last year myself, weighing each $1\frac{1}{2}$ lb., right away up beyond Ohiya short cut, and this in one day's fishing. So, how many, or rather how few, can have escaped the men who fish there frequently?

Why also preserve the Aldie stream so carefully, when the Dikoya and Agra rivers are crying out for fish?

They'll go on crying, I expect, for the next decade, whilst the fish in the Aldie are dying from disease through overstocking, unless our petty parochial Fishing Club can rise beyond the selfish idea, of all the fresh fish and the butter and the buns for our side of the country, if you please!—Yours, &c.,

JOHN FRASER.

WANTED:—CHEAP FREIGHTS TO AUSTRALIA:

1D. A LB. CHARGED ON CEYLON TEA ;
ONLY $\frac{1}{2}$ D. ON CHINA OR JAPAN
TEA ;—A REAL GRIEVANCE.

Colombo, Oct. 10.

SIR,—I have read with interest the correspondence which has recently appeared in the local press on the point of having cheap passages between this and Western Australia, a very desirable thing, and worthy of strong support from all our newspapers.

There is, however, something more important and more pressing than cheaper passages to Australia, and that is cheaper freight. You can ship cargo by P. & O. or other mail steamers to Hongkong, a voyage of 10 days, at R14 per ton, whereas for the voyage to Freemantle, a voyage of only 9 days, the unfortunate producer of tea has to pay R50 per ton.

Again you can ship by these A 1 mail steamers to Japan, a voyage of under 20 days, at R20 per ton, whereas to Adelaide, Melbourne and Sydney (three ports which, I believe, the Colombo tea market is strongly dependent upon) you again pay R50 per ton.

I have seen this subject mentioned from time to time in the proceedings of the Planters' Association or the "Thirty Committee," and I should like to know if there is any prospect of this glaring anomaly being "gone for" again, and more energetically than in the past.

Why should the struggling tea industry have to pay 1d per lb. freight to one of its largest and increasing consumers, when for one-third of this freight you are offered steamers of the same Companies for countries to which our exports are almost nil, and which even in the future are not likely to take our products, no matter how cheaply you could ship them? On the other hand, these very countries I refer to, viz.—China and Japan, can send their teas down at a freight of 3d per lb. to the Australian markets. 3d (three cents) per lb. on Ceylon teas would be a welcome addition to the income of many who hold

TEA SCRIP.

PLANTING NOTES.

THE GREAT VINE at Hampton Court is often referred to as showing how long a plant will live and bear pruning and cultivation. This vine is supposed to be over one hundred-and-thirty years old. The latest report is from a London paper dated September 24th:—

The great vine at Hampton Court Palace, which is now 134 years old, is this year only bearing 700 bunches of grapes, nearly 3,000 bunches having been thinned out to give the tree a rest.

THE EFFECTS OF FUEL OIL—in reducing freights, in the Western World principally, are fully dealt with by Sir Marcus Samuel in an article reproduced elsewhere from a home paper. The advantages associated with the substitution of fuel oil for coal are so apparent and manifold that it is surprising that in Eastern lines it is not more universally used. Its adoption in the West has literally revolutionised shipping freights: similar advantages would be welcomed in Ceylon and we trust these satisfactory results are but the precursor of what we will shortly experience through the adoption of liquid fuel by Eastern lines.

IN PURSUIT OF PARASITES—Mr Geo. Compere, the entomologist of the Department of Agriculture, departed yesterday on a journey to various portions of the globe in search of the parasites of certain noxious insects. He will proceed to Sydney, thence to China and Japan, where he will endeavour to get the parasite of the red scale. From Asia he will cross to Washington, and after a brief stay in the United States he will continue his journey to Italy, in which country he is hopeful of securing the parasite of the fruit fly, a pest which has caused heavy losses to fruitgrowers in several parts of the world.—*Australian paper*, Oct 4.

MANURING TEA.—Mr. W. D. Bosanquet has undoubtedly conferred a special benefit on his brother planters in tea by his very practical and sensible observations on this subject. He shows how the "forcing manure," most commonly in vogue, is open to condemnation, and he clearly indicates how each planter may do much better for his estate and work more economically as well. Mr. Bosanquet's motto must be "Science with practice." We wish he had told us something on the value of burying tea prunings. He speaks highly of the usefulness of albizzia trees among tea; but Mr. Bamber's recommendation is in favour of cultivating a leguminous plant like *Crotolaria striata*, a herb (2 to 3 feet high) common on waste ground in the low country and about Kandy: it flowers in December-February a dull yellow veined purple; pods long and plenty of seeds. We trust Mr. Bosanquet will have more to say about his manuring experiments ere long.

THE TOTAL YIELD OF GOLD FROM THE BRITISH ISLES (says Mr. J MacLaren, F.G.S. in the *Mining Journal*) may, with the exception of the quota from the Leadhills, in Scotland, be computed with sufficient approach to accuracy to give considerable value to the estimation:—

	£
England (North Molton, 1852-3) ..	581
Wales (Dolgelly area, since 1844) ...	281,497
Scotland (Leadhills area, 1511-1616) ...	100,000
Sutherland (1868-1869) ..	3,000
Ireland (County Wicklow, 1795-1873) ..	21,855
<hr/>	
Total gold yield of British Isles ...	413,933

Of this sum it will be seen that nearly all, with the exception of that from the Leadhills, has been obtained during the last century, and slightly more than half of it (£208,855) during the last 14 years.

ARBOR DAY.—It is gratifying to find that active steps have been taken to give practical effect to the suggestion made in the *Agricultural News*, of establishing an Arbor Day in the West Indies. At Trinidad Mr J H Hart reports that a tree was planted on Coronation Day (August 9), in the Queen's Park Savannah by His Excellency the Acting Governor, Sir C C Knollys, K C M G. Mr Hart continues:—"It is a practice which would tend largely to the benefit of the community and in which the poor as well as the rich may share; and August 9 each year (a specially suitable time in Trinidad) might well be commemorated by the planting of fruit, timber, or ornamental trees." At Grenada His Excellency the Governor planted a Genip-tree immediately after the Coronation service in the presence of a large number of the officials and other residents of the island. Mr Broadway, the Curator reports that in all eighty-five trees were planted some on July 2, the remainder on August 9. At Tobago and other islands also, several trees were planted on June 26 and several further Coronation trees on August 9. —*Gardeners Chronicle*, Sept 27.

THE DUCKWARI (CEYLON) TEA PLANTATION CO., LIMITED.

REPORT BY THE DIRECTORS TO THE TWELFTH ORDINARY GENERAL MEETING OF THE COMPANY.

17 Philpot Lane, London E C Sept.

The Directors beg to submit the accounts for the year ending June 30th, 1902.

Including the balance brought forward from last year, and after writing off ten per cent depreciation in value of Machinery and Buildings, the balance at credit of Profit and Loss Account, subject to Income Tax, is £1,506 5 6

From this has to be deducted an interim Dividend of 3½ per cent on Preference Shares, paid February 14th 1902 420 0 0

Leaving £1,086 5 6 which it is proposed to appropriate as follows:—

- (1) To pay 2 per cent arrears in Preference Dividend ... £240 0 0
- 2) To pay 3½ per cent Dividend on Preference Shares .. 420 0 0
- (3) To pay 2½ per cent Dividend on Ordinary Shares .. 200 0 0
- 4) To carry forward balance to next year 226 5 6

£1,086 5 6

The returns of crop have been 320,070 lb. Tea and 14,283 lb. Cardamoms, against 301,530 lb. Tea and 8,779 lb. Cardamoms in previous season.

The past twelve months have again been very unfavorable for Tea owing to the continued excessive supplies. On the other hand, the Company has much benefited by the large crop of Cardamoms received, the same being 5,283 lb. in excess of expectation.

The estimates for the coming season are 300,000 lb. Tea and 10,000 lb. Cardamoms.

The machinery and buildings are maintained in a good state of repair.

Mr SPENCE retires from the Direction by rotation, and being eligible, offers himself for re-election.

The Auditors, Messrs. BROWN, FLEMING and MURRAY, also retire, and offer themselves for re-appointment. G. P. SPENCE, Chairman. R. CROSS AIRKEN, Secretary.

GAME PROTECTION AND HUNTING IN THE HILLS OF CEYLON.

Mr W Ormiston, Hon. Secy. of the Haputale Branch of the C G P S, writes to our contemporary as follows:—

The only fault I have to find with the form of license agreed on at the meeting, is the inclusion of the old limit "over 4,000 feet elevation."

This is the main point on which our fight took place a year ago, and it was then unanimously agreed that the limit should be the country allotted for hunting to the knife by registered packs.

The boundaries of this country, in the province of Uva, were agreed on by the Assistant Conservator of Forest, Hill Reserves (Mr Spence), and myself; and I have sent them to the Government Agent, Uva, because a small corner of Uva is occasionally hunted by a knife pack (I understand the Horton Plains were only hunted once last year), the shooting of game over 4,000 feet elevation has been entirely prohibited and is now to be limited to stalking.

The minority may have their rights, but surely those of the majority require some consideration.

Another question which might, with advantage, have been discussed is that of limiting the number allowed to be killed under each license. When shooting in the Southern Province, I am limited to three sambhur (two bucks and one doe); if I hunt with knife in the Hills, there is no limit in number or sex.

I have been asked to bring this question forward at the next general meeting.

RUBBER IN TOBAGO BOTANIC STATION.

In April, 1900 ten plants were put out into the open ground, and in May, 1902 are in flower. In the young state the trees assume a shrubby appearance, but later takes on its true aboreous character. I have seen trees of this rubber [which rubber?—ED. C.O.] 80—100 feet in height in the forest behind Lagos. Even in a young state this tree produces latex which readily coagulates.

The following table shows the growth of the various rubbers at the station:—

Castilloa elastica planted 1900	..	19 feet
Hevea Braziliensis do	...	17 do
Funtumia elastica do	..	10 do
Manihot Glaziovii	15 do

Castilloa and Funtumia have both produced flowers.

RUBBER STATISTICS.

CONGO.—The British Consul at Congo, in his report of the trade during the year 1901, states that by far the most important article of export continued to be rubber, which accounted for £1,758,683 in special and £1,807,327 in general commerce, out of the totals of £2,019,536 and £2,160,302 respectively. According to destination the exports of rubber were divided as follows:—

Destination.	Value.	
	Special Commerce.	General Commerce. (including transit).
	£	£
Belgium	.. 1,713,992	1,747,323
Netherlands	.. 43,167	56,992
Germany	.. 272	433
United Kingdom	.. 188	1,162
Other Countries	.. 185	1,417
Total	£1,758,683	£1,807,327

GERMAN EAST AFRICA.—The prospects of the rubber trade here are not very promising: the value of that exported having fallen from £66,859 in 1899 to £52,933 in 1900. Efforts are being made to arrest the depression that threatens this trade, and the stations in the rubber districts are making extensive experiments with the planting of new trees.

CAMEROONS.—Rubber is one of the most important articles of native trade, though, in consequence of the falling-off of the supply in those parts of the country from which it has hitherto been obtained, it is only by the opening-up of fresh districts that the trade can be kept to its present standard.

VERA CRUZ.—Rubber passed through Vera Cruz during the two years from July 1st 1899, to June 30th, 1901, to the amount of (1899-1900) 85 tons, value £20,406, (1900-01) 60 tons, value £13,512, being a decrease of £6,894.

MOLLENDO.—Mr Vice Consul Robilliard reports as follows for the year 1901:—The rubber industry still occupies a good deal of attention, and although the quantity shipped this year only exceeds last year's output by fifteen tons, this is accounted for by the fact that large quantities are being prepared in the interior ready to ship when the dry weather sets in, which will be from the beginning of April. A few remarks on the difficulties that may attend this industry may be of interest. From the time of landing here, about fifteen days will be occupied in travelling by train, steamer, mule and canoe to get to the rubber districts. The first range of

the Andes has to be crossed at seventeen thousand feet above the level of the sea before the descent into the valleys can be effected. Sorata, in Bolivia, is the place at which nearly all the roads into the rubber and mining districts converge. The traveller will often be delayed for several days, all the owners of beasts of burden take advantage of the scarcity of the means of transport, and extort the highest possible freights for their animals. Once work has been started, the cheaper plan is to buy mules and horses. All supplies have to be carried in, as scarcely anything can be purchased there. However, stores are gradually being established on the different claims. The descent is very dangerous in some places, the incline being from thirty to forty-five degrees, and the animals often slip and are thrown over the precipices. This part of the road, twenty-three miles in length, takes twelve hours, when Pararani is reached 4,600 feet above the sea level. From Pararani to Mapiri the road is more practicable, and rubber, Peruvian bark, and coffee plantations are met. Mapiri is the centre of these regions, and from there one strikes off to wherever the claims may be. At least ninety per cent of the travellers fall sick with malarial fevers, more or less intense, although seldom fatal. From Mapiri, Guanay is reached in canoes, or rafts, made of nine sticks fastened with vines; three of these rafts form what is called a callopo, capable of carrying one and half tons of cargo. The distance is sixty-two miles, and can be done in one day, going down stream, but coming back it takes three days, current running six miles an hour. The Indians can only pull at the rate of one and half miles an hour. From Guanay there are roads that lead to the placer mines on the rivers Tipuani, Coyahuira, Challana, etc., in which, regions gold is found in abundance, but machinery is badly required, especially to dredge the rivers. The rubber exported from Molendo during the year 1901 was as follows:—To the United Kingdom (London) 13,061 kilos, (Liverpool) 206,142 kilos; to Germany (Hamburg) 60,707 kilos; to France (Havre) 3,119 kilos; to the United States (San Francisco) 12,859 kilos, making a total of 295,893 kilos, approximate value £58,180.

GAMBIA.—The quantity of rubber exported in 1900 was 125,446 lb. in 1901 146,573 lb. being a decrease of £1,254 in value.—*India Rubber and Gutta Percha Trade Journal*, Aug. 4.

THE RAILWAY AND COTTON-GROWING IN THE NORTH OF CEYLON.

The Government of Ceylon, writes one interested, should give full attention to Cotton-growing in the North (see Sir Ed. Octon's speech at Accrington); but there must be population to provide labour, and gins to gin the cotton on the spot. It will grow like a weed: not the slightest fear as to the growth and suitability of climate.

In this connection, it seems to me that Government, whilst constructing Railway and Irrigation works, should be taking steps now, either to induce the necessary population to come to the country, or to offer facilities to Syndicates or others willing to take up tracts of land for cultivation.

The most liberal terms should be offered and it is not a day too soon, to begin; for, it takes a long time to get people outside the island to become interested. It won't do for Government to wait till the line is running before they begin to invite settlers to cultivate."

THE BRITISH ASSOCIATION AND CEYLON.

Mr A K Coomaraswamy, B SC, FLS, FGS, read a "Note on the Scenery of Ceylon," in the Geology section on the 16th September. He stated that it was probable that Ceylon had been exposed to continuous denudation since very early Paleozoic times. The foliation of the crystalline rocks had a marked influence in determining the directions of the river valleys and the general configuration of the country. A characteristic feature of the scenery of Ceylon in many parts was its precipitous character; the seemingly "bedded" granulites formed mural escarpments and dipped slopes, as if they were a series of sedimentary rocks. The above remarks applied only to the mountainous districts which occupied the south-central part of Ceylon. A low coastal plain fringed the island, partly of alluvial and partly of raised beach origin; sea cliffs were absent or very unusual, and even any coast exposures of rock were not common. In the north a greater area was flat and low, and the scenery resembled that of Southern India. Isolated hills of gneiss (Dambulla and Sigiri) rose conspicuously from the plain.

PARAGUAYAN TEA.

Yerba Mate in Paraguay.—The British Consul reports that yerba mate, or Paraguayan tea, is largely exported to the various Republics of South America. A few sample packages have been shipped to the United States and to Germany. One sample has been forwarded from Consulate to a firm in London. A German house here prepares a refined form of yerba mate suitable for drinking like tea. It is packed in parcels of 2 lb., at a cost of 1s 6d. There seems, says the Consul, to be little doubt but that yerba mate is a great restorative in hot weather or after physical exhaustion.—*British and Colonial Druggist*, Sept. 5.

A VISITOR FROM JAVA.

Mr. H J H Netscher, a well-known proprietary planter in Java, after visiting the tea estates in Northern India—in Assam, the Doora, Darjeeling, &c.—arrived in Ceylon where he remained about three weeks last month. Mr. Netscher's property is in Western Java, and he chiefly cultivates tea and cinchona. Cacao he considers to be about the most troublesome of tropical products to cultivate—the plant, of all others, most liable to enemies—at least that is Mr. Netscher's experience in Java. This is in strange contrast with the Dutch writer's experience of cacao in Dutch Guiana, South America, where, he said, the trees began to crop well at 5 to 6 years, heavily at 9, and continued then for a hundred years to give regular crops and no trouble. [This Surinam news is, however, a little too much like the parrot the sailor bought because he was told it would speak after 100 years and he wanted to hear it!] In Java evidently cacao is not a

favourite with big planters, though it is grown freely by the natives along the wayside and in small gardens. Mr. Netscher speaks of the telephone connecting plantations all over Java with the capital and principal towns as extremely convenient. He can get switched on at the nearest railway station with his agent in Batavia over 100 miles off, and do business more satisfactorily in five minutes' conversation than through pages of a telegram. At the same time he can telegraph from his residence to any part of the world. The labour supply is no trouble nor difficulty in Java.

Mr. Nestcher, who carried a letter of introduction to the Governor Sir West Ridgeway, went first to Kandy and from thence made excursion into the planting districts. He also visited Nuwara Eliya and Bandarawela and returned to Colombo *via* the Kelani Valley and the Avissawella railway. We bespoke courteous attention to this intelligent visitor during his stay in our midst.

EXPERIMENTS WITH AUSTRALIAN FODDER GRASS.

The experiments made at Saharanpur with the Australian fodder grass, *Paspalum dilatatum*, did not indicate that the grass possessed any remarkable superiority over the best varieties of Indian fodder grass, and much the same conclusion is to be drawn from experiments made in the Central Provinces, though there, as at Saharanpur, it is considered necessary that further experiments should be tried before a definite opinion is pronounced. So far as the experiments have gone, they show that the yield of the new fodder grass is smaller than that of the local grasses, but the quality is much better. Though protected from grazing the plants died, unless irrigated after producing one crop. The grass failed to show any special drought resisting properties; in fact it dried up earlier than the local varieties. It did better on heavy black soil than on dry stony land, but did not spread and multiply as *dub* grass does. It failed to justify its reputation as a strong pushing variety able to oust weeds and other grasses; indeed, it was found necessary to weed it, to prevent its being smothered and overgrown.—*Madras Mail*, Sept. 2.

ADULTERATING RUBBER.

According to a Foreign Office report from our Consul at Dakar a crisis was due to the fall in the price of rubber, which, while it affected all the rubber-producing countries, was specially felt in French Guinea, eight-tenths of whose exports consist of that article. In addition, there were special reasons which caused the colony to suffer. Having been a rubber-producing country for many years, the vines owing to wasteful methods of tapping them, had become comparatively scarce, and in order to increase the quantity of rubber for sale, the natives adulterated it in various ways. The merchants, anxious to profit by the high market, accepted the bales without examination, with the result that the rubber bought from the natives during the season 1899-1900 contained as much as 25 per cent of impurities. The home markets, who could obtain rubber of a much higher quality from other sources, refused to buy the Guinea rubber, which thus remained on the hands of the merchants,

who in many cases were compelled to sell at a loss. So as to improve the quality of Guinea rubber, a decree was issued in May, 1900, forbidding the sale of rubber in unopened bales. This has already had a good effect, as the natives, finding they were certain of detection, ceased adding foreign matter, but as the method of coaguating the rubber in calabashes ordinarily employed by the natives made it difficult to detect adulteration with resins, a further decree was issued to the effect that, dating from the wet season of 1901, the only rubber allowed to be exported would be that prepared by the Foulah method, in red filaments, which was found to be the only one which permitted the detection of resinous adulteration. Palm kernels were usually mixed with about 30 per cent of shell. By a decree of February 1, 1901, the exportation was prohibited if the kernels contained more than 5 per cent of foreign bodies.

CACAO-PLANTING IN SAMOA AND FIJI

is fully discussed in Australian and Fiji papers to hand, and we shall quote interesting details to embody in our *Tropical Agriculturist*. Meantime we may state that Mr. F. Harman, Manager for an English Company with a capital of £10,000 to open 500 acres in cacao, speaks well of the German Government in Samoa. He has a plantation of 1,000 acres with good soil and in five years his cacao comes into full bearing at an outlay from of £20 to £25 an acre, including buildings, &c., while the crop is then, equal to 9 cwt. an acre of dried (prepared) cocoa, selling at 8d a lb. in Sydney and giving 6d nett to the planter or £25 an acre, equal to 100 per cent! *Credat Iudeus!* Leases of land are to be had at 2s to 3s per acre per annum in Samoa. Powell Bros. of Fiji, criticise Mr. Harman's figures; but with still more surprising statements. Samoan land they say is rugged with heavy timber and exceedingly difficult to work; labour will be an increasing difficulty; no crop can be grown between the young cacao; and the £20 to £25 outlay is contrasted with £12 to £15 in Trinidad; while in Fiji crops worth £30 an acre are grown between and before the cacao bears! Powell Bros. do not go further to tell us what the Fiji cacao crops and net returns are; but they leave us to infer they are quite as good as those of Samoa. Why, oh why then, did Ceylon planters ever give up Fiji—some after many years of a trial?! Nothing is said about hurricanes or other possible drawbacks.

TREE AND LEAF GROWTH IN CEYLON.

The following is an abstract of the paper read at the British Association, Belfast, on *Foliar Periodicity in Ceylon*, by Mr. Herbert Wright of the Gangaruwa Experimental Garden:—

The high temperature and humidity of the air in most parts of Ceylon allow almost continuous growth of the arborescent vegetation. There are, however, nearly two hundred species which become leafless at different times of the year.

External and internal factors affect the phenomena of defoliation and foliar renewal. The climatic effect is obvious from the fact that the majority of

our deciduous species become leafless during our hottest and driest months. The deciduous trees respond only to one hot dry period of three or four months, and not to the dry part of each monsoon. Some species undergo complete defoliation twice per year; others exhibit incremental foliar activity several times per year, in addition to a complete annual renewal, and many introduced species show great variation during their phase of acclimatisation. In the northern districts, where the rains of the south-west monsoon are very feeble as compared with those at Peradeniya, the defoliation is considerably delayed. The climatic conditions in Ceylon are not equable enough to allow continued development along personal lines, and botanists desiring to study the personal equation in plant life should select a more equable area.

Internal forces are, however, obviously at work, as evidenced by the following:—

(a) Species retain full possession of their foliage or put forth new leaves when the temperature and dryness of the air is at the maximum.

(b) Some species drop their leaves and remain bare during our wet, cool months, when transpiration is at the minimum.

(c) Plants of the same species, on the same plots, are deciduous at periods varying by many weeks and months.

(d) The same species may undergo defoliation at approximately the same time of the year, though under the dissimilar climates of Peradeniya, Colombo, and Mannar.

The irregularity of foliar periodicity is very pronounced. There is not a month when all the trees are in full leaf.

The foliar periodicity of the evergreens is as complex as that of the deciduous trees, the foliar renewal taking place annually, bi-annually, or weekly, all being subject to individual variations.

Complete defoliation and foliar renewal in temperate and tropical zones often results in the differentiation of rings of growth in the secondary xylem. The variation in our tropical species is so great that an exact knowledge of foliar activity must be at hand before the time-value of the rings of growth can be determined. Saplings may undergo foliar repletion in the first year, or several years may elapse before this occurs; mature plants may be characterised by annual, bi-annual, or incremental periods of leaf production; further, many trees are repeatedly defoliated by the ravages of insects, bats and fungi.

Foliar periodicity is the most potent factor in determining the number and significance of the rings of growth, but for the complete interpretation of these a further knowledge of the rate of cambial activity and the independent effect of a hot dry season is necessary.

The rate of cambial activity is of especial value in determining the varying significance if the xylem differentiations in slow-growing deciduous or quick-growing evergreen trees.

JAVA AND ITS TEA SUPPLY.

Some anxiety is felt as to the future of tea in Java. So far as we can learn, planting is not extending in that island: our Dutch neighbours have learned caution by their experience both in coffee and cinchona. The former industry has been wellnigh ruined by Brazil; while the price of bark and quinine can only with great difficulty be kept up to a remunerative level. The Java

Quinine Factory has helped greatly to benefit the local cinchona planters, and its capacity is to be doubled we learn. Meantime as regards tea, with the experience of India and Ceylon before them, Java tea planters are bound to be cautious and *festina lente* is their motto. Those who have tea fields or estates are trying to do the best they can by improved cultivation and manufacture; but any extensions of the area under this product will be few and far between for some years. Our latest news from Java is as follows:—"Java is just now experiencing a very severe drought. This should reduce the output of tea from that island to some extent this season."

A satisfactory feature about the Java tea enterprise is the very considerable and steadily increasing proportion of the produce which is shipped direct to Holland. This means the gradual conversion of a good many of the Dutch people to afternoon and, perhaps, morning tea. If this process continues and Belgium as well as the adjacent portion of Germany—the people of the Groningen and East Friesland provinces have always been great tea-drinkers—were induced to consume increasing quantities of Java tea, no one would regret some expansion in the Dutch planting enterprise. It is any increase in the shipments of Java tea to the London market, that Ceylon and Indian planters deprecate.

FREIGHTS AND PASSAGES TO AUSTRALIA.

CEYLON TEA PAYING 1D. A LB. IN FREIGHT!

"Tea Scrip" raises once again a very important question in his letter elsewhere. It is simply monstrous that the Ceylon tea planter should have to submit to the heavy and entirely inequitable rates of freight at present charged for his produce to Australian ports. Can it be doubted that the trade would still further expand until the Australasian market was nearly, if not, quite won over to "Ceylon's," or at any rate to British-grown teas, if only freights were at all reasonable. Surely, a remedy can be found by inviting competition with the existing steamers? We saw it mentioned the other day that the Japanese Company was to be approached with reference to running a steamer once a month right round the Australian ports. If she started from Colombo and called on her way back at Singapore, we do not think that due encouragement would be wanting. In fact in this might be found the solution of cheap passages as well as cheap freight to and from Australia. Failing a Japanese liner, we trust the Australasian S.N. Company will be enterprising enough to establish a branch line with Ceylon and India. Meantime, pending any such arrangement, the Planters' Association and Chamber of Commerce should enter a remonstrance with the existing Steamer Companies as to their high rate of freights.—The question of a closer connection between Ceylon and Western Australia is discussed in correspondence on our sixth page; but, we suspect only by securing a new and rival steamer can cheap tourist passage rates be established.

Monthly Shipments of Ceylon Black Tea to All Ports in 1901-1902.

[ESTIMATE for Nov. 1902—7½ to 8 million lb.]	

"GROWTH OF CEYLON TIMBERS."—We are promised Mr. Herbert Wright's paper on this subject for an early issue of our Monthly. Mr. Wright reports to us:—

In my paper I have tried to lay down some general statements on the subject and to explain the probable factors which determine the number and significance of the rings of growth in our Ceylon timbers.

MARKET RATES FOR OLD AND NEW PRODUCTS.

(From Lewis & Peat's Fortnightly Price Current, London, October, 1902.)

No Price Current having reached us in time for this issue, we omit the usual quotations and fill up the page with ordinary matter.

FIXATION OF NITROGEN BY ALGÆ.

When we expose pots of sand to which phosphates, potash, and magnesium salts have been added, to the usual soil of a garden, we soon find that they get covered with various green algæ; and if we chemically analyse the surface of the sand, we often find a considerable amount of nitrogen, rising sometimes to as much as 0.08 per cent.

Messrs. Schloesing, jun., and Laurent observed the fixation of nitrogen by algæ in experiments, in which they noticed the diminution in volume of this element in a confined atmosphere, even in the presence of Leguminous plants, if the sand were covered with green algæ. Later, M Kossowitsch has reported that this fixation of nitrogen from the atmosphere by the algæ only took place when these were associated with bacteria. M Bouilhac found by exact experiments that the algæ, *Nostoc punctiforme*, sown in a sterilised mineral solution without a supply of nitrogen, does not develop, but that it is otherwise when this algæ is associated with soil bacteria; this fact has been observed at Rothamsted. M Stoklasa often got vigorous blue Luins growing in sand, and yet bearing no nodules on their roots. M. Denoussy also observed the same fact, but only when the pots of sand had been invaded by algæ, and especially by certain species, which avoid full daylight, by retiring below the surface of the sand. It must, however, be recognised that though it is easy to observe the various algæ which cover the sand, and to note that the sand has gained nitrogen, it is much more difficult to see the bacteria presumably associated with the algæ. To sum up the subject, it is perfectly established that Leguminous plants bear bacterial nodules on their roots, and fix free and uncombined nitrogen from the atmosphere. This is a point gained, and it explains the name of ameliorant plants, by which they have long been designated. The question may be asked: Are these the only plants which have this power? Do the Algæ equally possess it? Can the lower plants get possession of atmospheric nitrogen only as far as they are associated with bacteria organisms? These points further investigations have to prove.

The above facts have been summarised from Prof. Deherain's second edition of his "Traite de Chimie Agricole, 1902. J J Willis, Harpenden. —Gardeners' Chronicle.

GUTTA-PERCHA AND RUBBER IN GERMAN NEW GUINEA.

The gutta-percha from gutta-percha trees which Mr R Schlechter discovered on his expedition to the South Sea in the Pinistere and Bismarck mountains of German New Guinea, as mentioned in our issue August 4th, has now been put to a test. All have come to the conclusion that it is a good medium gutta suitable for cable purposes, and similar to the Kelantan or hard white gutta-percha. Its loss through washing amounts only to fourteen per cent. It contains fifty-six to seventy-four per cent gutta-percha, and thirty-four to thirty-seven per cent resin, and has been estimated at about 6s, and even 8s to 10s per kilo.

The rubber samples from the same district have been tested and the sample of *Ficus elastica* has been found equal to a superior African of 5s 3d to 5s 9d per kilo in value. The rubber from *Castilloa elastica* proved to be similar in quality to good Peruvian balls, and had a value about 6s per kilo. The *Hevea brasiliensis* rubber showed a very good quality, similar to the Para rubber which now comes from Ceylon. This Para rubber on account of its dryness and light colour, is much in demand and fetches ten per cent more than actual Para rubber.—"Tropenpflanzer."—*India-Rubber Trades' Journal*, Sept. 1.

RUBBER YIELD OF GERMAN AFRICA.

The official reports on the German Colonies in Africa devote special attention to the development of their India-rubber resources, though the results in this direction have not yet proved so successful as was at one time anticipated. For one reason, as a recent report on Kamerun expresses it: "In consequence of the falling off of the supply of rubber and ivory in those parts of the country from which they have hitherto been obtained, it is only by the opening up of fresh districts that the trade can be kept up to its present standard." Still rubber and ivory continue to furnish the larger part of the exports from Kamerun, Togo, and German East Africa, and now and then, for a while, an increased yield is obtained. Meanwhile the Government is seeking to encourage the forming of rubber plantations, as well as to discourage the destruction of native rubber plants. According to a British report on recent trade in these German colonies, the value of the rubber exports were as follows:

Kamerun—£94,893 in 1899-1900; £102,926 in 1900-1901—the increase being due to higher prices realized.

Togo—£18,304 in 1899-1900; £26,068 in 1900-1901—more rubber having been gathered.

East Africa—£66,859 in 1899; £52,933 in 1900—exports having declined in volume.

From these figures it would appear that the average production of India-rubber in German Africa during the five years covered by the latest available statistics has been 1,757,414 pounds.

The imports of crude rubber into Germany from her African colonies, during five years past, have been:

		Togo and Kamerun.	East Africa.	Total.
1897	... pounds	744,709	167,200	911,900
1898	698,280	70,180	768,460
1899	1,111,800	140,800	1,252,600
1900	902,000	100,980	1,002,980
1901	847,800	120,340	968,140

The yearly average deduced from this table is 980,816 pounds, indicating that the mother country fails to profit from the handling of an important share of the rubber produced in her colonies. =During the same five years Great Britain imported rubber direct from Togo and Kamerun as follows:

	1897.	1898.	1899.	1900.	1901.
Pounds ..	152,208	177,632	156,688	146,944	147,728

In addition to the various native rubber species in German Africa, several imported species promise good results, and the experiments made in planting, under expert scientific supervision, seem likely to be of benefit to the cause of rubber culture generally.—*India Rubber World*, Sept. 1.

NOVEMBER, 1902.

[No. 5.

SCHOOL GARDENS.

VERY new movement experiences a period during which it is the subject of suspicion, and even of contempt. "Qui bono"? is the question that is uppermost in the mind of those who are not directly interested in it, and to give them a satisfactory reply is well-nigh impossible.

One of the greatest drawbacks in the connection with the establishing of School Gardens is the want of sympathy that is exhibited by those whose co-operation is as much to be desired as it was counted upon. But in place of sympathy and help there is often a supercilious curiosity, indicated by such a question as "What are you doing"? as though the answer could be given in a word!

Now for the benefit of those who honestly would be informed, we shall endeavour to clearly state the case for the School Garden scheme, enumerating its objects under different heads.

(1). We will take what some may smilingly term the æsthetic side of Schoolgardening. We will accept the description, and add that one of the objects of the scheme is [certainly to make the surroundings of school children congenial and pleasant to them. The bare hard walls and dreary surroundings of a school are far from inviting to a child. There is nothing to attract, nothing to brighten up the place, nothing to relieve the eye of the little scholar—in fact nothing suggestive to look upon, but everything impenetrable and irresponsive, and acting as a counterfoil to the lively intelligence and curiosity of the child-mind. Now, is it fair to the child that such should be the case, that, so far from providing "natural" food for the hungry mind to feed

upon, we should endeavour to dull the edge of curiosity, which, so to speak, is the spur that impels him to the acquisition of knowledge? On the other hand it is our duty to provide all that is cheering and suggestive and calculated to preserve and cultivate the natural buoyancy of heart. In many cases we find children drawn (oftener driven) from their bright and healthy surroundings to be immured within the dismal walls of a school-room, their elastic minds compressed and forced to dwell for hours together on the dull routine of class work and their own educational severity. It is here that the new scheme comes in, to lighten the burden of the scholar by keeping him from dwelling on the *drudgery* and making him think only of the *pleasure* of work. For it cannot be denied that it is environment and association that to a great extent control mental exercise and establish mental conditions; and it should be the object of all those who have the oversight of children to furnish their receptive minds with such associations of ideas as will in after life make them cheerful and hopeful individuals, ready to look on the bright side of the picture, and not drepressed and depressing, always taking a gloomy view of life.

Those who have seen school children in a garden will understand the degree of pleasure they derive from it. When the town child find himself among foliage and flowers he is not less delighted than a caged bird that has been released. Beauty, colour, variety, sweet odours, all these attributes are elements of pleasure to him, while arrangement, form, symmetry, order, neatness, all these qualities are bound to react on the mind, and, bearing fruit, establish such ideals and resolutions as we all hope for in our children.

(To be continued.)

OCCASIONAL NOTES.

To those who have been enquiring for the price of chillies in the London market we would state that the London *Grocer* quotes Zanzibar chillies at from 34 to 37 shillings per cwt. "Capsicums" range from 16 to 80 shillings per cwt.; "long peppers" 55 to 58 shillings per cwt.

The rainfall for October as recorded by us will give some idea of the nature of the weather last month. Our own measurements reached a total of 38.27 inches against 31.47 in the Fort the two places being within a distance of 3 miles from each other. Rain fell on all but two of the 31 days, and the heaviest fall was measured on 1st November, viz., 5.43 in. This is certainly very unusual, and some people are speculating whether there is any connection between the heavy rains and the comet of Perrine!

Cannabis sativa (Indian Hemp), is according to a co-respondent pretty commonly found growing around dwelling houses in the Balangoda district, but only in small enough numbers not to attract attention, as the general impression is that the cultivation of the shrub is prohibited. The plant is allowed to wither *in situ*, and is then further dried and sold to the Moorman "Cadger."

On this subject the *Ceylon Observer* says:—We do not think there is any Ordinance at present in the local list prohibiting the cultivation of Indian hemp, any more than of the poppy; because in deference to the Buddhist prohibition of such drugs, nothing has ever been done in Ceylon worth notice in this direction. But it will certainly become necessary now, in view of what our correspondent states, to pass such a law guarding the cultivation. Very possibly under the Opium or Bhang Ordinance any one turning the hemp or poppy into drugs for personal use or sale, can be punished.

NEW FODDERS.

Sorghum halapense, now known as *Andropogon halapensis*, and from which the widely-cultivated cereal *A. Sorghum* (Karal-iringu, S.) is supposed to be descended, has been more than once put forward as a good fodder. The grass is sometimes referred to as "Johnson grass," and it is curious to find people anxious to grow plants with a strange name, when they would never think of taking up some of the indigenous forms of vegetation and endeavouring to improve them. Such people were naturally disappointed to find that the far-famed Cow-pea was almost identical with the native beans known in Sinhalese as "Li-me" and "Nil-me"; and that the Florida velvet bean was of the same genus and species as the Tamil "Acharyapala."

Johnson grass, as we have indicated above, is a grass "not uncommon" as Thwaites puts it, in the Central Province of Ceylon, and probably seen every day by the inhabitants

who, however, do not connect it with the *Sorghum halapense* of Botanists or the Johnson grass of America.

A correspondent writing to the *Agricultural Journal* of the Cape, refers to information received by him as to "Johnson grass" making excellent grazing, and states that the seed can be sown on the dry ground and within a short time will grow most luxuriantly.

Mr. P. MacOwan, the Government Botanist at the Cape, writes:—" *Sorghum halapense*, the grass to which the Americans have given the absurd name of 'Johnson grass,' is one of the foddors or supposed foddors, like 'Teosinte' and 'Wagner's pea' introduced by speculative seedsmen, and praised far beyond their worth, just to make sales and rake in the money." He then quotes the experience of a N. S. W. farmer to this effect: "It is of no use as a fodder in this district. It is of no value and is a great trouble to get rid of after we once get it to grow, and all who have sowed it wish they have never seen the thing. No one who ever saw the Johnson grass growing would have anything to do with it. It grows very coarse and tall, and very hard. No cattle will eat it while there are any other kinds of grass." It is said to grow wild along the banks of the Orange River and other parts, much as the common reed does, but is not sought after by cattle.

Mr. MacOwan recommends *Pentzia virgata* as a wholesome and fattening fodder for the Karoo, where conditions do not admit of a regular grass crop, though, as he states, the food value of the veldt depends upon dwarf bushes which grow socially and with alternate use and rest prove a stand-by in all seasons.

RAINFALL TAKEN AT THE SCHOOL OF AGRICULTURE DURING THE MONTH OF OCTOBER, 1902.

COTTON CULTIVATION.

[Just now when Cotton is being spoken of as one of the likely crops for the large tracts of waste land in the North-Central Province that will be made accessible by the Northern Railway, the following account of Cotton Cultivation, based on experience in Queensland, should prove of considerable interest to many. The author is Mr. Daniel Jones of the Queensland Department of Agriculture, and we take over the paper from the *Agricultural Journal* of that colony.—ED. A.M.]

One important factor proved by our local experience and emphasised by scientific investigation in other countries where this crop is largely grown is, that this crop is about the least exhaustive to the soil of any we are acquainted with. Local experience has shown that the richest soils should not be chosen for this crop. Many errors were in this way committed in past years. The less fertile areas would have been far more suited to the cotton plant. Undoubtedly, at times, cotton will need fertilising. This, however, need not concern the planter at the outset of his operations, unless he farms very poor soil, which in Queensland is not very probable.

It will be well for the planter to keep this fact in mind, and not concern himself at first so much about the fertility of the soil as thorough cultivation of that which he crops.

In our past experience we always found that the rich land forced the plant so much to wood that not only was the yield meagre, but the quantity of resulting foliage and wood much retarded picking. This especially was the case in wet seasons, but, on the other hand, in seasons of sparse rainfall, the trouble was not so acute. An illustration of this is seen in this season's experiment at the Acclimatisation Society's plot at Bowen Park, where the dry conditions have so retarded the growth that little difference is noted between plants of very robust growth, such as Sea Island and Egyptian, as compared with the more modest growth of the Upland variety, which, despite the unparalleled dry season, has returned a very fair crop of cotton.

Cotton has always been regarded in Queensland as a dry-season crop. Its vitality under drought conditions is well recognised. The climatic influence most adversely affecting this crop is excessive wet, and to this cause the major part of our losses in the sixties and seventies, when cotton was largely grown, is to be attributed. The cycle seems to have now alternated to the other extreme for some years past; hence the risk from this cause need not, in the southern part of the colony, be so much feared.

THE VARIETIES TO PLANT

Will much depend on climatic conditions, and as far as many parts of the State are concerned must be, for some time, experimental. In the south, experience thus far has demonstrated that the Upland variety is the best suited to our region.

In the North, probably the longer-stapled varieties, such as Sea Island and Egyptian, will be grown. These three species, differing as they do in texture and length of fibre and value, appear to have become so blended and intercrossed as to almost conceal the original distinctive features of each species. Broadly speaking, we distinguish Sea Island by the clean black seed and extra long fibre; the Egyptian by its shorter fibre and brown or sometimes pale-green seed with the lint adhering somewhat. The Upland variety is the shortest staple with a grey seed, but is sometimes black in such varieties as the Okra, the fibre adhering closely to it.

An American authority expresses the opinion that the Upland cotton is a hybrid produced by blending the properties of several species under the cultivation of a long series of years. All who know American practice are well aware of the importance cotton-growers attach to such experiments, and we in Queensland can note the advance in quality of cotton grown to-day by comparison of that produced here thirty years ago. The species mentioned as growing in the cotton belt of the United States are given as *Gossypium herbaceum*, L.; *G. roseum*, Tod.; *G. nankin*, Mey.; *G. mexicanum*, Tod.; *G. maritimum*, Tod.; *G. hirsutum*, Mil.; *G. barbadense*, Lin.; *G. herbaceum*, the short-stapled variety, is the plant most favoured for cultivation, by reason of its more prolific yield and adaptation to regions where the Sea Island and Egyptian varieties from climatic causes do not prove profitable. So hardy is this plant that its cultivation is of the simplest; more especially is this observed in the Central and North Queensland coastal districts, where it grows uncared for once the seed is sown. The difference in growth of the shrub easily distinguishes the Upland from the other two varieties, the former being much more dwarfed than the others. Sea Island and Egyptian bushes often attain the height of 10 or 12 feet, and make spreading bushes. The Upland confines itself to a modest 4 or 5 feet bush, at the same time developing a denser foliage than the other sorts. This dwarf habit lends itself as more favourable both in regard to tillage operations as well as to the removal of the crop.

In the Central and Northern coastal districts, the Egyptian and Sea Island sorts, in conjunction with the Upland varieties, might well be tried. The specimens which I have seen growing in our Northern districts give no room to doubt but that the long-stapled sorts will do well as far as growth is concerned. The excessive rainfall in these areas will somewhat militate against achieving the best success; and the question resolves itself into the experiment of ascertaining if, by planting the crop at favourable periods, the ripening stage may be carried beyond the rainy season. In the event of this being practicable, there should be no apprehension as to successful cotton cultivation in our Northern regions. Thus far our practical knowledge of districts suitable for this crop is as yet but very meagre. Save for a few isolated

patches on the Darling Downs, a few experimental plots North and West, from which I have at various times received fair samples of cotton, Queensland, with the exception of the East and West Moreton districts, represents untried localities. There is every reason to believe that in the interior and drier parts this shrub will thrive, more especially as its drought-resisting qualities surpass most crops in ordinary cultivation. In deciding on varieties to plant, the planter must be guided somewhat by climatic influences. Long-stapled varieties do better in the Northern and more humid parts, and the short-stapled varieties do better in Southern and Western areas,

PREPARATION OF THE SOIL.

The cotton shrub being a plant depending a great deal on its tap root, which observers will note is the first prominent indication of vitality in the newly bursting seed, moderately deep tillage becomes necessary in order to get the best results. Of course, if grown in a deep, friable soil, so vigorous is the root extension of the shrub that in the short space of a few weeks the tap root penetrates to a depth much beyond the depth usually ploughed. This is undoubtedly one reason why the shrub is able so well to sustain the drought conditions often prevailing. This deep tillage is an advantage; nevertheless, this aspect in past practice did not receive more attention with our local cotton-growers than was usually given to maize or other crops.

The best that was done was to plough about 5 to 6 inches deep, harrow thoroughly and drill, sow the seed, keep the crop clean; and, under even this superficial system of cultivation, the crop thrived and yielded well. It is not to be expected that the intending planter can gain complete success by a system of indifferent tillage. So much depends on this feature with respect to yield, quality of fibre, condition of the lint as regards absence or presence of dirt in the form of weed seeds, vegetable matter, soil, &c., that the margin of profit is often materially affected thereby. Thorough tillage means financial advantage, and this must be borne in mind by the intending cotton-grower.

The main essentials, then, in preparing the soil are moderately deep ploughing—cross ploughing also, if necessary; thorough harrowing, to have proper pulverisation and a good seed bed free from lumps, so that the young plant shall be in no danger of the harrow or scuffler rolling on its little crown a mass of soil to its detriment.

These few hints are to the practical farmer scarcely necessary, but perhaps may be of some use as brief reminders to those who are new to the pursuit, and who will need to give attention to them.

SELECTION OF SEEDS.

The question of selection of seed is, for the present, one that until opportunities arise must to some extent remain in abeyance. Excepting a small supply, in the hands of the Acclimatisation Society, of the Upland, Sea Island, and Egyptian varieties, true to name and all of the best sorts, there is no seed in the State avail-

able for distribution, save some Upland variety of mixed but good sorts at the Ipswich Cotton Factory, which has been kindly placed at the disposal of this Department for distribution. Some of this seed, I may say, I have grown this season, and although it is now some five or six years old, about 50 per cent. appears, by experiments carried on by myself and the Acclimatisation Society, to be fertile seed. Thus, in order to supply the numerous demands made upon this Department, it is proposed in the absence of fresher seed to make distribution of what is available, notifying recipients of the need of allowing for about 50 per cent. of the seed as likely to be unfertile. This simply means sowing double the quantity than would otherwise be needed. Of course those fortunate enough to obtain seed from the Acclimatisation Society, who can only distribute in small quantities, will find that all their seed is fertile, and can sow sparingly.

In general practice, selection of seed is the result of observing and marking off the most prolific and largest podding plants in the field. In selecting, attention should be given to length of staple, texture of lint, strength of fibre, habit of growth, and other features that commend themselves to the planter. Selection in this manner gives the planter good seed for the succeeding sowing, and tends to the evolution of a better cotton plant having the prime points of advantage I have mentioned.

It is recognised that a difficulty often exists in tracing the origin of most of our varieties of cotton. The plant hybridises readily without human aid, and probably the interchange of seed from remote countries so varies the character of the shrub and its staple, causing the recognition of the original very hard to decipher. Most probably we are indebted to the good offices of our insect friends, by reason of their wonderful service as hybridisers in consonance with natural law, for the origin of many of our best varieties of cotton. The cotton-planter will do well to keep this point in view, and make selection of seed from such plants as appear to him to have had the benefit of cross-fertilisation and exhibit good qualities.

The kinds of cotton introduced some years since by the State Department of Agriculture, and which in mixed varieties will be distributed this season, are all of them good species of Upland cotton. Our experience of these fibres in manufacture in the Ipswich mill, and our knowledge of their suitability for plantation purposes in South Queensland, is such that we can recommend them as being varieties worthy of cultivation.

One important point in the selection of seed should not be overlooked—and that is the question of proportion of seed to lint after undergoing the ginning process. When the variety is characterised by large heavy seed and the lint adheres in unduly large quantity, it is wise to discard the same for a variety that does not carry these demerits. Cotton from which the lint can be cleanly removed, and of which the seed small, will be the most profitable for

farmer and merchant. A good variety of Upland, having the merit of small seed and easy and cleanly separation from the lint, will usually yield 300 lb. clean fibre to the 1,000 lb. of unginnged cotton. When the ratio of lint to seed goes below that stated, it is time for the planter to seek better varieties. Good varieties grown in West Moreton of the Upland sorts during the period of the cotton company's activity, and which can be recommended, were—Okra, Southern Hope, Jeff Welborn's Pet, Peerless, Jones' Improved, Elsworts' Trnitt's Improved, Champion Cluster, Hawkins' Improved.

SOWING THE SEED.

Presuming the farmer has his soil in good tith for his planting operations, his next duty is, in the absence of a properly constructed cotton drill and planter—an implement, unfortunately, as yet not obtainable in Queensland—to sow the seed by hand. He will use a light plough to strike out his drills either by means of guiding poles or with the more expeditious land marker, and care must be taken to have the drills uniform in depth and width, as each operation materially facilitates the subsequent cultivation of the crop. The usual plan adopted is to draw drills about 4 feet apart, 3 inches deep, dropping the seed by hand at such distances as to finally leave a stand of plants 2 feet or 3 feet apart in the drills. When seed is plentiful, it is prudent to sow thickly, and later on thin out the plants to the spaces mentioned. In poor soils, the lesser distance may be settled on, and in richer soils the wider space may be adopted or exceeded as experience of the fertility of the soil may suggest.

Frequently crickets and beetles make havoc among the young plants, destroying numbers while in the succulent tender stage of growth. It is, therefore, not prudent to finally thin out the plants to their standard distances until all danger from this quarter is past.

The seed is sown sometimes after soaking in water for twenty-four hours or so, and this is one advantage when the seed is old or when planting is intended in the absence of sufficient soil moisture, as sometimes happens in planting large areas when the land is quickly drying up. Generally, the seed is sown in the dry state and covered in, awaiting the rainfall. This is, of course, attended with some risk, as in the event of a partial rainfall sufficient moisture may be unavailable to bring the plant above soil, and the germinating seed may perish. This is a contingency that must be faced in all cultural pursuits, and is not common alone to this crop. It certainly is more trouble to sow in wet soil, but, on the other hand, when the areas are small and supply of seed a consideration, this system will probably be the safest. The seed can be covered in the drills either by harrowing, or, preferably, by removing the front and hind tines of the scuffler, and working the soil into the drill by running this implement up the furrows. This gives good cover, and proves better tillage, and at the same time checks the germination of grass and weeds much better than the harrow does. It must not be forgotten that young cotton plants cannot

stand the struggle for existence with weeds, and it is better to safeguard the plant in this way than have it succumb by reason of the struggle with pests and grasses. The number of plants per acre, calculating on distances of 4 feet by 3 feet, is 3,630; on the basis of 4 feet by 2 feet 6 inches, the number is 4,356.

Theoretically, 1 lb. of seed should be about sufficient for one acre. About 300 seeds weigh 1 oz. I merely wish to mention this fact in view of the scarcity of seed now available, and to indicate a method of sowing without waste. As in all probability the demand for seed this season will exceed the supply, intending planters are advised that by steeping the seed for twenty-four hours or so, and sowing by hand in wet soil, making allowance of about half for unfertile seed (if from the Ipswich stock, if from other sources this contingency need not be taken into account), a way is demonstrated of meeting the exigencies of the case. Sowing should be completed during October in the southern part of the State—early in the month is preferable, because the plants thus have a longer growing period, and thus the crop is increased. Cotton is a child of the sun; thus as soon as warmth appears in soil and atmosphere the crop will assert itself.

In our own practice our standard distances were frequently settled for some soils as close as 18 inches to 2 feet apart. This, of course, involves the use of much more seed, and is a question for the planter to determine for himself. American growers, I may state, endorse the system of planting at much the same distances as here indicated. Cotton sown under general conditions as regards moisture and warmth will appear above ground in from three to five days after sowing. Care must be observed that the seed is not buried too deep, 2 to 3 inches being the limit of depth at which it is advisable to sow.

BY HIGHWAYS AND HEDGES.

Some time ago we referred to the provision made for a "wet day" by the villagers in the Salpiti Korale, who preserve the pulp (as well as the seeds) of the jak by boiling and sun-drying. In the Anuradhapura district we found the people collecting the small variety of mushroom, which at certain seasons springs up in hordes in tank beds, and preserving them in the same way for future use.

There is a great deal written now-a-days about cattle fodders, especially for dry districts, where it is recommended that the leaves of suitable trees (whose deep roots render them safe against drought) should be depended upon rather than the herbage of shallow-rooted grasses. In this connection such plants as Erabedu (*Erythina indica*) and dhal (*Cajanus indicus*, Ratathora S.), and even the jak should not be lost sight of. In the Balangoda district it is a common sight to see cattle making a good meal of lantana flowers, while *Mimosa pudica* constitutes an alternative diet. In the N.C.P. "tora" (cassia) takes the place of the latter (which is an ug-

common weed), and "tora" seedlings are to be found springing up naturally from seed-beds of cattle dung, strikingly showing how seeds are disseminated after passing through the alimentary canal of animals.

Speaking of fodder plants we might mention that the Algaroba bean described in the *Agriculture Magazine* for June, 1901, is now fully established in the Colombo Stock Garden, and as it is easily propagated by cuttings there should be no difficulty in multiplying a tree specially recommended for drought-stricken districts.

The excessive dryness of the North-Central Province is said to render the destruction of trees by burning very easy. By lighting a fire round the foot the trees are slowly incinerated, even it is stated during showery weather, when the wood is consumed underneath the bark.

Another condition due no doubt to excessive dryness, is the hollowness of the trunks of trees of any age. The hollow stems of large tamarind trees—and they are much larger than in other parts—which mark the sites of old villages form a convenient harbour for snakes.

Many of the wild forms of vegetation in the Anuradhapura district have bright showy blossoms. Chief among these are *Memecylon umbellatum* which bears what Trimen calls "brilliant bosses of (blue) flowers along the entire length of the branches," *Cassia marginata*, and species of *Bauhinia*.

The hop and honeysuckle are generally cited as examples of plants that twine from right to left. Indigenous species which have the same property are *Limacia cuspidata* and *Dioscorea pentaphylla*.

In the "Buried Cities of Ceylon" mention is made of the viscid juice obtained from a tree, used with lime and coconut water for producing a polished surface on masonry work. The name of this tree is given as "para" (*Dillena dentata*). The popular name is apt to be confused with the rubber tree known as such, while the word *Dillena* is evidently a misprint for *Dillenia*. According to revised nomenclature the botanical name of the tree should be *Wormia triquetra*, while the native name correctly written is "Diya-para."

We all know the green rose, which might be looked upon as an abortion of a flower; but the latest novelty is the blue-rose which has been sent to Kew Gardens from the United States. The plant is said to have reached with blooms in excellent condition, and it is thought will claim rank with the choicest new orchid.

NATURE STUDY LESSONS.

SECOND COURSE IN THE STUDY OF PLANT LIFE.

2. THE ROOT.

The roots of plants are generally spoken of as the organs of nutrition, because it is by means of the roots that plants take up the food they obtain from the soil.

We must first distinguish the actual feeding roots from others. In a large tree, the bigger roots have lost the power of absorbing water (with plant food in solution) from the soil. They indeed collect nothing, and their chief duty is to fix the tree firmly to the ground, and to convey liquid matter through their woody tissue which is similar to that of the stem, about which we have already learnt something.

The roots which actually take part in the absorption of plant food from the soil are the *most delicate* roots, and absorption is confined to that part of each feeding root which is situated behind the extreme end. This absorptive region is covered with fine root-hairs—generally very closely packed together and so greatly increasing the absorbing surface.

In time this delicate part becomes discoloured and hardened, the root-hairs drop off, and the power of absorption is lost. But before that the rootlet has pushed into the soil and fresh hairs have formed on the new-formed length behind the root tip. And this process goes on on all healthy roots which, so to speak, travel in search of food.

To prove to yourself what you have been told, you should carefully—*very carefully*—raise a small plant or seedling of any kind with all the adhering earth, and gently place it in a basin of water till all the particles of earth attached to the roots are detached. If no injury to the delicate parts of the roots has taken place, you will be able to observe the root-hairs I have spoken of, and their situation on the roots.

You will now have some idea of the apparatus for absorbing plant food from the soil and how delicate it is; and you will no doubt begin to think a little of how we could best protect these delicate structures upon which the health and vigour of the plant so much depends, as well as how we could help them in their work of providing nutriment for the plant. But about these matters I shall have to tell you something when we come to speak of the soil.

The actual tip of the root that penetrates the earth will be found to be protected by a "root-cap" (which is constantly being renewed from within); so that each delicate root has, so to speak, a boring instrument at its end to burrow out a passage for it through the soil. You should try and make out these 'caps' at the end of roots. A magnifying glass will help you to do this. If you have the screw-pine (*Wetakeyiya*) growing anywhere near, examine the ends of the roots—even those above ground—and you will probably be able to see the root-caps on them.

But what is the nature of a root-hair? It is a hollow structure—a tube, so to speak, of the smallest capacity—and communicates with one of the cells of the root wall and so with the whole plant itself.

Now, I think, you have a fair idea of the way in which the roots perform their functions as nutritive organs. They do so, as it were, by innumerable minute mouths which drink in liquid food and pass it on from cell to cell, and so the fluid is transmitted upwards through the longer and larger roots on to the stem itself to be borne through its branches to the leaves.

But how, you will ask, does the plant get all its food in a liquid form—for I believe you know already that it is only liquid matter or solutions that can enter the cells, and hence that the various elements of plant food must be first dissolved before they can be available to the plants. Well, for the present it is sufficient for you to know that this dissolving out of plant food from the mass of soil is effected by water aided by certain agents in the soil as well as in the root hairs themselves. These solutions of plant food constitute the crude-sap to which we have already referred.

The larger roots may therefore be looked upon as merely continuations of the stem; these divide and subdivide into finer branches till we finally find them as delicate rootlets carrying the threadlike tubes we spoke of as root-hairs—the true absorbing media of plant food. Roots are produced under various conditions:—

1. *By the Germination of Seeds.*—Dig up germinating seeds of beans and Indian corn (or paddy) and observe the production of the roots. Notice that in the bean a main or tap-root will be first produced, while in the Indian corn or paddy several fine roots are produced.

You could also study the production and development of roots by germinating seeds of Indian corn or paddy—(previously soaked for a few hours) in a small box with a few sheets of damp blotting paper. Keep the paper damp and cover the box with a sheet of glass for a few days and watch results.

2. *From Cuttings.*—Place a cutting of croton in a bottle of water and observe the development of the roots. Wrap the bottle round with paper to exclude light and air in the production of roots.

3. *From Leaves.*—Take a leaf of Bryophyllum (Akapanana), tie a thread to the leaf stalk and suspend the leaf, against a wall, to a nail or pin. Keep the leaf damp by sprinkling water on to it and watch for the production of roots from the margin of the leaf.

4. *From Tubers.*—Divisions of potatoes and yams containing buds develop roots.

5. *From Branches.*—If a narrow ring of bark be removed from a rose branch, and the branch be fastened down to the ground at the point where the bark is cut, then covered with earth and kept damp, roots will spring out and enter the soil.

Or if a ring of bark be removed from a shoeflower branch, and two halves of a bamboo

pot be secured firmly round the part, and the pot filled with coir dust at the bottom and good soil above, roots will strike into the pot if kept damp. After a branch has been thus in the pot for some time a small notch should be cut below the pot, and the notch deepened gradually at intervals of 3 or 4 days till the branch, by now rooted, is severed and ready to form a new tree.

The production of roots on growing stems above ground you see in the Banyan (Ma-nuga), on the Vanilla (where the roots attach themselves to the bark of trees), in the pumpkin (which sends out roots from its trailing stem), in the Ioranthus (pilila) which fixes its roots on other trees and lives upon them, and so on. These and other peculiarities of roots you should make a point of observing in your walks through the country.

As in the case of stems, roots also act as stores of nutriment for the future use of the plant, and you are familiar with these swollen roots in the manioc (manyokka), sweet potato (batata), and radish (rabu), all of which are used as food for man.

Certain roots yield dye stuffs such as chaya root (sayamul), others are used medicinally, as, for instance, the root of the horse radish tree (murunga). The roots of cus-cus grass (sevandara) contain a fragrant otto, and sugar is prepared from the juice of the beet root.

RINDERPEST.

(Concluded.)

HOW TO EXTRACT THE BILE.

"The animal should be laid on its left side, and the skin and flesh on the right side immediately behind the last rib cut through; the ribs are then raised, and the gall-bladder becomes visible. The gall-bladder is then punctured with a small knife or trocar, and the gall allowed to escape into a wide-mouthed bottle, previously sterilised. If properly stoppered wide-mouthed bottles are not available, then ordinary white quart bottles may be used, with a glass or enamelled funnel, which can be procured from most country stores. Every precaution must be taken that the operation is performed in a thoroughly clean manner, the hands of the operators, and also all instruments and utensils, being thoroughly cleansed and sterilised before use. The surface of the gall-bladder should also be wiped over with an antiseptic solution before being punctured.

DIRECTIONS FOR THE SELECTION OF BILES, &C.

(a) Biles of all shades of colour, except those that are red from the presence of blood and thin, watery biles of a pale yellow colour, may be accepted so long as they are clear and free from sediment, and where practicable several different galls should be mixed together; this modifies and equalises the strength and safety of the gall. The selected galls should be kept separately for at least 12 hours; if any gall smells or changes

colour after keeping, it must be rejected. The good galls are then mixed together before being sent out.

(b) Gall is considered most effective and gives the best results when obtained from a sick beast on the 10th day after artificial inoculation, or on the 4th or 5th day after the visible symptoms have become apparent in natural infection. Earlier or later galls should be avoided, and gall taken from an animal which has died, unless the duration of the disease is known, is not to be recommended unless carefully examined.

(c) The gall should be used on the second day after being drawn if practicable, but if kept cool either by placing the bottles in iced chests, or wrapping them in wet cloths, and placing them in a cool draught, may be kept fresh and safe up to the third or even fourth day.

(d) Both before and after the gall is placed in the bottles, they should be disinfected, and also the cloths that are wrapped round them, before being sent to the inoculator.

(e) The inoculator should not extract the gall from the affected animal himself, nor come near to the infected cattle; but if it is necessary for him to do so, he should change his clothes and boots, and disinfect his hands well before commencing to inoculate, also see that everyone handling the cattle has been thoroughly disinfected.

(f) As it is never certain when inoculating within an infected area, that the herd is completely free from infection, the needle of the syringe should be cleaned, and disinfected in a five per cent. solution of carbolic acid or alcohol after each inoculation, and the skin of the animal at the seat of inoculation should be cleaned and disinfected both before and after the operation with Jeyes' Fluid or other similar disinfecting solution.

(g) The small cup or vessel containing the gall, from which the syringe is repeatedly filled, should be kept covered with a small piece of linen or calico, wrung out in the disinfecting solution, and the operator's hands and syringe should be frequently disinfected.

(h) As infection may be in any herd unknown to the operator, he should disinfect his hands and clothes well after inoculating each herd, and for the same reason, it is not desirable to have the same boys to assist in catching different herds of cattle.

The objections to Pure Bile Inoculations are:—

(a) Biles vary so much in their immunising properties, and there is no practical method of examination on the veld which will indicate whether the bile being used is strong or weak in immunising properties; hence the operator is unable to regulate the dose which he should inject, or to calculate the duration of the immunity which the inoculation will confer.

(b) Inoculation with pure bile does not produce its effects at once, complete immunity is not established until about the tenth day; an inoculated animal may contract a severe form of Rinderpest up to the sixth day after bile inoculation, if exposed to infection.

Further, there can be little doubt that many pure biles intensify the disease, and hasten the fatal termination in already infected animals; it

is, therefore, not so suitable for the inoculation of infected herds as glycerinated bile or serum.

(c) Bile inoculation—either pure or glycerinated—necessitates the destruction of a large proportion of the animals to be inoculated, not less than six per cent. when the necessary care is exercised in the selection of suitable bile. In this respect it compares very unfavourably with serum.

(d) Lastly, pure bile will not keep. Dr Turner says:—

"In the laboratory, using minute precautions to prevent the introduction of putrefactive organisms, and by placing the fluid in an ice chest, it is sometimes possible to preserve the bile, in a state in which it can be used without danger, for a period of ten days. But usually the bile is already infected with putrefactive organisms in the gall-bladder itself, so that any amount of care is futile"; and Veterinary Surgeon Shepherd, when referring to the formation of abscesses after bile inoculation, says "that these are not necessarily due to carelessness—I have frequently found microscopically putrefactive and other bacteria in abundance in the very best looking Koch gall."

Method of Inoculating.

"After having secured the animal to be operated on, the necessary dose of bile is injected under the skin of the dewlap by means of a hypodermic syringe, and well rubbed in. Care should be taken that the point of the needle is not inserted into the flesh, but between the shin and the flesh only. The local result of inoculation with bile is a hard, somewhat painful swelling, about the size of a man's fist, which gradually disappears in the course of a week or two.

Glycerinated Bile.

"Edington's Method is made by adding one part of glycerine to two parts of bile. The mixture should be well stirred together, and allowed to stand for eight days. Experience has taught us, however, that if urgently required, the glycerinated bile may be safely used, even for intravenous injection, forty-eight hours after being mixed. The dose of the glycerinated bile is from 15 to 35 c.c.—according to the size of the animal—injected into the cellular tissue under the loose skin of the dewlap, and well rubbed in. When used in an infected herd, large doses should be given, as it possesses distinct curative action; and in all animals which have a high temperature, indicating that the fever is already established, large doses should be injected into the jugular vein direct. It was claimed for glycerinated bile that it did not communicate the disease, as fresh pure bile was liable to do, the glycerine having the effect of destroying the active organism of Rinderpest, as well as those of putrefaction, but that it exercised no modifying action on the immunising substances contained in the bile, and although the immunity which it conferred was a passive one, this was considered an advantage rather than otherwise, as it rendered the inoculated animals susceptible to a modified reaction when injected, ten days after, with a dose of 0.1 c.c. of virulent blood. A second dose of virulent blood, of double the strength, was injected from

ten to fourteen days after the first. Unfortunately the difference in the strength and immunising properties of the different biles made it practically impossible to fix any exact dates on which to apply the blood inoculations with safety, and yet to give a reaction that would strengthen the immunity. In many herds no visible reaction followed the first blood inoculation, and yet the second blood inoculation caused such a general and severe attack, that a large percentage died of the disease. In some instances even the first blood inoculation caused a heavy mortality, clearly showing that some samples of glycerinated bile gave but a very evanescent immunity. To overcome these drawbacks, a larger dose of glycerinated bile was used, and it was followed up with blood inoculations at shorter intervals, beginning with 2 minims, and gradually increasing the dose. Several herds were immunised by this method, but it entailed a considerable amount of additional trouble and expense. Glycerinated bile is now used mainly to give a passive immunity similar to serum, until the infection in the herd, or in the near neighbourhood, has died out. If necessary it may with advantage be followed by a dose of pure bile. It is now rarely followed up by virulent blood, principally on account of the danger that exists in this country of communicating other diseases besides Rinderpest. The chief advantage of glycerinated bile over serum is that it can be prepared immediately on the outbreak of the disease, at any centre where serum is unobtainable. It will keep effective for many months—in one instance it proved effective after three years—and it requires very little skill to prepare it.

The question of defibrinated salted blood and serum as inoculating media for the prevention and cure of Rinderpest are also dealt with at length, and the pamphlet concludes with the following:—

CONSIDERATIONS FOR FUTURE ACTION.

Should Rinderpest become epizootic again in South Africa, and prevail in a virulent form over wide areas of the country, rendering the cattle liable to infection, and re-infection for many months, it would be necessary to give the herds an active immunity which would last until the danger were past, and such an immunity could only be conferred by an injection of one or other of the following immunising materials:—

- (a) Inoculation with pure bile.
- (b) Inoculation with glycerinated bile followed by pure bile, or repeated doses of virulent blood, or
- (c) The simultaneous inoculation with strong standardised serum and virulent blood.

There are, however, very strong objections to the use of virulent blood, whether after glycerinated bile, or along with serum,—

(a) Because it conveys active Rinderpest to the cattle, every inoculated herd becoming a fresh centre of infection, and

(b) On account of the danger of introducing other infectious diseases besides Rinderpest, such as Redwater, Anthrax, Quarter-evil, and other diseases of a similar character which affect cattle in South Africa, not yet clearly differentiated, but which are known to be communicated by blood

inoculation, and which cannot always be guarded against even by careful microscopic examination.

This is also the principal objection against the use of defibrinated salted blood.

We have, however, every hope and expectation now that the war has ceased, and with it the necessity for moving cattle about in all directions for transport, and protection, that the outbreaks of the disease will be more or less sporadic, and comparatively easily suppressed by strict quarantine, and the prompt inoculation with serum or bile, both pure and glycerinated. It is upon serum, however, that our principal reliance must be placed,—

(a) Because it can be produced in large quantities, and kept for long periods ready for use as required. The serum prepared by Drs. Turner and Kolle at Kimberley in 1898 retained its efficacy unimpaired for two and a half years, and some of it was used effectively after three years, but its strength was evidently becoming reduced at the latter date.

(b) Its strength can be ascertained before it is issued for use, hence the dose can be regulated.

(c) Its action is immediate, a clean animal is safe as soon as it is inoculated.

(d) It is also curative in its action in the early stages of the disease when used in large doses.

(e) It does not—as far as is known at present—communicate any other disease.

The methods of inoculation which I would recommend in future sporadic outbreaks of Rinderpest are briefly as follows:—

INFECTED HERDS.

These should be inoculated at once with either serum, glycerinated bile, or defibrinated immune blood. Every animal which indicates infection by a rise of temperature should receive a large dose of not less than 100 c.c. of strong serum, 30 c.c. of glycerinated bile, or 300 to 400 c.c. of ordinary immune blood, obtained from a recovered animal which had not been fortified. All affected animals should receive the inoculation direct into the jugular vein, as it acts more promptly and effectively than when injected under the skin. Fresh pure bile should not be used in an infected herd, if any of the other inoculating materials can be obtained, as some biles tend to intensify the character of the disease in those already infected, and its immunising effect is too slowly developed to protect the healthy cattle in the herd against infection, if they are kept in contact with the sick. If no other means are available, however, the temperature of the whole of the cattle in the infected herd should be carefully taken by clinical thermometer, and those only which register a normal temperature should be inoculated with pure bile; the others should be separated from the inoculated lot at once, and carefully attended to. If glycerine can be obtained, the spare bile should be mixed with it in the proportion of one of glycerine to two of bile. This mixture after standing for forty-eight hours, may be injected intravenously into the infected animals in large doses, not only with safety, but with marked benefit. Fresh, pure bile may, however, be used as a second injection, following serum or glyceri-

nated bile, in all animals in the herd which give no indication of being affected with the disease; this will confer a lasting immunity sufficient for all practical purposes.

CLEAN HERDS.

When it is decided to inoculate a clean herd which is in danger of becoming infected by reason of the proximity of the disease, I would recommend that all the cattle in the herd be inoculated with not less than 20 c.c. of glycerinated bile, 30 c.c. of strong serum, or 200 c.c. of defibrinated immune blood. The strength and endurance of the immunity conferred by these inoculating materials is proportionate to the amount injected, hence, if the disease is prevalent in the neighbourhood, larger doses may be used, or an injection of fresh, pure bile may be given ten to fifteen days later. This will confer a lasting immunity on the cattle, and obviate the loss arising from the inoculation, or risk of introducing the disease.

GENERAL ITEMS.

To accustom a weak-mouthed horse to a bit, or in other words, to harden its mouth, the *Cape Agricultural Journal* says a rubber-covered snaffle is the best. If the horse is young and only just broken, it is recommended that a mouthing bit be used every day till he gets used to the feel of it, and if he is to be driven a rubber-covered bit should be used.

Nutrient qualities of fruit vary considerably with the nature of the fruit; such as banana, fig, date, and grape ranking very highly: one pound of bananas is said to contain as much nourishment as half a pound of meat, and in their own indigenous country, Uganda, they are converted into jam, champagne, beer, vinegar, and brandy. The date also contains a large percentage of nutrient material, and the native of the country to which it is indigenous not only feeds himself on it, but gives it to his horse and camel. Figs also

are most wholesome and nutritious—grapes especially so. Apples are good for liver, brain, and throat complaints; oranges are nourishing, and have a slight tonic influence on the liver, while the lemon is a popular remedy for rheumatism, and has no equal in the treatment of skin diseases—it is not only curative but preventive in the latter. The constituents of fruits are sugar, acids (either citric, phosphoric, malic, or tartaric), distilled water, and a small percentage of fat and albumen. Important among the uses of fruits may be noted their diuretic and laxative effect, and the influence they exert upon the disease germs which may be in the system.

The proper distance to plant mango trees, says the *Queensland Agricultural Journal*, is 35 feet each way; oranges and lemons 30 feet. Any small crops may be planted between the trees for the first few seasons, provided deep cultivation and manuring are followed. This will keep your orchard on the "improve" all the while.

The same paper refers to two methods of curing chillies:—(1.) When the chillies are ripening, go over the field once a week, picking all the ripe ones. Leave a long stem on the pod. Expose the pods to the sun for a day or two to toughen the skins and stems. Then with a long, slim needle string them through the stem on strong twine 8 or 9 feet long. When the twine is full, hang it up in a dry cool shed where there is plenty of ventilation. Be careful not to string any poor or damaged pods. When dry, store them in a dry cool room, hanging them on poles or nails. (2.) Another, and a good plan, if the chillies are to be exported, is one which we know by experience to be good, as we have kept them for 12 months without their changing colour or strength. Make a fairly strong brine. Fill a stone jar or a keg with the chillies, and pour the cold brine over them, filling the vessel to the top. Bung down closely. In 2 or 3 months, or even after a longer interval, either strain the brine or make fresh, carefully washing out the vessel. They will keep fresh for a long period.

No. 6

JOURNEY TO A RUBBER PLANTATION ON THE ISTHMUS OF COLUMBIA.

By C. O. WEBER, Ph. D.*

THE well-known difficulty of investigating satisfactorily in Europe any of the numerous questions of importance connected with the collection of the latex from the rubber trees, its composition, and the most satisfactory manner of converting it into india-rubber, made the commission I received in the early part of this year, to inspect and report upon the state and possibilities of the extensive rubber plantation of the Las Cascadas Plantations Company, Limited, at the very outset an acceptable one. The fact that this plantation is situated in the Isthmus of Panama seemed to me a comparatively slight matter, although I must own to occasional apprehensive pangs on being treated by some of my friends, and others, to somewhat vivid descriptions of the terrors of mosquitos, malaria, yellow fever, and small-pox. I will say at once here that I found all these blood-curdling stories gross exaggerations. Colon is certainly an abominable hole, but had I to take the choice I would, without an instant's hesitation, prefer to live at Colon rather than in the slum districts of either London, Manchester, or Salford. The same, only more so, is to be said of Panama, which is a fairly well-built town upon rocky subsoil. Particularly the mosquito bogey appears to me an absurd exaggeration as far as the isthmus is concerned. Only once during the whole journey did I get really badly bitten; this was in my cabin on board the R.M.S. "Para" on the first night after leaving Jamaica for Colon. It appeared that besides taking in coal at that port, we had also shipped a liberal consignment of mosquitos.

The real trouble of an expedition like the one I undertook was never suggested to me; it consists in the fact that as soon as one leaves the beaten

track (Colon to Panama) every trace of civilised comforts at once vanish. The food is atrociously bad, the cooking worse; all drinks even water taken direct from the streams, are at almost fever heat, and often there is nothing to be had but rain water. It is this bad food, the monotony of the diet, and the insipidity of tepid drinks which I felt to render a stay in the Tropics rather trying. Of course, on a plantation with a well-established settlement all these difficulties largely disappear.

As is well known the stretch of the isthmus from Colon to Panama, through which runs the track of the illustrated Panama Canal, is all low-lying, on the Colon side largely swampy land, the mean elevation of which above sea-level does certainly not exceed 80 feet. There are a number of banana plantations alongside, or within near distance of the canal track, but nothing of any magnitude.

Shortly after leaving Colon, the mountain ranges appearing in the far distance, south and south-west of the town, begin slowly to close in upon the track of the canal, coming eventually, near Panama, right upon it, and it is this hill district which, intersected by innumerable small rivers and brooks, very gradually rises to altitudes 1,200 feet and upwards, which furnishes at altitudes of from 200 to 800 feet, or perhaps even somewhat higher, the most suitable land for the cultivation of India-rubber, cacao, and coffee.

In this hill district, connected by their own road with Las Cascadas station, lies the plantation of the Las Cascadas Plantations Company, Limited, which comprise a total area of very many acres a large part of which is planted out with rubber (*Castilloa elastica*), cacao, and coffee. The number of rubber trees on the plantation now amounts to 70,000, of which 15,000 are from 11 to 12 years old.

After arriving upon the plantation and fitting up the laboratory required for the examination of the latex, and the testing of rubber on the spot, my first concern was to ascertain the exact species of the *Castilloa* on the plantation. This appear to me all the more important, as there is one species of *Castilloa* known which yields plenty of a latex, but one containing no rubber, and there appear to

* From the *India Rubber and Gutta-Percha Trades' Journal*, Sept. 29, 1902.

be several varieties yielding either a poor quality, or very little rubber. Of course, coming on the plantation in the rainy season, when the trees bear neither flowers nor seeds, was not exactly calculated to facilitate the botanical determination, and I was, therefore, compelled to make a fairly close study of the morphological and physiological feature of the trees. On the other hand, had to be borne in mind the fact that the whole of our present-day information respecting the botanical characteristics of the various species of *Castilloa*, and the respective value of each of them for cultivation purposes, are in quite a hopeless state of confusion.

According to the usual description *Castilloa elastica* is a tree growing to a height of from 36 to 54 feet, the trunk at about 3 feet above ground attaining to a diameter of from 24 to 48 inches. The bark is smooth and yellow, the wood soft and perishable. The leaves are from 6 to 12 inches in length, of a clear and brilliant green, and their lower side is more or less covered with a growth of fine brown hairs. Very characteristic of *Castilloa elastica* is the phenomenon known as dimorphism of the branches and which consists in the branches which spring from the tree at an angle of 45 degrees at a certain point rather abruptly taking up a horizontal position. I purposely omit entering here upon a discussion of the flowers and fruits of *C. elastica* as a comparison of their characteristics with those produced by the trees at Las Cascadas is at the present moment not possible. Cross, the well-known Kew botanist, describes these trees as growing to a height of from 160 to 180 feet, with a diameter of 5 feet, but he gives no information respecting the age of these trees. In all probability these trees were an enormous age, to be reckoned by centuries rather than tens of years. J. H. Hart, Superintendent Royal Botanic Gardens, Trinidad, states that the oldest *Castilloa* tree, there is over 75 feet high and has girth of 4 feet at three feet above ground. Some trees 15 years old are from 58 to 61 inches in a girth. Against these two authorities we possess however, the certain information that in Mexico, Honduras, Nicaragua, and Ecuador the height of *C. elastica* varies between 40 and 60 feet.

There are a number of other species or varieties of *Castilloa*, with regard to which a considerable amount of uncertainty exists. Indeed, only one of these, *C. tunu* Hemsley, is satisfactorily established as a distinct and different species, which, moreover, although containing a large quantity of latex, yields no india-rubber at all. The *C. Markhamiana* described by Collins as being found in the isthmus is considered by several very competent authorities not to be a *Castilloa* at all, but a *Perebra*. I searched everywhere for this species without ever coming across it, nor had any of the various experienced native collectors I questioned ever heard of any other but the Caucho tree (*C. elastica*.)

Koschay, in a letter which last year appeared in the March issue of the "Tropenpflanzer," describes four different *Castilloa* as occurring in Costa Rica. Of these *C. tunu* has already been mentioned. Of the rubber yielding *Castilloa* the best is the one possessing a whitish bark; it yields plenty of excellent rubber. Another variety has a black bark with a rough and irregular surface; it yields a rubber as good as the white variety, but the tree is rapidly exhausted. A further variety is characterised by a reddish bark, very thin and fragile; it yields very little latex, but the rubber produced of good quality.

To this must be added that the *castilloa* of Panama appears to differ from all other known varieties by the occasionally quite enormous size of the leaves. Leaves 20 inches in length occur very commonly, especially upon young trees. For this reason it has been suggested that the *Castilloa* of Panama is a separate species.

Now, as regards the trees at Las Cascadas, while at first sight they certainly strike one as typical

Castilloa elastica, on closer examination show a number of differences which, at any rate in the absence of flowers, render the identification of the species none too easy. In the first instance, the bark of these trees, although very smooth, is certainly neither yellow nor white, but a delicate pale pinkish brown. The leaves even on the older trees are not very great, but still distinctly larger than the leaves on grown up trees of *C. elastica* in Guatemala, Honduras, Nicaragua, and Mexico. The hairy covering on the lower side of the leaves is much less striking, but the young leaf shoots at the end of the branches appear quite as densely haired as those of any typical *Castilloa*. Also the phenomenon above referred to as so characteristic of *Castilloa* is very strikingly displayed by all the *Castilloa* trees at Las Cascadas.

On the other hand, the only valueless species of *castilloa*, *C. tunu*, is absolutely unknown on the isthmus, and in my wandering I have never encountered it.* It is equally certain that the Las Cascadas *Castilloa* is entirely different from Koschay's black and red varieties; the appearance of its bark could not possibly be described in the terms used by Koschay for the latter two trees. In how far Koschay's white *Castilloa* corresponds to the Las Cascadas tree is difficult to say. The bark of the latter might, with some appearance of justification, be described in Koschay's term as "whitish," but considering that the large silvery patches on it do not appear to be the actual colour of the bark, but seem to be due to a lichen, and considering further that all the lichen-free portions of the bark are by no means whitish, but as I stated before, of a light pinkish brown colour, I prefer to adhere to this latter description.

Taking all these points in conjunction it will readily be seen that the Las Cascadas rubber trees exhibit all the characteristics of *Castilloa elastica* in regard to the general appearance of the tree, the shape of the leaf, the hairy growth on the margin of the leaves, their under side, leaf stem, and the leaf shoots, as also the phenomenon already alluded to as the "dimorphism of the branches." I hold these data sufficiently conclusive to demonstrate that the Las Cascadas rubber tree is indeed the true *Castilloa elastica*. The fact that these trees produce a good yield of an excellent quality of rubber may well be taken as contributory evidence in the same direction.

As regards the unquestionable differences of these trees from the *C. elastica* as generally described, I cannot say that I ascribe any importance to them. *Castilloa elastica* possesses such an enormously wide geographical distribution—from lat. 6° S. to lat. 22° N.—it occurs under so very greatly varying conditions of soil, elevation, humidity, and temperature limits that it would be most ext aduinary if it accommodated itself to all these different conditions without, at least some morphological change. Indeed, it seems highly probable that some of the varying statements regarding the growth of *Castilloa elastica* in different districts may find their explanation in the influence upon this tree of different climatic conditions. To some extent this may also be true with regard to the various conflicting statements regarding the yield of rubber obtainable from these trees.

On this question of the amount of rubber yielded by *Castilloa elastica* the information at our disposal from numerous sources is characterised by a degree of discrepancy perfectly appalling. According to Cross a *Castilloa* of from 18 to 24 inches in diameter produces 13 lb. of rubber annually, but he asserts that certain exceptional trees may yield as much as 100 lb. Collins observed that a 6 year old *Castilloa* possessing a diameter of 19 inches on being tapped in April, in the dry season furnished 20 gallons of

* Nor is it at all known, not even by hearsay, to the native rubber collectors on the Isthmus.

latex, from which 49 lb. of rubber were obtained and he declares this an average yield of all trees, the trunk of which, before branching out, reaches a height of from 18 to 27 feet above the soil. In Nicaragua it is found that from its sixth or seventh year a Castilloa tree yields from 4 to 6 lb. of rubber annually (Crawford). Dr. Morris states that a Castilloa, when first tapped, should yield 16 lb. of rubber. In Mexico, it appears to be generally assumed that Castilloa trees, when from 4 to 5 years old, will produce an average yield of 6 lb. of rubber. However, the "Bureau d'Informations Agricoles du Mexique" is rather more careful, giving the yield of the trees in question as amounting to from 4 to 5 lb. of latex, corresponding to 2 lb. 6 oz. of rubber.

J. H. Hart (Trinidad), states the yield of Castilloa as amounting to from 2 to 6 lb. but from quite a recent communication, I take it that an experimental tapping of one of his largest trees only produced about 14 oz. of rubber.

According to these above set out statements we would have to come to the delightful conclusion that, from its sixth or seventh year Castilloa elastica will yield from 6 to 49 lb. of rubber annually.

On the other hand, we have the results of the experiments of Dr. Trimen, Superintendent of the Botanical Gardens of Ceylon, and these results are as follows:—

5 years old.	Mean yield of 77 trees :	2.3 oz. per tree.
6 "	"	61 " 2.0 oz. "
8 "	"	61 " 1.8 oz. "
12 "	"	61 " 4.3 oz. "

My chief reason for quoting Dr. Trimen's figures is merely to call renewed attention to the absolute necessity of carefully ascertaining the yield of the Castilloa tree in any district in which it is intended to cultivate it. Dr. Trimen's figures can not be looked upon as representing the yield of Castilloa elastica anywhere but in Ceylon or Java, but they convey a vivid idea as to the extraordinary degree to which different conditions of soil and climate may affect the yield of rubber.

My own results obtained at Las Cascadas are as follows:—

Age of tree.	Yield of latex.	Per cent. of rubber in latex.	Yield of rubber.
6	1 lb. 13 oz.	26	7.5 oz.
7	2 " 5 "	26	9.6 "
8	3 " 1 "	29	14.2 "
11	5 " 3 "	31	1 lb. 9.7 "

As the trees can with perfect safety be tapped twice yearly, the annual rubber yield may be taken double that in the last column of the above table. These yields, as regards the trees of 8 and 11 years of age, respectively, are the means of a number of fully-developed trees of the two respective ages. The yields of the younger trees above given were obtained on tapping two representative trees of the respective ages, and taking the mean of the yield obtained as the real yield. I consider the above figures rather below than above the mark. But it is nevertheless well worth pointing out that as even Castilloa trees of the same age are apt to exhibit astonishing differences in their development it is only to be expected that they do so likewise as regards the quantity of rubber they produce, and it is, perhaps, not an altogether safe procedure to ascertain the aggregate yield of a rubber plantation by simply multiplying the number of trees on the plantation with the, however carefully, ascertained yield of a limited number of trees. It is further my opinion that the method of planting and rearing young rubber plantations, always speaking of Castilloa elastica, is a matter deserving of much closer and more careful study than it has so far obtained. The method of simply planting out in a forest clearing so many seeds, or seedlings, at so many feet distance I consider, altogether inadequate. With this highly important matter I propose to deal at some future occasions.

The question regarding the best method of tapping the rubber trees is one which just now is engaging the attention of most of those occupied rubber planting. Of course, there are always the methods of the natives to fall back upon, but it could not be said that these are on the whole calculated to inspire much confidence this for the simple reason that the native collectors in all parts of the world never show the slightest regard for the trees they are tapping. If they do not actually cut the trees down, or in some other way deliberately bleed them to death, they still tap them with an utter disregard of all precautions for their preservation. Such methods are out of the question when we come to tap the trees on the rubber plantation. Here absolutely the first consideration is not only to conduct the tapping in such away as to preserve the life of the tree, but even to prevent this operation from injuring its vigour and growth.

TAPPING.

It does not require much demonstration to show that the process of tapping must to a considerable extent depend upon the position, distribution, and arrangement of the laticiferous vessels in the trees. It is generally stated that the milk-ducts of rubber trees lie in the layer of bast underneath the bark, and that no milk-ducts are to be found in the inner parts of the trees, the wood or cambium. This as a general statement may be true enough, but it certainly does not strictly apply in the case of Castilloa elastica. If we chop one of the stout branches off a Castilloa tree, or, better still if we cut down a young tree, and carefully examine the cut, we can easily see with the naked eye that although the bulk of the exuding latex issues from the layer of bast immediately beneath the bark, still there are quite a number of apparently rather large milk-ducts distributed through the wood of the tree, and also that there is a considerable exudation in the lignified tissues surrounding the pith centre of the trees. It will be a highly interesting problem to ascertain by a careful microscopic study of the various strata of the trunk of the Castilloa tree, whether there is any direct communication (anastomoses) between these widely separated milk-ducts in the various parts of the tree. How far similar conditions exist in other rubber trees I am at present unable to say, but it seems to me very improbable that castilloa stands alone in this respect.

Whether there is any communication between the milk-ducts in the different parts of the tissues of the trunk of Castilloa or not, can, however, not alter the fact that in tapping the trees on a rubber plantation only those layers of the trunk situated on its periphery can be drawn upon. Indeed, it is the layer of bast only immediately underlying the bark which is worth considering for tapping purposes, as it is generally admitted that any cuts into the wood of the tree are liable to permanently injure, or even altogether destroy it. It is, therefore, quite clear that as regards the rubber plantation entrusted to me one of the most important questions to be solved was to ascertain and decide upon the most satisfactory method of tapping the trees.

A microscopic examination of longitudinal sections of the bast layer of Castilloa at once revealed the fact that while this layer contains an enormous number of milk-ducts running longitudinally through the tissue, there are surprisingly little evidence of lateral intercommunication (anastomoses) between them. In exact agreement with this observation is the fact that longitudinal incisions produced an absurdly small flow of latex, indeed, in many cases none at all, this for the simple reason that the number of milk-ducts opened by a vertical incision is, in the absence of horizontal branchings, simply the number of milk-ducts occupying the width of the cut in the horizontal direction. Compared with the total number of milk-ducts in the layer of bast

surrounding the cambium the former number is, of course, insignificantly small. Moreover, we must bear in mind that the latex is held in the milk ducts by capillary force, and in order to obtain a flow of it from any incision we largely depend upon the pressure exerted upon these milk-ducts by the turgescence of the cellulose tissues of the tree. It will readily be seen that a vertical incision largely relieves this pressure, and consequently the flow of latex obtainable by such an incision will not even be proportional to the number of milk-ducts, however small, which have been cut into.

HORIZONTAL CUTS.

On the other hand, very little reflection will show that in applying a horizontal incision, not only do we open all the milk-ducts running through the area defined by that incision, but moreover the pressure due to the above mentioned turgescence is not in the least interfered with, and assists materially in producing a most copious flow of latex. It would, therefore, appear to follow that while vertical cuts are entirely useless, at any rate, as far as *Castilloa elastica* is concerned, horizontal cuts produce the maximum flow of latex, and a system of horizontal cuts therefore offers the best prospects for an effectual tapping of the trees. This, no doubt, is so, but the circumstance must not be overlooked that a horizontal cut is not very satisfactory for the gathering up of the exuding latex, this particularly in conjunction with the fact that a *Castilloa* tree cannot be drained by a single small horizontal cut as is, for instance, the case with *Hevea*, but requires a whole series of cuts. This renders it desirable that instead of tapping *Castilloa* with a number of small cuts a continuous cut would be preferable and one which drains practically the whole area of the trunk. There is only one cut of this description, and this is the one known as the spiral cut which, indeed, has always been largely employed by the native collectors exploiting *Castilloa* trees. I have, indeed, satisfied myself that the flow of latex obtainable from a spiral cut applied at an angle of not more than 45 degrees produces excellent results as far as the flow of latex is concerned.

There is also the repeatedly advocated system of an ascending series of V-shaped cuts, the apices of which are connected by a vertical cut which serves as a channel down which the milk is enabled to flow. In the first instance, I consider this vertical cut objectionable, as, while it defaces the tree, it does not contribute to the yield of latex obtained. Moreover, in the case of the *Castilloa* trees at Las Cascadas this vertical cut would be quite useless as the latex yielded by the trees issues from the cuts as a thick cream which does not flow, so that in this case the V-shaped cuts would only about have the effect of a double system of crossing spiral cuts.

The next question to be settled was the tool with which the above-named spiral cuts are to be applied. The instrument in universal use for this purpose throughout Central America is the "machete," a sort of cutlass. This formidable tool requires very dexterous handling in order to produce a regular cut, and even in the hands of the most experienced "hulero" produces an enormous mass of woody *debris* which clings to the cuts, and subsequently are taken up with the latex. The extraordinary mass of wood and bark in the Central American rubbers is entirely due to the tapping being performed with the machete. There is certainly no difficulty of removing from the latex these particles of wood and bark, but it goes without saying that if it should be possible to avoid this or any other contamination at the outset it is much to be preferred to any, however effectual, process of subsequently removing it from the latex.

A NEW TOOL.

For this reason a narrow plane has been recommended for the tapping of the trees, but there are

several drawbacks to it. It certainly gives a perfectly continuous cut, and one free from the above-named *debris* but it very soon gets clogged. The layer of bast to be cut through in order to obtain the full yield of latex is very considerable, and necessitates the blade of the plane protruding very considerably a circumstance not calculated to facilitate its use. The thickness of the layer of bast to be cut through not only varies not inconsiderably from tree to tree, but it varies also in the same tree at different heights of the trunk. A plane gives under these conditions very little chance of adapting the depth of the cut to the depth of the layer of bast, and consequently, according to the setting of the plane either the layer of bast is not entirely penetrated, or the cuts pass more or less deeply into the wood itself.

I therefore made experiments with a triangular cutting tool, the cutting edge of which is formed by one of the (rounded) angles, and after several modifications, I arrived at a form which answers the purpose admirably*. To cut or tap the trees with this instrument requires some experience but certainly very much less than the machete. The cuts are absolutely clean and continuous, and their width is naturally regulated by the cutting angle and the depth of bast to be cut through. This is exactly as it should be. For trees of different age, or of different diameter, tools with different cutting angles may be employed.

It has often been proposed to provide the instruments used for tapping with guards so as to prevent their penetrating into the wood. This is, no doubt, a very praiseworthy notion, but unfortunately one which it will be found practically impossible to adopt for the already stated reason that the thickness of the layer to be cut through varies within such wide limits as to render the proposal quite impracticable.

The just described tapping tool does not, of course, prevent the penetration of the cuts into the wood, though I may at once state that its liability to do so is certainly much less than with any instrument operated by striking, such as the adze, or machete. But in the experiments I conducted at Las Cascadas I gradually came to the conclusion, rather heretical in view of the nature of the numerous statements, on this point, that the tapping to begin with has surprisingly little effect upon the well-being of the tree, and further that cuts penetrating into the wood of *Castilloa elastica*, although they may retard the healing up of the wounds, are not necessarily injurious to the tree. They certainly do not affect its physiological functions, but only represent a danger as they offer a chance to certain insects to lay their eggs into the wood, so that subsequently the trees may suffer from, or even succumb to the ravages of the larvæ and insects (wood-burrowing beetles) emanating from these eggs. But this danger is easily avoided by painting the cuts after the collection of the latex and "scraps" with an antiseptic paint. It also appears that this simple and inexpensive treatment assists materially in the healing of these cuts, as all the cuts thus treated began to heal up already within a week after the tapping.

(To be concluded.)

VANILLA.

CULTIVATION IN THE SEYCHELLES.

(Concluded from Page 160--Sept. 1902.)

CURING THE PODS FOR MARKET.

There are many different modes of preparing vanilla, but for brevity's sake one alone will be described; it is probably the simplest, and appears to be as successful as any other. About 400 of the longest pods are placed in a basket and plinned into hot

* I shall revert to this subject in a subsequent paper,

water (190° F.) for ten seconds; this is repeated twice, the dips being increased to twelve and fifteen seconds respectively, with intervals of half a minute between each two. After the third dip, when most of the water has drained off the pods are placed in a wooden box or barrel lined with blankets, and closely covered up with the same material. When lot 1 is finished, lot 2 is similarly treated, and for them the water may be a few degrees cooler, or the dipping times a trifle shortened; and so also with lot No. 3, while No. 4 may be treated as No. 2. Perhaps it is as well to add that 190° F. is not an absolutely essential heat, but it is about as high as it is safe to go; while even the longest pods may be adequately treated in water at 170° F. if they are kept in it long enough. An experienced preparer will be guided more by the appearance of the pod after each dip than by any fixed formula. When small quantities are dealt with less heat is needed, and the above figures are given for a boiler 22 inches in diameter by 12 inches deep. It is best to have good-sized boxes or barrels to sweat the pods in, those holding 2,000 or 3,000 each being preferable, for the more pods there are together the better heat is retained. The lots (1, 2, 3, and 4) should be kept apart, a fold of blanket being laid on each if all go into one box. By the following morning they should have changed to chocolate or puce colour, and are then ready to spread on the drying shelves; but if there is a large number together, and the heat has been well kept in, they may be left for another twenty-four hours.

A curing house for preparing a crop up to 2,000 pounds (dry) may have the following dimensions and fixings: 30 feet long, 15 feet broad, 13 feet in height of walls. It should be divided into four counterparts, two on the ground and two above, each being approximately 15 by 15 and 6½ feet high. One compartment on the ground floor is used as a hot room, having a flue 2 feet wide covered sheet iron running through the centre. If the heat is too intense from this, sand may be sprinkled on top to reduce it. Above this flue and around two sides of the hot chamber tiers of shelves are fixed 6 inches apart, on which the pods are spread to dry. The shelves may be conveniently made of laths, on top of which mats or canvas can be laid, or fine-meshed wire netting would serve the same purpose, perhaps, better than anything else. . . . The worker, sitting on the floor, keeps the four lots of pods—long, medium, short, and split—distinct on the shelves. This facilitates the sorting, the short and split pods needing to be examined sooner and oftener than the longer and sound sorts, as they dry more rapidly.

A good average heat for the hot chamber is 110° F. A few degrees more or less does not matter, but pods are apt to dry too quickly if the heat is much greater. The slower the progress the more uniform and better is the result. As they begin to turn soft and show longitudinal wrinkles the pods are removed from room 1 to 3, and after reaching a certain degree of flexibility they pass on to the shelves in room 4 and there finish their curing. If kept too long in either a hot or warm room the thin ends of pods shrink too quickly, and this is to be avoided. In a large crop there are always some inferior, ill-nourished pods in which this occurs, but the last remark will be useful to a beginner. When fully cured the pods are much wrinkled and pliable, bending easily around one's finger. There is considerable difference in the degree of dryness preferred by different curers. If the contents move easily all along a pod, without any unevenness being noticed when it is drawn between the finger and thumb, it is nearly dry enough; but the right stage can only be learned by experience. When finished the pods are well wiped with bits of soft flannel and then kept in boxes with close fitting lids. It is better to sort them roughly into lengths as each day's lot is put away, and tie up the various sizes

in bundles of about 200 each if the numbers allow of it, for they have to be examined once or twice a week in order to remove the moulded ones, and this is much more quickly done with bundles than when they are loose. Moreover, it makes the ultimate accurate measuring easier. Either at this time or later the different qualities are more exactly separated, none but faultless pods, without scar or defect in curing, being allowed in the first quality. The rest rank as seconds, etc. The split pods and the pods that have been cut on account of mould are also kept distinct. It is well to keep a crop at least three or four months before marketing. By that time nearly all shaly pods that are liable to mould will have shown themselves. All are then measured and tied up in neat bundles of 50 pods each of even length, the pods varying in length not more than one-eighth of an inch.

The general sightliness of a marketed crop has much influence on the price it will bring, and whatever whims buyers get into their heads the producer must conform to or suffer in pocket. Bundle tying is something of an art, and a deft hand at it is valuable. Sixteen or thereabouts of the shapeliest pods in each 50 are selected for the outside; the rest are tied up as a core, being kept in position by a few turns of the fibre-tying cord, while the chosen sixteen are carefully placed round them. The bundle is tied in either three places, near each end and in the middle, or in two places, an inch or more from the ends, according to the length of bundle. The core-holding string is pulled out before the final tie is fixed. Two-tie packets are boxed as they are. With those of three ties buyers prefer that the end cords be removed before packing, to enable them to examine the bundles inside and see if the contents are of uniform quality. If kept tied some time before being packed the bundles set, as it were and retain their neat shape. The tin boxes used here for packing vanilla in measure 12½ by 8½ inches in width, are 4½ inches deep, and hold about 12 pounds. Each box has a label pasted on it which bears the growers trade mark, the length and number of packets, their quality, and net weight, and a similar label is put inside. As some chemical action is set up when vanilla rests in contact with tin or iron, thin vegetable parchment paper is placed in the boxes to keep the two apart. The lids are then sealed close with pasted paper and the tins packed in wooden cases, six in each, and thus dispatched to market.—*Agricultural News.*

VANILLA.

The fruit of the *Vanilla planifolia* Andr. does not give out the characteristic odour of vanilla when freshly gathered; and it is only after the subsequent preparations that this odour is gradually developed. While writing a work on this subject for Planters in the French colonies M. Henri Lecomte found that this preparation which gives very variable results, is purely empirical; and he was induced to study the conditions under which vanilla is produced. The following particulars are taken from his notes on the subject communicated to the Paris Academy of Science by M. Guignard. At the outset M. Lecomte discovered, in the various parts of the vanilla plant, the constant presence of an oxidising ferment similar to those studied by M. G. Bertrand, and which are now known by the general denomination of "oxydases," their presence being noticed in the stalks and leaves of the plant, the liquid extracted from them, the green and ripe fruit, and also the prepared vanilla from Mexico, La Réunion, the Seychelles, and the Comores.

Strangely enough, while the most esteemed vanillas of commerce contain the oxydases in considerable proportion, those of inferior quality do not contain them at all, or only to a very slight extent. The

presence of manganese, which M. Bertrand regards as the vehicle of the oxygen, was noticed in all the matters at the author's disposal.

The above observations led to the belief that the oxydases contained in the fruit of the vanilla must play an important part in the preparation of the essence itself; but an apparently serious objection may be opposed to this supposition. In the method of preparation now adopted at La Réunion, the first operation to which the fruit is subjected consists in immersing it for about twenty seconds in water kept at the temperature of 80 to 85 degrees Centigrade. Now at this temperature the oxydases might be supposed to lose their characteristic property but experiments, repeated several times, showed that the interior of the fruit, immersed in boiling water for thirty seconds, did not acquire, after such immersion, a temperature higher than 55 degrees Centigrade. Now, in practice, whole basketsful of the fruit are immersed in hot water, which does not attain boiling point, but at most 85 degrees Centigrade while the immersion only lasts for twenty instead of thirty seconds. It may therefore be concluded that the temperature inside the fruit never attains 50 degrees Centigrade, and that under these conditions, not only is the oxydase not altered but that on the contrary the temperature it acquires is that which is very favourable to preservation of the essential properties.

There remained to determine the nature of the substances capable of being transformed into vanilla, under the influence of the oxidising agent. Following up this investigation, Mr. Lecomte found that the juice extracted from the vanilla plant contains another ferment possessing the property of hydrating the starch and which, acting on a solution of coniferine, promotes the formation of a substance possessing the same reactions as that the constant presence of which was noticed in the tissues of the vanilla plant. The simultaneous presence of two distinct ferments, one hydrating and the other oxidising, the existence of which appears intimately connected with the production of vanilline was, therefore, noticed in the vanilla plant.

In fact, having selected two similar specimens, A and B, of ripe fruit, forwarded in spirit from La Réunion, the author proceeded to prepare them by boiling. Specimen A was first raised to a temperature of 100 degrees Centigrade for ten minutes, while B was not subjected to this operation, the two specimens being otherwise prepared in the same manner and in the same space of time. Specimen A became soft, and only gave out a scarcely perceptible odour of vanilla; but B on the contrary assumed the characteristic odour of vanilla, while having become partially covered, after a few days, with small crystals, which were easily recognised as those of vanilline.

By way of conclusion, the following hypothesis may be ventured as to the formation of vanilline in the fruit during its preparation:—The hydrating ferment may be supposed to transform the nascent coniferine into coniferic alcohol and glucose, the presence of which latter substance is indeed constant in vanilla; and moreover, the coniferic alcohol is probably transformed into vanilline by the action of the oxydase.—*Journal of the Society of Arts.*

THE CACAO FUNGUS.

By ALBERT HOWARD, B.A.; A.R.C.S., F.L.S.,

Mycologist to the Imperial Department of Agriculture for the West Indies, late Scholar of St. John's College, Cambridge.

The Fungus found on the pods and branches of the cacao tree agrees, as far as the characters of the pycnidia and spores go, exactly with the form described above on the sugar-cane. In the case of the pods the

pycnidia are often formed singly just under the epidermis, and the latter is ruptured by the growth of these structures. In diseased branches, or on the trunk of the tree, the pycnidia occur usually in colonies just under the bark. The appearance of a branch attacked by the Fungus, which has been kept in a moist chamber a short time, is shown in Fig. 10, and a transverse section through one of the colonies is given in Fig. 11.

Some general indication of the appearance of cacao trees and pods apparently attacked by this Fungus may be of interest. It is quite common in Grenada to see cacao trees dying back to a slight extent at the extremities of the branches, a phenomenon probably due to poverty of soil, wind, drought, or defective root-action, or perhaps to a combination of these causes. In all such cases there is a sharp line of demarcation between the dead and living tissues, and although several Ascomycetes are to be found in the dead wood, they appear to be purely saprophytic in character. In many cases, however, dying back goes on to a very great extent, extending to the larger branches and the trunk, and, in spite of the production of suckers at the base, the trees are often killed outright. In such cases there is no boundary line between dead and living tissues, but an intermediate zone, often as much as two feet in length, always occurs between the obviously dead and living tissue. Mycelium can be easily detected in the young wood in this transition region, and the pycnidia referred to above are to be found under the bark. The mycelium can be detected in the wood at some distance in advance of the point at which it seems to end in the bark, a point which seems to indicate the saprophytic origin of the Fungus. The mycelium makes its way in the wood from element to element by means of the pits in the walls of the vessels and cells, and where the hyphae have commenced to darken in colour this point can be determined without staining (Fig. 12).

In cases where pods are apparently attacked by the Fungus this is very common near the 'breaking-grounds,' where the 'beans' are extracted by the pickers, and where it is the custom to leave the empty husks on the ground in heaps. The husks speedily become covered with the spores of the Fungus, as this form lives on them as a saprophyte. The rind of the pod turns brown and mycelium soon spreads to the macilage surrounding the seeds completely destroying the pod and its contents, usually in from six to ten days. The diseased areas commence as a brown spot, as a general rule either at the free end of the pod, or in the groove round the insertion of the stalk, or at the point where the pod comes in contact with the branch. These places are those which are liable to be moist long after the rest of the pod is dry, and indicate the probability that infection may here be effected by spores without any previous wounding.

The artificial cultivation of the Fungus was carried out in an exactly similar manner to that employed in the case of the sugar-cane Fungus described above and as far as possible similar cultures of the two forms were made and examined at the same time.

Stages in the germination of the spore are shown in Fig. 13. The germ-tube grows out into a long hypha, at first slowly, but afterwards much more rapidly, and extensive branching eventually takes place. Septation of the hyphae was not noted before twenty hours after sowing, and after two days fusions of the hyphae were common: about the same time the mycelium commenced to grow down towards the water on the floor of the moist chamber, reaching it four days after sowing (Fig. 7). When three days old the mycelium gradually changed colour, passing through various shades from light yellow to olive green, and at the same time the hyphal contents began to aggregate in certain portions of the mycelium, leaving the rest empty. Oil drops also made their appearance. The appearance of the mycelium, when eight days old, closely resembles

that shown in Fig. 8. No further development was noted in hanging-drops, except that the thickwalled oil containing hyphae became dark brown three weeks after sowing, and appeared identical with the old mycelium described above in the case of the cane Fungus. As in the sugar-cane Fungus, advantage was taken of the aerial development of mycelium in single-spore hanging-drops to prepare cultures free from Bacteria.

In plate-cultures in the cane extract medium a copious development of greyish mycelium was obtained on the third day, which formed a dense velvety pile, a quarter of an inch in height, on the surface of the gelatine, and in which dark bodies could be detected with the naked eye. When examined on the sixth day these dark bodies were found to be pycnidia in which paraphyses and spore formation could be detected, after the manner indicated in Fig. 9.

On sterilized cacao and oak-wood small dark bodies were noted in nine days, and these when twenty days old proved to be the pycnidia of the Fungus.

It will be seen therefore that the development, under artificial conditions, of the Fungus of the cacao tree corresponds exactly in all its details with that found on the sugar-cane, so that morphologically regarded the two forms are identical.

It was now necessary to perform infection-experiments on cacao trees and pods, with pure cultivations of the Fungus.

These were as follows:—

1. On cacao pods:—

(a) Two nearly ripe pods were selected for the experiment, and were washed with alcoholic corrosive sublimate, and at the points where incisions were to be made small cavities were made in the rind by lifting the surface and cutting out a small portion of the tissues underneath. Into one of these chambers actively growing mycelium, three days old and from a pure culture, was introduced and the pod was bound up with budding-tape. The other pod was treated in a similar way, except that no mycelium was introduced and thus served as a control. Five days afterwards, about a quarter of the surface of the infected pod had turned brown, and in eight days after infection the whole of the surface was deep brown, and there was a considerable development of pycnidia for some distance round the point of infection. The protrusion of the spores as a greyish 'tendrils', visible to the naked eye, from the ostiole of the pycnidium, and their gradual darkening were beautifully shown on this pod. Near the point of infection the spores were visible as a black dust on the surface of the pod, and in most cases the 'tendrils' had broken down into their constituent spores, each showing the transverse wall and the dark-brown colouration under the microscope. Further away the colour of the spores became lighter and 'tendrils' were more numerous. These were composed of spores loosely cemented together, in which the transverse wall had not yet appeared. The control pod in this experiment showed no infection.

(b) The above preliminary experiment was repeated and in this case two nearly ripe pods were infected with mycelium, and a third was used as a control. Distinct infection took place in three days while the control gave negative results.

(c) Next, for half-grown pods were selected for experiment, in order to determine whether the spread of the Fungus is as rapid here as in nearly ripe pods. In each case small cavities were made in the rind, and in the first pod ripe spores from the infected pod in experiment (a) above were placed in the cavity. In the second pod a portion of the rind containing growing mycelium from the infected pod (a) above was introduced, and in the third pod actively growing mycelium from a pure culture was used for infection. The fourth pod served as a control. Seven days afterwards distinct infection was noted in the first pod, the rind having turned brown about a quarter of an inch all round the cavity, and

in the discoloured tissue mycelium was extremely abundant. In the second pod infection had proceeded further, about one square inch of the surface being attacked. In the third pod about six square inches of the surface was decayed, and it was found that the mycelium had penetrated to the mucilage surrounding the seeds and had completely invaded the interior of the pod. Numerous pycnidia were observed under the epidermis near the point of infection. The control pod gave negative results. This experiment is of some interest as it throws light on the steps by which a saprophytic form may gradually become parasitic, and confirms previous observations on the influence of a nutritious food-material in increasing the activity of a Fungus.

(d) Next, a preliminary experiment was performed on two nearly ripe cacao-pods, in order to determine whether infection could be produced by spores without previously wounding the rind. A drop of sterile water containing spores was placed on the surface of the pod, and was covered by a small glass cell which was sealed on to the rind by means of a tuding wax. The cell was covered with a dark bandage to shield the spores from direct sunlight. Seven days afterwards the spores had developed a mycelium on the pod, but penetration of the intact rind by mycelium was not noted in either case. Unfortunately time did not permit of carrying out further experiments to settle this point definitely; but a consideration of natural infections seems to indicate that pods at any rate are capable of being infected by germinating spores directly. If this were not the case it is difficult to explain why infection almost always begins at those points on the pod which are moist for the longest time, viz. the free end of the pod, the groove at the insertion of the stalk, and the place where pods come in contact with the branches.

2. On the cacao trees:—

In the infection-experiments performed on the cacao tree itself, a small portion of the outer dry bark was carefully removed and the exposed bast washed with sterile water. A small chamber was made by taking the bark and cutting out a small portion of the bast down to the cambium. After introducing the infecting material, the bark of this chamber was depressed and the whole covered with a water-tight bandage of budding-tape. The control plants were treated in the same way, except that no mycelium or spores were purposely introduced into the cavity.

(a) Two branches of a healthy cacao tree were selected for the preliminary experiment. In one cavity actively growing mycelium in the cane-extract medium was introduced, while the other branch was used as a control. Eight days after infection the Fungus had killed the bast up to about eight inches above and below the chamber, at which point the branch was nearly ringed. The mycelium could be traced more than a foot above and below the chamber, both in the bast and in the wood, and to a considerable depth in the latter. Numerous pycnidia were developed under the attacked bark, some of which were liberating their spores. The control showed no infection.

(b) Eight healthy cacao plants about eight months old, growing in bamboo pots, were next selected for an experiment. Nos. 1 and 2 were infected with spores taken from a pod attacked by the Fungus, 3 and 4 with portions of the diseased rind of a pod containing actively growing mycelium, 4 and 5 with vigorous mycelium from a pure culture in cane extract and 7 and 8 were control plants. After binding up the wounds the plants were placed in the shade and watered daily. Eight days afterwards it was found that infection had taken place in all the plants from 1 to 6, while the control plants showed no infection. There was scarcely any difference in the amount of infection when spores or diseased cacao-pod rind were used, except that plant No. 1 was killed outright by the Fungus. When culture-mycelium was used

infection was more extensive, one of the plants being killed while the other was evidently dying. In each case (5 and 6) pycnidia were formed under the rind.

(c) Four vigorous young trees about eighteen months old were now selected. The first was used as a control, the second was infected with spores, the third with a portion of a diseased pod taken from near the still healthy tissue, and the fourth with pure culture-mycelium. Eight days afterwards distinct infection was noted in No 2, while in Nos. 3 and 4 the trees were nearly ringed near the infection chamber, and the mycelium could be traced in the bast and wood as far as six inches above and below this point. Pycnidia were noted under the bark near the chamber. The control tree showed no infection.

(d) Attempts to induce infection by spores growing in water on the bark, in a manner similar to that used in experiment 1 (b) above, failed. The spores germinated, but I could not detect any penetration of the living tissues by the hyphae.

These infection-experiments show that the Fungus can behave as a parasite towards cacao pods, and is a dangerous wound-parasite of the cacao tree itself. The nature of one of the tree diseases in Grenada, and of an important pod-disease, is therefore placed beyond doubt.

CULTURE OF THE PASSION VINE.

MR. G. ALBERTON, jun., writes:—"Would you kindly give me information re culture of passion vines and your opinion on prospects of growing same in a soil growing blackhuts, redgum, and stringybark. The soil in one part is composed of from one to two feet in depth of sandy loam, and in others, it is more of a sandy reddish clay. The latter is the heavier and moisture soil, but I fancy the other, because the situation is higher and the aspect is easterly. I propose to raise the passion vine from seeds sown in a seed-bed in spring, and transplanting to rows of, say 10 feet x 12 feet. Is this distance correct, and would it be best to trellis fence fashion, which would mean hand-hoeing all between the plants one way, or could I use trellises high enough for horse-work each way?"

I also intend to grow tomatoes between rows while vines are small. I mention this, as a market gardener told me he would not grow tomatoes on his farm, as the land will grow nothing after them.

Would you advise pruning passion vines each year, say, leaving a main leader to top rail of trellis, and pruning all laterals back to same each year (between growths)?

Would Jordan almonds bear in this district? The elevation is about 500 or 600 feet, and nearly free from frost?"

In reply, the Fruit Expert, Mr. W. J. Allen, expresses the opinion that the sandy loam referred to should grow good passion fruit, provided the frosts are not too severe. The vines would not do so well on the more clayey red soil. If it were a red sandy loam they would probably do well, but generally speaking, they do not do well when planted in heavy soil. Ten feet by 12 feet apart is as close as passion vines should be planted in rich ground, and they are better a little further apart. The best form of trellis is one of posts and wire, with a post between every second vine projecting 5 feet out of the ground; on the top of the posts are fastened two wires about 6 or 8 inches apart, the vine to be trained up a stick or small pole until it reaches the wires, then trained along the latter. Mr. Allen would not recommend a higher trellis than 5 feet. A good man with a horse and cultivator can work nearly all the ground without having to do much handwork. Mr. Allen would not advise growing anything between the vines unless manure is applied liberally, as, if the plantation is expected to pay, the ground must not be robbed of its best properties by rapidly maturing crops before the

vines themselves have come into bearing. It would be a great advantage to the vines if it were possible to lime the ground before planting. The dressing in the case of soil indicated should be at the rate of not more than one ton per acre.—*Agricultural Gazette of N. S. Wales*

PLANTING NOTES.

INSECT TORMENTORS OF HORSES.—The *Chasseur illustré* says that a decoction of 1 part of stramonium leaves to 3 parts of water, boiled for 20 minutes and applied, when cool, to the face, about the ears, inside the legs, about the belly and croup, is sufficient to keep a horse free from its insect tormentors during a whole day. Stramonium is said to be much efficacious when thus used than tobacco.—*Queensland Agricultural Journal*.

THE CURE OF SNAKE-BITE.—In an article recently published on the prevention of deaths from snake-bites, M. Henri de Parville cites several well-authenticated cases in which the anti-venomous serum of Dr. Calmette, head of the Pasteur Institute at Lille, has been the means of saving life. Dr. Calmette, it may be remembered, was himself bitten on the hand by a cobra when experimenting in his laboratory a short time ago, and only escaped death by the application of the serum discovered by himself. A mining engineer, in a letter to the writer from Australia, also relates how he was bitten in October by a deadly serpent, and an hour afterwards was fast losing consciousness, when the timely intervention of Dr. Calmette's antidote brought him back to life. But the most striking testimony to the value of the French professor's serum comes from India, where a woman recently bitten by a venomous snake of unusually large dimensions, and cured when she was at the point of death. To prepare the serum, the venom has to be procured from living serpents, and it was while engaged in this risky operation that Dr. Calmette came near losing his life. The Pasteur Institutes at Lille and Paris forward consignments of the saving serum to all countries in which venomous serpents are found.—*Australian Field*.

PRECAUTIONS TO BE TAKEN BY CONSUMERS OF VEGETABLES.—We (*La Revue Agricole de l' Ile Maurice*) think it will be useful to reproduce a paragraph inserted in the *Agriculture Moderne* relative to the treatment which raw vegetables should undergo before being eaten. The recommendations by Dr. Ceserole have all the more importance in hygiene, as market garden produce in the colonies is often treated with liquid manure. It has for a long time been known that intestinal worms are generally transmitted to us through the medium of vegetables. Dr. Ceserole, of Padua, has devoted careful study to the subject; he has examined the sediment of sterilised water in which various market vegetables had been washed, such as lettuce, endive, radish, celery, &c. The microscope revealed in this water the presence of fifty-two common species of fungi. But, besides these parasites, Dr. Ceserole found a number of microbes—notably, a bacillus analogous to that of typhoid fever, the septic bacillus, and the bacillus of tetanus. This infection of the vegetables is especially to be imputed to watering them with liquid manure. Great care has consequently to be exercised. Lately, Metchnikof, of the Pasteur Institute, has discovered that a certain number of parasites appeared to have their origin in intestinal worms. Dr. Ceserole recommends that, to avoid danger, the vegetables previously well washed should be plunged for half-an-hour into a 3 per cent. solution of tartaric acid, which has an agreeable flavour, is cheap, and of great antiseptic power.—*Queensland Agricultural Journal*.

AN EXTENSIVE APPLE ORCHARD.

A company composed of representative horticulturists in Iowa and Missouri has been organized with a capital stock of \$1,000,000, for the planting of what it is claimed is to be the largest orchard in the world. This orchard is to cover 5,000 acres of ground planted with 50 trees to the acre. The land for this experiment has been chosen in Laclede County, Missouri, about 150 miles southwest of St. Louis. This choice has been made because of the discovery that apples grown in this county have taken the first prize in competition with most of the other countries in the same State, which is peculiarly adapted both in soil and climate to the successful growth of fruit crops. About 100 acres of this land will be planted with trees next spring, and it is estimated that within six years the whole of the orchard will be bearing fruit. While the main object of the company is that of raising apples, many peach and other trees devoted to small fruit will be planted during the first years, in order to produce an early dividend upon the investment. The underlying principle of the company which is undertaking this work is that co-operation of a commercial character can be developed under the direction of men skilled in business and horticulture, and that if this assumption is correct, the venture can be made more profitable than is possible from individual investments in the same line, and that too the chances of loss incident to such investments when made in a small way are not so great. It is estimated that each of the 250,000 trees to be planted on this area will produce five bushels of apples thus making a total yield of 1,250,000 bushels, equivalent to about 500,000 barrels. It is expected that the bulk of this crop will be exported to Europe. During the fiscal year of 1901 the export of apples from the United States was 840,605 bushels, of which 794,660 were sent to the United Kingdom. As showing some of the methods to be adopted, a cold storage plant will be built in St. Louis as soon as this orchard has come into bearing. This will be the main shipping point and it is intended that the storage plant shall have a capacity for 150,000 bushels. Another interesting feature of the work is the announcement that the St. Louis and San Francisco Railroad has taken such an active interest in the plans of the company that it has agreed to construct a branch of about 3½ miles through the property. It will also build at frequent intervals along the line of this branch warehouses which, it is expected, will facilitate the prompt handling of the crop.—*London Times*, Oct. 4.

COCONUT PLANTING IN CEYLON:

SUCCESS IN DRY DISTRICTS: HOW TO GET APPROXIMATE AREA.

(By a Veteran.)

The number of coconut estates in the island that pay K100 an acre of profit may be counted on the fingers of your two hands. I was up in the Rajakadaluwa District two months ago, and an estate about a mile this side of Battuluoya, belonging to a native, just nearly made me envious. I never expected to see such bearing and such fine trees in a district with only 54 inches of rain—what I saw there and 15 miles

farther North on the road to Puttalam has caused me to modify considerably my views as to the bearing capabilities of the coconut palm incomparatively dry regions so long as the soil is free.

Although headmen's reports are not very reliable, they are the only means of knowing the acreage of the thousands of small gardens planted with coconuts in the different districts. It would be impossible for any European to get reliable information on this matter, and it would be only a very unreliable guess to try and form an estimate.

I am afraid you must be content with the information you can get through the different Kachebeis. [Until the Cadastral survey is closed.—*Ed. C.O.*]

RICE-CROP PROSPECTS, 1902-03, IN BURMAH.

The District Officers' reports on the rice-crop prospects on the 30th September 1902 in the 14 chief rice-producing districts of Lower Burma are to the following effect:—

Summary.—The estimated area under rice in the 14 principal rice-growing districts is reported to be 6,649,006 areas against 6,558,190 acres actually cultivated last year. Amherst reports on unexplained increase of 28,900 acres, and Pegu, Toungoo and Hanthawaddy report increases of over 10,000 acres. Floods have caused damage in Tharrawaddy and Thongwa and have caused a decrease in cultivation in Henzada. In Myaungya the fallow area is large owing to cattle disease and sickness among the cultivators, and in Prome owing to untimely rainfall. Otherwise prospects are bright.

THE TEA BUG OF ASSAM: IMPORTANT DISCOVERY BY MR. MANN.

CALCUTTA, Nov. 10, 7-55 a.m.

Mr. Mann, Scientific Adviser to the Planters, states that the Tea Bug in Assam is found from eggs onwards on the tea bushes and not in the ground.

THE STORY OF THE JAK TREE.

Mr. Garruthers' Lecture, the second one of the "Kandy Popular Lectures," was given at the Town Hall on Monday evening before a large and appreciative audience. The evening was fine, the lecturer in excellent form, the Chairman (Hon. Mr. H. Wace) jocular and the audience good-humoured. With these conditions combined "nobody could deny" that the lecture was a success. The lecturer (I cannot help calling him so) took pains to say his was not a "lecture." Of course, all knew only one, who rose to the heights of a "lecturer"—and that was, that grand old dame, Mrs. Caudle. As the Town Hall is devoid of mosquito curtains, the members of the male sex felt safe and happy that there was to be no "lecture." Mr. Garruthers said, he was going to treat us to "The Story of the Jak Tree." Delightful visions of dear old Hans Charles Andersen and Mrs. Prosser rose into our minds and we, indeed, got them reproduced in another form. The seed in its embryo state to the plant, the radicle, roots, stem and leaves and the flowers were described in a free and easy style. There was hardly anything of the technical. The lecture was illustrated by lantern slides from the "cradle" to plant-life. The drawings for the slides were stated to have been very good, but by the time they had to be shown they had

faded a good deal and were not very distinct on the screen. One especially when it came up, he described it heaving a deep sigh, as being in "the sere and yellow leaf." In his observations of tree and plan-life in the Gardens one bright moon-light while noting down, he of all people mistook a papaw tree for a cot on tree. You know, Sir, he is not the only one that has been moon struck. Many of us can freely confess to that experience once or more in their lives. It proves the truism, clearly, that the best of us after all is human.

The hour ran out much too fast and the worthy lecturer had reluctantly to close "The story of the Jak Tree." It was a good story.—Mr De Saram, the District Judge, moved a vote of thanks to the lecturer. It was judiciously delivered without one *if* or *but*, short and sweet. Mr Creleston seconded and announced that two reading circles had been formed. The audience as they got into the Hall were given a leaflet entitled "Notes for Students," being "an advance" introduction to the lecture which simplified it. It goes without saying that these educational efforts are due to the indefatigable exertions of the Honorary Secretary, Miss Gibbon. The next lecture will be "Charles Dickens." A good many are endeavouring to read up his life and works to be *en courrant* with the lecturer. The Secretary will, I am sure, be delighted to hear this piece of news. It will be next month and "may I be there to see."

CULTIVATION OF COTTON IN GERMAN COLONIES.

There is, says the *Hamburger Börsen Halle*, no doubt as to the value of cotton culture to the owner, as evidenced by the grand results of Russia in Turkistan, which will soon render the Russian cotton market completely independent of other countries. These results have drawn the attention of the leading circles in Germany to this branch of colonial economy. The endeavours of the Economic Committee of the German Colonial Society, regarding the production of cotton, are not to be limited to Togo, but Eastern Africa is also to benefit by them. Already the existence of indigenous cotton at Kilimatinde, Tanga, Wilhelmsthal, Mandra, Kissorawe, Kilwa, Kilossa, Bismarckburg, a primitive cotton-weaving establishment of the Wahunga, at Kilimatinde, at Rungwe-Urungu, and on the shore of the Tanganyika, does away with the doubt of the possibility of producing cotton in East Africa. A tabulated statement by Dr. Hans Maurer shows that the climatic circumstances and the amounts of the yearly rainfalls do not vary essentially from the quantity of rainfall in the cotton-producing districts in the North America. The cotton enterprise in East Africa is to be placed at once on a broad basis by founding a teaching institution, and by the settlement of American cotton farmers. The managers are instructed to concert proper measures for procuring the necessary means, so as to secure the undertaking for at least two years. The Government of German East Africa, a number of cotton-spinning associations and industrialists, have already granted financial help to the undertaking. North-American negroes from the Normal and Industrial Institution at Tuskegee are to be engaged for East Africa.—*London Chamber of Commerce Journal*, October.

THE INDIAN ACACIAS.

India can lay claim on only twenty species, which are distributed throughout the plains, two

species reaching an altitude of 5,000 feet above sea-level. But of these twenty species, three are of considerable commercial importance, viz., *A. arabica*, *A. catechu* and *A. senegal*; the remainder being more or less of ornamental character. A few foreign species have become completely naturalised in India, such as *A. dealbata*, the Australian Silver Wattle, and *A. melanoxylon*, the Australian Black-wood. These latter are now found plentifully in the warm temperate tracts of India, especially in the Nilgiri Hills of South India, where they are introduced so far back as 1840. *A. concinna*: The first species noticed is a scanty bush met with all over India, the pods of which are used as a detergent and often confounded with the soap nut (*Sapindus mukorossi*.) The bark is used in tanning, but its chief commercial value lies in its pods, which are largely imported into Bombay from Kanara. The pods are also largely employed in washing silk and woollen goods, as the best tinctorial results are obtained when yarn is washed with these pods previous to dying. Tarnished silver-plate washed with these pods attains great brilliancy. *A. Farnesiana* yields the well known "Cassie Flower" of perfumers. "Cassie Pomade" made in India at one time had a great reputation. It was prepared by an Anglo-Indian Engineer of Naini Tal who used to send supplies of it to London. After his death the trade in Indian Cassie Pomade died out. Mr. Umney, of Layman and Umney, considered the produce from Cassie Flowers grown in India, superior to that grown in Grasse, in France. However, the possibilities of a trade in Cassie Flowers are present, for the tree abounds in India; but it wants some one with enterprise to develop it. *Jacquemontii* is another valuable shrub, distributed throughout India, up to an altitude of 3,000 feet. It bears sweet-scented flowers, and its chief product is a gum, which is recognised as one of the serious gum arabics, which comes chiefly from Baluchistan and Sind. Messrs. Rowntree and Co., Ltd., of York, have pronounced the gum of this species as "the best of the series of Indian gums examined by them for the confectioners' requirements." It is described as strongly mucilaginous and sweet in flavour. *A. leucophlea* is another Indian species of some economic value; it is found all over the Punjab Rajputana, Central and South India and Burma. Its presence is held to denote a rich soil. It yields a gum of some commercial value, the bark affords a strange fibre, and is used largely as an astringent in alcoholic distillation by natives, and is therefore called the 'Distiller's Acacia.' We next come to *A. modesta*, the well-known 'Phulai' of the Punjab plains. It yields a good gum classed by Bombay merchants as 'Amritsar Gum;' and a beautiful, strong, durable timber, largely used for agricultural implements. *A. pennata* is a climbing shrub, met with in the sub-Himalaya region, East Bengal, South India and Burma. Its bark is a commercial product used to tan fishing nets in Bombay. *A. senegal* met with chiefly in Rajputana and Sind yields the true Gum Arabic of European commerce, the *verek* of the Negroes, and comes chiefly from the French Colony of Senegal. A very full account is given in the *Ledger* before us of the produce of this tree, and its commercial value. *A. Arabica* is the tree which yields the true Indian gum arabic, found over the greater part of India, and known as the *Kikal* or *Babul* tree. There are several varieties of this species, or rather, we

should say, several forms of it. It is the most important of all the Indian Acacias from the economic point of view. *Acacia catechu* is the tree that yields the well-known "kutch" or "kath" of India. In addition, it yields a very good gum and a hard, durable timber.—*Indian Gardening and Planting*, Oct. 9.

IRRIGATED COFFEE.

(To the Editor *Madras Mail*.)

Sir,—Will you kindly publish a recent experience of mine in regard to my Irrigation Coffee? I have a plot of four acres which has special facilities for irrigation during the hot months. A portion of my oldest trees (7 years) are planted there. They have given me four crops, including the present, and the last crop was 22 cwt out of these four acres. The plants did not suffer to any extent. On the contrary, they put on fine wood for this year, but I was rather disappointed with the existing crop,—I commenced picking in August—which I do not estimate at more than 7 or 8 cwt for the whole plot. To my very agreeable surprise, I find now that the plants are throwing out "spike," mostly in a "forward" condition, and in a fortnight or so I expect them to blossom; and this means that in May and June I shall have another crop, which, judging from the vigorous condition of the spike, must be rather abundant. One of the principal objections raised against coffee grown under irrigation is that the plants get no rest as in the Mulnaad, but the admirable condition of my plants, which are giving a fourth crop and are preparing for the fifth, shows that properly irrigated and well-manured, the plants take care of themselves, and take rest only when necessary.—C. MEENACSHAYA, Gowripuram.

THE FIBRE INDUSTRY.

Sir,—Mr. V T Vencataram Iyer, of Valavanur South Arcot, has done a great public service by publishing the results of his valuable experiment into the plantain-tree fibre, thereby drawing public attention to an industry which may prove a blessing to India where these trees are grown very largely, and he deserves the thanks of every well-wisher of India. Now that he has satisfied himself of the highly remunerative character of the fibre, I beg to make a suggestion to him, which, whilst conferring a great benefit upon the landlords who grow these fruit trees on a large scale in Southern India, may prove highly advantageous to himself. In Tanjore and Trichinopoly Districts, to my personal knowledge, these trees are grown largely. If he could practically instruct in person, or by an agent, some of these landlords, in the method of extracting the fibre, and arrange with them the sale to himself of the fibre, he could, while putting some money into their pockets for what hitherto had been a valueless article, gradually develop for himself an export trade, which might eventually grow into gigantic proportions. If there were many gentlemen amongst us who possess the same practical turn of mind as Mr. V. Iyer, such a suggestion would be needless, but our men are mere theorists carping, criticising and complaining, without any earnestness for making practical efforts.

Whilst on this subject, I take the liberty of suggesting another fibre of much greater value than plantain fibre, which could be extracted from pine-apple plants. These might be grown in a plantain-garden so that both these valuable

products could be had out of the same plantation. A very interesting and instructive letter on pine-apple fibre was published in the *Madras Mail* of the 24th June, 1901, and if Mr. V. Iyer cannot readily lay hands on this letter, I shall be most happy to send it to him. The process of extracting that fibre, adopted in Japan and the Philippines, as I learnt from Dr. Watts, is likewise simple.

C. MEENACSHAYA.

Gowripooram.

COCONUT BEETLE IN THE STRAITS.

The following resolution was proposed by Mr. E V Cary and seconded by Mr. C R Meikle:—"That in view of the alarming spread of the coconut beetle pest the Government be asked to appoint a special European Inspector in each State, whose duty it shall be to see that the provisions of Enactment V. of 1898 are strictly enforced. "That, in the opinion of this Association, it is essential that all trees which have been badly attacked shall be deemed to be 'beyond recovery' and forthwith uprooted, split up and burned, unless the owner can satisfy the Inspector that such trees have been regularly attended to in the past and are at the time of inspection free of beetle. "That for a second offence no excuse shall be accepted by the Inspector. That the burying of uprooted trees should not under any circumstances be allowed, the Enactment being amended, if necessary, to provide against this. That the Inspector should pay special attention to the enforcement of section 6 of the Enactment with respect to the breeding places of beetles. That all other palms which are infested by the coconut beetle shall be deemed to be 'breeding places' within the meaning of the Enactment and dealt with accordingly." It was agreed to alter the draft resolution and to insert the word European before Inspector. The Chairman said he was in opposition to state that the High Commissioner had interested himself in the matter and it was satisfactory to know that we had his sympathy. As regards the breeding places of the beetle he considered that all rubbish heaps, serdang, and sago trees where the beetles are known to breed should be treated as such, and that uprooted trees should on no account be buried. There seemed to be no complaint of beetle in either Negri Sembilan or Perak, and he thought that when the Enactment was properly carried out Selangor would also be free from them. Mr. Meikle said that he concurred entirely with what the Chairman had said, but if the matter was not taken in hand at once he was afraid that coconut cultivation would be impossible. He went over an estate a few days previously which was covered with dead serdang and other palms in which the beetle breeds, but the coconut trees showed no signs whatever of being attacked, proving that if the pest is taken in hand at once there need be no fear of the beetle attacks becoming dangerous.—*United Planters' Association F. M. S.*

GRAVE CHARGE AGAINST A MANURE MERCHANT.

Mr. A J Forest, chemical merchant, carrying on business in Brussels, was charged at the Mansion House Police-court, yesterday with obtaining large sums of money under false pretences from Mr. Henry Hollingshurst, chemical merchant, of 127, Fenchurch-street, in connection with the purchase of quantities of basic slag used as a fertiliser or manure.—Mr. Cranstoun, barrister, who prosecuted, said that Mr. Hollingshurst had entered into contracts with the defendant for the purchase of hundreds of tons of basic

slag, the stipulation being that the slag should contain from 38 to 45 per cent. phosphate of lime. Cargoes which were sent over from Brussels were subsequently re-sold by the complainant to customers in Ireland. There was an arrangement between the complainant and the defendant, under the terms of which 75 per cent. of the purchase money was to be paid on the analyst, by Dr. Dyer, a well-known analyst, of the sample of the cargo, and the balance on delivery. The allegations were that, whereas the samples submitted to Dr. Dyer contain the full proportion of phosphate of lime, on the faith of which the complainant made payment, the bulk of the cargo contained in some cases merely 7 to 8 per cent. of phosphate, and was practically useless, being, said counsel, little better than ground brick-dust. The customers of the prosecutor in Ireland were naturally furious when discovery was made with regard to the quality of the slag, and demanded back the money which they had paid, and in the result the prosecutor had necessarily sustained considerable monetary loss.—The prosecutor stated in evidence that he had paid the defendant in respect of slag over £1,900. Samples of cargoes showed a deficiency in one case of 20 per cent. phosphate of lime, and that it was quite unmerchantable. In round figures he was about £5,000 to the bad over the business. The case was adjourned, the defendant being admitted to bail.—*Globe*, Sept. 27.

COFFEE PLANTING IN SOUTHERN INDIA.

Nelliampatty Hills, Palghal, P.O. S.I.

You will probably be surprised to hear from me and will perhaps not remember me even when you see my name. I left the College in the spring of '94, and came out to India shortly after. As I believe a good many fellows go to India from the College, perhaps some of my remarks may be of use, and I shall certainly be very glad if they are.

I have been coffee-planting ever since I came out, and am not doing altogether badly as things go, but from want of capital have not been able to do as much as I should have liked. No fellow ought to come out here with anything under £1,800 if he wants to do anything in coffee, as superintendents' billets are hard to get, and there are already plenty of men in the country ready to jump at any place there is going. The best way for a fellow who has a little money, is to get a share in a young estate, not all opened, and try to get the superintendence or management of that. It is a mistake to put in money where there is much old coffee, as with prices in their present high condition not many men are inclined to part with it (unless there is something pretty far wrong).

The life of a coffee-planter is, generally speaking, very interesting and jolly, but of course not all beer and skittles; plenty of hard work, both in the field and in the office, and many fellows have to give up on account of fever, which is to be found in all coffee districts with very few (if any) exceptions.

As to kit, a fellow can bring out his ordinary English clothes and not go wrong, and it should be remembered that a few things can be obtained

in India. Clothes can be copied splendidly by native tailors if good patterns are brought out, and it is a mistake for a fellow to buy a huge kit "expressly made for India," the greater part of which he will probably find useless to him. I speak from my own experience. If a fellow intends going in for shikar or big game, he cannot do better than the following battery if he has money to dispose of: *i.e.*, one double-barrelled 8-bore for all thick-skinned beasts like elephants, bison, etc., one double-barrelled 450 express and one double 12 bore shot and ball gun. That is the most serviceable battery that can be had. I speak from my own experience there too, having had some with every variety of game there is in Southern India. If a man has only a moderate amount of money to expend on guns, he will find a 12-bore paradox the most useful. . . .
—*Empire Review*, Oct. A. G. M.

COFFEE IN BRAZIL

A telegram to *O Paiz* from Miracema states that the drought has ruined the coming coffee crop in the State of Rio, that had providentially escaped the frost and that great misery prevails. Since then it has been raining hard for several days, so we suppose telegrams will be received to the effect that the little flower left from the frost and drought has been finally washed away by the floods and that there will be no crop at all. Then, we suppose, everyone would be starving but happy.—*B. Review*, Oct. 1.

RUBBER: A GOOD STORY.

He is a bold man who attempts to predict the price of rubber a few weeks ahead. A friend of ours, some eight weeks ago, offered to bet a new hat that the price of "Para" would go up to 3s. 6d. before the end of November. We like to bet on certainties, and as this was not one, we did not accept his kind offer. He followed his opinions in good time and bought largely for his firm. May we be pardoned for saying that he is one of the few rubber men at the present time going about with an obvious smile and a whole-hearted contentedness delightful to witness. At the time of writing the price is still below his prophecy but he has still ten weeks or so to run. Let us hope he will still be chuckling at the end of that period. Some funny stories are told of how forecasts of the rubber markets are arrived at. We don't mean by this that the arduous study of its rise and fall is treated by any of the buyers with levity, but still on a matter which oftentimes defies the most careful calculations outside influences sometimes creep in. Perhaps the yarn is not new to some of our readers, but to most it will be. A buyer of rubber had wearied his brains out one evening late in December of 1901 in his attempt to come to a decision as to his purchase next day. He could not afford to let the matter stand over until the next sale. He went to bed late and for a while he could not sleep. When he did fall over he dreamed that he went into a shop where they sold rubber done up in packets like tea. He asked the shopman (who by the way resembled one of our best known brokers) for a pound and when he got it he laid down three shillings and one sixpence. Before the shopman could handle the money the sixpence went a missing mysteriously. After hunting for a time the shopman gave it up

with the words "It's lost for ever." When the buyer awoke next morning the yarn goes on to say that he remembered the dream so vividly that he could not bring himself to buy at the sale—the price being then just about 3s 6d, with an apparently rising market. The point of the story lies in the fact that within a fortnight the price had gone down to 3s 3d and within the month it had sunk to 3s. So if he had bought before his sixpence would have been "lost for ever." Such a dream may be merely a coincidence, but when it occurs it is apt to puzzle the man to account for it. The buyer in question has, we believe, never been visited again by such a truthful dream, nor had the subject of rubber even been prominent during his fleet before, nor has it been since. Any of the gentlemen engaged in the same occupation who have experienced similar "portents" are invited to let us hear them.—*SNAKE-BITES AND THEIR REMEDY*, *Snake-rubber Trades' Journal*, Sept. 15,

SNAKE BITES AND THEIR REMEDY.

Now that anti-venene is generally employed as a remedy for snake-bite in India, it may interest the public to know something of its methods of application. It should be premised that the effect of snake-bite depends on (1) the quantity of venom injected in relation to the weight of the human being or animal bitten; (2) whether the venom is injected into a blood vessel or into the tissues. If the fangs of the snake penetrated a blood-vessel and a sufficient amount of venom is injected into the circulation direct, the person or animal is doomed. In such a case there would be no time to use anti-venene or any other remedy, and death might take place in ten or fifteen minutes. Luckily cases of this kind are quite the exception. On the other hand, when the snake injects the venom into the tissues death does not occur for hours, and frequently no symptoms set in for hours, also. It is in these instances that anti-venene can be effectively employed. It has been demonstrated that the amount of venom which kills an animal of certain weight when given intra-venously takes from two to three hours to kill a similar animal of the same weight when given subcutaneously. The average time in which death takes place after cobra-bite is about eleven hours. The extremes vary from half-an-hour to twenty four hours; so in the great majority of cobra cases there is ample time to use the remedy. When the patient is seen in good time, and before the symptoms have become advanced, the treatment is by subcutaneous injection; if the dangerous stage seems to have been reached, it is best to inject direct into a vein. When given intra-venously, this antidote acts very quickly and patients can be saved at a stage of the poisoning when it is not possible to save them by the ordinary subcutaneous method. Anti-venene is now being prepared at the Pasteur Institute. Kasauli, and India should soon cease to be independent of Calmette's laboratory at Lille, whence it has mostly been obtained. While on this subject we may refer to some recent statements regarding bites from mad dogs or jackals, and the application of turpentine, ammonia, etc., to the wounds. Pure carbolic acid, phenyle, or the actual cautery are probably the best forms of local treatment. Other caustics and turpentine are also beneficial; but no form of local application can be thoroughly relied upon to prevent the subsequent onset of hydrophobia, unless the wounds are very super-

ficial and the caustic is immediately and most thoroughly applied. Cauterisation destroys some of the poison which the rabid animal implants in the wound, when the application is made within a few hours of the bite—some authorities even say up to twenty-four hours; but after twenty-four hours it is certainly useless. It is questionable whether it does any good after ten hours. In every case it is desirable to use cauterisation of some kind as early as possible; and if no application is available, the wound can always be thoroughly washed with water. The object aimed at is to get rid of as much of the poison from the wound as possible, either by applying caustic or by washing it out. By this means the incubation period is prolonged and time is gained for successful treatment at a Pasteur Institute.—*Pioneer*, Oct. 29.

AN AUXILIARY PRODUCT TO TEA.

(To the Editor of the *H. & C. Mail*.)

SIR,—At the last annual meeting of the Indian Tea Association I was glad to notice that Mr Robert Hart, who had for many years practical experience of tea planting and enjoys the reputation of being an authority on all that concerns tea, advised the planting out of an auxiliary product to tea, such as sisal fibre, grown from the "Sisalana Agave," and, better still, that he has the courage of his convictions, as I learn from good authority he has arranged for the necessary seedlings to plant out between six and seven hundred acres during the next three years.

This would serve as aid to the profitable working of tea concerns, not only by being in itself a valuable commercial product, but also by covering the cost of the obligatory employment of the whole labour force during the slackest part of the year, that is to say, the complete labour force in a garden is only required eight or nine months of the year, whilst the rest of the months a good half of the coolies are given employment in Sylhet, more with a view to their receiving living wages than for any direct benefit.

In planting out sisal on land belonging to a tea garden, the initial cost of the plants, and in three or for years' time the purchase of a fibre-extracting machine, would be the only items of prominent expenditure. The cost of planting should be small, as putting out from 700 to 1,000 plants per acre is all that is necessary. There would be the existing establishments, both European and native, engine and boiler, buildings, labour force, &c., to be further employed and used in the production of the fibre; the only direct chargeable items would be the actual pay of the coolies employed in planting out and upkeep of the plants. Besides the above advantages, land unsuitable for tea would be made productive under sisal. Belonging to most, if not all, tea estates such land is to be found. Also those parts of a garden planted with tea giving little, if any, remunerative results, would grow sisal to advantage. The benefits of planting out sisal as an aid to the prosperity of tea concerns should be great. The demand for fibre, such as the "Sisalana Agave" produces, according to all information obtained from reliable sources, promises well for some years to come, and even if with the natural increase of production, prices should fall, India, with its cheap labour, will always hold its own, certainly with all those countries which now produce it.

R. WOOD.

—*H. & C. Mail*, Oct. 10.

THE PEARLING INDUSTRY.

A most interesting report on the pearling industry by Mr. Justice Dashwood, the Government Resident of the North Territory, has been forwarded to the Acting Premier of the Commonwealth. In 1901 the pearl shell raised in the Torres Straits fisheries was valued at £105,403. The industry is carried on by coloured labour, white men being unable to stand the trying character of the life. The industry, it is said, will be practically killed by the White Australia policy.—*Commercial Intelligence*, Oct. 9.

CEYLON GAME PRESERVATION SOCIETY.

AND NILGIRI HARES.

Some time ago, the Nilgiri Game and Fish Preservation Association received a letter from the Fish and Game Preservation Association of Ceylon, asking that the Association might forward them fifty Nilgiri hares. The Association was then of opinion that there were not sufficient on the hills. They are now so plentiful and so great a nuisance to the native market gardeners that these men are everywhere seen, asking sportsmen to hunt them. I know a sportsman, says an Ooty correspondent, who has secured on putta land on an average two hares every time he was out, while the *Asian's* mighty porcupine-slayer, who has, the blessings of all Badaga cultivators, has, without the aid of firearms, accounted for no less than 55 porcupine, for the flesh of which he has constant applications. The greatest enemy of the hare is the jackal, and it is a pretty sight to see some three or four of these animals surrounding a hare and covering it down—especially on a moonlight night. Jackals are just now very plentiful in the nights near the Hobart Park, and are playing mischief with domestic poultry. Under the circumstances the Association might well give the Ceylon Association 500 not 50 hares.—*Indian Daily News*, Nov. 5.

QUININE AND ITS HISTORY.

The Cinchona trees were chiefly to be found upon the Eastern slopes of the Andes, and until the discovery of quinine the Peruvian bark of commerce was drawn in the main from this district, the finest quality, grown in the town of Loja, and known as Crown Bark, being long reserved for the Royal Family of Spain. Of course, the demands of Europe soon denuded the native forests of their trees, and led to the cultivation of Cinchona in other districts. The Dutch were the first to make the experiment of cultivating the plant in Java, where they met with much success, their example being followed by the Indian Government and by English residents in the East, with the result that for many years past there have been extensive plantations in the Neilgherry Hills, British Sikkim, Bombay, and British Burmah, while the growers of Ceylon have extensively planted it in Colombo.—W. N. Brown in *Journal of Horticultural*, Oct. 23.

* Not within 100 miles of Colombo which is by the seashore, but on the hills from 3,000 to 6,000 feet above sea-level.—Ed. T.A.

PASTURE:—GOOD INTEREST.

Mr. Alfred Tucker, secretary of the Totnes Union Chamber of Agriculture, writes to the *Western Morning News*:—In November last I applied on an eighth of an acre of pasture land after the rate of four hundredweight of kainit and two hundred-weight superphosphate an acre, and in the first week in April one hundred weight of nitrate of soda. The grass adjoining was unmanured. The grass was cut the middle of July and the hay carefully weighed, with the following results:—No manure, 27 cwt an acre; complete manure, 55 cwt an acre. I may add that the experiment was made on an old pasture field in good heart on clay and shale subsoil.—*Liverpool Echo*, 18th Aug. 1902.

ROCK SALT FOR STOCK.

Allow me through your paper to call the serious attention of all farmers, during this sadly wet and critical harvest, to the great importance of allowing all sheep and horned stock access constantly to as much rock salt as they will take, as well as a daily allowance of dry food. In the disastrous years of 1879-80, when I was farming largely for the late Duke of Bedford, I fully believe that many flocks of sheep that then perished with fluke and other liver rot would have been saved if these simple directions had been attended to.—H S Feaning in *Agricultural Gazette*. [Applicable to certain districts in Ceylon?—Ed. T.A.]

THE ORIGIN OF PEARLS.

From early classic times the question of how pearls were formed has been discussed, and various theories have been put forward to account for the occurrence of these gems in oysters and other molluscs. The identity of the material from which they are built up with that of the shell-substance has long been recognised, and among the causes suggested for their production may be enumerated concretions from the shell-forming fluid, perforation of, or other injury to, the shell, an aborted or displaced egg or a grain of sand, acting as a nucleus round which the shell-forming fluid accumulates, and, the action of a parasite, supposed to produce in the mollusc a result analogous to that caused in plants by the puncture of a gall-insect. Among those who have tried to produce pearls by artificial means, the most famous is Linnæus, who received from the Swedish Diet a reward of about £500 for his supposed discovery, which, however, turned out to be valueless. Nevertheless, it was, when first announced, rated so highly that it has been put forward by some writers as the reason why the great naturalist received the patent of nobility which is generally supposed to have been the reward for his services to Science. Dr H L Jamson, who has lately re-arranged the collection of pearl-bearing oysters in the British Museum (Natural History) has devoted a good deal of time and labour to the investigation of this matter and the results arrived at by him have just been published in the Proceedings of the Zoological Society. He has come to the conclusion that true pearls, which are found in the flesh substance of the oyster or mussel, are entirely due to the presence of a parasite. What he call 'blisters,' or secretions of pearly matter attached to the interior of the shell are produced by the deposit of naore or mother-of-pearl, in order to close an aperture, arising from injury, or to coat some irritating foreign substance introduced between the animal and its shell. Good examples of 'blisters' may be seen in the Natural History Museum in the small metal images of Buddha, inserted by the Chinese in the shell of a pearl-bearing, and coated with mother-of-pearl, and the same collection contains small fish and crabs similarly coated.

As Dr Jameson was unable to go again to the Southern Hemisphere (from which he had recently returned) to study the true pearl-oysters, he began his observations at Billers, in Morbihan, where there is a small, but somewhat noted, bed of pearl-bearing mussels. He was soon able to trace the formation of pearls in these molluscs to the larval form of a worm closely allied to the liver-fluke which infests sheep. The parasite which has been found on the inner surface of the shell makes its way into the flesh substance of the mussel, and then curls up and passes into a resting stage. Found it there is developed by the mussel a number of cells lining its resting-place, and these cells coalesce to form the pearl-sac in which the intruder is enveloped. In the ordinary course of events the larval worm becomes calcified in its prison, from the outer wall of which the pearl-substance is deposited layer on layer, and the growth of the pearl probably goes on at the same rate as the thickening of the shell. Dr Jameson has found that the larva may leave the sac, migrate in some other part of the body of its host, and there again settle down. This is evidenced by the fact that empty sacs have been met with in the body of the mussel. He was also successful in working out the life-history of the parasite, which, at Billers, migrates into the mussel from the tapestry shell, and at Piel, on the Lancashire coast, from the common cockle, these being in each case its first dwelling. The perfect stage, in which reproduction takes place, seems to be passed, at least at Morbihan, in the black scoter, one of the diving ducks widely distributed in the Northern Hemisphere, in which adult forms were discovered. The eggs expelled by the duck are probably carried into the tapestry shell, and there hatched out, the larvæ being carried out by the water to find their way into the mussels. At the Fish Hatchery at Piel, and at the Brighton Aquarium, Dr Jameson succeeded in artificially infesting mussels with the parasites and in producing small pearls. He is of opinion that the study of the parasites infesting the pearl-bearing oyster will throw light on the question of the artificial production of pearls. The life-history will probably correspond to that of the parasite infesting the pearl-bearing mussel. The first host will, no doubt, be some other mollusc found on the pearling-grounds, and the perfect stage will be reached in some of the file-fishes which feed on the pearl-oyster. Dr Jameson suggests that when these questions have been solved young pearl-oysters should be laid down in beds easily accessible, and with them the molluscs in which the parasite passes the first stages of its existence. In this way he thinks his investigations may be turned to economic account by inducing in the pearl-oyster the pathological condition which, as he has demonstrated, gives rise to pearls in the common mussel.—*Standard*, Aug. 28

THE PLANTAIN FIBRE INDUSTRY.

A good deal has been said and written of late years on the possibility of creating a plantain fibre industry in India, and it is interesting therefore to have the testimony of an intelligent Hindn landholder who has tried it. Mr V T Venkataraman Aiyar, of Valavanur, South Arcot, has placed at our disposal some practical notes on the subject which we cannot help thinking very valuable and instructive. In his experiments he has used the discarded stalks and sheaths of the common plantain, which are usually thrown away or burned after the fruit has been plucked. Samples of fibre extracted by him from these were sent three months ago to Messrs. Ide and Christie, the chief fibre-brokers of London, who valued them at prices ranging from £35 to £25 per ton. The following extract from Mr Venkataraman Aiyar's notes is particularly interesting:—

My experiments, the results whereof are more or less in accord with those reported to have been obtained in Kew Gardens, Jamaica, etc., show that an

average plantain stem cut for fruit would give about 1½ lb of the clean, lustrous, long stapled and commercially valuable fibre; and an adult with a week's experience can work about 8 stems a day, a boy being given to assist him in tearing the sheaths into longitudinal pieces of ½ inch width and in collecting the broken fibre and in drying, then and there in the sun, the fibres extracted. The adult's wages being put down at 4 as, and the boy's at 1½ as a day, we get 14 lb of fibre for 5½ as. (In other countries where plantain fibre industry is usually carried on, they get, it is said, over 2 lb a stem, but this I think is due to the dexterous experience in extracting the fibre with the help of "the cheap simple but effective contrivance"; and here too, after some experience I think the same results, if not more, can be had.) Even taking the outturn as per my experiment, and granting that special men are to be engaged for fibre-extracting work, the charges for extracting 1 ton of fibre from plantain stems as they are cut for fruits, amounts to R55 a ton; to this add R35 (this has been ascertained) for freight, traders' commission, insurance, etc., charges, and charges for bundling and pressing the fibre in bales, the total comes to R90. Even adding R10 to cover any extras, the charges to an agriculturist up to the stage of placing the fibres in the London market is R100. From Messrs Ide and Christie's quotations above given, even taking the value at only the lowest price, viz., £25 a ton, there is a net profit of 25 x 15 or R375—R100, or R275 for a ton of fibre. On an acre of plantain in these parts are grown about 1,200 stems; so the outturn per acre will be about a ton. Even taking this at only ½ a ton per acre, there is a clear additional income of R140 an acre; and as this means conversion into money of fruit-cut stems thrown away to rot on the ground, I venture to say it is opening a new source of agricultural wealth.

As regards the process of manufacture Mr Venkataraman Aiyar says:—

The cheap contrivance in use in the Philippine Islands is said to be the cheapest and most effective method yet invented. It consists of a small wooden plank and fixed to it is a blunt iron knife weighted with a lever under which the longitudinal strips of the plantain sheaths are drawn; this drawing process repeated twice or thrice separates the stalk and the juice from the sheaths and there remains in the hands of the operator a beautifully clean, long and lustrous fibre. This cheap contrivance can be made by a common blacksmith, locally for about a couple of rupees. I had one made to enable me to extract fibre for purposes of experiment.

At the same time, Mr Venkataraman Aiyar points out, that it is no use trying to start the industry on an acre or two of plants. The cost of extracting, cleaning, baling and transporting small quantities would be prohibitive, and he concludes that the only business-like plan is to plant considerable areas and to set up factories capable of dealing with the fibre in merchantable quantities. He himself wanted to buy from Government some 400 acres of waste land near his own village, for the purpose; but the land has since been auctioned to a number of persons, and he has been unable to carry out his purpose.—*M. Mail*, Oct. 21.

THE SILKY OAK—attains a height of 70 to 80 feet. The colour is a light grey, beautifully crossed with silvery waves, and when polished the surface has a delicate lustre. Bedroom suites made from this wood possess a dainty appearance.—*Commercial Intelligence*, Oct. 23. [This is the *Grevillea* so common in our planting districts: has any one in Ceylon utilised the timber for cabinet work and with what result?—ED, T.A.]

CACAO IN ST. LUCIA.

Mr Geo. S Hudson, the Agricultural Instructor, contributes the following interesting notes on cacao cultivation in St. Lucia:—The cacao crop promises fairly well. The first main crop pickings have already commenced, but the crop is a peculiar one. We have a small quantity of large ripening pods, and then an almost complete break in the crop, of a month or six weeks (corresponding with the very wet season experienced from May 24 to July 6), and then a large quantity of small pods, from July and August flowers, which will ripen mainly in December and January next. On the whole the crop promises somewhat better than it did this time last year.

MANURING CACAO.

At the September monthly meeting of the Soufrière Agricultural Society a useful paper was read by Mr Wm. M Smith, manager of Union Vale estate, on this subject, which it was decided to publish together with some notes by the writer on 'Artificial Manures for Cacao.' The concrete points argued in these papers are:—

1. That stable or pen manure is best preserved (for about three months) in a covered pit 4 feet deep, with a good layer of straw at the bottom to absorb moisture, and alternate layers of manure, straw and dry earth, watered daily with urine and stable washings collected in a receptacle from stables floored with concrete.

2. That such manure should be applied broadcast over the whole surface of adult plantations and lightly forked in.

3. That artificial manures have in many cases proved more efficacious and cheaper than natural manure.

4. That basic slag at the rate of 5 to 10 cwt. per acre, applied in December or January, followed by 1 cwt. of sulphate of ammonia the following August or September has given the best results in St. Lucia and also Grenada, on the experiment plots worked by the Imperial Department of Agriculture. The cost of such applications would be from £2 10s to £5 per acre. The results in increased crops have justified the expenditure several times over.

5. Nitrate of soda, 1 cwt. per acre, is clearly indicated in the attacks of *Dipodia* and other diseases where the foliage is first affected.

6. Bone meal, about $\frac{1}{2}$ lb to each hole, is the most satisfactory application when young plants are being put out.—*Agricultural News*, Oct. 11.

LIMES IN GRENADA.

The Grenada *Federalist* reports that at the recent meeting of the managing Committee of the Agricultural Society, the question of planting the Spout land in limes took place. It was urged that the lime industry was likely to prove a valuable assistant to cacao and spices, and that an object lesson was necessary to enable peasant proprietors to have some idea of the method of cultivation and a knowledge of the value of the product. Lime fruit had been recently selling locally for export, at very good prices which were more remunerative than anything that cacao could bring, and it was urged that the systematic cultivation of this plant, would, therefore, be of very great benefit to the community. A vote was agreed to for cultivating one acre of the Spout lands in limes.—*Agricultural News*, Oct. 11.

COCONUT BEETLES.

The following letter from the Inspector of Coconut Trees, to the Chairman of the United Planters' Association is interesting,

Sir,—I have the honour to inform you that the Government, through this office are taking immediate steps to see that the provisions under Enactment IV of 1898 for the preservation of Coconut Trees, is properly enforced.

2. The staff which I hope shortly to have at my disposal will I believe prove sufficient to carry out the necessary measures for this purpose, and I trust that before long the disastrous effects caused by the present ravages of beetles may be minimised as much as possible.

3. It must, however, especially in certain localities where the trees are seriously infested, take some considerable time before any really satisfactory improvement in many of the plantations can be looked for: meantime, I would ask your Association kindly to cooperate with me in the work and assist me in making the best progress possible.

4. In many of the coconut plantations, and this applies more particularly to native holdings where the ravages of beetles are worst, it will I fear be necessary to take very stringent measures, but I would prefer using most pressure by persuasive means, pointing out to owners and tenants alike how much it is to their own advantage, if they will themselves help in getting rid of these pests.

5. With regard to this a great deal of good can be done by their keeping their plantations clean and allowing no rubbish heaps, rotten stumps, or mounds of manure to accumulate, everything as far as possible should be burnt.

6. Your Association may therefore be able to afford me valuable assistance by using their influence with owners of plantations to take these ordinary precautions as far as it lies in their power.

7. I am aware that it may happen that any owner or occupier may be considerably hampered from keeping their plantation free from beetles owing to the trees in their immediate neighbourhood being neglected, and if this is so and reported to me I shall at once take measures to have this remedied.

8. In conclusion, I have only to add that I shall appreciate any information on the subject which your Association may be able to give me, and any suggestion that may be made will receive my best consideration.—I have the honour to be, Sir, Yours, etc., Inspector of Coconut Trees, F.M.S.—*Perak Pioneer*, Oct. 25.

MALTA'S NEW INDUSTRY VINES.

Baron Ugo Testaferrata, a member of the old Maltese nobility has established a new industry in Malta. After ten years' planting and experimenting he has proved that the vine can flourish on Maltese soil, and is now able to produce 10,000 gallons annually of excellent wine, with an alcoholic strength of 15 per cent., and maintaining an unaltered standard from vintage to vintage. This wine is in growing demand both in London and New York, and has been awarded a silver medal at an international wine exhibition at Turin.—*Daily Mail*, Oct. 27.

RUBBER COMBINE.

New York, Friday.—*Commercial Advertiser* this morning says that the United States Rubber Company, acting with Sir Martin Conway, of London, is forming a large combine to control the Bolivian supply of rubber. King Leopold of Belgium, it is stated, is a stock-holder in the concern. It is estimated that the new company will produce twelve million pounds of rubber annually.—*Central News*,

BEAR SHOOTING IN CEYLON.

Though not frequently met with, bears are by far the comomest of the "dangerous" animals of Ceylon. It is owing chiefly to their nocturnal habits, and the fact that they frequent the driest, rockiest and most difficult country, that sportsmen comparatively seldom get a shot at them; whilst natives hold the very name "wahaha" in such dread that even the reward offered by Government for their destruction does not often tempt them to molest the savage brutes.

For a certain friend of mine, however, they held a special fascination. G made bear shooting a regular pursuit, and though most reticent as to his fields of operation, used to whet my ready appetite with such alluring descriptions of various trips he had made, that I arrived at a pitch of keenness which seemed to touch him in a soft spot, and one day he promised to show me a famous locality for bears if I would accompany him and vow to keep the place dark. A second invitation was unnecessary—I fairly leapt at the idea. We talked it over far into the night, and before the sound of G.'s ricksha wheels had ceased to grate on the drive, I was making a list of my requirements, and consulting a map of the Uva Province, wherein lay our chosen district. The next day was spent in getting together a few necessaries, and on the following morning we started early, taking one attendant each and my cook Peter, who was invaluable whether at home or in camp, his only drawback being a marked upward tendency of the elbow, which periodically got him into trouble.

We shipped on a little British India coasting steamer, which ran round the island once a week, and were landed at Hambantotte late in the evening. Here we stayed the night, and early next morning two bullock carts were chartered, one for us and one for provisions, luggage, &c., and Peter was instructed to procure some fresh food in the shape of fowls and rice. The unwonted ease of his existence was too much for him, however, and he had been putting in all his spare moments getting hilariously drunk. Consequently when we were ready to start, Peter was conspicuous by his absence. After much searching we found him, chasing the fowls he had bought up and down a street, and stuffing them back one by one into the crate from which they had escaped. No sooner had he got them all back than he (at sight of us) dropped the bag of rice and spilt half its contents. During the flustered operation of gathering it up more fowls escaped, and, with a ready eye to the main chance, helped to pick up the rice. There was no time to chide the erring Peter, and eventually, amidst the creaking of cumbersome carts, the shouts and strange urgings of their drivers, and the screams of turbulent poultry, we made a start with as much dignity as our surroundings would allow.

We followed the road through the salt lakes, crossed the Mahagam river, and came to the banks of the Manik Ganga (Jewel River), the sandy bed of which is composed almost entirely of quartz, sapphires, and rubies. Whilst quite valueless, the effect is most Aladdin-like, the water magnifying the tiny particles into sparkling gems of enormous size. Following the river for some distance, we forded across, and, after fighting our way through creeper-covered tracks for another two hours, camped in about the worst bit of country I had ever seen. It was simply a tangle of dry jungle,

interspersed with small ravines, choked with boulders, and low, rocky hills, seared and jagged on all sides by fissures and gaping cracks. There was just time to run up a hut of jungle sticks and "talipot" mats before the sun set, and, after a dip in an adjacent pool, a good square meal, and a cheroot, we turned in and dreamt exaggerated dreams of what sport the morrow would bring.

Two hours before sunrise we were sipping tea and munching a biscuit, and G then led the way to a corner of his happy hunting ground, where it was likely that we should get a shot at some bear returning to his cave amongst the rocks above. Sending my boy Gregoris to a point of vantage, with instructions to whistle softly should he see anything, we took up our positions one on each side of a junction of two ravines, and waited. Fully half an hour passed and there was no sign from Gregoris, but suddenly I was startled by a shot from G, followed by the most human-like wails; and before I knew what had happened, a bear rushed into sight and was gone again without giving me a chance to draw a bead on him. G came tumbling down in his tracks, and we followed headlong in the direction the wounded animal had taken. We could just discern occasional spots of blood on the hard ground, and pressing on we came to a standstill at a small-mouthed cave in front of which were unmistakable signs that a family of bears lived within. It was quite light, though the sun had not yet risen, and again we hid among the broken rocks and waited in positions commanding the mouth of the cave. Scarcely had I recovered breath before I saw the ungainly, semi-comical figure of a young bear ambling along, stopping now and again to pounce upon some insect and, unconscious of danger, coming straight towards us. My excitement was intense, and I watched his movements with deep interest, wondering whether G could also see him, till suddenly he stopped and, protruding his loose, mobile lips, stood up and sniffed suspiciously. With my rifle resting on a rock, I took a quick but deliberate aim at the light mark on his chest, and pressed the trigger. It was a happy moment, and I tingled all over to see him collapse at the shot and drop dead without a sound.

We returned to camp and had a bath and breakfast, after which we prepared to bolt the other inmates of the cave, hoping to find G.'s animal and finish him off. Peter who loved to be thought a bit of a shikari, was deputed to carry my spare rifle and the crackers, and on arriving at the spot we made a careful survey, finding as we had expected another entrance to the cave about 15 yards from the first. Talking our loudest, we lit a candle and peered into the large entrance, and saw dimly that there were several deep holes in which the brutes were probably lying, listening to every sound we made. We directed the two boys to jabber their loudest and walk away. After their voices had died down, we left Peter at the large entrance and crept round to the other. At a sign from G Peter then lit one of the crackers and threw it in. There was a muffled report followed by the most infernal chorus of coughing barks, and to our consternation, out rushed a bear, not from the entrance we commanded but the one near which Peter stood. With a yell that would have wakened the Seven Sleepers, he dropped everything and ran like a rabbit, followed by the bear, which I at once noticed was going lame. We could not shoot as Peter, in dodging among the rocks, constantly crossed the line of fire. We went after him, but

could hardly run for laughter at the wretched Peter who was shedding portions of his raiment as he fled. G who was a little in advance to the right, at last got a chance and took a snapshot. The bear gave a roar and bolted up a stony gap on the left. I clambered up in hopes of cutting him off, and found myself face to face with the beast who was doubling back. He looked like charging, and I took a hasty shot, which sent him flying amongst a shower of loose stones. I shouted to G., thinking he was finished off, but not a bit of it. A moment later there was another shot and a loud "Hooroo!" The beast was at last dead, wedged in between two boulders between which he had fallen. He was the same animal G. had wounded in the morning, and was a large male, with a coarse, mangy coat covered with thicks. He must have been lying somewhere round the corner when Peter threw in his cracker the result of which was to bolt him out of the wrong door. Whether the rest of the family had left the cave we had not had time to see, and decided to revisit it at nightfall and lie in wait for them, whichever way they went. On getting back we found Peter with eyes protruding and teeth chattering. His fright had reduced him to a jibbering idiot for the time being, and every sentence he muttered held the word "walaha."

We spent the rest of the day exploring the immediate locality and found several caves, the dusty floors of which bore the clubfooted marks of bears. All these retreats had more than one entrance and deep pockets or fissures in which the brutes lay in security and darkness. That evening G. with a fine long shot dropped a female bear dead as she came shuffling out of her den, and I succeeded in missing one of the easiest of shots and scaring, not only the animal at which I fired, but two others of whose presence we were hitherto unaware. In giving chase G. stepped on a tie-polonga snake, which writhed round his foot and bit at the tough leather of his boot and gaiter before it was shaken off and killed. The occurrence had a decidedly damping effect, and G., with a face as white as his topi, sat down and thought for five minutes, then drained off his flask of brandy, and suggested curried fowl for dinner. Peter, whose culinary resources were unlimited, quite surpassed himself that night and gave us an excellent five-course dinner, the original materials for which were, as far as I can remember, tough chicken, tinned beef, jam and rice. G. soon forgot about the polonga, and was hardly visible through the smoke of his cheroot as he sketched our plans for the next day.

Unless there is any incident to distinguish it, the description of one day's bear shooting is so like another that it will suffice to say that we accounted for seven animals and a porcupine, which I killed with a shot gun, and which we ate, finding the meat excellent. We worked our way back slowly, coming across several good patches of snipe ground on the way. We also saw a great many peafowl on the borders of the coast forests, but, being the close season, we had to be content with seeing them. In one of the villages at which our bullocks were changed we saw a man whose face had, years before, been half bitten away by a bear. He was an awful-looking object, but for us, fresh from the haunts of these vicious brutes, he had a peculiar, if morbid, fascination. Peter, in view of a certain recollection, refused to look at him.

—Field, Sept. 6.

TOM-TIT.

WHERE GREEN TEA IS GROWN (? MADE.)

A Rangoon paper says that green tea is largely grown in Hsipaw and Taung Peng in the Northern Shan States, and now that the railway is extended to the former station, a considerable quantity will doubtless find its way to Burma. The last Administration Report says the new season has opened with brighter prospects; that prices have risen and the old stocks in Taung Peng have been absorbed. The greater part of this tea crop is used for pickled tea, an article to be found in every Burmese house and largely used by Burmese at every ceremony or in invitation to such ceremonies. But the manufacture of dry tea is increasing. It was noticed in many places last year where it had not been seen before, and it is believed some was taken on to Mandalay. The amount of pickled tea sent into Burma from the Shan States last year by rail was valued at over eight lakhs, and dry tea valued at three lakhs was sent during the same period. There is also a considerable amount carried by carts and pack animals in the dry season.—*Indian Daily News*, Oct. 8.

PEARL OYSTER INVESTIGATIONS IN CEYLON.

It is understood that the investigations at the Marine Laboratory, Galle, by Mr. James Hornell have resulted in the settlement of several problems that awaited solution and is very confident of successful fisheries, if Professor Herdman's recommendations to Government were carried out. Our contemporary says that Mr. Hornell has received authority to bring a cargo of young oysters to Galle, to be placed in the shallow water at the foot of the ramparts with a view to practically testing whether a transplantation of oysters on a large scale to Galle would be a useful measure. Mr. Hornell was to leave for Trincomalee by the ss. "Lady Havelock" last month to make another survey of the harbour there and of Lake Tamblegam, coming back in time to join Capt. Legge for the inspection of the pearl banks next month.

TEA AT PESHAWAR :

GOOD DEMAND FOR GREEN TEA.

We are indebted to the Rev. J Gelson Gregson (who writing on 4th October, had just completed a tour of 6,300 miles touching Cashmere, Peshawar, Simla &c.) for the following interesting information, to which we attract the attention of our planters:—

"It may interest you to hear something about the tea trade in Peshawar, a station I visited last month—and while there was taken through the City and was surprised to see a great many *tea shops*, where cups of tea are sold all day long. The Afghans and Pathans are great tea drinkers, so the *tea shops* were as numerous in Peshawar as *whisky shops* are in Glasgow. I could not help thinking that this would be an opening worth cultivating for Ceylon tea, especially when I tell you that a very large trade is done with China. I was very hospitably entertained by one of the largest native merchants in the

City, and he gave me very excellent China tea, out of beautiful China tea cups from *Russia*—he showed me the cases of China tea, and said that Afghans always drink *green China Tea*—his trade is not confined to Peshawar, but extends beyond the frontier to *Cabul* and other places and on the other side of the frontier.

"Here is an opening for good *green tea* and *Ceylon* ought to compete advantageously with *China*."

A BIG PARA RUBBER CROP.

According to the United States Consul at Para, it is believed that an exceptionally good crop of rubber will be harvested in that province this season. The rubber fields of the lower river, and especially in the islands, are slowly but surely failing, both in quantity and quality, but the decrease is more than made up by the development of new fields and the expansion of the old fields on the Upper Amazon. While all the more important tributaries of the Amazon are supplying their full quota of rubber, and even making a promising increase, interest, he says, will be centred in the now famous Acre territory and in South-Eastern Ecuador. In the regions reached by the Purus (of which the Acre is a tributary), Jurua, Beni, Madre de Dios, Javari, Ucayali, Japura and other great effluents of the Upper Amazon, which penetrate Peru, Bolivia and Ecuador, there are illimitable rubber forests as yet unexplored, which will now be gradually developed. Many seringueiros, or rubber gatherers, are making their way to these regions, and it is reported that several syndicates are about to begin operations in new fields in Bolivia and Peru.—*Home paper*.

FOR HOUSEKEEPERS.

"For keeping meat in hot weather.—Boil water until it whirls, and put the meat raw into it directly it comes from the butcher. Keep it in the water for ten minutes only—it can be either boiled or roasted afterwards."—*Home paper*.

GUATEMALA AGRICULTURAL PROGRESS.

According to the report by H M Consul at Guatemala for the year 1901, it is stated in the Government report issued by the Agricultural Board of Guatemala that considerable progress has been made in the acclimatisation and cultivation of various new products. To this end there has been imported from abroad seed of cotton and tobacco, maize from Chalco and Texcoco, Australian oak and other timber, &c. These seeds have been distributed amongst the agriculturists of the different zones so that experiments might be made. The Agricultural Board has had leaflets drawn up on such products as are new in the country, and distributed amongst all agricultural classes, so that the most modern and scientific rules as to planting, &c., might be observed when making experiments. There has been a great impulse given to the production of such grains and vegetables as are largely consumed in the country, more and more attention being paid to the cultivation of maize, beans, potatoes and wheat, and remunerative prices have been obtained. There is no doubt whatever that there is room for many vegetable and dairy farms, especially in

the high-lying districts and in the neighbourhood of the larger towns, and many of the smaller proprietors are turning their attention in this direction with result pecuniarily satisfactory to themselves. *Annual Series*, 2,863.—*Board of Trade Journal*, August 23.

BIPEDAL LOCOMOTION OF A CEYLONESE LIZARD.

I have frequently observed with interest the erect attitude assumed by the small Agamid lizard *Otocryptis bivittata*, Wiegman, when running rapidly, and have long suspected that the short front legs were not used at such times. But the rapidity with which the animal runs, and the nature of the ground which it usually frequent, have prevented very close observation. I have, however, recently fully satisfied myself that its action is truly bipedal. The lizard happens to be common in the Botanic Gardens here, and on several occasions one of them has crossed a smooth sanded road immediately in front of me. I have thus been able to see clearly that the anterior limbs are carried quite free from the ground, progress being effected solely by the long hind limbs:

It seems possible that the closely allied and similarly built lizard *Sitana ponticeriana*, Cuv., may have the same habit. Does the Indian species of *Otocryptis* (*O. beddomii*) progress in the same fashion?

At present the habit has been recorded only of one or more Australian lizards, notably the "frilled lizard" (*Chlamydosaurus kingi*), which has been very cleverly photographed in the erect attitude by Mr. Saville Kent.

EFFECT OF FUEL OIL.

HOW THE SUBSTITUTE FOR COAL HAS CHEAPENED FREIGHTS.

Sir Marcus Samuel has just called the attention of the British public to the possibilities of the future in connection with the substitution of oil for coal as a fuel for steam vessels. The steamer "Pectan" of the Shell Transport Company, has made a successful trial trip. Mr Melrose, of the U.S. Navy Department, predicts the use of oil in the near future as fuel for war-vessels. They might have gone farther and told of the remarkable conditions now existing on the Pacific coast of the United States. There fuel oil has long passed the experimental stage. Over fifty steamers now sail from the port of San Francisco with oil for fuel. The steamer Mariposa has just returned from Tahiti, a return trip of 7,200 miles, under steam generated exclusively by oil. Pressure and speed were easily maintained, and she reached port one day a head of her schedule. Her fuel cost just half as much as coal; there was no expense for painting ship such as is necessary when coal is used. Particularly interesting is the opinion of Lieutenant Winchell, who has reported on the voyage for the United States Government, as to the character of men that should be employed in the fire rooms where there is an oil-fuel installation. It neither requires physical endurance nor previous training with coal fire. The me

placed in charge of the contrivance, however, should have mechanical aptitude, and possess readiness of resource and nerve. The senses of sight, hearing, and touch must be exercised at all times, since it is essential to keep a good look out on the furnace to note by the sound the working of the blowers, and the completeness of combustion, and to check by the sense of touch the workings of mechanical contrivances. If fewer men are needed in the fire rooms it is requisite to secure men of high intelligence, who can judge quickly as to the tendency towards impairment.

THE MONEY SAVED.

Less space was occupied, the fixed charges for labour were greatly reduced, the feeding of the fuel took less time and cost less. In fact, no disadvantages, were discovered, and the advantages were manifold. It is estimated that on one troopship making the trip from San Francisco to Manila and return the saving on fuel through the use of oil has been at least £5,000 for every such voyage. The result of the lack of demand for coal is remarkable. In San Francisco harbour alone fully £600,000 worth of capital in ships has been forced into idleness. Shipowners and skippers no longer find it profitable to voyage to Japan and Australia and return to San Francisco, awaiting cargoes of grain to Europe. The competition in carrying the small imports of coal has been so keen and the freight rates are now so low that the shipowners prefer to have their vessels idly ride the becalmed waters of the bay rather than take the chance of obtaining valuable cargoes in foreign ports. One of the benefits is that grain importers of California can obtain low rates to Europe. The vessels engaged in carrying coal are usually designed also for the grain trade to Europe. As this coal trade is gone, there is only one source of revenue left, and that is the grain trade. Here, again, keen competition has entered, and as a result there are low rates on grain to European ports.

COLLIERS OUT OF WORK.

Twenty-three shillings is the present low price for a grain charter from San Francisco to Great Britain or the Continent. The use of fuel oil has put the colliers out of business, and in turn they have sought operations in other channels. The rapid increase in the shipping facilities of the world due in great part to the artificial demands for transportation growing out of the South African and Spanish wars, has induced a reduction in ocean freight rates for cargoes in bulk, and to that extent favoured the farmers and producers, if not the manufacturers. This favourable situation is accidental. When Mr. Morgan and his associates shall have completed their transportation arrangements, an oil-burning equipment for every vessel being a projected part of the plan, the tramp steamer will be out of the running. In connection with this oil question the Standard Oil Company has a great fight on its hands in California. The trouble lies between the Standard people and a big oil and transportation company. The Standard Oil people are building a pipe line 200 miles long from the great oil-fields in Kern County to tide water in San Francisco Bay. The Standard Oil Company will use this pipe line for the transportation of oil from wells acquired by the corporation. It will also carry oil for producers. The rate of transportation to producers will conform to that of the railway companies connecting with the oil-field, as the Standard Oil and the Southern

Pacific and Santa Fe Railway Companies are working under a tariff agreement.

CHEAP OIL.

A big California corporation, which owns some of the best wells in the oil district and owns a coast line of steamers engaged in the oil-carrying trade, has surveyed a direct route from the oil-field to ocean, and has agreed that if pledged freight to the extent of 10,000 barrels of oil daily it will build a railway, and thus furnish relief to the owners of wells having no connection with the Standard Oil Company or the railway companies. Thus far freight to the extent of 9,000 barrels of oil daily has been guaranteed. This fight is a very pretty one because the Californians in it are worth, in the aggregate, £20,000,000, and have already had several successful skirmishes with the railway companies. The outcome of the fight will be that oil will be the cheapest thing on the Pacific coast or the two companies will combine. The latter is the outcome to be expected. The issue of this shipping congestion is in doubt, but it will make American competition keener than ever, for the ocean freights will be so slow that they will be but a small matter in figuring prices in any part of the world. This will include the transportation of fuel oil for sale, and with the present situation along the Pacific coast in view it is but reasonable to suppose that a great majority of steam-going vessels will within a few years have substituted oil for coal. There is plenty of oil in the United States, and much in other countries. Its price is merely a question of transportation, and that again is merely a question of the construction of pipe lines to tide water. The last naval Appropriation Bill passed by the Congress of the United States carried an item of £4,000 for experiments to be made with oil on naval vessels and these experiments are now in progress. The same plant which has been used for years to test the efficiency of different grades of coals is now being used to test oil, a fact which speaks for itself. It may soon become a question with the various peoples of the earth not as to the future coal supply, but what of the oil supply? The balance of trade may hinge on this in the future, for the cheapest transportation governs the market.

—Home paper, Sept. 23.

RUBBER PRODUCTION IN SIAM.

H. S. Consular Assistant at Bangkok reports that among products which do not yet take a regular place in the exports of Siam, but for which there may be a future, is undoubtedly rubber. The question is now under consideration, and it is known that rubber-producing trees are found in some quantity in certain parts of the country, notably in the eastern province. One or two small experimental shipments have already been made, but little is known at present of the product or the possibility of cultivation, and the Ministry of the Interior are prosecuting enquiries. It is believed that traders from the French side of Mekong have been obtaining rubber from the eastern provinces of Siam for some times.—*Board of Trade Journal*, September 25.

BRAZIL CACAO CROP.

The United States Consul reports that the cacao market has been steady at average prices, and the demand fully equal to the supply. No

crop in Brazil is subject to such fluctuations as cacao, and for this reason comparisons with previous crops are valueless. Little interest is manifested in the product in this region. The total shipments from the Amazon for 1902 have been:—The total for seven months, January to July, being 2,890 tons. Something more than one-third has been taken by the United States, and the balance by Europe, France, as usual, is the largest consumer, with Holland second. The trade with the United States is, however, increasing, and before long that country will doubtless consume the bulk of the cacao product of South America.—*Board of Trade Journal*, Sept. 25.

MANURE YOUR COCONUT PALM.

Under this heading, an esteemed correspondent sends us the following valuable particular:—

There is a coconut estate in Heneratgodde which it is worth while to look at for those who are engaged in that occupation. The soil is generally hard and composed of large gravel, except as usual in the Agras. The trees stand, some 18 feet apart, some twenty, and some twenty-four. Almost every tree bears its indelible marks of early neglect. When the present proprietor took the estate in hand some six or seven years ago, the average yield per tree was ten nuts in the year. This can be readily believed when you look at the trees on the estates surrounding this one. For, they are certainly incapable of yielding more than ten nuts. By persistent manuring the present proprietor of the estate of which I speak has raised the average step by step to something over fifty nuts already. He is not likely to stop until he reaches the round hundred. I have obtained an average of 135 on an experimental block of two and a-half acres where the situation, soil, age and distance between trees are all more favourable. Some of those trees have given me more than 200. An average of 100 is, therefore, no impossible result for a proprietor who manures.

According to general experience a weak tree standing in the midst of strong healthy ones never regains its strength so as to bear as well as its neighbours. What I saw on the Heneratgodde estate seems to be exceptional. A weak tree standing among, and having a trunk the circumference of which is scarcely one third of that of its neighbours, bears here as well as they.

The cost of the manure used and its application cannot be computed at less than one rupee per tree, which represents the value of 25 nuts. Anything therefore that a tree-yields over 35 nuts must be put down as clear gain. Add to it the gain from the breeding of cattle, deer, sheep, pea fowl and bee, which takes place on this estate, and no proprietor has cause to grumble over the smallness of the return from the coconut as compared with other industries. The worst that can be said against the coconut is that it takes some 25 to 30 years to bear on hilly ground, though it flowers at the fifth year and brings a good income about the tenth year in lowlands composed of alluvium.

In Jaffna and Batticaloa it is usual for the natives to manure and plough their coconut estates. In the Colombo District only a very limited few do it. It is a means of quadrupling the income of one's estate. But here one prefers to extend one's acres instead of increasing the yield by manuring and ploughing a limited area. There seems to be no remedy for prejudice.—Ceylon "Catholic Messenger," Oct. 14.

CACAO.

EXPERIMENTAL PLOTS AT GRENADA.

A report by Mr. Murdo McNeill, the Agricultural Instructor for June last, gives an account of the work done in connexion with the experiment cacao plots at

Vendome, Belle Vue, Vincennes, Nianganfoix and Columbiere estates, and other agricultural efforts in that colony. Considerable improvement is recorded in the condition of the cacao trees in these plots since they were placed under the care of the Imperial Department of Agriculture. Results of the manurial experiments have been so far extremely satisfactory. At Nianganfoix estate, on Section A of the plot treated with pen manure, only an average yield of 5 bags per acre for the last two years were obtained, while on Section B, to which basic slag followed by sulphate of ammonia had been applied, an average yield of 6 bags per acre was obtained in 1900, and of 8½ bags per acre in 1901. This would seem to indicate that the latter method of manurial treatment is the one most likely to prove successful in renovating old and neglected cacao trees on red clay lands in the interior of the island. Several visits were paid by the Agricultural Instructor to the holdings of peasant cultivators and, where possible, practical demonstrations were given in budding oranges and other plants. Efforts are also being made to encourage the cultivation of limes in localities unsuited for the growth of cacao, and allusion is made to an interesting experiment in reforestation at present being carried on by the Hon. W. H. Lascelles near the Grand Etang Lake. The trees which consist of the native 'gommier' (*Dacryodes heandra*) planted 4ft. apart either way, are now two years old and are described as 'being' from two to two-and-a-half feet high and growing well.—*Agricultural News*, Aug. 30.

WEEDING OF GRAIN IN INDIA.

In the hilly districts of Western India, along the Sahidra mountains or Western Ghats, where rain falls nearly every night during June to September, and even in daylight hours the clouds descend with striking frequency, the weeding of the principal grain crop, called Natchni, is a carnival of hard work, conducted on a communal system.

The crop is a very prolific small-grained cereal, grown on steep hillsides under heavy rainfall, and transplanted when about a month from seed-sowing. Botanically it is Eleusine coracana, known as Natchni, Ragi, and many other names in India, Thibet, and Abyssinia.

Word having been sent round that the field belonging to Bagu, the son of Babaji, is ready for weeding, all the workers of the village, probably 100 or more, assemble soon after daylight at the house of Bagu. It may be raining heavily, and Bagu's house is not commodious; but as each guest carries a rain-hood made of split Bamboo and leaves, giving protection from crown to hip, and has Nature's water-proof on the limbs, the lack of house room is of little consequence. The guests arrange themselves in a semicircle, with back to the wind and with the knees at the breast, sit on the heels as only an Indian or a coal-miner can do, and eat a hearty breakfast of boiled Natchni, flavoured with Chillies and Asafetida, amid discussion of the season's prospects and the character of the latest tax-gatherer. Then, headed by the village musician beating a drum with his hands, they proceed in single file to the field, and range themselves on the windward margin; at a signal the weeding-hooks are unhitched, the naked brown legs, doubling in front of the body, disappear as by magic, and weeding is started in time with a harmonious refrain, describing the mercy of the gods, the liberality of their employer, and the probability of dinner being equal to their sumptuous breakfast. But this only a prelude; the drum is tapped faster,

the voices rise higher, and the weeds are spitted with feverish energy as the song describes the doings of the old chieftains who held the mountain peaks, and took all they wanted from the people of the plains; and the drummer in rear of the line dances to and fro, beating with frantic gesture wherever the line falls behind, and the wave of song passing along the line keeps everyone working with demoniacal energy, while the frequent passing clouds leave everything dripping with water.

The field appears a quagmire, but from the steep slope and frequent rain the cultural result is satisfactory, and from a distance the effect of the rude music, re-echoed from mountain and glen, is plaintive and weird as the notes rise and fall in gentle cadence, or scream with fierce joy of battle as the workers emulate the deeds of heroes on the hapless weeds.

Early in the afternoon the workers return to the house of their host, a bedraggled and worn-out crew, who have done as much work in six hours as is usually done in twenty; they leisurely eat another meal, learn whose field is to be done tomorrow, and by sunset retire to their own homes, to repeat the orgie of labour daily while the weeding season lasts. G. Marshall Woodrow.
—*Gardeners' Chronicle*, Aug. 23.

THE TEA CASES (CUSTOMS) IN AUSTRALIA.

THE LEADING JOURNAL UPON THE CASE.

The Melbourne *Argus* of 19th September contains the following editorial on the above subject:—The decision given yesterday in one of the tea prosecutions instituted by the Minister of Customs affords another illuminating example of Mr Kingston's methods, Parliamentary and Departmental. Under the Commonwealth Customs Act certain regulations created a special standard for tea and special tests of which Great Britain and America know nothing. These regulations came into force in November. In ignorance of their existence, shippers at the Indian and Ceylon ports sent to Australia, teas which would have been accepted in other parts of the world, but which failed to quite satisfy one test of the several imposed by regulation. The ash, which should not exceed 8 per cent, was found to be 8.5 per cent. In other respects the consignment more than satisfied the artificial standard set up here. The aqueous tea extract was said to be more than 26 per cent. above requirements, and the soluble ash also was considerably over the stipulated percentage. In short, the tea was a thoroughly good and sound commodity, which in a detail fell short of the new technical requirements. Mr Blackett, the Government analyst, called by the prosecution, was fain to admit that "he believed the tea was perfectly wholesome, and, apart from the regulations, was fit for use." On the strength of this evidence, the Court, which has power to fine up to £100 for adulteration detrimental to the public health, declared that the minimum penalty of £5 would meet the case. This is the view a court of justice takes of an affair which Mr Kingston represented in the House a few weeks ago filled him with virtuous indignation and convinced him that he must do his duty or submit to the brand of cowardice.

Truly this Minister's ideas upon courage and veracity would form a stranger subject of analysis than any of the 'goods imported' by the reputable

firms whom he seeks to stigmatise for unfair dealing. If words have any meaning, his language when challenged by Sir Malcolm M'Eacharn on this very point conveyed that he was fearlessly exposing and punishing men who attempted fraud and injury upon the public. He spoke of "those who would palm off Indian mud and charge for it;" of "old and decayed leaves, nauseous to taste and without aroma;" of "exhausted tea," of "rotten and decayed stuff." And the sequel of all this intemperate abuse, uttered by a politician quite unscrupulous as to what shifts he resorts to screen himself momentarily from attack, is the complete moral exoneration of the first defendants proceeded against. It really passes patience that the Minister at the head of a department requiring above all things unprejudiced, judicial administration should comfort himself in this spiteful and reckless fashion. Even if the absurd contention be granted that all cases of simple error or accidental breach must be adjudicated upon in a police court, it surely does not follow that the defendants must first be "ragged" and rated by Mr. Kingston as a prelude to being found innocent of any wrongful intent by a competent tribunal. What Mr. Kingston flaunted as a high-minded championship of the rights of the consumer proves, in Messrs. Gollin's case at least, to have been simply petty persecution. The firm's application to be allowed to reship the tea, as is done elsewhere, was treated with contemptuous silence. The minister would be satisfied with nothing less than the destruction of the shipment—a course taken under sensible and civilised administration only where a commodity is certified unfit for human use. When new regulations are introduced, it is only fair to treat considerably shippers who have acted in ignorance of the new conditions. The fair treatment in this case was to allow reshipment of goods sound and wholesome in themselves and saleable in open market elsewhere, and shipped to this port in ignorance of the new tests. But Mr Kingston only saw in the incident and opportunity to exercise his authority and to lampoon the traders. Sir Malcolm M'Eacharn's refusal to follow the lead of such a Minister will now be explicable to his constituents.

"CEYLON SILK-WORMS."

The following extract from a letter addressed by a well-known agriculturist in Algeria to the French Consul is of general interest and we have, with the permission of M. Labussiere, had it translated to lay before our readers:—

"As I intend to devote myself to various entomological experiments upon the various kinds of silk-worms more or less known, I take the liberty of making my request known, based on a purely scientific idea.

"The many ravages that are made in the silk-worm nurseries by diseases inherent in the domesticated silk-worms, have led me to believe, after many long years of experiment, that the best means of eradicating the disease which would ruin the silk-husbandry of France, would be to make some alliances between our domestic races and the wild ones.

"I would then make known to the Entomological Society of France, to which I belong, the results I should have obtained, and I hope, if I

succeed, to be able to create a race better able to resist disease. Cultivators would once more take courage.

"It appears that, in the neighbourhood of Colombo, there are different kinds of silk-worms, notably one called *Attacus Taprobanis*, living upon the cinnamon bush. The caterpillar of a green colour gives a large open cocoon in the shape of a pear, greyish brown. Could I obtain some eggs or some living cocoons, of these different kinds of silk-worm, or if not all, then of one of them, and would it be possible at the same time to inform me on what they feed? By lending me this help, you would enable to complete my work and would render a great service to science, which, so far, knows nothing whatever of those Ceylon kinds of worm. Of course I shall be happy to pay those who take the trouble to collect and send these."

In our Review of Agricultural and Other Industries in Ceylon, we notice "Silk-worms" and give a summary of what has been done in the past:—

"There is a spot on the banks of the Kelani river 3 or 4 miles above the Bridge of Boats *en route* to Hanwella called 'Orta Seda' or Silk Garden, where the Portuguese are believed to have fed silk-worms. The Dutch unsuccessfully attempted to propagate the silkworm, plant mulberry trees, and produce silk at Jaffna, (See Tennent, vol. I, page 265) Tennent also notices the presence of the Tusser silkworm which feeds on the country almond (*Terminalia Catappa*) and the very common *Palma Christi* or castor-oil plant; but nothing has been done with the Tusser to make it a commercial success. In the British period Bennett takes credit for introducing the white and digitated mulberry (as well as the opium poppy), and on 21st September 1829 a Government regulation was passed to encourage the growth of 'silk and opium' among other agricultural produce. He thought the Northern Province eminently adapted for the silkworm and mulberry plant being the least humid part of the island; as Tennent thought it best adapted for the Tusser silk and castor-oil plant. Bennett gives instructions (page 217) for the information of mulberry nurseries, and he quite hoped to see silk a staple of the north of Ceylon. He proposed shading the mulberry plant with plantains and afterwards to grow an under-crop of Indigo."

We have never heard of the Ceylon silkworm that feeds on the cinnamon bush; but our Entomologist, Mr. E. E. Green, will, we feel sure, tell us all about *Attacus Taprobanis*: whether it is likely to suit our Algerian friend's purpose, and, if so, the best way in which the Consul can secure and forward the needful supply of eggs.

THE CURRENCY QUESTION:

BANKING AND MERCANTILE

OPINIONS.

In view of the interest centered in the Currency Question at present, we have sought and obtained the opinion of some of the leading members of the Mercantile Community, and of some members of the staffs of

our Banking Offices in Ceylon. We submit them as received:—

A leading Fort merchant and an old resident writes:—

"Most of the large rice and other business now-a-days is financed by bank drafts, or 'boondies.' For rice from some of the small Indian ports, rupees may be shipped, but I don't think to any important extent. The rupees taken to the Coast in quantity are taken by the Tamil cooly, I don't see why in a little time he should not take sovereigns and half-sovereigns instead.

"As regards local currency, what the local 'Times' correspondent said the other evening is nonsense, *i.e.*:—The latest idea is to force small coins on the public. The public have not demanded small coins and do not require them; it is merely another attempt to retain the Gold Ordinance in force, for the benefit of the Banks. If a large quantity of small coin is minted it will merely lie in the vaults in company with the sovereigns." Most people in Ceylon would be as well satisfied to receive two 50 cent pieces as a rupee and, if Government would expedite the issue of these largely, the pinch would soon be relieved. At the same time I do not see any objection to a Ceylon rupee, coined so as to be easily distinguished from an Indian rupee, being put into circulation here; it would meet local requirements.

"It would not, however, be current in India and we need never ask the Government of India to permit it, for the maintenance of the value of the rupee is partly regulated by their restriction of the coinage of it in India. A Ceylon rupee would have to be exactly of the same fineness and intrinsic value as the Indian one. We don't require a mint for this; they can be coined where the present subsidiary coins are turned out."

A very different view is taken of the situation by a Banker as follows:—

"Run on its present lines this Gold Ordinance will never work, and the sooner it is repealed the better for all parties. It is absurd to attempt to force the sovereign on the public, who not only don't want it, but it is an absolutely useless coin for many purposes. As well make the American dollar or any other foreign coin legal tender. The Treasury are at a deadlock and will not part with a single rupee; a disgraceful state of affairs. Let them ship off their gold to India at once and import rupees; it is not for the public to do this, and as matters stand it is really the public in the long run who have to pay the cost of importing.

"A Ceylon Government rupee would lead to many complications. If the Treasury are unfit to supply small coins, how much worse it would be if they ran short of their own rupees."

Per contra, a merchant in a big way thinks,—

"I cannot see why our Bankers should be exempted from obligation to bring *some* rupees from India, any more than that Government should be. Suppose I sell a sterling bill to a Bank here, the Bank agrees to pay me for it at a certain rate of exchange, so many *rupees*; presumably the Bank has them, but, if not, why should Government supply the Bank with these rupees? I am unable to see why a Ceylon rupee should lead to any complications. Bankers should pay for sterling bills with them such as I refer to above. The only person for whom Indian rupees are wanted seems to be the Tamil cooly, but surely it would not be much of a hardship to

require him to take sovereigns or half-sovereigns much more easily carried, and easily convertible in India. I can see no reason for undoing recent legislation and I would be sorry to see it asked for."

To this still another Banker responds:—

"Banks do import rupees for their own constituents and several lacs have been imported within the last week or two. When a Bank buys a merchant's bill it is payable in the currency of the island, notes or gold, which are legal tender, not necessarily Indian rupees. A Ceylon rupee would do well enough as a purely local token. Indian rupees are wanted by the trader as well as the Tamil cooly. The trader buys rice at small ports in India where there is no Treasury or means of changing a sovereign for rupees. If the Government wish to encourage the trade of the island, they should use the best means for so doing, and that is in assisting the small trader by supplying him with a coin that he can trade with."

But here again is the opinion of still another leading merchant, who is very outspoken:—

"We are very ready to blame Government in all things; but if the cause of the present scarcity of silver in the island be enquired into, it will probably be found that the Banks have lately been importing unlimited supplies of gold at a profit and plugging Government with it in exchange for notes. They then take these notes to the Treasury and expect to get silver instead of gold in exchange. If the Banks find that they cannot supply their constituents with sufficient silver, why do they not import it, as they did the gold instead of looking to Government to do so for them?"

"The way for Government to prevent a recurrence of this state of things is to pass an Ordinance making legal tender consist of a certain proportion of gold and a certain proportion of silver, according to the ascertained average requirements of the community. The Banks would then be unable to flood the Treasurer with gold as they have lately been doing to their own profit, while grudging the expense of the importation of the silver they require."

Another Banker writes:—"Since the Government undertook to exchange notes for sovereigns the Banks greatly availed themselves of this mode of getting funds from India, when it was found necessary to import coin, not so much because sovereigns are cheaper to import (the difference between the cost of importing rupees and sovereigns is slight) but because the gold coin is so much easier to handle than is the rupee. Notwithstanding this, Banks have quite recently imported considerable quantities of rupees from India. What merchant in Colombo ever receives actual coin from the Bank in exchange for bills purchased, and if the Bank insisted on paying him in coin what would the merchant say? A Ceylon rupee would lead to no complications so far as internal circulation is concerned; but the native who trades with small Southern Indian Ports where there are no Banks would not require them. He wants something which is easily passed there, and the only thing which suits his purpose is the Indian rupee. Why he should not pay a premium for them here is another question. Up to the present the Banks have been good enough to import them for his benefit. The Tamil cooly also wants Indian Rupees but in smaller quantities than the trader does. Had the Government

before making the sovereign legal tender, appointed a small Committee of officials and representatives of the Mercantile Community to discuss the question, probably little would have been heard by the outside public about the Currency Question. Merchants should not overlook the fact that they benefit when Banks have a cheap and easy way of laying down funds in Ceylon inasmuch as they then get a better rate of exchange for their bills."

A member of the mercantile community, of some considerable experience, says:—

"I think Government is bound to produce rupees if that is the currency of the country. The Government of India makes about 6d. profit of every rupee she supplies to Ceylon and I certainly think she should give the Ceylon Government a share of that. A few years ago, when the value of silver was about 1/4, they made nothing, but now the value of silver is down to about 10d. and they still sell the rupee for 1/4. If this question had been brought up when the value of silver went down and when the exchange was fixed at 1/4, I think the Government of India would have acquiesced at once. With regard to the coining of rupees in Ceylon I think it would be very much better if Ceylon continues to get her supply from India and succeeded in getting a share of the profit which India gets at present—sufficient at least to cover the expenses of taking rupees from India to Ceylon. Government might threaten to coin her own rupees in order to coerce the Indian Government into giving a share of the profits."

Another merchant takes a decidedly anti-official view:—

"The first principle in currency legislation is or should be—*convenience* i.e., to facilitate the machinery of circulation whereby the commerce of the State is furthered. The stability of the rupee having been secured before the gold standard was established, the latter was not a necessary corollary and its imposition would only be intelligible on one of two grounds—(a) convenience in circulation and (b) a byway to profit for the Government.

"I believe this latter view has been before the authorities and inasmuch as it has been proved that the gold standard has seriously interfered with the smooth running of the country's trade and chief industry (See Hatton Bank's recent advertisements)—there is, to my mind, no justification for its continuance. To hamper the industries of a country for a little immediate profit is a proof of narrowness and want of statesmanship which sometimes marks those who are only experimentalists in finance—who lose the main principle in the attempt to carry out ingenious theories. I see no object in a Ceylon Government Rupee. We have all the needful machinery for the proper production of a silver currency close by.—Government largely profits by its own minting and the only aim, therefore, should be the weal of the State."

Yet another Banker:—"It is perfectly true that the Banks are importing gold to a considerable extent, but Government brought in an Ordinance, after, presumably, 'due deliberation,' notifying that they were prepared to receive sovereigns and why should not the Banks act up to the Ordinance as I may say Government is doing. Government in the Ordinance have the option of issuing gold or silver in exchange for their notes and they are exercising this option by issuing sovereigns and refusing to issue rupees,

"In the articles and correspondence that have recently taken place, the fact that Government is making Rs200,000 a year profit of the currency has apparently been lost sight of. Surely with this profit Government can afford to meet the requirements of the Colony, for it must be borne in mind that the profit on the currency is made out of the Public not out of Government money.

"If Government wish to put a stop to the present dilemma, they should cancel the ordinance and revert to the former position which worked satisfactorily for all parties concerned. As regard the position of the Gold Currency in India, the Indian Government will freely exchange rupees for sovereigns at their currency offices and this is exactly what the Ceylon Government will not do; hence all this inconvenience. If the Ceylon Government was not prepared to meet the public as the Indian Government has done, it should not have introduced the Gold Ordinance at all. The Indian Government, when the gold coinage was introduced, endeavoured to force sovereigns on the public, but soon found the public would not take them and gave up the attempt. Gold is of no use to native traders; they require silver to pay the small men with, to whom a sovereign is of no use unless it can be promptly changed for an equivalent in rupees.

"This cannot be done and, therefore, sovereigns are refused. A premium is now charged to change a sovereign into silver in the bazaar here, and I am informed a much higher premium up-country and in villages outside Colombo is ruling."

THE FUTURE OF GREEN TEA MANUFACTURE :

AMERICA ENTERS AS A COMPETITOR.

Those men in India and Ceylon, who have expended brains and money in working out and perfecting new processes for green tea manufacture, will have to hurry up with their patents, or they may be left behind by our American cousins. The South Carolina tea-growing experiment, which has made a good deal of noise for its size, and inspired many a spread-eagle "scare head" in the pages of the American daily press, is still pushing its way into notice, and has, according to the *Boston Herald* of the 7th September last, induced Congress to grant a sum of \$10,000 to be expended in further "green tea experiments." The illustrated printed page which is devoted to "booming" the Pinehurst venture, has this startling legend in large type:—"Green tea made by machinery at the Government Plantation. Discovery destined to drive Foreign Brands out of the American Markets." There is no secret made of the new process, which is to produce the green tea of the future, and start it on its conquering career. The prophetic soul of the journalist, who writes the subject up, "wears his heart upon his sleeve," takes the American public into his confidence, and is as open with his information as he is far-reaching with his vision. The green leaves, he tells us, are tumbled into a revolving metal cylinder, and exposed to a high temperature of about 400° Fahr.

Inside of the cylinder are flanges which catch up the leaves and keep them constantly tossed about. And that is nearly all! Of course, there are spicily paragraphs over and above which are purely scientific—sops thrown to the sapient souls among the *Herald's* readers—where much is made of "volatile oils," "oxidising processes," "chlorophyll" and "enzymes;" and which must cause the constituency of the paper to feel that when all is done, its intelligence, at least, is not affronted. It is a high note that is sounded throughout; but then there is nothing American intended to win the ear of American public which finds its way to notice on a minor key. "Secretary Wilson," we are told "believes that an excellent quality of tea can be produced in the Southern States at a cost of 20 cents (American) a pound, but there will be more profit in growing teas that retails at \$2 to \$20 a pound! There are plenty of rich people who are willing to pay such prices for teas which are of proportionably high quality." Happy American tea-growers! Ceylon might well question the advisability of sacrificing so much money to win for its green teas, an honoured place in the American market; but a corner of the "purdah" has been lifted on the Pinehurst venture, and there is disclosed the comical fact that 125 lb. an acre is the average outturn for a year's working! As we read these figures we are permitted to see that from whatever quarter of the globe the "hustler" is to come who is destined to displace us as the tea-growers for the world, it cannot be in South Carolina that we shall look for his advent.

The Pinehurst tea plantation is pretty much on a par with the ideal American infant of whom we read and marvel at. This child has a mission from the day it draws its first breath, is an object lesson to all other infants, and has the theme to demonstrate of "How to do it." The American infant is said to be able to amuse itself from the very first: objects to being walked about or fooled around with: wants a quiet time for thought: takes regular meals and when duly replenished, displays no weakness for more; keeps decent hours, and is never known to awake during the night! So it is with Pinehurst. Has it not amused itself from the first with its meagre acreage of tea trees, and tickled the fancy of the Eastern Planting World as it tabulated its total yearly crop of 3,000 lb.? Has it not insisted through its newspaper press and its Congress votes on being taken seriously, not a thing to be dandled or fooled around with: a wide-eyed bumptious youngster, appearing before the world attired in "scare-heads," and newspaper illustrations? Has it not a great future before it, on which at the slightest provocation, the American press fastens its attention and tootles to its glory in the highest of "high falutin'" strains? Ah! we are reminded that Ceylon too has an American Commissioner who, on a handsome salary, is supposed to ceaselessly forward the interests of Ceylon tea in the great Republic; and has for years been in a position to learn

how best to frame a statement, write a telling letter or make a taking speech, in order to win America to the drinking of our fragrant beverage: but when we contrast what he has done and at so high a figure, with what Pinehurst has accomplished—and for nothing—through the press especially, it is rather a humbling affair. It makes us think that although we *are* the people,—wisdom, after all, does not dwell with us.

However, Pinehurst is not likely to disturb the equanimity of the Ceylon tea-grower, with its pickanniny labour force, and a total tea outturn which would hardly affect the dividend of any decent-sized property in Ceylon, were the whole handed over to it as a gift. But the Americans are an ingenious and clever people, and it is not at all unlikely that when they take to training their brains on the mechanical appliances needed for tea manufacture that the effort will result in a good shot. For black teas, there is now really no necessity for anything new in the way of machines, the market being fully supplied. It is to perfect the manufacture of green tea, that the chances of today lie. Neither India nor Ceylon really need mechanical assistance from any one, there being plenty of local talent about. But now that South Carolina has taken to green tea manufacture, and has to model and make its own machinery, it is quite on the cards that the Premier Green Tea Apparatus may yet be of Western manufacture, and the product of the American brain!

PATENT GREEN TEA FISHING MACHINE.

In a couple of days more, Mr. Alleyn and his Agents, Messrs. Brown & Co., will come before the public with an invention in a new machine which, it is claimed, will produce true finished green teas, without the use of pans or other hot air apparatus,—teas which can compete with the best greens of China and Japan. This is important news for the Planting Community, more especially as the time taken—3½ hours—to turn uncoloured teas into true greens, is so moderate, and since no colouring or extraneous matter, whatever, is used. Considering what it can do, the price of the machine, R1,500, is by no means heavy; for, finished green teas fetch a good deal more than the ordinary raw greens. We congratulate Mr. Alleyn on bringing his invention to a successful issue, and we hope he and his agents may be well patronised.

USEFUL NOTES ON GREEN TEA MANUFACTURE.

To the Editor, *Indian Gardening and Planting*.
Sir,—I have much pleasure in giving you what information I can in reply to your correspondent's following queries:—

(a) What produce a metallic, steely taste in the cup, and how is this to be avoided?

Without personally witnessing the whole process of manufacture in your correspondent's factory, it is not easy to locate the exact cause of this objectionable flavour, as many things may produce it. However, if the following course is followed this defect should not be noticeable. The green leaf should be perfectly fresh, without any signs of natural withering, when it is first steamed or

roasted into a flaccid condition for rolling. All external moisture from steam, dew, rain etc., should be dried off before the rolling commences. The steam should not be carried through rusted pipes, or allowed to come in contact with any rusty ironwork before it reaches the leaf. The pans should be made of hard cast-iron, not wrought-iron; and always kept scrupulously clean and dry. When the leaf is in the pan, it should not be stirred about with any metallic implement, but with a smooth flat round-edged piece of wood, and a cotton cloth pad.

(b) How to avoid too green a colour, and obtain a uniform grey green, without artificial colouring?

The Drummond-Deane system has a tendency to produce a rather greenish tint. But a thorough panning, with the precautions previously mentioned, ought to modify the colours naturally to a grey-green. The panning is at fault somewhere.

(c) How is a grey colour produced with artificial colouring matter?

Such a shade can easily be brought on by putting a teaspoonful or so of fine pulverized soapstone (steatite) in four or five pounds of tea during the *last* panning, which should be carried on till all the soapstone has been taken up, and the leaf has assumed a glazed grey appearance. All artificial colouring should however be avoided, unless it is especially demanded as in the Asiatic markets. The vernacular name for soapstones is *sailkhar*.

(a) How is gunpowder tea manufactured?

The round gunpowder tea cannot easily be produced with any of the ordinary rolling machines. The roundness is the natural result of special hand rolling, and also rolling the leaf separately with little flat boards in a circular figure of-eight way on a flat surface. The Chinese recommend the addition of a little gum during this process. This class of green tea may be considered a by-product of Young Hyson and Hyson, and I do not think it worth the trouble of manufacturing. But if it is desired for any special reason, then all the coarser leaves should be sifted out after the first ordinary light rolling, and hand-rolled in the above described way. I once made a simple wooden rolling apparatus for this purpose, which did very effective work. But I consider it a mistake to multiply grades. Young Hyson, Hyson, and a little Dust and Broken Leaf, called *Samut* and *Sikkin*, respectively, by the natives, are the most paying kinds of green tea.

I hope in the above I have given all the information your correspondent requires; but without actually seeing the manufacture at any given place or time, I cannot be as exact in my replies as I would like to. I shall, however, always be most happy to help in all such cases to the best of my ability.

THE GREEN TEA OF BENGAL.

REPORT BY MR. J. B. LESLIE ROGERS.

As desired, I have much pleasure in submitting the following report on two samples of Bengal green tea, lately forwarded to me.

No. 1. The "Deane-Judge" (coloured or finished) pure green tea:—Appearance approaching Hyson quality. Leaf well rolled and fairly even. Colour very fair, but not of one uniform tint, which should be a good grey-green throughout. Aroma, good but requires bringing out more. Infusion:—Leaf, a pale

olive, tending too light a green. Liquor, a good pale straw-green. Flavour, very fair, but not fully developed and slightly raw. Aroma, faint and evanescent."

No. 2. The Drummond Deane" (uncoloured) Appearance, Young Hyson mixed with broken leaf. Leaf rather flat and broken. Colour very mixed and blackish green, lacking the uniform grey green tint admired in China teas. Aroma, slight and not as good as No. 1. Infusion:—Leaf, pale olive, tending to too light a green. Liquor, a pale straw-green, but little too thin. Flavour, fair, but somewhat raw and undeveloped. Aroma, very faint.

General Remarks:—Both these samples must *undoubtedly be classed as green teas*, but the defects of amateur manufacture are still very apparent. The "Deane-Judge" I consider superior to the "Drummond Deane." The former, however, still requires more development in manufacture. I would suggest that the fresh green leaf be made more flaccid before rolling, while the drying and final panning should be continued further. The panning process is most important, as it enhances the aroma, produces an even grey-green colour, and gives the leaf a glossy finished appearance. And I am of opinion a through panning also greatly increases the keeping quality of green tea. I have drunk panned green tea from Dehra Doon fourteen years old, and it was as sound as on the day it was manufactured.

To my mind the Drummond Deane system, though an advance in some ways, is still an incomplete process. It does not go far enough and hence its defects. The pannel No. 1 Deane-Judge is and undoubtedly improvement, but even that requires further experience before it can be said to produce perfect green teas.

India has marked advantages over Ceylon in the matter of green tea and there is every reason to believe that we will eventually produce the better article.

TEA IN THE UNITED STATES AND THE AMERICAN DUTY.

Writing to us direct from South Carolina under date September 15th, Mr. Charles U. Shepard, the pioneer of local "Tea Culture," reports as follows:—

"I have no further news to communicate than that the leaders of the dominant political party of the country are said to be seriously contemplating the re-establishment of the duty on foreign teas—and thus that Belgium will continue to enjoy the monopoly of a 'free breakfast table.' I should not be surprised to see the law in force when the present duty expires. But I shall beg for 20 cts. per lb."

Twenty cents a lb. is more than *tenpence!* An entirely outrageous impost, and Mr. Shepard must surely be in a jocative mood. We trust he will prove a bad prophet in regard to any duty being continued on tea after the 1st January next. We are quite content to leave the market of Pinehurst or even the markets of South Carolina for all the tea Mr. Shepard can grow; but surely he is interested in his countrymen elsewhere all over the States becoming consumers of his and our staple—and how is this to be accomplished if a prohibitory, or even the present, duty is continued? At present locally-produced American tea is such a curiosity, that it must command a fancy price, duty or

no duty. And as to the future, we are quite content for Mr. Shepard—if he only refrains meantime—to head an Agitation for a 20-cent duty, on the day that the production and manufacture of *one million lb.* of American tea is reached. If this is agreed to, we think, we should be safe, and Mr. Shepard be spared the necessity of adding the role of "agitator" to that of "planter", for quite a generation to come—and by that time (1932 A.D.) the United States should want 400 to 500 (in place of 80) million lb. of tea per annum! So mote to be.

TEA IN INDIA :

MR. ALLEYN'S VISIT TO CALCUTTA AND THE INDIAN TEA DISTRICTS.

NO INCREASED CROPS FROM INDIA TO BE ANTICIPATED FOR SEVERAL YEARS.

Mr. H. M. Alleyn is looking very well after his visit to Calcutta—a great city, but not to be compared with Colombo for cleanliness and scenic beauty—and the Indian Tea districts, including Upper and Lower Assam, Sylhet, and the Dooars. Mr. Alleyn was much impressed with the rich soil and fine tea gardens of Upper Assam, where very great attention is paid to the keeping up of a high standard in the teas turned out, through fine plucking and special attention to the manufacture. Generally in India, careful attention to the factory, through a special man, is the rule. In Lower Assam, coarser plucking is not uncommon; while in Sylhet the tea is not of the same quality; but in all these divisions, the labour question is becoming a very serious one, and entirely forbids the idea of any extensions of cultivation. In the Dooars, there is not the same difficulty about labour; but prices have, of late, become so unremunerative for the teas turned out, that greater care with less quantity is likely to be the rule. The soil is very fine. The idea of manuring to *increased* production, Mr. Alleyn found generally scouted—only to improve quality or maintain the condition of the trees is manuring sanctioned by agents or proprietors.

Altogether, Mr. Alleyn came to the conclusion that not much is to be feared from India for some years, in the way of increased tea exports.

THE TEA WAREHOUSING QUESTION.

[BY AN INDIAN TEA PLANTER.]

The Calcutta correspondent of the *Financial News* recently referred to the possibility of a break in the Indian tea warehouse ring. He said:—"I am told that the warehouse charges as they now stand are often equal to the cost per case of conveying tea from Calcutta to London." I can say positively that this is actually the fact. My disbursements for freight (Calcutta to London) and

warehouse charges for the past two years stand as follows, viz :—

	Freight.	Warehouse charges.	Quantity of tea.
1901 ..	£106 15 1 ..	£112 16 1 ..	67,930 lb.
1900 ...	111 17 3 ..	115 1 6 ..	67,547 lb.

the number of packages being 803 (of which 150 were boxes of 10 lb. net) and 639 full-sized chests.

If complaint is made to the warehouse proprietor that his charges are excessive, he will say he can make no reduction, by reason of the proportion he disburses to the dock companies. This may or may not be so; but it is impossible to get away from the fact that the bonded tea warehouse business is a protected one, inasmuch as there is reason to believe that the Customs authorities have refused to provide officers for warehouses beyond those now existing; further, there are directors and shareholders of tea companies holding interests in some of the existing warehouses; so what they lose at the one game they gain in the other.

These united forces, opposed to the weak combination of the planter-importer, and the lack of unanimity existing in their ranks, result in the payment of practically the same charges to-day as have obtained for years past, when the tea-planting industry was in a prosperous condition.—*H. and C. Mail*, Oct. 17.

A CEYLON PLANTER IN QUEENSLAND,

It was necessary to buckle too here and get an "agricultural billet." So we started work at 5s per day for an Australian

M. I. C.

and did up his flower garden. After a week at gardening we had a few days' compulsory rest and got another job at 4s per day and omnibus fare 6d extra. When working in this way, an occasional cup of tea and some bread and butter were brought out and a short spell from hard labour was much appreciated. Our third gardening billet in Brisbane was a six weeks' job with a quiet family in South Brisbane, the other side of the beautiful new Victoria Bridge spanning the Brisbane River.

THE CITY OF BRISBANE

is very much improved in twelve years and has become a very handsome-looking town. There was great depression in business, of course, and wages were very low, indeed. Situations were very difficult to obtain, employees being dismissed instead of new engagements being made. Even the Queensland Government is "dead broke" or any way very "hard up" judging from their recent dismissal of some old and valued public servants including Mr Wragge, the clerk of the weather, and Mr Bailey, the Government Botanist; also the staff of the Botanical Gardens including the "Ranger" and the "Propagator" and a host of clerks, in different departments of Government service left at the end of June, last, to save some thirty thousands of pounds per annum. It seems somewhat inconsistent to the writer's mind that useful men should be so roughly handled, and about the same time the tax was taken off tea and kerosine oil, making a dead loss to the Government of over £50,000. The labour party are said to have brought this about and it is likely there will be some more thinning out.

To return to my own personal experience: beyond smashing my thumb in a mowing

machine I got on pretty well with my No. 3 Agricultural employer. My last Brisbane boss had a fine collection of French roses trained against the walls around the lawns and tennis court. On the other side was a very costly fowl run or rather four separate fowl runs for prize fowls. In addition to hatching naturally, we hatched artificially by an American Incubator and raised chickens at a temperature of 102°, so that my time was taken up pretty well both by day and night gardening and hatching chickens. The climate of Brisbane during June, July, and August (the winter months) was simply delightful rather cold at 6 o'clock in the morning and after 6 p.m., but a perfect climate for a white man to work in. Now the scene is changed: the hot weather is beginning in September, and the Northern ports of Queensland are awful places for ticks and "scrub-itch," also small ticks that torment a man and prevent him from sleeping at night. The days are frightfully hot and uncomfortable and the water is not particularly good in many places I have had to live in lately. Most of the private houses and hotels are roofed with iron, making them cold before sunrise and as hot as the place where there is no snow at midday. After taking a great interest in my work and raising some splendid drum-head, cabbages, carrots, tomatoes, lettuce, water-cress and other vegetables, in spite of the drought, my boss told me he contemplated leaving Brisbane for a holiday with his family and that I had better find another job. I accordingly wrote to a "Coffee Planter" in Mackay and received a favourable reply: "A three months' job" at £1 per week and

"TUCKER."

The ss. "Aramac" of the A U S N Company was leaving Brisbane for Northern ports. Our passage was delightful, smooth sea, bright moon-light nights and pleasant passengers. Mackay looked green and fresh three months ago, but is dried up now. Driving over the Bridge spanning the Pioneer River we came to an anchor at Cremorne Hotel surrounded by coconut palms. Mrs Keller made me comfortable at Cremorne, and the maid told me there was a good bathing place in the Creek, so we took soap-dish and towel, the former was not required for it was salt water! There was a great kick-up in the town of Port Mackay and big guns went off and *broke the Hotel windows*. Everybody sang the National Anthem and the Band played "Sons of the Sea," it was a warm reception for me and celebrated Peace in South Africa.

MACKAY.

Mackay is a pretty little town with wide streets planted with shade trees in the centre of the main streets. Sydney and Victoria streets possess some good buildings and comfortable Hotels. Trade was very slack. A drive in the mail coach to the Leap through a large number of abandoned sugar plantations and shut down mills made rather a sad impression. There must have been a big sugar boom, for no less than *twenty-five* sugar mills have been shut down. Sugar is still cultivated in a small way, but the price is very low both for cane and made sugar. There is a great fuss about white-grown sugar, but very little of it produced up to date, Indians, Japs, Chinamen and other Asiatics are still working the cane fields and factories, the white man is at a considerable discount and it would

almost pay him to blacken his face! The Leap mail man dropped his letters and newspapers into the respective Post boxes nailed on trees by the road side. The Leap is a high mountain and projecting rock where an Australian "Gin" or native woman took a leap and passed into the next world when the Police were in pursuit of her husband. There is an Hotel and Post office but an exceedingly dead place—healthy situation, but no excitement but Kangaroo shooting and an occasional visit from Swagmen and poor fellows on the *Walaby*. Mrs Hunter at the Leap hotel and Mr and Mrs Hill of the Post-office have been there many years, but are not making a fortune. "Shank's Mare" carried your correspondent to Mount Jukes. We met a mounted bushman rounding in cattle now and again and saw a small patch of sugar-cane here and there with a lumpy or leaf hut. Gum trees—Gum trees—nothing but, gum-trees? No water fit to drink in the creeks, a dried up-country and very uninteresting. We passed one good shaded creek where some ladies were picnicking and overtook me before reaching Mount Jukes. We were tired and covered with ticks on arrival in the house of the Manager of the Mount Jukes Company. The same evening arrived at my destination "Inglenook," Mount Jukes another small coffee plantation opened up by Mr. H. F. Blaxland who had sent for me on a three months' engagement on £1 per week and found in everything. Here I found very good coffee four years old.

THIS COFFEE

had been planted under dense shade, but not found to answer and the shade trees were "barkringed" and the coffee bushes are bearing better this year in consequence. For two months I opened the centres and handled the trees and when engaged at the upper fields carried my lunch to the field after breakfast and a billycan of tea. The crop ripened in June, July and August, and we were gathering crop in September. Australian white boys gathering for five shillings per week and their "tucker" they gathered an average of 100 lb of cherry and had picked six thousand pounds of cherry up to the 6th of September when my engagement came to an end. Taking a cheque for £12 12s 0d for thirteen weeks, I waited in Mackay for a steamer to take me to Cairns where I was in hopes of finding another coffee planting engagement, but was disappointed after the expense of travelling long distances in visiting small coffee plantations. The train took me to the Barron Falls, a distance of 20 miles through 15 tunnels and a fine view of the Barron Falls and the fall of Stoney Creek. There was little water tumbling over the falls, but the scenery was wild and picturesque, the land too steep for planting purposes, only one very small coffee plantation situated upon the falls, the property of Mr. Alfred Street and worked by himself and three sons. The coffee had just given 7 tons from 10 acres and there were 4 acres more that gave less crop—10 cwt. per acre was very fair and the coffee was a good sample though only valued at 5½d per lb. Mr. Street could offer me nothing in the way of employment as he said

HIS COFFEE PLANTATION

only just paid its way working it with his family and a few natives to gather the crop, one son looking after the picking and ploughing between the rows of coffee planted 10×10 feet apart.

Another son dried the parchment pulped by a Gordon-brest-Pulper, the parchment was being dried like tea on trays over a slow fire (rather a new *modus operandi*) in curing coffee for market, after hulling, it is roasted and ground and put up in tins. Mr. Street put me over the Barron river in his punt and we lunched at the Hotel near the Kurunda station, the train left at 4 p.m. to Cairns. Next day I took the steam tram to Hamilden plantation, chiefly sugar with a central mill.

SUGAR—COFFEE—TEA.

Dr. Reed, the Manager, advised me to go on to Hillville Sugar Plantation to see Mr De Moleyns and Mr Butter, but both were away from home and I had the trudge to Hillville through the bush for nothing. Mr De Moleyns was at the Cairns Hotel and told me it was no use going out to his coffee plantation as they were reducing expenditure and looking after the coloured labour themselves—so here I am in Geraldton, another Northern Port of Queensland. Under these circumstances I would strongly advise Ceylon men to stay away from Queensland for there is no hospitality as in Ceylon for a planter looking for a berth, long experience goes for nothing.

A small patch of five acres of coffee on the Company's place was handed over to a Chinaman because it would not pay working expenditure. In leaving Cairns for Geraldton seems to be "jumping out of the frying pan into the fire" for here the Banana gardens are worked by Chinese proprietors and there is no coffee worth mentioning

Geraldton is the only place where there is a good rainfall—120 inches in a year, just the climate for tea, but no one has ventured on its culture, and there is no experimental Government plantation. Mr Howard Newport from India lives at Redlynch near Cairns, and is the "Government Coffee Expert"—up to date he seems to have made a very poor show in the advance of the coffee enterprise.

We had a couple of days Agri-Horticultural Show last week, and I saw a sample of tea made from the bushes grown at Cairns, but it seemed poor stuff. I believe the bushes are to be kept for seed-bearers.

BAD INVESTMENTS.

Now, to give your readers some idea of what has been done in coffee in Northern Queensland the only coffee plantation worth mentioning in Cairns, has cost four thousand pounds to open and does not pay. The Mount Jukes coffee plantation has got about five acres of good coffee to show for six thousand pounds expended; another little patch of 500 trees called the Blackwood Coffee Plantation, cost £1,500 and gave 65 lb of coffee in cherry! Two other coffee plantations in Mackay are abandoned after leaving a heavy loss and Mr Wood, a book-seller in Mackay, offered me one "selection" for £200 (two hundred acres of bush with a Cottage, the coffee was burnt by a bush fire).

The above report by an old Ceylon planter may prevent Ceylon and Indian planters from making mistakes, otherwise, easily made by reading magazine articles written by tourists and globe-trotters who make up a "hash in the pan" article. I hope my next letter will be more encouraging to intending visitors to Australia who want to commence *de novo*,
H. C.

SUBSIDIARY PRODUCTS IN THE CEYLON PLANTING DISTRICTS.

When our Governor Sir West Ridgeway in one of his home speeches said that if Tea were to go, Ceylon might stagger, but would in time right herself, he doubtless had in his mind's eye, the Subsidiary Products in the Planting Districts, together with Coconuts, Cinnamon, Mining and Trade generally, as the ground of his confident hope. Individually none of these subsidiary products may count for very much, nor run in statistical tables into the magnificent line of figures which tea can tabulate; but they are there as helps, and in the event of a disaster to tea—which Heaven forbid—would prove as useful in such distressful times, as cinchona did when coffee suffered its total eclipse and the outlook for the Colony was hopeless in the extreme. Homilies on the ancient text "Don't have all your eggs in the one basket," have been preached in these columns with a persistency which to some, may have seemed tiresome, but cannot by any be adjudged unwise; and to place planters, who were desirous of embarking in a subsidiary way in products other than tea, the *Observer* press has issued from time to time up-to-date Manuals and Handbooks for instruction and guidance, not to speak of the evergreen *Tropical Agriculturist*. We are glad to think that although the wilderness we had to cry in was at one time wide, we have not cried in vain; and today, planting opinion fully recognises the wisdom of having more than one string to the bow, and has acted on it.

The difficulty, which meets the man who is bent on an extension of interests, and a partial insurance for the future, is to find the product that will pay best in the long run. We would emphasise "the long run"; for the energy of the Ceylon planter is proverbial, and it is not once nor twice his zeal has so outrun his discretion that an opening which would have led the few to pleasant fields and pastures new, has been rushed by the many, and trampled into a waste which was profitable to none. We have had cinchona which helped many a man in the transition stage between coffee and tea, turned at last—through overproduction—into a commercial drug in every sense, sinking into chaos. The "deepest deep" which memory can recall in the case of Ceylon produce, being a parcel of "bark" which failed to cover shipping and London charges, and brought as its only return to the unfortunate proprietor—a debit note from London: reminding us of a Kentish fruit farmer who in return for a consignment of plums to Covent Garden, got a memo. showing 1s 6d balance *he had to pay!* Cinchona has not been the only minor product that showed a fair prospect of a decent return for a time and then gradually shrank into the limbo of the unprofitable. There is, of course, an outside public that benefits by all this; but planting is not a purely philanthropic occupation, nor is it run for

the benefit of the outsider; and enterprise is liable to be checked when disappointment so frequently dogs its footsteps. Still, the lesson to be learned from the past is not to cease from doing; but to be wary in your doing. There is a call for men to think for themselves, for independence of action, and for avoidance of the ruinous policy of "Follow the leader."

Among the subsidiary products of the island, CACAO takes a first place, and given a suitable soil and location, it has, on the whole, done handsomely for its growers. It stands, however, more on its own feet than most other by-products, is a cult of its own, needs unwearied attention, special observation, and each tree has to be studied. The scare of the bark fungus has now given the coarser and stronger varieties a first place; but there has been of late a return to the old love, and the plump round red beaned Caracas is again in evidence. "We know now how to deal with the fungus when it appears" say the men who are venturing on it, and as "knowledge is power," the chances are in their favour.

CINCHONA, after years of a discredited life, is again being played with; but there is a fearful pleasure connected with it. Not to speak of the chances of snuffing out—especially in the richer varieties—was there ever a more sensitive market than the bark one? The late slump in prices, brought about by unusually large shipments from Java, was not, we were informed, at all justified by the statistical position of the article. Yet a mere temporary increase in imports was productive of a serious alarm which found unpleasant expression in the lessened value of the unit of quinine. It is clear that cinchona is not a good stand-by for the man who *must* harvest; for if their numbers were to sensibly increase, there would be history repeating itself, and the tale of a vanished fortune would have again have to be re-told.

CARDAMOMS have, for some time, done so well that they have been extended both on estates and in native gardens. Activity too is reported from the world outside Ceylon. Companies, who have properties in favourable localities, sanction grevillea and other fire-wood clearings with cardamoms as an adjunct, to cover in time the cost of the extension; but while exports increase, prices decrease, and as the market for this spice is a limited one, the future is not without clouds on the horizon.

About RUBBER there is a glory. *It*, at least, cannot easily be over-done and Ceylon has shown that it is capable of producing a quality which commands top prices. Its growers are enthusiastic: old planters who meet them, with the pride of possession tinging their speech, are reminded of the halcyon days of cinchona culture, when by a species of simple arithmetic the growing plants were panned into sterling coin, and the owner, who was usually the demonstrator, was proved to be in possession of a prospective fortune. It went in this way:—Bark is worth so much. Each tree carries so many pounds; there are an ascertain-

able number of trees to the acre, and the acreage of the estate is known: hence—and here the calculation ran into thousands. Even when the cautious had allowed 25 aye and 50 per cent for contingencies, what a snack of fat things still remained! Alas! the sequel. But there is less chance of rubber being overdone; albeit in every country of the habitable globe where the tree can be grown, men of all races are today devoting thought and time to its cultivation; while the hovering shadow of chemical research bent on finding a substitute for rubber, is a little disquieting when we recall the fate of indigo.

Other Subsidiary Products Pepper, Nutmegs, Vanilla, Annatto, Croton and such like minor ones, all increase the revenue of estates at little cost, and are each worthy of attention. None of them, perhaps, is usable as a crutch; but valuable as a staff. What each man has to do is to find what he should select as the best adjunct to his primary culture; and, remembering that Agriculture and especially Tropical Agriculture, is subject to many ups and downs.—stick to his subsidiary products till the dark days pass and be ready to profit by the bright ones when they dawn, which they surely will do sooner or later. Ceylon may have produced many disappointments; but it knows nothing of despair.

FORTUNES IN RUBBER.

HOW AN AMERICAN FINANCIAL PAPER REGARDS THE PROBLEM.

One of the American financial papers, namely, "The Daily Financial News," of New York, has a long article on American enterprise in exploiting profitable rubber fields. This article contains a considerable portion of fact, but, when it comes to calculating the prices obtained for rubber it is very much out. For what it is worth, we quote it here:—

"Mexico is full of opportunities for enterprise and capital. The surest, cleanest and often the quickest fortunes are those made by, the intelligent development of the uncultivated resources of nature. "There is in the eastern and southern part of Mexico a long, irregular strip of land 15 or 20 miles wide, which has a soil as fertile as any in the world, and it is in this strip of land that the rubber trees thrive. Another fact that makes opportunity for Americans is that this rich territory, which was once almost inaccessible, is now reached by railroads which have been built through subsidies from the American Government. "By their crude methods the natives killed the trees which gave them a livelihood. Moreover, the native method tended to inferior rubber far from clean. For such crude rubber the natives got about 20 cents per lb. Then came the Americans with intelligent business methods. In the first place, it was obvious that, inasmuch as the supply of trees had been reduced through their destruction by the natives, the first step should be to plant more trees. Immense nurseries were started, the young, broad-leaved plants looking like fields of tobacco. The shoots are set out 400 to the acre. When they have started on a strong, assured growth they are thinned out, usually at six years old, and 200 are left standing. Each tree that is cut down at this stage will produce about 5 lb of rubber worth 70 cents, so that in this process of development each acre produces \$700. In some cases trees are tapped for rubber milk when they are four years old, 400 young trees, tapped by native methods, yielding 41 lb, worth \$30.80 at each tapping. It is usually considered advisable, however, to wait until the sixth or even the eighth year before beginning to draw

the rubber milk. The bark is cut carefully, and only a limited quantity of the milk is taken at a time, so that the tree is not injured and its growth not in the least retarded. From an eight-year-old tree 1 lb of rubber a year may be safely taken. When there are 200 trees to the acre the product of each acre a year would be 200 lb of rubber, worth \$140. This would be obtained without any expense or labour in maintaining or caring for the trees, the only work being the tapping.

ENORMOUS POSSIBILITIES.—"A man owning 100 acres would thus receive \$14,000 a year income. But rubber trees grow rapidly, and as they increase in size the quantity of the rubber milk which they will produce grows in an equal rapid ratio. A tree nine years old will give 1½ lb. of rubber; a tree ten years old, 2½ lb. in the same time; a tree fifteen years old will produce 5 lb. a year, so that 1 acre will yield 1,000 lb., worth \$700, and the product of 100 acres would be worth \$70,000. The enormous possibilities of the rubber business have led investors to buy large tracts of rubber land in Mexico, including Senator Clark, of Montana. Those who have bought rubber lands in Mexico have paid small prices. The land was formerly owned by native plantation owners, who did not cultivate it, being too indolent or too ignorant to develop its resources.

RUBBER FOR MARKET.—"American ingenuity has devised several new methods for getting rubber ready for the market. The milk is drawn from the bark by suction, so that the pure sap is obtained free from the grit, bark, and foreign substances which were always present in such large quantities in the rubber sold by natives. After the rubber milk is obtained the pure rubber is separated from the other ingredients of the sap, in much the same way that cream is separated from milk, by a patent process. In the new method introduced and practised by the Americans there is no waste of sap. By the natives half of it is wasted. When the rubber is coagulated it is tied up in bales and shipped to New York, where it sells at from 75 cents to \$1 a lb. and the total expense of extracting it, separating and coagulating it, and shipping it to the Eastern market, is not more than 5 cents a lb. This shows enormous profit."—*India Rubber Trades' Journal* Oct. 13.

EXTRACTION OF RUBBER FROM BARK.

The question of extracting rubber from the bark of certain rubber trees has repeatedly been suggested and experimented upon. So far, little success appears to have been achieved.

It certainly does not strike one as a very difficult matter to devise a process for the extraction of the rubber from a bark which really contains a fair amount of it. But it is certainly impossible to devise such a process without any direct reference to be operated upon. In other words, a thorough chemical examination of the bark in question is the first step to be taken. Further, there may be a large quantity of rubber in the bark, but it is most likely accompanied by a considerable proportion of resinous matter, the separation of which from the rubber would be quite as important as the elimination of the bark. Otherwise it might be found that the rubber extracted is of such inferior quality as to be almost valueless commercially. This, to a large extent, is what has been found in the various attempts of extracting gutta percha from the leaves of the gutta trees.

The resin accompanying the rubber in the different rubber trees varies very considerably in properties, and unless these are known it is quite impossible to give any directions as to their separation from the rubber. If the amount of

resinous matter present should turn to be so small that its presence in the rubber could be tolerated there would still be the question of the nature of the tissues of the bark which has to be separated from the rubber. Under favourable circumstances, it is quite conceivable that this might simply be dissolved away by a careful alkaline treatment, in which case a very pure rubber indeed might be obtained. But it is impossible to devise an efficient treatment of this kind without a very complete knowledge of the bark to be operated upon.

The first step towards the desired end is therefore obviously a thorough chemical examination of the bark referred to in the enquiry.—[Reply to Messrs C. & Co.—*India-Rubber Trades' Journal*, September 29.]

INDIARUBBER, GUTTAPERCHA, AND BALLATA : TREES SUITABLE FOR NATAL.

BY M. SEHOF,

Most people are under the impression that India rubber and gutta percha are the same product. This is not the case, as they come from different plants, and are used for different purposes. The Latin names show at once the difference—Gummi elasticum and Gummi plasticum—the former being the India rubber and the latter the gutta percha tree.

I once undertook a trading trip from Manaus, at the mouth of the Amazon, up the river in company with an old Spanish 'ragataos,' or trader, to supply the India rubber gatherers with foodstuffs, cotton prints, tools, etc. We bought our goods at the 'aviadore,' or merchant, consisting mainly of Farinha Maniok, carne secca (dried beef), salt, and also a good supply of cheap wine 'vino tinto' (red wine), and a few other things necessary to the seringueiros, or India rubber gatherers. It would take too long to give fuller details of this journey, which lasted close on nine months. I may also say that though I spoke Spanish fairly well I had no knowledge of Portuguese, and yet my partner never once tried to take advantage of my ignorance of the language spoken in those parts. Besides ourselves we had four boys in the boat and about two tons of goods. Without many stoppages, we rowed and sailed till we reached the Tapajós, a southern tributary of the Amazon, and here I saw for the first time how India rubber is collected. Each seringueiro, also called cauchero, has his estrada, or district of about 100 to 150 trees.

The true and best India rubber tree is the *Hevea brasiliensis*, called by the natives Xerringa. There are of course, many other kinds of rubber-producing trees and plants—*Hevea guyanensis*, *Syphonia elastica*, Manihot, etc. It is of the *Hevea brasiliensis* and the Manihot glazowii I wish to write, as of these two in particular I have personal knowledge.

The *Hevea brasiliensis* is a large tree. I have seen some over 60 ft. high; it has pretty yellow whitish flowers, hanging in long bunches. The husk of the seed has a peculiar way of bursting open with a loud noise and ejecting the seed with considerable force. The leaves are large, and set in three on one stem. The cauchero goes out to work either very early or late in the afternoon, to tap his trees. When he is working in a part of virgin forest he very often has to cut his way through the vegetation to get to the tree he wants to bleed, and when there, his first care is to clean the tree and sweep round about. He then cuts with a single tap of his short-handled "machado," or hatchet the bark but never the wood. According to the size of the tree, from 12 to 30 cuts are thus made. He starts as high as he can reach, and comes down

pretty low to the ground, and after each cut he fastens his little tin cup, or 'tigelinhas,' with a little mud under each of the cuts, into which the latex will drop, not flow, from one to three hours. If a slight rain happens to fall it will spoil the rubber very much, and this is one of the reasons why many caucheros prefer to tap in the evenings as it very seldom rains in the evenings. An estrada of 150 trees gives about 35 to 40kg. of rubber in one tapping. Of course, this varies greatly according to the size of the tree, and whether newly tapped or whether they have already been tapped for years. In one year each estrada will be tapped about 20 times, and can thus give nearly 750kg. of raw rubber. The trees are tapped about every two or three days. Having fastened all his cups, he starts again at those he fastened first, and taking them down empties the contents into a tin bucket or gourd; never into iron, as this spoils the colour of the rubber.

If he has far to go to his huts he puts a little ammonia into each bucket to prevent the latex thickening, and if his huts are close at hand, the buckets are emptied into large flat earthenware pans. After the whole harvest is over, the real work of preparing the rubber for the market begins and there are many different ways of doing this. I have personally only noticed two ways.

A large earthenware pot with a narrow hole is filled with wood or with nuts of the uauassu or Urucury palm which are plentiful on the Lower Amazon. Having lighted his fumeiro, the ground is carefully swept, and he puts his pans containing the latex close at hand to the fumeiro. As soon as he considers the smoke thick enough, the cauchero takes a wooden spoon, from four to six feet long (like a baker's peel); the broad flat end of this is first held in the smoke and then dipped in the latex. He allows a moment for any drippings to fall back in the vessel, and then quickly returns it to the smoke. The thin layer of latex sticking to the spoon dries almost immediately the water has evaporated, and the first thin sheet of India rubber is ready. The cauchero proceeds in this way, dipping his palette, or spoon, in and out till he has a lump of rubber about 5 to 7lb weight; he then takes it off. It comes off very easily, and he starts again. These lumps are then dried in the sun for several days, as it is most important to get them perfectly dry.

The other method of smoking is to hold a long stick, which is flattened in the middle, over the smoke and is kept turning round, while the assistants pour the latex very slowly over the middle of the stick till a large roll of rubber is formed. These biscuits or loaves, as they are termed, as soon as they are perfectly dry, are carried on poles to the river stations to be exchanged for goods or money. India rubber of the *Hevea brasiliensis* collected and prepared in this way, commands the highest price of all rubbers in the market. The price varies, according to the quality, at between 42; to 6s. per lb. in the European market.

There are two other trees which I wish to mention, because I firmly believe that both would be suitable for Natal. With one of these trees, the Manihot glazowii (Portuguese 'Manisoba Leitera'), I have had personal experience. At Sylva, which was then the terminus of the railway from Monte Video, Uruguay, the railway manager there gave me 1,500 two year old plants which had come by steamer from Ceara, Brazil, to plant out. The climate of Sylva is considerably cooler and certainly not wetter than that of Maritzburg, and yet these trees thrived well, although the soil was very poor, sandy, and rocky. Out of 1,500 1,200 grew into fine strong trees. They were about 8 ft when planted and in thirteen months stood from 12 to 13 ft high. I had also some seed which were very hard; I soaked them in water for five days, but three months passed before they sprouted. These seedlings in 8 months after sprouting were 4 to 5 ft high.

The Manihot, or Leitera, bears flowers and fruit. The fruit is something like a walnut, but very hard. It is tapped in its third year twice, allowing three days between each tapping. The rubber comes under

the name of 'Ceara scraps' on the market and fetches good prices, about 5s per lb, each tree giving about 500g gum when 5 years old, 700 to 800g when 10 years old, and by careful tapping will last from 50 to 100 years and more. I know of no other trees which increase so rapidly and surely, and which require so little attention.

I have seen the Manihot grow in bare rocky ground, where every other plant is killed by heat and dryness, but the Leitiera looking beautifully fresh and green.

The other tree is the *Bassia parki*, which is a North and Central African tree. I have seen it growing only in its wild state on the Upper Nile. It is also a very large tree, with long, dark green leaves, which stand in bunches at the end of peculiarly marked twigs. It bears a very pleasant tasting fruit, from which the natives make butter, which is known in the market as ghee or Karite butter. The fat of the fruit is also exported largely for the manufacture of soap and candles, and fetches good prices, and latterly the latex of this tree has come on the market as a first rate gutta percha, and has realised 1s 9d per lb. This tree I have only seen wild and have no further experience of it, but I believe it would grow well in Natal, and, what is more, would pay well.

Of balata I hope to write something in another issue of the *Journal*, as I have taken up too much space already.

[I have noticed with great pleasure some criticisms on my article *re P. insignis*. One of these, written by Mr James King, says that this or that particular tree, etc., should not be recommended for Natal. I did not recommend any particular tree, and distinctly said that I only mentioned *P. insignis* as an example how to plant a forest. To recommend any single class of tree for a whole country is, in my opinion, not very safe, and should be left to experts. —M Sehof, St. George's Estate, Hatting Spruit.]
—*Natal Agricultural Journal*, Sept 26.

CONCERNING COFFEE.

An international convention will be held in New York during November for the study of the production and consumption of coffee. At present, little is known of the best varieties as regards quality and methods of cultivation, the most profitable for different markets, amount of consumption and any other information that may tend to improve its use and quality. Hawaiian coffee, when care is taken in its cultivation, harvesting, drying and packing processes is not surpassed by any produced in other countries. Age adds greatly to the value of choice coffee. The pioneers in Hawaii had a practice of drying the berries in the sun for weeks, than bagging and storing for months drying in a loft. Those who can remember drinking genuine Kona coffee, will never forget the delicious aroma that filled the room when it was poured out at the breakfast table, reminding of the fabled "nectar of the gods." Customs change, however, with the passing years, and much of the coffee drunk nowadays is imported from the "faraway." A coffee plantation in Kona, Hawaii, well kept and with its crops well dried and aged, will pay as well now as in years past, if the coffee planters take care to have none but the best sent to market. Genuine Kona coffee is as good today as it ever was, but the older it is, the better its quality. In the American market, the principal coffees are the Rio, Maracaibo and Java. Pure old Kona, when genuine, is better than any of them.—*Hawaiian Planters' Monthly* for September.

THE SILK INDUSTRY IN BENGAL.

In his annual report for the past year, the Director of Land Records and Agriculture, Bengal, states that the work done by the Bengal Silk Committee with the assistance of Government in rehabilitating the silk rearing industry of the Province by teaching the rearers how to eradicate disease, continued to prosper. Malda seems to be a long way ahead of other Districts in the number of intelligent rearers who have learnt modern ideas. Many old rearing houses have been properly ventilated, new houses are being built on approved plans, and the Collector reports that mulberry cultivation is extending all over the District, especially in Gour.—*Madras Mail*, Nov. 11.

FERTILIZING BANANAS.

Experimenting on a banana plantation under irrigation, and where bananas have been grown for 12 years, sulphate of ammonia applied alone, very quickly give an impetus to vegetative vigour; the trees grew very large but produced bunches of very disappointing size relative to the huge plant. On another piece basic slag was applied; this fertiliser is rich in phosphate and lime, the trees were not forced to huge growth as with the sulphate of ammonia, but the bunches produced were very good and well repaid the cost of fertilizing. The bunches were about equal with both fertilizers, but the trees with sulphate of ammonia were the best looking. However, as the basic slag only cost £4 10s. a ton and the sulphate of ammonia, cost £15 a ton; the best net return was of course with the slag. An application of lime alone did not show any results where two tons and-a-half were applied per acre, but where five tons were applied the trees at once responded, the stems were stouter than on the rest of the plantation, and seemed very firm with very strong roots, and the fruit was much improved. Further experiments will probably be carried through with simple fertilizers like Bone Meal, which contains an appreciable amount of nitrogen, and is especially rich in phosphates; and with Coconut Meal from the Oil Factory, which contains nitrogen, phosphate and potash, but is richest in the first named. Then complete commercial fertilizers may be tried, that is, compounds of the different elements containing nitrogen, phosphoric acid and potash, calculated on the needs of the plants, and the soil, as indicated by the first simple experiments with single fertilizers. To get the maximum of crops the soil must be perfectly adapted to the needs of the plant, and the experiments are being carried through at some expense in the hope that some combination will be hit upon that will cause the fields to yield fruit quicker and of a higher grade, when, as in the case with fruit-growers generally in other lands, the result may give a good return on the outlay for fertilizing. The soil being already fairly rich in potash as shown by chemical analysis, no experiments have included potash, but in the great majority of soils, every fertilizer for fruit trees should be strong in potash.—*Jamaica Agricultural Society*, August.

A CRATE OF ORANGE PLANTS—from the Royal Botanical Gardens, Sibpur, Calcutta, arrived in the *Darius* on Monday. The case was consigned to the Secretary for Agriculture.—*W. Australia Morning Herald*, Oct. 29.

MALARIA IN CEYLON.

The *Lancet* has the following on Dr. Chalmers Report on Malaria:—

Dr. Albert J. Chalmers, Registrar to the Ceylon Medical College, has made a preliminary report on the prevalence of malaria in Ceylon, with a view to its prevention. The report contains much instructive and useful information and deals with some points which have hitherto hardly obtained the attention which they deserve. The paper contains three addenda of which the first is devoted to an interesting theory to explain how man and the anopheles originally became infected with the malarial parasite, and the second gives a copy of a pamphlet on malaria which has been distributed to the various stations in Ceylon. The theory of the origin of the disease which is propounded by Mr. A. Perry, Principal Medical Officer and Inspector of Hospitals, Ceylon, raises two points which are not without practical importance. They are: (1) Is it possible that the infection in man can take place by some other means than through the mosquito? and (2) If this be not possible how did the cycle of the life of the parasite start? In his account of the incidence of malaria in Ceylon, Dr. Chalmers first shows that the disorder is a powerful factor in the disease and death rates of the Island, and he proceeds to show that there is a definite relationship between the prevalence of the distemper and the amounts of the rainfall. In reference to the causal relation existing between the climatic conditions and the incidence of the malady the writer says: "There appears no doubt that the reason why so few, sometimes no, anopheles are seen in the dry season for months together—e.g., in Accra and Kumassi, West Africa—and then the sudden appearance of these insects in numbers is due to their hibernation in dark protected spots. They come out again in the wet season, as this is the time *par excellence* when they find the pools of water with suitable algae for propagating their species and, in my opinion, this is the reason of the relationship between malaria and the rainfall." Dr. Chalmers states that at the date at which he wrote his report, he had not had sufficient opportunity of studying the anopheletes and their haunts in Ceylon to make an exhaustive statement on them, but that he had found the anopheles Rossi, an anopheles which resembled ("but not quite exactly") the anopheles vanus, and third which he calls anopheles X, in which the costal margin of the wing was "decorated with two white spots." It is incidentally mentioned that there had lately been a severe outbreak of malarial fever at Katancudy during which Dr. Hallock, who was medical officer there, acted with great discernment and by promptly cleansing the village made at once a marked effect on the disease. Dr. Chalmers gives a brief account of the dwellings and of the habits of the different peoples who live in Ceylon—of the Europeans, Burghers and the Sinhalese, of the Tamils, the Mahomedans, and the coolies. The Hindoos, the Buddhists, and the Mahomedans are particularly liable to infection from mosquitoes, not only because they wear little clothing, but because their religious observances entail their attendance at the temples and at mosques during the night. Rice fields form a suitable breeding ground for the anopheles, and so well is this fact recognised that an Italian law passed as long ago as 1866 makes provision for regulations in regard to the distance from dwellings at which the culture

of rice is permissible. In regard to Ceylon it is thought that such restrictions could not properly be made, but it is suggested that the building of new houses near to existing rice fields might advantageously be forbidden. The importance of educating the people as to the cause of malaria is insisted upon in the report and it is suggested that the best way to accomplish this is to begin in the schools, and that as apothecaries are often sent to remote stations on the occurrence of a severe outbreak of malaria an opportunity should be given to them to learn how to take blood-films and how to recognise the anopheles and its larvæ. Such a course of study, it is noted, might advantageously be given at Ceylon Medical College. The most interesting points which the report shows may be briefly summarised as follows: (1) malaria at the present time is epidemic in Ceylon only in certain localities; (2) the island contains many anopheletes and the conditions which exist there are peculiarly suitable for their development; (3) a large proportion of the existing anopheletes are not infected with the malarial poison; (4) coolies affected with malaria are constantly being introduced from India to Ceylon. There is, therefore, a possibility that malaria may become more prevalent if these facts are not realised. The mode of spread of the distemper will be this, Coolies suffering from the disease will go to a part of the country which contains healthy anopheletes. The anopheletes by sucking the blood of the infected coolies will become affected, and in their turn will infect men previously free from the malady. Dr. Chalmers is justified in his belief that "anyone suffering from malarial fever in a country in which the anopheles abounds is a danger to public health." In the report this teaching is given as a personal opinion, but it is a fact about which there can be no shadow of a doubt, and Dr. Chalmers rightly founds his recommendations as to prophylaxis on the certainty of its truth.

COCONUT PLANTING IN BRITISH NORTH BORNEO.

In March of this year I visited a coconut plantation in British North Borneo and took the following notes, which may be of interest to some of your readers. Distance from Sandakan, two hours by steam launch. Six thousand coconut trees planted in 1896, of which 1100 are now in bearing, and the balance will all be in bearing in two years. Judging by the crop now on the trees and the usual yield in the district, the probable crop will be at least 3000 nuts per acre when the trees are in full bearing. Present selling price, \$36 per 1000 delivered in Sandakan; present value of dollar about 1s 9d. Arrangements have been made to plant other 9000 trees this year; terms, fifty cents per tree to be paid to the contractors when the trees are three years old, during which time cash advances are to be made to the contractors for food.

Fourteen families were engaged on the new plantings, and when I visited the plantation with the agent he told me no advances had yet been made, although the contractors had been at work some months clearing away the jungle and preparing the land for planting; but on coming away the agent showed me a list of moneys asked for by the contractors amounting in all to \$175, or about a sovereign to each contractor. I did not see the new coconut plantings, but I was told that most or all of the new land had been planted, and this was the first advance.

The contractors on this plantation are Philipinos, some of whom migrated to British North Borneo during the late war with America. The contractors are allowed to plant foodstuffs between the coconuts, such as potatoes, yams, bananas, pineapples. They soon have a stock of poultry, and nearly all the contract money should be in hand at the expiration of the contract time. Labour can be obtained in plenty for this kind of work. After the third year the chief work is to keep down the jungle growth, which should not cost more than \$3 per acre per year, and in the fourth year cattle may be introduced, and the cost of clearing the jungle will become still less. The great enemy of young coconut trees is the wild pig, but this plantation has not, so far, suffered much. Under the present contract system the loss, if any, during the first three years will fall on the contractors. Where wild pig are plentiful a barbed wire fence seems to be a safeguard against their depredations, which rarely continue after the third year.

I visited the manager's house, situated on the edge of the sea beach, and under the shade of the coconut trees now in bearing—a pleasant, breezy spot. He told me the drinking water was good, fish cheap and plentiful, poultry in plenty, and pigeons of several kinds could be shot. Meat was scarce, as it had to be brought from Sandakan. The manager was leaving, as the heavy work connected with the opening of the new plantation was finished, and the present acreage is too small to afford a European superintendent. I estimated the acreage at 200 acres, allowing seventy-five trees to the acre. The trees were planted too close, and it would be better to pay the contractors a little more and only allow fifty trees to the acre.

A smaller estate than 400 acres should not be attempted, as the living expenses of a European manager would be too heavy on a small acreage. The total cost of planting 400 acres I estimate at £7 to £8 per acre, which expenditure would be extended over seven years. In this estimate I have allowed a very liberal sum for unforeseen contingencies, and I allow £120 to £150 sterling a year for living expenses (salary of the proprietor until the trees come into bearing, after which the salary would probably be about £1 per acre. After the seventh year there should be an appreciable crop. One hears of coconuts bearing in five or six years, but it would be better not to rely on any appreciable crop until after the sixth year, and an average of 3,000 nuts per acre (allowing fifty trees to the acre) would probably not be obtained over the whole plantation until the tenth year, after which a certain amount of manure would be required to maintain this output.

I estimate the profit from 400 acres of coconuts at £2 to £2 10s per acre. The duration of a coconut estate seems to be unlimited. When the trees are worn out new ones are planted. The price of coconuts seems to have been well maintained for the last century. Mr. John Ferguson published in the *Ceylon Observer* about twenty years ago a list of prices obtained in Ceylon for coconuts from the beginning of the century, which showed a steady rise in value, and since 1880 the price of coconuts has risen considerably, partly due to the increasing quantity of soap made from coconut oil, and partly to the demand for coconut kernel in sweetmeats.

Young men with some capital who are willing to devote ten or twelve years to the task would find coconut planting in British North Borneo a very enjoyable out-of-door life, with plenty of leisure and a fairly certain income when the trees come into bearing. Very little knowledge is required by the coconut planter, and that little can be acquired while the trees are growing. The only caution I would offer is as regards selection of land. The prospects of a planter are rendered more favourable if the soil is good, and if labour, communication, and food supplies are duly taken into consideration when selecting the land. A railway has lately been made seventy miles along the west coast of British North Borneo which passes

through good land for coconuts, and is being extended thirty-three miles into the interior. I should advise land being taken up in the vicinity of the railway. When the interior line is completed it will be pleasant to go to the hills for a change. Very fine deerstalking can be obtained on the higher level. On the lower levels near the sea snipe abound in season, also wild duck, and, for those who want big game, both wild cattle and rhinoceros are to be had in British North Borneo. Wild elephant exist on the east coast, but a somewhat prohibitive tax of \$150 has to be paid for each elephant.

From the foregoing it may be gathered that a coconut planter's life does not entail much hard work. Before the plantation comes into bearing the amount of attention required is not sufficient to fill the time of an able-bodied European, and it would be as well if the proprietor could obtain some additional employment; but when the trees begin to crop, the supervision of the collection of the nuts and their sale, as well as the upkeep of the plantation, would afford a pleasant out-of-door employment, with plenty of leisure.

H. W.

—Field, Oct 18.

THE PEARLING INDUSTRY OF NORTHERN AUSTRALIA.

According to "Australasian Hardware and Machinery" for September, a report on the pearl-shelling industry in Northern Australia has been furnished to the Federal Government by Judge Dashwood, the Commissioner specially appointed for that purpose some time ago. At Port Darwin, according to this report, the industry gives employment to 291 persons, and at Thursday Island to 2,214, or 2,505 in all. Of the owners some 35 are Europeans, but 13 are Torres Strait islanders, while all the drivers are coloured—more or less. The Commissioner is of opinion that, given better wages and conditions of living, white men might be obtained to undertake the work, but he is satisfied that the industry could not be profitably carried on with the increase of expenditure which this would entail. Some time ago the transference of the headquarters from Thursday Island to Merauke, in Dutch New Guinea, was spoken of, but the Commissioner thinks this port would be altogether unsuitable. In 1900 the pearl-shell raised at Thursday Island was valued at 116,697*l.* A report by Mr M S Warton, the resident magistrate at Broome, Western Australia, on the pearling industry in the north-west of that State, has since been laid before the House of Representatives. It confirms Commissioner Dashwood's conclusion that the industry cannot be carried on by white labour alone. In Western Australia, says Mr Warton, 618 persons are engaged in pearl-shelling, of whom only 110 are white men. As indicating the value of the trade to the Commonwealth, it is shown that from the fleets engaged in collecting pearls 20,000*l.* is paid yearly in Custom's duties.—*Board of Trade Journal*, Oct. 23.

MICA MINING IN INDIA.

A very acceptable volume on the subject of the Mica Deposits of India, written by Mr T H Holland and published in continuation of the series of memoirs of the Geological Survey of India, has just been issued. It is of a far more entertaining character than have been many of its predecessors; and the writer has not scrupled in his descriptions of the mica mining industry to be as interesting as if the volume were not a scientific treatise. The primary object of the work is to

describe the Indian occurrences of mica commercially valuable, and of course this only implies a very limited area. Mr Holland points out that such an area must necessarily be restricted in extent as the combinations of circumstances necessary for the formation of mica-crystals of the proper size and without the flaws commonly produced by earth movements are always restricted in extent. I therefore follows that large mica deposits are commercially very valuable to the country which possesses them, and according to Mr Holland India possesses an area which should give her a good share of world's trade in mica, and at any rate should make mica mining of far more importance than it is at present. Mica appears to have been used in India in the past very extensively as medicine, it was considered to have magical as well as medicinal properties. Of course it is now used in India principally in the manufacture of ornaments. But mica is being largely used in other directions abroad, and as has been mentioned is a valuable commercial asset to any country. Mr Holland therefore mentions that it would not be very surprising if Government were to show an inclination to temper the encouragement already given to the mica miner with restrictions intended to discourage his wasteful methods of mining and the tendency which he has shown, not unnaturally, to secure immediate returns by want only excavating shallow workings over large areas. The paper is also intended to convey to the mica miner a brief resume of the nature and history of the mineral in which he is so largely interested. It is rather doubtful, however, whether the book will ever find its way to those who follow the industry and if it do whether Mr Holland's erudite discursion on the mineralogical and chemical characters of the mineral will be properly understood and appreciated. The mica deposits of India appear to be fairly widely distributed. The Tibet border, the Bombay Presidency, Burma, Central India, and the Central Provinces, Madras, and Mysore, the Punjab, and Rajputana, all claim valuable mica quarries, and there is not the slightest doubt that properly worked and safeguarded the mica mining industry could be developed to a far greater extent than it is at the present time. Considering that mica is now so largely used in the electrical industry exportations of the mineral would doubtless be heavy and profitable. Although the volume contains a good deal of information that will be of use in the industry itself, it is chiefly a mineralogical record, and as such it is complete and satisfactory.—*Bombay Gazette*, Oct. 6.

THE TEA BONDED WAREHOUSE RING.

A correspondent of the *Financial News* of October 23 writes :—"Allow me to add my testimony to the excessive charges made by the warehouses on the unfortunate tea Importer. Following the lines of your correspondent, 'An Indian Tea Planter,' in your issue of the 17th instant, here are the disbursements of an Indian tea garden for freight and warehouse charges, as well as the amount and value of the tea grown for the past two years :-

Year.	Tea sold.		Freight.			Wareho. Chs.	
	Lb.	Value.	£	p. c.	£	p. c.	
1901	90,514	3,171	135	4 25	165	5 20	
1900	141,826	4,360	243	5 57	220	5 04	

"The number of chests for 1901 was 1,087 and for 1900 1,455, being a total of 2,542. You will observe that the statement of your Calcutta correspondent, that he was told that the warehouse charges are often equal to the cost per case of conveying tea from Calcutta to London, is amply borne out by the above figures, where for 1900 the ware house charges amounted to 5 20 per cent of the value of tea, as against 4 25 per cent paid for freight,

This, however, is not the only grievance of which the importer has to complain in regard to these charges, though whether the warehouse proprietors are responsible for it I cannot say. The importer, before he can obtain possession of his tea, has to pay through his broker the charges for freight and warehousing, which, of course, no one complains of; but when he comes to receive his account sales he finds that he is charged, in addition, interest at 5 per cent for three months on both charges; so that on the above sums, amounting for the two years to £763, he is mulcted to the tune of over £10. One would naturally suppose that if these charges did not fall due for three months the importers should receive, and not pay interest. But it is 'the custom of the trade' one is told, and has meekly to submit. Again, should the importers wish to delay receiving the proceeds of the sale until prompt date—viz., three months—'the custom of the trade' comes in, and he is forced to take a cheque, less three months interest at 5 per cent, and which he has to deposit with his bankers, who will barely give him 3 per cent for it.

"Take, besides these iniquitous warehouse charges and the others already referred to, those for brokerage, agency, and miscellaneous, and can it be wondered at if the lot of the tea planter, with the price at 5 1/2d-6d per pound, is at the present time not a particularly happy one? To make one's meaning perfectly clear, copy of pro forma account sales is appended :-

ACCOUNT SALES OF TEA, &C.

AGRICULTURE IN CEYLON :

(In connection with subjects treated of in the "Agricultural Magazine.")

IRRIGATION

has done much for Ceylon. It has changed Anuradhapura, or rather the North-Central Province, from a howling, fever and parangi-stricken wilderness, into a fertile, smiling garden. It has done and is doing the same in other neglected parts of this island. In spite of Mr. Digby, it is doing much on the opposite continent to minimise the effects of recurring famines.

Now South Africa has come under British Rule, the attention of its administrators has been turned to irrigation. Mr. Wilcocks, C.M.G., M.I.C.E., has reported to Lord Milner that on irrigation, and irrigation alone will depend the permanent development of the country. Agriculture is neglected for gold and diamond mining and is, what it was fifty

years ago. It is primitive; and farmers move from the highlands to the lowlands and *vice versa* with the seasons. The necessity for irrigation is accentuated by the fact that the rainfall is uncertain and erratic. Water must be stored during the season of heavy rainfall, for use when the seasons are dry. Mr. Willcocks has experience of irrigation in India and in Egypt, and speaks of the "immense benefits" derived from irrigation in those countries. He makes a novel suggestion to raise the necessary funds for irrigation works. The mine-owners should be compelled by law to devote a percentage of their profits towards the execution of irrigation works, so that when the mines are exhausted, the country may not drop from the "height of prosperity to the depths of poverty"!

BETEL CULTIVATION

is carried on all over the island, but on a large scale, only in certain villages. Along over the main line of railway, the bulk of the traffic in betel leaves, is from Mahara and Henaratgoda. Why this is so, I cannot say. It may be that the soil of these villages is peculiarly suited for its cultivation. It is known to be a very paying crop, and a small plot of land planted with these vines is known to yield quite a respectable income. I doubt, however, whether the local yield can equal the reported yield in the Madras Presidency, which is said to be at the end of the first year R30 per acre per mensem. The vines in the island are trained on dead wood and are closely planted. In Madras, they are trained on "Katuru Murunga" trees, which are first planted on the land. The vines are evidently very carefully tended and cultivated in India, for it is said that they receive half-yearly supplies of annual renvenno and the delicate vines are fed with milk! In the island, the only manure used is, I believe, the leaves of the "Keppetiya."

"THE PROPER METHOD OF PLANTING TREES"

is a very useful and instructive article. It is written by Mr. A. Despeissis, of Western Australia and refers to the planting of orchards. However, there are many hints in it which will be useful to all classes of planters in the island. Holes should be wide enough to admit of the spread of the roots—the wider the better. Coconut planters take special note of this, especially those planting on stiff soils. A very good method of securing wide holes, is to fill them by cutting the surface soil all round them. By this means, a 3 in. by 3 in. hole nearly doubles itself. Where the sub-soil is stiff, it is said the holes should not be deeper than the free surface soil, else the hole acts as a basin for the retention of water and the roots of the plants rot and they die. One of the most troublesome of planting operations, is to plant in straight lines. It is difficult enough to line straight, but in cutting and filling the holes, the pegs are displaced and in planting, subsequently, the lines are hopelessly destroyed. A method is suggested for placing a plant exactly where the peg was, which, unfortunately, will not be found practicable on tea plantations, except at a prohibitive cost. The zig-zagging of the lines of a tea estate, are not very apparent owing to the formation of the bushes, but breaks in the lines of

COCONUT

trees, are an abomination and an eye-sore. The method suggested is to take a long narrow plant and cut a V shaped notch in the centre and at each end. Place the plant on the ground with the peg at the centre notch. Drive pegs deep into the ground at each notch at the ends of the plant, remove the centre peg and cut the hole to the required dimensions. When planting, place the plant on the ground so that the notches at the ends will fit into the pegs on the ground, and place the plant where the centre notch is, which will be the exact spot where the living peg was originally. All this may be slow and tedious, but it will ensure good work, and whatever is worth doing, is worth doing well.

For a hard impenetrable soil, as is occasionally met with on the cabook hillocks of

COCONUT PLANTATIONS,

it is suggested that the bottom of the hole should be shattered with dynamite or blasting powder. Crevices are formed which permits of the free passage of water and of roots. An idea is very prevalent amongst coconut planters, that placing the plants deep down in the holes is the perfection of planting. The evils of this system are seen in seasons of wet, when it becomes necessary to remove the plants from the holes, and plant them outside, to prevent their dying off. My system has always been to fill up the holes to within one-foot at the outside from the surface, however deep they may have been cut. This writer deprecates deep planting for the same reasons that I hold.

According to a lecture by Mr Orpen, the head of the Agricultural Department at Rhodesia, the

CHENA CROPS

in that country are similar to those in India and Ceylon. The crops are

INDIAN CORN, KURAKKAN

and what is called *kambu* in India. The first is consumed in the form of meal converted into porridge or bread and beer. For long journeys, the corn is parched or "sprung." In this form, it is called "porri" here and is always to be seen rendered by "kadala," or parched gram, women. The "sprung" corn ground and mixed with a little salt forms the ration of native soldiers on the ward. In a six weeks' march against Langahalele in 1873, the native soldiers were provided with the meal of parched corn and were able to perform the march successfully on this nutritious diet.

"KURAKKAN"

is supposed to be the most nitrogenous of farinaceous grains. The natives consider it more nutritious and satisfying than other grain. The same opinion obtains in the Wannie and other interior districts of this Island. A villager will, by preference, have a meal of kurakkan to one of rice. It is more satisfying, possibly owing to its indigestibility. He says he can go for a whole day on a meal of kurakkan, while before half-a-day is over, he grows hungry on a meal of rice. It is eaten in the form of "pittu" with scraped coconut, or boiled and made into large pills, dipped into curry gravy and pushed down the throat. Mixed with honey, it is made into "halapa." Ceylon has not as yet developed a trade in the export of its fruit. Perhaps time will help in the development of this trade, and a few notes on the packing of fruit for export, will be useful. The first requisite for the successful transit of fruit is careful picking. Fruit should not be allowed to drop on the ground and be injured. They should not be packed immediately after picking, but should be laid out for a few days to "harden" and for the superfluous moisture of the skin to dry up. In transit, cold chambers destroy the flavour. Cool, ventilated chambers are necessary. It is best that each layer of fruit should have a separate chamber, or in large cases, such as barrels, the lower layers of fruit, have to bear the weight of every thing above them. Valuable and large fruit, should have a compartment for each. Mangoes for export should not be picked ripe, but when "full" and ripening during transit.

GUATEMALA COFFEE CROP DESTROYED.—A San Francisco firm which is interested in the coffee business in Guatemala has received a cablegram, states Reuter, from its representative in that country stating that the entire coffee zone has been destroyed by the recent volcanic disturbances, and that enormous losses have been sustained. The eruption of Santa Maria continues. The coffee plantations are buried beneath several feet of sand and ashes.—*Westminster Budget*, Oct, 31,

TEA BUG OF ASSAM.

A DISPUTED POINT.

Mr H Harold H Mann, B Sc., contributes the following notes:—As is well-known *Helopeltis theivora*. "Tea Bug of Assam" as it was called by Mr Wood-Mason, the "Mosquito Blight" as it is generally termed—is the most alarming pest which has yet appeared on tea cultivated in India. It causes the more disquietude as it tends to increase as years go by,—fluctuating according to season, but generally increasing and invading new areas. During 1901, which was a particularly bad year in almost all districts subject to the pest, a very moderate estimate gives seven lakhs of rupees as the nett loss to the Indian Tea Industry from this cause alone.

Though we have a knowledge, thanks to Peal, Wood-Mason, Dudgeon, Watt and Green, of the general life-history of the insect from the egg to the adult stage, yet there remain several points which have been very obscure. Of these the most important is the question as to what becomes of the insect during the time when it apparently disappears from the tea bush. So complete is this disappearance, as a rule, that most planters living in affected districts in North-East India have hardly ever seen a single insect during January, February and March. Mr Dudgeon has suggested that it hibernates in the ground, but offers no evidence for his position, and declares frankly that he had not been able to verify his conjecture. It has also been supposed that hibernation takes place in water and swamps, but again, not a scrap of evidence in favour of the view exists, and the same may be said of the very general idea among tea planters that in the cold weather the *Helopeltis* goes on to various jungle trees.

With a view of acquiring information on this point, I have spent a considerable time in January, February and March of the present year in two of the districts most affected by the pest—Darjeeling-Teraï, and Cachar—at a period when the insect was supposed to be hibernating. As a result I have come to conclusions, of which the following is a summary. The *Helopeltis theivora* can be found on the tea bush in every stage of development during every period of the year. The cold weather kills off the bulk of the mature insects and practically all the larvæ, but at all times sufficient remain to carry on the pest to the next season, and in addition the bushes are full of eggs. These latter were found not only in the usual position on the young shoot, but also at a much lower part of the bush than had previously been noticed embedded in the usual fashion in the mid rib of the large mature leaves. The larvæ were found on 11th January in small numbers on unpruned and sheltered bushes, then forming about 2 per cent of the total number of insect caught. By 12th February, however, a very different proportion of adults and larvæ were obtained, and now instead of 2½ per cent the larvæ formed 80 per cent of the total catch. This proportion was approximately kept up during several weeks from that date. The difficulty in obtaining evidence of their presence at this time is due to their attacking almost entirely the slightly shaded young leaves, the surface growth being rarely injured in the early part of the year.

The insect could further not be found on any jungle plant at this time. Though jungle of very miscellaneous character was systematically searched both by myself and by the children who are regularly catching the insects and who are extremely expert at the work, not a single one was discovered in any form.

It appears, therefore, evident that there is from present knowledge no need to assume a hibernating stage at all for *Helopeltis theivora*, and that the insects remain and can be found in every stage of growth from the egg to the mature female full of eggs in the tea-bush, at all times of the year. Whether the egg found low down in the bush, as described above can be considered as a special hibernating egg, I can hardly say, but there certainly was no difference

in structure or in method of deposition from that usual during the regular season. Inasmuch, then as there is absolutely no evidence of the cold weather being passed by the insect in the soil, in water, or on other trees, and furthermore, as careful observation can always detect the insects and their eggs on tea bushes in affected districts, there is no need to imagine any hibernation stage at all in India, and beyond a certain retardation in development due to the reduced temperature, the reproduction of the insect may be considered to take place in a similar manner throughout the year, and to be carried out on the tea bush itself during the whole period. These observations have a practical interest, and may lead to a sound method of attempting to deal with the pest, and experiments in this direction are now in progress.—*Indian Daily News*, Nov. 10.

THE LONDON CIRCULAR ON THE
TEA CESS.

Dear Sir,—I am instructed by the Tea and Produce Committee of this Association to hand you the enclosed copy of a letter, dated 22nd September, 1902, from Mr A C Kingsford, Chairman of the Planters' Association of Ceylon, embodying a resolution of the Thirty Committee, dated 13th September, 1902, and to ask whether you are prepared, on behalf of the interests that you represent, to agree to the proposed increase of the Tea Cess from 30 cents to 50 cents per 100 lb.

I am further instructed to invite an expression of your opinion generally, and any suggestions you may have to make, as to the appropriation of the funds at the disposal of the "Thirty Committee."

At a meeting of the Tea and Produce Committee, held on the 22nd October, the following resolutions were passed, and are communicated for your information:—

1st.—"That, while the Committee approve of the encouragement given to the Green Tea industry, they do not consider it necessary or desirable at the present moment to increase the Cess as recommended by the 'Thirty Committee.'"

2nd.—"That the following suggestions put forward by Mr Rutherford meet with their approval:—
"That the 'Thirty Committee' guarantee 4 cents per lb. bonus on 7,000,000 lb. of green tea out of the 1903 Cess, which it is proposed should not be increased over its present rate, and in the event of there being insufficient funds from which to pay a bonus on green tea exported in 1903 in excess of 7,000,000, then the payment of the bonus of 4 cents on such excess quantity shall be a first charge on the unexpended balances for advertising, etc., and on the Cess of the following year."

Answers to this circular should be sent in on or before the 10th November, 1902.—I am, dear sir, yours faithfully,

WM. MARTIN LEAKE, Secretary.

61 and 62, Gracechurch Street, London, E. C.,
27th October, 1902.

PROTECTION OF BUILDINGS AGAINST
LIGHTNING.

There is a subject of great interest to people out here, as elsewhere, says "Max" in *Capital* of 30th ultimo, and that is how best to protect their buildings against destruction by lightning. The question has been discussed over and over again. I remember a good many years ago the *London Times* opened its columns to a lengthened correspondence on the point as to whether the

ordinary lightning rod which is considered so essential to all our chimney stalks and church steeples, and which appears to be so highly resented by the cock on the top of the Scotch Kirk in Calcutta as interfering with the dignity of his environment, was really of any use as a protection against destruction by lightning. At the end of that discussion, in which many experts took part, the balance of evidence inclined towards the opinion that the ordinary lightning conductor was really of very little use for the purpose for which it was erected, and that very often it was a positive danger to the building. Since then the "lightning rod" question has often cropped up for discussion, and always some little contribution to our knowledge on the subject, mainly gained by observation and experience, has been added. Again, I see there is a discussion going on, and a new generation is anxiously asking what engineers have to say on the best methods of protecting buildings from destruction by what we call lightning. *The Scientific American* says: "The rod should traverse the edges and peaks of the roof and the lower parts should go to the ground at all the corners of the building for best protection." The terminal points must go to wet earth, or into a well if one is handy. This looks like, not one rod, but a complete network or cage of rods. The journal above quoted also states that no insulators should be used on the rod. So far, *The Scientific American*. And now come the conclusions of a number of scientific men who formed themselves into a Lightning Research Committee, and which seem to bear out the American opinion. After nearly a year's investigation, these scientists found the old theory of the protective value of a single rod on a church steeple or tall chimney completely exploded. They found that lightning often struck a building and committed damage within a few feet of the conductor. The conclusion arrived at was that if a thorough protection of a building is possible, it can only be effected by a network of protectors spread over or around the building, and with many earth connections. It would be interesting to have the views of the chiefs of the Indian P W D on this subject, and it may be as well for all those who are living at ease under their old fashioned lightning rods to bestir themselves, and get into copper cages at once. All the unsightly single lightning rods that disfigure our public buildings may as well come down, in view of the proved fact that they are not only absolutely useless but may turn out to be sources of positive danger.

THE CAMPHOR INDUSTRY OF FORMOSA:

The camphor factory at Taikwan, one of the two most promising camphor districts near Taipeli, had to be closed the year before last (says the *Kobe Chronicle*) on account of the havoc wrought among the trees by the aborigines. The same course had to be taken at Nansho a few months ago, and this factory has also discontinued business. We now learn from the vernacular paper that it has been arranged to start the manufacture of camphor at Taikoyo, near Gilan, and that charters have been granted to the Komotsugumi and other firms. The yield of camphor during the present fiscal year at Taikoyo will, it is estimated amount to about 360,000 cattie. Preparations for the new station are now being pushed forward.—*Overland China Mail*, Oct. 25.

JAVA CINCHONA AND QUININE.

Notwithstanding the increased monthly shipment of cinchona bark from Java to Holland during 1901, prices realised were satisfactory. At the auctions in Holland the unit price rose from 7'25c in January to 10'45c in June, only, however, to recede to 7'65c in December. The average unit price was 8'30c for the ten auctions held, and the average percentage of quinine in the bark was 5'45 per cent. The equivalents of above quotations in sterling are:—

Currency.	Sterling.
Cents.	d.
7'25	1'45
10'45	2'09
7'65	1'53
8'30	1'66

The exports of bark from Java during last year compared with those of the four previous years are as follows:—

Year.	Quantity.
	lb.
1901	13,901,586
1900	12,068,718
1899	12,414,402
1898	12,123,310
1897	8,498,726

The quantity of sulphate of quinine produced by the Bandung factory and sold at auction in Batavia during 1901 was 1,014,000 oz. (English). The average price paid was 1 l-10d per oz., the equivalent of 1 7-10d per unit. The bulk of the quinine was shipped to the United States and London. Some parcels were also forwarded to Australia, British India, China, Japan, and the Straits Settlements.

The following are particulars of quantities sold and average prices realised at Batavia auctions last year:—

Date of Sale.	Quantity in oz.	Average price per oz.
February 27	120,000	11'67 pence
April 3	103,000	12'88 "
May 15	104,100	13'52 "
June 19	96,100	13'32 "
July 21	84,400	12'21 "
September 5	62,000	11'34 "
October 9	111,300	11'66 "
November 13	183,400	11'34 "
December 18	144,000	11'44 "

—*Tea.*

A NEW SYNTHETICAL GUTTA-PERCHA.

I thought we should not have to wait long. There has been such a lot of artificial, synthetical, and other wondrous kinds of rubber announced to the world that it is only fair that gutta-percha should at last have a look in. And it has got it. The "Electrical Review" tells us that "synthetical" gutta is an accomplished fact. But if anyone standing outside the rubber industry wishes to see what a farrago of nonsense and ignorance is looked upon as information to the rubber trade, and, alas, others besides he should peruse that article—and ponder.

That this artificial preparation is capable of replacing gutta-percha for insulating purposes, even for submarine lines, is by no means impossible, but it will take several years' practical test to establish beyond doubt the stability of this new preparation. On this point it is difficult to prophecy without even knowing the constituents of the new Gutta. All that can be said is that this stability will be determined by that of its most

unstable constituent, and as soon as this is known we shall be better placed for making a forecast.—*India-Rubber Trades' Journal*, Oct. 27.

HORNSBY-AKROYD OIL ENGINE.

We think the facts set forth in the advertisement of this oil engine are of sufficient importance to merit calling special attention to the same; for, we are told that "it has now been demonstrated without doubt, that the 'power-bill' for the whole of the island could, on a very conservative estimate, be reduced by one half, by using liquid fuel in a Hornsby-Akroyd Oil Engine." No doubt there are other "Oil Engines" which also show capital results according to the testimonials advertised to the value of "Campbell's," "Cundall's," "Clayton and Shuttleworth's," &c. The great matter is the economic gain by using liquid fuel.

PLANTING NOTES.

THE VINEGAR CURE.—"DC S" writes to the *Madras Mail*.—One of my chaprasis, whilst leaning up against a door post, suddenly jumped with a shout and then almost doubled himself up nursing his leg and groaning that the pain was shooting up to the top of his thigh. The cause of all this bother was discovered in the shape of a vigorous young scorpion which had landed its symmetrical sting in the calf of the chaprasi's leg, I almost at once had the calf well rubbed with vinegar, and in a very little while afterwards the chaprasi looked up with a beaming smile on his face and, much to the gratification of the other servants who were looking on, remarked to me:—"Sirkah babut atcha dawai Sahib." He was up and attending to his work in 20 or 30 minutes time as if nothing whatever had happened.

GOLD, GOLD EVERYWHERE!—Here is a bit of a warning for Sir West Ridgeway and any others who may expect to find paying gold deposits in Ceylon. In the *Empire Review* for November, "T. B.," writing from the Gold Coast, West Africa, says:—

"The colony, of course, can claim to be a gold-bearing country, and in my opinion and many others, that is all that can be said for it. Every yard of it I believe to be gold-bearing, but it is so fine and well distributed that it is well-nigh impossible to collect it; you can take a bit of float quartz from almost any part and get a colour from it, but still no reef has been found above water-level, and water-level is no great depth in this country (averages 100 feet) and no indications in leaders to denote better gold below. I am speaking from experience (from sinking shafts, striking leaders and following and from adit levels with 100 feet of backs), also I am situated so as to come in contact with some of the most prominent engineers that have been engaged in reporting on properties in West Africa. Nothing sensational has been met and certainly nothing is expected in that line. As things stand at present so much capital has been thrown into the country that companies are in duty bound to spend more till they get decided reports on their ventures; read what papers you will, in none can you find a report giving satisfaction or proving by the value of the mine. Promises, yes, by the score, but nothing tangible, and I do not think there ever will be."

A GOLD CURRENCY.—There are bankers in our midst who decidedly prefer gold as a currency if only there was silver to back it; and no wonder—for one small package of gold will bring as much value, as 25 packages with 3 lakhs of rupees. Think of, the extra trouble and cost in counting and packing, in freight, in delivery, in checking, etc., etc.!

"THE COARSER PRODUCT OF INDIA AND CEYLON!"—The *North China Herald* (October 1st) commenting on the report on the trade of Hankow "the future Chicago of China" says:—The gross value of the trade, in spite of a short tea crop and a serious falling-off in shipments of the leaf, "falls little short of the value for 1899 when the highest figures recorded for any year were reached. The business in black tea showed a considerable decline, but there was a marked recovery in the export of brick and tablet tea. When tea was the great staple of Hankow, and the British public had not been led away by its cheapness and strength to prefer the coarser product of India and Ceylon, the trade of Hankow was mainly in British hands; what was then known as "muck and truck" now bulks very largely in Hankow's exports, and it seems that Continental buyers can pay better prices than their British competitors for the hides, nutgalls, wood oil, vegetable and animal tallow, bristles, skins, sesamum seed, etc., which make up the deficiency caused by the decline in the demand for China tea.

CULTIVATION OF SUNFLOWERS.—The first year of the twentieth century closed with a curious sale, at the Baltic sales-room, of a cargo of Sunflower seeds, which changed hands at £11 5s per ton. Though a small trade has been done in Sunflower seeds for nearly 200 years, this transaction was the first in which a whole cargo—300 tons sent from Odessa—was dealt with. In Russia, where the cultivation of the Sunflower and the manufacture of oil from its seed is conducted on a large scale, the variety *grandiflora* is the one grown. The species rises in a slender stalk of 5 feet high, producing one monster head, the average yield being as much as 50 bushels of seed to the acre. So rich is it in oil, that that quantity of seed will yield 50 gallons of oil; while the refuse of the seed, after this quantity of oil has been expressed, weighs 1,500 lb. when made into cattle cakes. Few people in England who grow the Sunflower for ornament have any idea of its usefulness. It is among neglected crops in which there is money. Besides the seed, every other portion of the plant can be utilised. The leaves furnish an excellent fodder; while in Russia the stalks are prized as fuel, and their ashes, which contain 10 per cent. of potash, are readily sold to the soap-makers. Naturally in Russia the chief virtue of the Sunflower lies in the oil contained in its seed. The oil is of a clear, pale yellow colour, almost inodorous, and of an agreeable mild taste, so that it is in great request as a table article. Why Sunflowers are not cultivated on an extensive scale in England, it is difficult to say. Poultry and cattle like the seed, either in its natural state or crushed and made into cakes. No plant produces such fine honey and wax; when the flower is in bloom, the bees abound in it.—*Journal of the Department of Agriculture of Western Australia*.

TO THE PLANTING WORLD.

Seeds & Plants of Commercial Products.

Hevea Brasiliensis.—Orders being booked for the coming crop August-September delivery 1902, booking necessary before the end of April, quantities of 100,000 and over at special low rates. Plants available all the year round, 100,000 and over at special low rates. A leading Rubber planter in Sumatra, who purchased 50,000 seeds in 1899, and 100,000 in 1900, writes us, under date 15th November, 1900:—"I received your letter of 20th October, from which I learn that you added another case of 5,000 seeds to replace the loss, &c. I am satisfied hereby, and even after this adding I am satisfied by the whole delivery of this year." Special offer, post free on application.

Castilloa Elastica.—True superior variety cultivated in Mexico, seeds from specially reserved old untapped trees. Orders booked for August-September delivery 1902, immediate booking necessary; large quantities on special terms; Plants in Wardian cases.

A foreign firm of Planters writes under date 11th October, 1901:—"We beg to enquire whether you would procure us 100,000 Castilloa seeds, in which month we might expect them, and what would be the average price." Special offer, post free on application.

Manihot Glaziovii.—Seeds and Plants available all the year round, 100,000 and over at special low rates. A Mexican planter in sending an order for this seed wrote on the 22nd August, 1900:—"If they arrive fresh and germinate easily I may send you larger orders, as they are for high ground where the Castilloa does not thrive."

Ficus Elastica.—Seeds available in May-June; booking necessary before the end of March; also plants.

Mimusops Globosa (Balata) wood of the tree is much sought for buildings, fruits sweet like a plum and eaten, oil from seeds, said to yield as much as 45 lbs. of dry rubber per tree per annum, the milk is drunk and when diluted with water used as cow's milk, grow from-sea-level up to 2,000 feet, orders being booked for seeds and plants, price on application.

Cinnamomum Zeylanicum (Cinnamon superior variety).—New crop of seed in April to June; booking necessary before the end of February, also plants.

Coffee Arabica, Liberian Hybrid and Maragogopie Hybrid.—New crop March-April; immediate booking necessary.

A foreign Agricultural Department writes dating 9th September, 1901:—"Please accept our order for 175 lbs. of Tea seed and for 2,000 Coffee beans. In regard to Coffee seed I would say that this will be the first importation made by this department, and we will leave the selection of the varieties to be sent to your judgment."

OUR DESCRIPTIVE PRICE LISTS.

The following six Descriptive Price Lists are now being forwarded with Circulars and special offer of Seeds and Plants of Rubber and other Economic Products:—

1. Tropical Seeds and Plants of Commercial Products, enlarged edition for 1902.
2. Seeds and Plants of Shade, Timber, Wind-Belts, Fuel and Ornamental Trees, Trees for Road-sides, Parks, Open Spaces, Pasture Lands, Avenues, Hedges, and for planting among crops (Tea, Coffee, Cacao, Cardamoms, &c.)
3. Seeds and Plants of Tropical Fruit Trees including Mango grafts.
4. Bulbs, Tubers and Yams.
5. Orchids—Ceylon and Indian.
6. Seeds and Plants of Palms, Calamus, Pandanus, Cycads, Tree and other Ferns, Crotons, Roses, Dracinas, Shrubs and Creepers.

Special Arrangements made with foreign Governments, Botanical and Agricultural Departments, Planters and others for supplying seeds and plants of Commercial Products in large quantities.

"SOUTH AFRICA."—The great authority on South African affairs of 25th March, 1899, says:—"An interesting Catalogue reaches us from the East. It is issued by WILLIAM BROTHERS, Tropical Seed Merchants of Henaratgoda, Ceylon, and schedules all the useful and beautiful plants which will thrive in tropical and semi-tropical regions. We fancy Messrs. Williams should do good business, for now that the great Powers have grabbed all the waste places of the earth, they must turn to and prove that they were worth the grabbing. We recommend the great Powers and Concessionaries under them to go to William Brothers."

Agents in London:—MESSRS. P. W. WOOLLEY & Co., 90, Lower Thames Street.

Agent in Colombo, Ceylon:—E. B. CREASY, Esq.

Agent in British Central Africa:—T. H. LLOYD, Esq., Blantyre.

Telegraphic Address:

J. P. WILLIAM & BROTHERS.

WILLIAM, HENARATGODA, CEYLON.

Tropical Seed Merchants,

Liber's, A.I. and A.B.C. Cdes used.

HENARATGODA, CEYLON.

Correspondence.

To the Editor.

DIFFERENT EUCALYPTI (GUM TREES.)

Botanic Gardens, Sydney, Oct. 2.

DEAR SIR,—Noticing a remark in your Journal for September, page 196, I beg to inform you that the botanical name of the Tuart is *Eucalyptus gomphocephala* D.C. and that of the Crimson Flowering Gum is *E. ficifolia*, F.V.M.—Yours faithfully,

J. H. MAIDEN, Director.

A NEW REMEDY FOR MALARIAL FEVER.

London, Oct. 8.

DEAR MR. EDITOR,—In looking over the *Tropical Agriculturist* of the 1st September, I read on page 188 that "Brucea Sumatranæ is said to be as much a specific for dysentery as quinine is for malaria." This is no compliment to the drug because it is well-known now that quinine is not the medicine to take for malaria, and it is being abandoned in all parts where it is possible to obtain the extract made from Cassia Beareana. This remedy has been tried by hospitals in the United States, after reading the interesting account of the cure that this plant effects when it attacks the blackwater fever. From your remark I should think that you had not seen the book I am enclosing herewith, which is a republication from the "Lancet," and some remarks by Mr. Holmes appended.

Men are going out now to the East and West Coasts of Africa and also to Central Africa, with supplies of this drug, because they do not now dread attacks of this severe form of malarial fever, known as blackwater fever.

One doctor from the United States reports that one of his patients was attacked on the 16th May, 1902. He took quinine sulph. 8 grains on Friday, the 16th May and had a subsequent attack. He then took Cassia Beareana 30 drops in water every two hours, taking 1oz or a little more altogether. He had no subsequent attacks. The blood was examined on the 16th May, 1902, and contained the tertian parasite; on May 21st it was examined again and there was no sign of any organism. This shows how thoroughly the drug does its work.

If you know of anyone who would like to make experiments with this remedy, we should be pleased to send some if they are unable to obtain it out there.—Yours truly,

THO. CHRISTY.

GREEN TEAS.

London, Oct. 8.

SIR.—I am pleased to see much more attention given in the direction of making "greens," if only the proper class of greens could be turned out. In London it would appear that a large quantity could be placed if Ceylon arrived anywhere near the class of China greens asked for.—*Colouring greens*: now is it to be checked is the question put

The "Thirty Committee" should take up this, and endeavour to arrive at some method of check, as to colour tea bids farewell to Ceylon's boast of *Pure Ceylon Tea*. "TEA."

CACAO IN 1877 AND 1902:

A LEAF FROM THE PAST.

Among old papers we came across the following letter never published before:—

Gang Warily Estate, Gampola, Oct. 16, 1877.

DEAR SIR,—I enclose for the benefit of the readers of the *Observer*, and more particularly for those who are taking an interest in the advancement of the Cacao cultivation enterprise, some valuable information received from Home in the shape of an extract from the "Journal of Applied Science" for 1874,—a *multum in parvo* of all that relates to the cultivation and preparation of Cacao for the market. As this new product is exciting, and, I think, deservedly so, a good deal of attention at present in the Spicy Isle, the matter embodied in sheets sent, seems to me to be particularly applicable to its growth in Ceylon. As the enclosed is a copy of a copy some errors may have crept in, but, I daresay, they will be immaterial. I trust Sir James Longden will take an interest in this new industry in which his past experience would be sure to be a valuable help and guide to intending pioneers, and with a little encouragement from Government in the way of supplying plants of the most approved kinds, etc., a creditable future for this fine plant and excellent beverage may be safely predicted. There may be failures at first—but, if at first you don't succeed, why just "try, try, try again"!—Yours truly,

CA' CANNY.

[Referring the above to the writer, it has brought us the following very interesting reminiscences.—ED. T.A.]

Dolosbage, Oct. 16, 1902.

DEAR MR. EDITOR,—I was much interested in reading my old letter bearing date, 16th October, 1877, exactly a quarter of a century ago, and it recalled to my recollection all the early anticipations and struggles with this grand product. What sanguine estimates we used to frame, when Old King Coffee gave us the go-bye, of the new products which, we hoped, would take its place—Cinchona, Liberian Coffee, etc.—gone, gone, are all the old imaginary figures. How nice they looked on paper; but they may have served a purpose in keeping up one's spirits during troublous times. Even "Queen" Tea looks as if she were going to follow suit!

I think you will find by turning up old *Observers* that I was one of the first to call attention to cacao as worthy of cultivation. Hearing that there were old cacao trees on Pallekelly estate, I made a special visit there. I forget the date, but it shows it was an early one for the old trees I saw were in a neglected sort of state, and the late Mr. R B Tytler was not then very enthusiastic about its cultivation on a large scale.

The cacao article from the "Journal of Applied Science," I have carefully read over, and consider its matter good; but, of course, modifications must be made* when adapting it to the state of things

* Much that has been written in our *Tropical Agriculturist* and in Mr. Hart's useful little book has placed the article of 23 years ago out of date.—ED. T.A.]

in this beautiful Isle of the sea. I have no special remarks to make on cacao generally. There are younger and more up-to-date cacao planters now in the field who would be able to give you more information than I can. After 1896 I had personally little to do with it. Up to about that time I got fair yields from my place, and very good prices. Then the price went down with a run and cacao had to take a back seat. Tea was all the go, and chief favourite, and no wonder, seeing that it was more easily dealt with in planting, preparation, freedom from pests, and as giving quicker and better returns.

I consider this climate rather wet. My cacao elevation is from (say) 1,600 to 2,000 feet above sea level. My oldest trees were planted (with a view to extended cultivation) in November 1873—seed at stake, and they are still to the fore, though I must say *Helopeltis* has made its withering mark on some parts. Were I a young man, I should like to have another innings at cacao in spite of all the ills it is heir to, and they are many!

Experience, capital and suitable land there is no getting on without, and a lot of attention must be devoted to it from first to last. Cacao and Para Rubber should do well together. I wonder there is not more grown in Native gardens—a *la native* coffee—where there are hundreds, yea thousands, of ideal spots suitable for its growth. The prevalence of stealing is a great drawback. A villager cannot grow vegetables or fruits, etc., but some rascal, who toils not, watches his opportunity to rob, and the poor cultivator is left lamenting. And that is the reason a large quantity of unripe fruit and vegetables is brought to market.—Yours truly,

J. D.

GREEN TEA: A QUERY.

16th Oct.

DEAR SIR,—It would be interesting to know from manufacturers of Green Tea what outturn or percentage from leaf, for say a whole season, is generally secured as against that made into Black Tea, conditions being equal.—Yours truly,

VERDANT GREEN.

[The experience of some of the larger Green Tea manufacturers in Ceylon is, we believe, that they get quite as large a percentage of green tea from a given quantity of leaf, as they did formerly of black.—ED. T.A.]

HUMIDITY OF THE ATMOSPHERE.

Katugastota Estate, Oct. 18.

DEAR SIR,—Will you or any of the subscribers to your paper tell me how to work out the humidity of the atmosphere, *i.e.*, given the temperatures shown by the dry and wet bulb thermometer how can the humidity of the atmosphere be deducted.

HUMIDITY.

[The following table gives the information your correspondent requires: the saturation point being

taken at 100, the figures give the percentage of water vapour in the air:—

Difference between dry & wet bulbs.	Temperature of dry bulb thermometer.									
	60	62	64	66	68	70	72	74	76	78
0	100	100	100	100	100	100	100	100	100	100
2	88	6	88	6	89	5	90	5	90	5
4	76	5	78	5	79	4	80	4	81	4
6	66	4	68	4	71	4	72	4	73	4
8	58	4	60	4	63	4	64	4	66	3
10	50	3	52	3	55	3	57	3	59	3
12	43	3	46	3	49	3	51	3	53	3
14	37	3	40	3	43	2	45	2	48	2
16	32	2	35	2	38	2	41	2	43	2
18	28	2	31	2	34	2	36	2	38	2

Example.—What is the humidity when the dry bulb thermometer shows 86 and the difference between the dry and wet bulbs is 9°?

For temperature 84° and difference 8° the table gives 64; the difference for 1° being 4.

For temperature 84 and difference 9° the percentage is therefore 64+4=68.

Now with diff. 8° and temp. 84° the p'tage is 64 (from table.)

“ 8° ” 92° ” 66 (from table.)

For a diff. in temp. of 8° the diff. p'tage is 2 increasing, and “ for ” 2°

Hence the percentage of humidity at 86° with a difference of 9° is 60+ $\frac{1}{2}$ =60½%.

H. O. B.]

SEED OF “GMELAIIA ARBOREA”: A CHANCE FOR THE MANAGER OF ABBOTSFORD AND OTHERS.

October 20.

[To the Editor “Tropical Agriculturist.”]

SIR,—With reference to the letter in your number of 1st October, 1902, from “John Fraser,” I have the honour to state that there is a large amount of *Gmelia arborea* in the forests of the North Coimbatore division, and that I could supply him with seed at the proper season (March-June). This year was a magnificent seeding year and had I only known in time I could have supplied him with a large amount. Unfortunately, a heavy seeding year is generally followed by one or two bad years and so I have doubts about being able to collect large quantities for the next year or two. I should like to know about what amount Mr. John Fraser requires.—I have the honor to be, Sir, your most obdt. servant.

A. W. LUSHINGTON,

District Forest Officer, Coimbatore (North).

SILK-PRODUCING MOTHS.

Peradeniya, Ceylon. 20th Oct., 1902.

DEAR SIR,—By *Attacus taprobanensis*, your correspondent alludes to the insect now referred to as *Attacus atlas*, Linn.,—popularly known as the "Atlas" moth, the largest and one of the most handsome moths found in Ceylon. Our other representatives of the same family are the "Tussar Silk" moth (*Antheraea paphia*, Linn.) and the "Moon" moth (*Actias selene*, Hubn.). All of these species produce silk of a certain economic value; but they belong to the family *Saturniidae* which—though allied to—is distinct from the family *Bombycidae* to which the true silkworm (*Bombyx mori*, Linn.) belongs. With regard to the suggested crossing of domestic with wild forms, it should be noted that *Bombyx mori* (the true silkworm) is distinct, not only in species, but in genus and family also, from any of the large silk moths of Ceylon. *Bombyx mori* does not occur, in a wild state, either in Ceylon or India. It is a native of China, whence it has been introduced to all parts of the world.

It is a well-established fact that crosses, even between closely allied species, almost invariably produce infertile offspring, (e.g. mules). In the present case, where the proposed parents are separated by three stages of affinity (species, genus and family), I think it extremely improbable that

1stly,—the insects could be induced to pair:
2ndly,—if this initial difficulty were overcome, the resulting ova would probably be unfertilised:

3rdly,—If fertile eggs were actually produced resulting in healthy larvae which reached maturity, the hybrid moths would—almost certainly—be themselves infertile.

Under these circumstances success seems to me very problematical. However, the experiment can do no possible harm and, if your correspondent wishes to try it, there should be no difficulty in obtaining living cocoons of *Attacus atlas*, which is a fairly common species in Colombo. Any of the Colombo taxidermists (Mr. Lazarus for instance) could probably procure them in numbers. Packed in a light box, they should reach Algeria in good condition.

The known food-plants of *Attacus atlas* are "Mahogany" (*Swietenia mahogany*), Cinnamon, *Mimocylon umbellatum*, *Osebeckia* sp., Tea *Camellia*, Cardamom (*Elettaria cardamomum*), *Cinchona*, and *Phyllanthus emblematica*. The caterpillars have also been raised—in captivity—on apple leaves.

E. ERNST GREEN,
Govt. Entomologist.

GREEN TEA: QUERY AS TO PERCENTAGE FROM LEAF.

Oct. 21.

DEAR SIR,—I see no response to my query as to outturn of green tea from leaf. My experience does not agree with that of the authority you quoted in foot-note to my previous letter on subject. "Ball," in his book on green tea-making in China, puts

down 23 per cent as outturn of dry tea from leaf (panning system) and I am sorry to say that my experience, by steaming process, during a considerable period, coincides with this. Being a matter of so great importance to all concerned I hope others may be induced to give results of their experience.

—Yours faithfully, VERDANT GREEN.
[The authority we quoted for 25 per cent was backed by experience on several estates in a wet district.—ED. T.A.]

SALT AS MANURE.

Oct. 21.

DEAR SIR,—Can it be that the Government is at last awakening to a sense of its duty to Agriculture in one particular direction, with which the *Observer* has identified itself for years past? The Planters' Association, I believe, at one time sought to induce the Government to issue salt at special rates for manurial purposes, but it failed in its efforts. That must have been in prehistoric times. I can recall the agitation in your columns for the past 10 to 15 years, editorially and through intelligent correspondents, in order to convince the authorities that salt can be denatured so as to render it unfit for human consumption, and that, even if such salt can, by washing or otherwise, be used for food, efforts so to use it would be too infrequent and too seldom successful, to be regarded as a danger to the revenue or to be weighed in the balance against the benefits which agriculture and stock will derive from cheap salt. The Government Agent of the Western Province is said to have sent a sample of salt to at least one low-country planter, and made inquiries which point to an early concession. If such be granted, all honour to the Lieut.-Governor, during whose administration light seems to be dawning on the official mind.—Yours truly,

PROGRESS.

TEA AND ITS ENEMIES.

Shawlands, Lunugala, Oct. 22.

DEAR SIR,—I am enclosing you, $\frac{1}{2}$ dozen tea leaves all spotted over—as were the coffee leaves I sent to your office in 1870. The only difference, so far as I can recollect, is that those were yellow underneath. Have you seen anything like this before? I trust it is nothing serious—and I am yours faithfully, CHANNING ESDAILE.

[Our veteran friend Mr. Esdaile, who goes back further in Uva and Rangala than any planter now at work in Ceylon, brings "days of old" to mind with a vengeance, when he recalls what happened in 1870. In the previous year *Hemileia vastatrix* was seen for the first time in Ceylon in Madulsima, and how it spread and wore out coffee we need not repeat. Tea, we are glad to assure Mr. Esdaile is in a very different position: it has its enemies, especially in blights affecting the leaves of which this is one. We have seen bushes, often, we believe, similarly affected; but to make sure will send on the leaves to Mr. Carruthers for examination. In the meantime Mr. Esdaile

understands the vast difference between coffee and tea: in respect of pruning and of getting rid, by burning, of any pest affecting the leaves of tea in a way that could never be done with poor old coffee.—*Ed. T.A.]*

GREEN TEA: REPLY TO "VERDANT GREEN'S" QUERY.

Galpothagama, Horana, Oct. 23.

DEAR SIR,—In answer to "Verdant Greens'" query *re* percentage of outturn made tea from the green leaf in making green tea—the average outturn for a whole season would be about 22 per cent: daily outturns varying according to weather from 21 to 23 per cent—Yours truly,
"GREEN TEA."

[We are taken aback by this result obtained on a large lowcountry plantation, in view of the 24 to 25 per cent we were assured was obtained on other well-known places. How is the difference to be explained?—*Ed. T.A.]*

ELK DEER (GONAMUWA) AND OTHER KINDS OF DEER IN CEYLON.

Veyangoda, Oct. 24.

DEAR SIR,—On enquiry from the Director, Colombo Museum, as regards the different kinds of deer in Ceylon, I have been favoured with the following reply, dated 21st October, 1902:—"In reply to your letter of 18th inst., the following are the different kinds of deer found in Ceylon. 1, sambur or elk (*gona*); 2, chhubal or spotted deer (*ticmwa*); 3, muntjak or red deer (*velimuwa* or *oluwa*); 4, mouse deer (*meeminna*)." I find that there is another very scarce and peculiar kind found in Ceylon, called elk deer (*gonamuwa*), in colour somewhat similar to that of elk, a quite distinct kind, size and shape same as spotted deer, there are two rows of small white spots about half inch close, each on the back only, inside the ears, round the eye-brows and top of the tail is white. To anyone interested I can show a tame pair of this deer under one-year old. You may give my name and address.—Yours faithfully,
OWNER.

[The writer adds "The pair of elk referred to are to be seen at the Kola Estate, of Mr. J. P. Williams, within 1½ mile of Veyangoda railway station on the cart-road.—*Ed. T.A.]*

RAIN GAUGES AND MEASUREMENTS.

Columbia, Hewaheta, Ceylon, Oct. 25.

SIR,—My rain gauge have been a puzzle to me the last week. Perhaps you would help me to solve it. 8 find my gauge is 5 inches in diameter area= 19'635 inches (sq). Measuring glass is 1 6/ inches in diameter area = 2'4052885 inches (sq) How is the computation worked out that 4½ inches deep of water in measuring glass = 50 of rain?—Yours,
W. E. T.

[Our correspondent will be glad to have the following from a competent scientific authority:—

Suppose 50 inch to have fallen in the rain-gauge: the area of the gauge being 19'635 square inches, the total volume collected will

be 50 × 19' 5 = 9'868 cubic-inches. Now since this amount is received in a measuring glass, the area of which is 2'405 square inches, it will fill it to a height equal to 9'863 = 4'08 inches.

2'405

The difference between this result and 4'50 (the height measured by your correspondent) is due to the rounding of the bottom of the measuring glass and the irregular thickness of its sides. Its capacity is thus less than it would be if the interior were of the perfect cylindrical shape assumed in the above calculation. Measuring glasses are generally graduated by actual experiment.—*H. O. B.]*

THE EUCALYPTS AND THEIR OILS.

The Technological Museum, Sydney, Oct 25.

The Editor, "Tropical Agriculturist."

SIR.—I have much pleasure in forwarding by this post a copy of the work on 'Eucalypts and their essential oils' just completed at this Museum. It is the result of years of research on living material in the home of these interesting and valuable trees.—Your obedient servant,

RICH. F. BAKER, *Curator*,

[A notice of this very useful and important publication when it is received, will appear in due course.—*Ed. T.A.]*

DEER IN CEYLON.

Hambantota, Oct. 26.

DEAR SIR,—In connection with the letter *re* 'Elk Deer' in Friday's *Observer*, the deer referred to is the 'hog deer' or 'swamp deer' of India, the 'paddy field' deer of Ceylon, *Axis Porcinus* of Naturalists. It is found from Polgahawela through the Mirigama, Veyangoda, and Kalutara districts down to the Southern Province where it reaches as far East as the Matara district.

It is one of the four real deer found in Ceylon, of which the other three are the 'Elk' (the 'Sambur' of parts of India), the spotted deer (the 'Chitul' of parts of India) (*Axis Maculatus*), and the Muntjak, barking deer, rib faced deer or jungle sheep of Indian and Red deer of Ceylon sportsmen, 'Khakur' and 'Bukri,' of the N.-W. Provinces and Deccan, respectively, (*Cervus Aureus*).

The spots mentioned by your correspondent are always visible in the young of the *Axis Porcinus*; but disappear as the animal grows older when it assumes the slaty dun colour of the 'elk,' whence the combined name 'Elk-deer' in Sinhalese as the Sinhalese never, by any chance, speak of the Elk as a deer. It is, because of the spots in the other species when young and which are entirely absent in young elk that this last gets one of its scientific names of *Rusa Unicolor*.

The mouse-deer is not a deer.

W. F.

"SATURATION OF THE AIR."

DEAR SIR,—Will you kindly give the following information through the medium of your paper?

What is the maximum minimum and average mean degree of saturation of the air in Colombo?

How do the figures compare with Bombay, Madras and Calcutta?

How do they compare with Kandy and Nuwara Eliya?

What is meant by the term complete saturation of the atmosphere?

ONE WHO WANTS TO KNOW, YOU KNOW.

[Our scientific referee kindly answers the enquiry:—

"A given volume of air at a given temperature can hold a certain quantity of water vapour in the state of transparent gas. When this quantity is exceeded, the water vapour condenses into spherules which become visible as mist, fog or rain. The air is said to be saturated when it holds the greatest possible quantity of invisible vapour. The figures given in the above tables represent the proportion of invisible water vapour in the atmosphere at the time, to the maximum amount it can hold in that state; the latter being represented by 100.

	Mean		Yearly	
	max.	Month.	min.	Month. Avr.
Colombo	... 82	June	69	Feb. 77
Kandy	... 88	Aug.	62	March 71
Nuwara Eliya	... 92	Aug.	54	Feb. 76
Calcutta	... 90	Aug.	75	April 83
Bombay	... 88	Sept.	66	Dec. 78
Madras	... 85	Oct.	61	June 76

"The absolute maximum rises to 100 at every station in every heavy rain-storm. The absolute minima recorded are:—

Colombo	53 in April, 1884.
Nuwara Eliya	41 in March, 1892.
Kandy	41 in March, 1899.

"I regret I cannot supply you with the same information at the Indian stations.—H. O. B."]

TEA LEAVES FROM MADULSIMA.

[Here is Mr. Carruthers' report on the affected tea leaves sent us very lately by a Madulsima planter.—Ed. T.A.]

Royal Botanic Gardens, Oct. 29.

The diseased spots on these leaves are on naked eye or lens examination not typical of any of the injuries caused by any of our known fungi. The Government Entomologist to whom I showed the specimens, tells me that he has seen similar spots on tea leaves in upcountry estates, but was unable to find any proof of their being of insect origin.

On making sections of the leaves through the diseased spots, and searching under the microscope very little mycelium of a fungus is to be found and only in dead cells of the leaf. On the surface of the leaves are to be seen many of the fruiting stalks of a fungus *Penicillium sp.* These are confined to the dead portions of the leaf at the centre of the discoloured spots. As the fungi named *Penicillium* are all saprophytic, i.e., living on dead matter, it is probable that this fungus is an after effect, and not the cause of the disease. I have, however, begun an experiment of inoculating some leaves on a healthy tea bush with spores from these leaves, and will note if any effect is produced, that is if the fungus will grow on living tissue.

The material sent is not sufficient for a diagnosis of much value to be made. The earlier stages should be examined and the conditions under which it arose should be known.

All such leaves should be taken off and burnt and it should be noted whether there are any fresh cases after the old ones are removed,
J. B. CARRUTHERS.

GREEN TEA AND PERCENTAGES.

Nawalapitiya, Oct. 31.

DEAR SIR,—I have made Green Tea for the past two years and all you can turn out in a 12 months inclusive of fannings and big yellow leaves picked out, is 22½ per cent. The man, who can turn out 25 per cent on his blacks (unless he goes in for crediting 5 per cent below his actual plucking for each day) is a smart man and deserves well at the hands of his agents and employers.—Yours truly,
C. T.

INDIAN HEMP—OR "GANGA."

Oct. 31.

DEAR SIR,—Could you tell me what the law is as to the cultivation of Cannabis Sativa? I mean on a large scale, for it is a common thing in certain parts of the Island to see a few plants of "ganga" growing round dwelling houses. The produce of cannabis goes into the hands of the private moorman.—Yours truly,
D.

[We do not think there is any Ordinance at present in the local list prohibiting the cultivation of Indian hemp, any more than of the poppy; because in deference to the Buddhist prohibition of such drugs, nothing has ever been done in Ceylon worth notice in this direction. But it will certainly become necessary now, in view of what our correspondent states, to pass such a law regarding the cultivation. Very possibly under the Opium or Bhang Ordinance any one turning the hemp or poppy into drugs for personal use or sale, can be punished.—Ed. T.A.]

CURE FOR RHEUMATISM.

Colombo, 9th Nov., 1902.

DEAR SIR,—The following reference to a new "cure for rheumatism" taken from *Country Life* is worth reproducing.—Yours truly,
D.

About a year ago there was published in a London paper a recipe for the cure of rheumatism. Since then scores of people have written to thank the editor for it, many of them informing him that the simple prescription cured them after having been unsuccessfully treated by three or four physicians. Others, who have heard of the cure, have asked us to reprint the prescription. Everyone either suffers from rheumatism or knows someone who does, and we recommend our readers to paste the recipe on a card-board and take great care of it. Lord Anson feeling that it was a shame that such a recipe should be so little known, paid £300 to a medical man for the privilege of making it known to the public. These are the ingredients:—Sulphur 1 oz.; cream of tartar 1 oz.; rhubarb ½ oz.; gum guaiacum 1 drachm; honey 16 oz. A tablespoonful of this is taken night and morning in a tumblerful of white wine—hock, for instance—and hot water.

CENTIPEDES vs. SCORPIONS.

Galle, Nov. 3rd, 1902.

DEAR SIR,—There is an excellent native remedy for the bites of centipedes and scorpions. A mixture of burnt coir yarn and coconut oil applied to the bite will not only relieve the pain, but prevent any ill-effects by reducing the inflammation. The application should be continued for a few days till the swelling disappears.—Yours faithfully,

A.

CEYLON OOLONG TEA.

EXTRACT OF LETTER REFERRED TO FROM MR. C. P. LARKIN.

Toronto, Aug. 11, 1902.

Why do you not take up the matter of Oologs? As the case stands today you know that when we fought only with Ceylon Black teas we made extremely little or no headway with the Japan tea drinker, but when we gave him *his kind* of tea we made rapid headway. So far we have practically not touched the Oolong tea drinker, as the taste for Oologs is just as distinct as the taste for Black or Green Tea. Now the samples that I have had sent to me from some of the Gardens in Ceylon prove conclusively that Ceylon can produce a tea so much better than the ordinary Formosa Oolong and yet of similar character that with proper handling it will entirely displace those teas. Events have proved that my judgment in the past has been right in regard to Ceylon Blacks and more recently in regard to Greens; therefore I think my judgment should be taken in regard to Oologs. Besides it would benefit perhaps another class of Planters, that is, the owners of the high-grown Estates on which those fine Ceylon Oolong samples were produced. If there has been some grumbling on their part that the Green Tea Industry will only benefit the low-grown Estate Planters, why there will be reciprocity between them, each benefitting the other, as the Committee will be using their funds to create a demand for both kinds of tea. As to prices: you know that far better prices are paid for Oologs than for any other kind of tea. And as to any interference with the trade you have now, why there will be no more than if you were introducing Ceylon Cocoa, for as I said before *we are not touching the Oolong tea drinker to any extent today* nor do I expect that we will in time with Black or Green teas. If Ceylon had had Greens as well as Blacks with which to commence the campaign in America, you would not be sending less Black here than you are today, but *you would be sending infinitely more pounds of tea*. And if you add Oologs to your productions you will in no way injure the Black or Green Tea trade, but simply place another weapon in our hands with which to wipe out the productions of China and Japan. Do not throw this Oolog aside.—Yours truly,

(Signed) P. C. LARKIN.

RAW RUBBER NOTES.—The Balata export from the Dutch Colony, Surinam, amounted in 1901 to 237 tons, of a value of 593,475 guilden.—The German Consul of Cochabamba reports that, according to the Bolivian Government in Puerto Acre, the caemchone exported from the districts of Acre, and Aquiy amounted to 49,350 bales, weight 2,032,422 kilos.—The biggest quantity was shipped in May, namely, 125,374 kilos.—San José de Costa Rica exported in 1901 58,687 kilos, of raw rubber of a value of 76,293 dols.—*India-Rubber and Trades' Journal*, Oct. 27.

PLANTING NOTES.

THE VALUE OF GYPSUM as a dressing for grass land is now being shown by the appearance of a paddock in the Droon district, Gippsland, owned by Mr William Martin. Last season, Mr Martin states, he used eight tons of Haesell's 'Corso' gypsum, and the result has attracted the notice of many farmers and graziers in the district, who have noticed the vivid green of the dressed land. One paddock which was being attacked by grubs was dressed with 1½ cwt. of gypsum per acre, the result being that all the grubs were destroyed, and there is now a splendid sward of pasture.—*Agricultural Journal*, Oct. 10.

CURING VANILLA.—A Nilgiri correspondent writes to the *Madras Mail*:—It has now been established beyond all doubt that this valuable orchid can be successfully grown in this district. The planter whom I mentioned in some previous Notes as having taken up its cultivation has from 3,000 to 4,000 plants growing. Any intelligent Kurumber can be made to understand the artificial fertilisation of the flower. The culture would appear to be very simple. In Mexico shoots about 3 feet long are fastened to trees on the approach of the rainy season, and scarcely touching the ground. These soon strike roots attached to the bark and form plants which begin to fruit in three years, and remain fruitful for 30 or 40 years. The curing of vanilla pods is a tedious process and calls for the exercise of a good deal of care and judgment.—*Indian Gardening and Planting*, Nov. 13.

PROSPECTS FOR GREEN TEA: NEW MACHINERY.—*Indian Gardening and Planting*, October 30th—has the following:—

Under this latter head of finishing teas, Indian planters will soon be supplied. Two or three systems will compete for favour. That very clever Ceylon planter, Mr. Henry Alleyn, who has lately been in Calcutta, has, in conjunction with a well-known Ceylon engineer, invented a process which is both simple and practicable, and his machine will ere long be on the market. We have been favoured with a sight of his samples and were very favourably impressed by them. Messrs. Drummond Deane as judges will also have something in this line to offer to complete their present system, and the well known firm of Messrs. Davidson and Co. have paid attention to machinery for the purpose. The Alleyn Crieve machine is in the hands of the Calcutta agent for the Drummond Deane Process and will be exhibited at work as soon as machines arrive from Ceylon. From samples we have seen, we are very favourably impressed with it. Before next season Indian planters should be able to make a choice, and the field being a wide one there is room enough for all. Green tea with the present encouragement is bound to grow. The bounty is not so large as was expected, but green teas having secured such excellent prices this season, it was perhaps thought that a bonus sufficient to cover expenses of altering manufacture and the cost of the requisite machinery was sufficient. We agree with the London Committee that "the surest way of obtaining relief from the present excess of black tea is to be found in the manufacture on a large scale of green tea suitable for the American and other markets." Since also the green tea demand offers the only large field left for the expansion of British grown, it stands to reason that it would be unwise to neglect it.

THE ASSOCIATED TEA ESTATES CO. OF CEYLON, LTD.

DIRECTORS :—Sir Alexander Wilson, Chairman; A Bathune, Esq., J.P., S R Earle, Esq., and T C Owen, Esq.

Report of Directors and Accounts to June 30th, 1902 to be submitted at the Seventh Annual General Meeting of Shareholders, to be held at Cannon Street Hotel on Wednesday, 29th October, at 12 o'clock noon.

The Directors beg to submit herewith the Accounts of the Company for his year ending June 30th, 1902, showing a gross profit of £2,495 17s 2d., after deduction of the agreed proportion of manuring. Against this has to be put a sum of £446 13s 10d., being one-quarter of the amount standing against Buildings and Machinery, and Immature Cultivation.

After deduction of sundry charges, interest on loans, etc. there remains a credit balance of £787 0s 1d. to go against the loss shown in last year's Accounts of £963 11s 3d., making a debit balance of £176 11s 2d.

The yield of Tea for the year was as follows :—

	1901-2.	1900 1.
Silverkandy ..	121 217	112,045
Chesterford ..	372,550	345,292
Horagoda ..	33,504	42,833
Doragalla ..	270 697	229,035
Total ...	797,668	729,205

This shows an increase of 68,663 lb. on the total yield of the previous year, and exceeds Superintendents' estimates by 15,993 lb.

The cost of production per lb. f.o.b. Colombo, was as follows :—

	1901-2.		1900-1.	
	Exclusive of Manuring, Buildings, and New and Immature Cultivation.	Proportion of Cost of Manuring, Buildings, and New and Immature Cultivation.	Exclusive of Manuring, Buildings, and New and Immature Cultivation.	Proportion of Cost of Manuring, Buildings, and New and Immature Cultivation.
	Total.		Total.	
Silverkandy	32.13	3.10	35.23ct	35.15
Chesterford	24.27	2.39	26.63ct	25.34
Horagoda	27.67	.83	23.50ct	31.77
Doragalla	24.53	3.95	28.48ct	30.14

The average prices reduced to the London equivalents for purposes of comparison :—

	1901-2.	1900 1.
Silverkandy Gross	8.18d or 43.94ct	Gross 7.18d or 42.72ct
Chesterford do	5.73d or 29.19ct	do 5.59d or 28.74ct
Horagoda do	5.48d or 27.63ct	do 5.20d or 26.39ct
Doragalla do	6.24d or 32.21ct	do 6.61d or 34.47ct

The total tea sold for the year realised a gross average of 6.27d per lb., and cost, sold in London 5.21d exclusive of manuring. The exchange for the year averaged 1s 4 1/2d. The yield per acre was 4c4 lb over the fields in full bearing.

The Directors have decided that in the interest of the shareholders the cultivation of Horagoda Estate should be discontinued. This decision has been given effect to, and has met with Mr. Fraser's full approval. Excluding Horagoda the estimate for the season 1902 3 is 795,000 lb against a crop of 764,364 lb for 1901-2.

During the year Messrs. McMeekin and Co. relinquished the Secretaryship, and it was taken over by Messrs. Rowe, White and Co. of 16, Philpot Lane, E.C. Mr. John McEwan retired from the Board of Directors, and Mr. T C Owen who

has had over 20 years' practical experience as a planter in Ceylon, was elected in his place. Mr. A Bethune, the Director retiring by rotation, is eligible for re-election. Mr. J M Henderson, the Auditor to the Company, retires, and offers himself for re-election.

By order of the Board, ROWE, WHITE & Co., Secretaries.

16, Philpot Lane, London, E. C. 21st Oct. 1902.

THE SCOTTISH TRUST AND LOAN COMPANY OF CEYLON, LTD.

Capital, £125,000; First issue (fully subscribed), £75,000; Of which paid up, £45,000; Reserve Fund, £11,000.

DIRECTORS.—James Haldane, C A, Edinburgh; John Wilson, of Messrs Honeyman and Wilson Limited, Edinburgh; Henry Johnston, K C, Advocate, Edinburgh; George M Wood, S S C, Edinburgh.

SECRETARY.—Francis A Bringloe, C.A., 123 George Street, Edinburgh. Register Office: 123 George Street, Edinburgh. London Office: Adelaide Chambers, 52 Gracechurch Street, E.C. A Gordon Dickson London Agent, Agents in Ceylon, Messrs Cumberbatch & Co., Colombo.

REPORT by the Directors of the Scottish Trust and Loan Company of Ceylon Limited, to the Twenty-fifth Ordinary General Meeting of Shareholders, to be held within the Company's Registered Office, No. 123 George Street, Edinburgh, on Thursday, the 30th day of October 1902, at 3.30 p.m.

The directors present their Twenty-fifth Report, being for the year to 31st August 1902.

ESTATES IN THE COMPANY'S POSSESSION.—The year under review has again been a bad one for producers of tea, and prices have steadily decreased, and have now reached a very low figure. The total crop from the Company's properties amounted to 739,010 lb. or 36,000 lb. in excess of the estimate, and represents an increase over last year's figures of 32,313 lb. The average net price realised has been only 6.39s as against 7.12s for last season, or a fall of .73 of a penny per pound.

FACTORIES, BUILDINGS, AND MACHINERY.—These are in a thorough state of repair. During the year the extension to the Brookside Factory has been completed, and new machinery erected at the Alnwick Factory.

CULTIVATION OF ESTATES.—The movement to restrict the output of tea which was mentioned in the last report resulted in no definite scheme being adopted by producers. The Directors, however, decided to rest a proportion of the Company's tea, and with this end in view 116 acres have lain fallow throughout the year. Reports from Ceylon speak very favourably of the healthy appearance of the tea thus treated.

ACCOUNTS.—The balance at the credit of Profit and Loss Account is .. £3,548 15 0

And the Directors propose to pay a dividend of 6 per cent per annum, free of Income Tax, of which 2 1/2 per cent was paid as an Interim Dividend at Whitsunday 1902 ... 2,700 0 0

Leaving .. £348 15 0

to be carried forward to next Account.

Mortgage held in Ceylon by the Company.—The only remaining loan of the Company is now reduced to £2200

Directorate.—The Directors regret that Mr H Herbert Anderson has resigned his seat on the Board, but has consented to remain temporarily, in an advisory capacity, at the London Office. The Director retiring by rotation is Mr George M Wood, S S C., and he is eligible for re-election.

Auditors.—Messrs. Moncrieff & Horsburgh, C.A., are eligible, and offer themselves for re-election. By Order of the Board. FRANCIS A. BRINGLOE, Secretary.

—Edinburgh, 21st Oct. 1902.

THE CENTRAL PROVINCE CEYLON
TEA COMPANY, LIMITED.

REPORT OF THE DIRECTORS.

to be submitted to the shareholders at their sixth annual ordinary general meeting to be held in the Council Room, London Chamber of Commerce, Botolph House Eastcheap, E.C., on Monday, the 3rd November, 1902, at twelve o'clock noon.

The Directors beg to submit to the shareholders the audited accounts for the year ending 30th June, 1902.

The total crop of tea from the estates for the past season was 803,315lb. against 809,853lb. of the preceding year, being a decrease of 6,538lb.

The total sales, including bought tea, were 1,049,024lb. averaging 5-279d. per lb. net being -062d less than last year.

As regards cocoa, the crop amounted to 584 cwts., against 521 cwts. last year, the average price being 49s 5d per cwt. as against 66s 10d. Although the quantity has been larger the profits was very much less owing entirely to the fall in price.

There were during the season 62 acres of tea not yet in full bearing.

The rate of exchange, averaged 1s 4-20d per rupee, being practically the same as last year.

The net profit for the year amounts to £2,960 15s 0d after writing off £503 from estates account for depreciation, which with £1,759 9s 2d brought forward from last year, shows a sum of £4,720 4s 2d to be dealt with. Of this amount £1,500 has been applied to the payment of an interim dividend at the rate of 6 per cent per annum on the preference shares to 31st December, 1901. The Directors now recommend a dividend of 6 per cent per annum on the preference shares to 30th June, 1902 absorbing £1,500 and leaving £1,720 4s 2d to be carried forward to next account.

Some 50 acres of tea are being put out of cultivation as being unremunerative at present prices.

Mr F M Mackwood is the Director retiring by rotation, and being eligible, offers himself for re-election.

Messrs. Fuller, Wise & Fisher, chartered accountants, offer themselves for re-election as auditors.

THE CAROLINA TEA COMPANY OF
CEYLON, LIMITED.

Tenth annual report of the Directors to be submitted at the tenth annual general meeting of shareholders, to be held at the Offices of the Agents, Messrs. Frith, Sands & Co., Winchester House, Old Broad Street, E.C., on the 30th October, 1902.

Your Directors beg to submit the Balance Sheet and profit and loss account for the year ending 30th June, 1902.

The Nett Profit is	£6,657	8	5
Amount brought forward from last year at credit of the Ordinary Shares	£306	0	9
	£6,963	15	2
From which has to be deducted Deben- ture Interest	2,450	0	0
Leaving an available balance of ..	£4,513	15	2
which it is proposed to appropriate as follows:—			
To Reserve Fund ..	£1,200	0	0
To a Dividend on the Or- dinary Shares of 5 per cent (of which 2 per cent was paid on 24th April, 1902) ..	2,500	0	0
	3,700	0	0
And to carry forward to the credit of the Ordinary Shares ..	£813	15	2

The Crops secured during the season compare as follows with those of previous seasons:—

	Tea from Estates, lb.	Tea from Purchased Leaf, lb.	Cocoa from Estates, cwts.
1901-1902 ..	957,954	47,827	574
1900-1901 ..	953,399	29,575	466
1899-1900 ..	1,131,333	43,195	414
1898-1899 ..	961,757	32,862	555

The cost of the Tea crop has been reduced to 4-39d per lb. free on board Colombo, as against 4-78d for the two previous seasons. The average gross sale price of Tea has advanced to 6-99d per lb. from the low average of 6-31d in the preceding season. A large crop of Cocoa has been secured, but the market continued more or less unfavourable throughout the season. The total area of land now under cultivation is 2,608 acres, comprising:—

Tea in full bearing	1,801	acres.
Tea in partial bearing	630	„
	2,431	acres.
Cocoa, Coffee, &c. ..	177	„
	2,608	„

Owing to better market conditions during part of the year's working for the lower grades of Tea, and, to some extent, the improved quality of the Tea produced by the Company, the nett result of the past season is more satisfactory, enabling the Directors to write off from Revenue sums, amounting to £190 17s 10d and to recommend the usual sum of £1,200 being placed to Reserve. The Reports received from Mr Megginson, who is now visiting the Company's Estates, are of a satisfactory character. The Estates having been constantly maintained in a high state of cultivation has enabled the management to cope with the depressed condition of the Tea Industry by reducing appreciably the cost of the season's production of crops; but the policy of reverting to higher cultivation involving some increased expenditure in order to keep the properties in thoroughly sound condition, may be necessary, and has the careful consideration of your Board. The manufacture of Green Teas suitable to the requirements of foreign markets has been engaging the attention of your Directors, and this business is now being carried out on satisfactory terms. Your Directors have to express their satisfaction with the work of the Staff in the Company's employ, and with the Agents in London and in Colombo. The Directors retiring by rotation are Mr C A W Cameron and Mr H St. J Oscar Thompson, who, being eligible, offer themselves for re-election.

H. ST. J. OSCAR THOMPSON, Director.

London, 8th October, 1902.

THE LANKA PLANTATIONS CO., LTD.

DIRECTORS:—George Allen, Esq., Chairman, William Austin, Esq., Henry Bois, Esq., and Edward Pettit, Esq.

AGENTS IN COLOMBO—Messrs J M Robertson & Co. SECRETARY—Mr. Charles M Robertson.

Authorised Capital £200,000 in 15,000 ordinary shares of £10 each, and 5,000 preference shares of £10 each, of which latter only 1,470 have been issued.

Report to be presented at the Twenty-second ordinary general meeting of the Lanka Plantations Company, Limited, to be held at the Office of the Company, on Wednesday, the 12th November, 1902, at twelve o'clock noon precisely.

1. The Directors now submit their Report for the twelve months ending 30th June last, together with the balance sheet and accounts of the Company made up to that date and duly audited.

2. The coffee crop amounted to 3:0 cwt. and realised £1,323 19s 1d. Last year the crop was

189 cwt., and realised £490 12s 5d. This crop was gathered off the suckers growing on the uncultivated trees referred to in the last report.

3. The total crop of cocoa gathered on Yattawatte amounted to 938 cwt., and realised £2,417 13s 7d, against 1,026 cwt. last year, which realised £3,610 3s 10d. The shortage in crops of recent years has been due to the disease which attacked the cocoa trees in Ceylon. It is hoped that Yattawatte has now passed through the worst stage, and will recover as other estates have done which were attacked earlier. Of cardamoms 777 lb. were gathered, realising £27 14s 4d. A large number of Para and Castilloa rubber trees and also coconuts have been planted on this estate, and are doing well.

4. The total yield of tea was 934,650 lb. plucked off 2,181 acres being at the rate of 428 lb. an acre, and realized £25,142 9s 6d, the average being 6'46d per lb. net. Last year the crop amounted to 974,511 lb., which realized £26,979 17s 2d, the average being 6'64d per lb. net. A factory is in course of erection on Thotnlagalla, and when completed a considerable saving will be effected in cost of manufacturing tea on this estate. This capital expenditure is being charged to Suspense Account as usual.

5. The average rate at which drafts were negotiated on account of the seasons' crops was 1/4 1-32 per Rupee against 1/4 12-32 last year.

6. The following statement shows the approximate acreage and state cultivation of the Company's estates on the 30th June last, as per recent surveys.

Estate.	Tea	Cocoa.	Grass.	Chena and Platena and Waste.	Forest and Timber Trees.	Total.
Ampitiakande	291	—	4	—	70	365
Arnhall	174	—	—	255	—	429
Fruit Hill	229	—	—	8	—	237
Fordyce, Gar- bawn, Gona- gala and Para- matta	798	—	5	—	135	938
Rappahannock	322	—	31	30	90	473
Rillamule	195	—	—	343	22	560
Totulagalla	382	—	—	60	114	556
Yattawatte	—	751	95	312	82	1,240
	2,391	751	135	1,008	513	4,798

7. The net profits for the past year amounted to £4,108 15s 7d, to which must be added the sum of £1,144 0s 7d, the balance brought forward from the year 1900-01, making together £5,252 16s 2d.

8. Having already paid a half-year's interim dividend on the six per cent. Preference Shares to the 31st December, 1901, amounting (less property tax) to £415 5s 6d, the Directors recommend payment of the dividend on these shares to 30th June last, requiring (less property tax) £414 7s 2d, and having deducted £1,045 6s 9d, being one-tenth of the sums charged to suspense account during the ten years ending 30th June, 1901, they further recommend a dividend of 4s per share (free of income tax) being 2 per cent on the ordinary shares, amounting to £3,000, carrying forward the balance of £377 16s 9d to next account.

9. Mr. William Austin, the Director retiring on this occasion, being eligible offers himself for re-election.

Mr. John Smith, the Auditor retires and does not offer himself for re-election.—By order of the Board,
C. M. ROBERTSON, Secretary.

12, Fenchurch Street, London, E.C., 29th Oct., 1902.

THE MATURATA TEA COMPANY, LTD.

REPORT OF THE DIRECTORS

to be submitted to the Shareholders at the fifth annual ordinary general meeting, to be held at the offices of

the Company, 16, Philpot Lane, London, E.C., on Wednesday the 5th day of November, 1902, at 12 noon.

The Directors herewith beg to submit the fifth annual report and balance sheet for the year ending 30th June, 1902.

After bringing forward the unappropriated balance of £2,210 17s 3d from last year's account, and after payment of debenture interest and London charges (Directors' Fees, &c.), the net amount at credit of profit and loss account is £3,874 13s 8d.

An interim dividend of 3 per cent has been paid on the preference shares for the half-year, amounting to £120. And the final 3 per cent was paid on the preference shares on July 1st, making 6 per cent for the year, amounting to £120. It is proposed to pay a dividend of 10 per cent less income tax, on the ordinary share capital, which will absorb £800. Thus leaving to be carried forward to next year a balance of £2,834 13s 8d=£3,874 13s 8d.

The past year has been very trying to producers of high grown teas, as buyers have throughout the year almost entirely centred their interest upon low-medium descriptions; notwithstanding this, it has been a highly satisfactory one for the Company, owing to the fact that we have, to a very large extent, been independent of the London market, the bulk of our produce having been disposed of for export.

During the past year a further £500 of the debenture debt has been paid off. This reduces the debt to £6,000 thus enhancing the value of the preferred and ordinary shares.

The average of our tea is 8'17d as against an average of 7'06d per lb. for all Ceylon tea during the same period, and our crop shows an increase of 13,139 lb. The cost of putting the produce, F O B, Colombo, has been 4 cents cheaper than last year.

Mr Guy Owen retires in accordance with the articles of Association, but being eligible, offers himself for re-election as a Director.

The Auditors, Messrs. Chas. E Bradley & Co. also retire, but, being eligible, offer themselves for re-election.

THE SOUTH TRAVANCORE TEA COMPANY, LIMITED.

REPORT OF THE DIRECTORS

to be submitted at the sixth annual ordinary general meeting, to be held at the offices of the Company, 16, Philpot Lane, London, E.C., on Tuesday, November 11th, at 2'15 p.m.

The Directors beg to submit herewith their sixth annual report and balance sheet for the year ending 30th June, 1902.

The outturn of tea was 269,250 lb, being 45,750 lb below the original estimate, against 302,329 lb last year.

The average price realised was 4'82d per lb, as against 4'72d last year and 5'38d the year before. The gross profit was £599 6s 1d, against £1,294 13s 4d last year, and £2,158 13s 11d the year before.

After providing £250 for the Debenture Sinking Fund and writing off £250 for Depreciation of Machinery, there is shown a loss of £632 5s 2d, which after deducting the credit balance of £574 17s 7d carried forward from last year, leaves a debit balance of £57 7s 7d.

During the past year the tea industry has continued to suffer from the low prices alluded to last year. Mr Stewart, the Manager, has just returned to the estate after a visit to England for his health. He has relieved Mr Cook, who was acting for him during his absence.

Shortness of labour, owing to the construction of the new railway, resulted in a very heavy reduction in the crop, which was 33,179 lb below the low crop of the previous year.

This is a most disappointing result, and the Directors can only hope that Mr Stewart will be able to

get labour to harvest the full crop estimated for the new season.

The area under tea amounts to 730 acres.

The Manager's estimate for the present season is 310,000 lb.

In accordance with the Articles of Association, Lieutenant-Colonel Colville retires by rotation, and, being qualified, offers himself for re-election.

The Auditors Messrs. Jackson, Taylor, Abernethy & Co., retire, and, being eligible, offer themselves for re-election.

October 30th, 1902.

THE GOOMERA (CEYLON) TEA ESTATES COMPANY, LIMITED.

REPORT OF THE DIRECTORS.

The Directors beg to submit herewith their eighth annual report and balance sheet for the year ending 30th June 1902.

The accounts, after paying debenture interest and London expenses, show a profit of £404 10s 6d which deducted from the debit balance of £2,175 15s 10d brought forward from last year, leaves a loss of £1,771 5s 4d to be carried forward.

The total crop from the Company's estates amounted to 142,488 lb. realising a net average of 6d per lb., against 245,313 lb harvested from the Company's estates the previous year, which realised a net average of 4½d.

During the past year the system of high cultivation advocated by Mr. Joseph Fraser, and previously mentioned, has been continued by the Directors. The results have justified the wisdom of this step, as the figures for the past season show. In view of the serious crisis through which the tea industry is now passing, the result cannot be looked on as otherwise than satisfactory. The Directors consider that the prices realised for the tea reflect credit on the management of the Company's properties in Ceylon.

The estimate for the new season is 170,000 lb from Goomera, and 97,500 lb from Hunugalla, against a crop of 150,407 lb (exclusive of bought leaf) from Goomera and 89,480 lb from Hunugalla last year.

The Directors not having drawn any fees for some years, propose drawing half for the past season.

Mr. F E Cobb retires in accordance with the Articles of Association, and being eligible, offers himself for re-election.

The Auditor, Mr. J D Stewart Bogle, C.A. retires and offers himself for re-election.

October 28th, 1902.

CEYLON LAND AND PRODUCE COMPANY, LIMITED.

DIRECTORS.—James Wilson, Esq., Chairman, Wm. H Haslam, Esq., Alex. D Wilson, Esq.

Report of the Directors, to be submitted to the eighteenth annual general meeting of shareholders, (on Friday, the 14th day of November.

Your Directors have the pleasure to submit the annexed profit and loss account and balance sheet for the crop year ending 30th June, 1902, duly audited. 319 shares of £5 each, being part balance of the six per cent. Cumulative preference capital, were allotted during the past year, and the premiums received, less cost of issue, transferred to Reserve Fund in the sum of £185. The amount of credit of Profit and Loss account is £7,053 5s 1d, which, with the sum of £327 2s 1d brought forward from last year, leaves £7,380 7s 2d to be distributed. On the 22nd July last an Interim Dividend of 7½ per cent on the Ordinary

Shares and 3 per cent on the Preference Shares was paid, and your Directors now propose to pay on the 13th day of December, 1902, the balance of the fixed Cumulative Dividend on the Preference Shares (3 per cent) making 6 per cent for the year, and 7½ per cent on the Ordinary Shares, making 15 per cent for the year, all free of Income Tax, and carry forward the balance of £1,120 2s 2d, subject to the Directors' remuneration for the year under review and to the payment of income Tax, &c. A sum of £954 10s 10d spent upon permanent improvements during the year has been debited to Revenue. In accordance with a Resolution of the Board, a Call of 10s per Share was made upon all Members holding Preference Shares upon which £4 10s had been paid, and the same was payable on the 1st July last. These Shares are now fully paid.

Your Directors have to report that the total Crop of Tea from the Company's Estates for the year amounted to 986,862 lb, representing a shortage on the Estimates of 82,888 lb; there were, however, increases of 10,061 lb made from purchased leaf, and of 68,227 lb made from others, the outturn aggregating 1,440,150 lb, as compared with the provision made at the commencement of the season for 1,444,759 lb, a deficiency of only 4,600 lb. The net average price obtained is again low, it being only fractionally better than that recorded last year viz, 5.46, *versus* 5.23d; the mean rate of exchange (1s 4½d) remains the same, and Freights were the turn higher. Your board desire to point out that their declared policy of sparing no expense to bring the Company's Estates into the best possible state of cultivation has been persevered with, and there is no doubt the present condition of the properties fully justifies the course taken; during the year R24,318 (£1,659 3s. 11d.) were expended on manuring Tea and Cocoa, the whole of which has been debit to Revenue Account. The Coca crop totalled 2,865 cwt., as compared with an estimate of 2,325 cwt.; the prices, however, shew a marked falling off. The greatest efforts continue to be taken to keep Cocoa disease well under control, and as a matter of fact the Government Mycologist reports that the work of cutting out cankered parts of trees had been well done, and in his opinion was effective in curing the trees so treated in a very large proportion of cases; he adds, that the measures adopted promise excellently, and if vigorously carried out should ensure that very little need be spent per acre in the future. The census of Coconuts taken in June last indicates a total number of 47,088 trees, equal to 620 acres, at the rate of 76 trees per acre. It was found necessary to extend the North Matale and Strathisla Tea factories, and increase the machinery in the latter building to fully cope with the larger output; the Directors have under their consideration the question of erecting a Green Tea factory on Allooowihare.

TEA.—The output has been a fair average one in point of quality, although the standard of excellence reached in 1901 was not upheld. Unfortunately also the Indian crop contained a large proportion of medium and low class Tea, which, competing with Ceylon, kept prices for common and fair grades much under those of the year before, consequently rendering the result of working of many estates unsatisfactory. On the other hand, however, there was a brisk demand for all invoices with attractive flavour. * * *

COCOA.—The demand for this article during the first six months of the year was slow, and in consequence much lower prices were recorded. At the end of August values improved, owing to the demand from America, partly resulting from the short Java crop, and a material advance took place which has been since well maintained. Finest kinds—of which the supply is very small—are considerably higher than they were at the beginning of the year, and the Directors are of opinion that the prospects of good values for next season are very favourable. The statistical position of all kinds of Cocoa is good, the deliveries showing an increase on last year's, the stocks being now much smaller.

ACREAGES.—The following Statement shows the approximate acreage of the Company's Properties at date:—

Name of Estate.	Tea		Cocoa Bearing		Cocoa, Coffee, &c.	Forest, Grass, Chena abandoned, &c.	Total Acreage
	3 years.	over 3 years.	Cocoa Not Bearing.	Cocoa Bearing.

	2893½	1500					

† And Cocoa * And Tea

N.B.—In the absence of detailed surveys these figures, as mentioned above, are approximate only.

The Estimates for current year provide for a Crop of 1,089,025 lb. Tea from the Company's Estates, 128,000 lb. from bought leaf, and 240,000 lb made for others, a total of 1,457,025 lb., company with 1,440,150 lb. manufactured last year. The intake at date of latest advices compares favourable the Crop secured at the same time in 1901. The Crop of Cocoa is estimated to be 2,680 cwt.

A vacancy in the Directorate was caused by Mr L A Lewis ceasing to be a Member, and in accordance with the Articles of Association, this has been filled by Mr Wm. H Haslam, of Messrs. Geo. White & Co., 31 Fenchurch Street, E.C. Mr W H Haslam, by rotation, retires from the Directorate, but being eligible, offers himself for re-election. Mr James B Laurie, the Auditor, also retires, but he is eligible, and offers himself for re-election.

By order of the Board, JAMES WILSON, Chairman, ALFRED E. LOCK, Secretary.

KORALE TEA ESTATES, LIMITED.

Directors:—W. S. Bennett, Chairman, J. L. Shand, H. W. Brett; Secretary:—H. C. Dowling; Agents in Ceylon:—Cumberbatch & Co., Colombo; Agents and Offices:—Shand, Haldane & Co., 24, Rood Lane, London, E.C.; Auditors:—McAuliffe & Davis, Thread-needle House, 28-31, Bishopsgate Street, E.C.

Report of the Directors, to be submitted at the Sixth Annual Ordinary General Meeting of Shareholders, to be held at the Offices of the Company, on Thursday, 16th October, 1902, at 3 p.m.

The Directors now submit the Report and Accounts for the year ending 30th June, 1902, which have been duly audited.

The net amount at Credit of Profit and Loss Account, after providing for General Expenses is ... £ 939 1 4

To which should be added the balance brought forward from 30th June, 1901 ... 142 16 8

1,081 18 0

To dispose of which it is proposed to pay a dividend of 1½ per cent on the Preference Shares which will absorb ... 718 5 6

To write off Wewesse Factory account ... 100 0 0

Directors' Fees ... 150 0 0

And to carry forward a balance of 113 12 6

£1,081 18 0

Though the estimate of crop has been exceeded, and the cost of production upon all the estates lessened, the Directors regret that the continuation of low prices for all tea prevents the recommendation of a higher dividend. The crop might have been still further increased if the Directors had not continued to carefully nurse the younger fields, in addition which a considerable area of the older tea has been this year rested. The Directors are satisfied that this policy will be to the permanent advantage of the estates. The reports as to the order and condition of the estates are satisfactory, and the large area of promising young tea on Wewesse is likely to rapidly increase the crop yield. In accordance with the Articles of Association Mr. W. S. Bennett retires from the Board, and being eligible, offers himself for re-election. The Directors desire to express their satisfaction with the Agents and Managers in Ceylon, who have done their utmost to carry out the wishes of the Directors for the strictest economy compatible with the efficient working and up-keep of the Company's properties.

By Order of the Board, H. C. DOWLING, Secretary.

The General Managers are glad to be able to inform the Shareholders that the anticipations expressed in the last Annual Report have to a great extent been verified, with the result that the past season's operations have been much more favourable than those of the preceding year.

During the first six months of the past season, the weather in Ceylon was not favourable for the growth of tea, and at one time the falling off in the crops harvested, as compared with the previous year to the same date, amounted to nearly 150,000 lb; but, on the other hand, owing to short supplies and improved quality of the tea, the average price realised was much better. During the second six months of the season, however, these conditions were precisely reversed; the weather was very suitable for the flushing of tea, and the deficiency of crop was to a great extent recovered, but prices were poor. The net result of the year's operations has been to produce a crop of 1,726,241 lb tea, against 1,787,560 last year, at a cost 4 16 per lb, against 4 35d, while the price realised for the tea averaged 5½d per lb net against 5 5-16d for the previous season.

Exchange during the past season has averaged 1s 23-64d for drafts at three months' sight, which corresponds exactly with that of last year.

The amount realised for products other than tea has been much larger than usual, owing to the exceptional quantity of cinchona bark harvested. This bark realised £1,127 13s 7d, whereas last year the net proceeds amounted only to £299 8s 11d. The General Managers being of opinion that this product can hardly be treated as pure revenue, seeing that each time a tree is barked brings it nearer to final extinction, have decided to carry £500 of the above proceeds to credit of the Reserve Fund. Young trees are coming on to take the place of those that die out or have to be removed, but it takes some years for them to reach the productive stage.

The other extraneous products have realised about the amount estimated, and are all doing well.

No new properties have been acquired since the date of the last annual report, and the total acreage of the Company's estates remains unaltered, viz., 5,484 acres. But in accordance with the promise made in last year's report a careful survey has been made of

THE CONSOLIDATED ESTATES CO., LTD.

Authorised capital	£100,000
Divided into 5,000 preferred shares of £10 each entitled to a cumulative preferential dividend of 8 per cent	£50,000
5,000 ordinary shares of £10 each	50,000
	£100,000

Eleventh annual report of the General Managers, to be submitted to the shareholders at the general meeting, to be held at 34, Great St. Helens, E.C., on Wednesday, the fifteenth October, 1902, at 11'30 a.m.

The General Managers have the pleasure to submit their Eleventh Annual Report and Balance Sheet, together with Statement of Accounts for the Crop Year ending 30th June, 1902.

The Profit and Loss Account shows a balance (including £1,081 2s 9d brought forward from last year) of £6,777 8s 5d, after paying Interest on the Debentures, and an Interim Dividend of 4 per cent on the Preferred Shares.

Out of this sum the General Managers propose—

To pay a Balance Dividend of 4 per cent on the Preferred Shares, making 8 per cent for the whole year, which will absorb	£1,560 0 0
* To set aside for redemption of five per cent of the Debentures at 103	2,575 0 0
To pay a Dividend of 4 per cent on the Ordinary Shares	1,560 0 0
To place to Reserve Fund	500 0 0
Carrying forward the Balance, viz :—	582 8 5
	£6,777 8 5

* By the Articles of Association it is provided that no Dividend can be paid on the Ordinary Shares in any one year unless five per cent of the Debentures have been redeemed for that year.

The following shows the result of the year's working viz :—

the reserve land suitable for tea, and the following tabulated statement gives the result:—

Name of Estates.	Ceylon District.	Tea		Tea Recently Planted.
		Full Bearing.	Partial Bearing.	
Wattegodde	Dimbulla	800	Nil	25
Hoonocotua	Kotmale	559½	25	15
Tallagalla	Kalntara	515	48	54
Ellagalla	Matale	225	6	9
Rutland	Hewaheta	449½	3	66
Warriagalla	Nilambe	422½	83½	4
Sorana	Kalntara	421	79	45
Totals		3,392½	244½	218

Name of Estates.	Ceylon District.	Reserve Suitable for Tea.	Products, Total	
			Grass Waste, Water, &c.	Acres.
Wattegodde	Dimbulla	Nil	70	895
Hoonocotua	Kotmale	52	110½	762
Tallagalla	Kalntara	25	58	700
Ellagalla	Matale	15	190	445
Rutland	Hewaheta	17	127½	663
Warriagalla	Nilambe	150	601	1,261
Sorana	Kalntara	75	138	758
Totals		334	1,295½*	5,484

* Of which more than 300 acres are planted with Cardamoms, Cocoa, Cinnamon and Cinchona.

Last year's Estimate of Expenditure of Capital Account was £600 to £700, and the amount actually spent was £675 2s 4d, which has been carried to debit of the Factory and Extension Account. This account after having received credit for the proceeds of the New Issue referred in the last Report, shows a small debit balance of £405 9s 3d. The estimated expenditure on this account for the current season amounts to between £800 and £900, being chiefly for additional machinery required for Sorana and Warriagalla.

The Estimate of Crop Expenditure and Yield for the new season have been prepared as usual with much care, and are as follows, viz:—

	Expenditure.		Crop.
	R.	lb Tea.	
Wattegodde	116,719	450,000	
Hoonocotua	80,071	280,000	
Ellagalla	31,902	120,000	
Tallagalla	58,552	235,000	
Warriagalla	65,576	240,000	
Rutland	64,105	250,000	
Sorana	66,358	275,000	

Totals R483,283 @ 1/4½ = £32,974. 1,850,000
Also about 15,000 lb of Cinchona from Rutland, 10,000 lb Cardamoms and 15 cwt Cocoa from Warriagalla and 15,000 lb Cinnamon from Sorana; the value of the whole of such products being estimated at about £1,000 to £1,200.

The General Managers are glad to state that the very full Reports on the Estates which they receive from the Company's Ceylon Agents continue to be on the whole thoroughly satisfactory. The grey blight, which at one time caused considerable anxiety, has happily yielded to the remedial measures applied, and has almost entirely disappeared. So that with normal weather and even moderately good prices for Tea, the prospects for the coming season appear to be satisfactory.

ARBUTHNOT, LATHAM & Co., General Managers.
34, Great St. Helens, E.O., 6th Oct., 1902.

THE DOOMOO TEA COMPANY OF CEYLON, LIMITED.

THE REPORT.

The Directors have the pleasure to submit their Report and the Accounts for the year ending June 30th 1902.

The crop realized was 296,863 lb. against an Estimate of 260,000 lb. and netted 36 05 cts. per lb. against 04 29 cts. last year.

The falling-off in price is to some extent due to the fact that there were several alterations and additions to the factory and machinery about the middle of the year which hampered work and prevented the tea being made to the best advantage.

On the other hand the cost of the tea was only 24 33 cts. per lb. against 26 95 last year. This rate is not high and reflects credit on the Manager.

There is now a sum of R40,059 32 to be dealt with and the Directors recommend its being disposed of as follows:—

That there be passed to Depreciation account a sum of	R 5,000 00
That there be passed to Reserve account	5,000 00
That a Dividend of 7 per cent be paid, absorbing	28,000 00
And that there be carried forward a sum of	2,059 32
	<hr/> R 40,059 32

The Estimates for the current season provide for a crop of 275,000 lb. tea to cost R71,310 00 exclusive of Capital Expenditure which will not be large.

The acreage of the two estates is as follows:—
Doomoo .. 213 acres Tea 5 years old and upwards
12 do do under 1 year.
16 do Timber.
58 do Chena and Patana.

299 acres.

Verellapatna .. 500 acres Tea 5 years old and upwards.
24 do do 4 years old.
4 do do under 1 year.
6 do to be planted.
10 do Grass.
2 do Timber.
142 do Chena and Patana.

688 acres.

During the year Mr W Kingsbury having left the Island, Mr W Anderson was appointed a Director in his place. The latter gentleman retires in accordance with the Articles of Association but being eligible offers himself for re-election.

It will be necessary to appoint an Auditor for season 1902 03.

By order of the Board of Directors,
J. M. ROBERTSON & Co.
Colombo, 16th October, 1902.

BRITISH CENTRAL AFRICA COMPANY, LIMITED:

PLANTING PROGRESS.

The statutory general meeting was held yesterday (Oct. 31) at Winchester-house. Major George Wemyss who presided, observed that as a good deal of misconception existed in England as to the exact locality of British Central Africa, it might be as well if he stated that it was that region of Africa which would always be associated with the name of Livingstone and with the great Scotch missionary movement in the Shire Highlands and about Lake Nyassa. In 1883 the British interests in Nyasaland had become so considerable that Her Majesty's Government appointed a British Consul to Nyasaland with headquarters at Blantyre. This was immediately followed by the starting of the planting industry, which soon showed most encouraging results in the cultivation of coffee, cotton and tobacco. In 1889 the future of Nyasaland assumed an entirely new aspect by reason of the discovery or re-discovery by Mr J Rankin of a navigable entrance to the

Zambesi by the Chinde month. This opened up a direct waterway to the Shire districts, and disposed of the great obstacle to the development of the country caused by its only means of approach being through Portuguese territory. In the spring of 1891 a British protectorate was proclaimed over the countries adjoining Lake Nyasa, and the Protectorate of Nyasaland was instituted. In February 1893, the name of the protectorate was changed to the British Central Africa Protectorate, which this company had been formed for the purpose of developing by establishing through communication by water and rail between Chinde and the Central African lakes region and by developing the planting and mining industries, and British trade generally, within the protectorate. In British Central Africa they were not dealing with the raw uncivilized country one usually associated with the words "Central Africa" but with one which possessed a properly organized civil administration, with its post and telegraph, judicial, medical, scientific, and survey departments, and regularly organized military forces. How important the question of a railway was to the commercial development of the country was evidenced by Mr. Commissioner Sharpe's official report to the Foreign Office for the year 1900-1901, from which he quoted. From Chinde at the mouth of the Zambesi to the north end of Lake Nyasa was approximately 800 miles. For 600 miles there was a waterway upon which steamers were regularly plying—from Chinde to Chiromo 250 miles, and from the south end of Lake Nyasa to the north end 350 miles; but the whole utility of the route practically depended on the facilities for carriage over the connecting link of 200 miles between Chiromo and Lake Nyasa. At present the traffic over this connecting link was mainly dependent on native porters, and the traffic north of Chiromo was practically limited to what they could carry. In addition to providing for the wants of the protectorate and the rapidly increasing demands of the mineral districts of North-Eastern Rhodesia, &c.,

THE RAILWAY

would have to carry the whole trade of the Nyasaland regions, including that from German East Africa, which found its outlet at Langenberg at the north end of the lake; and the easiest and cheapest route even to lake Tanganyika, was undoubtedly by the Shire and Lake Nyasa. Existing means of transport had been utilized to their utmost limit, and the further development of the districts in question was absolutely dependent on the construction of a railway. His Majesty's Government being convinced of this fact, had agreed to grant to the Shire Highlands Railway Company (a subsidiary company of this company) a concession for the construction and working of a railway from Chiromo, via Zoa and the Cholo plateau to Blantyre, and thereafter northwards to a point completing the connexion with Lake Nyasa. The British South Africa Company also realizing the urgent necessity for this railway and the great assistance it would be in the development of their lands in Nyasaland and North-Eastern Rhodesia had assured this company of their support, in connexion with which negotiations were proceeding. The company would enter into an agreement with the Shire Highlands Railway Company to construct and equip the first section of the line at a certain sum per mile to be paid in debentures and ordinary shares of the railway

company, together with the land grant received from the British Government. In order to provide the necessary funds for this purpose it was proposed to make an issue of debentures of the British Central Africa Company at an early date. The company had also acquired as a going concern, Sharrer's Zambesi Traffic Company, which had been operating in the district since 1894 with satisfactory financial results. When railway connexion was made with Lake Nyasa, their company would be in a position to quote reduced through rates and fares between London and all stations on the whole of the route to the north end of the lake. The line was the connecting link of a through service from the coast to the north end of Lake Nyasa, a distance of over 800 miles. This service would practically control the whole of the carrying trade for the Nyasaland regions. The company had further acquired the Nyasaland estates comprising about 372,000 acres of freehold land, a considerable portion of which had already been laid out in plantations, from which "maiden" crops of coffee had already been received. The land was not only suitable for coffee, but also for cotton and tobacco. The only obstacle to the development of these industries were want of labour and proper transport facilities and these would be provided for by the railway. For many miles of its route the line from Chiromo to Blantyre would pass through the company's estates. In addition to the Nyasaland estates they would possess the land granted by the British Government in return for the construction of the first section of the railway—about 265,000 acres. A considerable proportion of this land was also in close proximity to the railway. The company had acquired the properties referred to for fully-paid ordinary shares, so that their debentures when issued would be a first charge, not only upon the railway that had to be constructed, but also upon the entire assets of the company. In acknowledging a vote of thanks, the chairman stated that 900 of the Central Africa Rifles who came from the protectorate were going to Somaliland with the relief expedition.—*London Times*, November 1,

LONDON TEA CHARGES.

A meeting of the Tea Clearing House has been held this week, at which it was decided to endeavour to arrange a conference with the trade with a view to the settlement of the point at issue. 'The trade, having unanimously asked for the withdrawal of the boycotting clause, will probably,' says the *Produce Market Review*, 'only consent to discuss other matters after that is out of the way, but apart from this there is a great deal that can be done by mutual and friendly discussion. The following rough estimate of the London tea charges in the course of a year shows the great importance of the issues to our tea growers, for a burden of some £350,000 a year is a heavy one for an unprosperous industry. It is a small detail in such an amount, but the charge entailed by weight notes is worse than useless, as it complicates matters unnecessarily, and leads to a lot of useless labour. The warrants issued are also far too numerous, and a reduction in their number, by putting more packages on each, would effect a reduction in the stamp charges and would be otherwise useful. Bulking and separate taring are heavy charges that might be avoided, as we have urged for many years. The

empty packages should be cut to scale so that they weigh alike, and bulking ought to be done in all cases on the gardens. We may mention that one of the results of the existing dispute is to advertise the extent of the tea charges, with the effect of leading to competition. For instance, an application is being made to the Customs for a fresh bond by a large waterside warehouse."

AGGREGATE LONDON DOCK OR WHARF CHARGES ON TEA.

Landing charges on tea imported into London for twelve months.—Say 2,200,000 (two million two hundred thousand chests). Average gross weight 90/129 lb.

Landing and Housing Rate, which includes landing, wharfage, housing, separating into chops, weighing, average taring, furnishing landing weights, examining and turning out and in for damage, mending, laying down for private inspection, lotting, nailing down, placing in delivery pile, and delivery by land at 1s 6d

	£	s	d
	165,000	0	0
Bulking and taring at 1s 2d	123,333	0	0
Rent.—10 weeks at 1s 2d per week	45,833	0	0
	£339,166	0	0

Off these gross charges the following discount is allowed to importers:—

Rent at 20 per cent	£9,166
Cost of weight notes on above quantity	£3,700
Warrant stamps at 3d	4,500
Total weight notes and warrants	£8,200

PLANTING NOTES.

COCONUT-PLANTING IN NORTH BORNEO.—"H. W." supplies *The Field* with an interesting paper on this subject (see page 404). Crops 3,000 of nuts from 50 trees per acre, are very good indeed; but the soil must be rich and the growth rapid and luxuriant to justify planting so widely—usually 70 trees per acre are allowed in Ceylon. "H. W."s figures are otherwise fairly reliable, we should say; but he is wrong in saying that we showed the price of coconuts to have continuously increased in the last century. We can recall Ceylon coconut oil a good deal higher than it is now; but still the present price in Colombo—R350 to R355 per ton is a very satisfactory one.

CAPACITY OF CISTERNS.—When calculating the capacity of cisterns (or tanks) 31½ gallons are estimated to one barrel and 63 gallons to one hoghead.

A Circular Cistern One Foot in Depth.

Five feet diameter holds	... 122½ gallons
Six do	... 176½ do
Seven do	... 240½ do
Eight do	... 314 do
Nine do	... 397½ do
Ten do	... 490½ do

A gallon of water weighs ten pounds, and measures 277·274 cubic inches; a cubic foot of water contains 6·23 gallons, and weighs 62·35 pounds; one cwt of water contains 11·2 gallons, and measures 1·8 cubic feet; one ton of water contains 224 gallons, and measures 35·9 cubic feet. *Home paper.*

ANTS AND CATERPILLARS.—A correspondent writes:—With reference to the account which I read with mingled interest and amusement of the ant and caterpillar fight recorded in your column, I have another story in the same category to relate. In my youth, I kept silkworms, and I very well remember how I and some of my schoolfellows once put several trays of the nearly full-grown fat white grubs out of doors for a treat. When we visited them, after an hour's absence, many had disappeared from the trays. We then saw that the ants were dragging them off, several of the insects tugging in unison at each silkworm. Several of the latter had been dragged down three steps of the iron staircase on which they had been placed. I am afraid it became a favourite amusement with us to give our fattest grubs to the ants to carry, but I may say that the former were not hurt in any way by the rough means of carriage to which they were subjected.—*Daily Mail*, Oct. 27.

AN ENTERPRISING PADRE.—We believe, says the *Rangoon Gazette*, the saw mill erected by the Rev Julius Smith at Thandaung which is now cutting up one thousand shingles per day, is the first instance in the province of utilising water power for the working of a saw mill. There are, of course, numerous instances along our rivers of raising water by means of Persian wheels. But we do not know of any other instance of wood cutting by water power than Mr Smith's and his example might profitably be followed by Burmans and Karens in cutting wood, or husking paddy wherever there are hill steamers to give the necessary power. The Pelton Water Wheel Co., of San Francisco and New York, is the system under which Mr Smith's mill is run. That it is economical and simple is shown by the fact that all the machinery and piping used at Thandaung have been erected by Mr Smith with the assistance of one experienced plumber at a cost of R1,750. Of this amount, of course, a considerable portion was consumed by freight between Toungoo and Thandaung, including eleven miles up the hill.

IMPERIAL DEPARTMENT OF AGRICULTURE FOR THE WEST INDIES.—Received: General Treatment of Fungoid Pests. By Albert Howard, B.A., A.R.C.S., F.L.S., F.C.S., Mycologist and Agricultural Lecturer, Imperial Department of Agriculture for the West Indies. *Preface.*—Amongst the enemies to be overcome by tropical planters the parasitic plants known as rots, moulds and mildews take a prominent place. It is impossible to ignore fungoid diseases as the aggregate loss caused by them to the sugar-cane, cacao and other industries amounts to several thousand pounds sterling annually. The object of the present pamphlet is to afford a simple and clear account of the life-history of fungi so that the injury done by them may be readily recognized and suitable remedies applied before it is too late. One of the most serviceable applications for fungoid diseases is what is known as 'Bordeaux Mixture.' Directions are given for the preparation of this (p. 37) as also for the use of knapsack and other spraying machines (pp. 38-39). Special attention is invited to the directions given on pp. 41-43 for collecting and forwarding specimens for examination by this Department. D MORRIS, Commissioner of Agriculture for the West Indies, September 10, 1902.

SCHOOL GARDENS.

WE shall now proceed to consider the educational side of School Gardens.

To understand their value as a means of imparting knowledge, we must think of them as a field for Nature Study.

By Nature Study is meant the study of the world around us, as seen in animate and inanimate nature. Every natural object, whether bird or butterfly, plant or flower, rock or stream, has a story to tell us, and it is the object of Nature Study to enable the child to learn the story of every object that presents itself to the eye. It may truly be said of the generality of children that seeing, they see not, since they look with what may be termed the external eye and not with that inward eye that the poet speaks of. What they see passes before them like a panorama—a mere succession of pictures—suggesting nothing to the mind. Many people go through life with the idea that they are leading a kind of separate existence, having nothing in common with other natural objects around them. They know nothing of the interdependence which binds everything in this world together as elements in a universal and marvellously designed whole. Such ignorance it is that begets self-conceit and self-love. On the other hand the student of Nature knows his own worth, and shows us what true humility is.

To know more about Nature, to understand the function of each natural object in the world's economy, is to put by in the mind a rich store of associations that should always supply the child with healthy mental exercise and leave no room for idle thoughts. How familiar is the vacant

look indicative of the mind that has no food for thought! Under ordinary systems of education the constant application to the written page brings about a revulsion of the mind, resulting in temporary mental apathy, or, what may perhaps be better termed, mental atrophy.

In Nature Study we see the direct opposite of ordinary methods of teaching. Instead of principles and rules the student deals directly with objects and phenomena, and, by observation and comparison, deduces in an intelligent, and indeed the only satisfactory manner, those truths, which when acquired merely as facts, are so much dead knowledge. In this way are grasped the principles which underlie natural science.

A habit which is acquired in youth is, as we all know, difficult to give up. So that if we are helping to inculcate the habit of observing, to evoke an interest in natural objects—a love of gardening—a respect for order and method—an appreciation of the dignity of labour, and the other concomitant advantages derived from the new system of instruction, then we are surely performing a valuable service to future generations.

OCCASIONAL NOTES.

A gentleman who has grown cotton experimentally in the Henaratgoda district is good enough to give us his experience in the following note :—
"I grew two varieties, viz., the Egyptian and South Sea Island, both good, and I succeeded fairly well and had good crops, but the rats and squirrels made sad havoc of the pods before they came to perfection, and the heavy rainfall just as the pods were ripening damaged the remainder of the crop. I should think it ought to do well in the Jaffna and Batticaloa districts."

The above shows that one of the chief things to be discovered about cotton growing is the proper time to plant, so as to get the crop in at the proper season. As regard rats,—so destructive to arrowroot and ground-nut as well—the only means of dealing with them is by poison baits. We learn that "Rough on Rats" has been used with great success in destroying rats on coconut trees in the Veyangoda district.

The "Life Tree of Jamaica" is said to grow for months after uprooting. Does this mean that its leaves do not wither, or that it grows in the sense of putting out a fresh growth of leafy shoots. If the latter, we have seen a cut log of *Ablizzia orodatissima* (Suriya mara) growing most vigorously for months, producing tuft-like leafy shoots. If the former, then we might call our common *Plumeria* (temple flower) the life-tree of Ceylon, owing to its wonderful tenacity for life, which enables it to keep its leaves green and blossoms fresh even when out of the soil, if left in the shade. Indeed, we have been told (with what truth we do not know) that the temple tree is emblematic of immortality among the Buddhists. Anyhow it is one of the chosen flowers used as offerings in the temples.

Cassia Beareana is the name of a plant reported to have greater medicinal virtues than quinine in curing malarial fever. Mr. Thos. Christy, writing to the "Ceylon Observer," says that quinine is being abandoned in favour of the extract from *Cassia Beareana*, supplies of which are said to be carried by those going out to the East and West Coasts of Africa, and Central Africa. We understand that the *Lancet* has written in favour of the drug.

The production of fruits from the roots of the Jak (lately discussed in the local press) is referred to in the article on the Jak tree. In the General Items column will be found a reference to the tendency of the plantain to bear fruit nearer the ground than usual.

In the account of a remarkable tree, reference is made to the extraordinary properties of *Litsea chinensis* in the setting of broken bones. We are informed by Mr. W. A. De. Silva that the same wonderful medicinal (or shall we say surgical) powers are also possessed by another common plant, namely, the *Loranthus* (Sin. *Pilla*). It would appear that all parts of the tree are taken together and prepared in the form of a "mellun" for application as a poultice for the space of about twenty minutes (and not much longer than that.) Those who employ this medicinal agent are said to be particular as to the host from which the parasitic *Loranthus* is obtained, as the potency of the drug is believed to vary with the host!

Recorded by ALEX. PERERA.

A REMARKABLE TREE.

If all that is said of *Litsea chinensis*, the Sinhalese *Bomi* and Tamil *Ellumpurukki* is correct, this is certainly a very remarkable tree. Trimen in this Flora says no more than that "the wood is used for house-building; bark glutinous, and used medicinally as an external application for bruises, &c."

The following extract from Ferguson's "All about Fibres, Drugs, &c." gives an account of its medicinal properties:—"There is a tree growing in Patchalapalla district, in the Northern Province, the name of which is Elamborekka, literally translated 'bone-setter.' The medicinal properties lie in the bark, and the native doctors are accustomed to apply the pounded drug in the shape of a poultice to a broken limb, for the space of about 20 minutes, or, as they calculate, for the time a pot of rice takes to boil, when it is removed and the limb bound up, in the confident expectation that the several parts will unite without further trouble. Fabulous stories are told, as a matter of course, of the virtues of this remedy, but a case came under my own observation which may as well be stated. A Sinhalese aged about fifty was brought to Mr. Simon Casie Chetty, late Judge of Chilaw, having been picked up on the roadside, where he was left by robbers. They had beaten him with sticks till his arm was smashed from shoulder to wrist, and the Judge was for calling in at once the Sub-Assistant Surgeon, but the man declined the offer with somewhat of scorn. He was, he said, a *veredale* (doctor) himself, and could get his arm right. Fortunately for him there happened to be a solitary Elamborekka tree in the jail compound, and he had the bark of it applied in the manner above detailed. It seemed impossible that he could escape am-

putation, but two months afterwards he was in the field superintending his labourers with a sound and apparently strong-limb. For the truth of this statement I can vouch, having seen the battered arm, and also seen the man after recovery."

The name of the above authority is not stated, but we may take it for granted that the account is perfectly reliable, seeing that it has been accepted by the Editors.

Dr. Watt, in his Dictionary of Economic Products of India, makes reference to *Litsea chinensis*, stating that the bark, which is feebly balsamic and mucilagenous, is one of the best known and most popular native drugs. In India, besides being employed as a demulcent and mild astringent in diarrhoea and dysentery, it is said to be used fresh ground with water or milk as an emolient and applied to bruises, as well as a styptic for wounds. Further, we are told that it is a local anodyne for venomous bites. (Watt mentions that *L. zeylanica*, our "wild Cinnamon" and the Sinhalese dawulkurundu [is also used for snake bite.] The oil from berries *L. chinensis* is employed in India as an ointment for rheumatism, while in China and Java candles are made from it.

Mr. E. Hoole, of Kandy, is good enough to write to us with reference to this tree:—The tree is found growing in the Peradeniya Botanic Gardens, and the coolies there seem to be aware of its medicinal properties. The bark, which is glutinous, is used as an external application to bruises and fractures—generally after being made into a poultice with the flour of kurakkan (*Eleusine coracana*).

In the list of drugs (with their uses) prepared for the Paris Exhibition, this tree is referred to, and it is stated that the bark is used in dislocations; also in bruises to produce dispersion of extravasated blood.

Dr. O'Shaughnessy, in his Bengal Dispensary and *Pharmacopœa* (1841) speaks of the bark as a favourite application to bruises and wounds. Here then is a tree the medicinal properties of which are well worthy the attention of local medical men. As a means of studying native treatment we would go the length of advocating the appointment of a recognised "Vedera" as a "Professor of Native Medicine" on the staff of the Medical College! A specimen of *Litsea chinensis* may be seen in the grounds of the late School of Agriculture, Flower Road.

PRICKLY-PEAR AS FOODER FOR CATTLE DURING SCARCITY.

We seem to have overlooked what is a decidedly useful report on the value of Prickly-pear as a "Famine Food" for Cattle. The use of this otherwise pestiferous weed for feeding stock has been the subject of a good deal of discussion in agricultural papers, but a report founded on actual experiment in India gives us all the information we could desire as to the possibilities of the plant as a fodder under tropical conditions.

The Prickly-pear (*Opuntia Dillenii*) is generally known as the "Cactus," and is not so common in the moist as in the dry districts, where it occurs in abundance near the coast. It is called "Katu-pathok" by the Sinhalese, and "Naka-kali" by the Tamils. In the Northern Province, where it is said to be a nuisance, there should be abundant opportunity for repeating, if necessary, the trial of the plant as a fodder in times of drought.

The Director of Land Records and Agriculture, Bombay, referring to the use of Prickly-pear as food for milch cows says:—"The experiment of feeding pampered milch cattle was a failure. Their milking qualities could not be kept up. . . . The animals, however, ate enough of the pears to prove that they could be kept alive on it."

We might, therefore, omit any further reference to its use for feeding milking stock, for indeed it is not for such animals that the question of a famine fodder arises. But the following details given by the Superintendent of Farms, Bombay, are worth carefully reading:—

I have the honour to report that the experiment directed by you to test the value of prickly-pear as a cattle food, has been completed. I am glad to be able to report favourably as to its undoubted value as an *auxiliary* cattle food in famine times.

An experiment was begun on the 19th February at the Poona Farm which did not prove satisfactory. An attempt was made to feed a cow and buffalo, both in milk, on it. These cattle, although not yielding much milk at the time, were previously liberally rationed, and naturally did not take kindly to the change. They had iterally to be starved before either the one or the other would taste the pear. The pear was chopped very fine, mixed with dāl husk, bran, and a little salt. The buffalo took the food first, but only after 30 hours' stinting. Neither the cow nor buffalo ate it greedily. The experiment was continued four days. Meantime, the cow gave milk regularly, but only about one-fourth of her usual quantity. The buffalo got irritable, then savage, and refused to give any milk at all. The cow when allowed her ordinary food soon gave her usual quantity of milk. The buffalo has since given less than her normal yield, and is now nearly dry. However, it is proved that milch cattle in high condition can, by severe stinting be made to eat prickly-pear.

On the 26th February an experiment was begun at the old Botanical Gardens, Ganesh Khind, with three cattle ranging in age from 18 months to 2 years. The condition and feeding of these cattle did not differ from ordinary rayats' stock. They had previously been allowed a fair allowance of hay at night, and were grazed on rather bare pasture during the day. They were all in fair thriving condition. Two were buffalo heifers, the third was a young bull out of a small Deccani cow. Their aggregate weights were 942 lbs. The experiment was continued 32 days.

The implements used, in preparing the pear, were identical with those sold in Bellary at 2 annas per set. The set consists of a rude hoop iron knife, a hoop iron tongs, and a pair of pincers fashioned like a sugar tong. Each limb

of the latter terminates in a spoon. This implement is the most serviceable of the three. The two spoons, when closed over a bunch of prickles, readily remove the bunch along with a small portion of the pulpy part of the leaf. It requires very little practice to get into the knack of removing the prickles quickly. It is waste of time to attempt to pull the prickles. The best way is to scoop out sufficient of the leaf to remove with it one bunch of prickles at a time. I question whether women, however active, can prepare 125 lbs. in a day (as in the recent Madras experiment) of the pear which grows on the poor land of the Deccan. Three prepared leaves average about one pound in weight. I offered 2 annas per 50 lbs., but there is no great want of other work here, and although several women of the Dâpodi village attempted the work, none would continue it. The thorns stick in their cloths, and until the worker gets expert, the work is disagreeable.

A garden hand at Rs. 8 per month removed the prickles from forty-five lbs. of pear per day, chopped up the prepared leaf fine, and gave it to the three cattle at two meals—the first meal at 7 o'clock in the morning, second at 5 o'clock in the evening— $7\frac{1}{2}$ lbs. to each animal each time. A pinch of salt, and during the first part of the experiment, $1\frac{1}{2}$ lbs. of mixed dâl husk and bran was allowed daily to each animal. This was mixed well through the pear. When the pear prepared in this manner was all eaten the cattle were each allowed 4 lbs. of hay, given at about 7 o'clock in the evening. They were kept tied up out of sight of the other cattle. Water was offered in a bucket three times a day. One buffalo took to the food at once. All ate it greedily after two days, and thereafter up to the end of the experiment. During the first four days no hay was given. Afterwards 4 lbs. per day was allowed to each animal. Not a scrap of hay or prepared food was wasted. Everything was eaten up clean. Every second day the cattle were taken out for a little exercise. During the last fortnight they drank a good deal of water owing to the heat of the weather.

The attendant had to walk about a mile to get the pear. He prepared it where it grew, taking from 6 to 7 hours to get the 45 lbs.

During the last week of the experiment the allowance of bran and chuni was discontinued, only a pinch of salt being added to the prepared pear; the cattle still continued to eat it greedily. On the 28th March the cattle were weighed. There was an aggregate increase of 41 lbs., two increasing little in weight, while the third had thriven considerably. I do not attach much importance to the increase in weight, because the cattle were drinking a good deal more water latterly than they did to begin with; but as one intimately acquainted with the appearance of farm stock, I can without any hesitation say that the three animals had the appearance of thriving throughout the experiment.

Regarding the rate at which prickly-pear can be prepared as cattle food, I have made careful experiment, and with leaves weighing 3 to 1 the lb., 1 lb. in $7\frac{1}{2}$ minutes is good practice, and 70 lbs. per day very good work.

During the first few days of the experiment, while the cattle were fed on prickly-pear without hay, it was noticeable that all three animals were inclined to scour. The inference is that prickly-pear alone is a too laxative food.

Two days after the experiment was completed, the same cattle were offered a feed each of prickly-pear at the same time as the evening allowance of hay was given. They ate the pear but preferred the hay.

POULTRY PICKINGS.

(From Various Sources.)

Mr. VanDresser, the well-known poultry expert, is reported to have made a discovery of the greatest interest to the poultry business, namely, how to make hens moult out of season. Shortly explained the process is as follows:—For two weeks the hens are shut up in their pens and fed only one quarter of a full ration. This reduces their flesh. Then they are let out into the sunshine and open air, and fed with a rush on the best possible food, all they can eat, peas, corn, &c., but particularly sunflower seed. This soon loosens up the old feathers, and they drop off so fast as to leave the hens almost bare. Under this heavy feeding the birds soon take on new plumage and the reddening of the comb which gives promise of fruitfulness.

If your fowls or chickens look mopy or are not doing well give them an occasional dose of Epsom salts. This is good for bowel trouble in young chicks, for hens that have had too much grain and not enough green stuff and meat food, and for over-fat hens. A tea spoonfull makes a full dose for two hens, six half-grown chicks, ten chicks from one to two months old, or twenty chicks a week or two old. The best way to give the salts is to dissolve it in the water you mix the soft food with. It cools the blood, soothes the irritated coat of the stomach where the bowel trouble is presented, and gives tone to the system.

Two troublesome intestinal poultry worms are the white worms scientifically known as *Heterakis papillosa* and *inflava*. This tiny white or creamy creatures chiefly occur in the duodenum in groups of 10 or 15, sometimes forming a plug which blocks up the alimentary canal. Affected birds have usually ravenous appetites and yet keep losing condition. In length the worms vary from $\frac{1}{2}$ to $\frac{3}{4}$ in. in the case of *H. papillosa* and from 1 to 4 in. in *H. inflava*. The eggs or embryos are probably taken in with dirty water but also off the ground. Diseased birds should be isolated and the worms expelled by a dose of thymol, one grain made up in a dough pill and given morning and night. Sometimes 3 grains santonine are used for expelling the worms.

Nothing can completely take the place of meat or milk in feeding poultry. Milk when given liberally, is a good substitute for meat, but no combination of grains or meals will take the place of either. All table scraps, offal, &c., are quickly

converted into a cash bringing commodity in the shape of eggs.

Keep chickens moderately hungry all day, but late in the evening give them all the grain they will eatup clean, and a little more will not hurt, for what they leave at night they will eat next morning for an early breakfast, which will keep them quiet until they are allowed out.

Some recognise the importance of supplying grit to fowls, while others do not know that such a thing is necessary for the fowls' health and profit. Without grit the birds will have poor digestion, and a yard of hens with poor digestion is an unprofitable possession.

EDIBLE CONVULVULACEAE.

The edible character of many *Convolvulaceae* is noticeable, though they do not constitute a very important item of diet. Among the Ipomoeas we have *I. muricata*, the native Alanga which has very characteristic pseudo-prickles on its twining stem. Alanga is a wholesome vegetable with a pleasant nutty flavour, and when taken very young forms an excellent ingredient in pickles. The vine is a very prolific bearer. We may here mention that the larger fruits of *I. bonanov* (producing the beautiful white moon flower) are also eaten, though to a less extent.

Perhaps we should have first mentioned another Ipomoea as the chief among edible Convolvulaceae, viz., *I. batatas* (*Batatas edulis*) which is so largely cultivated in all the warmer parts of the globe and used as food for man and horses.

A third Ipomoea is *I. aquatica*, a favourite as a native spinach, and known locally as "kaukun" supposed to be its Malay name.

While in the Ratnapura district we heard of, but did not see, a plant called "Mâdu" said to be a good standby fodder, and even eaten boiled by people.

Mr. W. A. de Silva informs us that the leaves probably contain a good deal of starch and have a pleasant taste; and refers us to three species, viz., *I. cymosa* (Maha-madu or Kiri-madu), *I. tridentata* (Hawari-madu), and *I. angustifolia* (Hin-madu). Mr. Silva is good enough to write with reference to this subject: *I. uniflora* (Potupala) is used for curry, and so are *I. chryseides* (Kaha tel-kola) and *I. sepriaria* (Rasa tel-kola). The two latter as their names imply are of an oily or fatty character.

NATURE STUDY LESSONS.

SECOND COURSE IN THE STUDY OF PLANT LIFE.

3. THE LEAVES.

The surface of leaves, above and below, is covered with a very thin skin which, in some cases, can be peeled off, as in American aloe (gonigas). This skin may be looked upon as a waterproof covering, protecting the leaf in the same way as the outer bark protects the stem.

Scattered throughout this outer skin or epidermis are—especially on the underside—numerous minute openings through which gases from the air can pass in and out. The interior of the leaf consists of soft and spongy tissue, in the cells of which certain important changes are brought about. Running through the soft tissue are the veins (best seen when a leaf is held up to the light) forming a sort of ground-work or skeleton. You will sometimes find, lying under a tree, leaves that have been reduced to skeletons by the decay of the softer tissues. The veins themselves are tough, being continuations of the woody tissue of the stem, and serve to carry the liquid food (ascending sap) to the leaves.

In a large class of plants the leaves show a netted arrangement of the veins, which are irregularly spread over the blade. In another large class the veins run parallel to one another. Compare the leaf of the mango or orange with that of the plantain.

You will now be thinking that there must be some important work going on within the leaf, seeing that the liquid food, absorbed through the roots as well as the gases that enter through the leaves, ultimately find their way there. So there is; and, in fact, the leaf is sometimes spoken of as the laboratory (or workshop) of the plant, because it is there that crude plant food is prepared, or brought into a fit condition to serve as nutriment to the plant, just as our food requires to undergo various changes before it can be assimilated. The elements of plant food derived from the soil, and those derived from the atmosphere combine to form compounds capable of nourishing the plant.

You now know something of the important functions performed by leaves in connection with plant nutrition, but it is also through the agency of leaves that the process of respiration is carried on. Plants, you must know, breathe just in the same way as animals. That is to say, they take up the life-giving oxygen from the air, and give out poisonous carbonic acid gas. This goes on through those minute openings we have already referred to (known as stomata) which may be looked upon as the leaf-mouths of the plant.

You will recollect that, in speaking of the upward flow of the crude sap through the wood tissue of the stem, we made reference to the large quantity of water that passes out of the plant, through the leaves, in the form of vapour. This process, called transpiration, is also carried on through the stomata.

So that the leaves, as you see, have very important functions to perform in connection with nutrition, respiration, and transpiration, about which I shall have more to tell you later.

Many species of leaves serve as human food such as cabbage (gowā) and lettuce (salada), but, besides such well-known vegetables, there are a large number of uncultivated plants, the leaves of which are used in this country, such as *Arua* (polkudupala) and other wild forms of vegetation which come in very handy for village diet.

As instances of medicinal leaves, I may mention the species of Cassia which yield the English drug

called senna, and *Herpestis* (lunuwila) so well known in native medicine. Examples of dye producing leaves are Indigo (nil-awari) and Memecylon (weli-kaha), which respectively yield blue and yellow dyes.

Tea leaves deserve to be specially mentioned owing to the extensive use of the prepared leaf as a standard beverage.

Oil is got from certain leaves such as those of the Cinnamon tree (kurundu) and Citronella grass (pangiri-mana).

The value of the leaves of many grasses as cattle food needs only to be mentioned to you. Of cultivated fodders we have in Ceylon only two, viz., Mauritius or watergrass (diya-tanakola) and Guinea-grass (rata-tana).

Of leaf fibres you have a very good instance in bowstring hemp (niyanda), while the coconut and palmyrah palm furnish examples of the special uses which leaves are put to in the tropics, such as for thatching, for mats, baskets, fans, brooms, and so on.

There is a peculiar class of plants (in which am sure you will be greatly interested) that have leaves of a special structure with special functions to perform. These are the plants which are able to capture, and, so to speak, devour insects. For the present I just wish to introduce two rather common plants of this class to you. One is the pitcher plant (bandura wel), in which the so-called pitcher is nothing more than a transformed leaf. Get a specimen, examine it carefully, and prove this for yourself. Some people fancy that the fluid in the pitcher is rain water. This is not so, as you will find pitchers with the lids still unopened, containing fluid, which is thus clearly supplied by the plant itself. Look for insects that have been drowned by falling into open pitchers. The lid is not, as some think, part of a trap for capturing, and the insects die through drowning in the irritating fluid into which they fall in their search for food. The peculiar structure of the leaf aids in their destruction.

Another of these plants, found also in damp sandy places, is the *Drosera* (wattaessa). The structure of the leaf is not so peculiar, but you will find the surface covered with stiffish red hairs which close on insects like so many fingers, and retain a hold on them till they are killed. Look for insects on the leaves of the *Drosera*. I am sure you will think these leaves very beautiful, with little drops of fluid at the ends of the red hairs, glistening like dew in the sun. Thus it is that the plant gets its name "Sun-Dew."

DISEASES INCIDENTAL TO PREGNANCY— AND PARTURITION IN THE COW.

[H. M. CRICHTON, M.R.C.S.V.]

PARTURIENT ECLAMPSIA.

Definition.—An epileptic and convulsive affection, affecting the cerebro-spinal nervous system accompanied by tonic and clonic spasms of the muscles of various regions of the body. It occurs in cows both before and after parturition.

Causes.—Opinions differ in regard to the cause; by some it is supposed to be due to the retention of urinary elements in the blood, by others to hyperæmia of the brain, and by others still to reflex irritation of nervous system, which bring about renal insufficiency and albuminuria, and exposure to cold winds and wet may bring on the disease.

Symptoms.—The cow takes suddenly ill by foaming at the mouth, champing the jaws, full wild staring eyes, excited expression of countenance, head turned to the side, sometimes pulling back on the chain, licking at fore leg, edge of feeding trough, or anywhere convenient; some cows bellow, others don't; twitching of the muscles of body and limbs, sometimes difficulty of respiration, sometimes cow becomes comatose. Most cases occur after calving, those which occur before are generally about mid-term, and in heifers. The attacks after calving generally occur from eight to sixteen days afterwards. The disease occurs in cows of all ages, and generally in cows of lean condition. The reverse to this happens in parturient apoplexy, as it is a fat cow and a good milker that goes down with it. The most of cases do not get off their feet, although I have had them that did, and lay for a night before getting up again. It might be possible to confound this disease with parturient apoplexy, but if we are careful to note the symptoms it should not happen. I will endeavour to point out the essential differences between the symptoms of the one and the other. There are about eight prominent symptoms that we should bear in mind when we are called in to see cases of this description. I will enumerate them as follows:—

Parturient Apoplexy.

It mostly occurs in cows at third calving and afterwards.

It never occurs before calving, and generally within forty-eight hours thereof.

One attack predisposes to another one.

Most common in fat cows.

Patient fails to keep standing.

Rapidly followed by coma.

Earliest period of recovery is generally eight to sixteen hours.

Prognosis generally very unfavourable till Schmidt treatment found out; now more favourable.

Parturient Eclampsia.

Occurs in cows of all ages, but mostly at first and second calving.

Occurs in cows before calving; if after calving hardly ever before the eighth to sixteenth days.

One attack not necessarily succeeded by another at next calving.

Most common in lean cows.

Patient mostly can stand through attack.

The cow only occasionally becomes comatose.

Recovery takes place in a few hours generally.

Prognosis favourable and the treatment successful.

Now, gentlemen, these are the principal features in contrasting these two diseases, and I will now give you the most successful treatment that I

have found for this disease after trying several remedies.

Treatment.—First get the cow made comfortable in a good warm box or byre free from draughts, and as the morbid condition of the nervous system may be brought about by cold winds, wet, or draught, it is necessary to do this most needful part of the treatment. Then if the bowels are correct I give no laxative, but prescribe from ʒi. to ʒii. ext. belladonna every three hours as long as necessary; bleeding may be resorted to if the foregoing treatment fails, but this is not usually the case. If kidneys don't act promptly and sufficiently I prescribe ʒii. spt. ether nit. in a little cold water, or along with the ext. belladonna; give about two quarts of linseed tea every few hours if the animal will have it, and this is usually all that is necessary for the treatment.—*Veterinary Journal.*

(To be continued.)

THE JACK (*ARTOCARPUS INTEGRIFOLIA*).

The acting Director of the Royal Botanic Gardens (Mr. J. B. Carruthers, F.L.S.), lately delivered a lecture entitled "The Story of the Jak Tree." The tree known in Sinhalese as *Kos* and in Tamil as *Pila*—was, however, taken to serve as a tropical specimen to illustrate a lesson on plant life. The account we give below is on the other hand a very complete account of the Jak and its uses. It is taken from the *Queensland Agricultural Gazette* and was written by the Manager of the State Nursery, Kamerunga, Cairns. As dealing with one of our commonest trees it should be of local interest, while our readers will find that there is something new in the article:—

The Jackfruit (*Artocarpus integrifolia*, Linn.) is of the same family and the nearest known relative of the famous Breadfruit (*A. incisa*). The name *Artocarpus* is derived from two Greek words literally translated, viz., *Artos*, bread; and *Carpos*, fruit, and its second name is purely botanical, *integrifolia* meaning entire leaved to distinguish it from *A. incisa*, the cut or incised leaved Breadfruit.

The Jack fruit, being of a much darker green, and having very much smaller leaves, and often being quite a different shape and size, the similarity of the two trees will often not be commonly apparent.

There are several allied species, as *A. Lakoochia*, *A. Chaplasha*, *A. Hirsuta*,* about which very little would seem to be known, and which do not appear to have an economic value proportionate to the two species mentioned. The Jack is a native of East India and the South Seas, inhabiting countries with a hot and moist climate, and is essentially a tropical tree. It will not generally thrive in a locality subject to strong winds, as it is somewhat brittle, and will not stand severe frost, though much harder in this respect than the Breadfruit.

*And in Ceylon *A. nobilis* which gives us a useful timber, and the seeds of which are roasted and eaten.—*Ed. A.M.*

It is an umbrageous or thick foliaged tree and an evergreen. One tree exists in this Nursery which is thriving particularly well, having readily adapted itself to the climatic conditions obtaining here. An illustration accompanies this article. The tree shown is about ten years old, and 35 to 40 feet in height; it has been in bearing four years or so. During the last season it bore a heavy crop of fifty or sixty fruit, averaging in weight from 5 to 10 or 12 lb.

I have observed a few trees here and there in North Queensland, mostly in old gardens where presumably it was grown more as a curiosity than for use; in any case very little advantage would seem to be taken of its useful properties. Several varieties of the tree exist, and some were probably introduced into Queensland at one time, though I have not yet met with more than one variety, which is by no means the best. The better varieties are known as the "Honey Jack" in India and Java, from the sweet syrup that is to be found within the pulp round the seed, and the "Root-bearing Jack," which produces its fruit entirely or partially underground. This latter is a specially fine fruit, and much valued in the Orient. Some writers seem to be of opinion that old trees of the ordinary or "Honey Jack" variety will bear fruit upon their roots in this way, but this is not authenticated. The root-cropping tree is generally considered a separate variety, and though I have seen, sown and cultivated thousands of these trees, have never yet seen an ordinary Jack that will do this from mere age. This root-bearing may, however, be brought about by artificial treatment occasionally, which methods I will describe later.

Another variety of the species is the "Wild Jack," which is a much larger tree than the cultivated or sweet one. The fruit is smaller, and though sweet, not so pleasant; the tree itself, however, is more spreading, contains more timber, and as a fodder tree is the more useful of the two.

The fruit of the Jack tree is oval or oblong, is muricated on the rind, and of a bright green colour, turning slightly darker or duller when approaching ripeness, but never becoming quite yellow. When opened it is white inside; the inner pulp or edible parts are separately attached to the centre core, and surrounded by or packed in viscid fibres. Each piece of pulp is about the size of an egg plum, pale yellow in colour, and contains one seed.

The tree, like the cocoa, bears its fruit upon the stem and thicker branches. The fruit has a somewhat strong scent, which is intensified if allowed to become over-ripe. The smell is disliked by some, but on becoming accustomed to it or on tasting the fruit, it ceases to be offensive or even noticeable.

The tree is very prolific, and the fruit often attains tremendous size and weight—fruit of 80 lb. have occasionally been met with. In Southern India I have obtained fifty to seventy fruit from one tree, and myself cut a specimen weighing 70 lb.

In Queensland, however, I have not met with any large specimens—the average would seem to be from 5 to 10 lb., although one fruit of 23 lb. is on record.

The tree comes into bearing here in three to four years, and while large fruit will contain as many as 200 seeds, ten to twelve seeds per fruit is more common. The cropping season is also very short in this State, usually lasting less than two months between January and March.

The fruit is distinctly palatable and is wholesome and nutritious. The smell, however, is apt to prejudice one against it on tasting it for the first time, and if, in ignorance, an over-ripe fruit is opened, not only is the smell intensified and rendered disagreeable, but the fruit is not so nice flavoured, for, like the Durian, to which it is sometimes likened, it must be taken at the right degree of ripeness to be appreciated.

If these over-ripe fruit are removed or buried, the smell is really no stronger than that of the mango, and not as disagreeable. To judge a ripe Jackfruit, however, needs a little practice, for one cannot judge by colour. The usual method is to tap the fruit or flip it with the finger, when the hollowness of the sound denotes the degree of ripeness.

The white milky juice, which is very sticky, renders an unripe fruit uneatable, and in an over-ripe one, the stringyness as well as strong smell makes it equally unpalatable. An ideal fruit should have the pulp firm but neither soft nor hard, and a pale yellow colour, when it will be found sweet and of a most agreeable flavour.

In its native countries the fruit is considered a delicacy; natives will pay 1s. to 1s. 4d. each for them, and Europeans become exceedingly fond of them. The pulp may also be cooked in various ways; I have had it boiled in milk, cooked in custards, fried in butter, and preserved in honey. In the latter form it is an excellent dessert. Bernays, in his "Cultural Industries," gives a receipt for boiling in milk, from which, however, the pulp would subsequently seem to be strained off.

In opening a fruit, the rind, which is about half-an-inch thick, should be cut through and the fruit then broken open. The pulp sacs containing the seed may then be picked out from the surrounding fibres. These should at once be cut open, the seed taken out, and put into a basin of water. The addition of a very little salt to the water improves them, and, it is said, eliminates what little smell may remain. If strained and served up promptly with icing sugar sifted over, they are not only palatable but excellent eating and quite odourless.

However, although it cannot be said that in this case "all love Jack," still all concur in attesting to the excellence of the nuts when roasted. These may be roasted like English chestnuts, which they much resemble, or boiled and used in curries or stews. After being boiled they are sometimes dried and ground, and cakes and nutritious farinaceous foods made from the flour.

(To be Concluded.)

GENERAL ITEMS.

The Station, Farm and Dairy referring to the value of manures and the conservatism of some cultivators who are prejudiced against them, says:—If Agriculturists continue to refuse the teaching of their fellowman, the least they should do is to give up farming, for unquestionably such men do not deserve the name of agriculturists, and by keeping to it they merely drag the name in the mud.

The same paper referring to Sunflower cultivation in Russia, says:—The industry which is stated to be very remunerative is rapidly increasing in proportions, and promises to still further develop before long. It is claimed that the sale of the oil-cake produced, in itself more than covers all the working expenditure of the mills. The stalks of the plant are used as fuel for driving the machinery, and the ash that remains gives from 25 to 30 per cent of potash. Briefly speaking, it would appear that the sunflower seed, when properly crushed, gives 23 per cent oil, 40 per cent cake, and 37 per cent stalk.

"Sunlight Oil Cake," advertised as the best food for stock and poultry, is nothing more than "Coconut ponnac," the residual cake after the express from copra of the oil used in the manufacture of sunlight soap. The wonder is that there is no local firm manufacturing soap. Messrs. Freudenberg & Co. did a business in coconut oil soap some years ago, but we believe they have given up the manufacture now.

Have any of our readers come across plantain trees bearing bunches of fruit about a yard from the ground? This is said to be as common in lower Bengal, especially in the variety known as "Beejee-kela."

The German Emperor has determined to help the agriculture of his own country by opening a new career for the potato. With this object he is doing all he can to extend the use of potato alcohol as fuel. He has already induced a number of firms, including that of Herr Krupp, to adopt potato alcohol for their motors.

To keep fruit trees clean of pests a correspondent to the *Queensland Agricultural Journal* recommends the following treatment:—"The soil about the roots of the trees was removed as far as the roots went, so that they were laid bare. Woodhouses dry and well preserved were strewn over the exposed roots and kerosine sprinkled over afterwards. The soil was then returned to its place. The trunks were tarred to the height of one foot, and beyond that washed with kerosine and warm water. At the same time the upper trunk and the limbs as far as convenient were whitewashed. All this need only be done when the trees have started budding." With a few valuable fruit trees this may be possible, and will be compensated for the fine yield of good fruit; but for large areas some modification of the above elaborate plan would have to be adopted, and may still be found beneficial.

No. 7.

JOTTINGS FROM A PLANTER'S NOTE BOOK.*

TEA planter without a pocket notebook would almost cease to be a planter, so consistent is the practice of carrying one. Verily, was the man who invented them sensible, for many interesting items find space therein which would otherwise escape from a fleeting memory.

After a few years' absence from the country one of the most striking features noticeable is the damage done by wash, more especially in the older and steeper districts. Though the harm done so far has scarcely been felt, I feel the gravity of it is worthy of more consideration than is given it. On every hand one sees the roots of grevilleas and tea exposed in a way that ought to cause alarm. The feeding roots of the bush are often to be seen, whereas they ought to be hidden just under the surface soil. This is not due to the growth of the trees, because the general tendency of roots is to keep under the soil. Then again we see the wash instanced on what were once good smooth roads. The earth around stones has been gradually carried away and roots have become exposed which are now traps for unwary pedestrians. As each year goes by more earth is swept away, so little that residents scarcely notice it and pay no heed. But this in the sum of years amounts to a very great deal, for it is in this manner that the physical features of a country are changed, through the slow process of countless years which are unnumbered by eternity.

The working expenses and profits of most tea estates will not admit of TERRACING, which was resorted to in the old coffee days. Something might be done in the way of coppicing with *mana* grass, but this is not always feasible. Trees have been very generally planted through the tea, not so much with the idea of preventing wash, but they do so to no small extent. For this purpose grevilleas appear to be the most suitable, when other important matters, such as

nutrition taken out of the soil, are considered. They provide a more plentiful, but not so fine a litter as *toonas* or *albizzias*.

In clearing out drains a little help can be given by throwing the silt upwards into the tea, instead of downwards as the general custom is. I feel safe in prognosticating that in a decade or two the question will become very acute in some places. Capital will be required that the difficulty may be met by re-planting—as is found necessary in most tea countries, or by terracing or other expensive methods that may be advanced for alleviating the situation. Where new land is available the point will arise, whether it is not better to open it up and to abandon the old.

On many estates too little attention is given to PRUNING and there is a general tendency to reduce the cost below a figure at which good pruning can be done. In fruit-growing countries the importance of this item is fully realized, it having been found that if the work is not well done, the trees cease to fruit proportionately. It is the same with tea. Where knots and old unproductive branches are not taken out of the bush, the sap has not a free course and is hindered if not stayed. This inevitably results in a smaller yield than would have otherwise been obtained. Non-paying estates would do well not to reduce the cost of pruning indiscriminately, for it stands to reason that if crop cannot be secured, profits will be all the more hardly obtained.

MANURING seems to me to be being carried too far. In a few years the present forcing manures will cease to affect tea as they do now and still more invigorating stimulants will be required. When these are no longer forthcoming a reaction must set in and a serious crisis will arrive on all highly manured properties. Then will come the turn of those, who, without injuring the industry by inordinate yields, apply a mild manure and are content with reasonable results. It will probably be futile to sound a word of warning to the owners of estates of medium elevation as well as to those who are extensively planting up the low country with rubber. Still it is well to draw their attention to the fact that rubber will be obtainable, as soon as it is

* Specially written for the *Tropical Agriculturist*.

available in Ceylon, in enormous quantities from Burma. The Straits, Borneo, the vast regions of the Congo and the, as yet, unexplored basins of huge Amazonian tributaries to which the rubber tree will undoubtedly be found endemic. They will probably prefer to believe the pessimistic rumours that the present supplies are nearly exhausted in S. America and that the demand for the commodity must ever be insatiable.

VANILLA is an article which should not be dealt in extensively. There must always necessarily be but a small demand, so that if it were largely plauted up, it would very soon share the same fate as cinchona. Planters who take interest in new products might do well in an attempt to naturalize trees producing cork and paper. If they were found suitable to the country, our cheapness of labor should make them very profitable products. An interesting experiment would be for planters at different elevations to ascertain the length of time taken by a tea shoot to develop according to the Fish, Half and Full leaf systems of packing and to compare results. I should be happy to give a basis to work on and data.

It may be useful to mention here that at a medium elevation PARA RUBBER seeds take about 20 days from the time of planting, to appear above ground.

Also, that it is ill-advised to grow vanilla vines on grevilleas as the suckers cling to the bark, which cracks and splits them. In Tahiti they are grown very successfully on guava trees, which growing wild, are very handy for the purpose.

A. T. FARMER.

VANILLA CULTIVATION.

The following are the remainder of Mr. Galbraith's miscellaneous notes on Vanilla cultivation in the Seychelles, and are in continuation of those given on page 375:—

SUN CURING:

During early crop gathering, before ripe pods are numerous enough to make it worth while using the hot room they are cured under blankets in the sun, but have to be taken in at the hottest part of the day if sunshine is continuous. This used to be the sole method of curing here and when used now gives excellent results in favourable weather; but dependence upon the sun is risky, and upon the whole the process is cumbersome and costly. Hand trays that can be piled up on top of each other and carried between two men, are used to spread the blankets on, a fold being below as well as above the pods, and these are supported on low double rails to keep them clear of the ground. In unsettled weather showers have to be watched for, and the trays carried under shelter till the weather again becomes fair.

If there is a pinch for space in the curing house, pods in the hot room may be spread two or three or more deep on the shelves and tumbled up daily, that is such of them as are not taken off and re-sorted.

MULCHING AND SHADE.

In mulching vanilla roots, and especially at crop time, the plants are much more benefited if the mulch be of two sorts, well-rotted leaf mould being put on first for immediate action, and above it a layer of withered fern or the like, which decays more slowly. When heavy top dressings of quick-decaying manure, grass, etc., have rotted down, they get beaten away by rain, the network of roots becomes exposed, and may with advantage be lightly covered with a thin sprinkling of good soil. Obviously it is better to apply this before the roots become bare or visible. The vanilla roots delight in twisting among stones, large and small, and flattening against their lower surface when not embedded in the soil. When these

are of a convenient size and handy in a plantation, the root circuit allowed to each vine may be ringed with them. Vanilla may be grown on trees of thick foliage if there are of a sort that will stand being well pruned annually. Wild cinnamon, which gives dense shade, is sometimes used for this purpose, the branches being nearly all cut off each year about pod-ripening time, which also lets the sun get at the vines for flowering. The contrast between the former somewhat dense shade, which has grown since last branch trimming, and the strong light let in by the pruning seems to help toward blossoming.

Under large, high trees, wide apart, where to plant vines on other small-growing wood between them would make the shade too close, vanilla may be fixed on tripods of durable wood, the three stakes being tied with wire crosswise some little way from their top ends, so as to furnish forks over which the vine creepers may climb. High up in the hills here the plants may be grown in this way without any shade at all, but the plan is only suitable for level grounds or moderate slopes.

SUMMARY.

The foregoing account of vanilla cultivation, being the outcome of experience gained in the Seychelles alone, and there chiefly in the hills, may need many modifications to adapt it to different circumstances pertaining to other lands, and, indeed, possibly may be of little use for such. For instance, in a drier climate irrigation might be needful, and it would not be necessary with a reliable, sufficient annual dry period to prepare vines for flowering by checking their sap flow in certain branches, as it is in this colony. This is not found necessary in certain districts where the rainfall is not such as to keep plants growing continuously, for they stop growing of themselves and come into flower without coaxing.

Again, under less favourable growing conditions the vines would need more nutriment and attention to stimulate growth.

These and similar considerations which will suggest themselves to the reader may serve to save a brief summary from appearing too dogmatic.

The following conditions of climate, method of growing, etc., appear to the writer to be most favourable to the successful cultivation and handling of the vanilla crop.

Climate.—With shade temperature ranging about 80° F., never much above or below it, and a humid, still atmosphere; a rainfall of 80 to 100 inches or more, evenly distributed through ten months in the year, the remaining two months being dry, with occasional short and very light showers—the ten wet months for continuous luxuriant growth, the two dry ones to check it and bring vines into flower.

Soil.—A skin of rich vegetable mould resting on a porous substratum. Failing that, with the above climate, vanilla should do well on any soil if the roots are kept covered with decaying vegetation.

Situation.—Moderate slopes.

Shades.—Small-leaved trees to let checkered sunlight through.

Plants.—Cuttings 10 to 12 feet long of growing shoots, which should not cease growing if planted after the dry season, but go straight on and flower fully in two years.

Planting.—Either in line on posts and bars, or on shrubs of suitable size and leafage, at the risk of whole sale destruction from disease; or plants well kept apart, each on its own support, so that any vine showing signs of sickness may be removed before infecting its neighbours.

Culture.—Plantations to be gone through bi-monthly shoots on the ground looped up; climbing branches brought down; decayed leaves, etc., laid on roots for manure, when needed. Preparations for flowering according to climate.

Cropping.—Flowers to be pollinated in forenoon, preferably such as will hang clear and grow straight pods, quantity regulated according to mass and vigour

of each vine, but not such as to hinder the start of new growth for more than two or three months. Pods should be gathered every other day.

Curing.—The slower, the better, beginning in a heated room at about 113° F. for some days, then in a cooler one, 90° to 100° F., finishing at ordinary temperature; humidity of air kept down if need be by charcoal braziers.

Marketing.—Qualities and lengths kept distinct, made up in packets of 50 pods, and neatly packed in tins holding about 12 pounds each.

Labour.—Cheapness and intelligence are of the greatest importance in vanilla production. The cultivator must himself have his eyes everywhere; the best of labour known here deteriorates quickly if left by itself.—*West Indies Agricultural News*.

CEYLON TEA IN AMERICA.

IMPORTANT ALLEGATION REGARDING RE-COLOURED
CEYLON TEAS.

(By T. Gossupp, of New York.)

It may be of interest to many of the planters of India and Ceylon to know a certain amount of actual facts about the American tea trade without being puzzled by a lot of figures.

In the first place, Ceylon teas are coming rapidly into favour here, and without doubt Ceylon green teas are slowly replacing Japan teas. Unfortunately, however, the Ceylon green teas are offering at rather higher prices than the buyers of sun-dried Japan are accustomed to pay, except for Japan sun-dried teas of real fine liquors.

Your writers may not be aware that there are three classes of Japan teas sold here, the "sun-dried" being similar to our uncoloured Ceylon greens but of much better make, having a darker colour and of rather more delicate flavour in the cup. Then there is the "pan-fired" Japan which is similar to a coloured Ceylon green, but the basket-fired Japan, to my mind as a tea expert, is far superior to anything I have seen with the exception of perhaps one invoice of Ceylon greens which came, I believe, from Bloomfield estate, but which was only a very small parcel.

I advocated some time ago that the Ceylon planters, in order to cope with the over-production of tea (from which they have been suffering) should endeavour to make an "Oolong" tea similar in flavour and style to the Formosa Oolongs which are in general use here. It would be very easy for any of your planters to write to Formosa or to Japan and get samples from these two countries in order that they may see from an actual sample the kind of tea which is wanted in America. The price of Oolongs to-day is 10d. per lb. c-i-f N. Y.

To take the United States first, it is necessary to remember that it is about 73 times as large as Great Britain and has a population of 76,000,000 people as against Great Britain's 40,000,000, so that you see if we can once induce the Americans to become tea-drinkers on the same scale as the British people generally, or even, say, they take three lbs. of tea per head, in a very few years to come we shall have no fear of over-production as America alone will be able to take nearly all the output of Indian and Ceylon. It is, therefore, a field we have to consider and during the last few months (when Japan teas have been very high), we had a chance of getting Ceylon green teas into favour, but the price held out for by the planter or merchant in Colombo, has prevented them from being more readily taken.

The grades wanted here are Hyson No. 1 and Hyson No. 2, and for these people are willing to pay from 6½d. to 7d. for the Hyson No. 1, and about 5½ to 6d. for the Hyson No. 2. The Young Hyson grade is generally coloured in New York, which can be done for 3d., per lb. and it is then sold as China green tea,

A great many of the Ceylon greens sold in the States are coloured, repacked, and either sold as coloured Japans or as China green teas, being packed in China packages and faced with the usual paper, *exactly*, to represent them as or China Japan teas.

With regard to Canada: this country is different, as there is a large population who have now become accustomed to Ceylon uncoloured greens, and the loyalty that exists in Canada prompts the consumer to support British tea in preference to Japan tea. Here again the question of price comes in, and the only way that Ceylon greens can oust China and Japan is by selling them at reasonable prices, as the grocer will always push the teas that show him the largest profit.

The labour in Ceylon and India is cheaper than in Japan, so one would think that the planters would have a great deal in their favour. The duty of 10 cents per lb., which was a war tax, is to be repealed on the 1st January, 1903, and it is anticipated that a much larger trade will be done.

Some of the favourite grades here are the Norwood, Labukellie, Condegalla, Meeriabeddie, Warwick, and similar liquoring teas so this will guide many of the planters (who are in these districts where this class of tea can be made), to get samples and follow them very carefully and closely, as there is regular demand for the light liquoring, flavoury, good quality (so called lemon-flavoured) Ceylon teas.

If a few of the estates shipping desirable and suitable teas for the American market were to create a demand here by shipping direct they would find that in a very short time the venture, would pay as the writer has seen tea sold here 2d. and 3d. per lb. above the price that they sold for in the London auction.

There are other matters I could write about in connection with the tea planters of Ceylon and India, the tea cess, the packages that are required for this market, the question of shipment, and several other matters which I will touch upon in my next letter.—*Local "Times."*

JOURNEY TO A RUBBER PLANTATION ON THE ISTHMUS OF COLUMBIA.

By C. O. WEBER, Ph. D.*

(Concluded from page 371.)

THE LATEX I have already stated that the latex obtained from *Castilloa elastica* at Las Cascadas does not flow like milk, but issues from the cuts in the form of a thick cream containing a very high percentage of india-rubber. This is certainly curious in view of the fact that the same tree in other districts produces a fairly thin milk although I have been told that the *Castilloa* trees in certain districts of Guatemala and Venezuela exhibit the same peculiarity. I have not been able to discover any reason for this difference. It cannot be due to a difference of species, nor to the elevation at which the trees are growing, nor to the temperature limits of the respective districts, as in other districts, at both higher and lower elevations, and higher and lower temperature limits, e.g., Mexico on the one part, and Ecuador on the other, the *Castilloa* trees produce a perfectly fluid latex. It is not impossible that the condition of the soil, and the annual rainfall may have some influence upon this point, but in the absence of any positive proof I prefer to leave this matter for the present undecided.

The latex of *castilloa* at the moment of issuing from the cuts forms an almost pure white, thick creamy mass, which, however, almost immediately begins to discolour, assuming at first a pale drab colouration, which, in the course of a very short

* From the *India Rubber and Gutta-Percha Trades Journal*, Sept. 29, 1902.

time darkens into a brownish black. This phenomenon, which is at least one of the causes of the very bad colour of all the Central American rubbers of the present day, in fact, of all the rubbers obtained from *Castilloa elastica*, I found to be due to the presence in the latex of an oxidising ferment (oxydase) and it is, therefore obvious that in attempting to produce a high-class, pure rubber from *Castilloa* latex the presence of this ferment has to be taken into consideration.

The taste of the *Castilloa* latex is intensely bitter. This appears to be due to the presence in it of a substance of the class of bodies chemically described as glucosides. It is this same body which is the cause of the intense dark green colouration produced by the addition to the latex, or better to its aqueous vehicle, of a few drops of a solution of ferric chloride. I presume that this reaction has been observed before, and led the observers to the altogether erroneous assumption that the *Castilloa* latex contains tannic acid, which latter as is well known, produces much the same colouration with ferric chloride. As a matter of fact, there is not the slightest trace of tannic acid to be found in this latex, and I doubt whether it occurs in the latex of any other rubber tree. It is really only necessary to state that the latex of *Castilloa elastica*, beside the bodies already named, contains a very large proportion of albumen, and to remind the reader that albumen may be quantitatively precipitated with tannic acid, in order to prove that the presence of tannic acid in the latex is an impossibility. Indeed, on adding to a solution of the aqueous vehicle of the latex of *Castilloa* a few drops of a dilute solution of tannic acid, a most copious precipitate of albumen tannate is at once obtained. Considering that all the different specimens of rubber latex I have so far as an opportunity of examining contain albumen in varying quantities, though none as much as the latex of *Castilloa elastica*, is at the same time sufficient proof of the absence of tannic acid in every case.

A quantitative determination of the amount of albumen and albuminous matters in general in the latex yielded the rather surprising result that there is as much as 11 per cent. of these bodies present. This, I believe, is the cause of the extreme ease with which the latex of *Castilloa elastica* can be coagulated. I am quite aware that this has been attributed to the comparatively large size of the rubber globules in the *Castilloa* latex, but for reasons, based upon evidence, I shall produce in another paper on this important subject, I believe this assumption to be erroneous.

In my communication I showed that the latex of an 11 year old *Castilloa* tree contains 31 per cent. of pure rubber, and it will, therefore, be seen from the above statement regarding the amount of albuminous matter in the latex that if we coagulate the latter without first removing from it this albuminous matter we obtain a rubber containing over 25 per cent. of albuminous matter. The native rubber collectors prepare the rubber from the latex in such a way that at least part of the aqueous vehicle of the latex is drained away before coagulation takes place, and consequently we never find a Central American rubber (crude) which contains as much as the above stated quantity (25 per cent. of albuminous matter), but lots containing from 9 to 13 per cent. are quite common. It is, indeed, the presence of such a large amount of albuminous matter in the Central American and some other *Castilloa* rubbers which is largely responsible for their frequently reaching American and European ports in a state of pronounced putrid fermentation, of the atrocious smell they emit on washing, and of their often very unsatisfactory behaviour in the process of vulcanisation. When such rubber in a state of advanced putrid fermentation is subjected to the washing process a very considerable proportion of the coagulated albuminous matter, rendered soluble by

the fermentation, is removed, but the rubber, although not taking itself an active part in this fermentation, is, nevertheless, found to have suffered more or less severely from it, to possess little strength, and, after vulcanisation, only very moderate distensibility (elasticity). If, on the other hand, the rubber reaches the factory in fair condition, it contains practically the whole of the albuminous matter in an insoluble condition and so intimately intermixed with the rubber that the washing altogether fails to remove more than a mere trace of it. We obtain then a washed rubber, which contains a very large proportion of albuminous matter, the presence of which in the washed and dried rubber is scarcely noticeable, but which is the cause of such rubber forming invariably a peculiarly "short" and non-resilient vulcanisation product. It will thus be seen that whatever happens to such rubber during transit it is always a very inferior product from what it might be if the albuminous matter were kept out of it. In fact, I scarcely think I want any further justification for the statement that the *Castilloa* rubber of the present day owing to the above discussed defect, occupies a much lower position than it would hold considering the intrinsic quality of the pure rubber it contains. I am, indeed, of the opinion that properly prepared *Castilloa* rubber is superior to most of the present day Para grades.

Incidentally I may remark here that the presence of substantial quantities of albuminous matter not only in *Castilloa* rubber, but also in some other (African) brands, and the odour they produce owing to fermentation has given rise to the now almost ineradicable nursery tale that in certain districts the rubber is coagulated by means of one of the by-products in the economy of the human body, the use of which would be far more commendable on account of its inexpensive character than for its attractiveness. This fable has never been substantiated, and I believe that its origin is simply to be found in the offensive urinal smell developed on the fermentation of the albuminous matter in crude rubber.

The methods followed by the native collectors for the coagulation of the *Castilloa* latex vary considerably:

1. The latex is washed with water, but just as often this is neglected, and then treated with a decoction of the crushed stem of the moon-plant, *Calonyction speciosum*. This, according to Dr. Morris, is the process practised in British Honduras.

2. The latex is treated with the juice expressed from *Ipomoea bona nox* which is stated to be highly alkaline. (?)

3. The latex is collected in shallow holes dug in the ground and mixed with a boiling solution of soap in water. This process is extensively practised in the Isthmus of Panama.

5. The latex is treated with a solution of alum.

These various methods call for the following remarks:—All of them effect the so-called coagulation by adding to the latex substances—acids, or alkalies—capable of coagulating the albumen. In other words there is no such thing as the coagulation of the *indiarubber itself*. What takes place is that through the addition to the latex of either an acid, or faintly alkaline solution the albumen, of which I have shown there is such a large amount in the *Castilloa* latex, is coagulated and carries down with it the rubber globules suspended in the latex. If the latex is entirely freed from all albuminous matter by a carefully conducted series of washings it may still be diluted with water, and then forms a liquid milky liquid of a somewhat lighter colour than the original latex, but otherwise indistinguishable from it. But if we now try to coagulate this albumin-free liquid with any of the above named coagulants we find that the rubber remains quite unaffected, no coagulation taking place. Therefore, whenever we coagulate the rubber, we can only do

so by coagulating it in conjunction with the albumen present, and we have at once a product possessing all the immediate drawbacks which above we discussed at some length.

On the plantation at Las Cascadas, Calonyction speciosum is very common, and I ascertained that decoctions prepared from it have a strongly acid reaction. Therefore, coagulation with such a decoction is simply the well-known coagulation of solutions of albumen with acids. I have not been able to discover at Las Cascadas Ipomoea bona nox, but I very much doubt the highly alkaline character of its juice which it is almost certain to possess likewise a distinctly acid reaction. The treatment with alum, a process due to H. A. Strauss, and purchased from him by the local government of the province of Pernambuco, owes its coagulating action entirely to the strongly acid reaction of that salt. This process is a bad one from every point of view. The removal of the alum solution from the coagulated rubber is physical impossibility, and the pernicious action of an alum solution upon the drying rubber is quite sufficient to render its continued employment most deplorable. The coagulation with soap as practised in the Isthmus of Panama is barbarous in the extreme, and it is not surprising that it yields a product of very bad quality indeed.

Amongst the above-named processes I have not enumerated a process said to be practised in Mexico, and simply consisting in the boiling of the latex in earthen vessels (jacaras). If this process is actually used, it can certainly not be carried out with the fresh latex for the simple reason that over and over again have I satisfied myself that even on very prolonged boiling of the slightly diluted latex furnished by the tree at Las Cascadas no coagulation can be obtained. The cause of this is to be found in the fact that the aqueous vehicle of this latex, although it certainly contains a large amount of albuminous matter when rapidly separated from the latex immediately after this has been obtained, is of a very light olive green colour and even on very prolonged boiling does not coagulate, nor even become turbid. On standing exposed to the air this aqueous vehicle very rapidly assumes a darker colour, and eventually forms an almost inky liquid. This, on boiling, undergoes immediate coagulation, and a most copious deposit of insoluble albumen is obtained. In entire agreement with this observation is the fact that if the Castilla latex be allowed to stand for sometime until it has assumed a very dark colour it will now be found that on short boiling rapid and complete coagulation takes place. I have not yet succeeded in ascertaining the cause of this curious phenomenon, but it is obvious that unless the Castilla latex obtained in Mexico differs very considerably from the latex yielded by the same trees in the Isthmus coagulation by boiling in Mexico, must be preceded by an ageing of the latex as otherwise no coagulation would take place.

It is not very easy to see that the chief point in attempting to prepare a pure rubber from the latex of Castilla elastica, and as a matter of fact, from the latex of any other rubber tree, must consist in the elimination from the rubber, prior to its "agglutination," of all albuminous matter. The first step in this direction is the diluting of the crude latex with water, of which at least five times the volume of the latex treated should be used. In the case of the thick, cloudy latex yielded by the trees at Las Cascadas it is preferable to use actually boiling water, but in how far this applies to the latex obtained in other districts or from different trees is a matter for experiment. Boiling water at once converts this latex into a thin, very fluid milk which through a common cotton gauze is strained in order to remove from it any insoluble impurities such as earth, wood, bark, and the like. This milk is best strained into thoroughly well-washed petroleum barrels. As soon

as the barrel is completely filled, about 8 ozs. of formaldehyde are added, the whole well stirred, and allowed to stand for 24 hours. The action of the formaldehyde appears to be twofold. In the first instance, it effectually prevents any tendency of the albumen to coagulate in the hot solution, and thereby to cause mischief. But, as comparative experiments showed beyond any doubt, it also has a most distinct effect upon the india-rubber, which collects on the top of the washwater in the form of a snow-white cake of rubber of such strength and toughness that it can in one mass be lifted out from the barrel. On cutting this cake open, it will be found that it is rather spongy, being full of little holes which are still filled with some of the albuminous, though very dilute, mother liquor. If, therefore, the rubber were dried in this state it is obvious that it would still contain a small quantity of the objectionable albuminous matter. For this reason the rubber contained should at once be taken, cut into strips, and subjected to a thorough washing upon an ordinary rubber washing machine. As all albuminous matter present is still in a state of perfect solubility there is no difficulty whatever of completely removing every trace of it by carrying out the washing with a plentiful supply of water on the washing rollers.

The rubber thus obtained is a product of a degree of purity in which no rubber, not even the finest brands of Para, has ever been offered to the manufacturer. It is absolutely free from solid impurities of any description, it contains no trace of either soluble or insoluble organic or inorganic impurities. Of course it contains a small amount of resinous matter combined with only a trace of the constituents known as "ash." The amount of these resinous matters is extremely small, and they are of an entirely innocuous nature, so that any attempts to remove them, which would call for a somewhat energetic chemical treatment, would be altogether out of place. In a further communication I intend to give the analytical data of this pure Castilla rubber.

When dry, the condition in which the owners of the Las Cascadas plantations intend to ship this rubber, it forms a product which requires no preparatory operation on the part of the rubber manufacturer, but which may at once be taken into operation for the manufacture of rubber goods of every description. Nor need any fear be entertained that rubber of this description is in the least liable to suffer such detrimental changes during transit in the ships' holds, which are at present so common owing to the "heating" (fermentation) of the rubber during transit. Indeed, a considerable lot of this which was purposely packed and shipped in the excessively wet condition in which it came off the rubber washer, had not undergone the least change, still less any deterioration on reaching this country.

An analysis of a sample taken of one of these dry sheets of rubber gave the following results:—

Resinous Matter	2.61 p.c.
Ash	0.44 p.c.
Nitrogenous Constituents ..	Nil.
Insoluble Constituents	Nil.

The sheets themselves are extremely light in colour, semi-transparent, and when dissolved in the usual rubber solvents form almost glass clear solutions. The characteristic rubber smell is almost entirely lacking, certainly much less noticeable than in even the finest Para rubber. The strength of these sheets is distinctly superior to that of washed and dried sheets of Para rubber. How this Castilla rubber after vulcanisation compares with Para rubber, and how in general it behaves in the vulcanising process as compared with Castilla rubber in its present day crude and impure form, I have not been able yet to ascertain. This work is, however, in progress, and in due course I will report the results obtained.

The amount of resin in Castilloa rubber shown above is absolutely unobjectionable, and does not in the least affect the quality of the rubber. I am quite aware that now and then all sorts of sinister actions are ascribed to the presence of resins in india-rubber, but there is not the least particle of evidence to show that they are intrinsically detrimental. As a matter of fact, in the manufacture of quite a number of rubber goods resins are deliberately added to the mixings.

It is highly interesting to observe that the amount of resin increases in the trees from the root upwards, as the following table will show :—

RESINS IN RUBBER DRAWN FROM				Per cent.
Trunk	2.61
Largest branches	3.77
Medium	4.88
Young	5.86
Leaves	7.50

A similar increase is observed the younger the trees from which the rubber is drawn :—

RESINS IN RUBBER FROM TREES.				Per cent.
2 years old	42.33
3 "	35.02
4 "	26.47
5 "	18.18
7 "	11.59
8 "	7.21

It will therefore be seen that my advice not to tap the trees until they are at least 8 years old is not only justified in the interest of the life and development of the trees, but also in the amount of resin which may safely be admitted in rubber of high quality.

There are very few such observations on the amount of resin in rubber trees at different periods of their life, and in different parts of the tree, but it can scarcely be doubted that other kinds of rubber trees will exhibit similar conditions, although the amount of resin accompanying the rubber in different trees appears to vary not inconsiderable. But they never are entirely absent, and I am inclined to think that the usual view of them as oxidation products of the india-rubber is altogether erroneous.

PURITY.—As far as can at the present moment be seen, the fact is amply demonstrated that it is possible to prepare from the latex of Castilloa elastica a rubber which for purity is absolutely without a rival, and the physical properties of which place it at least on the level with the finest grades of Para rubber. And this result is obtainable in working upon the milk of a tree, which so far has only been conspicuous for yielding the worst of all American rubbers. This is all the more gratifying, as these results are obtained at quite a trifling addition to the cost of production, which addition, on the other hand, is compensated for by an increased value of the final product by at least 40 per cent.

COST OF RUBBER.—From what I have shown in an earlier section of this article it will be seen that the Castilloa tree should not be tapped until it is 8 years of age. The cost of clearing the land for planting, transplanting the seedlings, and keeping the planted plots for seven years clear from undergrowth, is astonishingly small, and does not exceed, at the utmost, £25 per 1,000 trees for the whole period until they are 8 years old. If, therefore, at the end of the seventh year the trees are tapped for the first time, and only half a pound of rubber taken per tree, we obtain from these 1,000 trees 500 lb. of rubber, which at the very lowest estimate would be worth at least 3s. per lb. in Liverpool. Deducting, therefore, the cost of collection, preparation, and shipment of the rubber, a return of about 100 per cent. would be obtained in the eighth year. This, with careful management, would steadily increase for a number of years.

COST OF LAND.—Of course, the cost of the land will play a not unimportant part in such a calculation. I do not know under what conditions and at what price land suitable for rubber cultivation may be obtained in the various Central American States. In Colombia, at any rate in the territories adjoining the Isthmus, land is obtained on the old Roman principle, "res nullius cedit prius occupanti," or, in elementary English, "first come, first served." That is to say, any land not in private occupation may be taken legal possession of by "denouncing" it before a land commissioner, a very simple procedure involving merely payment of a nominal registration fee. For the maintenance of the title it is sufficient to prove the working of the grant. Labour to any amount is easily obtainable from Jamaica, and if the steady influx from this island should not suffice, the authorities of Barbados would be only too glad to grant facilities for the drafting of labour into Colombia from their enormous coloured surplus population, for whom no work can be found in Barbados. Wages for plantation workers (machete men) range at about \$1.20 per day (Colombian money), equal to \$0.50 gold, say, 2s., the men finding their own food.

PLANTING.—In planting Castilloa, it would appear that great care is required to make quite sure that the seeds used, or the seedlings obtained, are really those of the best variety of Castilloa elastica. It appears that there are at least three varieties of this Castilloa, which are respectively distinguished as Castilloa alba, Castilloa negra, and Castilloa rubra. There is not the slightest difference between these three varieties as regards the general form of the tree and its branches, and also the flowers and seeds are in all three apparently identical. The above descriptions refer to the colour of the bark. The difference even there is, however, so small that it requires a practised eye to recognise the different varieties. These, differ nevertheless, very greatly in their value to the rubber planter.

ALBA.—Castilloa elastica alba produces a thick creamy milk. It is the hardest of all Castilloa trees, and suffers very little from the tapping operation. It also yields the largest quantity of rubber. The bark of this variety is white, with a distinct yellowish or pinkish cast.

NEGRA.—Castilloa elastica negra is characterised by a very rough dark bark. It yields very readily a thin milk producing a good rubber, but the tree in tapping easily bleeds to death.

RUBRA.—Castilloa elastica rubra has a reddish bark which is very smooth, thin, and brittle; nor does it show the longitudinal furrows which are noticeable in the two first-named trees. This variety yields a very small quantity of milk, but the rubber obtained from it is good. The tree is very common all over Central America, and I am afraid that in a number of instances it was this tree which was planted instead of the white Castilloa. Indeed, Koschny is inclined to think that it is this variety with which the experiments in the botanical gardens of Ceylon and Java were made which gave such discouraging results.

SHADE OR OPEN.—The question whether Castilloa should be planted in the shade, or in open land has been answered both ways. It is possible that the climatic conditions of the district in which the plantation is situated may have some influence upon this point. However, all the reliable evidence seems to show that the trees grow badly in dense forests, and produce a poor yield of rubber when grown on open ground. They appear to prosper best when growing up together with other trees, so that the trunk is always shaded, whilst the top of the tree at least, for a certain time during the day, receives the direct rays of the sun. From what I have seen at Las Cascadas I entertain no doubt whatever that the last named condition is the most favourable for the growth of the trees.

CLEARING.—This being admitted, it is obvious that in planting *Castilloa* in open land it is necessary to plant at the same time trees to protect and partly shade it. As this adds very greatly to the cost of planting, it stands to reason that in selecting land for the cultivation of *Castilloa*, preference should be given to forest land. The larger trees are cut out—there are generally plenty of uses for them on the plantation—only the smaller trees being left standing between which the rubber trees are planted.

SOIL.—As regards the configuration of the land, and the best quality of the soil, some little discrimination is also required. Regarding the soil, it may be said that *Castilloa* is very modest indeed, but, of course, this does not mean that just any soil is good enough. The best results are undoubtedly obtained on a deep, loamy, only moderately sandy soil. Whether *Castilloa* should be planted on level or on hanging ground is a rather more important question. In Mexico, I believe, rather large level tracts have been planted, but then the rainfall in Mexico is considerably less than what it is in Colombia. It is quite certain that the trees require well-drained land, and this with a rainfall of 130 inches, the figure for the Isthmus, means hanging land. There are immense traces of unappropriated land of this description north and south of the Isthmus.

CLIMATE.—The climate of Colombia more particularly the districts north and south of the Isthmus, is a very great deal better than its reputation. I am inclined to think that the villainous climate of the stretch of land between Colon and Panama, and the frightful death-rate amongst the canal workers, has been taken to apply without distinction to the high-lying land adjoining the district. But it must not be forgotten that the susceptibility of the negro, at any rate those hailing from the West Indies, for zymotic diseases, is nothing short of extraordinary, the death rate amongst them even from measles being simply appalling. The white races under the same conditions enjoy comparative immunity. Moreover, the higher-lying districts adjoining the Isthmus are incomparably healthier. There is, therefore, no reason why in the next 10 or 20 years rubber cultivation in Colombia should not attain to huge dimensions. Land is to be had practically for the asking, the establishing of even a large rubber plantation is incredibly cheap, and the returns are large, certain, and permanent.

AMERICAN SWEET POTATOES FOR INDIA.

TO THE EDITOR, "INDIAN GARDENING AND PLANTING."

DEAR SIR,—I imported three American varieties of sweet potatoes last year, *viz.*, Nausemond, New Jersey, and Virginia. These were first tried on the Bombay Farms. The first Bombay crop was propagated from imported tubers, the second crop was propagated in the usual way from cuttings. It was planted on the 8th of April and was lifted at the end of July. A large number of cuttings were distributed from the first crop to various parts of India, therefore only about $\frac{1}{4}$ acre was planted for the second crop. The area was too small for very reliable outturn figures. I give however, the results as under:—

	lbs. per acre.
Nausemond	14,470
New Jersey	16,782
Virginia	21,113

The land was not directly manured, but was in good condition. The produce from the whole plot (21.80 acre) was sold for R 90, or R 320 per acre.

The crop also yielded a very large number of cuttings which have been used for distribution and for planting an extended area at the Bombay Farms. I have now seen these varieties growing on various descriptions of soil in the Pooja, Bengal, Central

Provinces and Bombay. The plants everywhere show great vigour of growth. I believe the introduction of these varieties to be an undoubted success. It is important, therefore, to have these American varieties tried in all districts where the crop is important. Cuttings can be supplied during October for experimental trials if applications are made to my office at Nagpur.

The crop does best on deep alluvial soil of a sandy or loamy character, but will also do well on any free working naturally dry soil of fair depth. The best crops are grown under irrigation in the *rabi* season, but in districts where the cold of winter is severe and the total rainfall is not excessive, the crop will probably do best if planted in June-July. The American varieties are not likely to thrive on deep black soil.

The results reported from Poona show that the tubers were all sound and of good shape and size. They were proved to cook well and have good flavour. The Virginia variety produced four or five tubers from each plant. These tubers were larger than those usually obtained from indigenous varieties. The Nausemond and New Jersey varieties produced, 16 to 18 tubers from one plant. These tubers were smaller than those from ordinary indigenous varieties but were all of good marketable size. Tubers of each variety grew not far from the surface in clusters and were much easier to dig than those of ordinary Indian varieties.

The cultivator of sweet potatoes is put to no particular expense for seed. He simply uses as cuttings the haulms of a previous crop. These cuttings may have to be planted in a nursery. A small nursery planted in March when the *rabi* crop is harvested will provide cuttings for planting a *kharif* crop in July, and this crop will, in its turn, provide cuttings for the next *rabi* crop, which should be planted in October-November.

Full details regarding methods of cultivating this crop are given in Vol. III of my Agricultural Text-Book, but for easy reference I may refer to important points here.

The soil should be of suitable class and be well worked by repeated ploughings and harrowings. Beds should be formed if irrigation is required. The crop can be propagated from tubers, but more economically from cuttings or pieces of mature stem having four nodes to each cutting. The best cuttings are got from the middle portion of the stems. The date of planting the main crop will depend upon the usual custom in any particular district. The main crop is sometimes planted in flat beds and sometimes in ridges made about 18 inches apart. The latter method is preferable. The cuttings if planted in ridges should be buried halfway between the base and the apex and on each side of each ridge, each cutting should be planted with two nodes buried and two ends above ground. A vigorous growth of long trailing stems is soon produced if the crop is healthy, and very little hand weeding is required. No irrigation is given in the rains, but if planted in the *rabi* season, irrigation is necessary every 8 to 15 days according to the character of the soil.

The stems when in contact with wet soil after rain or irrigation become attached to the soil by rooting at the nodes. This must be prevented, otherwise small thin tubers of no marketable value form at each point of attachment. The tubers which form at the main root, moreover, will not grow so large as when the stems are kept quite free. The stems during growth must be repeatedly lifted clear from the ground and turned over to prevent the formation of these roots. These operations must be done often if the crop is good and the foliage luxuriant, and always with care so that the stems and leaves are damaged as little as possible.

In a luxuriant crop the growing points of the long trailing stems may be pruned off without damaging

the crop in any way. These prunings provide a delicate vegetable.

The crop should be lifted when the stems near the growing point get hard and fibrous and the leaves turn yellow. The vines should be reaped close to the ground and cuttings selected for a nursery, such of the vines or portions thereof as are green and succulent can be used as cattle fodder. Irrigation water should be withheld as the crop approaches maturity. When the tubers are ripe, they should be lifted at once, otherwise much damage will be done by rats and white-ants, etc.

Yours faithfully,
JAS. MOLLISON,

Inspector-General of Agriculture in India NAGPUR,
13th October 1902.—*Indian Gardening and Planting.*

PAPAYA CULTIVATION.

It is, of course, well known that natives pluck the fruit in a green state and ripen it artificially. This system is responsible for the absence of flavour and quality so common in the fruit sold in the bazaars. If readers will observe the following directions, every one may grow and gather his or her own papayas, of really good quality.

Firstly, obtain seed of a good variety from the Superintendent of the State Gardens, Bangalore. Sow the seeds in pots or pans in common garden soil, say in July. As soon as the young plants are about six inches high transplant them simply into 12-inch pots, filled with a fairly rich soil. When these pots are filled with roots, transfer the plants bodily to ordinary tubs, or the largest sized pots obtainable, filled with good, rich soil. Water them in dry weather, and let them grow. If you have sufficient ground, put out the young plants into the open, in rich soil, and water in dry weather. In the following April and May you may gather your fruit and enjoy a really good Papaya. The tree fruits well when grown in tubs or large pots. In order to get fruits of large size, it is necessary to thin them out, and so give them a chance of swelling and developing.

The reason why I have recommended the procuring of seed from Bangalore is that it is the best variety of Papaya I have yet seen.

There is one point, however, which the grower must make himself acquainted with. The Papaya tree carries the male and female on separate trees. The male tree bears its flowers in large, loose bunches which hang down, and the stems on which the flowers are borne are from one to three feet long. The female tree bears stemless flowers, attached close to the main stem or trunk of the tree. Therefore, as soon as the trees show flowers, all the male trees except one, should be uprooted and thrown away. Some trees bear what botanists call "hermaphrodite" flowers, that is, they carry the two sexes in the same flower. These are no good as fruit bearers, and should be treated as males and thrown away, unless you wish to grow a plant or two as a curiosity. It is important to bear the foregoing in mind and thus avoid much disappointment. I have often heard my friends say that their Papaya trees never bear fruit, though they are covered with flowers. On looking at them, I have always found the trees to belong to the "male persuasion."

If you like the Papaya fruit and wish to get it of good quality, follow the foregoing hints. There is no reason why everyone should not have his or her own Papaya trees in pots and tubs, if there is no garden or grounds to grow the tree in. The tree fruits in one year from the time of sowing the seed, so it is easy enough.—Local "Times."

RUBBER IN CEYLON.

Mr. J. B. Tennant, of Barredewelle, Matale, went down to Kalutara in September to inspect the Para rubber cultivation on Culloden Estate, Neboda. A "Standard" representative, who was

in Kalutara on Saturday, in a brief conversation with Mr. R. W. Harrison, the manager of the estate, learnt that the prospects of Para rubber in the low country were very bright. Recent sales in London fetched exceedingly good prices. All the trees have been tapped, and are yielding very freely. Trees have been planted in all parts of the estate, (Culloden), which belongs to the Rosehaugh Tea Company of Ceylon, and is the best estate in the low country where Para Rubber has been fully planted, Arrapolakande (also in Neboda) coming next. Mr. Harrison informed our representative that he expects an output of nearly ten thousand pounds this year, which is considered a splendid record. Large quantities of seed have been sent to Southern India, and several local estates have also been supplied. Mr. Harrison used to do a tremendous business all over Java, Sumatra, the Cape, North Borneo, Thursday Island and Queensland. Small quantities have also been shipped to London and Paris, but the foreign is now practically over.—*Indiarubber and Gutta-percha Trades' Journal*

THE MOSQUITO BLIGHT OF TEA.

Mr. H. H. Mann's important note to the Indian Tea association has the following summary and appendix.—

SUMMARY.

In summary, therefore, I think we may say with regard to methods of dealing with mosquito-blight in serious cases, that the greatest promise is held out by the method of spraying the bushes with a solution of Cheswick Compound, or kerosene Emulsion in the spring within three or four weeks of pruning—save at the end of February, as described in the Appendix. The crux of the whole question lies not in the material used so much as in the time selected for spraying the bushes. The method is one of prevention not one of cure. It will be advisable to experiment in the coming year on a far larger scale with this method, and by the end of next season data enough ought to be in existence, to show whether indeed the blight can satisfactorily be dealt with by the system in question.

APPENDIX.

Kerosene Emulsion is prepared as follows:—

From one to two pounds of ordinary country soap are boiled with one gallon of water till thoroughly dissolved*. To this while still almost boiling, two gallons of low quality Kerosene are added slowly, the whole being thoroughly mixed with a syringe during the mixing. It then forms a creamy, almost buttery mass. The mixture is then allowed to cool, and when cool is made up with water to thirty gallons, and after thorough mixing can then be applied.

Cheswick Compound.—With this substance, which we understand is prepared from sulphur and soap, the spraying liquid is merely obtained by dissolving 30 lbs. in 200 gallons of water.

If either case 150 gallons per acre will be required if properly sprayed on the plants. It is no use to syringe the bushes with a garden syringe, the fine cloud-like form of the spray is far more effective and less wasteful. The best sprayer for the purpose at present on the Indian market is one made by the Gould's Manufacturing Co., of Seneca Falls, New York, and sold by Messrs. Jessop and Co., Calcutta. It is made to be fitted to a barrel, and should be furnished with much longer hose than has been the case hitherto, and the specification should include Vermorel nozzles. No other nozzle is as good as the Vermorel for the present purpose. The Cheswick Compound is apt to injure the rubber ann metal of the sprayer, and it should hence be very carefully used every time of using. The Kerosene Emulsion will not injure, the sprayer at all.—Local "Times."

* The quantity of soap needed depends on the hardness of the water. The softest water available should be used.

REDUCED OUTPUT OF TEA IN
CEYLON AND INDIA :
UNANIMITY AMONG PLANTERS AT
LAST :
NATURE'S DOING ?

For a long time now, the air of Ceylon has been filled with the advice to "reduce the output of tea," if the situation was to be saved at all; but the plans, which were proposed to effect this, were more numerous than practical. There was a number of ingenious brains at work both here and at home on the subject, and when a happy idea flashed across one of them, there arose the cry of "Eureka"; but in spite of the enthusiasm nothing was done. Now and again the idea formulated was taken up by the minds of the many, turned over, talked about, discussed, even voted on; but while some men swore by it as a sure remedy for the plague of over-plenty, others swore at it as certain to make matters worse, and aggravate the already intolerable situation. So we have seen the proposal to have a certain acreage of each estate lie fallow, grow in distinctness and favour till it all but touched the point when it should pass into an embodied fact, and then betake itself to the limbo of the might-have-been; the bold policy of closing down the factories of the island for a month, which savoured more of the practice in a cotton manufacturing district than the usual methods which obtain in tropical agriculture, rose for a short time to the surface, but soon sank again; and even "finer plucking" which caused least disturbance to every-day rules and methods was by no means universally supported, although it had the suffrages of very many and left its mark on the year's figures of the total output of tea. It seemed impossible to attain unanimity, or to devise a plan which would be universally adopted, or even approved. Every planter is so much accustomed to think and act for himself that it is hard for him to take a broad general view of any line of policy; and when he is called on for the sake of the many to march to the music of others' selection, and which has no echo of the lilt with which he has hitherto kept step, he is apt to decline, and so weaken the force of the desired general demonstration. All are, however, agreed that less tea would result in better prices and the re-appearing of the gilt on the ginger-bread. Only the question as to *whose* tea is to be lessened has never been settled. What, however, planters have been unable to do for themselves, nature is now doing for them, and the wet sponge whose persistent drip has been in such evidence for the last two months or more, is bringing about a *volens volens* unanimity of short crops all over the country. This sponge has wiped out many fair figures in estate estimates—has done more to reduce the

tea output, than could ever have been attained by any scheme that appealed to the willing suffrages of the planters of Ceylon, and it has alike affected all manner of estates under whatever classification they may elect to be ranked. The figures for recent local sales are telling this story eloquently enough, while the total sum of the tea shipped fully corroborates. Planters tell us that the diminished returns do not mean that the tea bush is in a less healthy condition than formerly; for estates look well. But, even manured fields which they were wont to assert were independent of weather, and could be reckoned on as certain, have this season been niggardly in their response to the liberal treatment they have received, though they look equal to anything. As to tea which is far from pruning, it amounts to almost a despair, there being a struggle even to produce "banji," and a poor tale at the end of the day.

From what we can learn we do not think that this going back means that if the conditions had been favourable the results would have been the same, and that the shortage represents—what some have asserted—that high water is past and that the ebb has set in. It is simply the effect of the weather, and given less cloud and more sunshine the tea bush would have asserted its right to grow, and the coolies instead of easily keeping up with its march would have been at the "double" long ere this, and considerably pressed to keep up the pace.

With the better reports from home of stocks and prospects, the probability that the island's tea estimates will be short, added to the early closing of the Indian gardens, has begun to have a hardening effect on the course of prices, and so we anticipate to some extent the incoming of those better times, which are so sadly needed, and whose advent has been heralded alike by those immediately interested, as well as by the observant on-looker. London private advices have for some time now spoken of a general existing feeling anticipatory of a rise in the near future, which will tend to consolidate itself in time and replenish the empty coffers of the much-ried tea planter; and His Excellency in his opening Address to Council agrees with this: "I hope," he said, "that I am not over-sanguine when I seem to see a silver lining in the dark cloud which has hovered so long over the tea industry, and in believing that in a year hence this brighter era will have fully dawned." Ceylon planters are often so very energetic, that what their hands find to do, is too frequently overdone, and when their zeal has turned out to their disadvantage and undoing, they are unable to agree among themselves as to a remedial plan of action.

To successfully lay down the lines for a general reduction of the tea-crop has been proved impossible. Nature, however, has this season taken up this work for them; and by means of cloudy days and weeks of constant rain has solved the problem of how to bring about a generally reduced output.

PROGRESS OF GOLD COAST COLONY :
INCREASING EXPORTS OF CACAO AND
OF COCONUT PRODUCTS.

Until our perusal of the Report of the Botanical Department of this Colony for 1901, received by a recent mail, we had no idea of the importance which the Gold Coast has suddenly assumed as a producer and exporter of Cacao. The development of the trade in this product since 1891 and especially within the last four years, as may be seen from the following figures, is phenomenal :—

Quality and value of Cocoa exports from Gold Coast Colony :—

Year.	Quality. lb.	Value.		
		£	s.	d.
1891 ...	80	4	0	0
1892 ...	210	4	5	0
1893 ...	3,460	93	17	10
1894 ...	20,812	546	17	4
1895 ...	28,906	470	11	7
1896 ...	86,854	2,275	13	3
1897 ...	156,672	3,195	14	7
1898 ...	414,201	9,616	4	0
1899 ...	714,929	16,063	19	5
1900 ...	1,200,794	27,280	9	7
1901 ...	2,195,571	42,837	0	0
Lb. 4,821,919		£102,388	12	7

The export for last year in the above list is about equal to what Ceylon produced in 1891; but if the Gold Coast goes on advancing, it will soon overtake our 50,000 cwt. (5,600,000 lb.). Evidently cultivation is extending on the African Coast, for 16,000 pods of cacao were sold for planting from the Gardens last year and the rest of the crop was distributed free. Twelve plants of the new species *Theobroma pentagona* had been received from the Kew and were growing satisfactorily. Here is an interesting fact :—

The Native planters have discovered another use for the Cocoa plants, other than the fruit; the young leaves are boiled and administered as a remedy for dysentery and diarrhoea, and, they state, with very beneficial results.

A good deal is being done with different kinds of coffee, cardamoms, fibres and tobacco; but it is still the day of small things with these. A new native fibre like jute had been valued in Liverpool at £12 to £13 per ton. The great advantage all the West African Colonies have is proximity to the Liverpool and London markets, and a trade in fruit is likely to be successfully established. But next to Cacao, the really important industries are for the present to be in Coconuts and Rubber. With reference to the former we are told :—

The coconut industry is in every respect adapted to the West African native, and the soil and climate along the Coast line are excellently suited to the successful cultivation of the tree, which is amply exemplified by the numbers of trees which already abound in a semi-cultivated state on the littoral lands of the Colony. Its most important product is the copra-oil, which is expressed by machinery from the dry, edible portion of the nut, known in commerce as copra, and which requires no other preparation for market than simply drying in the sun; the demand for this oil far exceeds the supply. Another valuable product of the coconut palm is

the fibre prepared from the husk of the fruit, commonly called Coir, and for which there is likewise a great demand. It is estimated that civilized, temperate countries would consume all the produce of the coconut palm that tropical countries are likely to produce. The tree does not commence to bear fruit until about the eighth year, but after that, with proper attention, the tree will continue productive for sixty or seventy years. Notwithstanding the rude methods of cultivation adopted by the natives in this country, the trees are reputed to yield from 75 to 100 nuts per year; while in countries where the tree is cultivated in a systematic manner, the reported annual average yield is 120 nuts, but has been known to reach 200. About twenty nuts yield one pound of copra; so that if we estimate the average yield at 75 nuts per year, the trees in the Christiansborg plantation may be expected to produce half a ton of copra per year per acre, value £15 per ton; or, if the oil is expressed locally, 66 gallons of oil, value £14, as 60 nuts yield about 1 gallon of oil, value 4s. 2d.; but this would, however, necessitate the employment of machinery.

A yield of 75 nuts per tree is very high for an average over any considerable area, especially as we see trees in the experimental Christiansborg plantations along the sea coast, are being planted ten yards apart, or about 45 trees only to the acre, against 50 to 70 the usual number in Ceylon.

In respect of Rubber, we are not told anything of a trade in the product of indigenous trees, but rather of the growth of plots of Para (200 trees), *Castilloa* (from seeds in 1898 now 9 feet high, 10 inches circumference, 3 feet from ground), *Assam Ficus*, and finally West Africa "*Euntumia elastica*," of which we read :—

One of these trees planted out in the Gardens in 1897 was tapped this year as an experiment to test the amount of rubber it was capable of producing at this age. The tree operated on had grown 25 feet high with a trunk of 1 foot 7 inches in circumference at 3 feet from the ground, and was about 2 years old when planted. After the moisture from the latex obtained by this experiment had been evaporated off, the dry rubber weighed $\frac{1}{4}$ lb. The result of this experiment is rather important from a financial point of view, as it has been pretty generally stated that no return from plantations of these trees could be expected until about the eighth or ninth year; whereas it is quite evident they are ready for tapping at the seventh year, and that trees planted at 15 feet apart, *i.e.*, 193 to the acre, would yield 48 lb of rubber per acre, value about £6 at the seventh year. Information with regard to the amount of rubber yielded, and the proper age to commence tapping *Euntumia elastica*, is much needed by persons interested in rubber plantations; and this experiment is the first of a series which it is proposed to conduct in order to determine these problems.

Mr. Biffen's patent rubber-separating machine is spoken of highly for its good work :—

The machine in question is made in a convenient size for transport, and only weighs about 40 lb. The latex to be operated on is poured into a receiver, which is capable of performing 10 to 15,000 revolutions per minute; the rubber globules being separated by centrifugal force. The machine can be manipulated by hand, and a man, or even a boy, could with ease separate 48 lb. of rubber per hour by this means; and all that would be then necessary to prepare this rubber for market would be to press and dry it in the sun; the resulting product being an exact reproduction of what is asked for by manufacturers *i.e.*, clean, dry, and free from decomposition.

One of the latest uses for rubber is said to be in the manufacture of waterproof paper in which to pack goods for export!

IN WEST AFRICA.

Here is a true picture by an old student of the Colonial College who, after six months, found himself and another, the only Europeans left of a party of ten who had arrived on the Gold Coast half-a-year before. Writing from Axim, he says:—

The first thing is the *climate*, which take it as you will is bad for a European, and 99 out of every 100 that land must have fever whether they like it or not; live as they may, they cannot escape the toll demanded by the coast. Of course fever does not necessarily mean death, but it is very unpleasant while it lasts. Most of our party had it within three weeks, and out of ten only two are left; one dead and the rest are back in England. I held out for four months in splendid health, and then went down with a crash that made up for lost time. The climate also affects the memory, and the term "coast memory" is not the sarcasm I took it to be, but a fact.

Next he gives an interesting account of the country and products:—

As the country was hundreds of years ago so it is at the present day, a dense jungle, so luxuriant that vines, trees, and undergrowth are so entwined that it is impossible to leave the bridle-paths (called roads) unless you cut your way with a machet, and the ground proper is covered with a leafy soil of ages, and is many feet deep. Almost any tropical fruits will grow here, but I have never been to any part of the world where fruit has been so scarce; occasionally I have had oranges, but they have a bitter taste; limes are indifferent; pine-apples are excellent, but scarce; Pau Pau, a native only of here, is more plentiful. Principal products are:—palm oil, palm kernels, rubber, ground nuts, kolo nuts, and mahogany. All these grow naturally, or I am afraid they do not figure in the exports. Mahogany perhaps is difficult to work, and is generally floated down in the rainy season from up-country. A log of wood is often paid for by the trader two years before he sees it at the coast, and some times he never gets it. I have myself seen good logs in the bush that have been cut down and squared, and probably paid for, and then the natives could or would not get them to the stream.

Coffee, rice, and coconuts will grow here, but at present no trouble is taken with them; a good trade could be made here with copra, as well as from the South Seas. The soil of the forest is very rich, in fact too strong for ordinary English vegetables. Lettuce grows from seed so quickly and runs to waste, radish grows right out of the ground, onions the same; these I have tried myself, but no doubt if the soil was worked and turned it would in time grow anything. In my work I had tracks cut through the bush for miles, and I noticed that nearly every shrub or bush, tree or creeper that was cut bled some kind of liquid; some indeed gave forth a very unpleasant odour, and to that, combined with the soil (which had lain for ages) being disturbed, and the smell of the fetid swamps, I attribute all the fever that fell to my share. The smell in the forest is what is known as the "West coast smell" of decayed

vegetation and wood, and is at times almost overpowering to the senses.

Finally we find two more passages of some interest:—

The whole length of the Gold Coast is most inhospitable to shipping, not a single harbour; the steamers have to lie off a considerable distance from the shore, and everything is landed in surf-boats. Some places, such as Acera and Cape Coast Castle, are very dangerous at times owing to the heavy surf that breaks on the beach, and occasionally some one is killed by the capsizing of a boat in the surf. Secondi and Axim are more favourable for landing, but even here merchandise is often spoiled by sea water. The great questions on the coast at present are transport and labour. I have read many ideas on the subject, but I think myself that railways are the only thing for *transport*, but of course that is impossible at present, and the next then is elephants; these animals can climb the hills, cross swamps and rivers, and probably could find food in the vegetation of the country. In the matter of labour some propose Chinese, Indian coolies, or Malays, but the climate will affect all nationalities that are brought here, for even the natives themselves find the country hard on them in the wet seasons; small-pox and fever carry off hundreds at a time; whole villages are swept away by the dread disease. The native of the country himself in time will provide all the labour that is required by his own free will; in the coast towns it is noticeable that the native is aping the white man, and to do this he must work.

There is practically speaking, no game in the Gold Coast Colony: leopards there are certainly, but so timid, prowling at night and keeping to the jungle, that they are never seen; there is also a small deer, and the same can be said for that; making a rifle a useless article for anyone to carry.

TEA-PLANTING IN TEXAS AND ON THE CAUCASUS.

On page 463 will be found an extract from a Texas paper showing that the American Secretary to the Department of Agriculture is ready to encourage an experiment in tea culture in that State and to offer very liberal terms. This paper is sent to us by an ex-Ceylon planter who, writing from Beaumont, Texas, under date 29th October, says:—"As I happen to be here for a few days on business, I read with some interest the enclosed which I think will form interesting news for your many readers. From what I can learn I believe were a few Ceylon tea planters to come to this locality they would soon make an immense fortune." We cannot understand how any one acquainted with the labour conditions in Ceylon and India, and again with those prevalent in the States can speak of a "fortune" from growing tea with negro or any labour available in America. We believe our correspondent had no experience in "tea" before leaving Ceylon, and so does not understand how much of the work—plucking especially—depends on cheap labour.

The same remark very much applies to "tea-growing on the Caucasus": the Russian Government is not likely to throw away much money in trying to grow a product which can be bought of a better quality for a fraction of the price it will cost to produce.

SOIL SURVEYS.

Field Operations of the Division Soils, 1900. By Milton Whitney, Chief (U.S. Department of Agriculture). Pp. 474+a case containing 24 maps. (Washington, 1901.)

Perhaps one of the greatest services which the scientific man can render to the agricultural community in any country is the classification of the soils into certain types, defined by their chemical or physical properties, and the allocation of these types to their appropriate areas, so as to obtain a soil map of the district in question.

Despite disturbing factors, certain types of soil persist over wide stretches of country and are characterised by a general physical and chemical resemblance and also by a corresponding similarity in natural flora, appropriateness to particular crops and responsiveness to certain kinds of manure. The constancy of these soil types is the result of a common origin from the same kind of rock, and the difficulty lies less in recognising the type than in tracing its boundary line.

As a fundamental basis comes the geological survey, particularly the "drift" maps showing the superficial deposits due to running water, ice, &c., which, though of no great geological importance, are the origin of soil survey of the soil proper. But for the purposes of a soil survey a little more than even a "drift" map is wanted; further subdivisions must be introduced to show changes in soils on the same formation due to variations in the lithological character of the formation, or those due to the sorting action of water in the case of soils of transport.

These variations, in fact soil classification generally must be based upon physical structure, must amplify and give exactitude to the practical man's division into clays, loams and sands; the chemical properties of the soil may vary concurrently, but are too much subject to casual change to serve as prime means of distinction. As an instance, the upper beds of the Lower Green sand in east and mid Kent give rise to rich loams, on which many fine hop and fruit plantations are situated; further west the formation gradually changes, until in west Surrey and Hampshire it is barren heathland the soil of which is alike wanting in the finer "clay" particles, carbonate of lime and the soluble salts which go to feed the plant. Again, in the book under notice many examples will be found of two or more distant soils of the same origin, e.g. the maricopa soils (p. 302), described as consisting of "colluvial materials . . . largely granite: . . . divided into four soils, depending upon the degree of comminution of the rock."

The volume before us represents a year's work of the Division of Soils of the United States Department of Agriculture in this particular direction of constructing a series of soil maps; twenty-four of the maps are given on a scale of 1 inch to the mile, and show, by a system of colouring similar to that of a geological map, the type to which the soil belongs. The accompanying text gives a mechanical analysis of the type soil i.e. its division into fractions each consisting of particles of a certain size, and in some cases a chemical analysis, also such information collected on the spot as the distance to ground water, climatic features, characteristic crops or natural flora and other local economic conditions.

It was found, according to Mr. Whitney's preliminary review, that it was quite possible to map these soil areas, independently of the geology of the area, or

the exact chemical or physical character of the soil; that the proper course was to construct maps in the field showing the area and distribution of the

SOIL TYPES;

to explain as fully as possible from geological considerations the origin of the soil and to leave the soil chemist and physicist study the differences. The fact is recognised that these chemical and physical properties of soils are so complex and difficult that it may take many years to explain them through laboratory investigation; but, pending this complete investigation, the maps themselves will be of the utmost value to agriculturists in indicating the areas over which certain soil conditions are found to prevail. . . . The recent successful growing of Sumatra tobacco on a certain soil in the Connecticut Valley is a very striking instance of the possibilities growing out of the detailed soil survey in any given locality.

The whole work is an excellent example of the thoroughness with which America carries out her State services; the maps themselves are clear and distinct; some of them, like the Saint Ana (California) sheet, represent a very complex distribution of soils, the survey of which must have involved no light amount of field work, while the accompanying text is most liberally illustrated with analyses, sketch maps and sections, and photographs illustrative of scenery, crops or vegetation, the ease with which photographic illustrations are now produced being perhaps responsible for the trivial nature of one or two of the objects selected.

Several of the sections of the survey deal with that interesting factor in all arid or semi-arid areas, the existence of alkali soils and their extension under irrigation, which is, unfortunately, almost the only method of farming possible.

Alkali is used in a generalised sense as indicating any predominance of soluble salts, generally sulphates and chlorides of sodium, magnesium and calcium, in the ground water, so that vegetation is destroyed or restricted to certain "salt" plants, and on occasion the salts effloresce in a white powder on the surface. Sometimes carbonates of the alkalis are also present, which by their injurious action upon the texture of the soil and their solution of the humic acids give rise to "black alkali" spots, more dreaded even than the white. These "alkalis" probably represent nothing more than the normal products of the weathering of the fundamental rock minerals, but owing to the limited rainfall there is no percolation through soil and subsoil, to wash everything soluble into the rivers. Instead the salts remain in the subsoil, and irrigation, by raising the level of the ground water, may easily bring the salts so near the surface that they rise in the capillary water to the surface and there are crystallised out. An instance of the damage due to careless irrigation and the rise of the subsoil water is given in the report before us in the account of the Salt River Valley, Arizona.

The phenomena of

ALKALI SOILS

and their increase through irrigation are neither new nor confined to the United States; any arid climate where the products of weathering are not removed in the "country drainage" shows the same problem. Our irrigation engineers in India and Egypt are regularly confronted with the problem, for which there is only one solution, under-drainage so that the cultivated soil may be washed from time to time, and careful cultivation to minimise all evaporation from the soil except through the leaves of the crop. But though the "alkali" problems are common in the old world, it has not been until this time of Hilgard, Whitney and the present Division of Soils in the U.S. Department of Agriculture that we have had any real knowledge of their composition, or any study of the physical and chemical principles underlying the movement of the injurious material in the soil.

The character of the information provided by a soil survey must largely depend upon the nature of the country; in many parts of the United States agriculture is so recent that there is no accumulation of experience as to suitable crops, hence the survey, by comparison of the texture of the soil, the climatic features, depth to ground water, &c., with the conditions prevailing in known areas, can directly advise the settler with what crops he is most likely to succeed.

But in a country like our own, the land has been under cultivation so long that a great mass of local information, based upon experience, exists as to the character even of individual fields. Hints as to methods of cultivation or cropping based upon analysis are likely to be too general to be of any service; the chief application is rather the information that can be afforded as to the use of manures, for enormous economies could still be effected in the manurebill of nearly every farmer who buys artificial manures, if they were properly adapted to his soils and crops.

In Britain, the great initial want is the publication of drift maps of the Geological Survey on the six-inch-to-the-mile scale; were this in existence, it could be rapidly supplemented by the work of the local agricultural colleges until every farmer could be put in possession of that exact knowledge of his soil which is fundamental for all farming operations. A. D. H.
—*Nature*, Nov. 6.

THE GUANO DEPOSITS OF THE SEYCHELLES.

In the report on the Seychelles for 1901 recently issued by the Colonial Office, the Curator of the Botanic Station states that, with regard to the manuring of the soil, it is very fortunate that, in a granitic country like Seychelles, guano deposits are found in many of its islands. This guano constitutes at the same time a mineral wealth of the Colony. The deposits are almost invariably ancient, and guano beds are in process of formation only in the distant islands where immense flocks of birds are still to be found. On many islands the guano is found in dusty layers on the surface of the soil. This surface guano is dark in colour, especially when it is moist. There are numerous tints, which vary between yellowish brown and reddish black. The lighter-coloured guanos are richer in phosphoric acid, and the dark ones are full of organic matters which increase the percentage of nitrogen. All this surface guano is now more or less mixed with vegetable decay.—*Board of Trade Journal*, Oct. 30.

LEASE OF GOVERNMENT LAND FOR CARDAMOM CULTIVATION.

The following appears in yesterday's *Gazette*:—Application having been made by Major Gordon Reeves, C.M.I., of Ratnatenna estate, Madulkele, to the Government Agent, Central Province, for the lease of land lots 13,683, 13,684, and 13,685 in preliminary plan No. 5,123, containing in extent 45A 1R 21P, situated in the village Kaludella in Palis pattu west of Pata Dumbara, for the purpose of cultivating cardamoms, it is hereby notified under regulation No 52 of Land Regulations, published in *Gazette* dated January 17, 1902, that the said lands will be leased to the said applicant under the following conditions:—

1. The rent to be R2 per acre, per annum.
2. The lease to be for ten years with the option of renewal at expiry.
3. No timber above 2 ft. in circumference to

be felled, and any valuable timber under that size felled to be paid for at Government rates.

4. Cardamoms only to be planted on the land leased.

5. That the land shall be forfeited to and vested in the Crown if at any time such land or any building thereon be applied, without the written consent of the Governor, to other purposes than those specified in the grant or lease, or if within a reasonable time the necessary steps have not been taken to apply the land to the purpose for which it was granted.

6. No permanent building to be erected on the land without the written consent of the Government Agent.

POPULAR SCIENTIFIC LECTURES. DR. CHALMERS ON "HOW ANIMALS CAUSE AND SPREAD DISEASE."

The lecture was most interesting and the learned lecturer (who was cordially received) with the aid of beautifully clear lantern illustrations, placed before his audience the deepest medical truths and theories in the most lucid and simple manner.

The Synopsis of the Lecture furnished to those present was more comprehensive than usual. It stated:—

In this Lecture I propose to consider the *role* of animals as a means of causing and spreading disease, and, therefore, it will be instructive first of all to know what is meant by disease. Disease may be defined as that deviation from the normal in the structure, the chemical composition, or the functions of a part or the whole of the body which exceeds physiological variation. This deviation may be brought about by the agency of—(1) Physical causes; (2) Chemical causes; (3) Biological causes. The biological causes may be either alteration in functions in the body itself, such as over-use or disuse of a part, or may be parasitic. The parasites are classified into—(1) The vegetal; (2) The animal. Disease once started in a human being or an animal may be spread by various agencies, such as air, food, water, &c., and among these by animals. We shall see how mosquitoes spread malaria, yellow fever, and filarial diseases; rats, mice, &c., spread plague; flies spread typhoid fever, &c.

The animal kingdom may be divided into two great sub-kingsdoms:—A.—Protozoa; unicellular animals. B.—Metazoa; multicellular animals. The Protozoa are the lowest known animals, and among them we must look for the first beginnings of disease. The Protozoa: The unicellular animals may be arranged in four classes—Class 1.—Sarcodina, with movable changeable processes; Class 2.—Mastigophora, Motile organs, flagella (whips); Class 3.—Infusoria, Motile organs, cilia; Class 4.—Sporozoa, Parasites without motile organs.

CLASS I.—As an example of this class may be taken *Ambœba Coli*, one of the causes of dysentery, which is probably introduced into the body by water, and which would not enter the body if the water was filtered, and which would be killed if the water was boiled.

CLASS II.—Mastigophora.—The Mastigophora which interest us are two:—A.—*Trypanosoma Brucei*. B.—*Trypanosoma Gambiense*. A.—*Trypanosoma Brucei*.—This is the cause of Surra or Nagana in the horses, mules and camels of

India. It is spread by a fly rather like the common house fly, called the Tse-tse fly (*Glossina morsitans*). B.—*Trypanosoma Gambiense*.—Only discovered last year in the blood of man, on the Gambia, West Africa, by Dr. Dutton. Since the discovery it has been seen several times, and is associated with disease characterised by puffiness of the face, especially of the lower eyelids, enlarged spleen, irregular fever and congested areas of skins. How it enters the human body is not known.

CLASS III.—*Infusoria*.—There are some parasites of not much importance in this class, which may be passed over.

CLASS IV.—*Sporozoa*.—All these animals are parasitic, and are most important, including among them the malarial fever micro-organisms. Two orders of the *Sporozoa* will concern us tonight:—A.—The *Coccididæ*. B.—The *Hæmosporidæ*. A.—*Coccididæ*.—The *Coccididæ*, as *Coccidium oviforme*, may be found in the cells of the alimentary canal and liver of man, rabbits and other animals. The life history of a typical *Coccidium* is divided into two different cycles:—(1) The asexual, called *Schizogony*; (2) The sexual, called *Sporogony*.

Proceeding the lecturer showed on the screen and explained the asexual cycle and the sexual cycle, and went on to deal with the *Hæmosporidæ*.—The *Hæmosporidæ* are *Sporozoa* which live in the red blood cells of vertebrate animals. They may have evolved, in the struggle for existence, from the *Coccididæ*. The *Hæmosporidæ* include many animals which cause disease in frogs, birds, cattle, bats and man.

The *Hæmosporidæ* of Man.—These are the organisms which cause malarial fever, and are classified into:—Genus 1.—*Hæmamoebidæ*.—The *Gamætoocytes* are similar to the *Schizonts*. Species A.—*Hæmamoeba Malaria*.—The parasite of quartan malarial fever. Species B.—*Hæmamoeba Vivax*.—The parasite of tertian malarial fever.

GENUS 2.—*HÆMOMENAS*.—The *Gamætoocytes* are dissimilar to the *Schizonts*.—Species.—*Hæmomenas Præcox*.—The parasite of Aestivoautumnal, or tropical fever.

LIFE HISTORY OF THE MALARIAL PARASITE.

The chief interest in the lecture centred under this head and after explaining A.—*Schizogony*, asexual reproduction, or cycle of Golgi; B.—*Sporogony*, sexual reproduction, or cycle of Ross, he showed how the *Anopheles* hit the man and sent the *Sporozoites* into his blood. Proceeding he said:—The mosquitoes in which the malarial germs develop are called *Anopheles* (hurtful). These *Anopheles* can be distinguished from the more common *Culex* by—(1) Their pose while resting—They stand on their heads on a horizontal surface and horizontally out from a vertical surface. (2) Their palpi are long in both sexes. (3) The second and third long veins of their wings project into the basal cells of those organs.

LIFE HISTORY OF AN ANOPHELES.

The *Anopheles* starts its life as an egg, which is laid in the early hours of the morning by its mother in water, which may be brackish or fresh, still or running (but not too swiftly), which contains green algae for the future larvæ to feed upon, and which is exposed to sunlight. In three to four days the egg hatches and out comes a curious little object called a larva, with a most

healthy appetite. This larva differs from the *Culex* larva by swimming on the surface of the water while breathing, and not hanging down from it. In about three weeks the larva turns into an extraordinary shaped object called a pupa. In about four days the pupa gives birth to the imago or insect which starts on its nuptial flight, after which it enters some house, and by means of its stilette, two knives and two saws, makes a hole in the tough skin of a human being, and through its long tube or proboscis sucks the blood by means of a little pump into the stomach. While it is making the holes its saliva is being injected into the human being, and along with the saliva the malarial germ. The blood which it sucks may contain the malarial germ, which thus gains an entry into the mosquito. The female mosquito alone sucks blood, but the reason, why it does this, is not clear. In the daytime the mosquito retires into some dark recess in the house, or into some shady retreat out of doors. The best time for mosquitoes is after the heavy rains are over, hence December and January are the great months for them in Ceylon. In the very dry weather they hibernate in shady nooks. *Anopheles* are very common in Ceylon, being found in Colombo, Kurunegala and its district, from Dambulla to Jaffna, in fact everywhere where I have looked for them I found *Anopheles*. Therefore one would expect that malaria would be fairly common in Ceylon. Luckily, however, the malarial germ is not very common in the *Anopheles* in Colombo.

MALARIA IN CEYLON.—Malaria is one of the commonest diseases of Ceylon. When the curve to total disease in Ceylon is compared with that of malaria, a great similarity is seen, especially in the region of the north-east monsoon.

CURVES OF MALARIA.—The curves illustrating malaria in Ceylon are divided into two charts, one representing the disease in the part of the Island affected by north east and south-west monsoons, and another representing the part affected by the north-east monsoon only. It will at once be seen that malarial fevers are most numerous in January, which is also the most unhealthy month in Ceylon. People ought not to visit places like Anuradhapura in December or January, as they are the worst months of the year. Yet unfortunately those are the months during which they are advised to go there.

RELATIONSHIP TO THE RAINFALL.—It will be noticed that the rains are always before the great increase of malaria.

The rise of the malarial curve is at first slow, due no doubt to the persons already infected getting chills and fever, for chill is a great predisposing cause of disease. During the rains the mosquito can only get about in the intervals, but when the rains cease and the ground is everywhere water-logged many pools exist: then is the time for the mosquito, and out they come; hence December and January are the great months for mosquitoes. Now the mosquitoes find the old cases of malarial fever ready for them with germs fresh from the chills of the rains. They swallow these germs and propagate them to new cases, hence the rapid rise in December and January.

PRACTICAL APPLICATION.—If we pay no heed to the spread of malaria by *Anopheles*, then the work of Manson, Ross, &c., might never have been done. Precautions should be taken to avoid malaria, for prevention is better than cure.

THE PREVENTION OF MALARIAL FEVERS.—Protect yourself as much as you can by mosquito curtains. If you are compelled to live in malarial districts in the worst times of the year, render your house gnat-proof. If this is too expensive, take quinine about twice a week, and an occasional purgative during the worst season. See that no water in little pools is allowed to remain in your compound, especially in December and January.

HÆMOSPORIDIUM IN CATTLE.—*Pyroplasma Bigeminum* is one of the *Hæmosporidæ* which causes hæmoglobinuric or Texas fever in cattle, and is spread by a tick called *Rhipicephalus Annulatus*, which, sucking the blood of the animal, transfers the parasite to its eggs, and by the larvæ the parasite is injected into the cattle.

THE METAZOA.—These are multicellular animals, and can be divided into two groups:—A.—The Invertebrata, without bones; B.—The Vertebrata, with bones.

A.—THE INVERTEBRATA.—Those invertebrata animals which mainly interest us with regard to disease belong to the groups of—I.—Vermes; II.—Arachnidæ; III.—Insectæ; IV.—Mollusca.

I.—VERMES.—A great many worms are parasitic and cause more or less disease in man, but of these I only wish to consider two:—*Anchylostoma Duodenale*; *Filaria Bancrofti*.

ANCHYLOSTOMA DUODENALE.—This is the cause of a great deal of disease and death in Ceylon among various classes, but especially among coolies. Its life history is most complicated, and unfortunately the way in which it gains access to man is at present quite unknown.

FILARIA BANCROFTI.—You must all have noticed the numbers of people who go about the streets of Colombo with an enormously enlarged foot and leg. This disease, which is common in Galle, is called Elephantiasis, and is due in the first instance to a worm called *Filaria Bancrofti*, which lives in the lymphatics, and the young of which enter the blood stream at night, being called the *Filaria Nocturna*. Very many people have filariæ in their systems, and they suffer no inconvenience from them till they injure a part, say the leg; then comes fever, and an attack like erysipelas, and when the attack is over the leg is found to be a little larger than it originally was. This is repeated till the large legs you know so well are produced. The embryos of *Filaria Bancrofti* are very small, and though none of them are to be found in the blood in the day time, yet many are found about midnight. Night is the time when the female mosquito is on the war path, but now it is the *Culex (Culex ciliaris)* which sucks the blood, and with it the young filariæ, into its own stomach. In the stomach they cast off their sheaths and pierce their way into the thoracic muscles of the mosquito, and then gradually, in about sixteen to twenty days, they undergo a metamorphosis. Then they pierce their way into the proboscis, and lie there among the stilette, knives and saws until they get the chance of entering a suitable subject. In this way the filarial worm is spread from man to man by the agency of a *Culex*.

II.—THE ARACHNIDÆ.—This is the class to which scorpions, spiders, mites and ticks belong and among them there are many parasites, some at present but little known. The ticks are interesting, as they are said to cause 'Tick fever' in Central Africa, a disease characterised by symp-

tons somewhat like dysentery associated with fever.

III.—THE INSECTA.—Of insects, the Diptera or flies are the most important in causing diseases. The common house fly is now proved to be one of the means of spreading typhoid fever. In Ceylon it often has filarial worms in its mouth parts, as was pointed out to me by Mr Green of Peradeniya, but only in the so-called Mad flies; but I am afraid all the wickedness of the common house fly is not yet known. The mosquitoes belong to the Diptera and of these, *Anopheles* is the spreader of malaria, *Culex* of filaria and another, called *Stegomyia fasciata*, has been proved to be the means of spreading yellow fever. A wingless Dipteron, called the Chigæ, started on its travels from South America in 1850, and having crossed Africa from west to east has arrived in India and causes much trouble by penetrating the feet. Another group called the Hymenoptera includes the ant which has been accused of spreading a plague in India.

IV.—THE MOLLUSCA.—Among molluscs, cysters, mussels and cockles have been convicted of spreading typhoid fever.

B.—THE VERTEBRATA.—Among the vertebrata, rats, cats, mice, squirrels and monkeys may spread the plague; horses may infect men with a disease called glanders; parasites may be introduced from fish, dogs, pigs and oxen; and man himself may spread disease to other men.

The Lecturer was loudly applauded on resuming his seat.

Dr. GRIFFIN, in proposing a vote of thanks to the lecturer, said:—Your Excellency, Ladies and Gentlemen,—I have the honour and pleasure of proposing a vote of thanks to Dr Chalmers for the very interesting lecture he has given us tonight. My only justification, or rather excuse, for taking this duty upon myself is that, perhaps, I am better aware than most of you what great interest and considerable labour Dr Chalmers has undertaken to inaugurate this series of lectures and more particularly to give us an interesting and instructive lecture tonight. Dr Chalmers has travelled in many lands and has well availed himself of the opportunity of studying the habits of these animals which spread disease; and I think not the least important of these lectures is this one tonight which gives us an outline of how many diseases are spread, and it will, I hope, be the means of interesting you and the rest of the public of Ceylon in measures to stop the spread of these diseases. (Applause.)

INDIAN PATENTS: TEA.

The 27th June 1902.—applications in respect of the undermentioned inventions have been filed. No 249 of 1902.—David Reid, Tea Planter, and John Dale, Engineer, both of Baraora, South Sylhet, Assam. *A tea-drying and glazing machine, called "Reid and Dale's tea-drying and glazing machine."* No 253 of 1902.—Horace Drummond Deane, Tea Planter, of Stagbrook Tea Estate, Peermaad, Travancore, and Charles George Landseer Judge, Journalist, of 47, Free School Street, and No 5-1, Council House Street, in the Town of Calcutta, both in British India. *An improved method and apparatus for manufacturing green tea.*—*Indian Engineer*, Nov. 29,

TEA, COFFEE AND CACAO.

It requires either a philosopher or a cynic to extract humour out of a serious situation, and perhaps our correspondent, "A simpleton," who writes to us on the subject of a communication we published last week claims to be either one or the other. We admit that the suggestion for

IMPROVING THE POSITION OF TEA

growers put forward in our last week's issue reads like a fairy tale or a jest, but we believe it was sent to us as a serious contribution, and we printed it. So many theories have been offered for the consideration of members of that tea industry of late that it would have been unfair to deprive our correspondent of publicity and the chance of competing with his neighbours. The idea that tea garden proprietors and their friends would, or could, subscribe the sum mentioned by our correspondent for the purpose indicated is, we allow, indicative of a sanguine temperament, but there is something refreshing about pure, unalloyed optimism, and as a sample of the real thing in that line our contributor's communication deserved publicity. We therefore leave to others the task of criticising a project which is bold, if nothing else, in its conception, and on that score deserves in recognition in some form.

COFFEE PLANTERS

will not, we imagine, drop a tributary tear over the woes of chicory growers, who are memorialising the Government about their troubles, but they may be interested in some particulars of this product which frequently masquerades as coffee. The memorial sets forth that between the year of its introduction in 1840 and the year 1860 and growth and cultivation of chicory root in Yorkshire and neighbouring counties was not only an important item of agriculture, but was a source of considerable profit to the farmer. The quantity grown in England was then about equal to the quantity imported from abroad. In the year 1860, however, a Customs duty of 6s per cwt was placed on imported chicory, and an excise duty of 3s per cwt on home-grown chicory; and in the year 1863 these duties were increased to 26s 6d and 21s 9d per cwt respectively; and in the year 1864 the excise duty on English chicory was further increased to 24s 3d, but no increase was made on foreign-grown chicory. The memorial states that as a result of such duties, during the period from 1860 to 1872 the importation of foreign chicory largely increased and the growth of English chicory diminished, and stood in the relation of four tons of the former to one ton of the latter. The memorial further points out that chicory is the only dutiable article grown in this country (the registration of wheat being confined to imports only), and that in the year 1901 the whole of the quantity of English chicory on which duty was paid was 89 tons, and that the revenue obtained therefrom is small and costly to collect. It is further urged that the reduction of the home excise duty of 3d per lb on present returns shows a loss of £412 only. This, it is argued, would do much to revive the industry and help to restore the prosperity formerly enjoyed.

On the subject of the import of chocolate and cocoa into Egypt, the "Montieur Officiel du Commerce," says: "The import of

CHOCOLATE AND COCOA

into Egypt is relatively restricted for a country which numbers nearly ten millions of inhabitants; it amounts in fact only to 104,000 kg., which is an insignificant quantity per head. Egypt possesses no chocolate factories, although sugar is very cheap there. This, no doubt, due to the small consumption. It is clear that the Arab does not patronise either cocoa or choco-

late, consequently the buyers are only Europeans. Among the importing countries France occupies the first place with 50,000 kg., next comes Italy with 22,000 kg., and then England with 19,000 kg. Whence arises this abstention, this repugnance, to an article which is a favourite with everybody generally? We have tried to find out, and the statement is that chocolate is only 'damaged coffee.' We do not think that all Arabs are of the same opinion, but rather think that their aversion arises from the circumstance that their confectionery is specially prepared to please their taste, containing almonds, nuts, &c.; they have also 'loukoums,' a kind of delicate pastry made with starch and perfumed with sandy essences. These sweets, which are sold very cheap, are more within reach of their means than the chocolates, the qualities of which, even the most inferior, are by far dearer than their best productions."—*H and C Mail*, Nov. 21.

The cost of producing them is not a heavy one, so that there is every reason to anticipate that the new discovery will lead to a sensible diminution in the price of the formerly precious stones. The rubes are obtained by a new process, in which the blow-pipe plays an important part, and the stones are both beautiful and of a goodly size. The specimen shown at the meeting of the Academy was much admired by the savants.—*Daily Mail*, Nov. 12.

RUBBER AT MANAOS.

New rubber fields have been discovered on Jurua, but the tree does not appear to be the *Hevea*, answering more nearly to the description which the India Rubber World has given of the Mexican *Castilloa*. The rubber obtained is said to be weak—*i.e.* to break easily on tension, but the captain of one of the river steamers informs me that the *seranby* (coarse) is excellent and even better than that obtained from the *Hevea*. I hope to visit the new rubber fields in October and to send you a fuller description of the same.

Some of last year's product of Upriver rubber was of rather poor quality, which, in the opinion of some, was due perhaps to the fact that the floods last season were less extensive than usual and rapidly subsided. It is held here that the longer the rubber fields are under water in any year, the better will be the quality of the rubber and the greater the amount obtained. If there is anything in his theory it may be that the irrigation of plantations may prove desirable where the same species of rubber is cultivated.—*India Rubber World*, Nov. 1.

COTTON-GROWING IN EGYPT.

The Egyptian cotton crop this season is expected to be a very large one, and it is estimated that it will be about 6,500,000 cantars, one cantar equalling about 99 lb., but the quality has been greatly damaged by fogs and rain. There has been a noticeable falling-off during the last few years in the quality of Mount Affifa cotton, but some of the cultivators are giving great attention to the improvement of the cotton and to a more careful selection of sowing seed. The total exports of cotton seed for the year ending December 31, 1901, were 393,804 tons, as against 378,702 in 1900 and 379,235 tons in 1899. Seed-crushing in Egypt continues active, and a new mill of thirty-two presses has, according to the annual report of the British Chamber of Commerce of Egypt, been erected at Kafr Zayat.—*Zanzibar Gazette*,

CRUDE RUBBER.

ANGOLA.—The most important African Colony belonging to Portugal, and the one in which the large fortunes have been made within the last thirty years' is Angola. The Colony of Angola comprises 517,000 square miles, and has a sea line of 870 miles. The climate, if tropical along the coast, has proved healthy enough for Europeans nearly everywhere in the interior. I speak from practical experience. There is no soil on the surface of the globe more fertile than that of Angola, and only a few years ago this colony was practically the second largest producer of rubber in the world. In 1899 it exported rubber, in the face of grave difficulties, to the value of 4,500,000 dols, besides large quantities of coffee and other products. The climate, topography, and soil of Angola would render comparatively easy the cultivation on a very large scale, of such crops as tobacco, coffee, rubber, and certain cereals. Native labour is ridiculously cheap, and, when intelligently directed, is most excellent. A man who for twelve years was at the head of a mercantile house, which at the time did the largest business with the African Colonies of Portugal, writes as follows:—

"The question of labour about which you ask, is not difficult to solve. The negroes are good workmen and the Portuguese colonists are hard-working, sensible men. The great product of these colonies for the present moment is rubber. There are apparently inexhaustible supplies of it. You ask me, then, if this is so, why Portuguese Africa has not prospered like the Congo country, which is administered by the Belgian Government, I will tell you. The whole difficulty is one of administration. The rubber in the Portuguese Colonies is brought down from the remotest interior districts by bearers, who have sometimes a journey of two months to the coast to exchange their produce for money or goods.

"As soon as one gets into the interior, there is an absence of roads and a great paucity of Government military stations or trading posts. The country is slightly policed. The consequence is that the negro bearer who carries his rubber has a long, dangerous difficult journey, and is robbed of a portion of his stock from time to time. . . . Notwithstanding all these grave difficulties and disadvantages of a practical nature, the trade in the Portuguese Colonies thrived enormously until the Congo State appeared. Then system, order, and far-seeing patience began to tell, as they always do. With admirable foresight, the Government of the Congo State developed a vast network of trading stations in the interior of its territory, and built flat launches to bring the produce to the tide water *via* the water ways and rivers of the country. This sort of navigation costs very little. In short, the Congo Government brought the market close to producer; and as a consequence of this system and organisation, it is able to underbid in the rubber trade the very country where rubber most abounds. The rubber is purchased on the spot, and the native is spared the danger and toil of a long journey to the coast.

"In this connection it should be observed that both the Congo and Angola only export rubber produced by wild-growing plants, and though the field is still an enormous one, and may be exploited in the present manner for thirty or forty years longer, the ultimate system will be to cultivate the rubber plant systematically. Already, a good beginning in the way, of setting out rubber plantations has been made in the Congo, but I think nothing of this sort has been done in Angola.

"With the highly-organised and scientific methods of the Congo State, the Portuguese merchants and dealers have found themselves unable to cope profitably. The negroes refuse to come to the coast with rubber; they prefer to sell on the spot, as it were, in the Congo.

'The rubber trade in Angola could readily be revived by proper combination and management. The

various existing interests would have to be consolidated in some well-working way, and this would be a comparatively easy matter."

The main difficulties which foreign investors in the African Colonies of Portugal are likely to encounter will arise from the variety of constructions put upon the law governing the creation and management of corporations formed for the purpose of transacting business in the Colonial possessions of that Kingdom. This law is not at present thought to be wholly favourable to the investment of foreign capital in the Colonies.—*India-Rubber and Gutta-Percha Trades' Journal*, Nov. 10.

THE TRADE IN COTTON SEED.

A few months ago we drew attention to the growing development of the Indian trade in Cotton seed with Europe. As food for cattle, the seed had long been popular in India; and both Sinhalese and Tamil cattle-owners here believe in it for its nutritious qualities, and specially as in increasing the yield of milk cows. The popularity of cotton seed is greatly enhanced by the fondness of cattle for it. Draught cattle, which have toiled all the week and have been fed with poonac-water, often poured down their throats with a bamboo, and not unfrequently of an age which makes itself felt to the olfactory, are allowed by some owners a feed of cotton seed on Sundays; and the rush they make to the weekly dainty is a sight to be seen. But it is the export trade in the article and its growing appreciation in Europe, which is now attracting special attention. The European importer, as we said when we last touched on the subject, is more concerned with the potentialities of cotton seed, as food for man, rather than for cattle; and as we are ourselves pressing for cotton cultivation in the Northern Districts of the Island, as one means of rescuing the Northern Railway from persistent financial failure, the information which is to hand in an Indian paper is of special interest.

Mr. Sly, the Director of Agriculture in the Central Provinces of India, is reported to be working hard to restore the agriculturists of that sorely tried region to a condition of normal prosperity, and at the same time to promote its economic welfare. One of the means which he has adopted, and with which we have become familiar since the appointment of our own energetic Director to the Botanic Gardens, is the issue of "bulletins," brimful of information, valuable to the agriculturist and the statistician. The latest bulletin deals with the prospects of the cotton seed industry in the Central Provinces—the exports having risen from 46,000 cwt. in 1896 to 225,000 in 1900, and to 2,036,000 cwt. last year. It is not the least satisfactory feature of this increase that practically the whole quantity was shipped to the United Kingdom, which had previously long drawn its supplies from Egypt. To what extent it is still supplied from the source we are not told, but America use up all its own seed, and has none to spare for export. That is probably one of the causes of the phenomenal demand—another

being that the high price to which linseed has risen, has driven dealers to look out for a substitute. That India has been able to meet the heavy demand is due, in a great measure, alas! to the recent famines which have materially reduced the number of cattle which remain to be fed; but the urgency of the demand may be gathered from the fact that Egyptian seed continued to rise, despite the quantities which India was able to throw into the London market. The appreciation of the seed in America seems to have been as recent as it has been ancient in India. In Texas there was a law making it penal to dump cotton seed into streams—a provision which would scarcely have been called for, had Yankee cuteness discovered the value of the seed earlier. Now, at least 500 mills are said to be crushing the seed, and the estimate of the annual value of the product is over £10,000,000!

The extent to which cotton seed is used in feeding cattle in India will militate against its rivalling America in the erection of mills, or in the export of the raw material to anything like that value; but, given the demand, it might utilise the seed in manufactures to an appreciable extent. We read that the seed "is used in Europe in the manufacture of innumerable products, such as lard, butter, candles, dyes, paints and general oils," and if there is no present demand for all these products in India, the crude oil might be exported with greater profit than the seed; but the local demand, especially for the oil, as food, is sure to grow. The present average price of cotton seed is given at R7 per candy of 658 lb., and the calculation is that a profit of 17.14 per cent is to be made on its conversion into oil which is now selling at £20 per ton in England. If America can no longer supply the London market, the price of oil is scarcely likely to fall, and India may find it profitable to retain the residuary products and ship the oil to Europe. Can the continuance of high prices for Ceylon Coconut Oil be connected with the active demand for Cotton Seed Oil which must be coming into competition with it in some directions?

THE POSITION IN THE TEA TRADE.

BY J. INNES ROGERS.

[SPECIAL FOR THE "INDIAN DAILY NEWS."]

London, Nov 7.

For several months past there has been a dispute in the tea trade upon a point which is of vast importance to the growers of tea in India and Ceylon. It has to do with what is known as the Clearing House, an institution where the home tea trade lodge their papers for the purpose of obtaining deliveries, instead of taking them round to the various wharves where the goods themselves are stored. A central office of this sort is, of course, a considerable convenience, and to its principle there can be no objection whatever. It was created some 14 years ago in consequence of the then existing difficulties, and at that time the whole of the home trade and of the wharves

and docks storing tea joined it. A condition of membership was inserted, among others of an ordinary character, which passed without much notice at the time, and was in fact then of no importance because the whole of those interested formed part of the Clearing House. It was to the effect that the home tea trade agreed only to buy teas lying at wharves and docks, the owners of which were members of the Clearing House. As was stated above, no particular importance was attached to this condition and up till quite recently the whole of the wharves storing tea were members of the

CLEARING HOUSE.

In the early part of last year, however, a wharf called Gun Wharf, obtained a bond from the Customs which enabled it to store tea. This was entirely a new departure, for the Customs had for some years past, in accordance with an agreement with the Clearing House, declined to issue fresh bonds for the warehousing of tea, thus giving the wharfingers a monopoly. This monopoly has recently been worked to create a pool or trust, among the warehouse keepers for a certain number of years of which the members agree to maintain the existing charges and to divide the profits or losses among themselves in certain proportions. The customs naturally resented this attempt to use Government facilities as a means of boycotting, and representations were made to them by some members of the home trade that they were desirous to no longer oppose the issue of bonds to fresh warehouses, and in fact that they desired competition because of the existing high charges on tea which had become increasingly burdensome as the price fell. The result of this was the issue of a bond to

GUN WHARF.

The proprietors of that place were refused admission to the Tea Warehouse pool or to the Clearing House, and they thereupon elected to fight on their own account, and to receive and distribute tea at prices some 30 per cent below those charged by the pool.

The appearance of Gun Wharf upon the scene placed the home trade in a position of some difficulty, for they were not as a whole directly interested in cheapening the import rates on tea, because, generally speaking, they buy in London after the parcels are landed. It was felt, however, that although this was the case, the crushing weight of the import charges, and of rent and sampling on tea, indirectly interested the home trade very much. They were, in fact, part of the excessive cost of distributing tea which has rendered the home trade so unprosperous. They were anxious also to come into touch more than hitherto, with the growers of tea and the large Indian and Ceylon importers in this market, and they felt that as the wharf charges formed so important a question for India and Ceylon, it was desirable to take up the question in the interests of our fellow countrymen abroad as well as indirectly in their own. The first step that was taken by

THE HOME TRADE

in this matter was to approach an Indian and Ceylon Association in London, and to hold private conferences with a number of leading importers. These, however, led to no results whatever. The trade were desirous of opening up the whole question of the cost of distributing tea in connection with the wharf charges, but no progress was made. Several large distributors of tea, after

some months of discussion, decided that they would cut the Gordian knot by giving the Clearing House notice that they intended to deal with tea lying at Gun Wharf. The reply of the Clearing House was to expect the members in question from their body, and to charge them increased rates for sampling and other matters besides withdrawing the facilities of monthly accounts for charges, and compelling the boy messengers of the firms in question to carry about a small amount in cash to pay each 2d or 3d in charges as it was incurred. Several leading brokers who had been entrusted with the sale of teas by a leading Indian importer who had placed his goods at Gun Wharf were also expelled from the Clearing House, deprived of its facilities and exposed to higher charges amounting in the case of some of the firms mentioned to a good many hundred pounds a year. In this position the

ANNUAL MEETING

took place at the London Tea Buyers' Association, a body which contains four-fifths of the buying power of the trade in this market. At this meeting after full discussion, a request was unanimously forwarded to the Clearing House to strike out the boycotting clause in its rules, and to enable buyers to purchase tea where they thought it desirable to do so. In reply to this the Clearing House refused point blank to do anything of the sort. This refusal was followed up by more notices to the Clearing House that buyers intended to purchase teas at Gun Wharf, and also by the appearance of two or three fresh wharves upon the scene who had not previously stored tea and who are now prepared to do so. The last stage of the controversy is that the Clearing House have asked the Tea Buyers' Association to meet them in conference to discuss the questions at issue. The Committee of the Tea Buyers' Association were to meet on Wednesday to agree upon their reply, which will probably be to the effect that they will be pleased to discuss the whole situation with the Clearing House, but the boycotting clause must first be removed as requested by the trade. The general feeling is that the trade are quite prepared to pay any reasonable sum for the facilities of the Clearing House, but that that institution in itself should have absolutely nothing to do with any pool arrangement. A considerable section of the home trade, however, think that the Clearing House might very reasonably form a central place of meeting for the use of tea growers, importers, brokers, dealers, blenders and other market buyers. If some meeting place, of this sort could be arranged, the whole question of the organisation of the tea trade, which sadly requires improving, could be discussed at leisure and in a friendly way. At present there is no communication whatever between the importers of tea and its distributors in this market, and the result has been most disastrous. The importers do not know even the names of their chief buyers, and the distributors in the same way are ignorant of whom they are buying. It is true that the brokers who sell from the importers to the distributors know these facts, but this is an entirely different matter to direct communications between the parties interested, especially as the brokers are completely satisfied with the existing position of things, and are unwilling to come forward as reformers with the risk of embroiling themselves with either one side or the other.

As is well known, tea in common with other

EASTERN PRODUCE,

was for many years a monopoly on the East Indian Company; that Company drew up a very complete and a most able system of dealing with the different articles of produce under its control. By degrees all other Eastern trade has shaken off the clever but antiquated and monopolist system imposed upon buyers three or four generations ago by the East Indian Company. Tea however, remains under the old rules, which have become absolutely useless in many respects, while they entail prodigious and unnecessary cost upon all who have to deal in it. The prompt (or time within which payment has to be made) is kept up on the old East India terms of three months, whereas all the similar articles of produce have now to be settled for within one month. To provide against the risk of what may happen to the market in so long a period as three months the buyers pay on purchase a deposit of £1 per package, which now amounts in some cases to more than half the value of the tea. To carry out this system, and to get security for the deposits, a document called the Weight Note is employed which is a contract, an invoice, a security for deposit, a delivery note, and other things besides. In other trades a single invoice is made out for the whole parcel, and if necessary the landing account is supplied by which it may be checked. In tea, however, (at an enormous aggregate cost which is perfectly useless), an invoice is made out for every six or nine packages, and its contents also bear all sorts of trifling particulars of a useless character which simply add to cost without giving any corresponding advantage. The whole of this complicated system requires to be swept away, and to be replaced by a reasonable and modern way of doing business. Again, the conditions of public sale require revision and to be brought up to date. Considerable reforms were, some time ago, actually agreed to by a committee, of importers and the home trade but they were blocked by the action of the brokers who do not desire any changes to be made, and there was not sufficient cohesion between the importers and the buyers to insist upon the alterations. If, however, the Tea trade is to be modernised these conditions of sale will have to be dealt with. At the same time the unnecessary cost of catalogues might be seen to. This suggests a point which may be interesting to the planters, especially in India and that is the enormous

COST OF SAMPLING

and dealing with the small parcels, or breaks, which they send to this market. In the old China days a chop might represent from six to seven hundred packages, the cost of dealing with the details of which was precisely the same as the 30, 40 and 60 chest lots which are now sent us from India and Ceylon.

Closely allied with this question of small breaks is that of bulking on the gardens. At present nearly all Indian Tea has to be rebulked in London at an enormous cost to the planters, and to the great injury of the tea. In Ceylon this cost and damage is commonly avoided, and there is no question at all that the same steps ought to be taken in India. Even careful and complete bulking in the gardens, so that the quality of a parcel should be uniform, would be insufficient, however, unless the different chests or empty packages

themselves have an even tare, that is, unless their weight is approximately regular. Unless this is the case, every chest of tea has to be turned out here in order that the Customs may ascertain the tare. In China Tea, with the much inferior appliances of the Chinese, this was never necessary, and the Customs simply had to tare a few packages out of hundreds to ascertain the actual weight of the chest. In further connection with the question of

BULKING,

it may be suggested to the tea-growers to consider whether the separation of their produce into so many different sized leaves pays them, and whether it would not be much better and more economical for all parties to obtain larger breaks, whether it would save not to sort out the tea at all. As a matter of fact all the tea elaborately separated out into different sized leaves in India has again to be rebulked here in the same small breaks at a tea warehouse, and then the different qualities after delivery are all mixed together in one blend, either by the whole sale or the retail blenders. This as a whole constitutes an immense addition to the cost of tea. The great fall in value of late years has not been distributed proportionately over the different qualities, but the fall has been greatest in the best teas, so that whereas the margin between the highest and lowest price in former years used to be very great indeed, the difference between the best and the commonest qualities is now very small. To a large degree this is due to the system of unrestricted public sales, the results of which with the cost of each lot are sent out broadcast to all the chief small, wholesale, and retail distributors throughout the Kingdom. One reason for this extreme publicity was that the planters were under the impression that what they called "Mincing Lane," that is the old established wholesale dealers in tea, were thought to obtain too heavy a profit at the cost of the planters. This was a very great delusion. The result of the present system of unregulated and enormous

TEA SALES,

has been practically to abolish the class of dealers whom the Planters had in mind. With their disappearance or retirement millions of capital have been withdrawn from the wholesale tea trade, which money was formerly employed in better prices being paid at a time when supplies were large, and keeping them up later in the season. The capitalists who conducted such operations naturally expected a fair return for their money, but with the present system this is impossible, and it pays no one to buy and hold the better classes of tea, because, in the first place, all their important customers are acquainted with the cost of each particular parcel, and secondly, because there is no security that at any moment similar tea may not be forced off without reserve upon the market, without the slightest consideration for the interests of previous holders. With the partial or entire departure of the old style of merchants dealing in tea, fresh classes of wholesale distributors have grown up. The first is that of wholesale blenders, who do not, as the old dealers did, sell a particular parcel on its merits, but mix a number of teas together, so that their identity is lost, and they can obtain, therefore, such prices as the merits of their mixture enable them to get without being limited, as in original teas, to a certain small proportion on a cost which their customers know. Several important blending houses

are public Companies, and their returns are published. Further than this, it is a matter of common knowledge that their gross and net profits infinitely exceed those of the old fashioned tea dealers whom the planters ignorantly put under the name of "Mincing Lane." Another great departure from the tea trade has been the introduction of

PACKET TEA

by wholesale firms who advertise largely. Here again the profits are very heavy indeed, and together with the cost of advertising, have largely to come out of the pockets of the tea planters. This is the price which the latter are paying for the abolition of what they call "Mincing Lane," and if it goes far enough, tea will fall or rise to the position of cocoa, where half the cost of a cup represents the expense of advertisements. Some efforts were made a short time ago to stop this condition of things by obtaining some privacy in the published prices of individual parcels at public sales. The question was entirely misrepresented to the planters, and it was held to be an attempt to help Mincing Lane to get back its old monopoly. Thereupon the proposal fell through, to whose detriment it has yet to be seen. The final result of the present system is that the average retail price of Tea throughout the country and the chief sale there of is at 1s 4d. per lb. If 6l. be taken off this for duty, and 3d. for the retailer's profit, it leaves 7d. per lb. for the cost of blending, and in the case of packet tea of packing and advertisement, without allowing in either case for the wholesale profits. It will be seen that if this state of things continues, the average price of tea, supposing the present duty is maintained must fall to something like 5d. per lb., and every day the finer teas will become relatively cheaper than the common ones, so that this disastrous tendency is progressive. The interest of the tea growers in this question is a vital one, but whether they, on full consideration, favour or do not favour any alteration in the system of distributing tea through dealers, blenders, or packers, they are every one of them most vitally interested in reducing the cost of importing and distributing tea to the wholesale buyers of and whatever class. It is to be hoped, therefore, that their support will be secured for the system by which economies will be effected in the warehousing and other import charges on tea. One way another some £250,000 a year in the aggregate might be saved in these respects by careful reforms. —*Indian Daily News*, Nov. 25.

GIFTS OF THE TROPICS.

Chief O P Austin of the U. S. Treasury Bureau of Statistics contributes to the June *Forum* an article on the growing importance of tropical imports, from which we abstract as follows:—

Tropical products which earlier generations considered luxuries are now necessities of life everywhere. The average consumption of sugar has risen from thirty-three pounds per capita in 1870 to sixty-eight pounds in 1901; coffee from six to nearly twelve pounds per capita; cocoa has increased six times; despite these gains of its rivals, consumption of tea is still as great; silks and satins are no longer luxuries; and rubber, a generation ago almost unknown, is now used everywhere.

The great railways have turned right angles and are facing towards the equator, bringing tropical products more into reach. The effect is

readily observed in the temperate zones in greater comfort, more variety of food, better health and longer life.

This is especially the case in the United States, which now imports over 1,000,000 dol of tropical products every day. This is more than for most other countries, since most of our sugar comes from the tropics, the others depending on beet. Our recent consumption is near one-half the cane sugar and more than one-half the coffee of the world. In 1901 our imports of tropical goods were over 400,000,000 dol, against 143,000,000 dol thirty years ago.

These figures fail to show the real growth because of the reduction in value per unit of quantity. The cost of sugar in the country exporting has since 1870 fallen from 5 to 2·3 cents; that of coffee from twelve to eighteen cents to seven cents; tea from twenty-four to thirty-seven cents to 12·3 cents; raw silk from over live dol to a little more than three dol a pound.

There are four ways to measure this growth, all bringing identical results. The first is to consider imports by grand divisions. Imports from Asia, Africa, Oceania, and America south of the United States were in 1870, 157,000,000 dol; 1875 224,000,000 dol; 1880, 265,000,000 dol; 1890, 298,000,000 dol; 1895, 310,000,000 dol; 1901, 414,000,000 dol. Total imports meanwhile were: 1870, 436,000,000 dollars; 1875, 533,000,000 dollars; 1880, 668,000,000 dollars; 1890, 739,000,000 dollars; 1895, 749,000,000 dol; 1901, 880,000,000 dol. The share of tropical imports thus rose from 36 per cent in 1870 to 47 per cent in 1901. Further, the population of the United States has increased meanwhile from 38,000,000 to 76,000,000, exactly doubling, while tropical imports increased from 167,000,000 dol to 414,000,000 dol, or 165 per cent. Meanwhile non-tropical imports increased 55 per cent.

Taking tropical products by articles, we find that the most important are: Sugar, coffee, raw silk, Indian rubber, cocoa, fibres, fruits and nuts, tobacco, cotton and tea. In 1901 these aggregated 340,954,707 dol or 84 per cent of total tropical imports of 414,000,000 dol. Since 1870, sugar rose from 70,000,000 dol to 114,000,000 dol; coffee from 24,000,000 dol to 70,000,000 dol; rubber from 3,500,000 dol to 28,000,000 dol; raw silk, from 3,000,000 to 40,000,000 dol; fibres, from 6,000,000 dol to 25,000,000 dol; fruits and nuts, from 7,500,000 dol to 20,000,000 dol; cotton, from 500,000 dol to 8,500,000 dol; tea has fallen from near 14,000,000 dol to 9,000,000 dol.

The total value of all tropical imports was in 1870, 144,000,000 dol; 1875, 207,000,000 dol; 1880, 246,000,000 dol; 1890, 333,000,000 dol; 1895, 325,000,000 dol; 1901, 405,000,000 dol, corresponding closely to the figures by grand divisions.

A study by articles shows a great variation in increase measured by value. Sugar increased only sixty-six per cent in value, while population increased one hundred per cent, yet consumption is twice as great as in 1870; coffee, however, increased nearly two hundred per cent and cocoa over one thousand per cent, tea decreased thirty-three per cent, though per capita the consumption was the same as in 1870.

Considering manufacturing articles, fibres and tobacco show nearly four times the value in 1870, rubber seven times, silk over twelve times, and

cotton over twenty-five times, though the United States is now the greatest cotton-producing country.

It is only by quantities that one can realize the real growth much more rapid than indicated by values. Since 1870 sugar increased from 1,196,000,000 to 4,569,000,000 pounds, about three hundred per cent, against an increase in value of sixty-six per cent; coffee from 235,000,000 to 1,074,000,000 pounds, or over three hundred per cent, against an increase in value of two hundred per cent; silk from 500,000 to over 12,000,000 pounds; rubber from less than 10,000,000 to over 55,000,000 pound; tobacco from 6,250,000 to nearly 29,000,000 pounds; cotton from less 2,000,000 to over 68,000,000 pounds; dye goods from 43,533 tons to 255,771 tons; cocoa from less than 4,000,000 to over 50,000,000 pounds; tea decreased in value thirty-three per cent, but increased in quantity fifty per cent.

The largest increase is thus in materials for manufacturing. Foods increased two hundred to three hundred per cent, materials for manufacturing three hundred to three thousand per cent, while population was increasing one hundred per cent.

In the fourth method of measurement we may make three groups—foods, raw material for manufacturing and manufactures and luxuries. Foods show a growth in value of ten per cent, which inclusion of Hawaii and Porto Rico for 1901 would raise to twenty-five per cent, manufactures and luxuries of thirty-three per cent, and manufacturers' materials of ninety per cent.

The chief growth in our imports is tropical products, and there must be a growing demand for these, since we lack the necessary climate, while manufactures and luxuries our own producers will supply in increasing quantities.

In the light of these figures is it not possible we have builded better than we know in our recent unsought tropical acquisitions? The products of Hawaii have increased over twenty fold since the reciprocity treaty of 1876, and exports to the United States twenty-five times. Porto Rico shows over three times the average before the new relationship. Our exports to Hawaii have multiplied twenty times, and to Porto Rico five times. In 1901 the Philippines supplied over twice the total of 1899; their nearest neighbours, the Dutch Indies supply us with more sugar than any other country save Cuba, with the Philippines twenty times as large as Hawaii and fifty times as populous, their possibilities are worthy of consideration.—*American Cultivator*.

POPULAR SCIENTIFIC LECTURES.

MR. J. B. CARRUTHERS, F.L.S., ON
SEA-WEEDS.

The second of the series of popular scientific lectures inaugurated by the Hon. Mr. Cooper some weeks ago was delivered in the Ceylon Medical College Hall on December 6th by Mr. J. B. Carruthers, F.L.S. The attendance was comparatively small, but when regarded in the light of the fact that those present made their way to the Hall in a downpour of rain was decidedly satisfactory. The lecture was on "Sea-weeds," and the lecturer treated his subject in a masterly and interesting manner which, indeed, at times, de-

veloped into raciness. Each subject, which he referred to was beautifully illustrated by a powerful lantern, and the revelations of the wonders of the deep, thus afforded the audience-repaired for their presence.

The lecturer was briefly introduced by Dr the Hon. A J Chalmers to the audience, among whom were the Hon Mr G M Fowler, Mr and Mrs. E E Green, Mr and Mrs Wackrill, Mr and Mrs. F Lewis, Mr. J Ferguson, Mr. and Mrs. F C Roles, Mr Cottle, the Hon. Mr. and Mrs. F A Cooper, Mr. C D Vigers, Dr. and Mrs. W H de Silva and Mr. W H Davies.

The synopsis of the lecturer provided to those present and which gives a fair idea of the lines taken by Mr. Carruthers was as follows:—

SEAWEEDS, or, to use their Latin and scientific name, *Algæ*, are of interest from many points of view. They are, in nearly all cases, things of beauty both in form and colour; they are of great economic importance as the basis of the nutrition of marine animal life; and they are in their structure and life-history among the most interesting of organisms that science investigates.

Colour, which is not available as a character for grouping other large classes of plants, coincides in the case of *algæ* with the natural classification—

- Red seaweeds, or Rhodophyceæ.
- Brown seaweeds, or Phæophyceæ.
- Green seaweeds, or Chlorophyceæ.
- Blue-green seaweeds, or Cyanophyceæ.

These primary divisions of *algæ* show also the distribution of the plants they include with regard to the depth of the sea where they are found. The green *algæ* are seen, as a rule, near to shore and at no distance from the surface; lower down we find the brown forms, and the red seaweeds occur at the greatest depths.

Light is essential to the life of *algæ*. At a depth of about three-quarters of a mile there is total darkness, and consequently no living seaweeds; but at a much less depth, not one-quarter of a mile, the light is of such a kind that the plants cannot grow. The most numerous *algæ* are those which from their size and habit are the most difficult to observe, *i.e.*, the free-floating or pelagic forms. These are not anchored to rocks, stones, ships' bottoms, &c., like the better known and larger seaweeds, but live in great quantities in the upper layers of water away from land, in some cases giving a green or red colour to lakes. They are of microscopic dimensions, and are usually captured by pumping sea water through fine silk gauze, when they remain as a scum, and can be placed for examination under the microscope. Many have hard, siliceous shells, the Diatoms, of which some 10,000 species are known, having in past ages formed the immense chalk beds. The continuous rain of dead shells which falls down to the bottom of the sea as these small organisms die, make the diatomaceous ooze, or deposit, which in the course of time becomes a hard stratum.

Algæ are perhaps easier to identify than other groups of plants; they are dried and preserved with very little trouble. The collection and study of seaweeds is therefore attractive and easy for the amateur, and in Ceylon will be sure to repay any time spent on them.

The lecturer concluded by remarking—I only hope these few remarks I have made

may induce some people to find out for themselves a good deal more than I am capable of telling you about sea-weeds, and I can assure anyone at all who has been about the subject that it would repay them, were they to take up this subject. I should be very glad to see any such up at Peradeniya where we have quite a respectable collection of seaweeds—many of which, I regret to say, are still unnamed. I can only add that I shall be quite satisfied if from this lecture every one is bitten with the love for sea-weeds. (Applause.)

The Hon. Mr G M FOWLER—in proposing a vote of thanks to the lecturer said, I was quite unprepared to be called on to propose a vote of thanks to the lecturer for his most interesting lecture, but have now the greatest pleasure in doing so. I am sorry to say I arrived so late that I did not hear his introductory remarks, but the remainder—I really forget now at what stage I entered—(laughter)—was most interesting. I am sure all of you are most interested in what you have heard and I hope there are a good many here who will profit by what we have heard and extend their research in that direction. I was rather startled by recognising a certain sea-weed on the screen which I thought had not been yet discovered. I came across it many years ago in Mannar and I treasured it. Tonight I heard it described as one of the many common sea-weeds. (Laughter). Excuse this personal reminiscence, but it is only one instance. I am sure I am expressing the sentiments of all present in thanking Mr Carruthers most heartily for his interesting lecture. (Applause).

INDIAN AND CEYLON TEA SHARE VALUES.

From the following figures, compiled, as usual, by Mr George Seton, of the Indian Tea Share Exchange, 120, Bishopsgate-street, E.C., it will be seen that the market value of the shares of 45 representative companies, registered in this country, has again risen slightly during October, and now shows an advance of £175,000 from the lowest point touched on 1st Sept. The rise is pretty well distributed all along the line.

Face value of 45 Companies	...	£9,500,000
Market value 1st July, 1897 (highest point)	£12,000,000	
Do 1st Jan., 1902	£7,000,000	
Do 1st July 1902 (corrected)	£6,225,000	
Do 1st Aug., 1902	£6,125,000	
Do 1st Sept., 1902 (lowest point)	£6,050,000	
Do 1st Oct., 1902	£6,150,000	
Do 1st Nov., 1902	£6,225,000	

As the total share and debenture capital of about 170 of such Companies, registered in the United Kingdom, with sterling capital, amounts to nearly £19,000,000, the fluctuation of the whole, based on the above figures, may be estimated as follows:—

Face value of about 170 sterling Cos.	£19,000,000
Highest value, 1st July, 1897	£24,000,000
Lowest value, 1st Sept., 1902	£12,100,000
Present market value	£12,450,000

or still a depreciation of £11,550,000; or about 48 per cent. from the highest point.

Even these augmented figures, it may be observed, take no account of either the privately-owned estates nor of the Calcutta, Madras and Colombo Companies, with rupee capital, in which the depreciation has frequently been still greater. Mr Seton adds, as a ridge

to his figures, that the tendency to recovery shown during the previous month has been further accentuated during the month just closed, and there are not wanting signs of further material improvement.—*Financial News*.

MICA IN GERMAN EAST AFRICA.

Mica has hitherto only been produced in German East Africa by persons possessed of very limited plant, and the supply has, in consequence, been restricted. A German firm in Mannheim dealing in mica, who had purchased the five mica mines in the Alugaru Mountains, have now formed a company for the further working of the same, under the name of the "Deutsch-Ostafrika Glimmerud Minen Werke," with a preliminary capital of 200,000 marks. Under the management of the former owner the production was 1,200 kilos, monthly; the new company reckon a production of at least 60,000 kilos, yearly, a quantity which, according to specialists, can easily be obtained by proper working. The import of mica into Germany last year through Hamburg was about 120,000 kilos., valued at 500,000 marks, and the demand for mica in the electrical industry is continually increasing. Mining is now going on uninterruptedly under the supervision of two engineers, with thirty natives, and it is probably that even in the first year the expected production of 60,000 kilos. will be achieved. By means of proper instruction to the natives, and the opening of new workings, the firm hope to reach an output of 100,000 kilos. per annum. Investigations conducted by the Government in 1897 showed that the existing mines in the Inbakana district were rich enough to warrant moderate working, whilst a cursory survey of the land disclosed numerous rich lodes, an indication that the deposits were richer than generally supposed.—*London Chamber of Commerce Journal*, November.

PROFITS FROM A RUBBER PLANTATION.

Mention has been made more than once in the "India Rubber World" of a rubber plantation in the state of Chiapas, Mexico, from which shipments of rubber have actually been made. About thirteen years ago a Mexican planter set out a number of rubber trees (*Castilloa elastica*) as a shade for cacao, which grew so rapidly that in time the cacao was practically starved out and of these trees some 5,000 are now standing, in a various condition. A few years ago Mr O H Harrison, engaged in coffee planting in Chiapas, bought this property including adjacent lands containing wild rubber trees, for \$12,000, Mexican. Within eight months he had sold in London enough rubber from the wild and cultivated trees to pay the purchase price for the property. This formed the basis for La Zacualpa rubber plantation. A like amount of rubber has been sold from the property each year since, and more land has been purchased, the cost of the whole having been met by the proceeds of the rubber sold. During this time there has been no outlay for labour in caring for the cultivated trees, beyond the collection of rubber. The land having been paid for, the proceeds of rubber sales will be devoted to dividends on La Zacualpa shares. Mr Harrison reports that these trees yield an average of at least 2 pounds of rubber a year—tapped once—and is convinced that a good profit could be made with a yield of half as much, which would give from 20 to 300 pounds of rubber per acre, according to the number of trees. The new planting on La Zacualpa plantation has been done with seeds from the productive trees referred to so that no doubt can exist as to the variety that is being planted.

PLANTING "CEARA RUBBER" IN NICARAGUA.

La Victoria Rubber Plantation has been formed at

La Paz, Nicaragua, for the cultivation on a considerable scale of the Ceara rubber tree (*Manihot Glaziovii*). The location is on the Pacific slope where the rainfall is slight as compared with that in Eastern Nicaragua, and in other respects the conditions resemble those of the Brazilian state of Ceara, the native habitat of this species of rubber. La Paz is on the railway extending from Grenada, on lake Nicaragua through the city of Managua to the Pacific coast, and is favourably situated for trade and transportation. This is a private enterprise, owned by George Adler, who for a number of years has given close study to the different species of rubber. Mr Adler is now in Nicaragua. The plantation manager is Fredrico Wagner. Alfred C Adler, of Waltham, Massachusetts, is also interested in the plantation. About 300 acres have been planted to date, and with such results in the growth of the trees that the work is to be extended.—*India Rubber World*, Nov. 1.

RUBBER IN AFRICA AND SOUTH AMERICA.

The following extracts are taken from an article by Emile Bonnechaux, explorer, published in "Le Vieux Corsaire":—

With the extending use of rubber and its thousand and one applications, a serious question presents itself. Will the forests producing rubber and bind weed become exhausted? Several trips to Madagascar and two voyages to Brazil for the purpose of exploring the forests may permit me to express an opinion on this subject. I believe that certain species will disappear in Africa, Madagascar and Brazil—in fact, in all the regions producing rubber now exploited.

Landolphias will disappear both in Madagascar and on the continent of Africa, by reason of the barbarous methods of extraction employed by the natives, which consist in tapping the bind weed close to the place where it issues from the ground, dividing it afterwards into sections about 20 inches in length, from which the milk is drained by placing the sections upright in a gutter of split bamboo supported above the receiving pail by two wooden forks. The *Euphorbiacée utisy* will also be exterminated in the southern part of Madagascar. The *utisy* yields a milky juice, as rich as that furnished by the *Hévea brasiliensis*, but it is impossible to obtain it pure, as the natives allow the juice to flow to the ground, where it at once makes an amalgam elastic only in name. Besides, in their greed to obtain the maximum yield, the natives do not hesitate to tap even the tubercles of the roots, thus killing in one moment what nature has taken a century to produce.

Other varieties will also disappear. But there is one not indigenous to either Africa or Madagascar, which will not. It lives in the forests which are included between 8° north latitude and 8° south latitude. It is a native of Brazil, Peru, Bolivia, Ecuador, Colombia and Venezuela. The species is called Seringa in the Brazilian tongue. The botanical name is *Hévea*, one of the large family of the *Euphorbiacées* which comprises a dozen varieties. The product of these trees is known on the markets of Europe by the name of Para fin, from the town of Para, near the mouth of the Amazon, through which all the gum passes. The denomination Para fin is, however, incorrect. The State of Para produces some rubber, but the greater part comes from the district of Amazonas, from Pern, etc.

In these countries, the *Hévea* has fortunately been protected. The extractors have every incentive to preserve the trees from injury, in order to insure an annual yield, which I estimate at from \$290 to \$347 for one hundred days of actual labour. Some affirm that the gatherers average from \$8 to \$10 per day. This estimate is exaggerated. The exploitation of the *Héveas* and other rubber trees of South America supports some 100,000 people. One can judge from this of the importance of this industry. The rubber tree is carefully treated here. Already the two States of

Brazil, Para and Amazonas, have regulations for the distribution of lands. Both have taken measures to protect their natural resources, in order to preserve the immense revenues obtained from them. Manaus, the capital of the State of Amazonas, a town of 60,000 inhabitants, alone receives 48,000,000 francs (\$9,264,000) revenue from the export duty.

I can affirm with certainty that the States of South America included within these latitudes have inexhaustible riches, if they continue to protect them. Brazil and Peru in particular would alone be able to satisfy the consumption of the entire world in rubber. The time is not come for the exhaustion of these immense treasures. Although we penetrate now to the very sources of the large rivers, only the great arteries easily accessible have been explored; the small affluents, which, in my opinion, are even richer in rubber, are yet unknown. Yet it must be acknowledged that Brazil is less known in France today than Central Africa. The whole world has had its eyes turned toward the Dark Continent. The boundless forests on the other side of the Atlantic contain forests accessible to anyone desiring to go there. Marseilles is the port plainly indicated to become the headquarters of this trade and an important market for rubber.

Why should we not go to Brazil, to Peru, and bring gums of the first quality, so necessary for our new industry—motorcycles and automobiles? The English and the Germans do this and are making fortunes. I know of one German house in Manaus which has realised from commissions alone more than \$20,000 profit. There is also an opening for a French line of navigation. One English house—Singlehurst Brookurst, of Liverpool—had, twenty-five years ago, a few sailing vessels coasting along the eastern shore of South America, which touched at Para. Today, under the name of the Red Cross Line, this house has made a fortune. Within the year, the Germans of Hamburg have successfully established a line touching at Havre; the Italians have inaugurated a line from Genoa, touching at Marseilles. The French should learn the lesson.—*India Rubber Trades' Journal*, Nov. 10.

THE TRADE OF CEYLON.

A MADRAS REVIEW AND CRITICISM.
A LECTURE PROPOSED.

The present financial condition of Ceylon is attributable to a large extent to the central position that the island occupies at the southern extremity of Hindustan, with China to the East, Africa to the West, and Australasia to the South of it, but it is mainly due to the world's demand for the varied products of its fertile soil. Its prosperity depends, therefore, not so much on the large revenue that it earns as a port of call and coaling station, as on its trade. The success of that trade hinged during the latter half of the late century on two great staples, not simultaneously, but in succession. The first of these was coffee, in the production of fine descriptions of which Ceylon for some time distanced all competitors for the world's favour. For a considerable period, therefore, "coffee was king" in the island, and there seemed every prospect of its reign being extended for many a decade. But, at first little by little, and ere long by leaps and bounds, the production of other lands disturbed the status of Ceylon coffee, while diseases of the tree itself added to the downfall; and then, almost with a rush, coffee was deposed from its pre-eminence in the island. It looked at that crisis as though the beautiful island, with its unexhausted soil, and its variety of climates, would be, for most intents and purposes ruined. There was a limit to the world's requirement of cinnamon, coconut products, cacao, cardamoms, camphor,

rubber, citronella oil, and other articles that Ceylon was in a position to grow to a large extent, and for a while, therefore, the outlook was grave indeed.

But eventually the prospect brightened, for it was perceived that salvation might be found in tea. The tentative efforts to grow tea from both China and Indian seed were so successful that estate owners and planters, who but recently had been almost on the brink of despair, not only pulled themselves together, but also pulled up the coffee bushes, and planted tea instead. Here a little, there a little, was the drastic experiment tried, and the more it was tried the more did the conviction gain ground that tea would yet pay "hand over fist." Thus it was that energies, numbed by unlooked-for failure in one direction, revived; and that Banks which had been compelled by the instinct of self-preservation to put the screw on planters in their distress, not only relaxed their severity, but gaily offered "facilities." So it came to pass that tea was escorted with all honour to the throne vacated by coffee, and was

PROCLAIMED KING.

As years glided by, tea increased and coffee decreased, until in 1900 the export of the former reached the great total of 149½ million lb, while the export of coffee dwindled to 10,777 cwt. In other directions Ceylon did well, but it was chiefly owing to tea that the Colonial Secretary was able to conclude his Report or 1900 with the significant paragraph:—"The last year of the century was the most prosperous in the history of the Island, and was marked by affluence and progress."

Ceylon is still affluent and progressive, but a change has come over its commercial position which it is easier to deplore than to repair; and one is irresistibly reminded of the cruel fate of its former fine trade in coffee, and therewith of the instability of human affairs. The Colonial Secretary, when reporting last August on the year 1901, stated:—"Though the past year showed no such pronounced increase of revenue as the phenomenal year 1900, the general prosperity of the Colony is unimpaired." This can hardly be the opinion of shareholders in Ceylon Tea Companies. For example, on the 29th ultimo, at the Annual Meeting in London of the Associated Tea Estates of Ceylon (Limited), the adoption of the Report was moved by Sir Alexander Wilson, the Chairman, and Mr Bethune, in seconding the motion, said that "it was evident that little could be done in the way of dividends with present level of prices." Tea is illustrating the truth of the maxim that one can have too much of a good thing. There is a limit to all mundane things, and the limit has been reached, for the present at least, of the capability of markets to absorb teas at prices that cover the cost of production. In a word, supply has more than overtaken consumption, and the planter pays the piper.

It can hardly, therefore, be the case that the general prosperity of Ceylon is "unimpaired." It would be more consistent with regrettable fact to say that it has been not a little impaired by the Colony's disregard, in common with India, of the immutable laws of supply and demand. Ceylon is suffering from the very defects of its virtue, its energy, its enterprise. It cut in bravely for a share in a great trade, and by sheer merit it won

all but the most prominent position in that trade. It assisted India to oust China from her indigenous trade, and it then vied with India in a race that could have but one issue. The more the two countries grew of the staple the more were markets at a distance depressed, and prices drooped and fell, while the mischief of over-production increased as new estates or new "extensions" came into bearing. The pace was fast: the cry of "the De'il tak' the hindmost" was in the air; and the inevitable came to pass.

The Colonial Secretary was not as optimistic on the 1st September, 1902, as he was on the 8th August last, though there might have been some excuse for his being so, since he then had to relate how the last year of the century had crowned the edifice. He was put on his guard by the knowledge that while the year had witnessed an increase in the export of 20 million lbs., "the price realised in London fell 10 per cent. to 7.20*d.* per pound." He then proceeded to say:—"Cultivation is extending in Southern India, Java, and elsewhere, and it is feared that the full effect of over-production has not yet been felt, and that the tea industry has a trying period before it. The remedy would appear to be in selecting specially-trained managers, plucking for quality rather than quantity, improvement of the *jat* of tea planted, careful protection against disease, and improved methods of manufacture." The Colonial Secretary's forecast was borne out in 1901, and, notwithstanding his remark about the "unimpaired" prosperity of the Colony in that year, he had to report that, though the export of tea had fallen eight million lb. in the year, and that consequently the stock of Ceylon tea in England had been considerably reduced "the average price is the lowest as yet recorded, 6.86*l* against 7.20 in 1900." He could not disguise from himself that the new century had opened unsatisfactorily, or with a "year of depression, but he entertained the hope that "prospects are more favourable," as "towards the end of the year prices were considerably improved." But tea prospects are still calculated to cause much anxiety. It is well to put a good ace on matters, to hope for the best, yet it is still undeniably true that "the tea industry has a trying period before it."

If tea should fail Ceylon she cannot fall back upon coffee, or, so far as can be seen, on any other great product. What then will she, what can she do in such a cruel dilemma? The Colonial Secretary remarks blandly, with special reference to 1901, that "there has been a slight revival in piumbago and no improvement in the prospects of tea, but coconuts continue to do well, and the many minor products in the Island are not unremunerative." It is true, he admits, that "the value of the trade of the Colony has fallen somewhat in the year under review, but later statistics show that there has been no further decline, and the prospects of trade are good." As it would be interesting to have his views in some detail of the paying possibilities of coconut oil, coir yarn, coir fibre, and minor products, he should prepare a lecture on the subject, and deliver it in the Colombo Chamber of Commerce, with open doors, and invite discussion thereon. He will deserve well of the Colony if he succeeds in showing how the best string in its bow can be replaced should the dread necessity arise.—*Madras Mail*, Nov. 19.

TEA CULTURE IN TEXAS:

U.S. DEPARTMENT OF AGRICULTURE
SUBMITS PROPOSITION TO MAKE EXPERI-
MENTS; WANTS THE LAND DONATED,

WILLING TO BEAR CONSIDERABLY MORE THAN
HALF THE EXPENSES AND DONATE
THE CROP.

Some time ago Beaumont was visited by two representatives of the United States Department of Agriculture for the purpose of making a superficial investigation of this section with a view of finding a suitable location for making an experiment with growing tea in Texas. It is believed that the gentlemen were very favourably impressed with the country about Beaumont and a study of the soil and climate requirements leads further to the opinion that Jefferson county will prove suitable for making the tea experiments and further, that it will result successfully. When Congressman Cooper visited Washington recently he unproved the opportunity to call upon the chief of the bureau to plant industries and inquire the progress of this matter. He did not receive a definite reply at the time but was informed that the department would furnish him all information as soon as possible. In this connection Congressman Cooper has received the following very full report on the matter. Contained in the letter is a very explicit proposal which the Government will make and the matter is in some respects up to the people of this section to take hold of and further push the plan:

Washington, D. C., Oct. 4.—Hon. S B Cooper, Beaumont, Texas. Sir, Referring to your personal inquiry, made a short time ago, in regard to plans for work on tea in Texas, I have to say that we have been carefully considering various plans in connection with this work, and have been waiting to be in a position to give you some definite facts before writing you.

I may say that it is the desire of the honorable secretary of agriculture to make a commercial test of the possibilities of growing tea in Texas. It is recognized that there are large tracts of land in many parts of the southern states adapted to this kind of work, but the important question of labor has always been more or less of a drawback to the successful production of the crop in question. The work at Summerville, South Carolina, has demonstrated, we think, the possibility of growing tea commercially, but there is still much to be done before capital can be interested in the project on any extensive scale. Our idea is, that to achieve the best results the department should secure the co-operation of the people of Texas, an effort being made to establish a well equipped tea farm and factory; and, after the work is on its feet, to allow private parties to continue it, providing it is found profitable. The Government is precluded from making any improvements on land that it does not own, or lease for a period of years. The Secretary does not think it advisable for the Government to purchase land for this sort of work; he thinks that land sufficient for the the purpose ought to be donated by interested parties, as this will keep up an interest in the work which could not be maintained in any other way. The plan is to start with about fifty acres with opportunities for increasing this to

one hundred acres if it is thought desirable to do so. A one hundred acre tea plantation, properly managed and in the right locality, should yield in from six to eight years, ten to fifteen thousand pounds of tea annually. Of course the first two or three years there will be little in the way of yield, as it takes about three years for the plants to reach sufficient size for first plucking.

Briefly, the following outline of a plan has been prepared for this work :

1. Land to be furnished to the department free of charge, under a guaranteed tenure of not less than ten years.
2. Such labor as may be necessary in clearing the land and putting it into condition for planting to be furnished to the department free of charge.
3. Teams and ordinary farm implements such as plows, harrows, etc., to be furnished to the department free of charge.
4. One-half the cost of all ordinary labor necessary in establishing and maintaining fifty acres of tea plants to be furnished to the department free of charge.
5. All buildings necessary for the work to be furnished to the department free of charge.
6. The department will furnish an expert superintendent who has had experience in growing and manufacturing tea.
7. The department will furnish all necessary machinery used in the manufacture of tea.
8. The department will furnish all seeds and plants.
9. The department will pay one-half the cost of ordinary labor necessary for the growing of plants and the handling of the product.
10. The product from the gardens will become the property of the donors of the land, but will be handled and sold subject to conditions which may be mutually agreed upon.

EXPLANATIONS.

The tea gardens should be located with due respect to soil, climate, rainfall and labor, particularly colored labor. The plans should be so made as to begin with not less than fifty acres with possibilities of extending to 100 acres within a few years, if it is thought best. The buildings required for the first two or three years will be small. After that, when the tea begins to come in in quantity, a suitable factory building will have to be erected. Such a building for a 100 acre plantation probably will not cost more than \$1,500. The full equipment of such a building with machinery, etc., for the handling of the yield of 100 acres will probably cost from \$4,500 to \$5,000. This portion of the expense will be borne by the government.

In a few days we shall have two of the department's agents visit Texas, with a view to looking over the territory and deciding on the best point to locate. We want, of course, to make this work a success, and to do so the best location should be secured. As already indicated, labour plays an important part in the work. Proper soil and sufficient rainfall are also important considerations. Rainfall, however, we consider less important than the other features mentioned, if it is practicable to secure irrigation. The ideal location would be where there is plenty of cheap labour, where the soil is sufficiently rich to grow good

crops of cotton or corn and where the rainfall exceeds fifty or sixty inches annually, or in lieu of this where irrigation water can be obtained in plentiful supply.

Thanking you for the great interest you have shown in this work, I remain, Very respectfully,
B T GALLOWAY, Chief of Bureau.
—*Beaumont Journal*, Texas, U.S.A., Oct. 25.

BRITISH AND GERMAN EAST AFRICA:

FUTURE PLANTING DEVELOPMENT.

From the letter of a recent visitor to East Africa, we are permitted to quote as follows :—

"There is a great future for this East coast belt which, almost throughout, is splendid land for coconut cultivation combined with tobacco, castor oil, sem sem ground nuts, etc., whilst flooded intervals and flooded river banks,—*e.g.*, the Nuri Tana districts—are ideal countries for the cultivation of rice and the date palm. No development of this sort can ever be done by the local natives, neither could it be effected in the same way in which Ceylon was first opened up by the European planter backed with a modest capital and his invaluable Tamil cooly; for he naturally looked for a return in his third or fourth year. In my opinion it can only be done by Companies. Imperial Companies subsidised by a strong Government in some shape or form and by the introduction of tens of thousands of the surplus starving population of the agricultural districts of India. The Germans are far ahead of us: 10 or 12 years ahead of us in the development of their East African possessions. They have now plantations—both Government estates and those belonging to Imperial subsidised Companies—with roughly speaking 50,000 (half in bearing) of coconut trees and thousands of acres of sisal hemp, yielding hundreds of tons of fibre. The cultivation is splendid and *thorough*, and they are now being repaid by enormous returns after patiently waiting 10 and 12 years to get something in lieu of gigantic expenditure."

BLACK V. GREEN TEA.

To the Editor of the *Home and Colonial Mail*.

Sir,—I hope you will allow me, as a shareholder in the Lanka Plantation Company and as one with an extensive knowledge of tea planting, to take exception to some of the statements made at the meeting of the company, a full report of which appeared in your last issue. I think it is a pity at the present time, when both India and Ceylon are suffering from an over-production of black or fermented tea, which has had effect of curtailing profits and producing a crisis, that the chairman of a well-known Ceylon company should deem it politic to discourage the efforts that are being made to relieve the pressure by manufacturing wholesome green tea for which there is a large demand. It should be quite immaterial to the planting interests whether the tea leaf is manufactured as black or green tea. They are both equally well-known articles of com-

merce, and it would be absurd for anyone to set up as an arbiter of taste to decide which should or should not be drunk. In America, at all restaurants and hotels it is usual to offer both black and green tea. It is a delusion to suppose that green tea, as manufactured in India and Ceylon, contains anything in the slightest degree resembling poisonous ingredients, and it is somewhat astounding to hear such an idea mooted.

I regret to see that one of the shareholders at the meeting (Mr Ford North) gave countenance to this idea by remarking that " unquestionably green tea is less wholesome than black."

It is unfortunate that meeting of shareholders interested in the production of tea should vote against a cess that has been, and is likely to still further be, an instrument in extending the knowledge of tea and opening up new markets in foreign countries.

I quite endorse all that was said by Mr Pettit on the subject. He was right in expressing his opinion that the whole of the cess should be used to encourage the manufacture of green tea, which, as he said, was not all unwholesome, and no one need drink it unless they liked it.

I trust in a year or two we shall obtain as considerable a share of the demand for green tea as we already have for black tea.—Yours faithfully,
SHAREHOLDER.

London, November 18th, 1902.

—H. and C. Mail, Nov. 21.

THE CEYLON POULTRY CLUB MAGAZINE

has now (in its second number) fully developed and apart from the interesting and profitable matter taken over from the allied Indian journal, there is a practical Ceylon article on "buying and selling"—eggs, chickens, full-grown birds—well-worth reading. This is followed by local notes and comments and some short "fowl" ads. Mr. M J Cary is acting for Mr. S P Jeffery, as Hon. Secretary and Treasurer. All who have poultry should get and study this little journal.

THE INDIAN TEA CESS.

Indian Tea Association, Calcutta, 8th Dec., 1902.

To all proprietors and agents of tea estates. The proposed Tea Cess. The subjoined letter upon this question is published for information.
W. PARSONS, Secretary.

No. 1001-O., dated Calcutta, 28th Nov. 1902.

From the Secretary, Indian Tea Association.

To the Secretary to the Government of India, Finance and Commerce Department.

I am directed by the General Committee of the Indian Tea Association to address you, in continuation of previous correspondence, upon the question of the proposed imposition of a compulsory Cess upon Indian tea.

2. This question was raised in March last by the representation to His Excellency the Governor-General in Council of a Memorial praying for the imposition of the Cess. The Memorial was signed by tea proprietors representing 416,140 acres of tea-bearing land. It received the favourable consideration of Government; and a resolution upon it was published by your Department on the 1st August last. In this resolution it was stated

that the request of the memorialists would be acceded to if the tea industry were of substantially one mind on the subject. It was added that the necessary legislation would be undertaken, during the forthcoming Calcutta session of the Imperial Legislative Council, provided that no weighty or widely entertained objections were raised in the meantime.

3. I am now to express to His Excellency the Governor-General in Council the respectful acknowledgments of the memorialists for the sympathetic manner in which His Excellency thus consented to meet their request. They are fully sensible of the fact that legislation of the character in question cannot be undertaken without that practical unanimity to which reference is made in the Resolution. But the General Committee, speaking on behalf of the memorialists, are convinced that they are entitled to claim that the Cess has received the consent of practically the whole of the Indian tea industry. The acreage represented by the memorialists is equal to about 80 per cent. of the whole area under tea cultivation in India. But in the principal producing districts, taking them separately, the percentage is higher. In Southern India it reaches 100 per cent.; in the Bengal-Dooars 86 per cent.; in the Brahmaputra Valley—the most extensive tea district in India—85 per cent.; and in the Sarma Valley 84 per cent. And even in those districts where the percentage is lower the movement is, nevertheless, strongly supported. Nor would it be right to assume that those proprietors who have not signed the Memorial are in even covert opposition. Indeed, the General Committee have good reasons for believing that an additional ten per cent. of the whole area may be safely regarded as, if not favourable, at least as neutral. The remainder would seem to be land which is chiefly in the occupation of small proprietors, both European and Native, who have expressed no opinion. The Committee regret that they are unable to furnish Government with statistics of the weight of tea annually produced by the supporters of the Cess. But, seeing that a majority of the best estates in the large districts are represented by the memorialists, it may be rightly inferred that, measured by this standard, the support given to the Cess reaches a higher percentage than when measured by the standard of area.

4. To summarise the position then it may, the Committee think, be said with confidence that practically the whole industry is in favour of the Cess being tried. Some proprietors may still be doubtful as to whether it will be, in the result, as successful as others anticipate; but the general opinion seems to be that the experiment should be made. Indeed, so far as the Committee can learn, no objections are entertained by any considerable, or in fact by any, section of tea producers. It is true that, in the course of the long discussion that the movement has provoked, something has been written on the opposite side. But it has been written anonymously for the most part, presumably by those who, not being themselves tea producers, are in the fortunate position of being able safely to give advice upon matters with which they are but imperfectly acquainted.

5. Believing, therefore, as the General Committee do, that the conditions laid down by Government in the August resolution are substantially fulfilled, they will now take the liberty of briefly ex-

plaining the proposals which have been formulated for constituting an executive body by whom the proceeds of the Cess may be administered. The ideal executive for such a purpose would undoubtedly be a small Committee of four or five experienced and capable business men, possessing the confidence of tea-producers. But the peculiar circumstances and conditions of the industry preclude the possibility of such a body being called into existence. For it is natural and right that all those who pay the Cess should expect to exercise direct control of the expending of its proceeds; and in the following proposals this expectation has been kept steadily in view.

6. It is proposed to form an Administrative Committee, consisting of members representing (a) tea-growers; and (b) the general commercial community. This is the principle underlying the constitution of the so-called "Thirty" Committee, by whom the Ceylon Cess Funds are administered; and it appears to be so sound that it has commended itself to the Indian industry. In the appointment of the members representing tea-growers it is advisable that both large and small tea companies, and private proprietors also, should, if possible, have a voice. After most careful consideration it has been agreed that this can be best ensured by permitting every tea district in India to appoint a representative, or more than one; and also by allowing the Indian Tea Association of London, and Calcutta, each to make appointments. The question of the representation of the general commercial community has been solved by inviting the Bengal Chamber of Commerce to agree to nominate three of its members. These nominations the Chamber has consented to make; and it is understood that, of the three members, one will be the President of the Chamber for the time being, and another a prominent banker.

7. There still remain the following points: (a) the number of members; (b) the precise method by which they will be appointed; and (c) their duties. Regarding (a) it is recognised that to provide for the equitable representation of the different districts is a matter of some difficulty. A proportionate representation, based on acreage or outturn, would be in theory the most desirable. But in practice it would give so great a preponderance to Assam and Bengal as to be unacceptable to the smaller districts. The most feasible plan will be, it seems, to allot two members to the Brahmaputra Valley, and one member to each of the other districts. These latter are Cachar, Sylhet, Darjeeling including the Terai, Jalpaiguri (the Dooars), the United Provinces (Dehra Dun and Kumaon), the Punjab (Kangra), Madras, and Travancore. There will thus be ten representatives of the various tea districts. The Indian Tea Association (Calcutta) might appoint five members; and the Indian Tea Association (London) two members. The Bengal Chamber of Commerce will, as has been stated, appoint three members. The new organisation will, therefore, consist of twenty members.

8. Taking now the second point (b) it is proposed that the district members should be appointed by the local Associations in such manner as may seem to them to be desirable. These local Associations are very representative of each district; and are the only existing machinery by which the appointments could be made. The nominees of the Indian Tea Association will be

elected at ordinary or special general meetings of the Association. And it is left to the Committee of the Bengal Chamber of Commerce to decide upon the mode of appointing the three representatives of that institution.

9. To discuss the duties of the new Committee is no easy task at this stage. But judging from its composition there can be little doubt that not more than one meeting at which all the members could be present, could be held in the course of the year. Early in December would probably be the most convenient time for this meeting; and at it a programme of work for the ensuing year could be drawn up and decided upon. So far as can be seen at present the work of carrying out the programme would, of necessity, devolve largely on those members who would remain in Calcutta throughout the year. But, of course, every member, whether a Calcutta resident or not, would have to be kept fully informed of all business transacted. Seeing that many details of the work will have to be carried out in London, it will probably be found necessary to appoint a small London Committee to work in conjunction with the governing body in Calcutta.

10. Such is in outline the scheme of administration which has been submitted by the General Committee to every district Association in India. Speaking broadly it has been approved, although, as is but natural, some districts have thought that the number of members allotted to them is insufficient. But the necessity for keeping the total number within workable limits is now, the General Committee think, fully understood; and they are persuaded that the scheme is accepted, as an initial measure, by all concerned. Time and experience will no doubt suggest many alterations and improvements; but it may, at any rate, be fairly claimed that the executive which will be created under the scheme will accurately reflect the views of practically the whole industry as it at present exists.

11. In conclusion I am to express the earnest hope of the Committee that it may be possible, as is anticipated in the Resolution, to pass the Cess into law during the coming session of the Legislative Council. It is in view of this that the present letter has been written; and it is almost needless to add that, should any further information be required, the General Committee will gladly and readily furnish it.

12. A statement of the statistics upon which the percentages quoted in para 3 are based is annexed:

STATEMENT.

	Area under cultivation. (a)	Area in favour of Cess. (b)	Percentage. (c)
Brahmaputra Valley ..	204,985	174,426	85
Surma Valley ...	132,342	111,512	84
Darjeeling ...	50,769	24,388	48
Dooars ...	76,278	65,527	86
Chittagong & Hill Tracts	4,241	1,733	41
Chota-Nagpur ...	3,284	448	14
Kangra Valley ...	9,745	4,501	46
Dehra Dun & Kumaon ..	8,055	2,029	25
Southern India ..	31,309	31,576	100
Total ..	521,008	416,140	79.87

Note.—The area under tea in Chittagong, Chota-Nagpur, the Kangra Valley, Dehra Dun and Kumaon is chiefly divided among a large number

of small proprietors, many of whom sell much of their production in India, and are, consequently, more or less indifferent to the Cess.

The figures of area are taken from the Director-General of Statistics' Report published on the 28th June 1901, which was the most recent issue when the Memorial was signed.

THE LABOUR QUESTION IN CEYLON: RECRUITING IMPERATIVE.

Short crops, low prices, and a poor labour-supply are a trinity of evils which dog the planter and help at times to take much of the brightness out of his life. Met singly, either of these evils are worrying enough; while a combined attack would be hard to put up with for any length of time. Although evils are said to be social in their disposition, and dearly love companionship, never appearing singly—as we are proverbially told—yet it is not often that the planters' dreaded trinity, are found in each other's company, or that he is called on to entrench himself against their combined advance. Short crops and low prices do not run as a pair at all, their natures are antagonistic, it is only the third item in the trinity, a short labour supply, which can work its evil way in the companionship of either of the others. A short crop and a short labour supply are possible, indeed, the latter, if in much evidence, may be the creator of the former and low prices and a restricted labour market have been, alas! common enough during these late lean years through which the planting industry has passed. Now, however, that the tea prospects are brightening, the danger immediately ahead of the planting industry is emphatically the labour question, and if that could be satisfactorily solved, it would lift a burden which, at present, oppresses the mind of many a man; while it would be conducive to the easy-running of estate work, and productive of the best results. Not that a superabundance of coolies is at all a blessing; for to have too many, we are told, is even worse than to have too few, leading as it does to slackness, short time, and poor check-roll balances, paid for later on when the inevitable reaction sets in, whereas the short out-turn, and the clamorous demands of fields claiming attention, whet the planter's wit, and often results in much cheaper working than was possible when the ranks of the morning parade were crowded. That the present labour force in the island has proved adequate on the whole during the last few months, is the result of the abnormal weather which lately held back flush, and fought on the side of the small battalions; for if the conditions had been otherwise—nature beneficent and the measure pressed down and over flowing there would certainly have been weedy fields, a weary pursuit of a runaway flush and a worried planter who hardly knew what end of him was up. The ease with which the busy season has this year been got through, ought not, however, to deceive nor create a fool's paradise. Coolies at the end of the busy

months always get restless; "tundus" are in demand, and the labour of the country gets shuffled for the new deal. Early as it is, we are informed, that already the flight of the "tundu" has begun, and those desiring immediate reinforcements to their labour force, are staggered at the amounts demanded to effect a transfer of the scant and ragged following by those who possess them. If the debts of the coolie generally were at all in proportion to what appears as the face-value of these early movers, things would be in a very bad way indeed; but most estates, which have heavily indebted gangs, are willing to be inconvenienced for a time by their transfer to others, with the hope that later on, the same outlay will replenish their now depleted force to double the present outgoing. But this shifting does nothing for the country as a whole—though individual estates may benefit—nay, it but locks up more of the planter's money in his advance account, which is the most unprofitable item in his finance; demanding a wary watchfulness, a bit and bridle to keep in any kind of order, and liable to sudden upheavals and depressions which end at times in the gall and worm wood of "writing off." The bidding up of advances is, without doubt, brought about by the desire to possess a trained force, and the unwillingness of kanganyies to recruit. It goes without saying that the expert field-hand is a desirable possession as compared to the raw arrival who must make sad havoc when turned loose on the tea flush; but the planting districts are unanimous that without new blood the labour-supply will fall far short of the demand, and soon the coolie will rule. To recruit is, therefore, an imperative necessity on all employers of labour, and if the old supply-fields are worked out, new ones must be found to save the situation. If estates are to have a competitive labour era, even of a short duration—when planter will vie with planter in bidding for coolies—the prospective profits from increased prices, will, to some extent, vanish. Ramasamy will play the increased advance game for any length of time. He has an unstable estimate of his own work which ranges from next to nothing up to his full weight in silver, and as he is much influenced by his "durai's" action and opinion he reflects accurately the planter's mind, settling quietly down when the tide runs in favour of restricted advances, or he becomes a restless insatiable nuisance—a daily demander of "tundus"—when he sees and hears of lavish out-goings. At the back of the coolie there are those too who press him when they think that more coin will be forthcoming if trouble be taken to make estate-labour unsatisfactory and restless:—chetties, kaddie-keepers and such like. The planter is himself the barometer of the labour market to a great extent, which is read by all men, and especially visible to the keen gaze of the needy kangany. When the planter gets excited and thinks that his force is going to be hopelessly short, he reflects this in his manner, and up goes the advances. If he suffered alone it would be nothing, but his whole neigh-

bourhood is more or less affected, and has to rise with him, to some extent, however, unwilling it may be.

In the old coffee days it was in the early months of the year that coast advances were given out, and it might be well for the planters to make a united effort *now*, and by pressure and persuasion try to re-open old labour channels, or exploit new ones. Ceylon has ever been a favourite place with the Tamil labourer, and the experience of the past has been that when recruiting has been energetically taken in hand, the Tamil has responded. Kanganyis, we are told, are disinclined to recruit—the field is worked out they say—but it may be that the kangany, in many cases dislikes the trouble, finds new coast coolies unsatisfactory at first, and would rather trust to a new labour struggle and higher stakes. What the planters have got to do is to make their backs stiff, insist upon an infusion of fresh blood, and although there may be disappointment to some, the result will, on the whole, we believe, prove satisfactory. Anyhow the bidding of planters against each other for the resident cooly is simply suicidal:—through that way there lies no avenue of hope.

TEA IN THE CAUCASUS.

INDIGENOUS TEA IN SIAM.

(TRANSLATED FROM FRENCH AGRICULTURAL MAGAZINES FOR 'CEYLON OBSERVER'.)

We have before us three such magazines: the *Journal d'Agriculture Tropicale*, published by M J Vibouchevitch; the *Revue des Cultures Coloniales*, by M A Milhe Ponting, also published in Paris; and the *Bulletin Economique*, issued by the Government of Indo-China at Hanoi. One is impressed by the earnest attention devoted to tropical cultivation and the scientific study now given at head-quarters. Take the last of the three named magazines, the September number for this year opens with an article on Tobacco in Indo-China, its Botanical Name and Characteristics, Native Methods of Culture, Harvesting, Yield, Preparation and Treatment of the Dried Leaf, Markets' Values and its Distribution throughout Indo-China. Then follows a Paper on a Practical Experiment in the Cultivation of Ramie Fibre in Bengal, founded on a letter from M Karpelès about his experiences in the north of Behar. These articles are both full of the information that an intending planter requires.

The *Journal d'Agriculture Tropicale* is very carefully edited and contains numerous brief articles upon Recent Inventions in Machinery as well as Agricultural Processes or Experiments. In the commercial portion, a notice of Tea in the Caucasus is of interest:—"The Report of the British Consul of Batoum of November, 1901, shows that the success of Tea in Caucasus has been much exaggerated. In the district of Batoum receipts of Tea did not exceed $13\frac{1}{2}$ tons, (29,240lb) It is only 10 years since the first tea was planted. The only two important producers are, until now, the Domaines Impériales at Chackva and the firm of Messrs. Popoff, well-known in the tea trade. In the former 164 hectares (390 acres are opened, but only 42 (1·5 acres) in bearing, having given 9,784 kilos (21,524lb) tea.

The plantation of Messrs. Popoff, only three years old, is of about 125 hectares (312 acres about) with 32 (80 acres) in bearing, having yielded 4,000 kilos (8,800 lb.) of tea, 9 francs the kilo (3s 5d per lb.) was the price of the best quality. Seed is being distributed to the peasants, but the figures quoted are nothing to cause alarm to Ceylon or India. In a favourable year four harvests may be made, beginning in the end of May and the others at three weeks' interval." Another chapter on "Kapok or Vegetable Ivory," the various sources of supply; trees used in Java and the value of Kapok as an industry.

"Tea in Siam Mai (Siamese Laos), regarded as a European enterprise," is the summary of information derived from the Report of the Vice-Consul of France at Nan. Tea trees grow spontaneously and on large areas in most of the higher valleys of the chain that divides the waters of the Méping and the Mé-Lao and Woung, as well as between these rivers and the Mé-Ing and the Mékong. These forests of tea-trees, known as "Va-Mieng" are cropped principally between the Mé-Ing and the Mé-Lao. But everywhere the natives, generally Khamons from the left bank of the river, crop only a small quantity, for which they pay a slight due by no means legal, to the village chiefs, or even to the first occupant who discovered this forest. The croppers content themselves with taking off the leaf stalks without any cultivation or attempt at multiplication. Four times a year they harvest the leaves, the first being the best; the green leaves piled up in small packets and first of all boiled with steam, are left aside during two months and, after this maceration, sold under name of "Mieng" for chewing, at about R12 the 60 kilos (135 lb.) The natives do not know that this same "Mieng," sold at this low price, is nothing else than tea. Even were they told this, they would not know how to prepare it. But it is certain the rational cultivation of these large groups of trees by an experienced colonist and with the help of head coolies imported from China or Ceylon, would give excellent results in a region so highly favoured by nature. This should be quite as remunerative as the cultivation of teak forests now so largely carried on there with European capital. It would have the advantage of requiring smaller capital and of being carried on for long periods, whereas the reserves of teak are being exhausted. Nothing would prevent a forester from carrying on the two cultivations. Besides, the working with teak presents this peculiarity that although a large staff of workmen must be hired by the year, yet they are often inactive, while waiting for a temporary rise that shall enable them to float some logs in the small streams, and there may be a further idle time while waiting for the next storm. Such enforced leisure might be well utilised.

The *Revue des Cultures Coloniales* seems especially valuable for its notices of recent Literature bearing on tropical cultivation whether English, French or German, though it also has long articles on planting subjects.

CARDAMOM CULTIVATION AND CONSUMPTION

The letter from Major Gordon Reeves affords a clear and straightforward explanation of the circumstances under which he has taken a lease of 45 acres of Crown land; and we cannot see any ground for

complaint, unless it be that such leases should be put up for competition, quite as much as land sold on freehold terms? It may be argued, of course, that Government should discourage the alienation, under any terms, of land avowedly intended for the cultivation of cardamoms, just as much as land for tea, under present circumstances; but 45 acres more or less cannot make much difference, and the transaction having been put through, we should say leave it alone, although it will be observed that Major Reeves is quite willing to give up his bargain, on being refunded his actual outlay.

There can be no doubt that Mr. J. A. Hunter's letter about increased crops in Travancore has created a scare among Ceylon cardamom planters. One of them (in a letter intended to reach us a week ago, but which through misdirection, only arrived yesterday) says:—"The question is whether old Cardamom growers in Ceylon, have India or the Ceylon Government to dread most? In India the planters have no doubt as to holding their own in the struggle with their compact estates and cheap gathering. Locally we have the possibility of move leases on nominal terms and free grant holders of land equally well adapted for the growth of this soon-to-be-over-produced *new product*, competing with lands originally bought from the Crown. I think it hardly fair if Government to look upon an industry which has helped Ceylon for the past 25 years as an 'experimental product,' and it, we are told will in a year or two be wiped out of Ceylon by its more formidable rival India. *Poor Ceylon*—is there nothing she can try which will not be over-produced?"

Now cardamoms are in large demand all over India. No spice is a greater favourite with the people of all grades and castes who can afford to purchase it. If it be expedient to exploit Indian markets, bazaars and towns with tea, how much more, we should say, with cardamoms! We recall one of the largest producers of cardamoms in Mysore informing us that he sold every lb. of his crop in Calcutta or Madras and shipped none to Europe. Cannot Mr. J. A. Hunter urge the Travancore planters to do something of this kind? to join forces with the South of India tea exploiting Syndicate, and get their cardamoms introduced into all likely quarters. Of course, there is a certain local market in Travancore itself, just as there is in Ceylon, for a portion of the crop, and we should fain hope as the prosperity of the natives locally extended, so will the market for cardamoms extend. But exploiting is, no doubt, very necessary: cardamoms are not a necessary, a food product, like rice, or coconuts, or even tea; but if they were brought before the people in every town and bazaar, at a moderate price, we should expect a much greater local consumption than is at present reported. Cannot our correspondent, "An Interested Planter," test some of the markets within his reach, for himself? A trustworthy agent might sell small parcels to the bazaar-keepers at a

distance from the cardamom-producing districts, and we should like to know how the markets of Batticaloa, Trincomalee, Jaffna, as well as Galle, Matara, Hambantota, etc. are served with cardamoms? If not readily procurable, very probably the boutique-keepers and the people make up their minds to do without the spice, when if made readily available, they would as readily make purchases. The strong objection we have to the open sale of opium in our villages,—that people who never used or saw the insidious, as well as dangerous, drug before, are tempted to become customers,—involves the principle which would tell favourably in the case of a wholesome condiment like cardamoms, and a food-product like tea: make them freely and cheaply available in town and village where they may be at present known—a permanent demand is sure to spring up.

EXPERIMENTAL CULTIVATION OF TOBACCO IN BURMA.

Two important attempts at experimental cultivation were made in Burma last year with, as far as can be gathered from the Land Records Administration Report, imperfect results in one case and practical failure in the other. In one case 12 pounds each of Havana and Virginia tobacco seed were distributed among the cultivators—the Havana seed, chiefly in Lower Burma and the Virginia seed in Upper Burma. The results, however, were very chequered. The experiments with ground-nut seeds imported from Pondicherry were on the other hand a failure in the great majority of cases.—*M. Mail*, Dec. 12.

SERICULTURE IN BENGAL.

The Government of Bengal, reviewing the report of the agricultural branch of the Department of Land Records and Agriculture for 1901-02 remarks that the efforts of the Bengal Silk Committee to assist production of healthy silkworms were attended, except in the district of Birbhum, with successful results. Enquiry is being made into the causes of the failure of the operations in that district. To enable the Committee to further expand the scope of their operations and to meet additional expenditure in connection with the erection of new model nurseries in the centres of important silk districts, the annual grant of Rs. 3,000, hitherto made by Government, was raised to Rs. 6,000 for the year 1902-03, with the prospect of its being continued at this increased rate for two years more. The course of sericultural instruction imparted at the Rampur Boalia Industrial School was remodelled on a more popular basis, the main object of the school being the training of cocoon rearers' sons. In their case the course of training was reduced to six months, and no educational qualifications are required. The one-year rearers' class has been retained for educated students to be trained for the posts of sub-overseers and inspectors in the villages. To encourage the training of rearers' sons in the elementary course, the majority of the District Board scholarships are to be assigned to them.

From the report we gather that Malda is a long way ahead of other silk districts in the number of intelligent rearers, who have learnt modern

ideas. The Committee are planning some interesting experiments with ruby and ultra-violet coloured glasses. Ruby colour is beneficial to insect-life, and it is expected that worms grown in a ruby light will grow to a large size. On the other hand, it is said that microbes cannot exist under ultra-violet rays. Experiments were also tried with worms grown from European seed. Moderate success was achieved, but the Committee have decided not to continue these experiments. They are more hopeful of the results to be obtained by using hybrid seed, bred from the male European, and the female Indian moth. The hybrid seed is multivoltine. Some very fine cocoons have been produced from hybrid worms in the Chandpur nursery.—*Planting Opinion*, Nov. 22.

CONCESSIONS FROM MEXICO.

CONCESSION FOR PEARL FISHING.—A despatch dated 5th November has been received at the Foreign Office, from H. M. Consul at Mexico City, forwarding a copy of the Mexican "Diario Oficial" of 30th ult., containing the text of a concession, in the form of a contract, granted by the Mexican Government to Messrs. Santa Cruz and Oliver for the purpose of exploiting for ten years the mother-of-pearl to be found from the mouth of the Rio Colorado South to the Port of Mazanillo and on the shores of the islands in the Gulf of California known as Tibron, San Esteban, San Pedro Martir, and San Pedro Nolasco. The concessionaires are also allowed, during the same period, to exploit the sheep and goats, phosphates and sulphates which exist on the islands of the Revillagigedo Archipelago in the Pacific Ocean, and also within a zone extending ten kilometres (six miles) round the coast of the last mentioned islands to exploit the fish, shell fish, and whales, the islands referred to being: Socorro, San Benedicto, Roca Partida and Clarion, as well as the oysters to be found on the last mentioned. The concessionaires are obliged to respect previously established fishing rights, especially those of small fishermen. By Article 4 the concessionaires will pay in rent as follows:—1 dol. for every ton of fish or shell-fish, 10 dols. for every ton of mother-of-pearl, 3 dols. for every ton of whale oil, 2 dols. for every ton of ordinary turtle, and 50 dols. for every ton of the *Eretmochelys Imbricata* producing tortoise-shell, 10 cents annually for each head of cattle given pasture on national lands within the zone, 50 cents annually for every hectare (2.471 acres) of national lands cultivated, 20 cents per ton of oyster shell, and 50 cents per ton of phosphates and sulphates which they will work, 50 cents for each sheep or goat utilised, besides an annual fixed sum of 400 dols. They must construct within three years a factory or packing house to tin, or otherwise preserve, the produce of their fisheries. They may build the same free of any charge on any national land within the zone of their concession. They will have to begin work within one year from the date of the present contract, and must contribute 12,000 dols. annually towards the expenses of Government inspection. It is interesting to note that among other reasons the contract will become void by paragraph 7 of Article 17 "for having given over the concession or having admitted into partnership any foreign Government or agent of such Government," but by Article 20 the concessionaires and the company which they may

form shall always be considered as Mexican even if one or all of its members were foreigners, and will in all cases be subject to the Courts of Law of Mexico. They cannot ever claim under the contract any rights in International Law, neither will they be allowed to make any appeal to any foreign Diplomatic Agent. The same number of the "Diario" contains another concession of a similar nature granted to Mr. R. Gilbert for prawn, lobster and sponge fishing off the coast of Yucatan, between Cape Cangrejo and Punta Flor.—*Board of Trade Journal*, Nov. 27.

PLANTING NOTES.

ARTIFICIAL CAMPHOR.—According to an American patent article camphor (identical with natural camphor) may be prepared by treating water-free turpentine with oxalic acid, whereby pinylic formate is produced. This is distilled with lime, and bornoil and camphor result, which may be distilled off.—*Pharm. Central*, 1902, 566.

CACAO FOR GERMANY—SAMOA.—A Decree issued by the Governor of Samoa, prohibits the importation of cocoa seed and cocoa plants into that island from Ceylon and the Dutch East Indies, and only permits such importation from other countries subject to previous permission of the Government. The decree was to have come into force on the 6th September last.

PEPPER AND OTHER PLANT DISEASES.—The Annual Report of the Government Botanist, Madras, has just reached us, and we extract the following:—

A disease in the Wynad pepper plantations received a certain amount of attention. After a careful examination of the specimens received it was decided that study at a distance was useless. Several pests were found, and it is always a matter of difficulty to determine which of these has attacked plants weakened from some other cause and which has made an onslaught on originally healthy plants.

The following were dealt with:—Rust in wheat from the Palnis; minute insects (Aptera) among *Cinchona* seedlings, determined to be harmless because of the character of their mouthparts; smutted Sorghum, remedies suggested and a scheme of experiments with recent methods drawn up for the Saidapet farm; turnip fleas (*Begrada picta*) in the Ootacamund gardens; plant bugs (*Nezara viridula* var.) in the gardens and notably in the *Cinchona* plantations; difference in colour of coffee beans; a destructive outbreak of green scale (*Aspidiotus Camelliae*) in the Kanan Devan Tea plantations; a coffee-root fungus in Coorg; a disease of the prickly-pear, unfortunately received in bad condition; *Striga enphrasoides*, etc., as pests in badly cultivated lands; and-binding plants as protection on the East Coast; salt bushes as fodder plants; the requirements of the Durian tree as regards climate and elevation; fibre machines suitable for "Aloe fibre"; and questions on *Hydnocarpus*, mosquitoes, *Balsamodendron Berryi* as a hedge plant, various species of *Cissia* as "senna," *Tephrosia* or "wild indigo" for green dressing, and many other references of minor importance.

Correspondence.

To the Editor.

MR. R. V. WEBSTER AND PURE CEYLON TEA:

“THE MAN FOR ST. LOUIS?”

Cullen, N.B., 4th Nov., 1902.

DEAR SIR,—I enclose a booklet that came to hand last night, sent by Mr. Webster and, I think, you will admit there is food for reflection in its contents:—

(1) Mr. Webster has for twelve years sold only pure Ceylon teas.

(2) He has hitherto sold them all in “foreign countries” and till now has sold none in Great Britain.

These I take it, are the essence of the aims of the “Thirty Committee’s” efforts and yet what recognition or assistance has he received at their hands? I recollect advocating his cause on the Planters’ Association Committee or “Thirty Committee” some years ago, about the time he was complaining that not only had his teas sent to Chicago Exhibition been improperly exhibited, but that the very copies of his illustrations in his booklet has been pirated by an opposing firm; but my efforts bore little fruit. Years have passed since then, and while the business of almost every Ceylon planter, who started tea-vending, has become bankrupt or sunk into insignificance, Mr. Webster’s business has increased all over the world, till it is now of considerable magnitude, and he is this year spending about £5,000 in advertisements alone, and hopes to bring his sales up to three to four million pounds.

He mentioned in conversation that he seriously contemplated making a new departure and selling blends with teas of other countries in them, as he could purchase Indians at better values than Ceylons, and as although he had consistently sold pure Ceylon teas hitherto his efforts had hardly been recognised, while he saw others subsidised with Ceylon planters’ moneys, selling blends containing Indian and China teas.

Till this booklet came to hand I was unaware that he had carried his ideas into execution and in losing him as a vendor of exclusively pure Ceylon teas we have lost the most enterprising and successful man who handled them. Under the circumstances he is quite right to handle the teas which will give him best returns, but whether the “Thirty Committee” would not do well to try and induce him to again handle purely Ceylon teas is another matter. I believe it would pay them well to do so.—Yours faithfully,

L. DAVIDSON.

P.S.—Mr. Webster told me that a shop-keeper in one of the ports, where the Boer

[*How long ago is it since Mr. Webster drew £500 from the Cess Fund—and was he not favored at the Paris Exhibition?—Ed. A.]

prisoners landed, secured 100 boxes imported, duty free, cheap, from the prisoners “with the compliments of the Planters’ Association” on them.

L. D.

THE COCONUT—AND QUESTIONS FROM AUSTRALIA.

Wahroonga, New South Wales, Nov. 17.

Sir,—Will you kindly inform me if coconut oil suitable for use as a substitute for dairy butter, mutton, beef and hog’s fat is produced in Ceylon? If so is the oil made from the fresh nuts or from copra? What other articles are produced from the coconut that are suitable for use in connection with human food?

About how many tons of copra are shipped from Ceylon per annum, and how much coconut oil and how much of other coconut products? I would like to see a copy of your paper with reply to above questions.—Yours,

M. G. KELLOGG, M.D.

[Dr. Kellogg will find a good deal of the information he wants in our “Manual of the Coconut Palm” and the needful statistics in the copy of our “T.A.” we send him. No doubt his enquiries are prompted by the fact that owing to the drought in Australia almost extinguishing the export of lard, coconut oil, “butter” and other products of the palm are in special demand.—ED. T.A.]

BEANS—AND BEANS.

Boer Camp, Nov. 20.

DEAR SIR,—Can you give me any particulars concerning the *Tongan Bean* advertised in your columns:—whether a heavy cropper or otherwise and if usable as a good cooking bean. I am forwarding you another *bean pod* which is strange to me, and the name of which I would like to have and also any other particulars concerning same. I have no doubt the information may be interesting to others besides—Yours etc.,

VISITOR.

[The Tonga, Tonka or Tonquin bean is the *Dipterix odorata* of botanists and this is what we are told about it:—

“*D. odorata* yields the fragrant seed called Tonquin, Tonka, or Tonga bean, used for scenting snuff. Perfumers also obtain an extract from it, which forms an ingredient in some bouquets, and the pulverised seed is employed in the preparation of sachet powders. The odour resembles that of new-mown hay, and is due to the presence of *coumarine*. The tree producing these seeds grows sixty or eighty feet high, and is a native of Cayenne. The fruit bears some resemblance to that of the almond tree, and the seed or bean is shaped like an almond, but much longer, and is covered with a shining black skin.”

The bean pods sent by our correspondent are surely of the ordinary broad-bean species—a little varied by climate and mode of cultivation? To settle the matter, “Visitor” should send a pod and leaves to Mr. Nock of the Hakala Gardens.—ED. T.A.]

THE COCONUT OIL PUZZLE.

Nov. 22.

DEAR SIR,—You drew attention last week to the sudden drop in the value of coconut oil by 25s in the London Market; but you did not note the rise by 20s just before—I believe the day before. I have heard the remark, which I saw in print, confirmed by business-men who ought to know, that no one seems to understand the course of the Oil and Copra Market. Is not the price of copra much below what it ought to be, having regard to the price of oil, even after the drop? We have drifted into the season of small crops, and yet the price of nuts seems to have receded, instead of advancing; and notwithstanding the very heavy crops reported from all districts, the exports scarcely show any advance. Oil is ahead of the last four years, but copra and nuts in the shell are lagging behind.—Yours,
PUZZLED.

COCONUT CULTIVATION IN CEYLON.

DEAR SIR,—I do not intend appearing before the public as a teacher but as an earnest learner, and as one who has made a study of practical agriculture since he engaged in planting, twenty-eight years ago.

It is an axiom in Agriculture, to conform as nearly as possible with the natural conditions under which a product grows, when its cultivation is engaged in.

Now what are the natural conditions under which the coconut-palm grows? Its original habitat was the sea-shore on which the nuts were thrown by the action of currents and waves.

The conditions, under which the tree grew and flourished, were on a free, sandy soil highly impregnated with salt and in an atmosphere that was salt-laden.

The extent of land that answers these conditions is limited, and as the cocout industry is a sure and certain one, and does not partake of the nature of gambling as some other industries do, the cultivation of the palm is carried farther and farther away inland, and it is removed farther and farther away from the natural condition under which it grows.

According to my thinking, the first and foremost aim of the coconut planter should be under these altered conditions to conform as nearly as possible with the natural conditions under which the palm grows. Here he will find scope for the exercise of intelligence and ingenuity. If he has a stiff, clayey or gravelly soil to deal with, he cannot make it sandy; but it is possible for him to make the soil sufficiently free, to allow of the free passage of roots through it. The first operation should be deep draining. The free passage of water and air through a stiff soil, will help to gradually alter its mechanical condition. An estate scored with drains, will have its transport arrangements interfered with. The drains should gradually be filled up with coconut branches and bushes, first along the line of a road. The drainage of the soil will not be interfered with, by packing it with branches, till such time as the bushes are thoroughly decayed and forms a compact mass. This will take many years, by which time, the roots of the palm will through the soil of of water saturated with decaying bushes cannot but add to its fertility.

Another operation, as for more necessary than draining, is to keep the soil round the trees in a thorough state of cultivation. If this can be undertaken when the plants are young, the benefit to the resulting trees will be very great. The large foraging roots will be helped to leave the surface of the ground and to obtain water for the use of the tree from the soil where it is permanently damp. Rain water will percolate through the soil, and there will always be moisture for the roots to draw upon in a season of drought. The feeding rootlets will have unrestricted liberty and manuring operations in later years will not be costly. If the tilling of the soil should take place when an estate is young the circle tilled should be enlarged annually till 8 or 10 feet radius be reached. I am inclined to the opinion that with this surface round a tree kept in thorough cultivation by tilling and manuring, ploughing will not become a necessity.

Where tilling of the ground round trees is undertaken in later years, I would suggest a complete turning over of the soil, so that the rank growth of grass, always to be found on a heavy soil, be turned into the soil. The benefits of green manuring will be attained by this. This will of necessity result in the cutting of the roots of the tree. Some people object to this, and think it will be harmful to the tree to injure the roots. The harm will be temporary, the gain from the operation of tilling will be enduring. I do not feel any squeamishness in injuring the roots of the coconut palm. Observation will show that the bole of the tree is constantly putting out new roots to replace those that are injured, which generally die.

I am of opinion that the roots of the coco-palm have no functions to perform on the surface of the soil, and that they are there by reason of the mechanical condition of the soil not permitting them to be where they should be, deep down below the surface of the ground performing the function of pumps. A coco-palm has no tap-root, and the main roots, I am inclined to think, perform all the functions of the tap-root. Observation induced this belief in me. The lateral or main roots of trees, generally spread out parallel with the surface of the soil and horizontally. The main-roots of the coconut tree have a downward direction, and in a sandy soil, as in its natural *habitat*, they generally go deep down into the ground. They are found on the surface, only when the condition of the soil does not permit them to go where nature intended they should be. I think it is for this reason—want of sufficient moisture—that the branches and fronds of young trees growing on stiff soil, hang down as a rule, while the exception is to find it in a sandy soil, where when it does occur, it is in a different degree. When roots are to be found on the surface of the soil, I think it is evidence that that soil has not been regularly cultivated and is crying out to be.

Observation shews us, that the butt-end of the mid-ribs of the fronds of the coco-palm is shaped like a spout. During a shower of rain, these catch the rain-water, and a stream runs down the stem or near it. I look upon this as a provision of nature to supply the tree with the large quantity of water it requires. The aim of the intelligent cultivator is to store up what nature provides. This is done by thoroughly tilling the ground round the coconut tree and where the ground slopes, levelling the surface. The necessity

for thus conserving the water nature provides, will be realised during a period of scanty rainfall. The fronds of a coco-palm are so arranged as to thoroughly protect the surface of the ground round the tree, where the rootlets abound, from the direct rays of the mid-day sun. The arrangement of the fronds also prevent rain-water reaching the shaded portion of the ground. Hence the wise provision of nature to counteract this, by the spout-like shape of the butt-ends of the fronds. As I said before, the aim of the planter should be to prevent the water provided by nature going to waste, by tilling the surface of the soil round the trees.

B.

A LEECH IN A DOG'S NOSE: WANTED ITS EVICTION.

Nonpareil, Ohiya, Nov. 23.

DEAR SIR,—Can any of your many readers tell me how to get rid of a leech which has got into the nose of one of my dogs?—It has been there four days now and all my efforts to get it out have been unsuccessful.—The famil name for this particular kind of leech is “neere-utta,” but of the English name I am ignorant. With apologies for troubling you,—Yours faithfully,

A. D. A.

[We first heard of the trouble Ceylon leeches give by creepings into the nose of cattle and dogs when they stoop to drink at a stream, by a still more peculiar experience: the little child (3 or 4 years) of a Haputale planter—the late Mr. Mitchell of Kelburne—in playing beside a small stream got a leech into its nose; but for some time the parents did not know what was the cause of the bleeding, the high fever and crying of the little one. Fortunately, Mr. W. H. Wright, who was then pioneering in East Haputale, came the way and soon discovered the cause and he proved it by taking the child into a dark corner when the leech popped out enough for Mr. Wright to seize and wrench it away. This is as we recall the story told us at Kelburne, alas, so long ago as March 1865; but if we are wrong the veteran planter now on his Mirigama coconut property, will correct us. Let “A. D. A.” then throw a cloth over his dog's head and watch if the leech does not obtrude sufficiently to enable it to be pulled away. There are no doubt other remedies which may be mentioned by correspondents, but the efficacy of the above plan has been repeatedly proved.—Ed. T.A.]

No. II.

Colombo, Dec 3.

SIR,—A successful way to extract a leech from a dog's nose, even on a rainy day, is to introduce a strong solution of common salt into the nostril occupied by the cruel intruder. The dog will sneeze him off,

“USUS.”

No. III.

Colombo, 28th Nov.

DEAR SIR,—Might I suggest a good pinch of snuff, sufficient to make the dog sneeze.—Yours faithfully, C. H.

No. IV.

Kotalena, 29th Nov.

SIR—In reply to the inquiry by “A D A” of Nonpareil, Ohiya, in your yesterday's issue for evicting a leech from his dog's nose, I would recommend him to use an injection of vinegar or a solution of salt as prescribed by Dr. E J Waring, M.D.

P. C. O.

No. V.

Nov. 30.

DEAR SIR,—In answer to “A.D.A.'s” query in your issue of 28th November as to how to extract a leech from a dog's nose:—

Keep the dog in the hot sun a short time. Then bring him into a cool room and dip his nose in a vessel of cold water, and with a handkerchief adjusted between the fore-finger and thumb, you will be able to sprag the leech firmly and he's got to come.—Yours, &c.,
PLANTER.

GREEN TEA AND BLACK: THE TURN IN THE TIDE.

Nov. 26.

DEAR SIR,—I really don't think the prospects of Ceylon Tea—I will not go so far as to say British-grown Teas—were ever brighter. I say so with recollection of the time when the average price was double what it now is. Then, there was the apprehension of a rush into the enterprise, since sadly fulfilled; and then we had not learnt the teachings of adversity, so helpful to thoroughness and economy. And the change has been brought about, within a few months, by a process as simple as that which has immortalised Columbus' egg! It was just like the Britisher. He knew there were Green Teas and Black; and he knew the Yankees (like some others!) were wedded to Greens; but they must be conquered not coaxed; the Black must be poured down their throats. But Jonathan is as tough a customer as his cousin John Bull; and we have had to give up the idea of force. And how many markets have not the British lost in manufactures by not consulting the wishes and needs of the buyer, as the Americans and the Germans do!

Take my word for it, in the next year or two our Green Teas will play such a part in the markets of the world, as to lay the ghost of over-production at least for a decade—may be for ever. Thanks to Rutherford's keenness, we have been spared an increase in the Cess; and in 1904 Greens will need no crutch, and it isn't from Mr. Black they will ask a helping hand. *Exit tributum!* And when that happy day dawns, let us think kindly of a Firm which has had more hard things said of it than any in the Tea business. For is it not Finlay, Muir & Co., who gave the fillip to Greens by their improved process which has enlisted an army of inventors—who laid, in fact, Colombo's egg at Ambewatte!—Yours,

P. D.

TONGA BEAN—I.

Nov. 29.

DEAR SIR,—In your issue of 25th inst., I see a letter from "Visitor" enquiring about the "Tongan" bean. The jat, I advertised, is a *vegetable*, a very heavy cropper and when cooked is of a more delicate flavour than the "French" bean.—I am, Sir, yours faithfully, "SEEDS" MADULKELE.

NO. II.

The Central Seed Stores, Kandy, Nov. 28.

SIR,—Your correspondent "Visitor," wishes to know the merits of the Tongan Bean, and I trust the following will be of some use.—Yours truly,

E. SPEARMAN HUGHES.

The wonderful Tongan Bean is a strong evergreen perennial climber, producing immense quantities of large flat beans of excellent quality, which are used like French Beans. It is estimated that, in a moderately warm situation and good soil, two plants of this bean will supply a small family with this delicious and wholesome vegetable for nine months in the year. The plant is also very ornamental, and may be utilised for covering unsightly objects. It requires to be sown rather late. The bean should be picked very young and boiled whole. Although it is a perennial, it is advisable to sow one or two beans every year, for though the old plants come into bearing much earlier than the young ones, still they do not bear such heavy crops nor the best beans. As the seeds are very slow to germinate, they should be soaked one or two hours in warm water before sowing.

CULTIVATION OF BEET, SWISS
CHARD, &c.Himalaya Seed Stores, Mussoorie, N.W.P.,
Nov. 29.

DEAR SIR,—I am enclosing a copy of a special Circular which I have just published on the "Cultivation of Sugar Beets, &c." and shall be glad if you will give a notice of it in one of the issues of your valuable paper.

I think that the articles treated of in the Circular would be found useful by District officials, &c. as famine crops, for feeding the millions who are, from time to time, thrown on the hands of Government at Relief Works, &c., and would be infinitely more valuable than the Carrot seed, which, a few years ago, was bought at great expense in Europe and ultimately thrown away, as the Natives would not make use of it.—Yours faithfully,

W. W. JOHNSTONE,

*General Manager.*NOTES ON THE CULTIVATION OF SUGAR
BEET, GIANT SEAKALE BEET AND
SWISS CHARD.

Some four years ago experiments were commenced at the Central Jail, Coimbatore, with a view of introducing some new kinds of vegetables to supplement those ordinarily grown in the Madras Presidency. A small consignment of Sugar Beet seed was obtained from Australia through a gentleman at Ootacamund. The seed was received in October and planted at once, and the result was sufficiently satisfactory to encourage further trials. The following year, seed was obtained from the Himalaya Seed Stores, Mussoorie, and the result was highly satisfactory. The roots

have since been grown year by year in several Jail gardens of this Presidency, and have proved a valuable addition to the Jail dietary.

SUGAR BEET.

The method of cultivation adopted at Coimbatore is as follows. The plot which is intended to grow the Beet is dug to a depth of about 18 inches and heavily manured with ordinary farm yard manure, about 2 months before the time for sowing the seed. When the June rains commence, the plot is laid out in beds for irrigation, and the seed sown in drills 1 foot apart, the young plants are subsequently thinned out to 1 foot between each, and during dry weather are irrigated once a week. The Beet is said to absorb a large amount of nitrogen and in some places it may be advisable to use nitrate of soda and superphosphate of lime as a manure, but here it has not been found necessary, owing to the large amount of lime in the soil. The practice on the Continent is to have the roots nine inches apart each way. This keeps them small and uniform in size, a matter of much importance where the roots are grown for sugar. When grown as vegetable for prisoners, uniformity of size is of no importance, whilst the larger they are, the greater the weight of vegetable produced. The roots grown by Mr. Prondlock in the Nilghiris, varied from 4 lb. 12 oz. to 5 lb. whilst those grown on the Continent vary from 1½ to 3 lb.* No particular attention has been paid to the weight of the roots grown here, and they have varied very much in size, owing to the fact that seedlings thinned out from the beds are planted in other beds. These do not as a rule form large or well shaped roots. It is a common thing here to find roots weighing from 10 to 12 lb., and the average weight of a well grown plot would certainly exceed 6 lb. It seems likely that the large size of the roots grown here is due to regular irrigation, and to free working up of the soil between the roots, added to the fact that the soil here seems particularly suited to all plants of the Beetroot family.

The crop takes about 6 months to mature, but for the purpose for which they are grown here, the roots can of course be utilised before they attain full maturity. It is difficult to store roots satisfactorily in this country but they have been kept for upwards of three months, by being heaped in a store room and after a few days, when the heat has escaped, being covered with dry sand. The kind of Sugar Beet ordinarily grown here is Vilmorin's Improved, but there are several other kinds, equally good, all of which can be obtained from the Himalaya Seed Stores.

MANGEL WURZEL.

Mangel Wurzel has also been grown here successfully under the same conditions as the Sugar Beet, some roots having attained a weight of close upon 20 lb.

If used for feeding cattle, Sugar Beet and Mangel Wurzel, should be well boiled and mixed with other food.

GIANT SEAKALE BEET.

This vegetable was first tried in the Jail garden in 1898. It is a large, comparatively new variety of the Spinach Beet, distinguished by an abnormally large white mid rib. This vegetable has been grown here with great success. It is easy of cultivation and gives a heavy crop in a short time. The seeds are sown in sheltered seed beds, and the young plants bedded to 15 inches each way, when large enough to handle. The plant will grow in any good garden soil and if in rich soil attains a very large size. The practice here is to allow the plants to attain such a size that they completely cover the ground. The leaves are then carefully removed, with the exception of a few of the tender ones in the centre. The soil is then dug up round the plants, which in a short time give a second crop. This plant, like all the Beetroot family, requires lime with manure, unless the soil itself contains a large percentage of lime.

* Mr. Pontler's reports on Sugar Beet grown on the Nilghiris.

SWISS CHARD.

Seeing that a considerable amount of the Giant Seakale Beet seed was being ordered for this Jail, the Manager of the Himalaya Seed Stores suggested that Swiss Chard might be tried here, as being very similar to the Seakale Beet and much less expensive. On his suggestion four varieties of this vegetable have been cultivated here with great success. The Swiss Chards, like the Seakale Beet, are all varieties of Spinach Beet. The seed is sown in seed beds and the plants put out about 1 foot apart. They require the same soil and treatment as the plants previously described. They are particularly handsome and give a good return in a short time. The outer leaves should be cut when the plants cover the ground completely, and a second crop will be obtained in about 6 weeks time. These plants when under irrigation, withstand the heat well, and can be grown here nearly all the year round. Of the varieties tried here, the White Silver Curled, and the Large Ribbed Scarlet are preferred.

It has been argued that these vegetables and the Giant Seakale Beet contain a very large percentage of water. No doubt they do contain a very large percentage when compared with the majority of English vegetables, but they compare favourably with most country vegetables. The great thing in their favour is that they are easy to cultivate, give good returns and are thoroughly wholesome. The prisoners also appear to like them, as no complaints of these vegetables are ever made.

Central Jail, Coimbatore,
20th July 1902.

E GADSDEN,
Superintendent.

We can supply any of the seeds referred to above at the following prices:—

Beet, Giant Seakale	per ounce	R1;	per lb.	R7-8
Swiss Chards of sorts	per lb.	R2-0
Sugar Beets of sorts	per lb.	R2-0

When very large quantities are required, orders should be registered not later than the end of January and supplies will then be sent on receipt of stock from Europe.

Apply to:—

The General Manager,
The Himalaya Seed Stores,
Mnssoorie, U. P. A. & O.

THE CARDAMOM POSITION, AND PROSPECTS.

Paniyar Estate, Devicolam, Dec. 1.

DEAR SIR,—Considerable anxiety regarding above has been expressed lately, by those interested, and a good deal of speculation indulged in as to over-production. As most reference has been made about Ceylon, it may be of interest to publish the following figures regarding India, and the Cardamom Hills of Travancore, the latter, probably the largest, and most prolific cardamom producing district of the present time. With the abolition of the Government Monopoly, and the advent of the Land Tax system into the Cardamom Hills, a great stimulus has been given to cardamom cultivation, and the acreage has been increased from 10,000 acres under old system to 15,650 acres in 1900 (Government Survey) and probably 1,500 more during 1901-02. There will therefore be about 17,000 acres under cardamom cultivation in these hills at date. The principal feature, however, is not exactly in the increased number of acres, but in the system of planting, and subsequent treatment, carried out on these later extensions, especially since the European Planter stepped in, (about 1899.) I venture to make the following definition, and estimate, of crop from the 17,000 acres, when in bearing, (this is derived from personal observation and is more a guess than an estimate):—10,000 acres

original monopoly gardens, never properly planted, or cultivated, and in a very bad condition, at 35 lb. per acre per annum, 350,000 lb.; 4,000 acres land taken up after 1896 on Land Tax system rather better planted, and cultivated, and comparatively fresh soil, at 60 lb. per acre, 240,000 lb.; 3,000 acres including European holdings (about 2,000 acres) mostly planted 1900-1, systematically planted, at 150 lb per acre 450,000. These figures aggregate 1,040,000 lb. and work out about 60 lb. per acre on the average. Last year the output entirely from native gardens was a little over 300,000 lb, this year the crop is not yet all gathered; but, the output from same source will not be less than 600,000 lb. This increase is partly due to a favourable season, but mostly due to extensions. The badly tended gardens are naturally very erratic in cropping, and will give little in an unfavourable season, and I would not put the annual output over 500,000 lb, on an average, but the later systematically planted acreage (3,000) will crop regularly, and we may expect the output from the Cardamom Hills to be not less than a million pounds in 1903-4. Without considering increased production from extensions in Mysore, Annamalais and other districts in South India, where is a market to be found for Ceylon's increase (over 100,000 lb as compared with same date last year) and the extra 300,000 from Cardamom Hills this year, with every likelihood of a similar further increase next year? It looks as if the cardamom market at present taking about a million-and-a-half pounds altogether, will be called upon to increase its capacity another half, or three-quarters of a million in the short space of two years, how is it likely to respond? The cardamom industry scattered over South India, and Ceylon, as it is, with a good many native participants, is not likely to unite in any scheme to open up new markets, so it will undoubtedly be the "survival of the fittest." European planters on the Cardamom Hills have compact estates, from 300 to 600 acres, of good fresh land, the home of the cardamom, with a distinct crop season making picking very cheap, and being close to lowcountry where curing can be carried out to best advantage, have little to fear in the coming struggle.—Yours faithfully,
J. A. HUNTER,

NEW COFFEE-HYBRIDS IN TRINIDAD.

Botanical Department, Trinidad, Oct. 30.

DEAR SIR,—I thank you for the notice of my annual report in your *Tropical Agriculturist*. You remark in reference to "coffee-hybrids" that "nothing is said as to their being proof against the fungus *Hemileia vastatrix*." I am glad to inform you that I was quite unable to do so, as *Hemileia* is as yet an unknown quantity, and I don't think we shall try to import it for the purpose. I hope, however, to put your Gardens in possession of seed, that may be tested as to immunity shortly.—I am, yours faithfully,

J. H. HART.

SNAKES ALIVE! A REMARKABLE MEAL FOR A COBRA.

Dangkande, Rattota, Dec. 13.

DEAR SIR,—The following is a sight not often seen:—

This morning as I was walking along my watercourse, a cobra, which was running by

itself on the edge, plumped into the water on seeing me and swam in the direction of the current.

On following up I noticed something hanging out of its mouth, which turned out to be a small portion of the tail of a snake. I thought I was to solve the knotty problem as to whether a snake swallows its young. Gradually, however, instead of one of its progeny, the cobra disgorged quite three-fourths of a rat-snake before I killed it. I hauled the remaining fourth of the rat-snake out of the cobra and on measuring the snakes, found that the cobra was 4ft. 8in. and the ratsnake 5ft. 2in. It would have taken the cobra a good long time to have digested such a meal—a snake 6in. longer than itself!—Yours faithfully,

H. L. BLACKLAW.

CARDAMOMS: CANNOT INDIA AND CEYLON MARKETS BE SPECIALLY EXPLOITED.

Dec. 13.

DEAR SIR,—I am afraid there is a good deal of truth in what Mr. Hunter says; but with the enormous number of natives in India who daily use cardamoms, I think India has a market within itself for all she is likely to produce, if planters and merchants there will take the trouble to meet, and encourage the demand for their produce. While Ceylon planters, with their facilities for conquering other foreign markets, should lose no opportunity of sending exhibits of their produce to every exhibition open to them. It is only by making known to the world the excellence of our products that we can expect to increase the demand for cardamoms which, as yet, are but little known. Yours truly,

AN INTERESTED PLANTER.

COCONUTS AND COPRA.

Dec. 16.

SIR,—Can you tell me what is the relation between a ton weight of Coconuts and a ton of Copra? How many nuts, in fact, are required for the latter; but at the same time, how do they compare in regard to bullock-cart loads.—Yours truly,

INEXPERIENCED.

["Inexperienced," as a coconut planter, should provide himself with our "Manual" and "Directory," in both of which are much useful information in daily request on coconut plantations. It requires from 170 to 200 nuts to make a cwt. of copra—say 3,700 nuts to the ton; and generally speaking, 6 cart loads of coconuts, if converted into copra, would make only one cart-load. We need not point out the advantage of retaining the husks on a plantation for manurial purposes—the veteran, Mr. W. H. Wright makes splendid use of them—but on the other hand, a good deal of labour and special care are needed in preparing copra properly.—ED. T.A.]

THE PRESSING NECESSITIES OF THE TEA INDUSTRY.*

Dikoya, Dec. 14.

SIR,—Your correspondent, G. N. T., in your issue of 4th instant, has done public service by formulating these into 3. His No. 3, "*The improved cultivation of estates*," I think should be left out, because it is a matter for the individual capitalist, not the public Planting body to attend to. I would substitute for this necessity "*The successful launching of the Green Tea Industry*."

We should then have the following necessities formulated:—

No. 1. The reduction and ultimate abolition of the Duty at home.

No. 2. The prevention of tea under a certain standard being shipped from Ceylon.

No. 3. The launching of the Green Tea Industry.

Of these 3 necessities No. 1 may be left to the British consumer; for we, planters, can do little more than support his protest whenever we see him agitating.*

No. 3 is being taken care of to the full by the Cessites, and the majority in favor of the Cess—as a temporary measure at any rate—will ensure it being carried.

No. 2 alone, while not lacking in moral support, has no practical scheme yet suggested for enforcing it.

In my opinion it is the most vital necessity of the 3, because it deals with a defect inherent to tea, and to no other product, viz., that it can be over-produced in inferior quality at a few weeks' notice, to flood the markets, shake the financial position of the Tea Share Market, and prejudice the consumption. No industry can expect to be stable that is exposed to such a risk, and, just as locks were invented against thieves, so must a safeguard be adopted against "spoilt" teas. The following is the scheme which I have to propose for the Press, and the planters to knock into shape:—

Let a qualified Expert be appointed to act with the "Thirty Committee" as Expert Adviser and Office Manager of a permanent Planters' Association Tea Industry Office in Colombo, which would be in touch equally with the Planters' Association and the Chamber of Commerce.

Let the duties of this official be to advise planters on manufacture for fixed fees, and to be the "smeller out" of bad—that is to say rotten—tea leaf in course of export whether on arrival for public sale or shipment otherwise.

In the event of the discovery of a parcel of "spoilt" tea, let it be the duty of the Censor to refer the sample to a Board of Tea Brokers' experts, associated with himself, and, if the tea is only verging on the line of condemnation, let that Board, as a preliminary step, issue a warning to the exporter, which warning could be published if necessary.

* Not so: we maintain that producers as feeling the pinch most should lead the way in agitation; for it is undoubted, that the 2d. extra duty to a great extent came off the prices.—ED. T.A.

Where the sample is proved to be flagrantly bad, let the Board issue a certificate to the Government for its condemnation, and let the latter on the same principle that it has out the Cess Tax into effect at the instance of the planter, enforce this. It must be remembered that such "spoilt" tea has still a market for its full value through Messrs. Böhlinger. I am of opinion that this scheme will be found perfectly practicable in principle, and would do more to give stability to the Industry and Share Market than any form of Combine that can possibly be invented. Its success in Ceylon would also, doubtless, lead to the adoption of a similar scheme in London in course of a little time.—Yours faithfully,
 PROPRIETOR.

DR. SHERIDAN LEA ON "WITHANIA COAGULANS."

Galagedara, Nov. 27.

SIR,—Many of the natives of India refuse to have anything to do with cheese prepared by means of animal rennet, and there is consequently there a large field for the employment of this plant. Some years ago Surgeon-Major Aitchison sent home an account of the peculiar property of the "Withania." The shrub grows freely in Afghanistan and Northern India and the natives there have for a long time employed an aqueous extract of the capsules to curdle their milk. Some dried material sent from thence to Kew was used by Dr. Lea in his investigations. Withania is a genus of the order Sobanaceæ and has a capsula fruit containing a large number of small seeds. In the dried material these seeds were enveloped in a coating of a peculiar resinous matter, which was probably the dried juice of the capsules in which they had ripened. The ferment was found to exist to a very slight amount in the stalks of the fruits, and to be extremely abundant in the seeds. From the ground seeds it could be extracted easily by maceration with solution of common salt, and by treatment with glycerine, so extracted, it was found to be destroyed on boiling, but to be able to withstand moderately prolonged exposure to alcohol. Its activity in a fairly strong extract was quite equal to that of most commercial samples of rennet prepared from the stomach. It could, moreover, be kept with as great security as the latter, by the aid of common salt and a little alcohol. Its commercial value is somewhat interfered with by the presence in the seeds, and in their extracts, of a peculiar yellowish-brown colouring matter which cannot be separated without destroying the rennet. These seeds were obtained from Mr. E Spearman Hughes, Florist, Kandy, some months ago and sent to the United States, and I am glad to state the recent glowing accounts of its great success will open a large field in our Colony for its cultivation.—Yours truly,

J. J. McK.

MATALE PARA RUBBER SELLING HIGH.

Keplitigalla, Matale, Dec. 5.

DEAR SIR,—As promised in my letter of October 1st last, which appeared in your daily issue, to let you know the results of the

sale of the 13 cases Para Rubber dispatched, I now have the pleasure in stating that the 13 cases sold for the handsome average price of 3s 11d per lb.—an average price second to none in the world, as very best Paras were selling at same sale at 3s 5½d. Valuation and sales of 13 cases, Keplitigalla, Matale, Ceylon, Para Rubber:—

London, Nov. 14.

To 4 cases 200 B. A1. valued at 3s 11d sold at 4s.

To 8 cases 400 B. A. valued at 3s 11d sold at 4s.

To 1 case 42 B. rough scrap valued at 2s 8d sold at 2s 10d.

I enclose London Agent's sales memo to verify above figures.—I am, Sir, yours faithfully,
 FRANCIS J. HOLLOWAY.

THE CARDAMOMS' POSITION AND PROSPECTS.

Gammaduwa, Dec. 7.

DEAR SIR,—Mr. Hunter's letter of the 1st inst. appears most opportunely. It was only the other week your readers were informed of an application to Government for 40 acres of land on 12 years' lease for the purpose of experimental cardamom cultivation, and about a year ago of a grant of 200 acre for a similar purpose. Old cardamom growers have reason to feel alarmed. With 8,000 odd acres of this product and an export, for eleven months, of 551,659 lb, with a probable 750,000 lb, next year, they think their cultivation is beyond the experimental stage. They are now warned they will have a big struggle for existence with their formidable rival India, and our Governor should note this while considering applications for grants and leases for cardamom cultivation. Perhaps, the experience of the older growers may help them in the fight.—Yours faithfully,

JAMES WESTLAND.

COCONUT CULTIVATION : SALT.—No. 2.

THE CASE FOR FREE SALT FOR AGRICULTURAL PURPOSES.

DEAR SIR,—In my last communication (in which by the way "husks" was made to read "bushes"), I pointed out how one of the natural conditions under which the cocopalms grew—a free soil—could be imitated by draining and tilling. In this communication I intend to dwell on the necessity of salt for coconut cultivation.

The history of the agitation to induce Government to issue salt for agricultural purposes at reduced rates goes back into the past. The agitation was started by the Coffee Planters headed by Mr R B Tyler, if I mistake not. Government met the agitation with the reply that salt could not be so de-naturalised as not to make it possible for it to be purified and made fit for culinary purposes. A practical Government would have dealt with probabilities rather than with possibilities. Was it probable that the ordinary cooly had a sufficient knowledge of practical chemistry to purify the salt that had been denaturalised, and was it by any means probable, that if he had that knowledge, he would utilise it and expend much valuable time to save a cent

or two on salt per diem? A practical Government would have answered these questions with a decided and emphatic negative. Besides, those who applied for the salt were ready to pay for a watcher, to be supplied by the Government, to see that the salt was used for no other purpose than agricultural.

The Government is sufficiently practical and enlightened to carry manures in their railways at reduced rates and to levy no tolls on manures, on the principle that bread cast upon the waters will return to it after many days, in the shape of increased produce. But it is not prepared to apply the same principle to the issues of salt at special rates for agricultural purposes.

As I am very strongly of opinion that salt is an absolute necessity in coconut cultivation, especially in inland districts having a heavy soil, I started an agitation for its issue at special rates, about fifteen years ago. It was met by the stereotyped reply. Of the benefits of its use in coconut cultivation, one reads occasionally in the papers of the experiments being carried out by Dr. Dias at Henaratgoda.

It was argued by Dr. Trimen at the time of my agitation, that as analyses showed that the coco-palm yielded but a small quantity of salt, and as this small quantity was very likely deposited during the monsoons, salt was not so great a necessity for coconut cultivation as I wanted to make out. I think his reasoning was fallacious. The quantity of any inorganic matter in any product, should not determine its necessity or otherwise. Besides, salt has other properties than manurial. It acts chemically and mechanically on a soil. It keeps the soil moist by absorbing the moisture of the atmosphere. It acts as a solvent and renders available the insoluble plant-food in a soil. Lime does not occur largely in vegetation, yet soils are limited to improve their chemical and mechanical condition. Dr. Thibben was evidently misled by Lepine's analytical results. Cochran, a few years ago, showed that they were wrong as regards the quantity of salt in the husks of the coconut. He was also surprised to find that the husks of a coconut grown on an estate at Kurunegala yielded more salt than in one grown on the sea shore at Kollupitiya.

Of all coconut planters, the late Mr. Davidson was, perhaps, the most intelligent and the one best versed in Agricultural Chemistry. His pupil, Mr. Jardine, is a worthy successor of his. He wrote in 1861:—"A tree requires annually 1'34 lb. salt and 9'79 lb. potash (according to Lepine's analyses), yet the larger amount may be less essential to its welfare than the smaller quantity, because this possesses properties which the other has not, and for the want of which nothing else will compensate. The weight of salt required, compared with the other in organic matter, does not exhibit fairly its relative value as a manure. Here (Jaffna) day after day may be seen strings of carts, creeping from the beach to the estates, laden with sea weed. For the sake of the salt it contains, we drive a cart-load of matter, which we could obtain much nearer home and at a little of the cost, because our Rulers persistently refuse to allow us, at the price they sell it for exportation, to purchase that salt for our estates, which it, sometimes, costs hundreds of pounds to destroy. The following offer was made to Government Parties to get salt at export price, would adulterate it with matter best adapted to render it unfit for culinary purposes, in the Government stores. They would enter into a penalty bond to the full value of the salt, at the market price, that it should be used solely as a manure for coconut trees and they would pay for a Government employee, who should certify to its application as specified. We deserve, perhaps, that our wants should be disregarded, for I do not remember that coconut planters have ever combined to have them fairly represented. With more of

unity and combination in our efforts, we should doubtless command success."

Possibly at the time Mr. Davidson wrote the above, coconut estates regularly cultivated existed only in the Northern and Eastern Provinces. Though the cultivation of the palm and the opening of estates have increased by leaps and bounds since then, the deplorable want of unity and combination which he then bewailed, still exists. If so shrewd and intelligent a planter as Mr. Davidson thought salt a necessity in coconut cultivation, and placed so high a value on it, even on the sea-border, surely I was right when I, ignorant of his opinion, advocated the use of salt for coconut cultivation, especially in inland districts.

To those who are ignorant of the fact, it will cause much surprise to be told that contractors supply the Government with salt at 25-35 cents the cwt. They re-sell it wholesale for local consumption at R2'36 the cwt., and for export for a little above cost price. Why strangers should be treated better than their own children. I have never been able to find out? Nor why the Government should prefer to export salt and even to wickedly destroy so useful a product, rather than to sell it at export rates to agriculturists, when it will result in increased crops, increased circulation of money, and increased revenue to Government, by the increased consumption of dutiable articles, increased traffic on railways, roads and canals, and increased duty on exports. Will not some member of Council again take the matter up? It appeals specially to the Planting and Ceylonese members.

Salt can be denaturalised at any one of our manure works by the addition of incinerator ashes, and some offensive smelling manure such as guano. Ceylonese know that only the lowest caste of natives can be induced to work at conservancy (with apologies to Mr. Hemming). If once it be known that salt used for manurial purposes is mixed with matter from latrines, not only will no one be so depraved as to attempt to use it for culinary purposes, but it will be difficult to get any one but pariah caste coolies to handle it. I feel certain that if Revenue Officers with a knowledge of the people and their prejudices be appealed to, they will unanimously give it as their opinion that the probabilities of salt denaturalised as I suggest, being used for culinary purposes are extremely remote. If salt be available at cheap rates, its use will gradually extend, till it assumes very large proportions. When one's neighbours see the benefits arising from its use, they will gradually follow suit. If nursery plants, before being put out, are steeped in brine, they become immune from the attack of white ants, and turn out healthier and stronger plants. If a small quantity of salt be sprinkled in coconut holes, insects are destroyed. If a sufficiency of salt be used to impregnate the soil, the plants will be able to resist droughts, as the impregnated soil will absorb moisture from the atmosphere. If salt be applied to coconut plants of larger growth and to trees, the soil is kept moist and free, if mulched simultaneously, the capillarity of the soil is increased and evaporation lessened, so that droughts will not seriously affect them. Salt, as stated before, is a solvent. When the soil is moist and the plant-food is rendered soluble, rootlets will be performing their functions of feeding, continuously. B.

PLANTING NOTES.

CACAO ENEMIES.—We learn that owing, probably, to the prolonged wet weather, there has been a recrudescence of disease—canker, fungus, etc.—among the cacao trees on several estates, North and South of Kandy. We trust the trouble will shortly disappear as the dry weather sets in.

CHINESE TEA.

The once important and lucrative tea industry has, says Acting Consul-General J Scott, of Canton, been almost ruined by Chinese apathy and neglect. Growers in the interior pay little or no attention to their plants, and do not trouble to renew the old bushes as they become decayed. The leaf is picked anyhow and at any time, as prices appear favourable, with the result that, carelessly handled and fired, the tea on reaching the London market is frequently found affected or deficient in strength, body, and colour. Thirty years ago Canton exported to Europe some 13,000,000 lb. of black tea and nearly 2,000,000 lb. of green, whereas now it amounts to less than 1,000,000 lb., chiefly Congou. The well-known

SCENTED CAPERS,

for which Canton was famous, and of which some 7,000,000 lb. were exported in 1872, figure for 1901 at an export of 5,790 lb., only. These figures do not, however, give an accurate return of the entire export, as many shipments are arranged in Hong Kong, to which port the tea is conveyed by junk, and does not, therefore, pass through the hands of the Imperial Maritime Customs. The following figures, obtained from an actual dealer, provide a comparison in the trade in scented capers during the past three years:—in 1899, 4,900,000 lb.; in 1900, 3,700,000 lb.; and in 1901, 3,000,000 lb. A further depressing feature is that the monthly returns of deliveries in London also mark a decline which would lead one to suppose that Canton scented capers are rapidly going out of consumption. The season now under review cannot be said to have been a favourable one as regards quality, nor was it remunerative either to foreign buyers or native sellers. Taken all round the various crops during the season were of a fair average quality, but there was a considerable quantity of leaf left on the hands of natives from the previous season. This they had to work off by mixing it with the new season's leaf—a practice that no doubt had a detrimental effect, and which would have been accentuated had not scented flower been abnormally cheap and abundant, whereby it was possible for the teas to be scented above the average. The recent decision of the Chinese Government to lower the export duty on tea to 5 per cent. *ad valorem* may have some beneficial effect upon the trade, and had this measure been adopted some ten years ago, the tea trade of Canton and China generally would not have fallen to its present low level. This considerable abatement in the export duty will enable low-priced Chinese teas to compete more favourably with those of India and Ceylon.—*London Chamber of Commerce Journal*, Nov.

A GOVERNMENT REPORT ON RUBBER.

In a report on "Agriculture in the Tropical Islands of United States," by Mr O F Cook, botanist in charge of investigations in tropical agriculture, less than two pages, under the heading "Rubber and Gutta-percha," form the single reference to the matter under discussion. The spirit in which Mr Cook writes is decidedly unfavourable to the formation of rubber plantations. He says, for example: "Notwithstanding widespread interest and the investment of millions of dollars, it cannot be said that rubber culture has passed the experimental stage, in indeed that period has been fairly reached." But there is no reference to any experiment made in any country, or to the results, in such detail as will enable the reader to look into

the subject further with a view to satisfying himself as to the present status of rubber cultivation, or to investigate the reasons for "the investment of millions of dollars" which is still going on.

Mr Cook says again; "Moreover, it is known that many rubber plantations established with the most lively expectations have been abandoned because the anticipation, of a profitable yield of rubber from cultivated trees proved to be fallacious." This report would have been more complete and more convincing had it been followed by a list of such plantations and of their locations. As a matter of fact, there has not been time, since the systematic planting of rubber on a commercial scale began actively, for very many of the plantations to become productive, and, so far as we can learn, the results attained have been such as to encourage very many others to engage in this branch of planting. There is reason to believe that more rubber trees have been planted in Ceylon, the Malay peninsula, Burma, Mexico, Central America, and the West Indies during the last twelve months than in any previous year, and in the list of plantations on record in the *India Rubber World* office—which includes all that we have been able to gain any of knowledge of during the past ten years—there has been no case of abandonment of trees once planted. Mr Cook admits, however, that "similar disappointments, misapprehensions, and misrepresentations"—referring to the prospectuses of certain companies formed to plant rubber in Mexico and Central Africa—have, of course, marked the early history of many finally successful and important industries."

INTERNATIONAL COFFEE CONGRESS.

According to *Dun's Review* of October 11th, the International Coffee Congress, then being held in New York, for the purpose of considering what measures should be adopted by the leading coffee-producing countries to improve the position of coffee in the world's markets, had held several sessions, and some progress had been made in the direction of giving definite expression to the views of its members on the important questions forming the subject of their deliberations. The Committee on Consumption reported the three following resolutions:—(1) Recommending to all the Governments and producing and consuming countries the compulsory use of pure coffee in the armies and navies. (2) Recommending to the Governments and countries which produce coffee that they establish, as soon as possible, in countries in which coffee is not now consumed, places for the demonstration of pure coffee. (3) That coffee-producing and consuming countries may prohibit the sale of adulterated coffee, and of substitutes bearing the name of coffee; and, in case this prohibition cannot be enforced, that a heavy duty be imposed on such articles. The Committee on the Causes of the Crises submitted a report of which the following is the resolution recommended:—"The International Conference for the Protection of the Coffee Industry recommends to the producing countries the adoption of differential tariffs for the collection of import duties, applicable to manufactured articles and staples of the consuming nations, proportionately to the tax charged upon imported coffee.—*London Chamber of Commerce Journal*, Nov.

PLUMBAGO REPORT.

There has been a distinct decline since our last We have lately visited all the users of Ceylon plumbago on the Continent and find them in no pleasant frame of mind. Nine-tenths of the ship-

ments to the Continent go to crucible manufacturers who claim of the infinitesimal margin of profit now obtainable on crucibles, largely owing to the comparatively high prices prevailing for the better qualities of plumbago. Trade generally in Germany is we all know, in a had way and this holds good to no small extent in the iron and steel trades. When one sees firms like Krupp of Essen working only half time, matters cannot be in a very prosperous state. One of the oldest and at one time the largest firm of crucible manufacturers in Germany has just thrown up the sponge and closed its works for all time. The manager informed us that they could no longer manufacture crucibles at a profit, and they would not go on working for the fun of the thing. Several others are working on the narrowest of margins. They do not care to shut down temporarily, as it would disorganize their labour, so they carry on hoping for better times. In America things are far from brisk, and we now hear of an American mine capable of producing 5,000 tons good crucible plumbago per annum. It is true that we have once or twice before heard of American plumbago, but that was the extent of it. When we asked for shipments there was ever some excuse; but the matter has been placed before us now in a much more definite way, and there may be something in it. We still have our doubts, but shall be better able to report on the subject in a few weeks' time. On spot, London, the following sales have been made during the week. Common lump, £18 to £12; good chippy dust, £7 10s.; medium chippy dust, £6 15s. For shipment finest O. L. has been sold at £36 to the Continent. Good quality at £32, medium at £25, and finest chips at £20. Several transactions have been made in plumbago from Southern India. The quality is poor, but it analyses well and gives an excellent polish. If this can be produced in any quantity it will interfere with the trade in Ceylon dust and flying dust. Common qualities of the latter are unsaleable but there is still a good demand both for England and the U.S. for medium chippy dust at about £7.—Messrs Chapman, Anthony & Co.'s Report to Local "Times."

TRAVANCORE FORESTS.

We have received a copy of "The Mine of Wealth" in the State Forests of Travancore: and what young Travancore can do to create industries—being a lecture delivered under the auspices of the Travancore Government Lecture Committee, by T Ponambalam Pillai, Acting Conservator of Forests, Travancore. The lecture was a long as well as interesting one and wound up as follows:—"I shall now conclude the paper. I have told you how beautiful are the Forests of this State and how their fame has reached other countries. I have also told you how they have made you independent of other countries by sending you eternal rain and by giving a sufficient supply of timber, firewood and other produce. I have in a way tried to demonstrate that few species of trees in the Forests are worth 25 years' revenue of the State, and the remaining species of timber are worth another 25 years' revenue. In fire-wood alone you have a third 25 years' revenue. From the minor products of which I have spoken, you can obtain a fourth 25 years' revenue. Thus your Forests of which you have every reason to be proud, contain wealth to the extent of one hundred years' revenue of the State or more. Speaking of industries I spoke of fire wood, of paper materials, of extraction of teak and sandal wood oil, of tar, varnish, gums, resins, dyeing and tanning materials, fibres, arrowroot, gutta percha and other

products of tubers, leaves, flowers, fruits and seeds of various trees both as edible and medicinal substances, and the preparation of Botanical specimens. Leaving the vegetable kingdom I spoke of the combination of the vegetable and mineral kingdom such as soap and saltpetre and referred to the various metals that can be worked. Lastly I spoke of the vegetable-animal products such as honey and silk. I also indicated how rare and useful trees and shrubs can be planted with advantage and how the water power can be used."

QUARTERLY CINNAMON SALES.

London, Nov. 25.

CINNAMON.—The last quarterly auctions of the year were held yesterday with a total offering of 234 bales "worked" quill, 944 hales "unworked," 101 bags chips and quillings, and 273 hales wild bark, compared with 825 hales in August, and 1,690 hales at this period, last year.

There was a good attendance of the trade, and with satisfactory competition throughout, the bulk was cleared.

The 234 hales "worked," fine and superior, met good competition and all sold. Firsts and seconds at fully 1d per lb, average advance. Thirds at fully last sales rates, and fourths on the whole rather easier. Firsts realised 1s 6d to 1s 9d, Seconds, 1s 4d to 1s 8d; Thirds, 1s 2d to 1s 5d; and Fourth, 7d to 11½d per lb.

Of 944 bales "unworked," 803 bales were cleared, a few small lots of Firsts at 1d advance, Seconds to Fourth, irregular but fairly steady on average. Firsts at 7d to 1s, Seconds, 6d to 10d; Thirds, 5½d to 9½; and Fourth, 5d to 8½d per lb.

101 bags chips sold at 3½d for bright, and 2½d for common, and up to 9½d per lb for quillings, &c

WILD BARK.—273 bags offered but met no offers. The limit was 1d per lb. 304 packages of this rubbish was sold on 19th inst. "without reserve"—quills at ¾d to 1½d, broken quills at ¾d, and coarse bark at ¾d per lb.

STOCKS:—

Plantation	2,689 hales,	against	2,291 bales	in 1901.
Chips	.. 730 bags	"	3,154 hags	" "
Wild	.. 1,829 hales	"	2,408 bales	" "
Wild Bark &				
Chips	.. 6,426 bales	"	7,891 "	" "

The next auctions are fixed for 23rd February, 1903.

FORBES, FORBES & Co., Ltd.

THE PRICE OF COCONUT OIL.—*Appropos* the information published by us from an out-station correspondent regarding the price of coconut oil, a European merchant writes:—"Your informant is quite wrong as to a rise of 10s in coconut oil just now. I had a wire from home yesterday. The prices offering in London are lower than they have been for at least this year."

INDIAN TEA AREA AND TEA CESS.—The long letter addressed by the Secretary of the Indian Tea Association to the Finance Secretary of the Government of India, contains a good deal of interesting reading; but the statistics it affords are disappointingly old, the area in cultivation being given as at the end of June 1901. We suppose that with fields abandoned the total area in tea in India does not much exceed 500,000 acres against 380,000 to 390,000 acres in Ceylon.

NEW FOOD PLANTS IN YUCATAN.

The gardens and fields of Yucatan are filled with succulent vegetables and sweet smelling herbs unknown to the outer world. In the cultivated fields at the proper season are grown Indian corn, beans, and tubers for which we have no name, for the reason that they have been neither seen nor heard of outside Yucatan. The forests and jungles contain fruits that, excellent even in their wild state, could be made delicious by scientific care and cultivation. There are many wild fruits that offer more promising results than did the bitter wild almond, the progenitor of the peach.

The most important of the large cereals is the

MAIZE OF THE MEXICANS,

the Indian corn of the Americans, and the *xim* of the Mayas of Yucatan. Like several other vegetable products, its origin as a cultivated plant is enveloped in obscurity, the wild plant from which it was evolved not yet having been identified. Many believe that the cultivated plant had its origin somewhere between Yucatan and the tableland of Mexico. The mother plant was probably a grass and the new grain spread to all parts, each one giving it certain characteristics until the varieties grown in the north hardly seem related to those of the southern lands. The United States Consul at Progres says that Yucatan has six varieties of this grain, and the Maya Indian reverently speaks of it as the "grace of God." The long stalked, large grained class known to the natives as *xnuc nal*, is the most prominent, and has by far the greatest acreage devoted to its cultivation in Yucatan. It is planted in May, is fully matured in January, and then is left to harden and season until gathered as needed. This class most nearly resembles the Indian corn of the United States. It has both the white and yellow grains. Under the haphazard methods of the native Indians, the corn produces in the limestone soil of Yucatan from 20 to 30 bushels to the acre. Under favourable conditions this yield is often doubled. The *xmehenal* is a small, quick growing variety, and the plants are rarely 4 feet high. The natives have a saying "that the cock can pick the flowers of the true *xmehenal* without stepping off the ground." One variety matures within sixty days of its planting, and the second needs fifteen days more. The *xmehenal xtup*, planted in May, can be gathered in July, and while the production per acre does not quite reach the figures of the *xnuc nal*, it has a greater capacity of resisting the extremes of heat and dryness. The plant or rather the running vine, known as the *macal box*, produces a tuberous root of great nutritive value. Entire families have lived upon this root for weeks at a time and were healthy and apparently well nourished. This plant is very productive. About the middle of May the green shoots first appear above the earth, they grow rapidly, and in November are ready to be dug. The tuber is about the size of a large potato, and is of a purplish colour, like a certain class of sweet potato, and it can be cooked in the same way as a sweet potato. The plant is hardy. A long drought may cause the vine to wither, but with the lightest rain it springs up anew. The roots left in the ground as too small for food propagate the plant, and each year the yield increases. It seems to be a kind of native yam; it grows in almost any kind of moderate rich soil, and when

cultivated intelligently should be of some value as a food plant. The *xnucnal macal*, like the *macal box*, appears in May and is gathered in November, but it yields only one or two tubers to the plant. These however, are of large size, resembling enormous potatoes. The interior is white and seems to be nearly pure starch. The plants grow close together and the yield per acre is said to be phenomenal. *Xmehenchican* seems to be a kind of artichoke, weighing when mature about a pound. The plants are running vines, rarely more than a yard long. An acre will yield an immense crop under favourable conditions. The plant sown August, can be gathered in November. *Xnucchi-can* is a larger root, weighing when mature about three pounds. It is a hardy plant and produces well. Both of these roots are eaten, roasted or boiled, and many like them raw.—*Journal of the Society of Arts*, Sept. 26.

TRADE OF SIERRA LEONE.

RUBBER.

The following comparative statement shows the quantity and value of rubber exported from the Colony to the under-mentioned countries during 1,900 and 1901:—

	Quantity.		Value.	
	1900.	1901.	1900.	1901
	lb.	lb.	£	£
United Kingdom...	244,316	105,360	22,335	7,174
Germany	30,330	26,295	3,406	2,029
Other Countries ..	274,646	131,655	25,741	9,203

The trade in rubber has declined owing to the article getting gradually less, and higher prices being offered in the adjoining Colony of French Guinea, as well as to the wasteful method by which it was gathered. In French Guinea the price is 2s. per lb., and only the best rubber is allowed to be exported, i.e. rubber containing not more than 1 per cent of dirty matter mixed with it, whereas in Sierra Leone good quality rubber and dirty adulterated rubber are both bought by merchants at prices varying from 1s to 1s 8d. per lb.

PALM KERNELS AND PALM OIL.

In palm kernels there was a slight decrease in 1901, over 1900, although the market value remained the same. The figures were as follows:—

	Palm Kernels.		Palm Oil.	
	Tous.	£	Gallons	£
1900	21,517	171,774	128,608	7,436

There is great scope for the extension of the palm oil and kernel trade; it is the difficulty of transport which has to be overcome. Unlike rubber, which can be more easily handled, and, owing to its greater value, can better bear the disproportionate expense of the carriage by head—which is the only land transport obtainable in the greater part of the Protectorate—the palm kernel or palm oil cannot reach a shipping port from any distance in the interior before the cost of transport exceeds its value. The completion of the railway will revolutionize the trade in this product, and be the means of bringing to the port the thousands of tons of kernels that at present are allowed to rot.—*London Chamber of Commerce Journal*, Nov.

CINNAMON IN LONDON.

The last quarterly cinnamon sale for the year, held in London on 24th Nvo., may be reckoned as one of the most satisfactory sales of recent times. The quantity of quilled bark offered was 1,178 bales, which, though in excess of the offerings in August last, amounting to 825 bales, was only about two-thirds of the quantity catalogued in November, 1901. Both the limited supply and the season—for the Christmas auctions generally go off with spirit—contributed to good prices. The attendance being good and the competition lively, the higher qualities, which are “worked” in London, sold at prices which recall old times—Firsts running up to 1s 9d and Seconds to 1s 8d, while Fourths fetched as high as 11½d. The whole quantity offered was disposed of under the hammer, at an advance generally of a penny on the previous sales’ rates. The best marks have their cinnamon unbaled and rebaled in London, according to traditional custom, and at a cost which ordinary kinds object to, and are honoured with the distinction “worked”! The “unworked” cinnamon constitutes the bulk of our exports, from estates which do not turn out “smarts,” or finely quilled spice, and the 944 bales of “unworked” seem to have been worked off as satisfactorily as the more attractive sorts. We do not read that any of the “unworked” spice, which amounted to four-fifths of the total, was bought in; and the prices named show that it shared in the advance which the best sorts secured. The rates at which chips were sold were higher than they had reached for a long time; while 9½d, the top price for quillings, has been touched but seldom.

The absence of any demand for “Wild” Cinnamon, so called, does not seem to have extinguished the trade; but nothing can long survive sales at a penny a lb! How that average can possibly cover all the charges which have to be provided for, from harvesting and transport to warehousing and sale, is more than we can guess; but, pending the total extinction of the trade, we can only hope that the article does not in any way go into human consumption. No doubt it rather forms part of the condiments which are said to be used in preparing “Thorley’s food for cattle.”

The prospects of genuine spice are bright, as the submersion of low lands, on which cinnamon is mostly grown, has arrested harvesting for weeks, if not months; and with the dry and windy months in prospect, there cannot be much crop taken in till after the Sinhalese New Year in April next.

On page 480 will be found the Report from the leading London firm which we usually quote once-a-quarter.

THE FORESTS OF UGANDA.

A Government report just issued furnishes information with regard to the Mau Forest, which extends for about 33 miles along the line of the Uganda Railway. The forest contains an

abundance of hardwood timbers—“too hard” is the complaint of those who have tried to work them. The Commissioner who is reporting, nevertheless, regards the forest as a splendid property, which will not, however, be realisable for many years. One of the conditions of a successful industry are big rivers, it appears, in the Mau: Under these circumstances, residents in the chief town find it cheaper to line their houses with Norwegian timber than to use that of the local forest. The report refers to the rapidity with which eucalyptus trees grow in Uganda, specimens of eucalyptus globulus three years old having reached a height of 30 ft.—*Timber Trades Journal*

TEA IN THE UNITED STATES.

Mr Wm. Sanders, the late eminent Superintendent of Public Grounds in Washington, was sent down to Sumterville, S. C. where Commissioner LeDuc was then engaged in making an experiment with tea culture which has since had such a gratifying success under Dr Shepard. Mr Sanders gave it as his opinion that if any more Government or private attempts were made to raise tea, they should be made in a locality farther South; and furthermore he expressed the belief that Florida offers the best opportunities and conditions for success.

We do not agree with Mr Sanders in this opinion. Tea has been grown in dozens of localities in the South; from the strong rolling clay uplands of Georgia to the moist sandy low lands of Louisiana, Mississippi and Florida; and there can be no question with men of wide observation that the rolling piedmont, clay uplands of Georgia produce much the most rapid and vigorous growth; thrifter finer and better developed plants, than could be found anywhere in the low country further south and nearer the seaboard.

Mr Sanders seems to have forgotten that most of Japan and the principal tea districts of China are farther north than Florida and have a lower mean annual temperature. Tea will grow and do moderately well anywhere in Florida; but if we had to establish a tea growing plantation in this State we should select the undulating clay uplands near Tallahassee and further west and north toward Quincy.

We do not think tea culture can be made generally profitable commercially under the present existing conditions, with the present price of labour and with our very imperfect knowledge of growing and manipulation. It is only fair to state, however, that Commissioner LeDuc’s superintendent Jackson, who claimed to be an expert in tea growing and preparation, stated to a newspaper visitor, that he could make an excellent article of tea in Georgia or Florida for 15 cents a pound. We are under the impression that Dr Shepard has publicly stated that under his present system of child labour, he can produce a marketable article for about the same figure. And it is well known to our readers, doubtless, that Dr Shepard’s tea has repeatedly sold up to seventy cents a pound, averaging for round lots, forty-five cents, or better.

The tea plant belonging to the Camellia family and requires about the same treatment as outdoor japonicas. It should have a good strong soil, enriched with a compost of dried muck or peat, bone dust, and ashes. The land must be all drained

and clearly cultivated. The seed should be planted as soon as ripe in mellow drills, like peas, and the plants may be transplanted from the seed beds when about a year old.

They do not withstand the hottest suns very well, and it is a good practice to place them in a partly shaded situation for another year before finally setting them out in the plantation. Use plenty of the compost above indicated for the young plants and continue the same regularly in the field, especially after you begin to gather the leaves, as that operation is exhausting to the bushes.—*Florida Agriculturist*, Oct. 22.

THE TEA CESS.

Memo :—The subjoined letter on this question is published for general information. W. Parsons, Secretary.

No. 6652 S.-R.—Calcutta, 13th December, 1902. From—The Government of India, Finance and Commerce Department. To—The Secretary, Indian Tea Association, Calcutta.

SIR,—I am directed to acknowledge the receipt of your letter No. 1001-O, dated the 28th November, 1902, communicating the views of the Indian Tea Association, Calcutta, in connection with the proposed levy of a cess upon Indian tea.

2. In the Resolution in this Department No. 4178 S.R. dated the 1st August, 1902, it was stated that the necessary legislation for the imposition of the cess would be undertaken during the present Calcutta session of the Legislative Council of the Governor-General, provided that no weighty or widely entertained objections were received in the interval. The objections received by Government have been only three in number, and cannot be considered to be either weighty or widely entertained. The Government of India have accordingly decided to proceed with the necessary legislation somewhat on the following lines :

1 From and after the 1st April, 1903, a cess at the rate of ¼ of a pie per lb. (or such lower rate as the Governor-General in Council may, from time to time, on the recommendation of the Committee hereinafter referred to prescribe) shall be levied on all tea, the produce of India, when exported by sea to any foreign port, or when exported by land to any territory to which the provisions of section 5 of the Indian Tariff Act 1894 (VIII of 1894), have been declared to apply.

2 The proceeds of the cess, after deduction of the cost of collection, if any, shall be paid over to a Committee of twenty, which shall include (a) 3 members nominated by the Bengal Chamber of Commerce; (b) 7 members nominated by the Indian Tea Association; and (c) 10 members nominated by such local bodies or Associations interested in tea as the Government of India may, from time to time, direct.

3 The fund placed at the disposal of the Committee of twenty shall be applied by them towards pushing the sale and increasing the consumption of Indian tea in India as well as in foreign countries.

4 The accounts of the Committee shall be subject to annual audit by officers to be appointed by Government, and the auditors shall be empowered to surcharge any item which, in their opinion, has been improperly expended.

5 The cess shall be in force for five years, and may be extended for a further term if the Government, on the recommendation of the Committee, shall so direct.

6 Government shall have power to make rules for the administration of the Act.

3. With reference to the suggestion in para 7 of your letter that the Indian Tea Association Calcutta, might nominate five members to serve on

the proposed Committee, and the Indian Tea Association, London, two members, I am to say that it is not clear how an Association which is not domiciled or represented in this country can nominate representatives, or how it can claim direct representation. It is understood that the London and Calcutta Indian Tea Associations are branches of one body, and that the former has no office nor recognised representative in India. In these circumstances, the Government propose to increase the number of members to be nominated by the Indian Tea Association, Calcutta, from five to seven, so as to enable the latter to nominate members on behalf of the London Association if they so desire.

4. I am to add that it is proposed that the Bill shall be introduced by an unofficial member of the Legislative Council of the Governor-General. I have the honour to be, Sir, your most obedient servant.

E N BAKER, Offg. Secy. to the Govt. of India.

AMERICAN CAPITAL AND ENTERPRISE.
THE FORMATION OF A RUBBER COMPANY TO EXPLOIT NORTH BORNEO.

Before leaving British North Borneo, H. E. the Governor entered into an agreement with Mr Alleyne Ireland for the formation of an American Company to work gutta and rubber in this country.

The Lessee will prospect for and select with as little delay as possible such tracts of land as he shall require; and the Lessee shall enjoy for the space of two years from the date of this agreement the sole right to select and acquire tracts of rubber and gutta forest or land for the purpose of planting and cultivating rubber or gutta within the State of British North Borneo.—*British North Borneo Herald*, Nov. 17.

THE MADRAS PLANTERS' LABOUR BILL.

The Planters' Labour Bill has been the occasion of a long discussion in the Madras Legislative Council. Three native members were in opposition.

The Hon. Mr G Stokes, in introducing the Bill, said :—Here in S. India many of us, even though we are not employers of organised labour, are familiar with the demand for advances on many occasions, but we do not realise perhaps how universal that demand is. Whenever labour on a large scale has to be organised it can only be done successfully under the system of advances. We need not, therefore, be surprised at finding that the labour on plantations is universally organised on this system. It is undoubtedly a bad system, but it is so universal and so deeply seated in the habits of the labourers that it is impossible either to ignore or overthrow it. Even in the great famine of 1876-1878 I remember when it was attempted to organise and move the people from the inland Districts to the Buckingham Canal, it was necessary to make advances and the case largely illustrated the inherent evil of the system; for not much above half the labourers to whom advances were made ever turned up on the works. Special officers were sent to accompany the gangs, but notwithstanding all watchfulness they melted at every stage of

the journey. It may be taken, I think, as undoubted that the planter must make large advances and that he must and does lose much money in consequence of the fraudulent disappearance of the labourers. * * * When we remember that the labourers employed in the coffee industry were reliably estimated a few years ago at over 300,000 persons of whom two-thirds were imported labourers, *i.e.*, labourers under advances, and that a considerable number of the labourers to whom advances were made never join the estate and that many more desert, it will I think be conceded that the fraudulent disappearance of the cooly or maistry with the advance made him is an evil of great magnitude, demoralising to the labourer and crippling to the planter and one which it is the duty of the State to correct. In para. 122 and Appendix VII. of their Report, the Planters Enquiry Committee gives statistics of planters' losses which it is unnecessary to quote here in detail, but the returns show that the losses from the desertion of labourers vary from two-thirds of a rupee per acre cultivated in Madras and Coorg to Rs 25 an acre in North Mysore. These figures do not include the losses suffered by maistries or planters outside the Associations making the returns, and are, therefore, much below the mark. * * * It is not the punishment of the cooly nor the repayment of the advance that the planter wants. What is essential in the case of that industry is to get the work done for which the advance is made, whether that work be the supply of coolies by the maistry or whether it be the agricultural work of the estate. This position has been expressed by the phrase that what is wanted is specific performance. In the Bill this is to be attained in the two following ways. Following the principle of the Penal Code and Act V of 1866, the breach of contract is itself made punishable, but power is given to the Magistrate to release and make over the maistry or cooly sentenced to imprisonment to his employer with an order to complete his contract. This is a provision taken from the Labour and Emigration Act of 1901. Specific performance is also recognised in the Bill in Sections 31, 32 and 33 under which conviction and imprisonment is not to operate as a release, the labourer being compelled to return to service after his term of imprisonment, the period not only of his absence from service but also of his imprisonment being added to the term for which he has contracted to serve. The whole term which can so be added is, however, limited to nine months.

The Hon. Mr. ACWORTH in seconding the motion said:—Your Excellency,—I rise to second the motion that the Bill be read in Council. I do not propose to say much at the present moment. As this Hon'ble Council is aware, this Bill has been very long under consideration and had been referred backwards and forwards to the Government of India and the Secretary of State several times. I should, were it not for Section 3, consider the Bill on the whole a good one, but Section 3 has been received with little less than consternation in some of the planting districts. From Wynaad the Government has already received a formal protest against the Section, and from the Nilgiris and Mysore protests against this Section have reached me, and I have been urged to do all in my power either, to get this Section expunged, or so modified as to meet the requirements of those who deal largely in local

labour. Government in the notes on the clauses says:—"The object of this clause is to prevent the concurrent application of Act XIII. of 1859 and the proposed labour law to contracts for work of any kind between employers and labourers as defined in the Bill. It is, however, intended that the power which planters have of resorting to the provisions of Act XIII. of 1859 in their dealings with persons, artisans or others, who fall entirely outside the scope of the proposed law, should be preserved." Now it is obvious that under the Bill as at present constructed, the planter will have no hold on the local labourer. * * * *

The Hon. Sir GEORGE ARBUTHNOT said that he was unable to follow very accurately the statistics given by the Hon. Member who had just spoken (the Hon. Mr. K PERRAZU), but he gathered that they were to the effect generally, that the planting industry in South India was an eminently prosperous and progressive one. He could only assure him from a position of authority and from his sad experience that it was not by any means the case, and that unless every possible help was given to the planting industry, there was no doubt that there would be soon no coolies, no pruners and no planters, and that the last of the industry would be seen. * * * *

The Hon. Mr. G SIRINIVASA RAO proposed to point out what he considered defects in the various provisions of the Bill, illustrating his remarks by reference to the particular sections. He remarked in particular that the penal provisions were harsher and severer not only as against the cooly but also against the planter and maistry, than they were in Act VI. of 1901. He concluded by observing that he had pointed out the manner in which the provisions of the Bill, if passed into law as it was, would work hardship not only on the coolies but maistries and planters also. If the defects pointed out by him were not taken note of and reminded, as he had no doubt they would be in the Select-Committee, the employers who welcomed the measure now would find it affecting them immensely worse than now.

The Hon'ble Mr. ACWORTH said that he desired to make a correction in Mr. Perrazu's speech where he said that planters made coolies work for seven days in the week; but, so far from this being the case, Sunday was always a recognised holiday. The difficulty planters had was to make coolies work six days in the week. The coolies always and habitually took one day in the week extra as a holiday. This would not appear in the planters' check roll, because the coolies did not always take the extra holiday on the same day. But to say that planters made coolies work for seven days was absolutely false. He could not help thinking that Mr. Perrazu had spoken without the slightest knowledge of planters, their estates, or the conditions of the labour that planters employed on their estates.

THE PRESIDENT'S ADDRESS.

His Excellency the President said:—The origin of the Planters' Labour Bill has been fully explained, and it has been drafted after protracted consultation with the Planters' Associations, the District Officers concerned, the Judges of the High Court, the Law Officers of Government, the Governments of Mysore and Coorg and the Government of India. The object of the Bill is twofold;

to ensure good and fair treatment to the labourer, in sickness and in health, and to protect the employer from the serious losses to which he has hitherto been exposed through the dishonesty, extortion or caprice of the labourer. It has been amply demonstrated that the ordinary civil law is inadequate in the peculiar circumstances of the planting industry and that the importance of the planting industry is sufficient to justify special legislation. The Province of Assam, where the planting industry is not more important than that of Southern India, has for many years past had its own special labour laws and there are stronger reasons for similar legislation in Southern India, in that the labour here is more migratory. The total labour force in the Assam plantations is not much greater than those of Southern India, but whereas in Assam, at any rate six years ago when the Committee reported, the annual immigration only amounted to one-tenth of the numbers employed, in Southern India it amounted to no less than four-fifths. The speeches of the Hon'ble Members opposite have destroyed my hope that there would be an unanimous assent to the introduction of the Bill, but I trust that the further deliberations for which there will be ample opportunity, will prove that the provisions which have been drafted after so much consultation fully and fairly carry out the objects of the proposed legislation.

The following Select Committee was then appointed:—The Hon'ble Mr Acworth, the Hon'ble Sir George Arbuthnot, the Hon'ble Mr G Srinivasa Rao, the Hon'ble Mr J N Atkinson, the Hon'ble the Advocate-General and the Hon'ble Mr Stokes.
—*M Mail*, Dec. 16.

THE PITCHER PLANT AS A PLANT PROTECTOR.

One of the greatest enemies to orchid plants in the West Indies is *Balatta americana*—the American cockroach. Numerous are the traps devised and the poisons compounded for the destruction of this insect and yet it does not appear to decrease in numbers, and regular plans of trapping and poisoning must be adopted by the cultivator if he is to keep his orchids free from these—almost ubiquitous—enemies. There are, however, natural checks which deserve attention. First among these comes a large spider, commonly though erroneously known in Trinidad as the "Tarantula." This spider with other large species, are very bitter enemies of the cockroach and assist not a little in preserving the balance of nature. When it is mentioned that one of these creatures is large enough to capture and kill a full grown mouse—an occurrence once witnessed in the Herbarium and recorded in *Bulletin*, January, 1895—it is easily understood how the cockroach falls an easy prey to it. Poultry and the larger lizards also feed upon the cockroach. To the barn-yard fowl, it appears to be a specially delicate morsel, as is recognised by the negro proverb "When cockroach gib' dance, him no ax fowl."

We have recently observed the help given to the cultivator in the destruction of these depredators by the various species of *Nepenthes* or Pitcher plants. As they assume full development, the pitchers developed in the end of the leaves, become filled with liquid, into which the cockroach is apparently attracted and eventually drowned. The liquid (contained in the pitchers) is of a similar character to the gastric fluids of the human stomach and renders any animal matter fit for absorption by the plant, so that the cockroach is ultimately digested as plant food. The *Nepenthes* have been found to be so useful for this

purpose that they have been deemed advisable to largely increase the number of these plants among orchids, as the damage done by the cockroach has been largely decreased by their aid. The various species of *Nepenthes* thrive well in the climate of Trinidad and are grown in suspended baskets made of cedar wood in a similar manner to orchids.—*Trinidad Bulletin*, October.

PRIZE ORANGES.

We have to acknowledge the receipt of some splendidly large oranges from Mr. Holloway, Wategama. They measure up to 12 inches in circumference and 15½ ounces in weight, each. Have larger oranges been grown in Ceylon?

BRITISH CENTRAL AFRICA. THE NEW RAILWAY-TO BE.

In a recent *Illustrated London News* a plan of the Railway route to Lake Nyassa and some pictures are given. The Railway is to begin in May as soon as the rains are over. Things are looking up in Blantyre and I think there is a great future before that region. The African Lakes Co. is a great success, and Lord Overton, one of the leading men in that concern, has taken an interest in Blantyre and East Africa too.
—*Cor.*

TEA CULTURE IN SOUTH CAROLINA, UNITED STATES.

We are indebted to Mr. Charles R. Shepard, of Pinehurst, South Carolina, the pioneer of tea cultivation in North America, for a very interesting, good-humoured and even amusing letter which will be found elsewhere. We can assure Mr. Shepard of our utmost good wishes for his success in all departments of his venture, and we hope to look in upon him and his fields of tea some time during 1904 if he will permit us. We were as much astonished as interested when the Secretary to the U.S. Agricultural Department showed us his fine tea bush growing in the open air at Washington, in March 1884. No one in Ceylon we feel sure, will grudge Mr. Shepard his attainment of a maximum crop of 17,000 lb. of tea from Pinehurst at the earliest possible date. All such tea grown on American soil might well be sold at a fancy price—so many dollars a lb.—to patriotic millionaires. The yield per acre is very good—for South Carolina; but from small areas of one or two acres by careful cultivation, ordinary yields everywhere can easily be doubled. Nevertheless, there is probably no more interesting tea-growing experiment in the world at the present moment than that of Mr. Shepard at Pinehurst, South Carolina, which is now brought under the auspices of the U.S. Department of Agriculture. Ceylon planters can never wish to see such teafields extinguished, even if their maximum crop rose to 170,000 lb. or to ten times the maximum to which, apparently Mr. Shepard aspires!

AMERICAN CAPITAL IN RUBBER EXPLOITATION.

PARA RUBBER PLANTATION COY.

The Para Rubber Plantation Company has been formed for the purpose of trading in crude rubber on a large scale in Venezuela, on lines somewhat different from those any large company previously organized. The company begins with the ownership of a tract of land about eight miles wide, lying on both sides of the Casiquiare river for its whole length of 175 miles, comprising about 1400 square miles, of territory, or nearly one million acres. The Casiquiare is a stream navigable at all seasons, connecting the Orinoco with the Rio Negro, the latter which empties into the Amazon a few miles below the city of Manaos. The Negro is navigable up to the Casiquiare as also is the Orinoco, with the exception of about thirty miles obstructed by cataracts above San Fernando, in Venezuela. For the present the company's property will be reached by way of Manaos, and that city will be the basis of the company's operations. It has been suggested by that means of a narrow gauge railway around the falls shipments could be made on the Orinoco more economically than in the other direction but such railway has not yet been projected. In spite of its name, the new company is in no sense a rubber planting enterprise.

Reports made on this territory, which have led to the organization of the company, are that it contain rubber trees in abundance of more than one species of *Hevea*, and that these trees, for the most part, have not been worked. The Casiquiare river does not overflow at any time, and the region is declared to be more healthful, for this and some other reasons, than much of the country that has been explored for rubber in the Amazon valley. The population is mainly of Indians, who are more docile than in some other regions of Venezuela and in portions of Columbia where rubber workers have been attacked by the natives.

The natives of this region have developed some degree of civilization, cultivating crops for their own use, and in places have engaged in a small way in gathering rubber. There are also some Brazilian settlers who are familiar with working in rubber, and the company proposes inducing more Brazilians, particularly Cearenses experienced in working rubber to enter its employ. The Casiquiare district is less remote than some of the upper Amazon rubber fields to which the Cearenses go annually, besides which it is adapted for permanent residence, which is not true of districts which are over-flooded every year.

It is the idea of the company that, having a rich and unworked rubber district of large extent, with many resident natives who are capable of being trained to work rubber, and with advantages attractive to Brazilian rubber workers, together with a large amount of capital and facilities for maintaining company stores, it will be able during the next crop season to begin operations extensively and to ship considerable rubber at a cost which will insure profits. One advantage that the company expects to have over some that have operated in the upper Amazon districts is that piracy of rubber will be practically impossible. The Para company will be able to so control the approaches to the Casiquiare that neither goods

can be entered nor rubber sent out without the knowledge of the company's agents, and there is no other means of communication with the outside world. The Para Rubber Plantation Company was incorporated August 11th 1902, under the laws of Arizona with five million dollars capital.

Venezuela is divided into thirteen states and two territories. The Casiquiare district lies in the extreme southwestern part of the republic and bounded on the west by Columbia and on the south by Brazil. The population of the territory is estimated at about 46,000, of whom 12,000 are civilized Indians.

RUBBER FROM MOLLENDO.

Rubber from this port on the Pacific has begun to reach the New York market direct, being the product of Bolivia, and particularly of certain concessions worked by capital from the United States. There are now two such companies working on a considerable scale—the Chicago-Bolivian Rubber Co., with its headquarters in Boston, and the Andes Rubber Company, with the headquarters in Baltimore. During the past month rubber has been received at New York, shipped by each of the two companies named.—*The India Rubber World* Nov. 1.

PLANTING NOTES.

RAINFALL FOR NOVEMBER.—The rainfall for November as registered at the School of Agriculture totalled 15.66 in. as compared with 20.10, the total for the same period according to the Surveyor-General's return. This shows that nearly 4½ inches more rain fell over the Fort, than over Cinnamon Gardens about 2½ miles inland, during November.

COFFEE INDUSTRY IN MYSORE.—A Conference of planters to consider the state of the coffee industry in the Mysore Province was held at Saklasapur and Mudgere, the particular problems considered being finance, labour and certain inconveniences which they experience in the present decadent state of the industry. By the desire of the planters and by command of the Maharajah, Mr Madhava Row, Revenue Commissioner, attended the meeting, and will report on the position of the industry and the best means of its amelioration.—*Pioneer*, Dec. 19.

ANOTHER "CURE" FOR SNAKEBITES.—I reference to the cure of scorpion stings by the use of malt vinegar, a correspondent states that it very strong acetic acid is gathered from the place of the Bengal grain, which is generally and largely cultivated in the black cotton soils of the Bellarey, Anantapur, Cuddapah, and Kistna Districts. The acid is collected by means of large clean sheets being spread over the plants, and the acidulous dew formed on the plants is shaken into the sheet and absorbed. The sheet is moved over the field till sufficiently wet. It is then squeezed out in a vessel and bottled. This is carefully preserved and highly prized by the ryot as very medicinal, and is successfully administered in cases of colic, cholera, and all stings. It is much stronger than malt vinegar. It is believed that his acid, which is very clean, forms part or is wholly the mantram or holy water usually employed by the so-called mantram-people in the cure of snakebite.—*Pioneer*, Oct. 13.

TO THE PLANTING WORLD.

Seeds & Plants of Commercial Products.

Hevea Brasiliensis.—Orders being booked for the coming crop August-September delivery 1902, booking necessary before the end of April, quantities of 100,000 and over at special low rates. Plants available all the year round, 100,000 and over at special low rates. A leading Rubber planter in Sumatra, who purchased 50,000 seeds in 1899, and 100,000 in 1900, writes us, under date 15th November, 1900 :—" I received your letter of 20th October, from which I learn that you added another case of 5,000 seeds to replace the loss, &c. I am satisfied hereby, and even after this adding I am satisfied by the whole delivery of this year." Special offer, post free on application.

Castilloa Elastica.—True superior variety cultivated in Mexico, seeds from specially reserved old untapped trees. Orders booked for August-September delivery 1902, immediate booking necessary; large quantities on special terms; Plants in Wardian cases.

A foreign firm of Planters writes under date 11th October, 1901 :—" We beg to enquire whether you would procure us 100,000 Castilloa seeds, in which month we might expect them, and what would be the average price." Special offer, post free on application.

Manihot Glaziovii.—Seeds and Plants available all the year round, 100,000 and over at special low rates. A Mexican planter in sending an order for this seed wrote on the 22nd August, 1900 :—"If they arrive fresh and germinate easily I may send you larger orders, as they are for high ground where the Castilloa does not thrive."

Ficus Elastica.—Seeds available in May-June; booking necessary before the end of March; also plants.

Mimusops Globosa (Balata) wood of the tree is much sought for buildings, fruits sweet like a plum and eaten, oil from seeds, said to yield as much as 45 lbs. of dry rubber per tree per annum, the milk is drunk and when diluted with water used as cow's milk, grow from-sea-level up to 2,000 feet, orders being booked for seeds and plants, price on application.

Cinnamomum Zeylanicum (Cinnamon superior variety).—New crop of seed in April to June; booking necessary before the end of February, also plants.

Coffea Arabica, Liberian Hybrid and Maragogopie Hybrid.—New crop March-April; immediate booking necessary.

A foreign Agricultural Department writes dating 9th September, 1901 :—" Please accept our order for 175 lbs. of Tea seed and for 2,000 Coffee beans. In regard to Coffee seed I would say that this will be the first importation made by this department, and we will leave the selection of the varieties to be sent to your judgment."

OUR DESCRIPTIVE PRICE LISTS.

The following six Descriptive Price Lists are now being forwarded with Circulars and special offer of Seeds and Plants of Rubber and other Economic Products :—

1. Tropical Seeds and Plants of Commercial Products, enlarged edition for 1902.
2. Seeds and Plants of Shade, Timber, Wind-Belts, Fuel and Ornamental Trees, Trees for Road-sides, Parks, Open Spaces, Pasture Lands, Avenues, Hedges, and for planting among crops (Tea, Coffee, Cacao, Cardamoms, &c.)
3. Seeds and Plants of Tropical Fruit Trees including Mango grafts.
4. Bulbs, Tubers and Yams.
5. Orchids—Ceylon and Indian.
6. Seeds and Plants of Palms, Calamus, Pandanus, Cycads, Tree and other Ferns, Crotons,

Roses, Dracinas, Shrubs and Creepers.
Special Arrangements made with foreign Governments, Botanical and Agricultural Departments, Planters and others for supplying seeds and plants of Commercial Products in large quantities.

"SOUTH AFRICA."—The great authority on South African affairs of 25th March, 1899, says :—" An interesting Catalogue reaches us from the East. It is issued by WILLIAM BROTHERS, Tropical Seed Merchants of Henaratgoda, Ceylon, and schedules all the useful and beautiful plants which will thrive in tropical and semi-tropical regions. We fancy Messrs. Williams should do good business, for now that the great Powers have grabbed all the waste places of the earth, they must turn to and prove that they were worth the grabbing. We recommend the great Powers and Concessionaries under them to go to William Brothers."

THE CALELONIAN (CEYLON) TEA
ESTATES, LIMITED.

REPORT OF THE DIRECTORS

to be submitted at the fifth annual general meeting of shareholders on Thursday, 27th November, at noon.

The Directors beg to submit the balance sheet and profit and loss account for the year ended 30th June, 1902, duly audited.

The working account, after providing for London charges, shows a profit of £4,134 12s 5d, and the Profit and Loss Account, including the balance brought forward from the previous year, and after payment of Interest on debentures, &c., leaves an available balance of £1,998 8s 5d.

From this sum the Directors now recommended the payment of a dividend of 6 per cent on the preference shares for the year to 30th June last, amounting to £1,920, leaving to be carried forward to the next year the balance of £78 8s 5d, =£1,998 8s 5d.

The Directors regret that they are again unable to declare any dividend on the ordinary shares.

The yield of tea from the Company's estates for the past and two previous seasons was as follows:—

	1901.2.	1900.01.	1899-900.
	lb.	lb.	lb.
Lawrence and Venture	410,120	399,087	402,535
Selegama	165,379	167,378	111,415
Wavina	112,695	94,979	40,763
	638,194	661,444	554,713

The gross average prices obtained in London were:—

	1901.2.	1900.01.	1899-900.
Lawrence	6.62d	6.84d	7.40d
Venture	6.78d	7.13d	7.59d
Selegama	5.70d	5.79d	6.52d
Wavina	7.78d	5.64d	6.39d

167 cwt. of cocoa were secured from Kahawatte and 18 cwt. from Wavina, and this realised a net average of about 50s per cwt.: 4,200 seed pods were also disposed of. The previous year's crop of cocoa was only 70 cwt.

The above figures show that the total quantity of tea produced was 26,750 lb. more than the previous season's crop, and 13,194 lb. over the estimates. The improvement in the market for Ceylon tea, notified at this time last year, was not maintained, and for a large portion of the crop lower prices had to be accepted; the result of the year's working, owing to the increase in the quantity of tea and cocoa gathered, is however, practically the same as that of the previous season.

The estimates for the current season are given by the managers in Ceylon, as follows:—

	lb.	
Lawrence and Venture	400,000	Tea
Selegama	175,000	do
Wavina	110,000	do and 20 cwt. Cocoa
Kahawatte	—	175 do do
	685,000	do
	195	do do

The cocoons on Kahawatte and Wavina are coming on well and promise to be a success; the para rubber trees on the latter estate are also progressing favourably.

The amount charged to capital in the accounts now rendered, includes the cost of a new bungalow on Wavina estate, and a new set of coolie lines on Selegama.

Further capital expenditure will be necessary to provide a factory for Wavina estate, as well as additional machinery and appliances on other estates, in order to keep pace with the new and improved methods of manufacture,

In accordance with the Articles of Association, S Alfred Dent retires from the Board, and being eligible offers himself for re-election.

The Auditors, Messrs, Singleton, Fabin & Co., also offer themselves for re-election.

THE HORNSEY TEA ESTATES COM-
PANY, LIMITED.

THE SIXTH ANNUAL REPORT, 1901-1902.

DIRECTORS.—Charles A Reiss (Chairman); Hamilton A Hancock; Walter S Sichel and W S T Saunders (Managing Director in Ceylon).

SECRETARY.—Albin B Tomkins.

The Directors beg to submit to the Shareholders the Report and Audited Accounts for the year closing 30th June last.

The Crop of Tea has weighed out 168,749 lb. against last year's 176,885 lb. or a decrease of 8,136 lb of made Tea.

The cost of production has been 26.62 cents; against last year 30.84 cents, or in sterling 4½d per lb, Colombo against 5d per lb Colombo, last year.

The London sales have totalled 31,130 lb of Tea, selling at an average 7.15d per lb gross, and the balance of the crop has been sold in Colombo, and realized an average of 89.74 cents per lb. The average sale price for the whole crop has been equivalent to a London price of 7.20½d per lb gross, against last year's 7.47d per lb, or a farthing per lb less.

Although the crop has been smaller than last year's, the advantages of having a factory are very marked. The cost of production has been 3d per lb lower and the profit on the working of the estate shows an increase over last year of £236 17s 3d.

The average selling price is again lower than the previous year. This is not due to a falling off in the quality or make of the Tea, which have been quite as good as usual, but to a low and adverse market, which has kept prices down during the period under review. Prospects for the current year are hopeful; the crop showing an increase of 7,800 lb since the first of July.

The Audited Accounts herewith show that after paying fixed charges and Preference Dividend for the twelve months, there is a credit balance of £21 14s 1½d, to Profit and Loss, and this amount has been written off Preliminary Expense Account.

The Directors have decided that in future the Preference Dividends shall not be paid before the end of March and the end of September. This change is deemed advisable as the crop is not entirely sold until the later date.

The Directors desire to express their thanks to Mr W S T Saunders, and to Messrs E Benham & Co, the Colombo agents, for the attention given to the Company's business during the year.

In accordance with the Articles of Association, Mr Hamilton A Hancock retires from the Board, and, being eligible, offers himself for re-election.

The Auditors, Messrs Singleton, Fabian & Co, offer themselves for re-election.

CHARLES A REISS and WALTER S SICHEL, Directors.
ALBIN B TOMKINS, Secretary.
51, Lime Street, E.C, London, Nov. 14.

DIGALLA CEYLON TEA ESTATE COM-
PANY, LIMITED.

Report of the Directors to be submitted at the Sixth Annual Ordinary General Meeting of Shareholders to be held at 20th, Eastcheap, E.C., on Tuesday, 16th December, 1902.

The Directors are pleased to say that the working of estate during the past season has given considerably better results than the previous year, and the profits have made it possible to wipe out the loss of last year, and to pay Preference Dividends to 30th June, 1902.

The crop for the year was 250,781 lb, as against 229,217 lb, for the previous year, and the price realised was 5'88d against 5'01d in 1901-02.

The yield per acre was 415 lb, as against 382 lb the previous year.

The rate of exchange was 1/4 11-32 compared with 1/4 7-16 the previous year.

Under clause No. 24 of the Articles of Association, Mr H K Rutherford retires on this occasion from the Board, and being eligible offers himself for re-election.

The Auditors, Messrs Harper Brothers, Chartered Accountants, also retire from office, and offer themselves for re-election.

By order of the Board,
London, 6th Dec., 1902. Wm. JOHNSTON, Secy.

CEYLON AND INDIAN PLANTERS' ASSOCIATION, LIMITED.

DIRECTORS.—Charles Arthur Reiss, (Chairman) Thomas North Christie, Charles Frederick Dickinson and John Humphery.

SECRETARY.—Albin B. Tomkins.

FIFTH ANNUAL REPORT, 1901-1902.

The Directors beg to submit their Report and the Audited Accounts for the year ending 30th June last. TEA.—The total yield has been 855,816 lb, against last year's 799,739 lb of made Tea, an increase of 56,077 lb.

The average selling price has been generally lower, but cost of production has been also less, and has more than compensated for the drop in the selling price, so that profits on Tea are £722 4s more than the previous year. It is satisfactory to note that St Andrew's and the Maba Eliya Estates have both done better, and made fair profits, considering the bad time through which the industry is still passing.

The accounts show that after paying Debenture Interest, Preference Dividend, and all fixed charges, there is a balance at credit of Profit and Loss Account of £599 10s 5d. The Directors recommended that £500 be written off machinery account and the balance account of £99 10s 5d be carried forward to next year.

PLUMBAGO.—It is with some satisfaction that the Directors can report fair progress; 206 tons of the mineral have been mined and sold during the twelve months. The average sale price has been R248 or £16 11s 4d net per ton. The market for Plumbago has been more favourable, and the net profit is £1,520 18s 6d, against £1,003 6s 8d last year.

The Directors regret that the funds available are insufficient for the payment of a dividend on the Ordinary Shares. Regarding the future it seems probable that the limits of production in Indian and Ceylon Tea have been nearly reached, and with consumption slowly but ever increasing, it is possible that prices have reached the lowest level, and that some recovery may be established before the next report is issued. Prospects also for Plumbago for the current year are not unfavourable, and the mineral is being steadily mined and sent to market.

The Directors desire to record their thanks to Mr George Greig and staff in Ceylon, and also to Messrs. Skrine & Co., and the Colombo Agents for the attention given to the Company's business during the year.

By the Articles of Association, Mr Charles A Reiss retires from the Board, and being eligible, offers himself for re-election.

The Auditors, Messrs. Singleton, Fabian & Co., also offer themselves for re-election.

Directors.—Charles A Reiss and Charles F Dickinson. Secretary.—Albin B Tomkins, 51, Lime Street.

London, Nov. 21st.

ANNUAL GENERAL MEETING OF THE CEYLON FISHING CLUB.

At the annual general meeting of the Ceylon Fishing Club held at the Hill Club on Dec. 20, 1902, at 3 p.m., Mr. E M de Coucy Short presided, when there were also present Messrs G G Ross Clarke, F Dew, John Fraser, A W A Plâte, C H Bagot, and J Wickwar.

Notice calling the meeting having been read, the Chairman called on Mr. H D Elhart to read the following

ANNUAL REPORT FOR THE YEAR 1902.

The last annual report for this Club was read at the general meeting held on the 21st December, 1901, after which date one general meeting was held on the 4th February, 1902; and in accordance with a resolution to the effect that a managing Committee meeting shall be held on the last Saturday of each month. The meeting Committee met for the transaction of business nearly every month.

FINANCES.—The amount standing to the balance of the Club at the close of the year is R411.30. The outstanding debts of the Club are as follows:—£43 5s 11d. to the Earl of Denbigh's fish hatcheries and £6 13s 3d. to the Otago Acclimatisation Society for Ova supplied.

OVA.—A consignment of 20,000 brown trout ova was received from the Wyresdale Fishery early in the year, in splendid condition yielding about 12,000 fry.—Attempt was made to rear them in rearing troughs, but owing probably to over-crowding heavy mortality set in, the fry were, therefore, put out into the streams as quickly as possible, being distributed as follows:—Mr Ross Clarke's Stewpond at Nannoaya 250, Mr J Fraser's Stewpond at Nannoaya 250, Mr F H Turner's Stewpond at Nannoaya 250, Mr R Jackson's Stewpond at Sita Eliya 250, Hawa Eliya Stream 300, Batuhela 300, Hon E Rosling's Stewpond at Nannoaya 200, Horton Plains 3,750, Nuwara Eliya Stream 1,882, Maskeliya Stream 500 and Nuwara Eliya Stewponds 535.—Total, 8,467.

Two consignments each 20,000 Rainbow ova were received from the Earl of Denbigh's fish Hatcheries—both in bad condition—from the first consignment 1,548 fry were distributed as follows:—Mr Ross Clarke's Stewpond at Nannoaya 300, Buluhela Stream 100, Kandapola Stream 100, Mr J Fraser's Stewpond at Nannoaya 250, Sita Eliya Stream 200, Maskeliya Stream 500, Mr Turner for Hewaheta Stream 74 and Mr Cotton for experimental purposes 24.—Total, 1,548.

The second Rainbow consignment yielded nothing. Both consignments arrived in dried condition, and and looked hopeless from the first. The trial shipment of 5,000 Rainbow ova received from the Otago Acclimatisation Society, also arrived perfectly dry and useless. It has now been definitely ascertained that Rainbow Trout are breeding in large numbers both in the Horton Plains and Nuwara Eliya streams, and the Committee has arranged for locally-bred Rainbow fry to be put out into the tributaries of the main stream in Nuwara Eliya during the year.

OTTERS.—Twelve otters were killed during the year for which the sum of R90 was paid as reward.

CLOSE SEASON.—The close season for the year 1902-1903 was fixed as follows:—For the Central and Sabaragamuwa Provinces from 1st October, 1902, to 28th, February, 1903.—Signed, E M de Coucy Short, J Wickwar, Hon. Secy., C.F.C.

Mr. J. WICKWAR thought that the number of fish taken during the year may be added to the report submitted so as to give members an idea of what the year's fishing had been like.

Mr. JOHN FRASER, said he felt sanguine that a good many residents were not aware that the annual subscription was only R10, and as he was anxious to see the number of members of the Ceylon fishing Club largely increased, he thought

that the annual subscription of the Club could be quoted with advantage on the year's report.

The CHAIRMAN remarked that the report before the meeting was hurriedly got together. He had just returned from furlough, and had not the time to do better. The report, as submitted, was adopted and it was also resolved that the suggestions of Messrs. Fraser and Wickwar be included prior to passing for print—and circulation.

ELECTION OF GENERAL AND MANAGING COMMITTEES.

On the suggestion of the CHAIRMAN the meeting resolved that the following members of last year's General Committee be re-elected, viz.:—Messrs. C H Bagot, H G Cuff, A H Dunsmure, Thomas Farr, W F Dew, G G Ross-Clarke, W Maitland, G M Fowler, S Payne Gallway, C P Hayes, G B de Mowbray, C A Hartley, R MacLure, C Bayley, F H Turner, H V Masefield, J Fraser, R Jackson, J Wickwar and the Hon. E Rosling. Messrs. J M Purdon and Cecil de Winton having left the island on long furlough, it was unanimously thought prudent to substitute their names by electing two new members in their stead.

On the proposal of Mr. JOHN FRASER, seconded by Mr. G G ROSS-CLARKE, Mr. W F Dew was elected vice Mr. J M Purdon.

On the proposal of Mr. G G ROSS-CLARKE, seconded by Mr. JOHN FRASER, Mr. F H Turner was elected vice Mr. Cecil de Winton.

On the suggestion of Mr. C H BAGOT it was resolved that the following members of the last year's Committee be re-elected, viz.:—Messrs. J Fraser, Thomas Farr, H V Masefield, R Jackson, G H Bagot, C J Bayley, G G Ross-Clarke and the Hon. E Rosling. In this instance, too, the meeting thought it advisable to elect members in place of Messrs. Cecil de Winton and J M Purdon, whereon it was resolved that Messrs. D Lyall and North C Davidson be elected to serve on the Managing Committee in their stead.

ACCOUNTS TABLED.

The statement of the year's accounts was tabled and shewed a receipt during the year of a sum of	R3,546 45
To this was added	1,266 55
which was the amount brought forward last year, thus giving a total of	R4,813 00
Of this sum	4,401 70
had been expended during the year	411 30
which left a balance of	411 30

The CHAIRMAN said that the liabilities of the Club was £49 19s 2d which was owing by the Club for ova imported from the Earl of Denbigh's and the Otago Acclimatisation Society hatcheries. But he did think that the Club was going to pay that debt in full owing to the bad condition in which the ova had been received.

Mr J FRASER said he thought not, but as that was a matter for the Managing Committee to decide, he thought that it may be safely left in their hands—as they could depend on the Managing Committee to their utmost to make the best possible terms as would be possible, for the mutual interests of all parties.

MR. J. FRASER'S MOTION.

"That all members of the Club desirous of stocking ponds or streams with rainbow trout, considered by the Managing Committee as suitable for the purpose, be presented by the Club with 50 country-bred fish was next put by the Chairman to the meeting." Mr Fraser, in support of his motion, said

that he brought forward this resolution to encourage those distant from Nuwara Eliya and the Horton Plains to take an interest in fishing, if sub-sections were formed throughout other districts to further this scheme where there was decent water for trout. He thought it would be a sure way of inducing members to join the Club. It was now beyond doubt that rainbow trout was breeding in and about the Nuwara Eliya streams and that the bigger fish have been proved to be, swarming in the lake. He thought that rather than overcrowd streams and lake, the fish may be thinned out with advantage and distributed. He would however make no proposals as to how the fish were to be caught. He would leave that to the Managing Committee to decide.

Mr C H BAGOT said that he had had a letter from Mr Thomas Farr, dated the 16th December, bearing on this resolution, which was in a way an amendment on Mr Fraser's motion, but the substance of it was the same. He would, with the permission of the Chairman, read an extract from Mr Farr's letter. The Chairman having given his consent Mr Bagot read, an extract from letter as follows:—

"Should you be at the meeting of the C F C on the 20th instant would you mind reading this letter. Just now I am too busy to attend myself.

"With regard to Mr Fraser's motion I think 50 fish to every applicant too much; but I would give 100 where conditions were especially favourable to the well being and propagation of rainbow trout. Besides what is to prevent a man joining the Club getting his 50 fish and then ceasing to be a member. I would propose as an amendment:—"That the Ceylon Fishing Club being desirous of stocking all suitable water in the island with Rainbow Trout is prepared to receive applications through the Honorary Secretary for country-bred fish, all applicants to be members of the C F C."

Mr Fraser said that he was content to withdraw his resolution in favor of Mr Farr's amendment, as it met his views on the subject. All he was anxious about was to see the distribution of country-bred fish where they would be cared for. To interest non-fishing Club members, joining in the movement, and advancing the Fishing Club to a larger organisation than it is at present was what he wanted to see done.

The CHAIRMAN—said that as the meeting was in favour of Mr Farr's amendment, and as Mr Fraser had withdrawn his original resolution—the amendment would have to be seconded before it could be adopted.

Mr C H BAGOT—thereon seconded the amendment—which was carried. Mr C H Bagot wanted to know from the Chairman, if there had been any prosecutions and convictions during the year for poaching trout.

The CHAIRMAN said:—He thought not.

Mr C H BAGOT—and yet I know of cases in which trout have been caught and eaten by poachers.

Mr J FRASER:—Why did you not prosecute?

Mr C H BAGOT:—Oh! I came to know it a week or ten days after the fish had been eaten.

Mr D LYALL—enquired of the Chairman what the penalty fine would be if a cooly or anybody else was caught poaching trout.

The CHAIRMAN:—It will depend: if it be a cooly R5, if an European, perhaps, very much more. It would all depend on circumstances to a cooly R5 would mean his half month's pay; to an

European any sum would not be too much, as he would be able to afford it.

Mr J FRASER:—I am afraid, Mr. Chairman, your idea of what Europeans are paid up this way is rather an exaggerated one. (Laughter.)

Mr. C H BAGOT—thought R100 should be the maximum fine for anybody caught poaching.

The CHAIRMAN:—A cooly would not be able to afford that sum, a fine of R5 as I said before would mean to him his half month's pay, to an European a sum of R100 would be nothing.

Mr. G G ROSS CLARKE:—A cooly may have his friends who would get together and subscribe towards the R5 fine.

Mr. F W DEW—thought a fine of R5 inadequate as a poacher, who caught a lot of trout, would sell them for much more than R5. So small a fine would be no terror to him, and he very probably may not desist from continuing to poach trout.

The CHAIRMAN:—The fine will depend on what is proved against poacher, and he will be dealt with accordingly.

Mr. C H BAGOT.—said he had on behalf of Mr. Farr to move for the adoption of the following motion:—I would propose that a local Committee be formed for the Horton Plains consisting of members from Maskeliya, Dikoya, Dimbula, and West Haputale.

Mr. FARR supported his motion with the remarks "My reason for this is that the members I have in my mind are regular visitors to the Horton Plains, that they fish no where else, that they are too far from Nuwara Eliya to attend meetings. That in view of the different conditions with regard to the Rainbow Trout as compared with this fish in Nuwara Eliya, such as its remarkable productiveness in some places and its tendency to work up stream as well as down—what would be advisable in Nuwara Eliya might not be thought so on the Horton Plains." I would also in view of the supposed tendency of the Rainbow trout to drop down stream when they become catching—reduce the limit of takeable fish to the same as the Brown Trout.

It was resolved that in view of sufficient notice in connection with Mr Farr's proposal *re* Sub-Committee for Horton Plains not having been given that the motion be postponed for consideration at next meeting when, it is hoped, Mr Farr may be present. It was also resolved in accordance with Mr Farr's suggestion *re* amendment of Rule 11 that the required notice be given and that the matter be brought up at the next meeting.

AMENDMENT OF RULE 4.

Resolved that rule four be amended and read as follows:—

4. Fly fishing is allowed in all Club waters, but fishing with artificial spinning bait is restricted to the lakes within the notice board. Fishing with live or dead bait (worms included) or with hooks larger than No. 6 of the Redditch scale in the rivers and streams is prohibited. No restrictions are placed upon the bait to be used in the lakes.

The original rule has been added to by the insertion of the words *within the notice boards*.

The meeting adjourned at 4 p.m. after the usual vote of thanks to the Chair, proposed by Mr G G ROSS CLARKE, seconded by Mr D LYALL, had been recorded.

TEA PRODUCERS' COMBINATION.

(To the Editor of the *Home and Colonial Mail*.)

SIR,—Mr Seton is right, and this matter ought not to be brushed aside. Tea producers, though individually estimable, collectively are fools! The language may seem strong, but look at the facts.

The present price of Indian tea is even now lower than it was this time last year, notwithstanding a better statistical position and prospects far better than we have seen for years.

But for our folly we might easily be getting 2d per lb more for our produce. Think of it, £1,250,000 per annum lost!

The reasons are not far to seek, and are these:—

- (a) Buyers combine and sellers do not.
- (b) Buyers are few, and sellers are many.
- (c) A few sellers are even now making fair profits.
- (d) Sellers are jealous of each other.

The number of sellers is the main difficulty, but should not be insuperable if the fact that 2d per lb could easily be added to the present price were brought home to proprietors, shareholders and agents.

The same argument applies to the few who are still making profits, for a rise of 2d per lb. would more than double these profits.

Jealousy must always continue, but its existence need not necessarily be obstructive.

Want of concerted action and want of money are the pressing evils of the industry.

Never was there a better time to bring about concerted action, never can the effects of the want of it be better demonstrated.

Now, how can the difficulties be met? I suggest the following:—

1. Establish an Indian Tea Producers' Combination, which to be effective, must be representative of at least 75 per cent of the industry. (Ceylon should be invited to join, but Ceylon's aloofness would not necessarily hurt us, because Ceylon's supplies to U K are not nearly sufficient to satisfy the requirements of buyers, because Ceylon teas arrive all the year round and because Ceylon teas won't keep, and therefore, must be sold as they arrive.)
2. Establish type standards of all grades of each district, and appoint a valuing committee of brokers to value all the teas of the combination against these standards (each merchant's broker would watch and protect his respective interests).
3. A committee of the Producers' Combination would fix the selling price of each standard rapidly raising against the price by 2d per lb., and no teas should be sold under the fixed price after allowing for variation from the standard.
4. All teas in the Combination should be sold through one representative of the brokers, whether privately or publicly.
5. The auctions should be held in a room under our own control. (This alone would probably suffice to bring in a large proportion of those who might wish to be outside the combination.) The present system is enough to sicken one by the disorderly way the auctions are at times conducted.
6. Calcutta sales should be made on exactly the same bases.
7. All account sales of garden teas, Calcutta and London, should be charged, say, 1-12 of a penny per lb, which charge would be paid to the

Combination funds for its benefit. Estimating the Indian crop at 150 million lb, and deducting 25 per cent, for abstentions, a fund of upwards of £40,000 per annum would thus be raised, and be sufficient to make the combination strong enough financially to be respected. In years of over-production it could be utilised for compensating growers for holding back a portion of their crops, and at other times for the general benefit of the industry.

9. No extensions should be made by members of the Combination beyond, say, 5 per cent. of their existing acreage to make up for deteriorating areas.

Surely something on these lines is practicable? If not, why not? Who will move in the matter? The Tea Associations seem helpless. Will proprietors, agents and shareholders, approving generally, notify their willingness to meet and discuss it?

If sufficient support is forthcoming a meeting shall be called under the auspices of a chairman of repute.

TEA PRODUCER.

[If tea producers willing to meet to discuss the above will signify the same to us we will notify the writer (with or without disclosure of name as may be desired), and if support seems likely to be forthcoming, arrange for the meeting to be called.—ED. *Home and Colonial Mail*.]—*H and C Mail*, Dec. 5.

MOSQUITOES AND MALARIA.

THE GREAT MALARIA PROBLEM AND ITS SOLUTION.

(From "Old Colonist.")

Recently I went to hear a lecture delivered by Major Ross of the Tropical School of Medicine, Liverpool, on Mosquitoes and Malaria, thereby gathering a few "wrinkles" which, I think, is worthy of being recorded for the *Observer*. The subject is not altogether new here; for it was in Aberdeen that the final link was supplied which binds together the insect and the disease. Dr. Manson went to the Roman Campagna, got some mosquitoes to bite a malarial patient, and then despatched them to Aberdeen, where his son let them loose upon himself in his own bedroom, was bitten, and in due course developed malarial fever, discovering in his own blood the unmistakable organisms brought from Italy. Thanks to quinine, he got better of the bite—the mosquito it was that died.

Major Ross is a clever scientist, for some years a well-paid doctor in the Indian Government Service. He confesses, that as such, his duties were extremely light, and that he was glad to devote his leisure to the study of so important a problem. By means of a good map, coloured to show the chief malarial districts of the world—amongst which I note certain spots on Ceylon indicated—the lecturer proceeded to show the extent of the ravages by this dire malady, which keeps the richest portions of the world in a state of barbarism. In India, alone, he said, 5,000,000 of the people are returned as dying from the fever every year. Every year 18,000 whites and 82,000 natives were admitted to hospital, suffering from the disease, and many came in over and over again. He could not give figures for Africa. He did not even know the population; but

this he knew, that nearly all the children on the West Coast of Africa were more or less infected by fever. This he could tell by catching them wild, and examining their blood; as a matter of fact they came in hundreds, offering their blood at 1 penny per drop! and in that of nearly all the children the parasites of malaria were found. A year or two ago anything more wretched than the condition of these children could not be conceived, but already a striking improvement has been effected, and the death-rate marvellously lowered, by simply draining and filling up stagnant pools, and applying kerosine to the margins of lagoons. This chiefly in Freetown which, he sees no reason to doubt, can be made as healthy as any other tropical city, Major Ross is very severe; and justly so, I think, on Colonial Governments for their apathy and meanness in this matter of sanitation. Ever ready to subscribe liberally to imperial displays; in a matter which affects the life of many thousands of helpless subjects, they take not the remotest interest. At Lagos and Freetown there are now employed at the above-mentioned work, from 60 to 80 men with two European Superintendents, but not a sixpence has yet been obtained from Government, the whole cost being defrayed by a wealthy and generous Scotsman. Yes, my critical friend; you like to cackle about the "close-fisted Scot"; but we would like to see a little more of such generosity from the predominant partners! Major Ross now proceeded to describe his initial work undertaken in order to prove to himself the truth of Dr. Manson's theories,

THE DISSECTING OF MOSQUITOES

he, found to be a very difficult and tedious task, but he persevered for month after month, amidst many discouragements. The object was to ascertain if the parasites really existed in the blood of these insects. He continued his experiments for 2½ years examining hundreds of mosquitoes under the microscope. At length, at the close of a hard day's work, he discovered malaria germs in a new species of mosquito brought to him by an assistant. This is the *anopheles*, the female of which—as far as known, is the only species of the mosquito conveying malaria. The malaria germs pass into the stomach of the mosquito, where they develop and make their way into the blood and where they disseminate in minute thread-like forms, collecting in the glands, thence projected through the proboscis into the unlucky victims.

The Major nursed up a family of a few dozen Anophele and immediately set to work to experiment—not only on human beings, but the feathered tribe was equally susceptible from a bite of the jilt female insect. Sparrows by the score, and even crows died of malaria, after a single bite! Now an insect-bite that would kill, say, a Colombo crow would, I imagine, kill any living creature. But how is it, if crows be really so susceptible of fever, they do not get exterminated? Herein lies a 'wrinkle,' the crows sleep in trees or on the top of houses, and the anopheles only rise a few feet above the water in which they breed. The ancient Incas must have had an inkling of this, when they raised mounds 100 feet high on which to build their dwellings, and the Colombo-wallah who built an upper storey to his bungalow was wise in his generation, though what became of the poor prophet in the chamber below?

Major Ross experimented in other directions, for instance, he had freshly dug virgin soil from malarial localities placed under his bed, and there he slept without any evil ever befalling him.

Now, in days of old—indeed, up till 1894—we were taught by sage professors that the disturbing of the earth in malarial districts set free certain gases which frequently proved fatal. I was told so on arriving in Ceylon; I was told so more pointedly in crossing Panama. Now, it seems that, like the fable of the Upas tree, this superstition is for ever exploded, and for the future we must keep our eye on the mosquito. Hitherto I had been disposed to look upon it as a sort of God-send—sent to warn man that there was decaying vegetation or dangerous stagnant water near. Now the vile thing has been found out!

On one point I could not quite follow the Major. He said that malaria was always at its worst, in *wet* districts and during the *wet* monsoon—instancing Lagos with 200 inches—but the reverse is our experience in Ceylon, and in Peru. In localities where it *never* rains, the same fever is very rife. Another matter on which we require more light is: Why certain districts are worse than others? Why Kurunegala is worse than Ratnapura? Why Dumbura is worse than Ganipola?

It would, I fear, be hopeless to expect the Ceylon Government to spend anything on such an investigation; but surely the Colombo Council might do a little towards purifying the unsavoury margin of your lake; while even the impecunious Municipality of Kandy might afford a few gallons of kerosine to apply to the puddles around Bogambra.

CACAO AND ITS ENEMIES.

(From a planter.)

Thanks many for the Hamel-Smith circular *re* Cacao-tree scrubbing brushes. I will certainly give them a trial and order a dozen to start with, but it is a pity he has not sent you out a sample. [We have one brush to show in *Observer* Office.—ED. T.A.] I believe in keeping bark as clean as possible though it is just possible some insects may be our *friends* in destroying other pests, etc?

Cacao has had a soaking this year, but this glorious sunshine will do a world of good to trees, beast and man. Mosquitoes are holding high revels and growing to the size of winged leeches, luckily they don't carry lanterns like glow-flies.

COCOA BUTTER.

SOME AMERICAN REPORTS FROM THE NETHERLANDS AND FRANCE.

So many of our readers are interested in cocoa butter that we reproduce in part two American Consular Reports on the subject, made at the instance of a New York firm.

U S Consul-General S Listoe, of Rotterdam, says:—

Cocoa butter is a by-product of the manufacture of cocoa powder. It is derived from cocoa beans by the following process of manufacture: The beans are roasted, separated from the husks and ground; the fluid cocoa, obtained by grinding, is placed in steam-heated hydraulic presses, which brings it under a pressure of 60,000 kilograms (about 132,000 pounds) by 75 atmospheres, and about 30 kilograms (66 pounds) of butter is pressed out of 100 kilograms (220 pounds)

of fluid cocoa. The butter flows off in liquid form, and is caught in moulds, where it is given time to cool and harden.

There are no firms engaged exclusively in the manufacture of cocoa butter; the manufacturers producing the largest quantities of cocoa powder are also the largest producers of cocoa butter.

In 1901, of 1,081 tons of Dutch cocoa butter were sold in the auction sales at Amsterdam.

On January 1 last the average market price of cocoa butter was 0.69 florin (27.6 cents) per one-half kilogram (1.1 pounds), and on July 1 last the articles were sold at 0.74½ florin (29.7 cents) per one-half kilogram.

Cocoa butter is used principally by confectioners, but also to a limited extent by pharmacists and in the manufacture of fine fancy soaps.

Mr F D Hill, U S Consul at Amsterdam, says:—

The bulk of the cocoa butter is disposed of at monthly public sales held at Amsterdam. The sales are made on customary "fall-of-the-hammer" conditions, and without commission to the second highest bidder. The cocoa butter is packed in bales of eight cakes, each cake being separately wrapped in strong paper.

COPRA PRODUCTS AT MARSEILLES,

The U S Consul-General at Marseilles says:—

The manufacture of copra oil is nowhere so extensively carried on as at Marseilles. From 55,000 to 65,000 tons are made annually by the following concerns, principally:

Rocca, Tassy and de Roux, 22 rue Montgrand.

Magnan Freres, 14 Allee de Meilhan.

Charles Diemer et Cie, 1 rue Picpus.

Fritsch et Cie, 7 Place Estrangin Pastre.

The effort to extract an edible grease from an oil produced upon so vast a scale and formerly available only for the manufacture of soap, gave promise of valuable returns if successful; and that this promise was not delusive may be judged from the circumstance that the factory of Rocca, Tassy and de Roux, which produced 25 tons of butter per month in 1900, now turns out 600 tons per month. I imagine that the success of Messrs. Maguan Freres has also been considerable.

The butter of Messrs Rocca, Tassy and de Roux is styled "vegetaline" and "cocoaline," the greater demand being for the former. The first-named melts at 26° C, and the latter at 31° C, being by that fact better suited for warm climates. Messrs Magnan Freres sell their product as "cocose." The best export markets at present seem to be Holland, England, Norway and Sweden, and Denmark. It is offered for sale in tins, and is almost tasteless.

Just how these imitation butters are made is a matter of violent curiosity in Marseilles, where the story goes that

£12,000 HAS BEEN OFFERED FOR THE SECRET. I have not been able to obtain it upon demand. It appears that expensive machinery is required.

The oil having by nature much the consistency of genuine butter, the main problem has been to bleach it, to remove the principles which cause rancidity; and to increase the point of fusion. The bleaching operation is doubtless accomplished by the free use of fuller's earth, which, being beaten in the oil, absorbs the colouring matter and is then precipitated and removed. What next occurs is difficult to say; certainly, a chemical process is employed. English manufacturers have lately learned something of the bleaching method as in use here, and are employing in it.

Present prices of copra products f o b Marseilles, per 100 kilograms (220 pounds), are now quoted:—

	Francs.	
Vegetaline	89.00
Cocose	87.00
Cochin neutre	77.00
Cochin neige	74.00
Ceylon quality	71.50
Ordinary soap	70.00

The above prices for oil in barrels, of Marseilles make, are for September and October delivery. —*Commercial Intelligence.*

PADDY CULTIVATION IN THE STRAITS. USE OF MACHINERY ADVOCATED.

(To the Editor *S. F. Press.*)

DEAR SIR,—I see that upon two or three occasions you have drawn attention to the advisability of cultivating paddy more extensively in the Peninsula and am therefore induced to make a few remarks upon the subject. In a country where the natural conditions are favourable for the cultivation of rice and where the amount produced is only an infinitesimal portion of that which is consumed, it is a matter of surprise that the subject has not been taken up more energetically. I see a suggestion has been made that Malays should be compelled to plant, which no doubt will be an excellent thing for the Malays, but a measure that will not make the country less dependent (or hardly so upon outside sources of supply) as long as they employ the primitive methods that have hitherto been in use. I have cultivated 'dry' or 'upland' paddy now for two years as a 'catcherops' and have had to make use of their primitive methods, my land being planted up with permanent crops such as rubber and coconuts. By using this system and employing day labourers in opening up land for paddy solely, I feel convinced that there would be no margin for profit. This being the case there is little inducement for capitalists to take the matter up without which nothing very much can be accomplished. I venture to suggest that the solution lies in the employment of machinery from the ploughing of the land and through the various stages until the rice is graded and bagged. It is being done in America and in Queensland to a limited extent, and surely the same methods could be applied here. A study of the American system would undoubtedly be of great benefit to those interested in pushing the culture of rice here. Unless some such measures are taken in hand this country will never be anything like self-supporting in this respect such as you, Sir, have suggested would be advisable. —I remain, Dear Sir, yours faithfully,

FRANCIS PEARS.

Lanadrow Estate, Muar, Dec. 13.

—*Singapore Free Press, Dec. 17.*

"SOLUBLE TEA."

We direct attention to Mr. John Rogers' notes (see page 495) on this subject—one that he has made peculiarly his own by a long course of study and experiment. The result has been talked of for some time, and has met with the approval of experts, as a thoroughly sound, wholesome and pure tea. All Ceylon producers are therefore specially interested in the success of the article, more especially when it is in demand for countries which have as yet taken little of our ordinary product in chest; and for purposes—such as for the use of travellers explorers, navigators—where bulk is a consideration. We certainly think the promoters of "Soluble Tea" deserve countenance and aid (if required) from the "Thirty Committee"; while they should make a special exhibit of their development at the St. Louis Exposition for the benefit of the American people.

ON "SOLUBLE" TEA. SOME IRRESPONSIBLE NOTES.

The "Soluble" tea is the very latest and most successful development in the art of producing a thoroughly sound and wholesome, and absolutely pure tea. But, although, the "Soluble" tea is still in its infancy, and will not for some weeks yet be introduced to the public, the idea is very old indeed, and probably has been entertained by many clever people, ever since tea began to be the popular beverage it now is, and an article of daily use. Much ingenuity and large sums of money have been wasted on innumerable attempts to produce a pure extract of tea, which would retain the aroma, flavour, and invigorating properties of the cup that cheers. These attempts mostly failed from their being made with the prepared leaf, or ordinary made tea, and from the fact that the aromatic and finer principles of tea are largely due to an essential oil which, immediately heat is applied, becomes more volatile than steam, and is, therefore, most liable to be lost in any of the well-known ordinary processes of producing extracts. Tea is naturally of so delicate a character that it will not stand such treatment as many of the so-called essences undergo. Some ten years ago, it occurred to the writer that it would be an easy thing to extract the juice from the tea leaf in its green state, and evaporate it down to dryness, and so produce a pure soluble tea. But all such attempts completely failed, and the writer not being a chemist, or at all a scientific person, could not make out why these simple attempts did not succeed, and why it would not come out right. He consulted scientific folk and chemists of standing, but was invariably told, that though it would of course be quite possible for them to produce a pure extract of tea, securing all the fine aroma and flavour of the popular cup at its best (I never yet met a scientist who would admit anything as quite impossible to him) yet it could not be so done as to pay the cost of production. It was not until the writer met with the book by

MR. KELWAY BAMBER,

the well-known authority on the Chemistry of Tea, that he began to think that he was on the right tack at last. When Mr Kelway Bamber was induced to take up the idea, and to advise, and help to work out experiments in London and afterwards, when the writer came to Ceylon for the purpose, then progress became apparent. But it was years before the present very successful results were arrived at and not till after many most disheartening disappointments and failures with chemicals or chemical processes had been experienced. A truly lovely cup of tea was soon produced in "Soluble" tea form, but alas! the extract never would "keep" for any time. Chemicals were at last entirely discarded, much to the delight of the non-scientific operator in these experiments, and the present purely mechanical or automatic process was ultimately arrived at. Referring to our note-book, I find the first entirely successful experiment, on the present lines, was made on 31st May, 1900, and there is a marginal note saying that news had just come of Mr Kruger's flight, and of the immediate entry into Pretoria of the British troops—and a hope is expressed that this may prove a lucky day all round, and for us in particular in our work. It was indeed. The process of that

day has never been materially altered since, and the samples of "Soluble" tea then made, after being kept over two years, have been pronounced excellent by all sorts and conditions including even such experts as old ladies and professional tea-tasters, and in many different countries of the world. Of course there have been exceptions. The writer heard of one competent tea-taster some time ago, who pronounced against "Soluble" tea, being under the very erroneous impression that it was made from tea dust and factory sweepings, or (as he said) "rubbish." When he was informed that it was and could only be made from the

BEST GREEN TEA LEAVES,

freshly plucked from the bush, he tasted the tea and altered his opinion entirely. Again the other day, the writer had been tasting some samples of "Soluble" tea in a Colombo office, with some well-known tea-tasters, and it was found very good.

The advantages we claim for our invention will many of them be at once apparent, but, perhaps, some of the most important may not be so soon or so easily recognised. The portability and convenience in use of the "Soluble" tea will naturally be recognised by all and will commend it for use by Armies and Navies, and for expeditions of all kinds, and to Colonists, and all people who live in out-of-the-way places, or where transport is difficult, to travellers, and to the man in a hurry. It is not anticipated that "Soluble" tea will at all displace ordinary leaf tea in general use—but where leaf tea cannot be conveniently obtained, or easily infused, then "Soluble" tea, which requires no infusion, but only the mere addition of water, of any temperature desired, to a very small quantity of the powder will often be resorted to. The "Soluble" tea would no doubt have been a boon to our soldiers in South Africa as has been said by members of the Ceylon Contingent who have seen and tasted it, as a man could easily have carried in his belt enough to make two or three hundred cups of tea. Here I may mention that one of the Dutch Doctors, who was a prisoner here lately told the writer that he believed the use of this "Soluble" tea in the water by our soldiers in South Africa might have prevented, in some measure at least, the enteric which was so prevalent. This is an important point, which has, however, yet to be proved.

In Australia and other Colonies, where distances are often very long, and where in many cases, it may be a matter of some trouble and expense to transport so bulky an article as a large chest of tea, it is probable that the carriage of a few pounds of "Soluble" tea which will give an equal quantity of infusion, or as many cups of tea, may be preferred, and tea thus become a more common beverage than it is now in such localities.

But beside its advantages in portability and convenience in use, the writer holds that "Soluble" tea is absolutely the purest and most wholesome form of tea that can possibly be used. That all teas are not absolutely pure and wholesome may be perhaps, admitted, but that the British Planter is—or, rather, let us say that British-grown teas are—like Caesar's wife is, of course, everywhere allowed, and the writer (as one of the Pioneers of the Tea industry in Ceylon) would be the last to cast any shadow of doubt on such an opinion. It goes then, without saying, that Ceylon and Indian teas

are as absolutely pure and unadulterated as it is possible for leaf tea to be. But I think a little consideration will show, that by a process, in which the leaf, or the fibre or woody part is wholly eliminated, and no insoluble matter can possibly remain, the absolute purity of the extract must be still further assured. It is true also that there are teas and teas, and that some, it has been darkly hinted even of British-grown teas, are not —well, not quite so nectar like as others; and there have been more than hints of some mysterious and terribly baneful stuff called tannin being present in an injurious excess in some of the commoner or lower-priced teas. Tannin was an easy word to pronounce, and yet had a learned sort of flavour about it which made it quickly catch on with the public; so poor tannin was blamed for all the bitterness and any bad flavour found in tea, and for any bad effects on digestive organs caused by excess in tea-drinking.

Here the writer would beg his readers to remember, that he does not wish to, nor has he the slightest claim to pose as a Scientist or Chemist, except in the smallest degree, and he admits that the views given in these notes are solely his own unsupported theories and based on his own personal but unlearned observation. He regrets that the undoubted and acknowledged authority of his co-patented is not available at this juncture, when these notes on our invention have been called for. Years ago, the writer made a special study of the tea leaf at home, in connection with another matter altogether, having the advantage of a considerable quantity of green tea leaves from small plants growing in pots at the time in a nursery near London. It is an old story now, but may be repeated, that a pound of tea was made from leaf plucked from these plants, probably the

FIRST AND ONLY POUND OF TEA

ever made from leaf grown in England, and probably also the most valuable, as something over three guineas an ounce was refused for it, the London tea packet firm to whom it belonged preferring to present it to Her late Majesty, who was graciously pleased to accept it, the firm no doubt thus making a very paying advertisement out of it. The writer at that time came to the conclusion that the extreme bitterness sometimes complained of in tea, is not altogether due to the much abused tannin, but in great measure to what Mr Kelway Bamber calls in his book on the "Chemistry of Tea" bitter or fatty acids, and that these are simply the juices contained in certain parts of the leaf which have not been reached in the several processes of manufacture, such as rolling, fermenting and drying. The juices in such portions of the leaf would naturally become rancid and bitter in the extreme, and would take longer to extract in infusion than the tannin in the properly prepared parts of the leaf. No one complains of excessive bitterness until the tea has infused a long time, and, I think, it is an admitted fact that the great bulk of the tannin, extracted by ordinary infusion in a tea pot, comes out in from five to seven minutes. The complaints about tannin are of comparatively recent date, and the writer believes the presence of green, or raw, or uncured parts of the leaf, containing these bitter rancid acids, might be traced back to the same period, and for this reason. In the early pioneer days, in Ceylon at least, and before the introduction of all the ela-

borate machinery now in use, so much more time was spent, especially in firing or drying the leaf over chulahs, or in machines without any artificial draught apparatus, and so much more care taken in plucking and in manufacture, that it was practically impossible that any leaves or parts of leaves could escape being perfectly cured. I do not mean to insinuate that the present day Tea-maker does not take as much care and personal interest in his work as his predecessor of twenty or more years ago. It would be untrue and absurd in the extreme to say anything of the kind in reference to either Tea-makers or Superintendents, but in those early days,

THE TEA-MAKER

had only a very small quantity of leaf to deal with, and that small lot, he had more thoroughly under his own control. With the present enormous quantities being made, and, in many cases at least, the larger leaf being plucked, and the remarkable developments in tea machinery, it is a very different story now. It appears to me that the attention of inventors in Tea machinery has been directed almost solely to the cheapening of manufacture, by inventing machines to turn out the greatest possible quantity in the shortest possible time, and that more attention ought to have been paid to retaining the fine flavour and aroma, and generally to keeping up the fine quality of the tea. For example, I do not think that the use of the powerful fans in drying or firing tea has been an unmixed blessing, but that this powerful drawing off of the steam or moisture from the wet rolled leaf, immediately a strong heat has been applied to it, must draw off much of the delicate aroma contained in the very volatile essential oils. Some years ago, on a former visit to Ceylon, the writer ventured to express these views, which he has never yet seen contradicted or proved to be erroneous. In any case I think those of us, who remember the small quantity of teas made twenty years ago, will agree that they were of much finer quality than the enormously greater quantity of teas now being put on the market. (By the way they fetched a trifle of something like a shilling more than the present average.) The young expert in tea of the present day will not admit this, but then it is probable that about the time I refer to, he spent more of his valuable time in absorbing milk without tea, than in tasting teas without milk. I hope, I shall not get into trouble over these remarks if they ever do see the light.

What I wish to claim in regard to "Soluble" tea is, that no such injurious results as may arise, or are said to arise from drinking an imperfect or too hurriedly manufactured leaf tea can possibly obtain in the use of "Soluble" tea from which all the insoluble part of the leaf or insoluble matter of any kind has been eliminated. As to the much abused tannin, I suppose most people know now that without tannin, tea would not be drinkable. In "Soluble" tea, though there is undoubtedly weight for weight, more tannin than there is in leaf tea, yet it may be taken for granted that owing to the smallness of the quantity required for a cup, each cup of "Soluble" tea must contain

LESS TANNIN

than a cup of ordinary leaf tea, but from what I have said, it may be gathered, that for my

dart, I do not lay much stress on that fact. Complaints are constantly being heard of good leaf teas being spoiled in the making or infusion. The water has not been at the exact boiling point when put on the leaf, or has been allowed to stand half-a-minute too long, or half-a-moment too short a time on the tea leaves. For "Soluble" tea, water of any desired temperature will do, and it may be claimed, that it is impossible to spoil it in the making. At least the writer would have confidently claimed this for it, until the other day, when he happened to meet some business gentlemen in a Colombo office. They had just been tasting some "Soluble" tea, and were remarkably unanimous in abusing it. What was wrong? It was far too strong! It turned out that they had put into one cup enough to make ten cups. When the proper quantity was put in, it was pronounced all right. The writer was rather depressed when relating this experience to an upcountry friend, saying how could one calculate on, or think of guarding against such an instance, say, of idiosyncrasy as that? But his friend assured him that he "need not worry about that," adding, "You really must not gauge the intelligence of the general public by what you may see or hear in a Colombo office." To the ordinary man, it would naturally occur to add more water if the tea is too strong, or to put less stuff in next time. The "Soluble" tea will, no doubt, have many detractors, especially amongst those who regret most that they are not themselves directly interested in its success, or by a few foolish persons in the trade who may fear that their interests may suffer by it in some way. But all new enterprises have to contend against, and profit by such opposition. The writer is old enough to remember the dismal forebodings and adverse opinions very confidently expressed as to the future of extract of meat, when first introduced by Baron Liebig, and later as to condensed milk. Liebig's was not nice in appearance—it was nasty to handle—one could not tell exactly how much to use at a time, once the bottle was opened, the stuff would not keep good any time, and lastly it did not taste like beef. Yet we all know how such extracts have become essentials now, and I never heard of any farmer, cattle breeder or butcher being ruined by the introduction of "Liebig." Everyone knows that nothing will "keep" in Ceylon, when once exposed to the exceptionally humid atmosphere. The "Soluble" tea like all such extracts in powder form, must be hygroscopic, absorbing moisture even more readily than leaf tea, and in such a moist climate as this must be kept in its air-tight bottle or packet, and the powder must not be exposed to the air longer than is necessary in its use. The general public are, however, now well accustomed to such articles, and know to keep the

BOTTLE WELL CORKED

when not in use, and yet I have been told that some people have spread it on paper and laid it out on a table to dry? or have put it on a chair, and sat on it to compress it?—the result in this latter case was disastrous to the seat of the chair—or have emptied some out of the air-tight bottle into the waist-coat pocket, with like unfortunate results to the waist-coat. But my upcountry friend again consoles me. He says only very clever people do that kind of thing, and that there are not many such very clever people in the world. That the common or garden duffer will do just as

he is told on the label, put a little into a cup, pour on water and make a drink of it, and that is exactly what the "Soluble" tea is meant for. As has been said, "Soluble" tea will never displace ordinary tea in general use, it is ridiculous to suppose it will; but there is already evidence, that it is likely to open up new markets for itself, and to introduce the use of tea amongst people, and other places where tea has hitherto been an unknown quantity, and if the taste for tea is thus created, is it unreasonable to suppose, that it may lead to a demand for ordinary leaf tea in such localities. I shall not, therefore, be surprised to hear soon that that Friend-in-Need, "The Thirty Committee," has come forward and offered some of their spare cash for advertising purposes to the "Soluble" Tea Syndicate Limited, or that the Government have voted a special little grant to these public benefactors, in the interests of the Tea Industry of Ceylon. J R.

Dec. 18.

P.S.—The writer has just been informed that orders for trial lots have already been received from some most unlikely quarters by the Secretarie and Agents of the "Soluble" Tea Syndicate, Colombo, Ceylon.

TEA PLANTING INTERESTS:

THE NORMAL VALUE OF THE BRITISH
TEA INDUSTRY: THE CAUSES OF
DEPRECIATION: OVER CAPITALI-
SATION CONTESTED: THE
QUESTION OF ORIGINAL
COST: A NEED FOR
ORGANIZED CO-
OPERATION;
BY SUUM CUIQUE.

There appears to be in some quarters a general impression that the British tea industry, as a public investment, is over-capitalised. Doubtless there are companies which are in that position; but to equalise these there are many others which have for years put by large reserves, so as to fully compensate the industry generally for any loss it may have sustained from those whose capital exceeds their normal value. Many of the former seem to have just hit upon the locality where, from some hidden cause, specially fine teas can be produced; and these have naturally appreciated in value; while many of the latter have depreciated from just the opposite cause.

The chief reason for the present position of the industry arises from (1) a slight over-production which, I believe, never exceeded 5 per cent. of the requirements of the market—or, say, about a *fortnight's requirements*, (2) made more apparent by the combined action of the large buyers; (3) but chiefly what a leading Tea Company Chairman described as "a want of cohesion among producers." One point I believe all will agree in, that the industry could not be reproduced upon a capital materially below its present nominal value, and to establish this I will submit the best evidence at my disposal.

In Mr George Seton's interesting table on the "Results of the Working of 45 Indian Tea Companies" for the year 1901, he shows that the entire return on the nine millions odd sterling, invested in these 45 representative companies, averages only 3½ per cent. These figures, low as they are, make no allowance for depreciation in any form whatever, being simply profits as shown,

without any provision for wear and tear. To arrive at some practical purpose let us divide these 45 companies into two; *i.e.*, that proportion which pays over 5½ per cent or its capital, and that proportion which pays less than 5½ per cent. I have chosen 5½ per cent, as I look upon it as the mean average rate upon which loans can be obtained on fair tea property, either on mortgage, or in the form of debentures. Consequently, before any profit to the ordinary shareholder can be paid interest upon debentures and mortgages, and any intervening preference share dividend, has to be covered. From this table I gather that 15 of these companies paid 5½ per cent. and over and 30 companies paid less than 5½ per cent. Furthermore that these 30 companies, of themselves, only aggregate a total profit on their capital of 2.17 per cent. and this, too, without any allowance being previously deducted for depreciation of buildings, or machinery, or, in fact, in any manner whatever. The proportions in acreage, actually work out as follows:—

15 Companies	55,104 acres	29 per cent.
30 do	132,311 do	71 do
45 do	187,415 do	100 do

It will thus be seen, that a little more than 2 to 1 represents the larger part; but I shall adhere to one-third and two-thirds, as the simplest form of investigation, and quite near enough for general purposes.

SEVENTY-ONE PER CENT OF THE INDUSTRY WORKED AT A LOSS.

I notice the average price obtained for produce per pound in the London market from these 45 companies is 7.61d, which is slightly higher than the average for all teas from India during 1901; while in Ceylon, although teas on the whole obtain a lower price, they also entail a lower average cost of production. Thus all considered, this carefully arranged table may be taken to represent approximately a section in every detail of the British tea industry generally. The only disparity that might arise being in the slight difference of average cost of production between India and Ceylon, which is practically equalised by the slightly lower price obtained for Ceylon teas. Thus all things considered, the analogy is a fair one, and if it errs it is slightly on the side of a more favourable result for the 45 companies. It may, therefore, I think, be concluded that under present conditions, one-third of the British tea industry is paying its owners over, and two-thirds are paying under, the borrowing rate of capital. Now, if this order were reversed, so that two-thirds paid over the borrowing rate, and one-third only 2.17 per cent, I could almost understand the wisdom of leaving it to the so-called laws of self-adjustment. But here we have actually 71 per cent, of the entire industry being worked at a loss, without any apparent reasonable and combined effort being made for its redemption.

ORIGINAL COST, APPRECIATION AND DEPRECIATION.

Putting down the total extent of the Indian and Ceylon tea gardens at 900,000 acres, which is slightly under the computed area, and costing in the aggregate £40 an acre to bring into full bearing including land purchase, buildings, machinery, communications with interest on money until productive, we have a total cost of £36,000,000. In reckoning £40 an acre as the cost

of bringing tea-land into bearing in India and Ceylon, I do not imply that that its value has remained at £40; for some has become more valuable and some has depreciated; what I mean is that everything fairly considered, from Darjeeling to Ceylon, and where work is rightly completed, that the figures I state will be fairly close. One certain fact is evident, the more land planted with tea just now, the less the value of the whole industry; or expressed in other words, every extra acre opened now means something taken from, rather than added to the general value of the whole, as indeed may be reckoned any unnecessarily excessive production, no matter how small. The cost of the industry may be understood better in the following tables:—

ITS COST AS DESCRIBED ABOVE.

300,000 acres paying over 9 per cent, costing	£40 per acre, £12,000,000
600,000 acres paying 2.17 per cent, costing	£40 per acre, £24,000,000
900,000 acres averaging 3.50 per cent, profit costing £40 per acre, £36,000,000	

COST BETTER ANALYSED AS FOLLOWS:—

300,000 acres paying satisfactorily,	cost £12,000,000	
600,000	{ exhausted in paying interest	
	{ at 5½ per cent	cost £9,000,000
	{ chiefly ordinary shares absolutely unprofitable	cost £15,000,000

900,000	£36,000,000
---------	-------------

Thus far I have dealt with cost. It will be well now to consider how far this original cost has altered under the fair and legitimate, or, unbiassed process of supply and demand.

AN APPROXIMATE NORMAL VALUE.

300,000 acres at £60 the acre	£18,000,000
550,000 "	£31 "
50,000 "	£20 "
	£1,000,000

900,000 "	£40 "	£36,000,000
-----------	-------	-------------

Some explanation may be necessary in arriving at these figures: why one third is valued at sixty pounds the acre and nearly two-thirds at no more than thirty-one. My reason is that the smaller proportion pays over 9 per cent on invested capital, and the larger only at present 2.17 per cent; but I cannot believe otherwise than if the same premeditated care were exercised by the sellers, that the buyers exercise in buying, and which sooner or later they will have to adopt whether they like it or not, that this great disparity could not exist. For apart from all other causes, if a body of labourers, retailers or wholesale dealers, part with what they put into the market at less than its costs, or what I may denote as "a living wage," not only is much needless suffering entailed, but in nine cases out of ten it is nobody's fault but their own. On the other hand, £31 an acre may appear relatively high, compared with what pays 9 per cent.; but we must remember it is the bulk of the industry which has during the last three months been suffering from an over-supply, of, at most, possibly 2 to 3 per cent. on the actual yearly requirements of the market—say, 11 days' consumption. A quantity, far beneath the increase that may any year arise from a favourable flushing season, and probably less than a fourth of what would follow a reversion to the grade of plucking adopted, practically everywhere, up to two years ago. The final 50,000 acres, valued at £20 an acre, is relatively, probably for its worth, the highest valuation of the whole; yet its total value

does not amount to what the industry has lost yearly since 1899. Most of it pays altogether little more than commission on sales, freights, and insurances, and beyond this will I never believe be quite satisfactory. Doubtless some acres of similar land have already been abandoned during recent bad times; and, doubtless, if our present system continues, this too will be eventually eliminated at a cost to us of many times its worth.

What precedes this, surely shows that the industry is not over capitalised. That in the aggregate it has cost its owners fully what it represents in paid-up capital. That the depreciation of its 71 per cent, is met by the improved value of its 29 per cent; also that the larger proportion could not with full modern machinery buildings, etc., be opened at £31 the acre. I also think that it is satisfactorily shown that we are suffering from a small over-supply, which hitherto we have not had the courage to rightly face. The actual depreciation, beyond what I call the normal value of tea properly, and from which we are suffering, must for the present represent some £15,000,000 sterling; and judging from what we see done elsewhere is quite capable of more permanent re-establishment.

THE EVER-RECURRING WANT OF ORGANIZED CO-OPERATION.

So far in this paper my chief aim and object has been to show where the unprofitable portion of the industry comes in. It will be seen that it is represented by two-thirds of the total tea area, so practically incorporating all the medium and common teas. I think it may be assumed that the owners of the one-third with its 9 per cent profit are quite satisfied with their position, but how about the owners of the medium and common teas? If the former average 9s, it may surely be assumed that the latter are worth, relatively, 8s. and 7d. instead of something less than 7d. all round. Now, is there no way of coming together over these two-thirds of the industry? Even though the efforts have hitherto failed over the whole, cannot a more successful attempt be made by the guardians of the two-thirds? To show how utterly we are beating the air to no purpose, let me bring forward two extracts from sale reports, in which I need hardly add that the italics are mine:—

"A decided firmness was noticeable in the earlier part of the week, and became gradually more pronounced, finally resulting in a round decline in price *many large buyers keeping almost entirely out of the market.* Happily the auctions of both Indian and Ceylon teas, so far advertised for next week, are comparatively light, and may thus tend to relieve the position, *but unless supplies are brought forward moderately* the depression may continue *in spite of the improved statistical position, etc.*

"The average of all Indian and Ceylon tea sold for the month of October is a *1d. per lb. under last season's corresponding month, and is not justified by either the position or quality.*"

There is a very little originality in these reports. The same has been the "shibboleth" for the past three years with one exception, "the improved statistical position now"; and yet, notwithstanding this improvement, teas are 1d. lower than a year ago. In other words, as statistics in prove, so far prices are worse. Doubtless, there may be a special reason for this, but we want consistent prices, consistent with the conditions of the market, not these con-

tinual suggestions for improvement, or, at least some really practical method of meeting this ever recurring difficulty.

Sooner or later, but how much sooner or later, in spite of strenuous efforts to keep a low level of prices, the market will make some natural adjustment, though not to the permanent degree we require. So long as the larger buyers can, as these sale reports tell us, withdraw their buyers if prices do not please them; and so long as they act collectively, and we individually, they will have the advantage. So long as they can appoint one man each, to represent several buyers, reducing buying to a system, and when if a few hundred chests more happen to be put up than immediate wants require; I do not see prospectively, nor do those sale reports help me to see; how the tea industry can assume a permanently right position. They are useful in their way, but they lack the method of an unmolested supply and demand market, which ours has long ceased to be. Still the same difficulty is before us. The first buyer and first seller are unequally placed, and any position short of absolute inadequate supply, will be in favour of the first buyer. Such would, if prices reached too high a range, entail an inrush of cheap and common teas; and with them inferior Chinas would reassume a position. Surely stopping short of this is our right course. If steadily and firmly, during the past three years, an effort in London had been maintained by holding steadily three weeks extra supplies in our own hands throughout, the market I believe would have been steadied and our chief losses avoided. With a strong lead from the heads in London all the markets would be strengthened, and restriction of output abroad would have a chance of possibility. Weakness in the centre means weakness throughout the whole organisation. Mr Andrew Carnegie tells us, that a prosperous and strong market is the chief source of success, both at home and abroad, so can we not in the future take a leaf out of his book and strengthen ourselves by unity of action?

SHAREHOLDERS AND EMPLOYEES ALL SUFFER.

It is desirable that something should be done if only in the interests of superannuated tea planters and others, of widows and orphans; and the long string of suffering shareholders who are deprived of their incomes from the defaulting 15 millions before referred to. Neither does the pressure of these starvation, and, I believe needlessly starvation prices, stop at shareholders; they penetrate the whole industry; garden managers, assistants, and labour are all down on their lowest cut-down wages. Even the tea business in London is becoming a by-word by those employed. Remove extreme pressure, and all will be relieved, and with them, I believe, even the large and small dealers will in the long run benefit, for a too low market produces a trying and unnecessary pressure on all affected.

In the perusal of what I have written, some may consider that I have over estimated the cost of bringing tea into bearing. In my experience, I know of very few instances where I may say land has been brought from jungle into bearing, upon the originally estimated sum, especially in later years. Those low, sanguine estimates never complete work; which usually means that the fourth and fifth years returns are needed in finishing up; promised dividends are deferred, and thus estimated

outlay kept down. I refer of course to the later periods of lower margins, combined with the necessity of more costly equipment. Many, however, have cost more and many less, than the figure I have quoted. A great misconception has often existed as to the extent of outlay upon a truly efficient factory. Personally, I believe, and few will differ from me, that nothing pays like early efficiency in tea; in its management, in its material, and transport facilities.

It is now four years since some regulation of sales was strongly recommended in London, and for a short time tried. Had this been more thoroughly organised and continued, it is a moderate computation to conclude that by now an average advantage of $\frac{1}{2}$ per lb. would have been added to the standard price of our staple. One of my reasons for saying so, is that, less than a year ago, it was reported that the Indian Association intended to resume the regulation of sales, which had the immediate effect of sending all teas up pretty close upon $\frac{1}{2}$ per lb. An aggregate increase of $\frac{3}{4}$ per lb. for one year on all tea produced in India and Ceylon, would mean 2 per cent on capital invested—nearly three-quarters of a million sterling. It would also have raised the general average profit of forty-five companies from $3\frac{1}{2}$ per cent to $5\frac{1}{2}$ per cent, and would have been almost equivalent to a gain of 5 per cent on the defaulting fifteen millions before referred to. Merchants, directors, shareholders, and all concerned, should remember that strength is the winning order of modern business; the sole apology for failure is weakness, either morally or financially; and that still the first holder is initially in the strongest position, if he only chooses to exercise it in his favour, even to one-half the device that the same power is exercised against him.—*Tea for Nov.*

SALT IN AGRICULTURE.

On the threshold of a New Year, we are called on to defend ourselves against a charge of neglect of duty. Our offence, as laid out in the indictment, is that, on a date not mentioned, but easy of ascertainment by the industrious, we failed to support a communication on "Salt" with editorial backing. The charge assumes that support was necessary; and if an impartial jury, under the direction of a competent Judge, should find, that the eloquence on Salt, of a seasoned correspondent, to whose instructive lucubrations and arguments, extending over a series of years, we have afforded due prominence, with frequent editorial benedictions, demanded support in his latest deliverance, we are prepared to abide by the penalty prescribed for what, we believe, the lawyers call *laches*. Our submission will not, we give notice, be wholly unqualified. In the first place, we should dissent from the verdict, as one to be taken *cum grano salis*, for reasons to be hereafter stated. In the second place, we should require an assurance that the penalty be not the same as that provided for the use of the knife—lightened though it has been by recent merciful legislation, as to its *maximum*, by one-twenty fifth! With these reservations, we are prepared to go before a

Judge and Jury. Now to our argument. The "communication" referred to spoke sufficiently for itself: it needed no support. The correspondence of our opinion of Salt with the Biblical, is well-known. But, just as Salt which has lost its savour is worthless so surely is excess of Salt unpalatable, and even injurious to the digestion. We claim, therefore, to have done a service to our correspondent in not having weighted the special number of the *Observer* to which he refers, with a saline editorial. In the next place, we desire to give our numerous public-spirited and able correspondents, who have with laudable persistency proclaimed the virtues of Salt in our columns, full credit for the part they have taken in impressing on the Government its duty to the agriculturist and the stock-breeder. Why should we do or say aught which would detract from their services when victory was in sight, and draw attention on ourselves. Is the complainant not aware—is it not written in the *Chronicles of the Taxation Commission*?—that the Governor, already one of the highest authorities and most brilliant exponents of Attic Salt, intends making special inquiries himself into the article as produced at Puttalam and Haubantota? With that assurance, and with the knowledge that the Government is appreciating the unwisdom of saying to those who come to it, for Salt, that it has none to sell, we do not for a moment believe that it will continue the unnatural policy of denying its own children the wherewithal for increasing their food. Land, therefore, is in sight. It would not become us to stand between our correspondents and their full share in the victory, even if it be not a sufficient excuse for our silence that it is impossible for an editor to find time and space for expressing his approval of all the views set forth in his columns. In token, however, of our agreement with our correspondent as to the importance of Salt in Agriculture (and in Stock-breeding), and the duty of the Government to issue Salt for these purposes on special terms, we give editorial prominence to his complaint:—

"I was surprised to find the communication on Salt, published in your columns without one line of editorial comment. After the interest you took in the subject recently, and strongly urged on the Government the advisability of issuing salt for agricultural purposes at special rates, the least one expected from you was an editorial.

"I send you an extract on the virtues of salt from an old book I came across quite accidentally. You will see that one of the properties claimed for salt, is its ability to prevent the dissipation of ammonia in manures. A booklet issued locally, claims for kainit the same properties, and suggests its being sprinkled over manure heaps on this account. Perhaps it is the chloride of sodium in kainit that has this useful property:—

FUNCTION OF SALT IN AGRICULTURE.

Mr. A. Beauchamp Natche has communicated to the *Philosophical Magazine* No. 65, a paper of experiments undertaken to ascertain the rationale of the action of salt in increasing the fertility of certain lands.

We have not space for details but quote Mr. Northcote's conclusions:—"The results, then, at which we must arrive are, that agricultural salt is a most energetic absorbent of ammonia, both in virtue of its chloride of sodium and of its soluble lime-salt, and that the proportion of the latter especially, most powerfully affects its action, but that at the same time its agency does not seem to be altogether a permanent one; it will collect the ammonia, but it is questionable whether it can retain it for any great length of time, because in the very decompositions which happen in order to render the ammonia more stable, salts are formed which have a direct tendency to liberate ammonia from its more fixed combinations. It may, however, retain it quite long enough for agricultural purposes, if the young plants are there ready to receive it. Its state of gradual liberation may be for them the most advantageous possible; and to this conclusion all experiments on a large scale appear most obviously to tend. It is described as an excellent check to the too forcing power of guano; and from M Barral's experiment we see that it either prevents the too rapid eremacansis of the latter, or stores up the ammonia as it is formed. As a manure for growing crops, all experience and all theoretical considerations therefore show it to be most valuable; but when employed to mix with manure heaps which have to stand for considerable periods of time, theory would pronounce, as practice has in many cases done, that its power of retaining ammonia under those circumstances is at the best doubtful."

CEYLON COOLY TIN TICKET SYSTEM :
THE AMENDED REGULATIONS.

(Copy)

General 5 (F)—Circular No. 6682a.

From the Hon. the Government Agent, W.P., to the Chairman, Planters' Association, Kandy.

Dated Colombo — December, 1902.

Subject: (Amended tin ticket regulations.)

Referring to your No. ———

Sir,—I have the honour to enclose for your information a copy of the amended regulations under the Tin Ticket System, and to state that Estate Superintendents, who wish to have copies of the same, can obtain them on application to the Kacheheri of your District—I am, Sir, your obedient servant, A. M. GALBRAITH, for Government Agent.

[Printed at the request of the Secretary of the P.A.:—]

The attention of Superintendent of estates is invited to the following amended Regulations:—

1. It is necessary that each immigrant cooly should have a tin ticket. The letter and number on that ticket supply all the information that is required to enable the Superintendent at Ragama to forward the cooly to the estate. Either one ticket may be given to each individual cooly on his departure to enable him to return, or a supply may be given to kanganyies who are going to the coast to bring coolies.

2. In point of fact the system is simply one by which coolies are forwarded as packages of goods, the tin ticket being the address. By its means a cooly travelling from Tuticorin, Tataparai, Tondi, Ammapatam or Paumben is delivered at the railway station nearest to his estate without the necessity for his expending a cent on his way. All his expenses are borne by Government and recovered subsequently from the estate to which he goes, through the local Kacheheri. Individual numbers as well as estate numbers are entered on the tickets, thus: 270 17 in circle.

If the "7" is entered on the check-roll it will give valuable information as to the identity of the person who presents the tickets.

3. All estates must be registered at the local Kacheheri, where a number will be assigned to each estate, and tin tickets will be issued if required. Tin tickets are supplied at Rs.50 per hundred, stamped with the district letter and estate number, and consecutive individual numbers.

Even if no tin tickets are required, registration of the estate is necessary to enable the Superintendent to issue certificates for coolies travelling within the Island. These certificates must be on the form issued by the Railway Department.

4. In the case of large estates, so many numbers should be allotted to each Kangany. These numbers being entered on the bill from the Kacheheri, it will be seen at once to which Kangany the coolies belonged. Care should be taken to issue the numbers consecutively. All tin tickets issued should be collected on the arrival of the coolies on the estate, checking the individual numbers and keeping them under lock and key.

5. Immigrant coolies who have received advances can still pay their expenses on the journey, but they can no longer obtain cheap cooly rates by rail and steamer, except on the production of tin tickets.

6. All coolies holding tin tickets will be despatched by the 6 a.m. train on the morning of the second day after their arrival at Ragama. Thus, coolies who arrive on Monday will be despatched by the morning train on Wednesday, Tuesday's arrivals on Thursday, and so on. If, however, the estate is so far from a telegraph station that the Kangany has not time to meet Wednesday's train after the receipt of a telegram despatched from Ragama on Monday afternoon, the Superintendent of the estate should write to the Superintendent of the Cooly Camps at Ragama, stating the number of days' detention that is necessary; these instructions will be carried out. Thus, if the Superintendent is satisfied that he cannot meet Monday's arrivals before Thursday, or even Friday, the coolies will be despatched on the day named. The telegram will be in one of the following forms:—

"5, 2, 1, Saturday, 42, Ramasamy, second," or
"1 woman, 2 children, Saturday, 42, Ramasamy, second."

The first of these means that five men, two women, and one child are being forwarded on Saturday; "42" is the first individual number on their tickets; "Ramasamy" is the name of their Kangany; and "second" is the number of the division, in the case of large estates, to which they belong. The second form is used when there are only men and women, men and children, or women and children in the gang.

The day mentioned will be that of departure from the camp, and therefore that of arrival at the railway station. Kanganyies who go to meet coolies should have one of the estate tickets. Each cooly, will of course, have a similar ticket and the letter and number of the estate will be entered on the railway ticket, so that the Station Master can point out to the Kangany the coolies who belong to him. If the coolies, whose departure from Ragama has been telegraphed, do not arrive by their proper train, the Superintend-

tendent should at once communicate with the Station Master, and failing a satisfactory reply, write to the Superintendent at Ragama.

7. It must be distinctly understood that Government does not hold itself responsible for the safe delivery of the coolies on the estate, but merely at the railway station nearest to their estate. Any Superintendent who does not wish intimation of the arrival of coolies to be sent by telegraph should inform the Superintendent, Ragama Camp, accordingly.

8. Coolies will be given bread and tea before they leave the camp. They will also be given $\frac{1}{2}$ lb. of bread a-piece to take with them. If any Superintendent thinks it necessary that his coolies should receive money for their maintenance between the railway station and the estate, an amount not exceeding 50 cents, a cooly, will be paid to each before he is put into the train. The Superintendent must write and state the amount to be given. If such instructions are given, the amount will always be paid to all coolies for that estate, the Superintendent at Ragama cannot undertake to issue it to some coolies and not to others.

9. Payment of the expenses incurred on account of coolies must be made to the local Kachcheri just in the same way as hospital bills. In correspondence with reference to accounts, Superintendents should always refer to the serial number in the account.
Colonial Secretary's Office, Colombo, Dec. 4th, 1902.

INDIAN TOBACCO.

(To the Editor of the *London Times*.)

Sir,—As the writer of the interesting special article in *The Times* of the 22nd instant on Indian Tobacco and its Possibilities makes reference to reports written by me, perhaps you will kindly allow me the privilege of space for a word on the subject.

Much as I sympathise with the laudable desire of the writer for the development of an Indian industry, I venture to doubt whether his suggestion for the manufacture here of cigarettes from Indian Tobacco is well designed for the attainment of the end desired. My hint to the manufacturers of Indian cigars to enlarge their operations by the inclusion of cigarettes was based on two considerations. In the first place, the recent increase in the importation of cigarettes—which totalled a value of about 21 lakhs of rupees last year, say £140,000—is mainly due to the adoption in Calcutta and some urban areas in Eastern and Northern India of a new habit in suppression of the practice of smoking the *hukka* or water-pipe. Amongst especially the younger generation the old-fashioned "hubble-bubble" has been found clumsy and time-wasting and been discarded, as the churchwarden pipe has been discarded here. That the new habit will spread extensively is inevitable; and my suggestion to the Indian cigar manufacturer was, in effect, that he should turn his attention to the meeting of a rapidly and continuously increasing indigenous demand by the supply of cigarettes of indigenous tobacco, even if it were necessary to roll them in imported paper.

In the second place, I did not and do not believe that a foreign market of any extent can be found for cigarettes of Indian tobacco. The excellence of Indian tobacco has been eloquently described by many, as well as by Sir Richard Temple, whom the writer of the article quoted. Nevertheless, it must be taken as a fact that Indian tobacco possesses a peculiar flavour of its own which is not easy of appreciation except by those who have smoked nothing else for years. The distinctive merit of Indian cigars in India is their cheapness. When a man can smoke freely at a cost of less than a penny a cigar he is not inclined—in India at any rate, where none of us are rolling in wealth—to indulge in Havanas, even Dutch Havanas,

at very much larger cost. But he is also not much inclined to confess that he smokes a cheap cigar because he can not afford the more expensive kinds, and he learns to make himself believe that he likes the indigenous cigar better. I do not wish in any way to decry the real merit of the Indian cigar, well rolled from well-cured tobacco, but, in fact, the best of them are covered with Java leaf; and I have not yet met the man who, being offered at another's expense the choice between an Indian cigar and a good imported cigar, selected the former. There is something in the physical conditions of the soil and climate which precludes us from growing and making such tobacco as that of Cuba, Puertorico or the Philippines. Much money and energy have been expended fruitlessly during the last 30 or 40 years on the introduction of the best exotic seed, and on the improvement of processes of cultivation and manufacture. These latter are susceptible of further improvement; but, as with many other products, it seems vain to hope for essential change in the quality and distinctive aroma of Indian tobacco. The statistics of the export trade in Indian cigars confirm the view that there is but a restricted demand for them, and the demand does not seem to have any tendency to expand. It is true that last year there was a very large increase in the exports but that increase in the main represented cigars sent to the troops in the field in South Africa.

It seems to me that, if the demand for Indian cigars remains small and non-progressive after many years of effort to create a market, there is not much reason to expect a more active demand for Indian cigarettes whether made here or in India. Nor do I think it would be expedient to make the cigarettes here of Indian tobacco for consumption in India, where, as I have said, the consumers would be natives. The cost of the article would be augmented by the charge for freight on the tobacco to England and back to India, by the wages of the more highly-paid labour employed here, and by the import duty which would be charged on the entry of the cigarettes at the Indian Custom-houses. All this additional cost would prevent such manufactures from competing successfully with cigarettes made in India, and perhaps even with the cigarettes made in the United States which are now so largely consumed by natives in India. But that there is a fairly wide field for the profitable employment of capital and skill in India in the improvement of native tobacco and in its manufacture into cigarettes admits of no reasonable doubt.

I am afraid I have written at excessive length, but I am anxious that British capitalists, who already look askance at Indian enterprises should not be misled into the entertainment of projects which must be dismissed as soon as inquiry is made into the facts.—I am, Sir, yours obediently,
J. E. O'CONNOR.
November 24.—*London Times*, Nov. 28.

PLANTING NOTES.

TRINIDAD CACAO PLANTERS—profit by the American market. Thus in the Port of Spain report of 5th December, we read:—

"Although it will be seen from above figures that Cacao is coming in very freely, there has been so active a demand from America that prices have kept up, and we make no change in late quotations of \$12.75 to \$13.50 as to quality."

ARTIFICIAL CINNAMON OIL.—A Leipzig firm of essential oil dealers have taken up a patent for the preparation of artificial cinnamon oil, depending on the mixing together of such of its constituents as have so far been detected. These bodies are cinnamic aldehyde, amyl-methyl ketone, nonyl aldehyde, cumic aldehyde, caryophyllene, linalol and its isobutyl ester, cymene, benzaldehyde, phenyl-propyl aldehyde, furfural, pinene, and eugenol methyl ether,—*Apotheker Zeitung*, 1902, 760.

Correspondence.

To the Editor.

TEA CULTURE IN SOUTH CAROLINA,

U.S.—MR. SHEPHARD REPLIES.

"Pinehurst," Summerville, S.C., Nov. 22.

DEAR SIR,—Some kind soul has caused to be sent to me copies of your issues of October 20th and 22nd wherein your "funny-man" has distorted himself at my expense and to my very considerable amusement. It was about my turn and I should not complain; for I have throughout the past summer intensely enjoyed the India-Ceylon green tea controversy as conducted in those valuable journals, *The Tropical Agriculturist* and the "Indian Gardening and Planting." Incidentally I would state my surprise that the old Indian process of lightening the color of green tea by panning or attrition (described by Dr. A. Tschich in 1892) should have been overlooked by so many of your able scholars and planters for so long a time, and adulteration at least contemplated!

The Pinehurst Experimentation has received so much notice from the Press of this and other countries that it has become almost impossible for me to correct the frequently erroneous statements as to its object and results, and has compelled me to ignore personal attacks.

But as I am indebted to the Ceylon Tea Industry and especially its mouth-piece, *The Tropical Agriculturist*, for so much valuable information, I deem it proper to call your attention to some errors into which you have inadvertently fallen, and which in your desire to continue as a faithful historian you may choose to publish. The Pinehurst undertaking has been experimental from the start until now; at first and until within a few years at my own expense, but lately it has received generous and welcome aid from the U.S. Department of Agriculture after official investigation had shown that its object was not commercial, but an attempt to prove the feasibility of establishing a new and profitable industry in the Southern States, with all of the attendant benefits. It should be superfluous to inform you that the experiments although on a small scale (none of my gardens are larger than a few acres in extent), have been directed so as to cover as many sorts of tea-seed and as different types of soil and exposure as possible. It was expected that success—measured pecuniarily—might attend very few of the experiments, but it was hoped that some of them might result favourably. I will leave to your own judgment whether the following returns for this season may be regarded as promising, especially as the limit of production does not yet appear to have been reached:—

Old Rose Garden, Assam hybrid seed, 392 lb dry tea from 83/100 acre, or at the rate of 472½ lb to the acre, or over 7 oz to the bush.

Lincoln Garden, Darjeeling seed, 554 lb dry tea from 1 90/100 acre, or at the rate of 290 lb to the acre, or over 2 oz to the bush.

South Fraser Garden, Chinese seed, 530½ lb dry tea from 2 acres, or at the rate of 250 lb to the acre, or 1½ oz to the bush.

I will not exhaust your patience with comparisons with Asiatic production.

Yield of Pinehurst tea for 1902 (don't laugh, please) about 8,500 lb. It is neither expected nor desired to exceed double that amount (don't be alarmed, please).

As to that little, cheap rotary sterilizer for the Green-tea manufacture, it does its work so well that the product sells very readily in the American market at a price which my respect for your feelings forbids me to quote.

In concluding this too lengthy note, I would ask you to favour me with any further notice that you may deign to bestow on this modest undertaking, even though it may be some fireworks from your aforesaid "funny-man."—Yours very truly,

CHARLES R. SHEPHARD.

SNAKE AGAINST SNAKE: A QUERY.

Dec. 17.

DEAR SIR,—Can you, or any of your readers inform me through the medium of your much esteemed paper whether the bite of one venomous snake is fatal to another of a different species—and also venomous. And does a snake really prey upon another for food, or use the means of deglutition as a mode of vanquishing its adversary—and, subsequently, disgorging its inanimate body.

Re Mr. Blacklaw's disclosure I have seen the kinds "Karavilla" and "Tollavissa" in conflict, and both seemed to be making more than mere efforts at destroying each other by biting. In this instance, the former snake (always when full-grown larger than the latter) was getting the better in the fight. Being then at school and quite disinterested in the matter we, school boys, stopped the battle to the death of both combatants without waiting for results. Natives tell of the deadly conflict between the cobra and polonga, in which the former is always victorious over the latter by the more deadly nature of its venom, but this statement seems to be mere tradition as I have never heard the report from an eye-witness. In my opinion one snake uses the act of swallowing as a means of defence when its poison is of no avail against its opponent. However, Mr. Blacklaw's discovery and evidence are very singular—(the more so as the rat snake is not very venomous) and ought to be closely studied by all interested.—I am, Sir, Yours, &c.,
VIRUS.

P.S.—I have seen Koravens (gipsies) keep polonga and cobra together.

MOSQUITO BLIGHT ON THE HILLS?

Dec. 18.

DEAR SIR,—I was told, not long ago, that I was wrong as to Mosquito Blight being possible at 6,000 feet—so I daren't express an opinion. No sign of it this year yet; but I'll take careful "stock" should what I think is Mosquito, appear again and then I will be able to follow what Mr. Harold Mann has written on the subject. If Mosquito Blight is prevalent in Assam, Cachar,

parts of Darjeeling, etc., so far North of the Equator,—why should it not give trouble up to 6,000 feet in Ceylon?—Yours truly,

PLANTER.

[We suppose Mr. Green will say that it is not impossible for the pest to travel to our higher districts; but that so far, as a matter of fact, it has not been verified at or above 6,000 feet?—Ed. T.A.]

CEYLON TEA ON THE CONTINENT OF EUROPE.

Bâle, Switzerland, 19th Dec., 1902.

DEAR SIR,—In your London letter, dated the 10th October, I note your London correspondent is somewhat sceptical about my statement to a friend as to selling hundreds of thousands of one-ounce tins filled with pure Ceylon tea on the Continent. It may interest your correspondent to know that in France and Switzerland alone during the past twelve months I have sold through the Tea Planters, Ltd., of Bale, 225,000 Quaker one ounce decorated tins filled with pure Ceylon tea, beside which considerable numbers of Koh-i-noor, Ugalla, Bee and Maravilla one-ounce tins are distributed every week, samples of which I send you per post. Further my distribution of teas in one-ounce tins, is not confined to France and Switzerland but is extended to all parts of the globe.

If the sale of a few hundred thousand one-ounce tins produce such scepticism in your correspondent, I fear for the results when he hears that my last order for decorated tins (for delivery within twelve months) is,—150,000 half lb., 150,000 one lb., 150,000 two lb. and 150,000 three lb. It might also interest him to know that I have placed an order for over a million two-ounce parchment tea bags printed in nine colours, and that my largest sale up to date is in lead packets. This statement can be confirmed by the General Manager of the Tea Planters, Ltd., Bale, who will be pleased to show the original contracts signed by me for the above tins and bags.—Yours faithfully,

R. VALENTINE WEBSTER,

Chairman, Tea Planters Ltd., Bale.

COCONUTS AND COPRA.

Hanwella, Dec. 23.

DEAR SIR,—In reply to the "Inexperienced." on the above subject, and your remarks thereon, in your paper of the 18th inst., I think your estimate of nuts to a ton is too low, unless the nuts should be extra big in size. My experience here is that between 4,000 to 4,500 dried nuts go to a ton. A cart load of copra, is generally five candies; a cart load of unhusked nuts=500 and of nuts in the shell 1,000 to 1,200. Here is a sample of my copra cured in the estate. I generally get top price for my produce.

PLANTER

[The samples of copra sent are very good—both clean and white and well dried.—Ed. T.A.]

PLANTAINS: DIFFERENT VARIETIES.

Hanwella, Dec 23.

DEAR SIR,—In answer to your question in T. A. re plantains. I may mention that I have a variety called 'Bimkehal' alias 'Neukehal,' Bim=ground, kehal=plantains—the plantains which grow close to the ground. Neu=ships, kehal=plantains=plantains of the ships. It is a dwarf variety, bearing bunches within 3½ to 4 feet off the ground. Last month there were two bunches of plantains of this kind, on my plantation, almost touching the ground, having 13 and 11 coubs respectively, bearing 10 to 15 fruits in each comb. The variety is used both for culinary purposes and dessert.—Yours faithfully,

G. E. AMARASEKERA.

THE LAKE FLY NUISANCE.

[The following instructive letter has been addressed to our senior morning contemporary by Dr. Willey, F.R.S.]

Colombo Museum, Jan. 2.

DEAR SIR,—In your issue of December 31st there is a paragraph stating that the Sanitary Officers have commenced a campaign against the Lake Fly by prohibiting fishing in a portion of the Lake. In an interview with one of your representatives last May or June, shortly after my arrival in the Island, I suggested the desirability of ascertaining the natural enemy of the Lake Fly.

After a brief stay at Negombo last August, I began to think that the abundance of flies might be correlated with the paucity of fishes, due to over-fishing of the Colombo Lake, and I mentioned this view freely in conversation.

Later still I came across a statement emanating from a well-known German fishery expert to the effect that the larva of *Chironomus* (the genus to which the Lake Fly belongs) is a favourite morsel with the carps. One of the commonest fishes of the Colombo Lake is a carp called *Barbus dorsalis*, and there are others with similar tastes.—Yours faithfully,

ARTHUR WILLEY.

THROUGH RANGALA AND MEDAMAHA-
NUWARA ;
ALL ABOUT CARDAMOMS.

Jan. 2.

SIR,—A few notes of a trip through the less-frequented district lying to the east of Kandy and bordering on the great 'Never-Never' country of Ceylon, which extends from the foot of the Walapane ranges across Bintenna to the Coast near Batticaloa, may possibly prove of some interest to your readers. Owing to the absence of railway or other facilities it is as yet quite out of the beaten track ; although the enterprise of the

RANGALA AND MEDAMAHANUWARA

planters, who, in spite of transport difficulties, carry on their industrial occupation and wage persevering warfare against the elements which here oppose their sterner and more unpropitious phases, is deserving of a larger share of recognition and encouragement than it appears to have yet met with from the 'powers-that-be.' My own recollection of the district goes back to very nearly forty years, and so far as the means of transport are concerned matters seem to be very much *in statu quo*. It would look as if the Ceylon Government, alarmed at the too rapid exploitation of places of interest all over the globe, had determined that here at least a sanctuary should be reserved where the ubiquitous globe-trotter should not penetrate, or if he did, that it should be only by means of the antiquated gharry-wallah and the exacting resthouse-keeper. It struck me, however, that in this corner of our 'undeveloped estate' a good deal might be done to bring its attractions to the notice of the tourist. A look through the visitors' book at the Teldeniya rest-house showed that a few travellers had come this way ; and their remarks were indicative of pleasure and satisfaction. The expense of carriage-hire and the discomfort of a slow journey through the hot Dumbara Valley must, however, to a large extent, discount the pleasure received and it is not likely this route will be favoured until cheaper and easier means of access are available. The drive out to Teldeniya along the banks of the Mahaweliganga is picturesque and interesting ; and the crossing the ferry at Gonawatte and drive through the Palikelle and Rajawala

COCOA GROVES,

with peeps of the hill ranges in the distance, and then arrival at the pretty little resthouse with a good appetite for breakfast, and a chat with the worthy dame who attends to one's comfort and provides an excellent breakfast—all go to make things agreeable. But this is but a stage on the journey. The ascent towards the hills now begins, and a real tug-of-war it is, both for man and beast.* The scenery, too, alters in

character, and as one rises above the river valley, the hills become more rugged and abrupt. The road winds up through narrow gorges, and presently another village,—

URUGALLA

—is reached. It boasts of a Court-house and Police station and a few bazaars ; but the general aspect of the place gives one the impression that it ought not to be there. Three miles up the road there is a gap in the range, and that is where one would naturally expect to find a small centre, and there ought to be a resthouse ; as it is here that a really grand view is obtained of the country on both sides of the mountain range. Not far from here the Mahaweliganga bursts through the circumvallation of hills, which has hitherto confined its course and debouches into the flatter country through which it meanders to its outlet at Trincomalee. The hills rise so sharply on both sides as to form almost a perfect wall, and here and there their summits are broken into battlements and embrasures having all the appearance of Titanic fortifications. The rock-capped peak of

NUGATENNA

frowns imposingly across the gateway towards his fellow-sentinels, Hanguranketa and Madulsima, challenging the intruder, be he human power or mightier foe, battalion or storm. The road now divides and a branch goes off hugging the base of the scarped cliffs in the direction of the Nitre Cave district, while the other tends towards the park country of Bintenna, a favourite resort of sportsmen, being now made a little more accessible through the gradual extension of the cart-road. Some thriving villages here nestle among the villages and ravines ; but the cultivation is limited, owing to the comparative dryness of the climate. At the time of our visit, however, all was green and smiling, giving occasion for surprise at the apparent sparseness of population ; but this may be due partly to the want of better means of communication with the outer world. As a grazing district this would give the impression of having a future before it ; as at certain seasons there is an abundant rainfall, which, by means of small tanks, might be conserved for the benefit of both human population and stock. Our visit, however, was chiefly to the region of

CARDAMOM CULTIVATION

and we were agreeably surprised and delighted to find such fine groves, gardens or plantations,—I don't know how they are usually denominated—flourishing luxuriantly, and bearing such crops as it was refreshing to one's eyesight to see. Around us were the relics of a bygone régime when King Coffee held sway and the ruins of old stores, pulping-houses and bungalows recalled to memory the names of many a friend and fellow-planter gone to join the majority ; and a touch of sadness could not but steal over us and we felt like

"One who treads

Some banquet hall deserted,
When lights are low, and guests are fled,
And all but one departed."

Reverie is not out of place in a scene such as we have here ; but the age is too busy for any such indulgence, and our motto is rather

"Let the dead past bury its dead
Work, work in the living present ;
Heart within and God o'erhead."

So mote it be !

* We made the trip up and down in March, 1864.

—Ed. T.A.

Revenons à nos moutons—CARDAMOMS rather. This cultivation bids fair to regain some measure of former prosperity, and the prospect is cheering. The past year has been very favourable owing to an abundant rainfall, and the owners of cardamom fields are rejoicing; although the ever-present shadow of declining markets and lowered prices, like the spectre at the feast, takes the gilt off the ginger-bread. The cultivation of cardamoms has some attractions and, perhaps, fewer drawbacks than are incidental to the majority of tropical products. They are generally grown under the shade of the larger jungle trees from underneath which the smaller under-growth has been cleared, leaving all vegetable matter to form *humus* on the surface which is constantly renewed by the falling leaves; and this style of cultivation is *par excellence* the desideratum for a country like Ceylon, when the denudation of the soil results in wash and impoverishment from the action of torrential rains on steep hill-sides. The upkeep of the fields is comparatively simple, cost of weeding and pruning almost nominal, and the buildings required for curing the produce do not need to be of an elaborate or expensive construction, as hardly any machinery is necessary. The fruit is merely dried, bleached and sorted, when it is ready for packing into boxes of the same kind as tea-chests, but without the lead-lining. Like all fruit-growers

THE CARDAMOM PLANTER

—is not without his enemies in the shape of squirrels, monkeys, as well as bipeds of a higher degree of intelligence, who are here afforded an opportunity of supplying the missing link between the 'spicy breezes' and that peculiar trait of the human race which the poet has characterised as 'vile.' Verily a Garden of Eden, but alas! the trail of the serpent is here too; although it is satisfactory to find that the missionary has penetrated into these wilds and planted his schools here and there wherever an opening can be got. More power to his elbow! Here, as elsewhere, he is in the fore-front of enterprise, seeking to reclaim a lost race from out of the wilderness of sin and ignorance, and planting the flag of peace and good will. It is an end worthy of attainment and it needs courage, perseverance and—cash!

Had time permitted a visit to some of these villages would have afforded us great pleasure and given material for a fuller description of the work being done, but we had to pass on. The spell of fine weather which had so far favoured us now came to an end and the curtain literally dropped upon the scene. Passing through the Nugatenna Gap we kept along the Eastern face of the range and climbed up through Kobonella in drenching rain and mist and were not sorry to find ourselves once more under shelter of the hospitable bungalow we were making for. The next morning was wet again and, our time being up, we made good our retreat, reluctantly postponing any further description of the country until another time.

PERIPATETIC.

BEE-KEEPING IN CEYLON:

SEVERAL EXPERIMENTS.

Colombo, Jan. 5.

DEAR SIR,—With reference to your remarks on page 508, may I point out that there are a number of experiments in

improved bee-keeping, with frame hives, now in progress. The most notably successful of these is that of Mr. Charles Andree, of Kurunegala, who has regularly exhibited working hives at our Colombo Agri-Horticultural Shows, and fully explained the whole process of honey-making by practical demonstration. Similar hives are being kept at the stock garden (in the late School of Agriculture), by Messrs. F Beven, Veyangoda, D. C. Jayawardene, Nanuoya, and others.—Yours truly,

BEEKEEPER.

[We are very pleased, indeed, to have the above information: we missed the last Agri-Horticultural Show through being up-country.—ED. T.A.]

GREEN TEAS IN CEYLON IN 1902.—The bonus table for December 16th-31st 1902 is somewhat late in appearing, owing, perhaps, to its large size and the intervention of the holidays. The sum of Rs. 19,440.30 paid during the fortnight is larger than for any similar period, we believe, since the green tea bonus began and indicates the activity with which manufacture of this safety-valve of the black tea industry is proceeding in Ceylon. A number of new estate names also appear in the list on page 38. It will be interesting to give a table of the twenty-four half-monthly totals of the past year, as follows:—

Date, 1902.	lb.	Rs.
January 15th	65,020	4,086.16
31st	87,853	5,271.18
February 15th	63,474	3,600.89
28th	75,650	4,160.72
March 15th	65,811	3,464.36
31st	104,239	5,211.95
April 15th	155,427	7,771.35
30th	128,710	6,435.50
May 15th	61,771	3,088.55
31st	237,900	11,895.00
June 17th	183,872	9,193.60
30th	184,664	9,233.20
July 15th	222,046	11,102.30
31st	189,216	9,460.30
August 16th	114,282	5,714.10
31st	153,353	7,667.65
September 15th	139,000	6,950.00
30th	231,785	11,539.25
October 15th	139,457	9,471.85
31st	217,714	10,885.70
November 17th	200,193	10,009.65
30th	193,097	9,654.85
December 15th	260,742	13,037.10
31st	338,806	19,440.30
Total	3,914,062	198,396.01

Though the figures for 1902 are not yet quite complete, we see that there is at least an increase of 2,324,072 lb. over the total for 1901. The special monthly table for 1902 we have prepared elsewhere, together with that for 1901, provide some interesting points of comparison.

BRITISH AND SIAMESE MALAYA.

At a meeting of the Royal Colonial Institute, held on Tuesday, Dec. 9, at the Whitehall Rooms, Hotel Metropole, Mr. Hugh Clifford, C.M.G., read a paper on "British and Siamese Malaya," which was illustrated by lantern slides. Sir William Robinson was in the chair.

Mr. Clifford said that the Malay Peninsula was a country with a strong individuality, but it continued inexplicably to attract only a very small measure of attention from Great Britain. After describing some of the chief characteristics of the country, he said that in 1895, the year immediately preceding the federation of the States, the joint revenue of the protectorate amounted to \$8,334,677; and the returns for last year showed that the total had reached \$17,541,507 (nearly £1,500,000 sterling), which was more than double the joint revenue of the States six years ago. As to the sources of the revenue, he remarked that the main wealth of the peninsula had hitherto been in its vast alluvial tin fields, from which nearly 47,000 tons, valued at £5,240,000 were exported during 1901. Upon that the Government levied a duty. Another source of revenue was the firms, let by public tender, for the collection of import duties on opium and spirits. The taxes to which he had referred might roughly be stated to fall almost wholly upon the foreign—that was, practically, the Chinese—portion of the community. Railways, too, were a source of revenue, and had been and were being constructed by the Government out of surplus revenue, without any recourse being had to loans. This fact would perhaps show the extraordinary wealth of the country and the successful results which had attended its administration under the protection of Great Britain. At the beginning of this year the assets exceeded the liabilities by over \$5,000,000, and the actual cost of administration, as represented by the cost of the Government civil establishment, amounted to only 17.63 per cent of the revenue. This demonstrated how economical was the system of government which had been introduced and how successful the temptation to extravagance had been resisted in the case of this British protectorate. An examination of the Blue Book relating to the Federated Malay States showed that the Malay population had increased during the decade ended 1901 by 35 per cent. But while the population increased it was found that their own land now yielded the people all the support they needed, and they were enjoying a complete individual liberty. It must be confessed that in a land such as the Federated States, where every enterprise was chiefly hampered by a lack of sufficient labour, the temptation to adopt the Dutch system was very great. The sight of the entire native population loafing away its days, and giving to its fields a *minimum* of grudging labour, was an outrage to the economist; for there was a vast quantity of potential energy suffered to go to waste.

Whatever the feelings of the Asiatic populations might be elsewhere, in the Malay States it was certain that if a *plebiscite* were taken today it would return an overwhelming majority in favour of our rule as against the ancient *régime*. As matters stood at the present time, the most urgent and crying need of the Federated Malay States was a sufficient supply of labour. So far, the stream of Chinese immigration had flowed with hardly an interruption, but as a set off against it the counter-stream of Chinamen returning to their homes must be borne in mind, and it was not in the power of

the British Government to control the emigration. It would appear that Malaya was specially created to serve as a receptacle for the overflow of the natives of India—a natural refuge for a population which annually counted the number of those on famine relief by the hundred thousand. The efforts in this direction had proved woefully disappointing, and the Government of India evinced no great desire to utilise the means of relief which the Malay States offered. After referring to Pahang, the most recently acquired and the least prosperous of the States, he briefly alluded to the portion of the peninsula which lay beyond the limits of the British Protectorate, and, in conclusion, said that, if the Siamese administration of the Malay States was to be saved from failure, they must secure the aid of a Civil service such as had been at the disposal of the British Government in Malaya during the past 30 years. (Hear, hear.)

A discussion followed and the proceedings closed.—London *Times*, Dec. 11.

VANILLA.

A consignment of about 300 kilos of vanilla cultivated in German East Africa, arrived in Hamburg a short time ago. The beans are said to be of the fine dark chocolate colour, and are commencing to crystallise. They are of various lengths, and are reported to compare favourably with the best Bourbon quality.—*Chemist and Druggist*, Dec. 13.

THE SHORTAGE IN GUTTA PERCHA.

If anybody doubted it, the recent enormous rises in the price of crude gutta-percha make it perfectly obvious that, taking it all round, the supply is not equal to the demand. Of course, the rise in crude gutta from about 5s 5d per lb to 9s per lb is very largely due to the new cable projects, but, as the tendency is for more cables in every direction, this rise promises to maintain itself for a long time to come, and it is, moreover, very definite proof of the fact that the production of gutta is extremely limited, and does not seem to be capable of extension in the near future. If additional proof for this contention were wanted it could easily be found in the fact that for several years there has been a marked and increasing deterioration in the quality of the gutta shipped. All this leaves no doubt that the present is an excellent time for a substitute like Gutzsch's New Gutta-percha to assert and demonstrate its merits.—*India-Rubber Journal*, Dec. 8.

ZANZIBAR.—In 1901, Zanzibar exported £25,130 worth of rubber, against £25,236 in 1900. Of this, Germany received £7,828 more than in the previous year.

FRENCH GUINEA.—The import and export of this colony show a decided decline during 1901. This is chiefly caused by the rubber trade crisis, the chief product which the country exports. The export of raw rubber decreased from 7,580,120 francs in 1901. As the natives had not taken notice of the warning of the Government not to forget the culture of other products over rubber, they were unable, at the general fall in prices, to make their usual purchases, which caused the big fall in imports.—*India Rubber Journal*, Dec. 8.

TEA IN PERSIA AND BEYOND.

The British Consul at Meshed, in a report of the trade of Khorassan, states that the taste for tea is strongly developed. It is mainly of the Indian product. The value of the tea imported by the Bandar Abbas, Bushire and Seistan routes was £50,267, but a considerable proportion of the tea brought by the two former routes is said to have been China tea for exportation to Trans-Caspia and Turkestan. - *L. and O Express*, Dec 19.

API CULTURE.—A correspondent asks how it is that "beekeeping" is not more attended to by the natives of Ceylon? We can only reply that the natives are content to profit by gathering wild honey when such is available in a good flowering season; but that (with the solitary exception of the late Mudaliyar Jayatilake of Kurunegala) we have never known any local bee-keepers, and yet Ceylon has two indigenous bees good honey makers one, a large bee, common in the forests of the interior; and the other a bee not larger than a house fly, found chiefly in the maritime districts. We had this fact brought before us first by an American visitor, Mr. Frank Benton, Professor of Apiculture in Michigan University. While visiting Cyprus, he got a commission from the Dutch Government to convey a colony of Cyprian bees to Java, which he accomplished successfully. Calling at Galle on his way back, he had some curious adventures (in getting the fly-bee) before coming to Colombo in search of the large forest-bee. We sent him to the Kurunegala Mudaliyar who gave him guides to the jungle where he got plenty of the bees to take home, but also a severe dose of malarial fever. Mr Benton wrote freely in *Observer* and *Tropical Agriculturist* at the time. He successfully conveyed the Ceylon bees to America; but we fear they died out after some time. The latest news of our friend was that he had been transferred to the headquarters of the Agricultural Department at Washington.—Meantime an experiment in "bee-keeping" after the most approved pattern should be begun at Ganguaruwa Experimental Station.

COLOMBO PRICE CURRENT.

(Furnished by the Chamber of Commerce.)

EXPORTS

Colombo, Dec. 22nd, 1902.

CEYLON TEA: MONTHLY SHIPMENTS TO UNITED KINGDOM AND ESTIMATE.

Estimate for	Dec. 1902—	9½ to 10 mill. lb.
Total Shipments	Do 1902—	9,000,000 lb.
Do Do	Do 1901—	12,235,867 lb.
Do Do	Do 1900—	11,241,918 lb.
[ESTIMATE for Jan. 1903—9½ to 10 million lb.]		

SIERRA LEONE.—The raw rubber export of Sierra Leone has fallen considerably in 1901. In 1899, it amounted to 545,385 lb, in 1900 to 274,616 lb, and in 1901 131,655 lb only. By the irrational method of the natives in tapping the trees many of them have perished, which, together with the keen competition of the neighbouring French Colony of Guinea, would, no doubt, account for the decline. The French product is considerably better,

COLOMBO, FEBRUARY 2ND, 1902.

No. 8.

REPORT ON HEVEA BRASILIENSIS IN THE MALAY PENINSULA.

BY STANLEY ARDEN,

Superintendent, Experimental Plantations, Federated
Malay States, 1902.

HEVEA BRASILIENSIS.

SHORT HISTORY.

HEVEA BRASILIENSIS, the tree furnishing the Para rubber of commerce, is a native of Tropical America and was introduced into the British possessions in the East, at considerable cost and trouble, by the Indian Government in 1876

through the instrumentality of Kew. According to the Kew Report for that year a Mr. Wickham was commissioned to collect seeds at the rate of £10 per 1,000. "He succeeded in obtaining 70,000 in the Siringals of the Rio Sapajos which he packed with the greatest care and with a full knowledge of their evanescent vitality; and coming straight home with them arrived at Kew on 14th June, 1876. Although sown on the following day, of these only 3½ per cent germinated." At Sir Joseph Hooker's suggestion, it was arranged that the seedlings should be sent to Ceylon, to be cultivated and propagated for subsequent distribution to the hot and moist districts of the Indian Empire, and the late Dr. Trimen (then Director of the Peradeniya Gardens reports, that thirtyeight Wardian cases, containing 1,919 plants, despatched from Kew on August 12th, were received at Peradeniya in very good order.

In the same year (1876) plants of Para rubber were forwarded direct from Kew to Singapore, and the following year, Mr. Murton reported that "our climate is evidently suited for the growth of Hevea, judging by the progress the plants sent last year have made." It was introduced into Perak at the same time by Sir Hugh Low, but whether he obtained his plants from Singapore or Ceylon I have

been unable to find out. That they were some of the original lot there is little doubt, for in 1879 he reports that "the Heveas are now 12 to 14 feet high. They take to the country immensely," and in 1883 he reports "the trees are now six years old."

In the year 1887 some seeds were obtained from these trees and planted in the Museum Grounds at Taiping; others were sown at Kummuning Estate (Perak) and a few years later at S'tiawau (Perak).

There seems to have been very little interest taken in the product, however, by planters, presumably on account of the high prices ruling for coffee about this time, and with the exception of the trees cited above, there are very few trees in the Native States over four years old. But with a decline in the price of coffee, planters began to look for other cultivations and during the season 1896-1897 the planting of rubber was taken up seriously. Since then its cultivation has received great attention and there are at the present time, in the Malay Peninsula alone, at least 12,000 acres planted with Hevea, representing about 1,500,000 trees, presumably the whole being the progeny of the trees originally introduced by the Government of India.

Of the many trees yielding commercial India-rubber the various species of Hevea are the most important, furnishing about one-third of the world's supply or 45,000,000 pounds of rubber annually, and always obtaining a market value in excess of that of all other commercial rubbers. To a certain extent this is no doubt due to the fact that Para rubber reaches the market in a purer and drier condition than most rubbers; the method of coagulation in vogue in Brazil not lending itself to adulteration to the same extent as is practised by collectors in other parts of the tropics,

CULTIVATION.

Conditions of Growth.—Although a native of the tropics of the New World, *Hevea brasiliensis* is admirably suited to the conditions obtaining in the Malay Peninsula and adjoining islands and its cultivation

here is a comparatively easy matter. From reports to hand it would appear that this tree naturally affects swampy places; but here it thrives in any locality—at low elevations, and on almost any kind of soil. Swampy districts or places that are periodically inundated are not essential to success and fine specimens are to be seen growing in what would generally be supposed to be the most undesirable spots. A good tree for instance is growing in the Penang Botanic Gardens on a dry stony bank “not at all the place I should choose,” and although probably much smaller than if grown under better conditions, this tree has given an average annual yield of over 2½ pounds of rubber from the eleventh to the fifteenth year of its existence.

Other good specimens, 11 years old, 70-75 feet high with a mean girth of about 4½ feet at 3 feet from the base, are to be found in Perak, growing on disused mining land which is about as devoid of plant food as it is possible to find. If the reports concerning the conditions under which this tree grows in a wild state are correct, it is somewhat strange that it should flourish here under such different root conditions, for the only trees I have seen in the Peninsula which could hardly be said to be thriving were those which were planted in a swamp. I find the same fact is reported from Zanzibar, where the Director of Agriculture states that “although planted in typical rice swamps they are nearly all dead.” This at any rate goes to strengthen the theory that plants do not *always* occur naturally, under those conditions to which they are best adapted, although as a general rule it is as well in the cultivation of plants to imitate as far as possible the conditions which the plant is known to affect.

There are many instances of plants succeeding much better in the country of their adoption, and the orange may be cited as an example; this plant although indigenous to eastern Asia succeeds nowhere so well as it does in Southern Europe and California. Some writers have advocated the cultivation of Heveas on partly cleared land or in lines cut through the jungle; and others to plant it very closely on the assumption that being a jungle plant it would require plenty of shade. But this I venture to think is a mistake, for we are informed that in the forests of Brazil it towers above all other vegetation, thus indicating, that so far from being a shade loving plant it enjoys plenty of light.

Nothing could succeed better than this tree does in the Federated Malay States, planted on newly cleared, well drained land; and although it is often stated that partial shade, swampy places and other conditions are essential to success, given a climate with a uniform temperature of about 90° F., and a large rainfall equally distributed throughout the year, the conditions laid down above are eminently suitable. So far as I can judge it does not appear that the nature of the soil affects either the quantity or the quality of the latex (milk) but in any case it is advisable to plant on a fairly rich soil, a loamy soil for preference, as under such circumstances the tree would grow quicker and stronger, and probably give a return at a younger age than if grown on land deficient in the necessary constituents of plant life. The rate of growth is very rapid, and I have measured trees grown under the conditions recommended, which were 2 feet 6 inches in girth at a yard from the base, and approximately 30 feet high though only 4 years old; although this must not be taken as an average size. The mean girth of an acre containing 161 trees, 3½ years old, was 17·51 inches, and that of an acre of 4 year old trees 22·45 inches, while 10 year old trees, growing on a very sandy soil at S'tiawan, Perak, were approximately 65 to 75 feet high, having an average circumference of about 4 feet 6 inches taken at 3 feet from the ground, the largest being 5 feet 5 inches.

Germination of the seed.—The usual method adopted when planting Hevea is to germinate the seeds in nurseries, where they remain until they are about 5 to 6 feet high, when they are cut down to within 6 inches or a foot of the ground; the stumps being then planted in the open, in holes previously cut and filled with surface soil, without any shade, and needing very little care beyond keeping the ground free from weeds for the first 3 or 4 years. This method, although retarding the growth for a short time, is perhaps advisable, especially on land which has previously been used for other cultivations, as a precaution against the attacks of vermin, which would greedily devour the seeds were they planted “at stake”; though on land from which the jungle has recently been burned off, the advantages do not appear to be quite so great.

Another very successful method is to germinate the seeds in small baskets—similar to the small strawberry baskets so familiar on the home markets and which could be made by coolies on the estate at a very cheap rate, or in bamboo pots—the hollow bamboo cut into lengths of about a foot. These should be nearly filled with soil and one seed placed in the centre of each, about 1½ inches deep, and the baskets or bamboo stood out in blocks, as near as possible to the place in which it is intended to plant them. When the ground is ready they can be put out into holes, without being removed from the basket, which will soon rot and the plants will thus avoid any check whatever. If bamboo pots are used, they should be split down each side, and the pieces can then be drawn out after the plant has been placed in the hole and surrounded with soil. This method is recommended when planting must be done in dry seasons, and although a little more expensive at first, will, I consider, repay the extra attention bestowed on the seedlings by avoiding the check which must necessarily ensue, when the system of planting from stumps is followed.

The watering of the seed in the nursery beds is a matter requiring careful attention. Before sowing, the soil should be thoroughly moistened, and if the surface becomes hard it must be stirred up again before watering, otherwise the water will not soak into it. The aim of the cultivator, however, should be to avoid the necessity of watering, by shading the beds fairly heavily, but if it becomes necessary it should be done *thoroughly not frequently*. The effect of ‘sprinkling the seeds’ when the soil has become dry, is disastrous, as it simply attracts the young growing tips of the roots towards the surface, there to be shrivelled up immediately the surface becomes dry again.

The chief difficulty in planting the seed “at stake,” *i.e.*, in the position it is to permanently occupy, is that as it retains its vitality for so short a period, planting can only take place at definite intervals, for it is essential that the seed be sown within a week from the time it arrives at maturity. Nevertheless, I am of opinion that when possible this practice has points which recommend it to the consideration of those concerned. I refer more especially to the method invariably adopted by planters, of cutting away the tap-root when transplanting stumps from the nurseries. Now it should be remembered that in addition to it being an organ for the absorption of food, one of the functions of the root is to act as an organ of support, so that to cut away the tap-root is to deprive the plant of its main support.

Moreover, I consider it very probable that white ants effect an entry into the heart of the tree by means of the root so injured. I have examined scores of trees that have fallen over, due to the ravages of these insects, and the fact that at the time of falling, these trees were, almost without exception, to all appearances in a robust state of health, shews that the cambium layer was not affected, or at least only to a very small extent, while on examination the trunk of the tree was found to be completely riddled. I very much doubt whether these ants could enter into the heart of the tree protected as it is by the laticiferous

* C. Curtis, F.L.S., Annual Report, 1900.

tissue (unless in very young trees where the tissue is only slightly developed) except by means of a wound previously made.

Some trees tapped somewhat severely about a year ago, and whose wounds are not yet healed over have been noticed. At the time of tapping, they were quite free from ants, but now are very badly attacked. In this case the wounds are 6 feet from the ground, and the ants after constructing earthworks up to the wounds, have entered the tree at a point where they have not encountered any laticiferous tissue. On other trees they will construct earthworks up to a height of 30 or 40 feet, sometimes more, in order to enter the tree at a point where the snapping off of a branch or a crack caused by the wind affords them a place of least resistance.

There is also the fungus to be taken into consideration; recently determined by Mr. Masee of Kew, as a species of *Helicobasidium*, 'a root parasite, nearly allied to *H. nompæ* . . . very destructive to the mulberry tree in Japan': and it is probable that the injured root proves an acceptable host to this fungus, which exists on the living tissue. There has been some discussion as to whether the loss of trees is attributable to this fungus or to the ravages of the white ants, or to both, but in the large majority of trees I have examined neither one nor the other could be said to have killed the tree. Had the trees been killed by the fungus there would doubtless have been some indication of its presence some time previous to the tree falling over; but, as already stated, at the time of falling the tree generally appeared to be in a robust condition, and I incline to the belief that the fungus had prepared the way for the ants, which by eating away the heart of the trunk had caused the tree to fall simply for want of support.

Distancing.—A great difference of opinion exists on this subject, and at the present time this tree is being planted at distances varying from 10' x 10' (435 to the acre) to 36' x 36' or 33 trees per acre. Close planting is sometimes recommended as a means of obtaining a long straight trunk—a large tapping surface 'but if it results in a diminished girth, I venture to think it a mistake, for, as will be seen later, the lower part of the trunk yields the largest proportion of latex. In order to procure a good stout trunk, over-crowding must be avoided, and the tree allowed plenty of light and air, so that it may produce a maximum amount of foliage, for a well developed crown invariably results in a good strong trunk. Again, if the latex acts as a reserve material, as it sometimes supposed, upon which the tree can rely in 'hard times' we might imagine that the laticiferous tissue, i.e., the latex producing tissue, would be most fully developed in those trees with the largest crowns for the following reason. In dry weather, evaporation by means of the foliage take place at an enormous rate, and the greater the amount of foliage the greater the evaporation which occurs and consequently the greater the necessity of a large food reserve, and it is reasonable to presume that the laticiferous tissue will be developed in accordance with the requirements of the individual tree. I have noticed repeatedly that trees growing on the edge of a plantation, or in more or less isolated spots and consequently able to obtain a maximum amount of light and air have given by far the best returns.

There does not appear to be any necessity to plant closely, even to ensure a tall tree, for *Hevea* seldom branches during the first two or three years of its existence, during which time it runs up forming a whip-like stem 20 to 30 feet high. To give some idea of the space required to allow this tree to develop itself, I may say that I have measured trees planted 36' x 36' which were touching each other at the tops and producing a dense canopy, nine years from the time of planting. Assuming that the roots cover the same area as the crown of the tree, which may be taken as a fact, it will be easy to imagine what a struggle for existence must ensue when trees are planted to 10' x 10'. It may however, be found, that although the individual tree yields a smaller quantity of latex

when close planting is followed, that the loss will be compensated for by having a large number of trees to the acre. This, however, remains to be proved. There is the undoubted advantage that the cost of weeding will be reduced by planting closely, while on the other hand it will necessitate a deal of extra labour when tapping operations commence. However, taking all things into consideration, I am of opinion that in a country where land and labour is cheap, close planting is false economy.

INSECT PESTS AND FUNGOID DISEASES.

Of insect pests by far the most troublesome and destructive is the 'white ant,' *Termites gestroi*, previously referred to. With a view to exterminating this pest almost everything conceivable likely to prove beneficial has been tried, including lime, tar, arsenic, sulphate of copper, Jeye's fluid, etc., but up to the present nothing has been found which keeps the trees free for any length of time. Gondal fluid has recently been reported from India as an effectual remedy, but so far as I am aware has not yet been tried in this country: it is intended to experiment in this direction.

The only means of protecting the trees at present seems to be by constantly harassing the ants by destroying their earthworks which they built on the trunk, but although by this means the trunk of the tree is protected, the ants are still at liberty to attack the roots, which they often do, and thereby cause the death of the tree.

A species of weevil, nearly allied to, if not identical with *Astyehus lateralis*, has recently been discovered eating the foliage of *Hevea*, the life history of which is given by Mr. Wray.* In the beetle stage it feeds on the young foliage and when abundant is very destructive. The only remedy is systematic band-picking, which may be readily accomplished, as on the least agitation of the branch on which the insect is feeding, the insect falls to the ground and shams death, and may be collected and destroyed. So far this insect has only been noticed on one estate and as it breeds but slowly, should be easily kept in hand if a smart look-out is kept from the time of its first appearance.

Fungoid diseases are, so far as I know, restricted to the species previously mentioned. Whenever this fungus is observed precautions should at once be taken to prevent it from spreading, for it will probably be useless to try and save the tree when once infected. An effectual preventative is to dig a trench all round the tree at a distance of 8 to 10 feet from the trunk and about 2 feet deep, taking care to throw all the soil removed from the trench towards the centre of the circle thus to throw all the soil removed from the trench towards the centre of the circle thus formed. A liberal dressing of lime or sulphate of copper should then be thrown into the trench and over the soil excavated; this will arrest the growth of the mycelium. The dead tree should not be allowed to lie on the ground, but chopped up and burnt.

When a tree has been tapped I would strongly advise that a coating of tar be applied to the exposed wood, to the exclusion of rain which might lodge in wounds and lead to decay, and as a protection against the growth of fungi, which are always difficult to eradicate when once established, and in some cases are exceedingly destructive.

EXTRACTION OF THE LATEX.

Under this heading the following points are dealt with, viz:—

1. Method of tapping:

- (a). Instruments employed.
- (b). The style of incision.
- (c). Area of trunk to be worked.
- (d). Length and distance between the incisions

* Perak Museum Notes, II., Part I. (1897.)

2. The effect of wounding the tree on the flow of the latex :

- (a). The number of times the incisions can be advantageously renewed.
- (b). The length of time that should elapse before renewing the incisions.

Preparatory to tapping, that part of the trunk it is intended to work should be well cleaned of all loose particles of bark and dirt. In old trees the rough outer bark may be shaved off with a blunt knife and then rubbed down with the husk of a coconut ; but in the case of young trees where the bark is not so thick and rough, a good rubbing over with a coconut husk will suffice. It cannot be too firmly borne in mind that foreign matter of every description decreases the value of the prepared rubber, and every endeavour should be made to avoid its inclusion from the commencement.

When tapping trees in isolated positions or on the edge of a plantation, the shady side of the tree should be selected, as the sun has the effect of coagulating the latex on the wound, thereby preventing a further flow and adding to the percentage of "scrap" or second grade rubber.

(a). *Instruments employed.*—The instruments used during these experiments were an ordinary five-eighth inch wood chisel and wooden mallet, and a sharp pruning knife. The chisel and mallet were ultimately discarded in favour of the knife, as it was found that with the latter the work could be done quicker and better ; while there was not quite the same danger of cutting into the wood, thereby causing permanent injury to the tree. Whatever form of knife is used, it should be kept very sharp so as to enable the operator to make as clean a cut as possible ; any tearing of the bark resulting from the use of a blunt instrument will tend to close up the cells and prevent a free egression of latex.

The collecting vessel used was a tin cup, about the size and shape of an ordinary cigarette tin, to which was affixed a metal lip. This lip being filed at the edge pierces the bark, rendering impossible any escape of latex between the tree and the collecting receptacle avoids the necessity of the use of luting material. The tin is also supported by this means so that nails, wire, etc., are unnecessary.

(b). *The kind of incision.*—The laticiferous or milk-producing tissue is composed of a number of vessels or tubes which by constant branching (anastomosing) have formed a complete network of tissue. In some trees, this system of communication between the cells is only developed to a very small degree ; while in others—notably in the *Dichopsis spp.*, which furnish the gutta-percha of commerce, the cells containing the latex remain isolated. The more completely this system is developed the easier it becomes to extract the latex, as it is evident, that other things being equal, a less number of incisions will be required to extract a given quantity of latex.

The vessels constituting this tissue are chiefly distributed throughout the phloem or inner layer of bark so that whatever form the incision takes, it must be sufficiently deep to cut through this layer. Immediately beneath the laticiferous tissue lies a layer of active cells known as the cambium, and the operations should be conducted with care so as to incur as little injury to this layer as possible. I have found that it is practically impossible to cut through the milk-producing tissue without injuring, at least to some extent, the cambium ; but fortunately the tree is very hardy in this respect, so that if ordinary care is exercised, no serious consequence result.

The thickness of the bark varies from $\frac{1}{4}$ to 3-8 of an inch, gradually thickening as the base of the tree is approached.

In actual practice the object to be attained is to puncture the maximum number of the laticiferous tubes while doing as little injury to the tree as possible and as these tubes run more or less longitudinally, it is clear that a horizontal or an oblique incision will puncture more tubes than a vertical one. The difficulties arising in collecting the latex from a horizontal incision are obvious, so it remains to be seen what form the oblique incision should take ; whether it is advisable to make a single incision (/), or a double incision (V), or a number of double incisions feeding a central vertical channel and forming what is known as the "herring-bone" incision.

Experiments have been conducted at S'tiawan, Perak, with a view to ascertaining the difference in yield by these various methods, and the result of tapping five trees with single oblique incisions is shown below. The incisions were made 6 inches apart, ranging from the ground to a height of 6 feet up the trunk, and in each case were 6 inches long, running at an angle of 30 degrees with the perpendicular.

Age of trees 9 years	Mean girth at 3 feet from base 4 feet 2 inches
120 incisions yielded	... 23.75 ounces of dry rubber
Average yield per incision	.19 " "

Twelve months later the same trees were tapped with double oblique incisions, the two lines forming the V being in each case 6 inches long. As in the former experiment, the incisions were equally distributed over the first 6 feet of the trunk, commencing at the base. The result was :—

Age of trees, 10 years.	Mean girth at 3 feet from base 4 feet 3 inches.
120 incisions yielded	.. 41.25 ounces of dry rubber
Average yield per incision	.36 " "

Thus it will be seen that the V incisions gave considerably more, almost double, the amount obtained from the single incisions ; but as twice the amount of labour was required and twice the amount of injury inflicted upon the tree, the result may be said to be slightly in favour of the former method. The reason the yield is not quite in proportion to the labour expended, or rather to the surface exposed, is due to the fact that the two lines forming the V become so close to each other as they approach the base of the incision, that they probably puncture the same tubes.

We have now to compare the V incision with the herring-bone incision, which is practically the same principle, except that in this case there are a number of V incisions feeding a vertical channel, the latex being conducted by the oblique incisions towards the central channel at the base of which is placed the collecting tin. The feeders should be made to join the vertical incision at an angle sufficiently acute to enable the latex to escape freely—say 40 to 45 degrees, and care should be taken that these incisions do not join the central incision opposite to each other, or the result will be an ugly wound (Fig. B, a) which will take a considerable time to heal.

Fig. A shows the method to be followed and Fig. B the incorrect method.

Fig. A.

Fig. B.

The yield from 22 trees tapped on this principal, with two incisions per tree, one between the base and a height of 3 feet, the other on the opposite side of the tree at a height of 3 to 6 feet was as follows:—

Age of trees, 9 years. Mean girth at 3 feet from base 4 feet 1 inch.

41 incisions made on 22 trees gave 29 ounces of dry rubber

Average yield per incision .65 " "

The central channel in each case was 2 feet 6 inches long and the 'feeders' 1 foot long. These were 1 foot apart, there being three on each side of the vertical channel.

Taking into consideration that the exposed surface, or the total length of the incision on these trees was 8 feet 6 inches, as against 1 foot in the case of those trees tapped with a V incision, and also that a much larger area was operated upon the yield is at first surprisingly small, being less than double the amount obtained from those trees tapped with V incisions while eight times the amount of labour was entailed in making the extra incisions. It is evident then that some other force is at work viz., the effect of wounding on the flow of latex, for, in this experiment the whole of the trunk was tapped on the same day, while in the two previous experiments there were five incisions per tree and the operations were carried on over a period of 21 days. This question will be considered later.

(To be continued.)

THE FIBRE INDUSTRIES.

The Textile Fibres of Commerce. By William S. Hauna. Pp. x + 236. (London: Charles Griffin and Co., Ltd., 1902.) Price 9s. net.

The title of this work raised a hope that the author had seized the opportunity open to any specialist of carrying on the critical labours of Vettillart, Wiesnet, Hugo Muller, J. Christie, Otto Witt, and the experts of the Colonial and Indian Exhibition, now almost of

ancient history. The opportunity is a great one; for the subject matter is vast, the interests involved are stupendous while the first principles of the subject are few, very few, and so are they who recognise them. The opportunity is one, not merely for a book enunciating in one comprehensive view the relationships of our highly developed textile methods to one another and to the properties of the ultimate spinning units, but for a definite forecast of the progressive future, which is of obvious commercial moment.

The book before us, however, neither aims at nor claims to reach the pioneer standard of technical literature, and must be judged accordingly. The author's labours have no doubt been exhaustive and minute. But the failure to attain to the ideal standard is self-predicted by the opening sentence of the introduction:—

"The vegetable and mineral fibres of commerce may be arranged in four groups, viz. (1) plumose fibres (2) stem and leaf fibres; (3) fruit fibres (all derived from plants); and (4) mineral fibres. These groups are represented by the fibres used in various important industries, and by other vegetable fibres which at present are of special interest from a scientific point of view only."

This classification has no morphological basis and is devoid of technical significance. The sentence stands immediately beneath the title "The textile Fibres of Commerce," and the reference to these "other fibres," which are, in fact, from the point of view of commerce or industry, mere lumber, introduces us to the supposed antithesis of science to commerce, which is archaic, but in these days misleading, and were better left out. The introduction, in short, prepares us for the plan actually followed in the book, which is that of alphabetical sequence of the conventional or trivial names of the fibres; perhaps the best in the absence of a positive, critical basis and consequent classification. The reader is thus prepared to find the book a non-critical compilation, and although the title suggests the subordination of the matter to commercial that is industrial, proportionate, the expert will be disappointed and the lay reader will get little instruction in the practical science of the subject.

Of course, be it understood, a book of 230 pages, upon such a subject, and containing 150 illustrations, mostly the original work of the author and friends, affords much interesting reading. This interest belongs to the subject, which is fascinating from whatever point of view it may be handled. We have no wish to depreciate the author's evident aim to popularise the subject; on the contrary, we wish for the book a successful run, and that a second edition may see a considerable improvement in the matter. But as we take the request in the preface for "any suggestions that will enable me to add to the utility of this work" as an honest invitation to the critic, we feel we should be wanting in honesty and in a duty to the technical public if we shirked the task of pointing out by a few examples the author's want of precision in handling fundamental questions. We cite first the introductory sentence of the section "Vegetable Fibres," p. 3, "Physical and Chemical Properties," which reads, "The principal vegetable fibres are plumose and bast. Both are used for spinning and weaving, and their prices fluctuate in accordance with the quality and quantity of the annual crops. The plumose fibres are composed of cellulose.

Plumose and bast should not be coupled with the same term "fibre" unless the author intends "ultimate fibre." We take it that the spinning unit is intended, and in the case of the bast fibres the unit is a more or less complex filament. Fibres are not used for spinning and weaving; the fibres or filaments are spun into yarns and the yarns woven. It is fairly obvious that prices vary with supply and quality, but there is something to be said for demand. Why, however, interject this superficial reference to the important question of value under the heading of "Physical and Chemical Properties"?

Lastly, to describe the plumose fibres as "composed of cellulose" is misleading. In the cotton substance the non-cellulose, it is true, is small in proportion, but the composition of the *eviodendron floss*, as of other seed hairs, is widely divergent. Later in the section we find the bast fibres described as made up of cells of which the "walls are composed of more or less thickened lignin or woody material." This is quite inaccurate in regard to the most important of them viz. flax, hemp and rhea. Again, the good "commercial qualities" of the fibro-vascular bundles of monocotyledons 'depends upon their moderate length, strength, flexibility, and the number of fibre cells in each bundle. Without reference to the grammatical slip, we will fix the looseness of the phraseology by transposing the terms to another case. "The good commercial qualities of gold depend upon its moderately yellow colour, specific gravity, ductility, and the number of silver coins of equivalent value"?

We have dealt with this section on "Physical and Chemical Properties" at disproportionate length, for the author exhausts it in a single page of matter. The failure to lay a solid critical foundation by an adequate treatment of the section, of obviously fundamental import, measures the failure of the work to contribute to the systematic development of the subject. We are bound, further, to particularise some strange inaccuracies in the information conveyed to the perhaps unsuspecting reader. Jute is described under the heading "Jute, Common," and the description contains many curious statements. Thus:—

"The fibres are several feet in length, have a satiny lustre on account of which they are sometimes used in the manufacture of the cheaper silks."

There is a popular confusion, we presume, between jute and "jute"; there is also a slang word "water" well known, "in the city" but we suggest that only in the official mind of a judge of the High Court would there be any possible confusion of the material with the immaterial "water." So we venture to think that the author has served up a popular error in relation to "jute" as an industrial fact in relation to jute.

In particularising the applications of jute yarns we find, "the backing of hearthrugs, the lining of ladies, slippers, the collars of gentlemen's coats and burlaps for bales of jute or hemp coverings."

We refer the author to Dundee for information. Lastly, "the jute fibre readily dissolves in alkalies and mineral acids at a low temperature." The reader may correct this statement by reference to any of the standard works on cellulose chemistry. The chemistry of the fibre substances is dealt with generally in a superficial way. The author should have been careful to avoid such statements as the following in reference to cotton (p. 91):—

"Acids have so destructive an effect upon cotton that their use in the cotton industry ought generally to be dispensed with since alkalies such as soap . . . can be employed for scouring and cleaning cotton fibres without materially injuring them."

And again (p. 97),

"Cotton fibres have some affinity for vegetable dye stuffs such as Indigo . . . but little or none for coal-tar dyes." The section on "Cotton" otherwise contains useful information of a conventional commercial order, and as it comprises some forty-five pages is clearly the most important of the book. In the categorical description of the various cottons, the dimensions are given in inches and fractions of an inch. This in a scientific text-book is a gratuitous concession to the rigid conservatism of our industrial system. We should like to ask if the expression 1/1180 inch conveys any definite mental impression to the reader?

We briefly notice the section "Paper Fibre Plants." We all know that paper can be made from an endless variety of fibrous materials, and the author is evidently more impressed with the fact than with the advantage of using the qualifying term "commercial" as a winnow for separating the grain from the chaff. The paper maker will find the section of little practical im-

portance. The subsection "Woodpulp" opens with the curious sentence, "This is rather confused and mixed up with paper-making." The remainder of the section may be similarly described. A subsection on "Woodpulp silk" is rather out of place at the conclusion of the section on "Silk." The treatment of this highly important industry indicates that it lies outside the author's range of experience and does not invite serious criticism.

The author is entitled to the credit of having produced an interesting book on a universally attractive subject. That it does not take the place of a standard text-book of critical importance is due to the fact that he has not sufficiently grasped the trend of the progressive scientific movement which underlies the many-sided "commercial" developments of the fibre industries,—*The Nature*.

THE PAPAYA AND HOW TO GROW IT.

The fruit called the Papaya or Papow is so well known in India that I feel some diffidence writing about it.

The papaya tree belongs to the natural order *Papayaceæ* several species of which are remarkable for their poisonous properties. The Papaya itself has long been known as an excellent fruit yielding, and recently the fruit has become very popular with Europeans in India. It is believed to be a native of Tropical South America, but is naturalised in India. Some weird and wonderful properties are assigned to this tree. For instance, it has been stated that tough meat wrapped in its leaves and kept for a few hours, is rendered tender and toothsome. Of course, this is one of those stories that will not be killed. Scientists have however, found that the fruit contains a substance called papain, which, like pepsine, has the power of helping digestion of food. And as dyspepsia is one of the ailments from which modern humanity suffers considerably, the fruit of the Papaya tree should become very popular with those afflicted with a weak digestion. But apart from this important property, the fruit is not only wholesome and beneficial, but is of a flavour and consistency which cannot fail to commend it to the consumer. Unfortunately, in India, this fruit like many others, is grown in such a haphazard manner, that its peculiar flavour and delicacy are not developed, and the consumer is obliged to be content with the insipid fruit commonly met with in the bazaars.

Now there is no reason why the consumer should not Papaya fruit of good quality. It is a very simple matter. The tree can be raised from seed sown during the rainy season; and the plants so raised will yield fruit of good quality the following year. The tree is of very rapid growth. The point to be kept in view is to sow seed obtained from really good fruit ripened on the tree.

It is, of course, well known that natives pluck the fruit in a green state and ripen it artificially. This system is responsible for the absence of flavour and quality so common in the fruit sold in the bazaars. If the readers of *Indian Gardening and Planting* will observe the following directions, every one may grow and gather his or her own Papayas of really good quality.

Firstly, obtain seed of good variety from the Superintendent of the State Gardens, Bangalore. Sow the seed in pots or pans in common garden soil, say in July. As soon as the young plants are about six inches high, transplant them simply into 12 inch pots, filled with a fairly rich soil. When these pots are filled with roots, transfer the plants bodily to ordinary tubs, or the largest sized pots obtainable, filled with good, rich soil. Water them in dry weather and let them grow. If you have sufficient ground, put out the young plants into the open, in rich soil, and water in dry weather. In the following April and May you may gather your fruit and enjoy a really good Papaya. The tree fruits well when grown in tubs or large pots. In order to get fruits of large size, it is necessary to thin them out, and so give them a chance of swelling and developing.

The reason why I have recommended the procuring of seed from Bangalore is that it is the best variety of Papaya I have yet seen.

There is one point, however, which the grower must make himself acquainted with. The Papaya tree carries the male and female on separate trees. The male tree bears its flowers in large loose bunches which hang down, and the stems on which the flowers are borne are from one to three feet long. The female tree bears stemless flowers, attached close to the main stem or trunk of the tree. Therefore, as soon as the trees show flowers, all the male trees, except one, should be uprooted and thrown away. Some trees bear what botanists call "hermaphrodite" flowers, that is, they carry the two sexes in the same flower. These are no good as fruit bearers and should be treated as males and thrown away unless you wish to grow a plant or two as a curiosity. It is important to bear the foregoing in mind and thus avoid much disappointment. I have often heard my friends say that their Papaya trees never bear fruit, though they are covered with flowers. On looking at them, I have always found the trees to belong to the 'male persuasion.'

If you like the Papaya fruit and wish to get it of good quality follow the foregoing hints. There is no reason why everyone should not have his or her own Papaya trees in pots and tubs if there is no garden or grounds to grow the tree in. The tree fruits in one year from time of sowing the seed, so it is easy enough.

AMATEUR GARDENER.
The Indian Agriculturist.

BUDDED AND SEEDLING ORANGE TREES.

BUDDED ORANGE TREES ARE DYING OUT BY SCORES IN SOME GROVES, WHILE THE GOOD OLD SEEDLINGS IN THE PASTURES GO ON BEARING MERRILY.—LETTER FROM CORRESPONDENT.

Although the practice of using budded citrus trees has become generally adopted in the island, there are still a great many who look askance at the innovation, and remain staunch in their belief that seedlings make the most reliable and best trees. They point to seedling orange trees, self-grown, half wild unattended, uncultivated, which have been bearing steadily as far back, perhaps, as they remember; strong, upstanding, healthy trees proof against scale insects, against drought, or wet, dieback or footrot, blight or beetles. And they compare *such* (note the *such*) seedlings common everywhere in woodland and pasture, with *certain* budded trees in *certain* groves, (note the *certain*) grown from seed, sown in beds, transplanted, and well tended then transplanted to a nursery, budded, kept clean, and then planted out in a grove, where they are kept hoed fairly clean, forked round, limed, perhaps and manured and yet in two or three years, snails and beetles attack the leaves, grubs eat the roots, scale insects infest the whole tree, so that washing and spraying are begun as a necessary part of the cultivation or else the trees die out. Even with all such attention many trees die. This is all apparently plain, as is pointed out by many who do not believe in new fauled things (though the "new" things are often methods as old as the Pyramids), and often the planter of budded trees can only feebly excuse himself to the enthusiastic advocate of things as they were, and seedling trees, by saying he will get a crop in three or four years against the seedling man's seven or eight, and that his will come true while the seedling tree may turn out half-sour.

Now let us bring common sense only to bear on this subject, and leave out all thought of mystery and magic, fads and fancies, theories and tall talk.

The stout seedling tree in the pasture, never cultivated, yet, proof against disease, and always bearing well, has germinated as the fittest of a million seeds deposited on the soil around has grown from thou-

sands that sprang through the soil, has survived of hundreds of young trees that grew up, has alone reached bearing of scores of its companions, has kept on bearing of dozens that bore fruit and afterwards died out. Between this stray tree and the neighbouring strong orange tree, may be a space of 50 or 60 feet, and between, bush of many kinds, a pear, a breadfruit, an ackee, and so on. It invariably happens where there are clumps of seedling trees or two or three close together, that they are infested with parasites and pests of some kind, and are poor trees, only their great grip of the soil np-keeping them. Almost every tree, or plant has its peculiar pests, and as a rule these do not prey indiscriminately upon plants of opposite characteristics so that when there is some inimical scale on an orange tree, and that tree is well separated by other trees from neighbours, there is not much chance of one particular pest, spreading fast or gaining the upper hand, for there is also likely to be some specific enemies preying upon it, enemies that may also be on the other kinds of trees between, ready to intercept it. Or if there does happen to be an indiscriminate pest, there are also sure to be many enemies to prey upon it. It is this mixing up of economic plants in Jamaica, this apparently hopeless muddle of coffee cocoa, orange, breadfruit, pear ackee, bananas, plantains, etc., all through each other that has actually saved the island from the trouble, annoyance and loss through insect pests and diseases, that agriculturists in other lands have suffered and are suffering from. California and Florida suffer heavily from these, and large sums have to be spent yearly in combating them. In Ceylon, where there were miles upon miles of land under coffee alone, planted after plantation adjoining, beautifully planted and well kept, the coffee industry was ruined by a leaf disease, and the planters took to tea and cocoa. Now the cocoa trees have caused serious anxiety through dying out from a widespread and general disease, so that the loss was calculated at 15 to 20 per cent. of the annual crop, and a specialist had to be engaged to make minute investigations into the matter. Here, we have not had, with the exception of sugar and bananas, large stretches planted to one kind of plant alone, an estate after estate adjoining, growing one and the same product. But lately, we have had groves of orange trees set out, row upon row of nothing but orange trees. Hence, as in other orange growing countries, these are excellent nurseries for the specific scale insects and other pests that feed upon citrus plants; and more than that, the various grubs and slugs that lurk in the soil especially about rotten wood, finding every other thing cleared off, have therefore to feed upon what they can get. Even if they had never before touched the roots of orange trees it is certain that necessity, especially through hunger, knows no law, and they would quickly adapt their tastes to what they could get. Hence the troubles of our orange growers, who finds insects of various kinds feeding on their trees, and injuring them, and grubs—the larvæ of various beetles, but particularly the "Fidler" beetles and their larvæ the "makaka" grubs—feeding on the roots of the orange trees. The larvæ formerly found plenty of rotten wood, in some form or other in the ground; now they can find almost nothing but roots of orange trees. If these were entirely strong and healthy they would probably not touch them; but they find some injured, or bruised or diseased from some cause and they immediately find feeding ground. They are probably voracious too, from their numbers and the scarcity of food, and a small abrasion of a root that where enemies were not instantly on the spot to attack, would likely have healed quickly in a healthy tree and in sweet soil, is instantly attacked. So that above and below our orange trees find enemies. But, we should fancy the enemies of these pests should increase proportionately? Yes perhaps if we all knew what these

were; but it so happens, that we ourselves have seen the deadliest enemy of scale insects destroyed as an "ugly red bug," both by picking off and spraying, namely the lady bird beetle, the same insect that Californians hunted the world to get found one kind in, and introduced it from Australia and which saved their orange groves from destruction by the "San Jose Scale," while lately after searching the world through they have found a more voracious species of "Ladybird" in the heart of China. There may be other friends of our trees insects or birds unknown to us, which get scant mercy at our hands. Is not all this worthy of special study and investigation, by an entomologist? I daresay in saving the cost of an entomologist, we are losing one hundred times as much in the time and labour involved, in every man attempting to being his own doctor of his trees and still losing them. We have doctors for men, another branch for horses and cattle, so why not a plant doctor? It is hard to see scores of trees that have just reached bearing age, dying out; but it is just at the stage when the great call is made on the constitution of the tree, that its weakness become apparent, and it cannot stand the strain. The whole trouble, we think can be traced. It is not in the fact of budding or grafting, for the bud is part of another tree and if there is any weakness in its constitution that can only affect the top of the tree, while our most serious trouble is at the roots, and these roots are those of the stock, grown from a seed. It is in fact seedling sour orange trees that are dying out in our groves from root troubles, exactly what the advocates of seedling trees forget. The sweet seedling trees in wood and pasture are subject to exactly the same, and to all diseases that the budded trees in groves suffer from, and every day some are dying out; you can see them diseased and decaying on every estate, only certain of the very fittest almost disease-proof surviving, as we have pointed out, and there is in every cultivated grove always the same thing, certain stout, strong, healthy trees, that cannot be killed. But never having had much, if any money, spent on them, and little or no care, these dead or dying seedlings are not particularly noticed. Still they do not suffer as much from disease of the roots as do budded trees; that is evident; wild self-planted seedlings are diseased above ground, seldom below, while it is the opposite with most of the budded trees the growth of which is so unsatisfactory in many places. Is it not evident from this that there is some fault in the transplanting and in the treatment generally of these grove trees. The fact is, the whole operations from planting the seed in a nursery on, have been bad. The self-sown seedling select themselves by the fittest surviving; but no selection has been made by the planter, as a rule. He has not chosen the sour orange tree that was perfect and free from disease, and well loaded with large fruit; nor has he chosen the plumpest seed from these fruits. We question whether in transplanting the small seedling trees from a bed to a nursery, the treatment has been such as could be calculated to make them strong and vigorous. Both in off nursery beds and in groves—and generally with all our horticultural operations,—the ground has been too quickly and roughly prepared. It is mainly old fallow ground, which is cleared, holes dug, and trees put in all in a week. The soil with this treatment cannot be in condition for tender trees to make growth,—tender, for all transplanted trees are tender, and the soil must be of the sweetest and finest for the cut surfaces to heal and put forth the little feeble roots to take food material, and they consequently get a bad start. But a seedling never interfered with grows slowly and steadily, its tap root is deep down; as it puts forth a fresh root, it is seedling all the time through a hundred others. Our treatment therefore has not been tender enough, has been too rough and ready. When deep planting is added to this, the death of the tree is certain,

What is required is to plant fewer trees, and take more time in all the cultural operations from the beginning, for what does it profit to have ground cleared, holes dug, and 5,000 trees might be looked over that are bound to give trouble and anxiety and loss later, when 1,000 trees very carefully and minutely looked after will probably give as a large a return. There is far more money in 100 trees bearing 1,000 oranges each than in 1,000 trees bearing only 100, and poor ones at that. We also want a special study made to find the most deadly enemies to our greatest pests; what for instance would prey most upon Fidler beetles, and what upon their larvae the oily "makakas?" At present the only enemies to the "makakas" we know are poultry, and young pigs, let loose in the grove, and these rout and scrape these grubs up. If the roots are thoroughly healthy the tops will never likely die off mysteriously. Spraying the foliage and branches for all sorts of diseases is not an unmixed blessing if you kill off the lady birds which are so valiant in our interests. Without healthy roots there can be no healthy tree. The proper preparation of the soil and the careful planting of the young trees are things to be looked upon with respect. To dig a row of holes in raw soils and get any odd worker about the place to stick the trees in up to the bud as fast as the holes were dug was the general style of planting some of these very trees that are now dying out. There is a science in planting trees that may not be learned in a day, however easy it looks—*Journal of the Jamaica Agricultural Society.*

CULTIVATION OF SUN FLOWERS.

The first year of the twentieth century closed with a curious sale, on the Baltic, of a cargo of sunflower seeds, which changed hands at £11 5s. per ton. Though a small trade has been done in sunflower seeds for close on 200 years, this transaction was the first in which a whole cargo—300 tons from Odessa—was dealt with. In Russia, where the cultivation of the sunflower and the manufacture of oil from its seed is conducted on a large scale, the Grandi Flora is the variety grown. The species rises in a slender stalk of 5ft. high, producing one monster head, the average yield being as much as fifty bushels of seed to the acre. So rich is it in oil that that quantity of seed will yield fifty gallons of oil, while the refuse of the seed, after the quantity of oil has been expressed, weighs 1,500 lb. when made into cattle cakes. Few people in England who grow the sunflower for ornaments have any idea of its usefulness. It is among neglected crops in which there is money, as is shown by the price paid a few days ago. Besides the seed, every other portion of the plant can be utilised. The leaves furnish an excellent fodder; while in Russia the stalks are prized as fuel, and their ashes, which contain 10 per cent. of potash, are readily sold to soapmakers. Naturally, in Russia the chief virtue of the sunflower lies in oil contained in its seed. The oil is of a clear pale yellow colour, almost inodorous, and of an agreeable, mild taste, so that it is in great request as a table article. Why sunflowers are not cultivated on an extensive scale in England, it is difficult to say. Poultry and cattle like the seed either in its natural state or crushed and made into cakes. No plant produces such fine honey and wax; when the flower is in bloom the bees abound in it.—*Journal of the Department of Agriculture of Western Australia.*

A LARGE INDIAN MELON.—A very fine fruit of the Indian Melon (*Cucumis Melo var. momordica*) was grown at Government House, Singapore, in sandy soil. It was dark green, mottled with lighter colour, and weighed 16½ lb., with a length of 2 feet 3 inches and a circumference at the broadest end of 1 foot 10 inches. It had not much flavour, but is said to be very wholesome, and is an important article of food in India.—*Gardeners' Chronicle.*

VANILLA GROWING, AND CURING.

[For the following Essay we are indebted to Mr. A. McFarlane, Planter of Tahiti. The work bears the marks of practical experience, and as a record of such will doubtless be welcome to many who are attempting to grow this plant in the West Indies. Mr. McFarlane remarks that after many years practical work he "does not claim to know all about the subject." His modesty is commendable, but it will be patent to most cultivators by a perusal of his Essay, that his knowledge of the methods adopted in successful cultivation, is well worthy of being put on record, for the benefit and instruction of those who have been less favoured in opportunities of obtaining information. —Ed.]

VANILLA.

The Plant Vanilla is produced by a terrestrial, climbing vine, belonging to the Orchid family, having the oddly-shaped flower of its family, and like many of its relatives lacks the power of self-fertilisation. This can be learned from any encyclopædia. Here I learned as a beginner that there was but one variety, and that the reason why Tahiti Vanilla only brought about one quarter the price of the same article grown in Mexico, was in the difference in the soils, the soil of Tahiti containing some deleterious ingredient, which changed the odour. I never could understand this statement, as I knew that the best Mexican Vanilla grows on volcanic soil, and Rennon, which produces a very superior quality, only second to that of Mexico, is of volcanic formation as is also Tahiti. I have since then learned that we have three varieties, all of course imported as Vanilla is not indigenous to any of these islands. "La Vanille"* mentions eight varieties, five of which are indigenous to Mexico. The three varieties which we have, are *Vanilla planifolia*, *V. sylvatica*, and *V. pompona*. This last yields the Tahiti Vanilla, known in Mexico as *V. nilon* and in the English market as *Vanillos*, *V. planifolia*, here yields a bean equal to that grown in Rennon, but is not grown to any appreciable extent, and I only know of a few vines of *V. sylvatica*. Although all of these varieties were imported at the same time, *V. pompona* quickly recommended itself to the Kanaka planter, with the result that the others were discarded and what few plants of them were left were only to be found in some deserted plantation, while *V. pompona* was rapidly distributed over Tahiti and the adjacent islands.

Now, a few plantations of *V. planifolia* have been started, since we have learned its value. To describe the vines as they appear to me (an entirely unscientific description), *V. planifolia* is very distinct, the stems are large, as large as the little finger, and the leaves are short and broad. The vines does not grow as rapidly as do the other two. The bean is long, thin and round, and the blossom end is at a sharp angle to the bean. The blossom end of *V. pompona* is at right angles, or nearly so, to the bean, and there is a decided difference in odour, (a decisive test if beans of the two varieties should happen to be mixed) *V. sylvatica* and *V. pompona* and very similar in habit, with long narrow leaves, of rapid growth, slightly dissimilar in the flowers, but the difference is very marked in the fruit. *V. pompona* has short thick beans which can be left on the vine until they become brown while *V. sylvatica* has a very long bean which splits badly and has to be gathered early, in order to save it. In odour it more nearly approaches *V. planifolia*. The stems of *V. pompona* are only about half as large as those of *V. planifolia* and the joints are longer.

THE PLANTATION.

THE SITE.—It is in the selection of this that the greatest care has to be exercised. From the nature of

* To a valuable little work, published by the French Government in Tahiti (La Vanille, by Dr. A. Delteil), I am indebted for such statements as I have made regarding the culture, methods of curing, etc., pursued in other countries than Tahiti.

the vine it is at once seen that it will not thrive everywhere, although to look at the various plantations in Tahiti one would imagine that the native grower thinks it will. Here it is planted upon every conceivable sort of soil from swamp to sand, and with any tree, shrub, post or rock, that may be most convenient for a support. Of course with such treatment it cannot be expected to yield a good return. I claim that the steep little valleys with which these islands abound, are an ideal home for the vine, and have proved it (at least to my own satisfaction) on my own plantation which is in one of these valleys, and although only about half a mile from the sea and a couple of hundred feet above it, my beans average over an inch longer than those grown close to the beach or on flat undrained soil. Vanilla revels in moisture (but it wants no stagnant water about its roots) and the hill side plantation gives it that. Heavy dews, more or less moisture constantly descending from the hills above, almost obviate the necessity of rain, while the natural drainage keeps the ground always sweet, no matter how heavy or how prolonged a rain may be. The vine also delights to send its roots around and among rocks, probably in search of nutriment and moisture. Of course, the advocates of planting on low level ground have many arguments in their favour such as ease of working, possibility or rather certainty of getting more plants on equal sized pieces of ground and probably of getting a larger weight of beans. These and any other claims which may be advanced I contend are more than balanced by the fact that the Vanilla on the hill sides is, as nearly as possible, its natural condition; that the vine looks stronger and healthier, and should be in better condition to withstand disease and finally, that the beans certainly are no longer, and that the largest beans command the best price. My advice is, eschew level ground, select a piece with a moderate slope for ease of working (as Vanilla does not care how steep the ground may be but the work man does) and let it be if possible in a valley not of too great extent.

After the ground is located, it is necessary to prepare it for planting. There are two ways of starting a plantation. The first is to cut away such of the trees originally growing upon the land as may be necessary, saving such as may be required for shade or to plant the vines upon filling in the gaps with posts. The second is to chop everything off the ground and to plant posts (of such trees as will grow from cuttings) or young tree plants at regular intervals. The second plan gives the prettiest plantation and when once established requires less labour in keeping it in condition, but takes longer in the first place before it brings in any return. Besides the original cost is more. Whatever plan is adopted, never resort to fire as an aid in the clearing. Chop all the trees and branches into small pieces and leave them to rot on the ground as food for the Vanilla.

As to what variety of tree is the best to use as a support, I have tried a number, and have found several that I like, and also some, recommended by others, which I do not like. I would advise trying the trees indigenous to the place where the plantation is to be started as it is certain that some of the native trees would prove suitable. The best tree is one which will grow from "cuttings." That is one the majority of pieces cut from which will grow when planted—posts to be from three to eight inches in diameter and seven or eight feet long. One which is a moderate grower, which takes a good hold of the soil and which does not give too dense a shade. All these requisites I have found in one of our native trees, the botanical name of which, unfortunately, I do not know. The following are recommended in "La Vanille":—*Avanago*, *Acacia Lebeck*, *Pterocarpus indicus*, *Artocarpus integrifolia*, *Eriobotrya japonica*, *Laurus persica*, *Bombax malabaricum*, *Ficus classica* and *indica*, *Jatropha Caracas*, *Draecna tessellata* and *Jatropha Manihot*. The three last are employed in plantations exposed to the sun and without shade, grow rapidly and furnish plenty

of good shade." Of these I have only tried one or two. I have been told that in Fiji, the only plant which will carry the Vanilla through a hurricane is the Croton Oil plant, *Croton tiglium*. I do not like it. Its stems look too much like those of a cabbage and it appears to be short-lived. My favourite trees, besides the native one already mentioned are *Bauhinia purpurea* and *Bixa orellana*. The *bixa* gives the deeper shade of the two. Both grow easily and rapidly from seed and make good supports in from eighteen months to two years after planting. The candle nut tree of these islands also makes a good post.

Six by eight, or eight by eight feet is a good distance to leave between the posts. I have seen them at four foot intervals and also the Vanilla planted on fences or trellises, but the posts at four feet are much too close together and trellises when they begin to rot and fall entail too much labour in the replacing. In fact it is hardly worth while to try and replace Vanilla which has fallen with a post, let alone a wall of it. I have spent hours in replacing posts which have rotted and putting the vines upon the new posts and have never made a satisfactory job of it. Of course it is sometimes necessary in order to save such immature beans as may be on the vine when it falls, but for future use I would prefer to root out the old vine and plant a new one. Here I refer to vines of three or four years' growth which is about the time that trellises and dead wood posts take to rot here. Where wood eating insects are had, only live posts should be used.

While the plantation has been preparing, a stock of vines should have been provided. Here we have no trouble as any quantity is to be had for the cutting but in starting a plantation in a place where no old plantations were "come-at-able" it might be necessary to have recourse to growing them from seed. This I have never tried, but I give the method recommended in "La Vanille." "The seeds are extracted from the bean placed in a cloth and washed many times with strong soap-suds, in order to remove the greasy matter which envelopes them. They are then exposed to the sun until dry and when dry are mixed with fine sand or ashes to separate the grains. They are then sowed in a box on a soil composed of equal parts of humus, sand and fern soil (*terre de scolopendre*) which has been well mixed and passed through a fine sieve. With care in watering and a moderate exposure to the sun it is possible to obtain the young plants." Where a limited number of vines only are to be had, they may be cut into lengths of three or four joints and planted in a bed composed of decayed and partially decayed leaves and leaf mould. By keeping them well matured and shaded, in a couple of months they will have made good roots and can be removed to the plantation. This is preferable to planting small cuttings at once in place. Such plants will not give a crop under two, or two and a half years. The plan followed here is to plant vines of three or four yards in length. These will give a few beans in a year or eighteen months from the time of planting. Some people claim that by using such long vines, the resulting plant is weaker than one produced from short cuttings, but I have not found it so.

At any rate whether a vine of six joints or one of six yards is to be planted the method to be followed is the same. A slanting hole is made about a foot from the post and a couple of inches in depth. Into this the end of the vine is inserted, and the soil pressed tightly around it. The vine is then laid flat on the ground from the hole to the post and tied to the post. The part upon the ground should be of a length of two or three joints. This is thickly covered with rotten and dead leaves and rotten wood, and on top of all one or two stones to keep the vine and its covering in place. While the vine emits roots and its cut end still the strongest roots are sent out at the joints, hence the necessity of covering one or two of these. The best time to plant is at the beginning of the rainy season,

I have seen it seriously stated that a hole two feet deep should be made and the vine planted in that. This I do not recommend, as the Vanilla is essentially a surface feeder, the roots spreading between the soil proper and the layer of decaying matter which covers it. On this account it is not only unnecessary to dig or plough the ground, but I believe positively hurtful. It is on the contrary very necessary to keep the surface covered with decaying vegetable matter, and if the trees supporting and shading the vines do not yield sufficient material, then manuring should be resorted to. That is by applying a coating of rotting material such as the leaves and stumps of bananas, coconut leaves, stable manure, guano, &c. Artificial manure should not be used. Although doubtless much nicer looking I do not like a "clean" plantation. By this I mean one which is kept weeded. I prefer to have mine well covered with weeds of various sorts. These act as a mulch for the surface feeding roots of the vanilla, a very good thing in a dry spell, and the deep rooting varieties are constantly bringing up nourishment from the deeper layers of soil which the roots of the vanilla do not reach, converting it into food (in the shape of their fallen leaves, &c.), which the Vanilla can assimilate and placing it where it will be likely to do most good, thus constantly manuring the vine. *Tradescantias* although surface feeders, act as a mulch, and keeps the ground cool and moist, and where I have seen it, the Vanilla seems to thrive. After the vines are planted all the care that the plantation requires, until the blooming begins, is to keep the growing posts pruned, and in case any of the vines grow too high to turn them down. On short posts and trees of course the Vanilla turns down of its own accord, but on the taller trees it must not be allowed to travel out of reach. The turning down is a most important operation (*Erl. Italics*), and must not be neglected. The plantation should be gone over at least every two months and vines which have reached a height of ten or twelve feet should be carefully loosened from the tree, for the upper half of their length and hung over convenient branches. These hanging vines are the ones which produce the flowers. Hence, the necessity of turning down. *As long as the vine can continue climbing it will not bloom.* Do not let the vine hang nearer than a foot from the ground. Pinch in the end when it has reached that length. The vines have in climbing wrapped their tendrils around their support, and some authorities direct that great care must be exercised in loosening them so that they may not be injured. From this I differ. After the vine is separated from the tree the tendrils have no further work to do and are of no further use to the vine, consequently, when letting down I simply cut them off close to the vine thereby saving time and in many cases the vine also when a tendril is wrapped two or three times around a twig it takes time to remove and often, as the vine is much the more brittle of the two it is broken before the tendril is cleared.

PRUNING.—It is the same with Vanilla as with fruit trees. When they run too much to wood they do not give a full crop of fruit. In consequence rank growing vines have to be kept within bounds with the knife. The plant is also benefited by removing the old vines which have fruited. These may only have given two or three bunches of beans and may still have several buds left on them which might produce flowers, but if cut off close to the top of the post, the plant will replace them with one of the full necessary length by next flowering season, which will give more bloom than the old one would have done and probably produce better beans. For this turning down and pruning a small portable step ladder is useful.

FERTILISING.

Here *V. pompona* gives two crops of flowers in the year, and occasionally a few flowers at other seasons. The main or largest flowering season begins

about the first or middle of July and lasts until September. The second begins usually in January and runs through February into March. This flowering gives the longest bears. This is doubtless owing to the fact that the July bloom comes in mid-winter and the cold checks the growth of the bean. In Tubuai, one of the Austral Group, four hundred miles south of these islands and where a limited quantity of Vanilla is grown, the July crop is frequently a failure, a succession of Southerly winds causing the flowers to drop from the vine.

V. planifolia blooms only once, the season lasting from September, through October and into November.

During the height of the blooming season, the planter must procure extra labour, as the flowers remain open but one day, and all have to be fertilised on that day. Here we principally employ women and girls as they are more nimble-fingered and quicker than men. The flowers are very erratic in their opening. Some days the bunches may have two or three flowers open and the work people will be taxed to finish by three p. m., at which time the flowers begin to close. Upon another day there will be but a scattering of bloom, and the day's work will be ended by ten or eleven a.m.

The following record of my last flowering will give some idea of this variation:—

Jan.	24	540	Feb. 7	Rain	Feb. 21	12,500
"	25	520	" 8*	300	" 22	6,940
"	27	1,080	" 10	2,320	" 24	14,740

					" 7	1,280

On the days marked with a star, worked was stopped by rain. February 3 was a most remarkable day as there were absolutely no flowers open upon any of the plantations in this neighbourhood.

Many statements are extant regarding the number of flowers that a single individual can fertilise in a day.* These range all the way from one to six thousand. This last figure is regarded as quite fallacious as it is not considered possible that it can be reached. Experience teaches that a quick worker with vines growing close together and in heavy bloom, can fertilise three thousand in the day, but I think that is about the limit. Two thousand three hundred is my best day's work, and it meant a hard day. From fifteen hundred to two thousand is a good average.†

The operation is simplicity itself and can be learned in five minutes if one has the opportunity of watching one who already knows how. To explain it in writing is more difficult. In the first place the only tool required is a small pointed stick, similar in size and shape to a wooden toothpick. This can be made of almost anything in the shape of wood, and is so made by the Kuakas. The best however is either a silver of bamboo, or the mid-rib of a coconut leaflet, sharpened at both ends (this simply for convenience as then it does not matter which end is uppermost in the hand). We make half a dozen in advance and carry them stuck in our hats and if one is dropped, no time is lost in looking for it, but another pulled out of the hat. As to the operation itself. Holding the flower in the left hand; the "petticoat" or lip is stripped down, exposing the column, the top of which is then held between the finger and thumb. The point of the operating

stick is now drawn upward, raising the cover of the stigma and the anther, which by a gentle pressure of the finger and thumb holding the column are kept open, while with the point of the stick the pollen mass is removed from the anther and placed under the cover of the stigma. The pressure of the fingers being removed this flies back into place and holds the pollen securely and the flower is fertilised. By this method the operator sees that the mass of pollen reaches the stigma. Another method which is slightly more rapid is the following: A very thin stick is used. Instead of using the point the side is made use of. With this, the cover of the stigma is raised and pressed flat against the column under the anther, which is then pressed downward by the thumb and by this pressure the pollen mass is transferred to the stigma. My objection to this method (I won't allow it to be used on my flowers) is that the operator does not see the pollen enter the opening of the stigma. It ought to and in most cases does, but sometimes fails to remain and the flower is lost. With the other method every part of the operation is visible and there is no possibility of making a mistake. The difference in rapidity is but slight and is more than made up by the certainty of the first method. It requires but a very slight touch to disengage the pollen mass from the anther, and it adheres to the stick not one in a hundred falling. When placed on the stigma it at once leaves the stick as there is an adhesive substance which retains it. The planter who has several work-people fertilising his flowers will do well to occasionally examine flowers which have been finished, in order to see that the pollen has been placed upon the stigma. It has frequently happened here that, when a woman has been behind or is in a hurry to finish, she simply breaks the "petticoat" and goes on, leaving the flower unfertile, although to outward appearance properly finished.

The flower is upon the end of a slim round stem, usually about two inches long. This is the bean in embryo, and is upright while the flower is open, but upon the following day is found to have bent over and to be hanging down. By the second or third day there is no mistaking the flowers which have taken. If the operation is carefully performed, very few fail. The bean in the meantime will have grown sensibly longer, and the petals have withered about the column. In the case of an unfertilised flower, the column falls off together with the faded flower. The column remains attached to the growing bean until it is nearly ripe, that is for seven or eight months. There are, however, exceptions. Flowers fertilised late in the day, say after three o'clock or when they have begun to close, will still take, but I am of opinion that they are responsible for a number of the beans, the columns of which have fallen off. Sometimes a bean has only grown two or three inches long when its column falls off. This appears to have an evil effect upon the future growth, for while the bean continues on the vine and eventually ripens with the others, it is always short. I have never yet seen a long bean which had lost its column early in its growth. There may be a spell of rainy weather just when the vines are in bloom. A little rain makes no difference, but a heavy downpour of half an hour or more causes the pollen to run, an instead of a dry mass put upon the stigma, it is a kind of yellow soup. These or some of these beans take, but the softened pollen masses have not apparently given them the necessary amount of vitality to carry them to full growth and the column drops off. In fact it indicates partial fertilisation.

From the time the flower is fertilised the bean grows very rapidly, attaining its full length in about three months. Thus upon one bunch the first bean may have attained a length of four or five inches before the last flower blooms. This is the time to see that they grow in the way they should go. In turning from the upright position of the flower

* Taking the day as eight hours, viz., from seven a.m. to three p.m.

† In the height of the season we breakfast when the flowers are finished.

to the pendant one of the growing bean, the bean often turns over a branch or leaf or the withering flower sticks to something thus preventing the bean from hanging straight. This makes a crooked bean and crooked beans invariably lead to crooked language on the part of the curer, when he has to tie them into bundles. Unless taken in hand young there is no hope straightening these crooked ones, so each bunch should be looked over several times during the fertilising season and the beans arranged so that they can grow straight.

The flowering shoots appear at the axils of the leaves, and on each of these shoots are from five to twenty five flowers.* Authorities differ as to the number of flowers which should be fertilised but I think all are of the opinion that some of the last flowers should be removed. Here the planter must use his own judgement. While one vine may be able to carry ten beans to a bunch, another might have difficulty in carrying three. No hard and fast rule should be set. In my practice with *V. pompona* I fertilise from eight to fifteen flowers on a bunch and latter reduce them to anywhere from six to twelve beans by removing the shortest beans. I like to have about one fifth more flowers fertilise than I intend to have beans just for this purpose of selection. *V. Planifolia* should have fewer beans left, never more than eight to a bunch. In our market all beans are bought at one price, so it is not very necessary for the grower to be very particular in cutting the short ones. Had I to sell my beans in a market where an increased price was paid for the longest beans, I would leave yet fewer on the vines than I have recommended. - *Trinidad Bulletin for August.*

(To be continued.)

GERMAN SOUTH WEST AFRICA. NATIVE VEGETATION.

I am sending you a small bag containing seeds of the so-called Caffir Water-Melon, a variety of *Citrullus vulgaris*, largely grown by the Hereros in Okahandya, and many other places in Hereroland. [Sent to Chiswick, En.]. The whites do not cultivate it. Whilst I was there, two months ago, no Water-Melons were to be bought; the Caffir Water-Melon being very late, it is but now beginning to ripen. Caffir Water-Melons can be found in the native gardens of Okahandya in various forms, differing in shape, colour and weight, but I believe not in the seeds, the colour of these being always red, but never black or white, at least I saw red ones only. You will find the seeds rather larger than those of our sweet varieties. The weight of Caffir Melons of all the three or four varieties is generally 6 to 10 kilograms. The flesh is very solid, and when not fully ripe and still tender, it may well be used instead of Cucumber, which is not easy to cultivate; the female flowers are generally fertilised by a fly. The ripe fruits remain hard, and are not sweet, but they may be kept four months in a dry room without rotting. The Hereros slice them, and dry the slices in the sun for winter provision. As required, the dry slices are boiled with water to a soup.

In the dry east wind sandy region (Onamek) which forms part of the Kalchahi, there grows in many places in masses, the so-called "Sweet Dachammas" the common or bitter Dachammas is *Citrullus vulgaris*, the ancestor of our sweet Water-Melons, which is not at all sweet, but is at any rate perfectly free from clovequint flavour, as is the cultivated Caffir Melon. That waterless area is in some parts habitable for men and oxen only, owing to the presence of the sweet Dachammas." The Caffir Water Melon requiring no cultivation, might advantageously be naturalised in waterless, desert regions, as for instance, along the Southern Algerian *wadis* (our rivers), Egypt, S. California, and West and Central Australia.

* Often 30 to 40.—(Ed.)

Okahandya is doubtless the most promising place for horticulture in the central part of our colony. Broad meadows, consisting exclusively of *Cynodon dactylon* grass, edge the Okahandya river, interspersed with welcome groups of *Acacia hebeclada*, and sometimes of *Acacia spirocarpodes*; 1.50 to 2m. below the thick, grassy carpet, the water percolates in quantities, and is of the purest quality. The alluvial soil below the grass (to extract which is a rather expensive work, the long stolons being as tough as wire) is a highly fertile clayey sand.

The cultivation of Tobacco is increasing in a very satisfactory manner. For sowing Tobacco, clay pots 4 to 5 inches in diameter are now used; formerly the seed was sown broadcast in beds, and the seedlings were planted out without balls of earth, so that they flagged for three weeks, in spite of small huts covering them against the burning sun; they are now planted in any weather, when of the proper size, and with a large ball of earth. Planted in this condition, and at once watered they do not flag for a single hour, but continue to grow uninterruptedly.

Although pots obtained from Germany are rather expensive here, this method of raising Tobacco is unquestionably to be preferred to all other ways. Every plant, once in the plantation, grows, and there are no dead plants to be replaced; the expensive building of huts made of grass, dry dung, &c., over each transplanted seedling is obviated, and the planting from pots can be effected even by careless natives. This planting out from pots may be strongly recommended to Coffee-planters for these reasons as well as to foresters for any kind of evergreen tree even in the driest tropical places, where the seeds are not sown directly in their final position; thus one transplanting is avoided. For this purpose, pots of firm cardboard, which Schmidt & Co., Elberfeld, have introduced, may be used with great advantage. They are to be had in several sizes, and very cheaply and they do not break as do clay pots: the carriage also is inexpensive (2,000 pots of 7 centimetres, price per mile 18 marks, make only nine post-parcels of 5 kilograms each). These pots last until the trees reared in them are large enough to be planted out. It is true a clay pot lasts for three or four years on an average when carefully handled, but the price for 5,000 such pots of 7 centimetres, costing at Erfurt about 75 marks, is here, in the interior, about 400 marks. To return to my account of the Tobacco: the fermenting is now done here in a proper manner, the leaves are first partly dried, then sprinkled with water, and then fermented: or they are fermented green as they come from the plantation.

The latest plan, which is carried out by one firm is, that the quite fresh leaves are cut with the tobacco-cutting machine, and put into large heaps. Such heaps get warm very quickly, and they are then turned over inside out in a few minutes, whilst the same quantity of leaves would require the labour of one man for half a day. The product is very uniform as regards colour, which is almost black. All the Tobacco cultivated in the country is for local consumption as good cigar tobaccos cannot apparently be cultivated here, the weed being too rich in nicotine. At this moment only American varieties are cultivated, very seldom *N. rustica*. Although in Okahandya in winter as much as 40° C. and even more is often experienced, the place being over 1,000 metres above the sea level, and on the borders of a river from 600 to 800 metres broad, highly radiating, unhindered, the sunshine absorbed in the daytime.

Banana cultivation is found possible and steadily increasing; and it is not that of the wild small kinds like *M. Cavendishi*, but one of the medium-sized forms, which are so extensively cultivated in the Canaries. I am convinced, that under proper cultivation Bananas would yield remunerative crops at Okahandya and in many other places situated north of this village, not for export, but for home consumption. There are, even at Windhoek, several gardens where

the same Panama flourishes splendidly and ripens fruit. Windhoek, is situated 1,660 metres above the sea. Near Okabandya there is a tannery where tanning material, the pounded rhizomes of *Hydnora africana*? are exclusively used with the most satisfactory result. The *Hydnora* grows there in quantities already diminishing on the roots of *Acacia horrida*. In Gibeon Namaland, there is another tannery, where *Elephan orrhisa* Burchelli only is used.

I have not found in the *Gardeners' Chronicle* any articles about forestry in the inner parts of Cape Colony, the Transvaal and Orange River Colony. Can you not induce some experienced forester there to write a series of articles about forestry in those parts especially about Eucalyptus planting. It would be indispensable to state the average rainfall, temperature, &c. Thus the statements would serve as a guide for foresters in regions with similar climates. Is there any book on this subject?—DINTER.—*Gardeners' Chronicle*.

PLANTING RUBBER SEED.

To the Editor of THE INDIA-RUBBER JOURNAL.

In my last article I promised a letter explaining our method of "Planting Rubber-seed at Stake." For the best results the ground should be well burnt over; all trees, after felling, should be "well lopped"—i.e., the branches should be cut from the trees so that they all lie flat on the ground, so as to ensure a first-class burn; everything that will burn should be consumed, and only the largest trunks of trees left. There may be quite a number of cedar as well as mahogany trees, and other hard woods of value. The fire does these very little harm, and they may be sawed up later with a whip-saw, or if the owner can afford it a small saw-mill, either for sale or for building purposes, on the plantation.

After the burning is over staking and lining is done, and stakes put in at whatever distance may be decided upon; but here let me give a word of caution. Put in hard wood stakes that will not rot for at least two years. These stakes serve to show the weeders where the little plants are, and so save them from being cut down with the weeds for at least the first and second weeding. Should the seed not germinate, there is the mark to show just where the supply should be put.

I put two or more seeds at each stake, always in front and rear—as the lines run. Never allow them to be put on the sides of the stake, as this would make a very crooked line but you can see that by planting seed in front and rear—while the plants will be a few inches nearer or further—they will be in a straight line. I open the soil the width of the hoe and about 1 in. deep, two men can do this work to the best advantage, one in front opening the holes, the other closing after dropping the seed and covering them with the soil dug out by his partner, knocking the same back with his foot. In this way they can plant about two acres a day.

Some years this mode of planting rubber does well; at other seasons it is a complete failure. Last year with us it was a complete success. Thousands of our trees planted on July 4th 1901, measured 4 in. to 8 in. in circumference on October 15th this year, while a few measured 12 in. We have planted corn with our stake-planted rubber this season, and have a very fine crop I should say about forty bushels to the acre.

Our rubber this year has been planted 9ft. by 9ft., with two rows of corn between. No doubt it will be interesting to your readers to learn how the Indians plant corn: They take a long stake say about 6 ft., point it at one end, then stick it into the ground about 4 in., throw in three to four grains of corn into each hole, and the corn is planted. No earth is thrown in. Ours was planted in this manner, with the result that we get about 40 bushels to the acre. No weeding is done after the corn is sown till it is saved. When I first saw corn planted in this manner I said, "What fools these mortals be!"

We have a gentleman with us now who saw one my letters in the *India-rubber Journal* when he was twenty-five days' journey up the Amazon River. While they have more rubber trees there, he says they are fast dying out from greed in tapping; but for cultivating rubber, he considers the isthmus of Tehuantepec far superior to the Upper Amazon country.

I have received quite a large number of letters since writing these notes in the *Journal* about lands in Mexico for rubber and other tropical crops. To one and all I would say, "Come and see for yourself." There are new railroads being opened up from Vera Cruz, South, down into the very heart of the Tropics, and land will be going up in price. I have none for sale; I am simply a planter. If intending purchasers cannot come themselves, get some of your countrymen to do the inspecting for you. Good land near railroads can be had just now in 1,000 acre lots at 2½s. to 25s. per acre, and much cheaper as you get away from transportation facilities; but remember, the purchase price is paid but once, while transportation charges have to be paid as long as the property is productive. I think we have solved the question of the expenses in coffee cultivation on this plantation; after this no more land will be cleared for coffee; all land will be planted for rubber, and two years after, coffee will be planted under the rubber; then while you are cultivating rubber, why, the coffee is cleared for nothing, and, if coffee will not pay in this way the sooner we know it the better for all concerned. I see in some East India papers that coffee planters there are going to cultivate their coffee after the Brazil method. They are to send a delegation out there to look into the *Brazil modus operandi* in cultivation, to find out how they make coffee pay when it sells the lowest of any, and pay just ten times more for labour than the East India planter. I would advise them to try rubber where they are not too high up, but I feel certain rubber will not pay at high altitudes.

Where rubber is planted by itself, after three years it can be turned into a cattle pasture, and cattle-rearing pays well here in South Mexico; hundreds are shipped to Cuba every month but no doubt, sugar-planting is one of the best paying industries on the isthmus. Mexico consumes more sugar than is made in the Republic and a very large import duty is imposed on all imports that come in competition with any agricultural product that can be produced in the country.

I would like to see other tropical economical plants introduced such as nutmegs, cloves, cola, as all these could be cultivated with the rubber plant and, after the cost of planting is met the cultivating part—which is of course the heaviest—would be done as the rubber is cleared. I trust to be able to call on the Editor after the middle of December.

JAMES MAUNDER.

[*Editorial Note*.—Since writing this letter Mr. Maunder has paid *The India-Rubber Journal* a visit, bringing with him some extremely fine specimens. Particularly of interest were two samples of corn grown among the rubber which we have seldom seen anything to beat. By the time this has appeared in type Mr. Maunder will have left these shores. He is extremely well informed on rubber cultivation, takes a very great interest in everything concerning it and is enthusiastic concerning the certainty of the future success of rubber plantation.]—*India-rubber Journal*, Dec. 22.

THE TOBACCO AND PALM INDUSTRIES OF SOUTH CHINA.

There are few objects more attractive to the eye than tobacco fields and palm groves in full bloom. They flourish very luxuriantly in the rich soil of which the delta of the Canton River is composed. No doubt, the vast corn-fields of Canada and the extensive fruit orchards of California are more magnificent, but the deep dark green of tobacco and palm fields are full of beauty.

Tobacco has been cultivated in the district around the San Ui city for many decades. It is stated that during recent years, however, the average under cultivation has considerably increased. The assigned reason is that the farmer can command a larger financial return than from any other crop, and, as Tonquin rice is now imported, he can venture to depart from the time-honoured custom of growing, on his little plot, sufficient rice to support his own family. The young tobacco shoot is transplanted from its seed-bed in January, and rapidly springs into a straggling plant provided the soil is suitable and the manure liberal. It is planted on ridges, and, in the ditches between these, water flows plentifully. In April or May the lower leaves, being dark and juicy, are carefully plucked, for the Chinese gather them as they gather their mulberry leaves, as they mature, whilst the immature leaves are left to ripen. About three thousand plants are planted in a plot equivalent to an English acre. When the leaves are picked the imperfect ones are discarded—theoretically—and the drying process begins. A piece of bamboo wicker-work, about six feet by five, is laid upon the ground, and covered with leaves carefully flattened out. Another layer of bamboo is placed upon them, and the two are fastened together. By this simple method, the leaves cannot curl up, and they can easily be moved from place to place. After a week's exposure to the hot sun, the leaves are quite dry, and ready for export. Those who have charge of the drying have a very responsible task, for, as we know, at this season rain often falls, and very little water will spoil the leaves. When they have been dried, they are packed in bales of 30 lb. weight, and shipped to Canton and Hongkong. It is reported that a large quantity is sent to Yunnan. Some, too, is exported to foreign countries.

One Chinese acre will produce about 830 worth of leaf. Tobacco demands a rich soil and plenty of manure, and even then is not satisfied, for it leaves the soil poorer than it found it, and consequently the farmer cannot cultivate it in the same plot two successive seasons without courting failure.

What the leaf would be if prepared for Europeans, according to Western methods, is perhaps difficult to say, for though a little of it is now made into cheap cigars in Canton, for native use, the bulk of it is prepared to suit the Chinese taste, and is so steeped and saturated with native oils that no foreigner, however seasoned by Manilas, can attempt to smoke it, and few can endure the smell of the smoke without an internal revolt.

One has often wondered why some enterprising capitalist has not attempted a cigar factory in Hongkong. One would think that, good tobacco being available over the way, such an industry would have been tempting and remunerative.

When we stand and admire the palms that decorate the verandahs and gardens of our Hongkong houses, we do not perhaps consider the important part these plants play in the economic life of the Chinese. Nor can we adequately imagine the fine natural scene that a plantation of these palms present. They grow so thickly that the tufted tops meet each other, and when the wind passeth over them there is, between earth and heaven, a glorious undulation of 'living green.' A Chinese acre, one-third of its English equivalent, will support about four hundred of these plants. If the reader can imagine twelve hundred of these growing in an English acre, each encircled with a beautiful green crown, his picture is correct. These palm plantations are, like the tobacco gardens, planted in the very richest and deepest alluvial soil of these deposits, for it is found that in the long run this pays best. The young plant begins to bear marketable leaves about five years after planting, and will continue to do so under favourable conditions, for thirty or forty years. As a matter of fact, however, these plantations never fail, for young plants are set among the older ones long before age renders these latter useless, and when these fall, they lie and die and so

form nonnishment for the young life surrounding them. The leaves of a healthy tree in the full vigour of life may be cut three times a year, but the rule is two harvests, and yearly growth about twenty leaves. The labour involved in preparing these leaves for their respective uses is very considerable, and thousands of hands are employed at the industry. The labour of cutting these leaves and bringing them into the city is not very difficult, for canals make transit easy. They are then dried in the sun, and afterwards stacked as corn is stacked at home, and will then retain their freshness for years.

A large number of these leaves are manufactured into fans. First their ragged fringes are clipped off, then they are passed over a flaming fire in order that the crooked ones may be straightened; after this, they are passed into the homes of the people, where women and girls hem their edges, and so they make a cheap and effective fan, the stem, of course, being the handle.

The trade in these palm-leaf fans is very great, and Chinese merchants are constantly shipping large quantities of them to their *confines* abroad, especially to those who have made their home in the Straits Settlements. And, verily, they are a great boon to the poor, for the coolie—even though he be an opium smoker—is not too poor to obtain one, and not forgetful of the comfort he gets from one. They are strong; they are cheap; they are as effective as the most costly in the hands of the rich. There are many other uses to which these leaves are put, and the Chinese could almost as well spare their bamboo, as their palm, but enough has been said to give a general outline of this industry.—*Overland China Mail.*

CEYLON TEA IN AMERICA.

IMPORTANT ALLEGATION REGARDING RE-COLOURED

CEYLON TEAS.

(By T. Gossupp, of New York.)

It may be of interest to many of the planters of India and Ceylon to know a certain amount of actual facts about the American tea trade without being puzzled by a lot of figures.

In the first place, Ceylon teas are coming rapidly into favour here, and without doubt Ceylon green teas are slowly replacing Japan teas. Unfortunately, however, the Ceylon green teas are offering at rather higher prices than the buyers of sun-dried Japan are accustomed to pay, except for Japan sun-dried teas of really fine liquors.

Your writers may not be aware that there are three classes of Japan teas sold here, the "sun-dried" being similar to our uncoloured Ceylon greens but of much better make, having a darker colour and of rather more delicate flavour in the cup. Then there is the "pan-fired" Japan which is similar to a coloured Ceylon green, but the basket-fired Japan, to my mind as a tea expert, is far superior to anything I have seen with the exception of perhaps one invoice of Ceylon greens which came, I believe, from Bloomfield estate, but which was only a very small parcel.

I advocated some time ago that the Ceylon planters, in order to cope with the over-production of tea (from which they have been suffering) should endeavour to make an "Oolong" tea similar in flavour and style to the Formosa Oolongs which are in general use here. It would be very easy for any of your planters to write to Formosa or to Japan and get samples from these two countries in order that they may see from an actual sample the kind of tea which is wanted in America. The price of Oolongs to-day is 10d. per lb. c-i-f. N. Y.

To take the United States first, it is necessary to remember that it is about 73 times as large as Great Britain and has a population of 76,000,000 people as against Great Britain's 40,000,000 so that you see we can once induce the Americans to become tea

drinkers on the same scale as the British people generally, or even, say, they take three lb. of tea per head, in a very few years to come we shall have no fear of over production, as America alone will be able to take nearly all the output of Italian and Ceylon. It is therefore, a field we have to consider and during the last few months (when Japan teas have been very high), we had a chance of getting Ceylon green teas into favour, but the prices held out for by the planter or merchant in Colombo, has prevented them from being more readily taken.

The grades wanted here are Hyson No. 1 and Hyson No. 2, and for these people are willing to pay from 6½d to 7d. for the Hyson No. 1 and about 5½d to 6d. for the Hyson No. 2. The Young Hyson grade is generally coloured in New York, which can be done for ½d., per lb. and it is then sold as China Green tea.

A great many of the Ceylon greens sold in the States are coloured, repacked and either sold as coloured Japans or as 'china green teas, being packed in China packages and faced with the usual paper exactly, to represent them as China or Japan teas.

With regard to Canada; this country is different as there is a large population who have now become accustomed to Ceylon uncoloured greens, and the loyalty that exists in Canada prompts the consumer to support British tea in preference to Japan tea. Here again the question of price comes in and the only way that Ceylon greens can contest China and Japan is by selling them at reasonable prices, as the grocer will always push the teas that show him the largest profit.

The labour in Ceylon and India is cheaper than in Japan, so one would think that the planters would have a great deal in their favour. The duty of 10 cents per lb., which was a war tax, is to be repealed on the 1st January, 1903, and it is anticipated that a much larger trade will be done.

Some of the favourite grades here are the Norwood, Labnakkelle, Coudegalla, Meeriab-dille, Warwick and similar liquoring teas, so this will guide many of the planters (who are in these districts where this class of tea can be made), to get samples and follow them very carefully and closely, as there is a regular demand for the light liquoring, flavony, good quality (so called lemon flavoured) Ceylon teas.

If a few of the estates shipping desirable and suitable teas for the American market were to create a demand here by shipping direct, they would find that in a very short time the venture would pay as the writer has seen tea sold here 2l. and 3d. per lb. above the price that they sold for in the London auction.

There are other matters I could write about in connection with the tea planters of Ceylon and India, the tea cess, the packages that are required for this market, the question of shipment, and several other matters which I will touch upon in my next letter. —Local "Times"

IMPROVING JAFFNA TOBACCO.

Mr. Gibson's ideas as to the destination of his cured leaf is to send the samples of necessary weight to the various European markets he has decided upon, but the bulk he considers should be made into cigars. The present country-made cigars are mostly of a very rauln nature; and he believes there is an increasing market to be built up amongst the many Ceylon-born lawyers, doctors, clerks, and the money-d classes in the island, who are beginning to get tired of the black, dirty Jaffna cheroot so long in use. They would, he thinks, purchase cigars of better-cured tobacco at an increased price. As to his future intentions, Mr. Gibson is most

anxious to go on. His faith in the capacity of the island to turn out good tobacco is unbounded, and he is hopeful that the result of the present experiment will make Europeans who are in this island and many others anxious to give his experiment a much extended trial. Jaffna methods of cultivation in small gardens will not, however, satisfy his requirements, and the system of watering the tobacco carried out by each small cultivator would never suit a large property. His idea is that some of the excellent land lying near the Karachi tank could be very successfully utilised. Since he has been in Jaffna Mr. Gibson has not been passive in the matter of the grant of land, which Government led him to believe may be given to him. He has applied more than once to Government to get the matter on a more assured basis; but the absence of H. E. Sir West Ridgeway from the island has, doubtless, been the cause of his making no progress. We trust everything he has been led to expect in this connection will be accorded to him, for the opportunity to test such an important new product as tobacco is one which may not occur again for a long time, should Mr. Gibson be illiberally treated. It was suggested to him in one of these communications that he should wait until the experiment was a success before a definite answer could be expected; but we submit that this is scarcely the way to look at Mr. Gibson's effort, for experiments are not always successful at the first start, and it must be remembered that Mr. Gibson is working in, to him, an entirely new country. We understand that the Ceylon leaf according to Mr. Gibson's idea, will not clash, for instance, with Sumatra grown tobacco which is so excellent for covers in the great markets. The jet of tobacco which is produced in Jaffna is more useful for filling than for being used as outside covers for cigars. It is a tobacco with a flavour and that is the desideratum. As a pipe tobacco the Jaffna leaf will it is also believed, be well received.—Local "Times."

COFFEE CULTURE IN QUEENSLAND

(From Report Mr. Newport the Instructor).

Sir,—I have the honour to submit my report 1900 1901:—The past year has, on the whole, being a fairly good one for coffee. The crops throughout the colony have been fairly good, in several localities averaging well over 10 cwt. to the acre. A somewhat onious though not very serious effect of the long dry season was noticed this year in the parchment skin, or putamen, being thinner than is usual. The crops in this past season have, in direct consequence of pruning and cultivation, ripened up much more uniformly. Labour for picking has been, on the larger estates, somewhat of a difficulty, except to a few exceptionally situated ones. In the North where aboriginal labour was available, use was made of it, but picking by contract by white men, women, and children, has been much more general. Rates for picking have varied from 2 to 3 lb. of cherry, 1d.; and wages of 30s. and over per week with rations have been made. New machinery, both for drying and pulping, has been erected and put in use this year, for the first time by a number of growers in all districts; others have replaced, by good machines, their rough-and-ready or home-made apparatus. Stores and drying sheds have also been built and more use made generally of time and labour saving appliances, the building of a very mill, replete with modern machinery, by Messrs. De Molyns and Butter, of the Lower Russell being a noticeable instance. Crops have in most instances been locally bought up this year, and a few growers, not having pulping machines of their own, disposed of their crop to their neighbours, who have generally purchased it outright at rates varying from 1d. to 1½d. per lb. in the cherry. No coffee this year has been sent to the London market, due mainly to the fact

that fairly good prices have been obtained in Queensland for the higher grades, and of the medium qualities there has not been sufficient to ship a consignment large enough to make its export to so distant a market worth while.—*Annual Report of the Department of Agriculture.*

PLANTING NOTES.

A CANADIAN NOTE.—A good project is now afoot for extending Railway communication from Ontario to the Pacific coast of British Columbia. The length to the projected railway is 3,000 miles, and trade with the Far East will thus be greatly facilitated and encouraged. Canada has vast stores of horticultural and agricultural produce to dispose of, as well as valuable minerals, and it says much for the pluck and determination of our Canadian brethren, that to look at it one way—they have designed a "fall" with the combines of the United States with such admirable "play."—*Gardeners' Chronicle.*

GUAVAS.—In the *Report of the Agricultural Experiment Station of the University of California*, part 1, published in 1902, we find an article by Mr. J. Burt Davy on the cultivated Guavas, and their botanical differences. Our colonial brethren will do well to consult this article. The cultivated species referred to are: 1 *Psidium guajava*, with three varieties, sapidissimum, pyriferrum, and pomiferum; 2 *P. polycarpon*; 3, *P. araca*; 4 *P. guianense*; 5, *P. Cattleyanum*, the Strawberry-Guava, with a variety lucidum. Other less known species are mentioned by name. The distinguishing characteristics lie in the four angled, two angled, or cylindrical stems, as well as in the form and colour of the fruit.—*Ibid.*

UTILIZATION OF HOME PRODUCTS.—Dr. Morris, who is exerting his energies so laudably in the promotion of applied botany in the West Indies, points out in the *Agricultural News* (Barbados) that in the days when sugar-growing was very profitable, everything was sacrificed to make way for the planting of Sugar-canes. Then sugar sold for £20, or even £30 a ton; now it is only worth as many dollars; nevertheless, enormous amounts of food-stuff, and other articles are imported, a great part of which could and should be produced locally. The high value of molasses as a feeding-stuff for horses is pointed out, and yet molasses are sold at very low rates in the Islands whilst thousands of bushels of high-priced Oats and corns are annually imported from the United States.—*Ibid.*

FRENCH COLONIAL SCHOOLS.—It is a pleasant duty to have to record the appointment of another Kewite to a post of importance. In this instance the fortunate individual is Mr. H. Navel, who after having been educated at the National School of Horticulture at Versailles, and having stayed at Whiteley's nurseries long enough to learn the English language, made a stay of twelve months at the Royal Gardens, Kew. He then returned to Franco, and after spending some months in the "Jardin Colonial" of Vincennes, under the direction of M. J. Dąbowski, has recently been appointed *Directeur des Cultures de l'Institut Colonial de Nantes*, a post lately created by the French Government for the development of the instruction and also for the rearing of economic plants useful to intending planters in the French colonies. Our best wishes to the new director who, during part of his stay in England, occupied the position of Vice-President of that useful institution the Société Française d'Horticulture de Londres, which has done so much during the last twelve years on behalf of the young French gardeners who have resided in this country, and the few English gardeners who have sought its help and support to procure for them suitable situations on the continent. It is a society to which every English gardener, having even a small knowledge of French, might well belong.—*Ibid.*

FOOD OF PLANTS.—M. Laurent in a recent number of the *Comptes Rendus* shows that glucose, saccharose, and other sugars, as well as glycérine supply excellent food for plants, and that humic acid in the form of humate of potassium modifies those interchanges of gases which lead to the assimilation of carbon in the plants. On reading this, one wonders whether refuse sugar-canes, from which all the sugar cannot be extracted, would be serviceable as manures.—*Ibid.*

THE RUBBER INDUSTRY.—In Ceylon, and in the Straits Settlements, large plantations of Para rubber (*Hevea brasiliensis*) have been made by private enterprise. The Government of India now propose to plant 10,000 acres in Burmah with the same tree, a proceeding viewed with dismay by the private growers in the colonies aforesaid. The Secretary for the Colonies has been memorialised on the subject, but the demand for rubber is so great that it is hardly likely that steps will be taken to limit the output in any way.—*Ibid.*

KEEPING BIRDS OUT OF FRUIT TREES.—The birds of Ceylon must have different ideas of the value of material objects from those entertained by our Queensland felons in feathers, the fruit-eaters. In our February issue we described a plan for obstructing their nefarious proceedings by means of looking glasses, as given by the *Ceylon Tropical Agriculturist*. A correspondent from Georgetown, Etheledge, not, writes to say that he has found looking glasses to be a complete failure. The bower birds simply danced round them with delight, and one even tried to carry off a bit of the broken glass. Our informant bought a dozen of cracked mirrors and hung them by strings from sticks stuck in the ground and on the branches. It appeared, however, that the birds were rather attracted than repelled by the glitter of the mirrors. Those who know the habits of the bower bird will not be surprised at that dancing dervish amongst birds trying to run away with the glass for they seize on anything shining, as well as shells, to scatter round their bowers, which are often 'halls of dazzling light.'—*Queensland Agricultural Journal.*

EDUCATION IN THE NETHERLANDS.—There has just been issued, through the King's printers (Eyre & Spottiswoode, West Harding St., E. C., price 5), what may be termed a supplementary report on the system of education established in the Netherlands, the result of enquiries by a commissioner sent over for the purpose of gathering up facts, possibly for use by the House of Commons in its struggles over the Education Bill, now on the legislative "stocks," and where it is likely to remain some time longer ere being launched into history as a full fledged Act of Parliament. We can only hope that our legislators may find the little book of use to them, as it surely will be of interest, seeing that we are being assured that we are ever so much behind every body else in the matter of education. Our Dutch friends are very earnest educators, and those who are being educated must also be very earnest in the subjects to pass in which is necessary to matriculation. Amongst other things being three languages (modern) mathematics, chemistry, theoretical and practical mechanics, and goodness knows how many more. In all "centres" these are subjects common to all; in some, selections are made: agriculture is well cared for; and botany, it may be said, of course, runs side by side; and botany, it may be said, of course, runs side by side; or is forestry forgotten. We are under the impression that the sons of farmers do not sufficiently estimate the advantages of the education provided for them by State and Commune. Evening classes are felt to be a boon by very many, and compulsory attendance at day school has resulted in nearly all juniors finding their way to the classroom. The little book is well worth perusal by all who take an interest in the proper education of the rising generation.—*Gardeners' Chronicle.*

TEA PROSPECTS.

With reference to recent articles in the periodical "Tea"—the latest of which we reproduced on page 497,—a Ceylon proprietor writes from London, Dec. 11th:—

"There is not the slightest doubt but that we shall never be permanently right until we can have some organisation among the sellers, as well as among the buyers."

We attract attention to the contribution by "Suum Cuique" given elsewhere. He makes the bold statement as regards "overproduction" that it has never exceeded 5 per cent of the requirements of the market and that the trouble and low prices are due to the combined action of large buyers and the want of cohesion among producers. All that he writes on the subject should therefore be carefully studied by planters.

EXPORTS OF CEYLON TEA TO THE UNITED KINGDOM IN 1902.

The following are the monthly shipments of Ceylon tea to the United Kingdom during the past year, in round numbers:—

	lb.
January	9,250,000
February	8,000,000
March	8,500,000
April	9,000,000
May	9,750,000
June	13,000,000
July	10,750,000
August	7,250,000
September	6,750,000
October	7,000,000
November	6,250,000
December	9,000,000
Total	104,500,000

Estimate for January 1903—9½ to 10 millions lb.]

SUGAR AND RUBBER IN THE STRAITS.

We were sorry to miss Mr. John Turner, the General Manager of the largest Sugar Cultivation Company in the Straits: he arrived by the ss. "Arcadia" recently and left in a few hours by the ss. "Coromandel" for Penang. Referring to Sugar prospects, Mr. Turner writes to us:—

"You will no doubt have seen what has been taking place in connection with sugar bounties. Prices have already gone up considerably and we look for a further rise. So that with our new estates we are in a position to take full advantage of the rise."

Mr. Turner is also interested in rubber.

SWEET POTATO FROM BARBADOES.

(From a home Correspondent.)

Messrs W Pink and Sons, the well-known wholesale fruit merchants, have begun a new departure to which Mr Alleyne, M L C, Barbadoes, has been drawing attention in the newspapers. They are now regularly importing

SWEET POTATOES AND YAMS

into this country from Barbadoes and hope to develop a good market ere long. They have, at present, only stocks of sweet potatoes, Mr Pink tells me, but after Christmas he expects large deliveries of yams. The sweet potatoes they sell in baskets of about 17 lb and 34 lb and barrels of 124 lb, prices being respectively 3s 6d, 6s 6d, and 16s, carriage paid to nearest Railway station. The endeavour to introduce those vegetables is further assisted by recipes stating how to cook Barbadoes' potatoes, taken from a pamphlet issued by Ceylon's old friend, Dr Morris, C M G, Commissioner of Agriculture for the West Indies. I append a few of those at the end of this letter for the benefit of any Ceylon housekeeper who may sigh for something new for dinner. Housekeepers here, who have more variety to select from, are yet showing interest in the new vegetables from the West Indies, and the idea seems worthy of support in view of the distress of West Indian Industries at the moment. It is said yams and sweet potatoes are very deliciously cooked in this country where really good butter can be incorporated with them in various ways. That may be, but some of the recipes Dr Morris brings forth out of his treasury of knowledge smell of indigestion to the experienced stomach to which the yam is not entirely a new creation, notably the rich pastry dish, which prudent "lovers of the table" (vide Cocker's pills) will put off trying till the New Year festivities are safely past!

RECIPES FOR BARBADOES POTATOES.

(Broiled.)

Potatoes to be half-boiled, the skin removed, and put in the oven till brown. Cut into pieces, serve hot.

(Rechauffé of Cold Barbadoes Potatoes.)

Mash till perfectly free from lumps, stir into every pound of potatoes two table-spoonfuls of flour, two of minced onion and 1 oz. butter; add sufficient milk to moisten well, press in a mould, bake in a moderate oven till brown and turn out.

(Barbadoes Pie.)

One quart of Barbadoes potatoes boiled and mashed; three beaten eggs, three table-spoonfuls of sugar one table-spoonful of butter, half a nutmeg (grated), half tea-spoonful ground cinnamon, a little ground cloves, a little lemon peel, enough cream to mix together to a batter. Line the pudding dish with a rich pastry, pour in the mixture, and bake with a top crust.

PRODUCE AND PLANTING.

We published last week a vigorous appeal from a correspondent calling upon

TEA PRODUCERS TO COMBINE.

Our correspondent, after putting forward proposals for meeting the present difficulties of tea-growers, asked who will move in this matter? Some days have elapsed since our correspondent's letter appeared, and up to now there is, so far as London is concerned, but small indication of any movement on the part of those chiefly interested. We have received some letters, but so far the attempt on the part of our correspondent to inspire the leaders of the tea industry with life and action, even to the extent of calling a meeting to discuss preliminaries, has met with no overwhelming response. Possibly some step indicating concerted action may be contemplated, but if this be so, nothing has leaked out in confirmation. We trust that those who desire to initiate some movement

for the general welfare of the tea industry will not be left to the empty echo of their appeals. It may be premature yet to write that nothing is likely to result. Those who are prepared to act must wait a little longer before finally deciding that their efforts are in vain, but it would have been encouraging at least if some enthusiasm could be traced in favour of a live movement towards unanimity and a practical plan of campaign. The operation of crying in the wilderness is disheartening, and is calculated to lead to the conclusion, which we trust is not yet completely justified, that any attempt to bind the interests of tea growers which may conflict in minor matters but should be identical in the main, is doomed to failure.

While the British-grown tea industry is under a cloud because of over-production and other causes, reports are received of a threatened extension of tea growing in lands when the experiment will be new. Texas will make an attempt, and we hear also that M Prudhomme, Director of Agriculture in

MADAGASCAR

believes that tea can be cultivated in almost the whole of the island, but especially on the East Coast, which is moist and rainy. There may be some slips between the cup and the attempt to fill it with tea from Texas and Madagascar, but it shows the keen desire exhibited on all sides to cultivate tea where climatic conditions render it possible.

With reference to this

PROPOSED TEA CULTIVATION IN TEXAS

the "Sun Antonio Express" says:—J H Kinsler, representative of the Department of Agriculture, who has been investigating the adaptability of the soil of Eastern Texas to the cultivation of tea, has returned to Washington. The Department of Agriculture will put in an experimental farm for tea. Just where the experiments will be conducted is not known. The citizens of Nacogdoches have formed a stock company recently for the purpose of furnishing to the Government the land and help and building necessary to experiment with the growing and curing tobacco. Something was said at that meeting about tea, but no action was taken. Whenever the Government believes the tea farm should be placed, there is little doubt that the citizens will get together the necessary funds to provide the lands.

THE JAPAN TEA COMPANIES

are reported to be forming a combine consisting of the following firms, viz: The Kynsu Tea Export Co., the Nagasaki Brick Tea Manufacturing Company, the Fukuoka Tea Manufacturing Company, of Fukuoka, and the Higo Tea Manufacturing Company, of Kumamoto. The aim of the combined companies is to extend the business of tea export into Siberia. The agreement that has been entered into sets forth that the three last named companies shall procure their tea from Kyushu Tea Export Company, which will undertake the actual business of exporting for the combination.

INDIAN TEA IN CENTRAL ASIA.

In his new book, "Across Coveted Land," just published by Macmillan, Mr A H Savage Landor, referring to Seistan, the half-way house between Quetta, in British India, and Meshed, in Persia, says that a greatly developed Indian tea trade will, in all probability, pass through it some day. Mr Landor, in his interesting chapter on this subject, believes that only an understanding with Russia is needed to procure for Indian teas a most profitable market, not merely in central and Western Asia, but all over Europe.

TEA IN CANADA.

Whatever sceptical persons may have thought a short time ago, it is evident that British-grown green tea have secured a permanent footing upon the market, says the "Canadian Grocer." Of course, their use is very small when the quantities of China

and Japan greens that are annually consumed are taken into account, but the fact that their consumption is steadily increasing, and that they are now figuring in the statistics which are from time to time issued in regard to tea is evidence of this. A return recently issued, giving the distribution of green tea from January 1st to the end of September, shows that there has been a substantial increase over the same period last year. The quantity exported to all countries was 637,224 lb, while this year for the same period the quantity was 1,593,063 lb. In 1901, Russia took no Ceylon green tea, but this year she took 106,435 lb. Africa also appeared for the first time as a consumer of Ceylon greens. Australia and China on the other hand, while they took small quantities last year did not take any this year during the period in question. Our readers are, no doubt, mostly interested in the figures relating to the quantities exported to this continent. These show that while for the nine months last year the quantity was 457,982 lb this year for the same period it was 993,970 lb, an increase of about 117 per cent. Our own trade returns giving the imports of green tea into Canada show that for the fiscal year ending June 30, 1901, we took 81,574 lb of Indian and 335,815 lb of Ceylon green. This year, however, the figures were 71,466 lb of Indian green and 523,480 lb of Ceylon green tea. The dearth and scarcity of China and Japan green teas have, no doubt, materially added to the consumption of British grown green teas on this continent, but, of course, to what extent cannot be estimated. Whatever may be the causes, the fact remains that the consumption is increasing, and not only in America, but elsewhere.—*H. and C. Mail*, Dec. 12.

AN AERIAL ROPEWAY IN SOUTHERN INDIA.

BY L. DAVIDSON.

The native State of Travancore pays an annual tribute to Britain of £80,000, and has a population of about 2,500,000. It occupies a strip of land of 6,730 square miles on the extreme south-west of India, and Cape Comorin is situated at its southern extremity. From the sea coast, which forms the western limit of this native state, the land rises eastward to the summit of the range of hills which, running almost parallel to the coast, separate Travancore from British Territory. On the eastern, or British, side these hills are too steep for railway—and in many places for road—construction, but on them are large areas of rich land, which are to some extent cultivated with very profitable results. The greatest difficulty attending their development lies in easy and cheap means of communication, for the transport of labour and food to the estates, and of the produce to the lower land, where it finds a market.

An example of how this difficulty has been overcome on one large estate is of considerable interest. It is located at a point where the rise from the plains to the cliffs at the top of the "ghaut" is unusually steep and rugged, in some parts there being an almost perpendicular face of rock from 1,000 feet to 1,500 feet in height; below this are several thousand feet of steep, rugged grass land, sparsely dotted with trees and broken up with innumerable ravines. The crest of this ridge is 6,000 feet or more in elevation, and the plains at the foot are about 1,200 feet above sea level, so that there is the extraordinary rise of nearly 5,000 feet in an average horizontal distance of about five or six miles. The eastern side is British territory, and very dry, much cultivation being done with the aid of wells, though the recent completion of the Periya-aar irrigation works, which comprise a dam in one of the valleys on the Travancore side of the range, with a "bund" 150 feet deep, and a tunnel through the hills to the dry British side of the country, enables a large tract of land to be irrigated which

would otherwise be subject to the vicissitudes of irregular rainfall, and it is hoped, from this source alone, that 100,000 acres of rice land will be kept under permanent cultivation.

The rainfall in Travancore side of the range is very heavy, amounting to 250 inches per annum, and even more in some parts; while it is not over 30 inches on the British side, only a few miles distant. An agricultural company secured a concession from the Travancore Government of some 100,000 acres of land, and has of recent years been developing the suitable portions for the cultivation of tea and coffee, cardamoms and chinchona; about 20,000 acres are now under these varied crops. The laborers required in connection with the gardens, together with their families, number about twenty thousand, and in order to feed them some three thousand transport ponies, donkeys, and cattle were employed, besides a large force of probably not less than eight hundred coolies for carrying head loads.

The principle base of operations, Munnar, was thirty-two miles from the end of the cart road on the plains, which ran from that point to a station on the South Indian Railway; along this road it is hoped that a narrow-gauge railway will be laid by a company which has secured a concession from the Government. The road has been extended recently by the Agricultural Company ten miles of a valley to the base of the steep ghaut, and from the top of the range about forty miles of cart road have been constructed in various directions to serve the estates. It was to connect those two points that it was decided to erect an aerial ropeway capable of filling the company's requirements, as well as those of the general public, for many years to come. A cart road up this ghaut would have been impossible to make or to work except at a prohibitive cost. The question of cutting a cart road in a westerly direction was also duly considered, but the heavy cost of construction through virgin forest in an unhealthy country, with a rainfall of upwards of 250 inches, and the fact that fifty miles of such road would have had to be made and maintained under difficult conditions, resulted in the abandonment of the idea. It was finally decided to join up the steep section between the ends of the two roadways by an aerial rope line, and the type to be adopted received careful consideration. The local engineer of the company, Mr Kemlo, finally designed the installation with a view to erect an efficient ropeway with materials of as light a section as was compatible with strength, as the cost of transporting material in the very unhealthy ghaut was excessively heavy. His design took the form of a moving rope carrying its own loads, and although the trouble in connection with its installation was great, the results have more than fulfilled expectations. This is probably the steepest ropeway of its class in existence, and its success is in a large measure due to the grip carriers which will be described presently. The total length of the ropeway is 2.6 miles, measured along the slope of the ground, and the rise is about 4,000 feet. It is divided into two sections, the lower one being 7,400 feet in horizontal length, with a rise of 2,150 feet; the upper section has a horizontal length of 5,840 feet, and a rise of 1,850 feet. In the lower sections, there are thirteen spans, the longest being 1,028 feet horizontal, and in the upper section there are nine spans, the longest 1,566 feet horizontal. The slope is fairly uniform throughout, except, that the lowest four spans are less steep than the rest of the line.

Fig. 1, Plate XLV, is a profile of the line. The positions of the standards are numbered consecutively from 1 to 18, and the information on the section is so complete as to render any further reference unnecessary.

The reasons for working the rope in two sections are (1) in the event of breakdown only half of the installation would be out of work; (2) that part of the stress at the top, which is due to the weight of the rope, is diminished, and thus its load-carrying capacity is increased; and (3) the climate at the foot

of the Ghaut is so unhealthy that no European could stand it, while by the present arrangements the ropeway is worked from the central station, which, being at an elevation of nearly 4,000 feet, is comparatively healthy. The rope is of good quality plough steel, $\frac{3}{8}$ inch in diameter, and about 1 lb weight per foot. It was sent out on eight drums with an interchangeable axle and wheels, and each drum was rolled into the line of ropeway and unwound on the axle, the hauling being done by $\frac{3}{8}$ inch steel ropes on hand winches, a tedious process. Four drums of rope were required for each section; the splices were 60 feet long, and have stood well. The rope is supported on 18 inches pulleys, with groove of 1 inch radius, and the pulleys are carried on light angle steel standards of various heights to suit the nature and slope of the ground, varying from 10 feet for the lowest to 40 feet for the highest standard. The feet are in most cases embedded in concrete blocks, though in some instances they are bolted on the rocks that happened to be in the line of ropeway. One rock shown in the engraving, Fig. 2, Plate XLVI, was 120 feet high, and an iron ladder was fixed to its almost vertical side to enable the work to be done at all.

The engraving, Fig. 3, Plate XLVI, shows the standards very clearly and indeed gives a good idea of the ropeway generally. The other illustrations on this plate are characteristic of the work. Fig. 4 shows one of the terminal stations, and Fig. 5 shows the zigzag cart road approach to the upper terminus. The tension gears are at the top and bottom stations (see Figs 6 and 7, Plate XLVII). The tension wheels are 8 ft in diameter, carried on a sliding arrangement 35 ft long. The requisite power is got by a worm wheel winch and three block sheaves with a half inch specially flexible wire; and the anchors are heavy masonry and concrete blocks over 30 tons in weight.

The driving arrangements are at the central station, and consist of two electric motors, either of which can be used geared on to a counter-shaft which, in its turn, operates, through a rope drive, a vertical shaft and pinion geared on to two 8 ft spur wheels. These spur wheels have bolted on to them hard wood pulleys, by which the ropes are driven. The upper and lower sections of the ropeway are connected by shunt rails, along which the loads pass one road to another, and at the terminal loads automatically run off the rope on to shunt rails, or off the rails on to the rope, without any loss of time.

The current for supplying the electric motors is generated about a mile farther down, at a point where a head of 750 ft. of water is available. This operates two Pelton wheels; they in their turn drive two dynamos, each supplying 40 amperes at 500 volts. One of these is sufficient to work the ropeway at two miles an hour, while the other is always ready in case of accidents. No water power was available nearer the central station than at this point, so that electric transmission was indispensable.

The general form of carriers is shown in Fig 8 to 12, Plate XLV. It consists of a frame or hanger, B, which carries the load clear of the standard head pulleys. To the upper end of this frame the rope-gripping arrangement is attached. It is made up of the frame, A, carrying two pendant jaws, E E, which are so arranged that when the load is run along the shunt rail, and the jaws come in contact with the rope, they automatically close on and grip it with a force proportional to the weight of the load. The other letters on this figure refer to the following parts: I is the carrying pulley; F is the shunt rail; and O is the supplementary pulley running on the shunt rail and taking the load off the rope.

Enlarged details of the jaws are given in Fig 9 and 10. In Fig 9 the jaws are shown closed over the rope, a result due to, and varying with, the amount of load suspended. In Fig 10 the jaws are open and the rope released, the weight on it being removed. It will be noticed that the proportions of the jaws do not interfere with the free running over the pulleys.

Fig 11 and 12 show a somewhat modified form of the grip arrangement.

The large groove in the standard head pulleys has the advantage of altogether preventing the rope from being jerked off, which is a common fault with the ordinary rope-carrying pulleys having a groove only half the diameter of the rope.

The top bracket A, of the grip frame shown in Fig 3 carries a rail pulley D, already referred to. This comes in contact with the shunt rail F, when the load reaches the end of its journey, and as the shunt rail is laid at a flatter down grade than the rope at this point the weight of the load is taken up by the rail, and the pendant jaws open and release the rope automatically. This process is reversed at the loading side, the shunt rail being almost level while the rope has an upward slope at this point, so that as the load travels along the shunt rail, the open pendant jaws close on the rope, and the load is automatically taken up by the rope from the shunt rail.

The loads carried are limited to 5 cwt each, but necessarily most of them are less, as it is easier to handle lighter loads though the ropeway is capable of taking far more than the existing traffic.

Assuming forty loads as about the average number on the rope at one time, a delivery is ensured of fifteen loads at both ends per hour, when the rope is running at the rate of two miles an hour, and working ten hours with 4 cwt loads. This gives an average of 30 tons a day each way, or more than double the ropeway has actually to carry. The speeds arranged for are one, two, three, and four miles per hour, but at two miles the line handles more than has been required of it hitherto. The economy in working, as compared with the old methods of transportation, is close on £1 per ton. The advantages of being able to erect an aerial rope of this class on steep grades are obvious, as not only does it effect a considerable saving in regard to the original cost of the installation, but by the use of the grip carrier described, the life of the rope is greatly prolonged, owing to the fact that they probably never grip exactly the same part of the rope twice, and the wear and tear is thus equalised throughout its length.

The prospects of success when the work was commenced were small, but the results obtained have been very satisfactory.—*Traction and Transmission* for Nov. 1902.

A NEW CEYLON PUBLICATION:

"SPOLIA ZEYLANICA."

"Spolia Zeylanica" is to be the title of a new publication issued by the Ceylon Government Museum, Colombo, for taking the initiative in which credit is due to the new Director, Dr. A. Willey, F.R.S. The publication will be commenced shortly in the form of an Illustrated Quarterly Journal, containing Records and Contributions, together with Notes, Abstracts and Reviews, relating to the Economic and Systematic Knowledge of the Natural Resources (Zoology, Anthropology, Palæontology) of the Island and of the surrounding Seas. The subscription will be Rs 5 per annum, payable to the Director, Colombo Museum. We wish the new Quarterly all success.

BLENDING INDIAN AND CEYLON TEA;

SAUCE FOR THE GOOSE MUST BE SO FOR THE GANDER.

Lately our evening contemporary contended that it was an advantage to Indian tea planters that Ceylon tea should be admitted free:— Indian tea is not so palatable as a blend of Indian and Ceylon teas, and that, as a matter of fact, the use of such a blend will be to the advantage

of their consumer and to no real disadvantage of Indian producers.

The "Indian Planter's Gazette" is not to be caught after this fashion:—

If it was a fact that the indigenous article was undrinkable by itself, and unsuitable to the palates of consumers without the admixture of an exotic brand such as Ceylon, surely the largest firm of tea dealers, Messrs. Brooke, Bond & Co., Ltd., would have taken cognisance of it, and would not have confined themselves to selling blends of pure Indian tea. We have their assurance that the blends they are selling in this country are all blends of pure Indian teas. This statement cannot be gainsaid, so where does the contention of our contemporaries come in? Some time ago it was suggested that the Ceylon import duty should at least be abolished on Indian tea, so as to permit of blends of Ceylon and Indian teas being made in Colombo. But our Island contemporaries would not hear of it. Now, however, in their attempt to drive in the thin edge of the wedge, they put forward the cool proposition that their product should be blended with ours in order to make it go down the throats of our *hoi polloi* the more easily. Such a procedure, we are told, will make our teas demotic. But, needless to say, we are well able, with the great varieties of tea we produce in this country, to cater to the wants of our proletariat, without the assistance of any adventitious aids. With Ceylon, however, it is otherwise.

Our Calcutta contemporary is inexcusably wrong in part of the above; for he has had evidence before him more than once that the *Ceylon Observer* has consistently advocated the abolition of the Ceylon import duty on tea as an antiquated, unjust and altogether indefensible levy,—the proper substitute being expert inspection at our Customs to keep out any teas below a certain standard.

CHINA TEA EXPORTS—it will be seen from the latest reliable figures published elsewhere—are still far ahead of the preceding year. To the end of the year 1902 the increase was 13,725,567 lb. America has taken about 10 million lb. more than on the previous year, Russia has taken some 4 millions less, and England 2 millions less.

"COLOURED" CEYLON GREEN TEA REJECTED IN AMERICA.—We direct attention to the information conveyed to the Ceylon Planters' Association by Mr. William Mackenzie regarding the rejection of 38 packages of green tea in New York. From the statement "some colouring trick had been tried on it" it would appear that Mr. Mackenzie's friend is under the impression that colouring Ceylon Tea is unusual in America. This is not so. After the above disquieting statement we should like to be sure that of the green tea which leaves Ceylon for America none continues to be similarly treated before shipment; though our Commissioner does not actually state the present "trick" took place in Ceylon. We have credible authority for saying that much of the Ceylon tea which leaves here as pure Ceylon green tea is treated in America before being placed on the market. Perhaps the American buyers prefer to do their own colouring, with colouring matter, before the green tea is sold; for then they know exactly what they are offering to the public?

TEA IN 1903 :

THE PROSPECT FOR WEATHER AND CROPS ;
EXPORTS FOR 1902 AND ESTIMATES FOR 1903.

The year, which has just closed, has not been a red letter one for the tea planter. Abnormally wet weather has been the main factor in the untoward result, and further emphasis was supplied by a long continuance of low prices. But that season is now behind us ; and with past experiences as a guide, our thoughts naturally turn to the opening year with its fresh hopes and probable possibilities, and we ask ourselves what the future months have in store for the premier culture of the island. A great deal depends on the weather, and how uncertain that is, goes without saying. And yet in this age of possible impossibilities, a new prophet, Mr. Hugh Clements, has arisen, with Mr. Wm. Digby, C.I.E., formerly of the *Observer* staff, as his mouth-piece, who claims in the latter gentleman's work on "Natural Law in Terrestrial Phenomena," to have found the secret to enable him to forecast the seasons. As Mr. Hugh Clements, however, will likely have all his time employed in defending his theory, and will not be available for the service of the Ceylon planters, we are forced back from the region of exact science to the land of incertitude and the rule of thumb.

Meteorologists tell us that the longer it has rained the chances are that the longer it will rain ; and Ceylon has had its wet cycles, but happily also its dry ones. What a prospect we would have before us of soddenness and green mould if the rule mentioned above was inviolable ! Happily it is not. Tropical agriculture has found its best interpretation rather in "the swing of the pendulum" ; and the poet's saying "all things will come round to those who will but wait," has been vividly illustrated in many a pathetic story of planting life. Last year having been a poor year for tea, we instinctively feel that this year should be better, and, given decent weather, we feel sure it ought to be. Tea is in good heart, is healthy and free from blights, and whatever there may be in the idea that the flood-tide of production is past and increase by "leaps and bounds" only now to be a memory, to expect in 1903 such beggarly months as was November of last year, is, in planting circles, to anticipate the incredible. Planters, in submitting crop estimates, do not, as a rule, add a "D. V." to the tabulated figures ; but it is unconsciously done when they postulate a normal season, a rule which the wise ones adopt. If planters could approximately forecast the weather, there would be no necessity for the occurrence of shortage of estimates, nor the apologetic eloquence which Chairmen of Companies indulge in, in explanation thereof. After so much rain, it is quite within the range of possibility, that the present year may prove a dry one. In 1891 the rainfall in Colombo was 119 inches, and 1892 followed

with only 60 inches. If this should be duplicated this season, the tea crop might even suffer, and instead of the anticipated increased outturn, there would be receding figures. High estates would gain through an excess of sunshine and a paucity of rain, and the reserved energy, which has so long been kept in check by the cold and wet, might burst out into exuberant flushing, and bring about a busy time. Medium and low places would, however, fall off, and as these properties are in the majority, a serious deficit might easily occur. It used to be held that it did not matter very much to have a period of poor returns, as it was certain to be made up later on ; but we are not sure that this idea obtains now to anything like the same extent that it did formerly, nay, the more general experience is that it is a hard task to recover lost ground, and that the tea bush, unless stimulated by manures, has a horizon limited by today, and is pretty much unaffected by what was left undone yesterday, or the day before that.

Another point to be considered in a speculative estimate of the coming season, is the Labour Question, which is too important to be over-looked. Granted a season of pressed down and overflowing measure, could it be effectively harvested by the present labourers at command ? For some time back there has been no high pressure from flush, which would have withdrawn all hands from other work, and yet spite of this slackness, our planting reports hint at work so necessary as pruning, being far behind on certain places, and other needs clamouring vainly for attention. The estate, which is well supplied today with coolies, is somewhat exceptional, while the bulk of places—in many districts if not in all—register "short," or "very short," as the condition of the labour force. It is a kind of hand-to-mouth existence which, we fear, is the present condition of labour in many parts of the planting districts and while it may be possible to get along during the slack months in a kind of crippled and worrying way, a real good season—unless a determined effort be generally made to recruit new coolies, and gangs are strongly reinforced—would be no blessing, except, perhaps that disguised kind which the optimist always discovers, hidden somewhere under the shadows cast by disaster. If the squeeze, at present, were severer, there would be more hope of immediate action to relieve it ; but as it can be borne without much inconvenience the industry may drift into the future busy months badly equipped, unless planters wake up, and there may be later on, a real regret, when regret is unavailing.

From the home side there is every reason to expect substantial returns for tea shipped. There are, of course, the large blending Companies who charge solid, and with determination to break down prices ; but restricted offerings in the London market, circumvent their selfish plans, and the law of supply and demand comes into free play and reflects itself in the markets' bidding. The home outlook is very hopeful, and the regular trade circulars, which have been for so long a time, dreary

reading, and have had for their key-notes the imperative need for a reduced output and a higher quality of tea, are now becoming quite chirpy in the growing brightness of the dawn of better times. Private advices also, which had acquired a stereotyped style—apologetic in tone for the wretched market and its low rates, with a saving clause that the teas arriving were poor—are today much changed. Planters are said to read them now with real pleasure and every tea-maker swaggers around with an uncoiled air of being master of the craft of manufacture! A leading London agency firm, writing last mail on the prospects in view, said:—"About half the Indian crop remains to be sold between this time and 31st May, and the quantity offered each week will probably average 37,000 packages. This makes a total much less than last season's and as supplies of Ceylon teas are at present not in excess, there is reason for a continuance of good markets." The present year, therefore, has opened both in London and Colombo—to judge by yesterday's sales—with much promise; and, given a fair weather record and an increased influx of Tamil immigrants, its close should be more heavily gilt, than the year which has just expired.

As regards ESTIMATES of the EXPORTS for the current year, there are several, we hear, floating about Fort offices of more or less authority. In our last *Overland* summary, we ventured on the best approximation within our scope at the present time. Against a total of 148,994,730 lb. of all kinds of tea shipped in 1902, we put down 153 millions for 1903; but of this 8 millions are given as green tea—leaving 145 millions (100 to United Kingdom against 103 millions in 1902; and 45 against 43½ millions to other places) for Exports of Black tea to all countries. It may be said, indeed, that as not much green tea goes to the United Kingdom we put down nearly 52 millions lb. altogether of our teas as likely to be sent to "Other Countries" during the present year. This is surely a liberal enough estimate? A merchant with special interest in tea crops, who has seen our figures and who remarks on the discrepancy between the Chamber's and P.A. figures for "greens" (so much green tea really shipped as "black") writes:—

"Bounty was paid in 1902 on 3,914,062 lb. greens. Shipments of greens have therefore probably been about 3½ millions, against 2,806,844 lb. per Chamber of Commerce. A good many fresh estates are making greens, but the 388,806 lb. for the last half of December may be partly accounted for by a rush of applications before the bounty is reduced to 4 cents. I see Mr. Philip does not give the lbs. on which 5 cents bounty can still be paid, as he usually does? I think your estimate of 153,000,000 lb. a very fair one and reasonably, I don't think crop will be more."

For further details, we can only refer to last *Overland* Summary, meantime emphasizing the fact that if weather prove unfavourable, or labour runs short by April-May, we may not even see 150 millions of exports realised. At the same time the

London market cannot complain if we only send them 100 millions lb. of black and perhaps 1½ million lb. of green tea, during 1903.

TEA IN PARIS.

Under the heading "Paris at Five o'clock." Mrs Alec Tweedie described last week in the *Pall Mall Gazette* the craze for tea-drinking in the gay city. In the course of her article Mrs Tweedie said:—"There have been several revolutions in Paris; but none more complete than the

REVOLUTION OF THE TEA CUP.

Tea cost forty francs a pound at the time of the coup d'état, and was only indulged in on rare occasions by the wealthy. Afternoon tea was almost unheard of ten years ago in Paris, and yet today it is the fashion everywhere. There is no doubt about it: afternoon tea is a particularly British institution. Rich and poor alike enjoy that stimulating beverage between four and five o'clock, and look upon it as a necessity of existence. This has been the custom for years, ever since the duty went down and the imports from China went up; but until lately Britain has stood alone as a drinker of afternoon tea. Is the present craze in Paris the outcome of the International Exhibition of 1900? Is it the result of the British invasion at that time, which clamoured for afternoon tea, a habit followed by other weary sightseeing folk, who in their turn found it so refreshing that they have kept to the habit? Or is it that fashionable Parisians dined so much later nowadays, they find refreshment of some sort is necessary between a twelve o'clock déjeuner and an eight o'clock dinner? Whatever the cause, the revolution is complete, and Paris has succumbed. In many of the fashionable hotels a notice is posted in the hall intimating that the band will play from four to six o'clock, when tea will be served. The idea of smart hotels is being quickly followed by smaller shops, and bills announcing in English 'Five o'Clock Tea' may be seen on every side. So completely have Parisians adopted our custom, they speak of the meal as 'le five o'clock,' the word 'tea' being often omitted altogether.

"THE REVOLUTION IN TEA"

has gone even further. We have lately stayed in three delightful old French châteaux, where nothing is more noticeable within the last few years than the decline of coffee and the ascendancy of tea. Formerly everyone took 'café au lait' at their early breakfast in their own rooms; now tea is almost as universally drunk as coffee. Formerly everyone drank café-noir after déjeuner and dinner; now, apparently, only half of the people do so. Formerly coffee was excellent it was a treat to go to France for the sake of the coffee alone; but this is changed. So many people have given up drinking coffee and those take it black so often drown its flavour with liqueurs, that a cup of really good coffee is now the exception and not the rule. The tea has improved as much as the coffee appears to have deteriorated. The afternoon tea custom which has started in Paris has spread to the country house. Every afternoon we found the valet de chambre brought in his silver tray with tea-things arranged upon it as in England. The daughter of the house deftly dispensed her wares, and the other noticeable differences between England and France were—

the tea was weaker, the lumps of sugar larger, the teapot always had a silver strainer hanging from its spout to hold back the leaves, and instead of eating the cakes dry many of the people preferred to *tremper* them—that is to say, dip them in their tea and eat them soaked with that beverage. When visitors came to call, tea was immediately offered, as it is in Russia. Until lately Russia was the only country which ran us anywhere close in the matter of afternoon tea; but then in Russia tea is going on all day long, and the samovar is in constant requisition. In Russia, however, the tea is served in tumblers without milk, a piece of lemon being added to bring out the flavour. Russian tea is excellent; but then the very finest China tea goes to Russia, where the colour and the aroma are as much considered as these qualities are by a connoisseur of good wine. PARIS HAS NOT COPIED THE RUSSIAN WAY OF

DRINKING TEA,

but has adopted our thoroughly British institution and mode of enjoying that beverage at five o'clock and at five o'clock every afternoon the smart folk of the city may be seen enjoying their tea as to the manner born. Paris has been besieged, and has capitulated in favour of afternoon tea."

Mrs. Tweedie's inquiry whether the tea-drinking habit of the Parisian is the outcome of the exhibition of 1900 has brought a reply from Mr Edward F Langdale, one of the tea representatives at the exhibition. He says:—"Most assuredly yes. And I hope that by virtue of the office I held at the exhibition I may claim to give my opinion so decidedly. Acting under the influential auspices of their respective tea associations, and by the authority of the Indian and Ceylon Committee of the Royal Commission, Paris Exhibition, 1900, the representatives of the tea interests of India and Ceylon were able to do good work at the exhibition itself, and, what is more important, to lay the foundation in Paris of a trade or business which is, I believe, becoming the permanent one of which Mrs Alec Tweedie has now so agreeably treated. Tea interests, generally, are now in such a precarious state that all who are closely concerned with them are naturally grateful when the Press gives its powerful aid to find fresh outlets for the present over-production of tea. The following Press notice was written in 1900, and the opinions therein expressed are, I think, now being verified:—

"Nothing of this kind has ever been done before in Paris, or has succeeded so well. The attempt to sell tea to the public at previous exhibitions has usually ended in disappointment. The object of the association, to popularise tea, is evidently been attained; the tea has become popular, and a nucleus has now been formed for a business which should be continued after the exhibition is at an end."

"Mrs Tweedie also asks if the 'craze' is the result of any British invasion of the exhibition?"

"I do not think so, for my own experience, so far as regards the Indian tea courts, was that our fellow-countrymen were more conspicuous by their absence than by their presence. The tea courts were the resort daily of some of the best French society, members of which were known to say that the Indian tea courts were the most chic of any in the exhibition, and that the Grand Prix should have been awarded for the manner in which the tea was served as well as for the goodness of the tea itself.

"As a further proof that the

TASTE FOR TEA IN FRANCE

became more general at the time of the exhibition, many people particularly those from the provinces bought small packets of tea to take home with them. These sales direct to the public were most encouraging for the prospects of tea, for they showed the desire of the purchasers to try and cultivate a taste for it. Also, they showed visitors to the exhibition that good tea is obtainable at as low a price as from 3 to 4 francs a pound instead of at such a prohibitive one as from 8 to 12 francs, which I often saw marked up in the shops in Paris.

"By the enterprise of India and Ceylon, particularly of Ceylon, tea is now often obtainable in the cup at many of the cafes, but the knowledge how to make it properly has yet to be gained. There are also depots and tea-rooms, run mostly by English people. One, very tastefully decorated, is an offshoot of the exhibition, and is situated nearly opposite the British Embassy. The proprietor is a French gentleman who evidently believes in the ultimate success of tea drinking in France. If only tea-rooms after the kind of those of our Aërated Bread Company's shops could be dotted about Paris, the middle classes would probably be secured and then, in course of time, the masses, who are as yet much averse from tea, and treat it as medicine. There is, however,

ONE DANGER AHEAD

which cannot be ignored—that is, that the French Government might increase the Customs duty, still as high, I believe, as 1 franc 25 cents per pound, and thus blight the hopes of importers of tea into France. Their hopes must rest on the Chambers of Commerce of France and England, between which two bodies there is evidently an excellent good feeling and understanding. At the time of the exhibition there was some talk of the duty on tea being increased. 'Hinc illæ lachrymæ!'

Another correspondent writes:—"It is not in Paris that a taste for tea is spreading. A week or two ago I happened to be in Rheims, and noticed that there was quite as much tea as coffee exposed to view in the grocers' windows. But, in provincial France, at least, there is still evidently a

PREJUDICE AGAINST TEA GROWN IN THE BRITISH DOMINIONS.

I am not enough of an expert in tea to tell from its appearance where it is grown. But perhaps you will allow me to quote some of the labels under which tea is sold in Rheims—a town, it should be remembered, which has a large English population. One sample was thus described. 'Thé de l'Île Bourbon. C'est par son arôme et sa finesse est sans rival, ayant le goût du thé anglais de Ceylon, *il lui est supérieur*. (The italics are in the original). Another sort is 'Thé d'Annam grosses feuilles fort en thé. Se recommande pour boissons hygiéniques.' A third variety is described as 'Royal Souchong.—Thé noir, très digestif.'

"It is quite possible that all three are Indian or Cingalese blends masquerading under popular titles. May I, as an Anglo-Indian not in any way interested in the tea trade, suggests to Mr Langdale that Rheims, an important town in which Englishmen are already strongly represented in the cloth and champagne trade, might be a good scene for a crusade in support of Indian tea. The 'tea-habit' is already formed, but the Reimois is educated to believe that tea grown French colonies is superior to the product of our

gardens, which is very much as if an English grocer were to advertise 'gooseberry' as superior to the wine of Sillery or Ay."—*H and C Mail* Dec. 19.

THE GROWTH OF A NEW INDUSTRY : ONIONS IN THE WEST INDIES.

Some twelve years ago there were probably no onions, to speak of, grown in the West Indies. Large supplies were consumed, and for these the colonies were dependent on importations. The profits arising from the cultivation of these onions went, not to West Indian agriculturists but to the onion growers of the Canary Islands, Bermuda, etc. In about 1890 an old Bermuda grower, resident in Antigua, put his practical knowledge to account and made an experiment in onion cultivation. The attempt was successful, and by 1896 he had ten acres under onion cultivation in the island. (See *West Indian Bulletin*, Vol. II, p. 163). The question had meanwhile been vigorously taken up by the Botanic Station, and in 1895 to '96, onion cultivation may be said to have attained the rank of a minor industry in Antigua. It has thriven year by year, and its present position may be gauged by the fact that last year, in addition to the large quantities consumed locally, Antigua was able to export over 27,000 lb. of onions to the intercolonial and New York markets. The industry has also been attempted in other islands, where with the advantage of the valuable experience gained at Antigua, progress has naturally been more rapid. In Dominica experiments in growing onions from sets, imported by the Botanic Station, were made in 1899. The results proved that the conditions were suitable, and the experiments were repeated in 1903. One or two crates were exported, and gained a good report at New York. Last year both seeds and sets were imported, and the onions exported from the Agricultural School and the Botanic Station to New York were reported as being equal to any from Bermuda and Cuba. Montserrat has not been behindhand in endeavouring to found a new industry. The first efforts were made at the Experiment Stations, in 1900-01, and the cultivation has progressed so rapidly that last year Montserrat exported no less than 3,410 lb. of onions to various parts of the West Indies, and 450 lb. to New York. In the growth of this comparatively small industry we have an excellent example of progress in the right direction. The imports of onions into the various colonies are large, and are still mainly obtained from outside sources. In 1900 Barbados imported onions to the value of £1,187, Grenada £737, British Guiana £2,833, St. Vincent £145. It has been conclusively shown that onions of excellent quality can be grown at Antigua, Montserrat and Dominica. Experiments are about to be made in other islands, and we trust that within a few years the West Indies will not only grow onions in sufficient quantity for local consumption, but also to maintain a valuable export trade with the United States and elsewhere.—*West Indies Agricultural News*, Nov. 22.

CASTILLOA AND COFFEE.

Mr J Hill, a coffee planter at Santa Anna, Salvador, is making the experiment of planting *Castilloa elastica* amongst the coffee trees on his plantation. Two years ago he planted six

thousand castilloa trees, which have already reached a height of from one to two and half yards. There are between thirty thousand and forty thousand castilloa trees one year old, and in this year he hopes to bring the total number of trees to sixty thousand. It seems as if at the comparatively high altitude at which the coffee plantation is situated, the castilloa trees grow somewhat slowly, and only future experience can show whether the yield of rubber is not affected thereby. Mr Hill appears to feel a little apprehensive regarding the effect of these trees upon his coffee. He writes according to the "*Tropenpflanzer*," 1902, p. 542: "Many condemn the mode of planting as likely to be prejudicial to the coffee when the rubber covers it, but I am going to try anyhow, and I will let you know later on how the thing works, so that others may profit by the experiment."

How the rubber trees will thrive in that locality I have no data to express an opinion upon, but I think I may reassure him on the question of influence of the castilloa trees upon his coffee. *Castilloa elastica* does not develop a dense crown, and could, therefore, hardly be considered a shade tree. Moreover, there is a considerable plot planted in exactly the same manner on the plantation at Las Cascadas, and while the rubber trees are doing extremely well, there is not the least evidence that they interfere with the bearing of the coffee trees. At the time of my visit to that plantation the coffee trees amongst the rubber trees were in full, rich bearing.—*India Rubber Journal*, Dec. 8.

SWEET POTATOES AND YAMS.

During the period of stress which our sugar-growing colonies in the West Indies are passing through pending the abolition of the foreign sugar bounties, the attention of the planters has naturally been given to other produce. In Barbados great success has been achieved in the cultivation of sweet potatoes and yams of the very best quality, and an endeavour is now being made to introduce these into this country. The sweet potato is a cheap and palatable vegetable, but a good yam is a positive luxury.

During a long residence in London I imported several barrels every year for my own use, and out of the numerous guests who tasted them at our table there was not one who did not highly appreciate them. I may add that here the flavour is even more delicious than in the West Indies, as the butter which is a vital ingredient in a well-cooked yam, is so much better.

I am returning to Barbados almost immediately but any information on this subject will be given by Messrs. W Pink and Sons of Portsmouth who are importing regular supplies. Receipts for various ways of cooking both sweet potatoes and yams resent out with every parcel.

FORSTER M. ALLEYNE, Legislative Council
—*Journal of the Society of Arts*— of Barbados.

A RICH ISLAND.—The Southern Philippine Island known by the name of Paragua or Palawan, is now coming into prominence, says the *Straits Times*, Jan. 2nd. Captain William A. Phillips, Governor of the island, in speaking of the conditions, states that probably no part of the archipelago offers more inducements to capital than does Paragua. The vast forests containing rubber trees in great abundance are fortunes in themselves, saying nothing of the other industries,

FRESH BUTTER FOR INDIA.

[FROM OUR OWN CORRESPONDENT.]

A few years ago, so few as to be well within the memory of the present generation of Anglo-Indians, the Government of India brought out a young Scandinavian to initiate the people of this country into the mysteries of butter-making. It was an experiment, like many another, conceived in the vague hope that something useful might come of it, but with only an indefinite idea as to how this something was to be accomplished. That a large proportion of the European inhabitants had from time immemorial been able to obtain only an oleagenous mess in place of butter, was the reason for attempting it, but very few looked upon it as anything else than a comparatively harmless method of wasting public funds.

Today, this experiment has become an established success. The young Scandinavian is the head of an industry which supplies well-to-do members of the European community in Calcutta and Simla with really first class butter, and which is likely to considerably extend its operations in the near future. Branches are being opened in Rangoon and in Darjeeling. Even Fort Sandeman, in the wilds of the distant frontier, is not too far away to share in the great boon of obtaining fresh butter.

The achievement is so remarkable, and its success is so important to the health of the European in this country, that it is worth while to visit Aligarh, the headquarters of the industry, to see how it has been accomplished. On a bright morning last November, your correspondent happened to be in the neighbourhood of the dairy. The latter is located in a big, substantially built enclosure standing in an open plain, some three miles from the civil stations. Around is a wide expanse of thin pasture broken with scrub and trees, the surface white and bare in patches where the soil is impregnated with "reh" salt, verdant in narrow belts where irrigation channels are situated. A wide gate, through which runs a light railway for conveying fodder, leads to a central building well separated from the sheds in which the cattle are stalled. This building is of solid masonry with great arched verandahs that make it delightfully cool. Within it the whole of the processes of manufacture are carried on.

The milk is brought in from the sheds, some of which are within the enclosure while others are located in neighbouring villages, and on arrival, goes at once into the separator. This separator is so small as to appear almost a toy. In reality, it can deal with the produce of five hundred milch kine daily. In appearance and size it is not unlike a tea-table with a kettle with two crooked spouts set on the top and various cogwheels below. On lifting the upper part of the kettle a humming-top like arrangement is disclosed within; which spins with giddy speed when the machinery is set in motion. The milk goes in above and is set whirling by the humming top. The heaviest constituents, which is the watery skim-milk, flies, by centrifugal action, to the circumference and pours in a continuous stream out of one of the spouts. The lightest constituent, which is beautiful rich cream, takes on less of the centrifugal energy and gravitates to the centre where it is drawn off through the second spout. Milk, warm from the buffalo, is thus separated and there is none of the delay and exposure, with the attendant risk of turning sour, which awaits the time honoured

process of standing for the cream to rise. The separation process is also infinitely more complete, almost the whole, instead of only a part, of the butter-making constituents, being turned to useful account. From the separator the cream goes straight into the churns, great barrels revolving on axles, with wooden beaters inside, by which it is shaken and jarred into butter. From the churns the butter is mechanically lifted to a round rotating wooden table, raised in the centre so as to be like a circular lectern and with a gutter around the edge. Here the great yellow mass is manipulated by the help of wooden spades and squeezed and washed. A wooden roller, thick at one end where the table is low and then at the other where the table rises into a peak in the centre, is fixed so as to revolve as the table rotates. The butter passes under the roller which squeezes it flat. On emerging it is turned and heaped by the use of the spades, water playing on it the while, so that before it has made the round and reached the roller again much of the butter-milk has been eliminated. The process is continued until the mass is completely consolidated.

The next process is even more interesting. It consists in the digging out with wooden spades of equal sized lumps and the weighing and wrapping of them in paper. Up to this point the butter has not been touched by hand, but one thinks that this part of the process is impossible without the aid of the fingers of the attendants. The operator stands, in big white apron, in front of the scales. In front of him is a small mountain of butter in either hand he has a small wooden spade. With lightning speed he transfers a lump to the scales, thence it passes on and is folded into clean white paper. The slightest miscalculation in the size of the spadeful he takes means a portion to be added or subtracted at the weighing, but so skilful does the workman become that hardly a correction is necessary. The spade picks up the exact amount, be it a quarter of a pound or a pound, that goes into a packet. There is no halt in the process and a human finger never touches the butter. From the time the milk enters the separator, to the moment when the paper packets of golden butter leave the ice house for the train, the whole of the handling is mechanical, wooden spades being the sole instruments employed to aid the machines in their task.

The milk used is that of buffaloes, and the only extraneous matter introduced, in the course of manufacture, is a microscopic amount of harmless vegetable essence which deepens the yellow of the pats. A cleaner, more wholesome, or speedier process it would be difficult to imagine. The rooms are cooled with ice, and the result of the care that is taken is that the butter can be conveyed immense distances by rail, without deterioration, even along routes where ice packing is impossible.

Condensing engines where ice is manufactured in great solid slabs, are attached to the dairy. Other plant is in course of erection which will eventually enable the churns and separator to be driven by steam, instead, as at present, by manual labour.

From the dairy the cattle sheds are easily reached. They are long, well elevated, and carefully paved structures, the sides open to the sunshine and the wind, the feeding troughs ample and convenient. Here one may see buffaloes that are a

revelation to the ordinary dweller in this country. A playful young bull, of the size of a growing elephant, sleek and covered with hairlike fur, was getting its morning meal when your correspondent arrived upon the scene. It was the kind of animal to inspire ability to climb through the thorniest of fences in the shortest of time, but the genial proprietor did not hesitate to pat and caress the animal and the latter evidently appreciated the attention. Mangel-wurzels grown in the locality, and gram and butter milk, with any amount of green fodder, are what the buffaloes are given to eat. They also have grazing in the open. Their wonderful condition and the surprising quantity of milk they yield afford remarkable illustration of what care and good management will effect with the elsewhere neglected Indian buffalo.

The enterprise is entirely self-supporting and deserves the prosperity it has attained.—*Bombay Gazette*, Dec. 29.

TRADE IN STRAITS PRODUCTS FOR 1902.

The following is the report on certain products exported from Singapore, in which Ceylon is more or less interested:—

COPRA.—Export figures of this article shew a very marked increase over 1901, being indeed almost double what they were in that year, and as prices have ruled very high, touching at one time \$11.25 per picul for Bali and similar types, this industry must have been an exceedingly remunerative one for those engaged in the cultivation of coconuts. Demand throughout the year has been good and a feature to be recorded is the steadily increasing consumption by local Oil Mills.

BLACK PEPPER.—From Jan./June prices varied from \$29½ to \$33 and July/Dec. \$29½ to \$37, value on 31st Dec. being \$37. Supplies have increased about 15 per cent on last year and are likely to show a further increase in 1903. Stocks in Europe and America are considerably smaller than they were at the end of 1901, which proves that the consumption has exceeded production.

WHITE PEPPER opened in January at \$53 (5 per cent loss in weight) and declined to \$46½ in March, advancing again in June to \$56½. Heavy arrivals in Aug./Sep. drove the price back again to \$51½ but a recovery soon afterwards took place and the market advanced steadily to \$61½ which is closing quotation. Had a number of the Sarawak plantations not been destroyed by floods, supplies would have shown an important increase, but as it is they total only about 7½ per cent above last year. The demand for the United Kingdom and Continent has been active and prices have kept firm throughout the last three or four months.

LIBERIAN COFFEE.—At the close of last year No. 1 Liberian Coffee was valued at about \$19 per picul, and with a few fluctuations the price has advanced to \$22. Quality on the whole shows an improvement, and less has been heard of claims for sourness said to be caused by defective curing. During the last two months supplies have been small and a good demand for India has led to as much as \$24 being paid for small lots of good quality.

NUTMEGS AND MACE.—After a long period of depression during which 110s Nutmegs were sold as low as \$44 per picul and Banda Mace \$63, an active demand has sprung up, and prices have advanced to \$65 for the former and \$120 for the latter. The average quality of Nutmegs coming to market is far from satisfactory, and the proportion of shrivelled and unsound Nuts seems to increase every season.—*Straits Times*, Dec. 31,

AN EXPERT ON GREEN TEA.

Having seen a good deal of the green tea industry both here and in other countries perhaps a few views may be acceptable to my fellow tea men. As, I suppose, is but natural there appear to be very confused ideas prevalent in India regarding the varieties of green tea on the markets of the world, Indian planters seeming to think that it is a plain article, the same fundamentally throughout without regard to its outside appearance in the dry leaf which is diversified. It follows from this erroneous impression that many efforts are directed towards producing a non-descript style of tea, with the appearance of one kind and the characteristics of another. Now, if we are to follow the lead of Far Eastern countries and produce teas sufficiently close to theirs to compete with them successfully in countries where they have established the national taste it is clear that we should study the characteristics of their teas thoroughly and in working to our end endeavour to follow out the principles on which their teas are made.

To begin with, I have been informed by several tea makers that their ambition was to reproduce the round roll of China hysons, gun-powders and imperials. Now these same tea makers were producing their green tea by the steam process. The result of rolling steam-made tea in the Chinese fashion would be to produce a tea which would possess a liquor of quite a different character to that of Chinese tea, and consequently the tea would not reproduce Chinese, and having the Chinese roll would equally not represent any other description.

The two standard descriptions of green tea are, of course, the Chinese and the Japanese, and they differ very fundamentally in their character. The initial operation which destroys the fermenting principle of the tea leaf, and thus divides green (or unfermented) from black (or fermented) tea manufacture is differently carried out in China and Japan. In both countries heat is the agent used for sterilising the fresh leaf, after which operation it is not subject to fermentation, but the heat is applied in a different manner in the two countries. In China dry heat is used; the leaf is thrown upon open pans heated by stoves, and the contact of the leaf with the heated metal causes the temperature to rise above the point at which the natural ferment in the leaf dies. This preserves the whole constituents in the leaf, which is, after being thoroughly panned, rolled and dried in the usual manner, and panned again at the end of the manufacture to bring up the grey-green colour characteristic of the dry tea. The Chinese roll by hand in a manner to secure the round curly teas with which the market is familiar. Very good imitations of these teas are produced in the North-West of India tea estates. These North-Western teas truly represent China characteristics in form, colour and cup, and are as they should be, for this style of manufacture. The China teas are pungent and bitter, of great strength with a darkish liquor, but they do not possess the delicacy of Japan teas for a reason to be explained.

The Japanese, on the other hand, sterilise their fresh tea leaf by the moist heat of boiling water, which from the first differentiates their manufacture from that of China. The leaf treated in this way becomes wet, and in the process of rolling, which immediately follows, a good deal of the juice of the leaf is expressed and comes away

with the hot water with which the leaf is saturated. Simple as this fact may seem, it makes all the difference in the cup character between Chinese and Japanese tea. In Japanese tea manufacture, as stated, a good deal of the juice of the tea leaf is expressed and much of the bitter property is lost, the resulting tea being much more delicate in flavour than the Chinese variety, in which all these bitter properties are preserved. An analysis of the juice naturally expressed with the excess of water shows it to consist chiefly of tannin, a substance which is not advisable in excess in any tea. Japanese tea is therefore more wholesome as well as more distinguished in flavour than Chinese, and the fact made it a universal favourite in the great tea-drinking countries of America. The Japanese system of green tea-making is very fairly represented by the Ceylon patent steam process of Mr. Drummond Deane, and the teas so produced answer very well to Japanese teas in cup characteristics. To show the confusion of thought which exists in India, and the danger which arises from arguing on *a priori* principles from very insufficient knowledge, I may here state that some of the juice expressed in the steam process of green tea-making was submitted to a scientific man for analysis and report. He stated it to consist chiefly of tannin, but volunteered the statement that the system of tea manufacture by which this juice was expressed was erroneous and faulty, because in his opinion all the constituents of the leaf should be preserved. This was indeed a case of the cobbler going beyond his last, for he it noted the "expert" condemned the very process by which the superior delicacy and purity of Japanese teas are secured. The lesson to be learned from this case, of course, is that it is necessary to know the history and actual living facts of an article before setting up as a critic on its manufacture. Japanese tea has obtained its vogue by its special characteristics, and these characteristics are obtained by the incidental circumstances of its manufacture, the loss of a certain proportion of tannin, etc., in manipulating the wet leaf. It follows, therefore, that when we are endeavouring to reproduce this article, which is such an established favorite, it is absurd to say off-hand that it is wrong in principle to lose any of the constituents of the leaf; when by the very loss of that excess the superior delicacy characteristic of the article is produced.

There are thus two well-established descriptions of green tea, the strong, darkish liquoring bitter teas of China, rolled round or curly; and the delicate, pale liquoring, pungent teas of Japan, rolled straight. The latter roll can be very well reproduced in an ordinary black tea rolling machine, but as yet the China roll can only be imitated by hand. The steam process possesses great advantages in convenience, for the penetrative action of the vapour renders the sterilising of the leaf very rapid indeed, and large quantities can be readily dealt with. But the teas so made, possessing Japanese characteristics in cup, it stands to reason should be rolled in the Japanese manner to secure the familiar Japanese appearance. To roll steam teas to the China appearance most necessarily make a tea which is neither Japanese nor Chinese in style. The addition of panning either by hand or machine gives the dry leaf the appearance of the Chinese and Japanese teas, and where these countries add foreign ingredients to

secure colour, we can very readily secure the same pure, but I deprecate the mixing up of styles, that is, the roll of one with the cup of the other.

THEA VIRIDIS.

—*Indian Planting and Gardening*, Jan. 10.

RUBBER MARKETS

[MESSRS. LEWIS & PEAT REPORT.]

Dec 12.—Ceylon—21 cases bought in. Borneo—8 cases bought in.

Nyassaland—247 bags sold; small red and white clean ball, 2s 11d to 2s 11½d; ditto part heated 2s 5d to 2s 9d; good rooty ball 2s 7d; strong white ball 2s 9½d to 2s 10d per pound.

Dec. 19.—Para.—We have had an excited market during the week, and prices have rapidly advanced fully 3d to 4d per pound on the average. Fine herd from 3s 5d to 3s 8d spot, and 3s 8½d forward; fine soft, 3s 2d to 3s d spot and forward; scapy and Peruvian ball, 2s 9d to 3s; Mollendo 3s 2½d to 3s 5½d. Receipts continue very moderate and all medium grades are in active request, but very scarce.—*India-Rubber Journal*, Dec. 22.

PRODUCE AND PLANTING.

The report on last year's TRADE IN KHORASSAN sent by Lieutenant-Colonel Whyte, Acting British Consul-General at Meshed, shows that although there is a preponderance of Russian trade in Khorassan, practically the entire foreign trade of Seistan is in British hands. The value of British and British Indian imports during 1901-2 was £131,775. Chief among British and British Indian imports to Khorassan and Seistan is tea. This is and should continue to be as safe a British monopoly as sugar is a Russian monopoly. There is said to have been a large accumulation of India tea in Meshed at the end of 1900-01, and the tea trade during 1901-02 is described as not having been as brisk in consequence as in recent years. The taste for tea is strongly developed, even among the poorer classes of Persians, and there is always likely to be a strong and steady demand for it in Khorassan and Seistan. The value of the tea imported by the Bandar Abbas, Bushire and Seistan routes, was £50,267, but a considerable proportion of the tea brought by the two former routes is said to have been Chinese tea for exportation to Trans-Caspia and Turkestan. The following note of prices ruling in Meshed in November, 1902, has been prepared by Mr. T J Greensill, Government canvasser for trade in Khorassan and Seistan:—Tea.—There are several kinds of both black and green sold here, but the most in demand are the following:—Black Tea.—Fine Pekoe leaf—wiry and even with few tips—known here as "Kalami" present rate 20 krans (kran equals 4d to 5d) per Meshed "man" (the Meshed tea "man" is 7 lb), with a credit of fifteen months, equivalent to 17 krans cash. Leafy kinds are not much in demand, but some would sell at 20 krans, carrying twenty to twenty-five months' credit equivalent to 15 to 16 krans cash. Green Tea.—Gunpowder—bold, even leaf, coloured greenish—known as "Sabz," present rate 21 krans per Meshed "man" (7 lb), with four months' credit, equivalent to about 20 krans cash. For natural unfaced or faced there is no demand, but coloured after the China style, in India known as Bombay tea, would find ready sale if not too expensive. Heavy soap-stoned greens are rejected at once. White or silver-tipped tea, known here as "Lamsa," is really a mixed tea, consisting of about 15 per cent silver tips and about 85 per cent uneven orange Pekoe and Pekoe leaf, and comes chiefly from Java, usually packed in 5 lb lead-lined wooden boxes, and sells here at 40 krans per "man" (7 lb), with twelve months' credit, which is equivalent to about 35 krans cash. Those with more white tips fetch slightly better rates, but the demand is very limited.

THE CAPE COLONY IMPORTED TEA

during 1901 to the value of £138,092, while the value of the tea imported into Natal was £37,401.

IN A REVIEW OF THE COCOA TRADE

the *Grocer* says:—"This article is of yearly increasing importance, and each branch of the trade is continually making fresh strides towards a higher point of advancement than it had ever reached before. Apart from mere assertions, statistics prove that the quantities received and delivered in the United Kingdom are far ahead of those in previous years, and, confining the figures as taken from the official accounts to this year and last, it will be seen that the total importations of raw cocoa during the past eleven months have amounted to 53,009,256 lb, against 49,406,166 lb, in the same period of 1901. A corresponding improvement was observable in the duty-paid entries for home use, which were 42,619,394 lb, in comparison with 39,833,326 lb last year; and the quantity taken for exportation was also much heavier than in the first eleven months of 1901, being 12,253,700 lb, instead of 10,710,189 lb. As a result of these extra outgoings, the bonded stock in the U. K., as officially stated, was by the 30th ult. reduced to 10,030,000 lb, against 15,097,000 lb in the preceding year. As a defect which mars the completeness of the Board of Trade returns it may be noticed here, in passing that the compilers do not distinguish one description of cocoa from another, and keep colonial separate from foreign sorts. The latter mode, it is but fair to say, is that regularly adopted by the authorities at the Port of London, where the landings and clearances of the leading kinds of cocoa are kept totally distinct from each other. They are on that account doubly interesting to the importer, dealer, and exporter, who carefully note every new movement that shows itself in this article of commerce and manufacture. To follow out this plan we therefore give particulars of both colonial and foreign cocoa as they enter and leave London, from which it will be observed that of the two main growths the former forms the chief portion of what is lauded and delivered from time to time as the season progresses. Thus, in the first fifty weeks of the present year, in comparison with those in 1901, the receipts and clearances of cocoa, as returned at this port, have been as annexed:—

	Landings.		Home deliveries.	
Colonial pkgs.	102,450	87,850	72,700	72,550
Ceylon	35,350	32,750	25,850	12,200
Foreign	80,850	89,500	62,500	58,700
Totals	218,650	210,100	161,050	143,450

	Exports.		Stocks, December 13.	
Colonial pkgs.	30,600	20,500	22,700	24,900
Ceylon	17,600	10,400	6,600	14,400
Foreign	24,900	30,600	33,700	41,400
Totals	73,100	61,500	63,000	80,700

"These totals confirm in a remarkable manner the general outlines of the Board of Trade returns above alluded to where in most cases the amounts entered during 1902 exhibited appreciable increases over those in 1901. It is, consequently, no wonder that, with an aggregate supply more than sufficient to satisfy all requirements (though leaving stocks materially lighter than in last December) prices of cocoa almost throughout the year have been materially below those in 1901. For instance, under the influence of a large crop of Trinidad cocoa now beginning to arrive, fine red quality has lately been sold at 65s. per cwt, whereas last year it was fetching over 70s. The same may be said of the Grenada description, which offers at 59s to 62s, instead of at 63s to 68s in 1901, or 8s per cwt cheaper than the article was in 1900. African cocoa has, however, been little affected by the depression existing for colonial sorts, as its principal market is in Liverpool; where between 4,000

and 5,000 bags come in every week from St Thome, via Lisbon, and about 15,000 bags have already been sold, sub rosa, for arrival next February on terms equivalent to those for 'spot' parcels in London. Guayaquil, on the contrary, is an exception to the prevailing depreciation in values, and is actually shillings dearer than it was a year ago. Beyond this there are faint signs of improvement or better prices in the cocoa market, owing to the fact that supplies nearly everywhere are most abundant, and more than equal to the demands from consumers."

As is well known, the various

SOUTH AMERICAN STATES

play a very important part in the production of produce of all kinds. Venezuela's chief industry is COFFEE PLANTING, and its greatest exports are, in the order of importance named:—Coffee, cocoa, hides and skins, timber, coprah, and cotton. Bolivia is a wonderfully productive country, and it is difficult to imagine a tree, grain, fruit, or vegetable that could not be successfully grown. Bolivia grows barley, oats, wheat, beans, potatoes, maize, and all kinds of vegetables and fruits upon the uplands; and oranges, pineapples, bananas, coffee, rice, cocoa, chocolate, vanilla, sugar-cane, manioc and rubber in the forest-covered regions. There are others as the quinoa, a grain indigenous to the mountain regions; the oca, a kind of potato; the oherimoya or custard-apple; the tembe, a fruit of a species of palm; the guava, the granadilla, the fruit of the passion-flower, and many more. Thus great areas of the country may be designated huge gardens, and there are millions of acres of the finest timber, watered by navigable rivers. British Honduras has not merely its mahogany and logwood to depend upon, but vanilla cacao, rubber, sapodilla, and other valuable products, as well as useful woods of many sorts, are indigenous and abundant, and the soil in many large areas is peculiarly fertile and suitable for the growth of sugar cane. Bananas, oranges, rice, and maize are only a few of the products which grow luxuriantly, but scarcely anything is done with them, and the bounteousness of nature has made existence so easy that the inhabitants have lived almost solely by cutting their mahogany. Even the natural forest produce remains ungathered. The vanilla grows so abundantly that the traveller when riding through the forest roads has often to clear away the vine of this valuable orchid with his machete before he can pass. The cochineal nut, which yields the finest table oil, grows in immense quantities, and is also entirely wasted.—*H and C Mail*, Dec. 26.

"COCONUT OIL PRODUCTS."

New York, Nov. 12.

An article in the Oct. 20th issue of the *Oil, Paint and Drug Reporter* under the heading of "Copra Products in Marseilles" has come before my notice and being personally connected with the largest refiners of these goods, I feel justified in making some little comment on the subject.

I trust that you will give me an opportunity of correcting any possible misunderstanding to which former statements may have given rise that the Germans and French are ahead of British manufacturers in this particular industry.

The demand for high grade and guaranteed pure, coconut butter is increasing with enormous rapidity in this country, among both the chocolate and candy manufacturers as an entirely satisfactory substitute for cocoa butter, and among cake and biscuit makers and confectioners generally in place of lard and butter.

In view of this I think it is only fair that Johnny Bull should get his due and it may interest your readers to know that considerably more coconut

butter is made and sold in England than by the whole of the factories manufacturing this article on the Continent and America combined.

Toward the end of the article in your Oct. 20th. issue the writer says: "English manufacturers have lately learned something of the bleaching method as in use here (meaning Marseilles) and are employing it."

I venture to suggest that "lately" is hardly the right word to use, for the manufacture in England of a hard coconut butter was undertaken about sixteen years ago by the predecessors of Loders & Nucoline, of London.

Furthermore, the "bleaching" is not the serious difficulty, nor is the elimination of the three volatile fatty acids mentioned in your articles, viz: caproic, capric and caprylic.

The value of a perfect process lies more in the entire elimination of the non-volatile fatty acids and in certain preliminary and final treatments.

The large chocolate manufacturers in this country make a very thorough and scientific examination of their raw materials; they require coconut butter to be guaranteed pure and to consist only of the searime of oil of the coconut (*Cocos nucifera* and *Cocos butyracea*). It must contain no extraneous matter, and yet have a high melting point in order that the candies produced with it may "stand up" well in hot weather.

It must also be refined to a nicety and be absolutely neutral.

The patents and secrets of manipulation used in producing a first-class coconut butter are exceedingly valuable, no doubt, but there is no royal road to the manufacture, and when a perfect product is aimed at, great care at all stages of the process is the first consideration.

As "touchin' on and appertainin' to" this subject, the following reprint of an extract from the recent controversy in the English scientific journals may be found of interest.

The original article which was headed "Utilizing the Coconut," concluded by saying:—

The coconut is utilised entirely—the fiber from the husk being used for coconut mats, matting and brushes; the shell is used for fuel, and the cake which remains in the hydraulic press after squeezing out all the oil is a valuable feeding cake for cattle, whilst the dreg which is extracted in the refining of the oil is very largely used for making soap and candles.

The manufacture of "desiccated coconut" was not, however, included. This is very largely an American industry and right in New York over 30,000 selected nuts are treated daily by the Danham Manufacturing Co., who own large palm plantations in Cuba.—*Oil, Paint and Drug Reporter.*

COCONUT CULTIVATION IN TRAVANCORE.

The Settlement Operations in Travancore have involved the counting of nearly 800,000 coconut trees, and as an area of slightly over ten thousand acres, or one-sixth of the occupied area in the State, pays no taxes, we may take it that the number of coconut palms is far in excess of that which has been accounted for. Indeed, if we bear in mind that very many years ago, it was calculated that there were twenty millions of coconut palm trees in the south-west of Ceylon alone, then Travancore ought surely to be credited with a good deal over a million trees for all along the coast as well as in the belt of

flat country which runs ten miles inland, there is nothing but a dense, unbroken, mass of coconut and areca groves, and forty coconut trees to the acre is a very moderate computation.

So important is the coconut industry in Travancore that on certain Crown lands, in addition to the money tax on coconut trees, the tenant has to contribute one coconut frond for every anna of his assessment and about twenty thousand fronds are thus paid in on these particular lands. The staple industry in Travancore is the cultivation of the coconut tree, rice being grown only in the hollows between the laterite ridges and the amount reaped does not suffice even for home consumption. Lord Curzon, when he visited the State two years ago, remarked with characteristic humour: "Here every man has three acres and a palm tree." Hereupon, Mr Mackenzie, the British Resident, told us not long afterwards, that if Lord Curzon had said: "three acres and thirty palm trees," he would have been much nearer the truth, and we may add that his analysis shows that the average holding of a ryot is two and one-third acres, with thirty-five fruit trees.

The assessment of lands in Travancore is all in favour of the taxpayer, for the average demand on garden and dry lands is Re. 1 1 8, in addition to an assessment ranging from eight pies to one anna eight pies on each coconut tree, and as each tree is estimated to bring in from R2 to R4 a year, the poorest ryot can very well afford to meet the assessment, more especially as the soil, the warmth and humidity of the climate, the neighbourhood of the sea, the brackish lakes, and the equable distribution of the rainfall are all congenial to the growth of the tree. In some parts no labour whatever is required and the tree almost grows wild. It has been observed that the cultivation increases steadily from year to year, but we fear, this is not altogether to be commended, for though within recent years new economic uses have been found for the palm, among others, the manufacture of coconut butter, there is always the danger of overproduction. Moreover, the overstocking of gardens is calculated to produce deterioration in the quality of the fruit. Up to now, nothing of this sort has perhaps occurred, and a few years ago at a local exhibition, a bunch of coconuts with 153 nuts was on show, and another, with ninety-five, though the number required in the prize list was fixed at no more than forty. Of course every tree does not bear like this, but, as a rule, the Travancore coconut produces very prolifically, and would be a far larger source of income to the husbandman were it not for the ravages of its numerous insect and animal enemies. Among these are two very destructive coleopterous beetles. Then, there are the rats, monkeys, toddy cats, flying squirrels and other rodents, which do considerable damage to plantations. The natives are so supine in all matters affecting their own welfare that beyond an occasional rat hunt or an excursion after beetles, undertaken at distant and irregular intervals, they have never realised the great value of combining and organising their forces with the object of destroying these enemies of theirs. This is one of those matters in which the enlightened and progressive Government of the State might usefully undertake to educate the ryots, with profit both to the State coffers and to the purse of the taxpayer. —"C" in *Capital.*

BUTTER MAKING: A NEW INVENTION.

We are indebted to Mr. Thos. Christy, F.L.S. for the following:—

"Now I am going to give you a few lines upon an experiment which may appear to you improbable, but I have tried it myself. Take a small quantity of cream, say a pint, or, if you can afford it, go up to a quart, get a thin muslin cloth and on this place a large sheet of filtering paper, or blotting paper will do for the experiment, then suspend the muslin at the four corners and pour the cream into it gently. You will in a few minutes find that the water has run out of the cream, and you can then fold the butter together, press it slightly, and when you have added a little salt it is ready to eat. I may tell you that the filtering paper appears to be the only means by which the inventor can get any protection or return for his invention, and it is only fair to say that the inventor is an American. There is no waste. In fact the volume of butter coming from this cream is about 5 per cent to 20 per cent more than if it is made in a churn."

Residents at Nuwara Eliya and planters' wives everywhere, will, we have no doubt, be among the first to experiment on the lines of the above discovery. It is as simple and would seem to be as notable, as the case of Columbus and the egg; but let us have a local practical report, before saying more.

A "planter's wife," who had heard of the above in time to make an experiment, writes:—"I don't think that butter experiment will be a success. I have carried out directions to the letter; water is dripping out slowly, but cream is still cream and not butter and it has been dripping for an hour. I will have another try, but cream is *very* scarce with us just now. I think the blotting paper we have is too thick; if I had proper filtering paper, results might be different. The experiment is worth trying."—An hour later: "I really think that with proper paper, the butter *will* be a success, only it takes about 1½ hour to extract all the butter-milk."—We are sending a few sheets of chemical filtering paper, to enable a proper trial to be made.

MR. ALEX WHYTE, OF EAST
AFRICA.

Some readers of the *T.A.* would have noticed a short time ago in its columns, a letter from Mr ALEX WHYTE, the Naturalist, who was then on his way home invalidated from East Africa. The doctors then considered an operation would be necessary and ordered him home. He has since been in hospital in Edinburgh, I understand, but the more up-to-date surgeons there took a more cheerful view of his case, and he has been improving gradually without undergoing any operation whatever. He hopes to be able to come to London to his sister's, Mrs Millar for Christmas, being due in Chelsea about the 23rd, I believe, and is not without confidence that he will in time be sufficiently confirmed in health to return to work and complete his survey of the area round Mombasa, which he undertook to visit for Government and report on the best products to be in-

roduced into the district. After finishing this task, Mr Whyte hopes to retire and come home for good. He has done excellent work of recent years for the British Government in Africa, and his friends will all be pleased to know that there is a good prospect that he may be able to complete it.
—*London Cor.*, Dec. 19.

A NEW MANURE FOR RICE FIELDS.

A writer in the *Madras Mail* of January 13, says:—"It has been brought to my notice by cultivators now and then, and it is my experience too, that 'tobacco backbones' now either thrown out or sold at low prices for *beedi* manufacture, can be utilised as a useful manure for rice fields—especially for first crop, that is Kar produce. Lands once cultivated with this manure continue to yield very favourable crops for the next two years. I wish that landowners and Zemindars would consider the matter and make a trial."

TROPICAL PRODUCTS IN COOK
ISLANDS.

NEW ZEALAND EXPERT TO REPORT.

Mr. T W Kirk, chief of the division of biology and horticulture of the Agricultural Department, left by the "Countess of Ranfurly" on Friday for our new possessions, the Cook Islands, under instructions from the New Zealand Government, to report as to the growth and production of coffee, cotton, vanilla, cocoa, citrus and other fruits in these islands. Mr. W A Boucher, one of the fruit experts of the Department, who has had considerable experience of the growth of citrus fruits in California, accompanies him; the idea of the Government evidently being to ascertain what steps are necessary to encourage the growth of tropical products in this portion of New Zealand's territory.—*Auckland News*, Dec. 18.

PRECIOUS STONES IN THE
UNITED STATES:

IMPORTS AT NEW YORK IN ONE YEAR
OVER £5,000,000.

Nearly every mail brings us one or more useful publications from the United States authorities, in their Agricultural, Mineral or Scientific Departments. The latest is from the "Department of the Interior"—U. S. Geological Survey—and is a pamphlet on "The Production of Precious Stones" by George F. Kunz. We receive, indeed, two carefully compiled summaries of the results for 1900 and 1901; and to make his information complete for 1902, Professor Kunz is anxious that we should give him all possible information regarding the gems, plumbago and other minerals of Ceylon. It will be inferred from this that attention is not confined to the outturn of precious stones in the United States, although that is much more considerable than we had at all conceived. Diamonds in Montana and Georgia, sapphire and corundum in Montana, ruby, golden beryl and moonstone in North Carolina, varieties of quartz (amethyst, etc.)

turquoise and garnets in half-a-dozen States, tourmaline in California, opal in New Mexico, afford evidence of the richness in gems of many of the American States. But the country is so rich that far more than all the local production is absorbed; for the value of precious stones imported in 1901 at New York alone was 24½ million dollars, quite five million pounds sterling! But we must quote Mr. Kunz's pithy introduction to his Report for 1901:—

The chief points of interest concerning precious stones in the United States during the year 1901 are:—

(1) The finding of a diamond in Lee County, Ga., which adds a new locality to those previously known; (2) the increased yield of sapphires in Fergus County, Mont., where two companies are now engaged, and further exploration for the fancy-colored sapphires at Rock Creek, Granite County, in the same State; (3) an extensive output of rhodolite garnets in the Cowee Valley, Macon County, N. C., and also considerable mining in other parts of that State for blue, green and yellow beryls, amethyst and the new emerald-matrix; (4) continued activity in the remarkable locality for colored tourmalines at Mesa Grande, San Diego County, Cal., and the discovery of a new deposit adjacent to the first; (5) further work at several chrysoptase localities near Visalia, Cal., and the purchase or control of them secured by a company; (6) sustained and enlarged production of turquoises, chiefly in New Mexico, where several important companies are actively engaged in mining them, and the discovery of new turquoise localities in Colorado and Nevada; (7) the finding of epidote crystals, magnificent in size and colour, at Prince of Wales Island, Alaska; (8) and the discovery of a beautiful jade-like compact idocrase Siskiyou County, Cal.

The importation of precious stones for the year 1901 at the port of New York amounted to \$24,500,000. The importation of diamonds has exceeded that of any previous year, and never have larger or finer stones been brought into the United States. Emeralds have greatly increased in public favour; and coral, long out of fashion, has once more become popular.

Although turquoise is now mined by six different companies, and they all had fair yields, the popularity of the stone has been such that the entire product was consumed.

The first year of the new century has been the greatest in the history of the precious stone industry in the United States.

Never has the prosperity and growth of a country been more faithfully indicated, as if by a sensitive barometer, than by the wonderful increase in values and business in the jewelry trade in the United States during the past year. Never were more diamonds, pearls or emeralds sold, nor did fine gems ever before command better prices, nor were they ever more firmly held; and yet diamonds are likely to advance still further during the present year.

Not since the famous looting of the Chinese Summer-Palace in 1862 have so many treasures of jade, rock-crystal, pearls and other precious-stone objects reached not only this country but every country in Europe. The distressing fact remains that many objects, such as an altar set, or a writing set, or the funeral offering at the tomb of an emperor, empress or a noble, and made up of two or three pieces, were divided among several soldiers. Often a superb scepter, or some similar object, will have upon its

upper side a thick coating of dirt, the firmly knit dust of ages, and the lower side will be as clean as it was when laid upon the tomb a century or more ago. No class of objects, whether the seal of the imperial post-office, or the tomb ornaments of generations ago, or the name of an emperor in jade, escaped the rapacity of the soldiers, who would secrete them in their baggage with other hard stones, or with metal objects, and then carry them in this crude manner halfway round the globe, thus breaking, scratching and nicking objects of priceless and historic value. Never has the more open boast of 'loot' been made with the memory of man. Frequently the objects offered for sale have a complete history, as having been the jade tablets of some famous altar.

Thus three times has China been sacked of its priceless, precious Yu jade objects—at the looting of the Summer Palace, again during the Japan-China war, and finally in the late international war with China; so that today New York, Berlin, London and Paris hold more such objects than any Chinese city.

The Carolina ruby is not first-class; but the amethysts and moonstones are good; Montana sapphires are well spoken of, and so are the turquoises of Colorado. The following curious bit of information is given in regard to "amber":—

Dr. Hapke mentions a single enormous piece weighing 3,125 kilograms, 6,875 pounds, of mingled straw colour and greenish yellow, which had been found in the 70's by some fishermen in Langlujensand. Other discoveries had also been made in clay and sand in Binnenlande. This amber of the north-west coast rarely shows enclosures, as it is mostly opaque or subtranslucent.

We have more than once mentioned the close alliance between the diamond, amber, plumbago, coal, peat and petroleum—all having their basis in carbon. Most people dispute the place of amber in the list; but a reference to authority shows that the percentage of carbon is between 80 and 90 per cent.

Dr. Kunz gives a good deal of information in regard to precious stones in Borneo; but he does not seem to have seen our publication on "Gold, Gems and Pearls in Ceylon," so slight are his references to our island. We must enlighten him as far as we can; and he is sure to learn a great deal further at the St. Louis Exposition in 1904.

THE TEA MOSQUITO.

The hunting and tracking to its lair, of the tea-mosquito, by the scientific officer to the Indian Tea Association, Mr Harold H Mann, B Sc., forms the interesting subject of a pamphlet recently issued. This insect is a totally different fellow from the human blood-sucker we are acquainted with in Calcutta. He has four wings; ours has only two. The tea pest is a plant-bug; the house mosquito is a fly, and in its earlier stages is an aquatic grub totally different in every particular from the mosquito itself. The planter's pest passes its early stages in a form not widely different in appearance or habits (except in the absence of wings) from that of the adult insect. The non-recognition of this ab-

solute distinction has led to much lack of comprehension, and many mistakes in treatment of the insect

The tracking down of the little rascal by Mr Mann until he found its place of hibernation in the tea bush itself, is well told in the pamphlet, and deserves to be widely read by all interested in the cultivation of tea. Mr Mann, like all careful scientists, is very chary in making large generalisations, from a few experiments. But he seems to be on the right track. These experiments, along the lines of his working hypothesis, all confirmed each other in their results, and it looks as if he had not only found out all about the nature of this expensive pest, but has also been able to put tea planters in possession of the means of ridding themselves of what hitherto has been the perennial cause of blighted leaf entailing heavy loss. One hundred and fifty gallons of a very cheap emulsion, of which a pound or two of country soap and two gallons of low kerosine oil form the basis, are all that an acre of tea plants require. It has to be put on in a fine cloud-like form of spray about the end of February, and Mr Mann says that the best instrument for doing this is one made by the Goulds' Manufacturing Co., New York, and sold by Messrs. Jessop & Co., Calcutta.

The Tea Association never did a better stroke of business than when they appointed a scientific expert to fight the enemies of the tea plant. Every other crop has its own specific enemies, but as these crops are not raised like tea, by European capital under European management, the enemies of the crops get leave to commit ravages as they please. The success which has followed the efforts of the Tea Association ought to stimulate our paternal Government to put their Bureau of Agriculture in efficient working order, and to put thoroughly trained and well-equipped scientists on to every crop that is raised in India. If they would fight the enemies of cotton, jute, hemp, wheat, rice, the oil seeds, and other chief products of the soil as Mr Mann has fought the pests of Assam, they would deserve to have their memories perpetuated by statues or by hospitals or in any other manner a grateful people might devise. After all, let it be remembered that agriculture is the first and prime asset of the inhabitants of India. When it fails, everything else is wrong.—*Capital*, Dec. 24.

PLANTING NOTES.

COARSE PLUCKING: A WARNING.—The Ceylon Association deserves credit for its most timely warning, in view of the recent rise in the market and the natural tendency of local producers to return to coarse plucking; but we trust the latter will do all in their power to falsify the anticipations of the London buyers who apparently regard India as alone understanding the necessity for controlling its output. The warning cannot be too sternly and persistently emphasised. By fine and careful plucking the market has been improved and now, when from this and other causes supply and demand is becoming somewhat equalised, it would be genuinely suicidal were planters to allow their discretion to be eclipsed by a desire for quantity and return to coarse plucking.

PARA RUBBER doing so well at 1,600 feet elevation as Mr. F. J. Holloway reports on page 543, is a very interesting fact which may tend to increase the area over which this kind of rubber can be profitably cultivated in Ceylon.

A NEW STYLE OF TEA DRIER—is to be introduced, in which the tea to be dried is steam-heated *in vacuo*. Certain advantages are claimed for the new process, but having some experience of machines in which vacuum processes are employed, we are inclined to think that it will prove troublesome and costly.—*Indian Planting and Gardening*, Jan. 10.

THE LAKE-FLY NUISANCE.—Dr. Willey elsewhere replies to Mr. Theobald's suggestion that, to destroy the lake-fly nuisance, Colombo Lake should be emptied and refilled with sea-water. His trenchant letter scarcely leaves room for hope that the scheme will be generally regarded as either imperative or practicable! But experiments are first required.

THE CULTIVATION OF "ONIONS"—in West Indian islands is described on page 534, as "the development of a new industry," and it causes us to enquire why more is not done in Ceylon in growing this useful vegetable? That there is great room for a home industry is shown by the fact that during the past five years we imported "Onions" into Ceylon as follows:—1898=131,003 cwt., R786,019; 1899 148,281 cwt., R444,844; 1900 157,116 cwt., R471,350; 1901 161,927 cwt., R582,578; 11 months of 1902 151,558 cwt., R454,832.

HOW LONG WILL GREEN TEA CONTINUE TO BOOM?—This is a question many in Ceylon would like answered. That it is booming now, no one will deny, and we have heard of low-country teas recently having sold at 36 cents, plus 5 cents bonus, bringing the seller 41 cents—considerably over what his black teas would fetch. The great caution shown by buyers seems to indicate that prices will not be maintained. For instance when prices were at 32 and 33 cents buyers readily took contracts. Now that 34, 35 and 36 cents are obtained buyers strictly refrain from making contracts, evidently believing that green tea has already reached its high water mark. Referring to a recent allusion of ours to these contracts, *Indian Gardening and Planting* of January 10th, just to hand, says:—

"These transactions certainly offer a good inducement to Indian planters to follow suit. 35 cents, or 5 annas 7 pies steady average without any anxiety whatever as to the rise and fall of the market, would pay very many concerns well, to say nothing of the bonus which would defray the extra cost of machinery. The contracts are, of course, for uncoloured tea, and it should not be difficult, considering the excellent quality of green tea turned out in India, for some of these contracts to be secured locally. The effect upon the development of the new industry of such arrangements must be most marked, for the buying contractors will necessarily make every effort to get the tea into consumption."

Correspondence.

To the Editor.

"PINEHURST" TEA IN AMERICA.

Toronto, Dec. 9th, 1902.

DEAR SIR,—I read with interest the editorial in your issue of October 22nd, was highly amused by it, and think it is the proper spirit in which to take any statements that appear in the Press about the "Pinehurst Tea Plantation" in America, for it is a huge joke; but when your article went on to state that "The Pinehurst Plantation" accomplished the publicity that it got in "The Boston Herald," for the mere writing of the said article, then you evidently do not understand newspaper methods here. If you think "The Boston Herald" would allow any institution or person, to boom itself at the expense of the proprietors of the "Herald," then you are mistaken. Every line of the article you allude to was paid for, and paid roundly for, and in fact it is articles like this that bring around the donations from the Government of \$10,000 to \$20,000 to help on the "experiments" of the "Pinehurst Plantation." Therefore when you reflect on your Commissioner for not getting similar articles inserted free, you are doing him an injustice. I will venture to say that Ceylon tea has had more free reading articles in the Press of the United States twenty times over than the "Pinehurst Plantation," but this has been done not only by making the articles interesting, but also by buying much space in their advertising columns.—Yours truly,

P. B. LARKIN.

PARA RUBBER IN THE MALAYAN PENINSULA.

Resident General's Office, Selangor, Malay Peninsula, 24th Dec., 1902.

SIR,—I am directed by the Resident-General to enclose for your information one copy of a report on *Hevea Brasiliensis* in the Malay Peninsula, by Mr. Stanley Arden, Superintendent, Experimental Plantations, Federated Malay States.—I have the honour to be, Sir, your obedient servant.

O. W. H. COCHRANE,

for Secretary to the Resident-General,
Federated Malay States.

[We are much obliged to the Resident-General for his attention. The importance of Mr. Arden's Report can be judged from his covering letter:—

Secretary to the Resident-General, Federated Malay States.

Batu Tiga, Selangor, 27th September, 1902.

SIR,—I have the honour to forward a report on *Hevea brasiliensis*, the tree furnishing the "Para" rubber of commerce.

2. The report deals with:—(a) A Short History of its Introduction into the East. (b) Cultivation. (c) Extraction of the Latex. (d) Yield. (e) Preparation of Marketable Rubber. (f) Cost of Opening and Maintaining a Plantation. (g) Probable Returns,

Many of these questions need much further investigation, work which is greatly handicapped owing to the very few trees at any disposal and the disparity in yield of trees growing under similar conditions, which necessitates the conduction of experiments over a large number of trees if reliable information is to be obtained.

3. The age at which tapping might profitably commence is still a matter of conjecture, but I have ventured the opinion that probably 50 per cent of five year old trees will give an average yield of eight ounces per tree, and that from 75 per cent of six year old trees an average yield of 12 ounces may be expected. Experimental tapping of young trees will be continued and the matter should be definitely settled within another eighteen months or two years.

4. The report on the rubber prepared by various methods will be made as soon as possible.—I have the honour to be, Sir, Your obedient servant,

STANLEY ARDEN, Superintendent, Experimental Plantations, Federated Malay States.

—ED. T. A.]

RUBBER AT 1,600 FEET ELEVATION.

Kepitigalla, Matale, Jan. 7.

DEAR SIR,—In reply to "Cha's" enquiry whether Para rubber would be profitable if grown at an elevation of 1,600 to 1,800 feet? I am now tapping some trees at about 1,600 feet on a hillside, and am very pleased with the excellent results obtained. Trees at this elevation, although a good deal smaller than the ones of the same age at a lower elevation, are now being proved to yield *better* than those lower down. They only require one incision in the morning and the cups are emptied at 11 a.m. and replaced under the same cut immediately, and are again emptied at 3 p.m., thus giving the same yield from one cut as would be obtained from two cuts on trees at the lower elevation. I have never been able to do this at the low elevation, as the latex does not flow after 10 a.m. This is proof positive that Para rubber yields better at 1,600 than at 600 feet.

I think this a very important fact, and one that will no doubt be noted by all concerned in Para. It is probably due to the cooler atmosphere at the higher elevation, which does not tend to coagulate the pure latex as it exudes from the wound. Whereas at the lower elevation the temperature being much higher, the latex scarcely has time to run into the cups before it coagulates on the way, owing to the heat.—Yours, &c.,

FRANCIS J. HOLLOWAY.

RAINFALL NEAR NAWALAPITIYA.

Donside, Nawalapitiya, Jan. 8.

SIR,—The following rainfall may be of interest to you, as also some of your readers, as there seems to be no register kept in this district by any of the Government officials:—1891, 194.88 inches; 1892, 130.61; 1893, 124.95; 1894, 100.51; 1895, 130.19; 1896, 133.61; 1897, 131.51; 1898, 107.19; 1899, 132.83; 1900, 149.26; 1901, 118.33; 1902, 126.3.—Total 1,580.21 for the 12 years: an average of 131.68 inches.—Yours, &c.,

R. B. HECTOR.

[So that, strange to say, last year's rainfall—at Donside, close to Nawalapitiya—was below the average.—ED. T. A.]

BUTTER-MAKING.

Jan. 11.

DEAR SIR,—To give that new style of butter-making a fair trial, I put about a pint of cream into the muslin and filtering paper: it took 3 or 4 hours for the moisture to trickle through and the butter was softer than if made by the old way viz., the cream put in a bowl and stirred with a spoon; by this method the butter was made in 5 minutes, as with this cold weather the cream is thick and firm and makes into butter very quickly and it is nice firm butter too, so that on the whole I like the old system best.—Yours truly,

HOUSE-KEEPER.

P.S.—I'll give that butter-making yet another trial.—H.

COARSE PLUCKING: A WARNING
FROM LONDON.

Kandy, Jan. 13.

SIR,—I enclose for publication the following telegram, received here today from London, which explains itself.—I am, Sir, yours faithfully,

A. PHILIP,

Secretary to the Planters' Association of Ceylon.

"Big London buyers recognise India means control quantities auction; spite strong statistic position, buyers confident able to keep down prices, because Ceylon resorting as before coarse plucking flood market: warn planters earnestly against coarse plucking. Ceylon Association."

THE LAKE-FLY NUISANCE: AN EXPERT REPLY TO THE "SEA-WATER" SUGGESTION.

Colombo Museum, Jan. 14.

DEAR SIR,—Referring to Mr. Theobald's suggestion regarding the extermination of the Lake Fly, I have read his letter and may say that, as for the practicability of converting the Colombo Lake into a temporary arm of the sea, I have no doubt that this herculean method of purification would be child's play to an engineer—other things, of course, being equal. With regard to the question as to whether it would be likely to achieve the required object, it is necessary to know certain facts before an opinion based upon biological considerations could be hazarded, e.g., the differences in density and salinity between the lake-water and the sea-water, the degree of salinity which could be endured for a longer or a shorter period with impunity, firstly by the larvæ and secondly by the eggs of the fly.—Yours faithfully,

ARTHUR WILLEY.

THE LAKE-FLY NUISANCE.

Colombo, Jan. 14.

DEAR SIR,—While thanking Mr. Willey for his reply to my letter in your columns re the "Lake Fly Nuisance" I fail to see that his remarks are in any way conclusive that my proposal is impracticable. The engineering difficulties appear to me the

easier of the two, but we need not waste time discussing this till we know whether sea-water will exterminate the flies. On this point Mr. Willey is not definite. Perhaps, if he would kindly make a few experiments he would be able to give a decided opinion.—Yours faithfully,

F. C. THEOBALD.

COARSE PLUCKING AND RESPONSIBLE PARTIES.

Up-country, Jan. 16.

SIR,—You can put "Avoid Coarse Plucking" in a prominent place in every issue of your paper, but it will do little good unless the country is supported by the Colombo agents and certain V. A's., who, at present, are in that habit of jumping on their Superintendents for not keeping down the cost of plucking. If the Colombo agents would insist on their Superintendents spending say $\frac{1}{2}$ cent per lb., more in 1903 than it cost to pluck in 1902, they would reap a penny profit for the $\frac{1}{2}$ cent extra outlay. There are so few properties in private hands now, that the matters of supply and demand lie entirely in the hands of the Colombo agents. A Superintendent is not going to pluck "fine" or "medium" if it means the "sack" for exceeding his estimate for plucking. I have always maintained that since nearly all Ceylon tea estates fell into the hands of Companies, the Colombo agents have been the arbiters as far as yield is concerned. Mr. Figg apparently agrees with me.—Yours, &c.,

NORTH C. DAVIDSON.

PLANTING NOTES.

NOTES ON PLANTAIN (MUSA) FIBRE INDUSTRY—by V T Venkatraman Aiyar, Valavanur South Arcot District—is a useful little pamphlet; but there is not much in addition to what we have already heard from Kew, Drs. Watt and Morris.

JAVA CINCHONA EXPORTS FOR 1902—are given at 13,143,000 Amsterdam lb. of bark as against 12,606,000 for 1901. In English lb. the comparison runs:—

1902 ... 29,440,320

1901 ... 28,237,440

The Amsterdam *pond* is equal to 2.24 English pounds—the French kilogramme being 2.20.

RUBBER.—It is certainly quite time that the Chamber of Commerce added rubber to their list of exports since the one district of Kalutara is expected to give a crop of 7 tons or over 15,000 lb.; and this is bound to increase year by year as younger trees come into bearing. No doubt there are other districts, such as Matale which will contribute so that the youngest product in the list should make a brave show before long. From the Customs accounts for the first eleven months of 1902 we see that 161 cwt. (18,000 lb.) of rubber were exported, valued at R34,086.

COCOS ISLANDS.

Governor Sir F A Swettenham forwards to Mr Chamberlain a report by Mr L H Clayton, District Officer, Christmas Island, who was deputed to pay the annual visit to the Cocos Islands. Sir Frank remarks:—"The report shows that the islands continue to prosper under the paternal rule of Mr. George Clunies-Ross and that the people are on the whole well-to-do and contented. There are no new developments which call for special remarks." Mr Clayton reports that the islands are still happy and contented, though they suffered severely from a cyclone in March, when the natives ran to lagoons and stood up to their necks in water, as the only place of safety. Existence at Cocos Islands is otherwise uneventful, but they now have a doctor, who is a great acquisition, for hitherto cases of illness have been diagnosed and treated by telegraph from Perth (Western Australia). The next great event will be the establishment of a Lloyd's signal station. The following is extracted from the report:—

I have nothing to add to what has been stated in former reports as to the excellent condition of the Cocos and Bantamese villages. The Cocos-born people are tidier and more attractive than the Bantamese, and, in the same way, the village of the former presents a better appearance, but in neither case did I see anything to call for adverse comment.

I visited Direction Island, a portion of which has been leased to the Eastern Extension Telegraph Company. There are resident there at present in temporary buildings Mr. Cameron and nine European assistants, with 14 Chinese servants and four Malay boatmen. In addition to these there are three Europeans and 39 Chinese engaged on the erection of permanent buildings for the staff. Eight or nine houses of various sizes will be required, and I should imagine it will be over a year before the staff are finally settled down. The chief difficulty that they have encountered has, I understand, been the lack of water. No water is obtainable on Direction Island, and at first they were supplied from the other islands by boat. A condenser has now been erected, and as the buildings are completed water will be collected from the roofs. The yearly rainfall is almost certainly over 80 inches.

In order to avoid the necessity of chartering ships to take the copra away, Mr Ross has recently purchased a sailing vessel, the "Broughton," a barque of 571 tons register. The only shipment of copra made in the past year was one of 706 tons sent to Europe by this vessel in May last. The quality of the Cocos copra appears to be as high as ever, as the shipment fetched the excellent price of £18 5s per ton, the highest figure reached for some years. There have been no other exports. About 190 tons of copra were in store ready for shipment, and I was told that 15 tons were produced in an average week's work.

The natives complain about their clothes. I share Mr Carter's opinion, in last year's report, that the difficulty of obtaining nice clothes is obviously not insuperable. A sailing race was also held for prizes given by Commander MacHutchin, and the winners had their choice of a piece of serge or a pair of substantial boots as prizes. The

serge was chosen, as the men explained that boots were of no use except to dance in.

The ship went to North Keeling with Mr Ross on board. The island has only once been visited (1893) by a man-of-war, and in that year Mr Ross decided not to continue working it. No one had in consequence set foot there for nine years. Under the circumstances I was surprised to find that the undergrowth was not particularly thick, and that we had little difficulty in getting about. The house formerly occupied by Mr Ross was standing, although of course out of repair. The stock of food left in case of shipwreck had not been touched, and the well was in good order. Only slight damage had been done by the cyclone, and Mr Ross decided after inspection to work the island again in October. Every tree and bush is covered with the nests of frigate-birds, boobys, gannets, terns, &c. The birds are quite tame and have no fear of man. The white tern, to my mind the prettiest of all, is most inquisitive, and numbers of them kept fluttering round our heads. Mr Ross showed us one of the bird's egg *in situ*. It has been laid so as to rest between two ribs of a cocoa-nut leaf, and was so placed that the swaying of the leaf in the wind did not shake it off. There was no nest of any kind.

During my stay at the Cocos very few complaints were made to me, and those chiefly by the women. Poverty and the high prices charged at Mr. Ross's store were the principal grievances, but it did not seem to me there was much foundation for them. Mr. Ross told me that he had already detected among his people signs of restlessness owing to presence of the employés of the Telegraph Company. I cannot say, however, that I observed any indication of it.

The extraordinary influence exercised by Mr. Ross over the natives, and the wonderful success of his administration, made a great impression upon me, and I am confident that so long as the present proprietor retains his health there need be no fear that justice will not be fairly and evenly administered, or that welfare of the inhabitants will not be properly attended to. So long, moreover, as the conditions of life are as favourable as they are at present, I do not think that any complaint can be made if every legitimate inducement is held out to natives to remain there. —*London and China Express*, Dec. 5.

CEYLON TEA IN VIENNA.

We have received a copy of the illustrated "Wiener Bilder" of December 24th, which contains, beside Mr. Marinitich's regular advertisement, nearly a page of illustrations devoted to "Tea Culture" with corresponding letter-press and a portrait of Mr. Marinitich—all of which is well calculated to interest readers in our staple industry and the product recommended to their notice.

The writer, who has gained his information while interviewing Mr. Marinitich in his warehouse in Vienna, gives a full and interesting account of tea cultivation, packing, and exports. As the duty on tea in Austro-Hungary is double that levied in Germany, it must still be too dear to become the people's drink, which, he says, it ought to be throughout the Continent.

THE "THIRTY COMMITTEE."

Minutes of a meeting of the "Thirty Committee" held at the Victoria Commemoration Buildings, Kandy, on Saturday, 10th January, 1903. (7-30 a.m.). Present:—

Messrs A C Kingsford (Chairman); A Philip (Secretary); Hon. Mr J N Campbell, M.L.C.; Hon. Mr Edward Rosling, M.L.C.; Hon. Mr Stanley Bois, M.L.C.; Messrs Gordon Pyper, Edgar Turner, James F Headrick, Hercules J Scott, W Shakspeare, Walter J Smith, C E Welldon, R Morison, W D Gibbon, G H Alston, H V Masefield, W Forsythe, Frank S Vowler, W D Bosanquet, T C Huxley, James Westland, Joseph Fraser, W R Tatham, R A Galton, Fred. Hadden and E Webb, (26 members.)

(After Formalities.) MISCELLANEOUS.—Read letter from Mr R V Webster regarding a new Tea Company for Switzerland. Read letters from the Co-operative Tea Gardens Company transmitting newspaper advertisements in Honolulu, America, Egypt, Malta, and Africa and sundry advertising matter in connection with Mr R V Webster's vote, for pushing and advertising Ceylon Tea. Read letter from Messrs Rodewald & Heath, Colombo. Submitted correspondence with Mr Charles Stonter. Read letter from Mr O H Greenslade and from Mr W Wilson Smith regarding selling of Tea in California, Mexico, Arizona and the Mining towns in the desert. "Resolved:—That the Committee regret being unable to entertain the applications."

TEA TRADE IN ANNAM.—Submitted correspondence with the Ceylon Chamber of Commerce.

MEMBERS OF COMMITTEE.—Read letter from Capt Gordon resigning his membership in the "Thirty Committee" in view of his departure from Ceylon.

CORRESPONDENCE, &C. CIRCULATED.

CEYLON TEA IN AMERICA.—Letters from Mr Mackenzie to Mr Kingsford, dated, Chicago, 27th October and Toronto 30th October; Montreal 4th November New York 14th and 7th November; to Mr Kingsford, Hampstead 5th December; Mr P C Larkin to Secretary, Toronto 3rd November; Mr R V Webster to Mr Kingsford, 4th December; Mr P C Larkin to Mr Kingsford, Toronto, 20th November; Mr Mackenzie to Mr Kingsford, Hampstead 12th December, 1902.

COMMISSIONER ON THE CONTINENT OF EUROPE.—Letters from Mr Renton to Mr Kingsford, dated, 2nd November and Berlin 13th November Buckeburg, 27th and 30th November; (2) 4th and 5th December.

CEYLON TEA (NEW MARKETS) FUND.—Letter to Secretary, from Government, dated, Colombo, 29th November, 1902.

PROPOSED INCREASE OF THE TEA CESS.—Letters received by the Ceylon Association in London in reply to Circular letter on the subject. Correspondence received from the Secretary, Ceylon Association in London, showing the opposition raised against the increase of the Tea Cess in 1901.—Submitted letters from Treasurer of the Colony.

CEYLON GREEN TEAS GRANT 1901-1902.—Memo. of payments made at 15th December, 1902. Amended Green Tea Memo. up to 15th December, 1902, in lieu of previous one with printers' error.

FINANCES.—Interim Sketch of Ceylon Tea (New Markets) Fund at 31, 12, 1902 subject to closing entries indicated.—Submitted Correspondence with National Bank of India.

CEYLON TEA IN AMERICA.—Letters from Mr Mackenzie to Mr Kingsford, dated, New York, 17th and 21st Oct., 1902.

COMMISSIONER ON THE CONTINENT.—Letters from Mr Renton to Mr Kingsford, dated, Stuttgart, October 10th, Lyons, 20th, Orleans, 24th, Paris, 26th, Paris, 28th, and Lyons, 17th 1902.

CEYLON OOLONG TEA.—The process in Formosa described, (printed.)

CEYLON TEA IN AFGHANISTAN.—Letters from Mr Foley to Mr Kingsford, dated, Quetta, 20th and 29th October and 13th and 29th Nov., 1902.

CEYLON TEA (NEW MARKETS FUND).—Memo. of Payments since July, 1902

CEYLON GREEN TEAS.—Statement of lb on which payment was made during 1901 and 1902.

CEYLON TEA (NEW MARKETS) FUND.—Submitted letters from the Treasurer of the Colony.

GOVERNOR IN EXECUTIVE COUNCIL.—Read letters from Government stating that His Excellency the Governor had been pleased with the advice of the Executive Council to sanction a further expenditure of R1,500, in presenting the Boer Prisoners-of-War who are returning to South Africa, with gifts of Ceylon Tea; and to sanction the following proposed appropriations from the Ceylon Tea Fund of a sum of R470,000:—

Green Teas, 7,000,000 lb. at 4 cts. . .	R280,000'00
America	105,000'00
Continent of Europe	75,000'00
Administration Contingencies	10,000'00

R470,000'00

CEYLON TEA IN AMERICA, REPRESENTATIVE IN AMERICA, WORLD'S FAIR, ST. LOUIS, U.S.A. IN 1904.—Submitted correspondence circulated. Read letter from Mr Wm. Mackenzie, dated London, 19th December, 1902, in reference to Ceylon Green Teas. Resolved:—"That the extract from the New York correspondence be published in the newspapers."—Read letter and Memo of Instructions from the Chairman to the Hon. Mr William Henry Figg, representative in St. Louis, U.S.A. on a preliminary mission for report regarding the World's Fair there in 1904.

PROPOSED INCREASE OF THE TEA CESS.—Submitted correspondence and discussed the question. Resolved:—(1) "That it be publicly notified that the funds available are only capable of meeting the payment of a bonus at 4 cts. on 7,000,000 lb. spread over the year and that should larger quantities be made, say than an average of $\frac{2}{3}$ million lb. per month, payment will have to be held over from time to time until funds are available (1) that the "Thirty Committee" considers Mr Rutherford's proposal to guarantee a bonus of 4 cents a lb. for 1903 payable partly out of 1904 funds is extremely inadvisable (11) that Proprietors at Home be again approached through the Ceylon Association in London and that it be represented that in view of the outturn of Green Tea during December, 1902 having been, say 700,000 lb. and the estimated manufacture for 1903 (submitted in detail), amounting to 12,000,000 lb., the Committee would again ask the Ceylon Association in London to consider the question of an increase of the Cess, and would push for an increase up to $\frac{1}{2}$ a cent per lb. limited to eight months, 1st May to 31st December, 1903, thus providing funds for the payment of a further amount of, say, 5,000,000 lb. at 3 cents per lb.

CEYLON TEA IN AFGHANISTAN.—Read correspondence with Messrs Crosfield Lampard & Co. Submitted correspondence with Mr E G Foley.

CEYLON TEA IN HONOLULU AND WEST INDIES.—Read correspondence with Messrs Bosanquet & Co., and Mr R Valentine Webster, and intimated that the sum of R7,500, had been paid for credit of Mr R V Webster in full settlement of Grant voted to him in connection with pushing of Ceylon Tea in Honolulu, West Indies, North and South Africa.—The "Thirty Committee" then adjourned. A PHILIP.

Secretary to the Thirty Committee.

DETAILS OF EXPENDITURE.

CONTINENT OF EUROPE: R67,649-60—being cost of £4,500 remitted Mr Renton, details of this expenditure will be shown later in Mr Renton's account.

RUSSIA: R2,273-69.—Amount paid Messrs. Crosfield Lampard & Co. being balance of £1,000 voted them in 1898 for pushing Ceylon tea in Russia. Against this vote of £1,000 Messrs. Crosfield Lampard & Co. show shipments of 5 million pounds during the three years.

AMERICA. R75,099-75—being cost of £5,000 remitted Mr. Mackenzie, details of this expenditure will be shown later in Mr. Mackenzie's account.

Green Tea Bonus:	R202,362-60	R	c.
Claim on account, 1901.	18,183 lb. at 1½ cts.	272	24
Being bonus on 36,995 lb. at 6½ cts.		2,404	66
137,863 lb. at 6 cts.		8,271	78
151,883 lb. at 5½ cts.		8,353	52
3,661,198 lb. at 5 cts.		183,059	90

Total.. 3,987,939 lb. 1902

1,590,000 lb. 1901

472,294 lb. 1900

86,327 lb. 1899

13,302 lb. 1898

6,149,862 lb. to date 31st December, 1902, on which a bonus has been paid. Amount remaining of 5 cents bonus, R7,454-83 for 149,095 lb.

SOUTH AFRICA AND WEST INDIES. R7,500—being grant of £500 voted Mr. R V Webster in 1900 for pushing Ceylon tea in North and South Africa, Honolulu, the West Indies, Malta and Gibraltar.

AFGHANISTAN, R7,182-31—No. 2 account received from Mr. Foley R3,000.

Despatched 120 half-chests Green Tea costing	R	c.

Paid Messrs. McIver Mackenzie & Co.. (Being Duty, landing and forwarding charges about R690 less proceeds of damaged tea)	265	24
	<u>Total</u>	<u>R7,322 70</u>
Less amount at credit No. 2 account..	150	39

Total outstanding ... R7,182 31

Of this amount about R5,000 is recoverable from Mr. Foley.

Total amount of tea shipped Mr. Foley about 14,500 lb BOER PRISONERS-OF-WAR.—R9,408 50—being the cost of 4,585, five pound boxes of tea presented to all prisoners-of-war returning to South Africa. Total amount of tea 22,925 lb. costing with boxes 41-04 cents per lb. This tea was distributed before landing in South Africa and was allowed into the country free of duty.

"Golden Tips" R249.—Cost of 50 copies of "Golden Tips" sent to Mr. Mackenzie for distribution in America.

Salaries and Sundries, R10,000.

GREEN TEA AND PATENTS.

Writing under date, 7th January, Mr Drummond-Deane mentions:—"My Ceylon patent for the Deane-Judge Strainer hangs fire owing to the usual red-tape, though it has been granted long ago for India. I am of opinion that the 'Thirty Committee' bonus on green teas should be on a sliding scale; otherwise, as black teas rise in value, greens will fall back. I suggest as worthy of consideration that with black tea average 8d or over, the green tea bonus should be not less than 8 cents which, with such an average, the black tea producers can well afford and that for every farthing fall (or fraction of a farthing) there should be $\frac{1}{2}$ a cent reduction down to 6d average, where it should remain at $\frac{1}{2}$ cents. Something on these lines is wanted if you don't want to nip the green tea industry in the bud. We shall shortly have a Deane-Judge Finishing and Pan-firing Machine for the Ceylon public."

Mr Drummond-Deane will see that we cannot go on even at 4 cents and that there are many who think green tea could stand by itself, so good have been the prices paid at Colombo sales lately. What does our correspondent think of 36 cents

for low-country greens apart from bonus? But the question is now pertinently asked as to whether the fostering of a *new industry* is not peculiarly the duty of the Government.

TEA CULTIVATION IN THE CAUCASUS ASIATIC RUSSIA.

With reference to the notice on pp. 368-9 of the *Board of Trade Journal* for 15th November, 1900, H M Consul at Batoum, in his recent report, states that the cultivation of the tea plant in the Southern Trans-Caucasus, and principally in the vicinity of Batoum, is making great strides. It is only some nine years since the first attempts in the culture of tea were made on the coast of the Black Sea by a Russian gentleman, and his undertaking was then looked upon most sceptically by the majority of the agricultural people in the district. Since then it has, however, become evident that tea can be cultivated to advantage, and several other persons in the district also began to grow tea on their estates, among them the managers of the Imperial Domains, who now have 500 to 600 acres under tea.

During the present year the tea crop surpassed all expectations, 1 dessiatine (2.7 acres) having, on an average, yielded 20 pounds, or 800 Russian lb (720 lb avoirdupois weight), which, at the rate of 1 rouble per pound, the a-l-round wholesale price at which it has been sold, has brought in 800 roubles per dessiatine; or, as near as possible, 30% per acre.

Owing to the satisfactory results obtained during the period, under review, the Russian Ministry of Agriculture, it is understood, is about to adopt a series of measures in order to encourage and foster the cultivation of tea by the small peasant classes, and books containing instructions and explanations with regard to the industry, are being widely circulated among the farmers of the locality in which the tea is grown.

Under the conditions set forth above, the theory that tea growing in the Caucasus would not be generally adopted on account of the unfavourable climatic conditions and other difficulties which have to be encountered, including the high rate of wage paid for labour, or that the tea industry and trade of the Caucasus could not possibly expand to a stage which would render it, even at a remote date, of commercial importance, is apparently an exploded idea. The results obtained during this season show that quite the contrary is likely to be the case, and that there is every reason to believe that the cultivation and manufacture of tea promises to be one of the most prosperous and profitable agricultural pursuits in the Trans-Caucasus.—*Board of Trade Journal*, Dec. 24.

TEA TRADE CHARGES.

The recent regrettable failure of an old and honourable City firm of tea merchants, who attributed their losses chiefly to the changing conditions of their business, has directed attention to the almost complete revolution that has taken place in the tea trade of late years. So far as the retail buyers are concerned, it has come about so silently and gently that they have fallen in with it, quite unconscious that any transformations were proceeding. They are vaguely aware that China tea has to all intents and purposes passed out of their grocer's shop, and they are learning that tea should be drunk when freshly made. Price remains their chief standard of comparison, and the average householder feels she has acted rightly when she orders a quantity at 2s. a

ponnd for general use, and a smaller amount at 2s. 6d. for her weekly "At Home" day. But how it has come about that month after month she can rely upon having the same quality of tea, and

THE SAME "ROBUST" OR "SOFT" FLAVOUR, to cite the terms of the dealer's list, she knows not, nor has she any idea of the skill and science which have ousted the rough and ready methods of by-gone days. The old-fashioned tea-caddy, with its divisions for black and green tea, which were mixed at the discretion of the lady of the house, seems as far from the elaborate machinery of scientific blending of today as the tallow candle from the electric light.

To understand the present conditions of a trade of such vast proportions and Imperial moment, it is necessary to go back to the early sixties, when the experiment of tea-growing were first made in India China was then supplying the world, or rather, such portions of it as consumed tea, and gentlemen of long experience in the trade can tell one that about 1868 the general quality of this tea was at its best, though 1879 saw the "record" of bulk ever furnished by the Celestial Empire. Meantime, it was steadily deteriorating, however, and India was becoming a more and more formidable rival. Ceylon came into the lists, too, and by 1886 was sending in 6,600,000 lb, and every year has made enormous strides. It is interesting to note, therefore, the

RELATIVE PROPORTIONS OF THE TEA

now drunk in this country by the figures of last year. Roundly, India furnished us with 148,000,000 lb, Ceylon with 91,000,000 lb, and China with 10,000,000. According to the latest available statistics, India has nearly 5,500,000 acres now under tea cultivation, and Ceylon 387,000. Tea is a growth that is most easily affected by soil, height, the wetness or dryness of a season, and a score of other influences, and the products of certain estates are known to be superior to those of others. With the varying conditions of such a wide area, and tea good, bad, and indifferent available, how is it that it reaches the consumer so unvarying in the standard of quality and flavour?

It is due entirely to the expert ability of the blender and when new methods were introduced about 1888, the transforming change began. Previous to that the grocer, judging approximately the amount he would require, ordered a few chests of China and Assam tea of varying degrees of pungency or mildness, and according to his own judgment mixed any two or three of them, and gave them labels and designations as he thought most likely to commend them. He did not possess the super-cultivated palate

ESSENTIAL TO A TEA-TASTER;

his ideas of combinations were essentially primitive and restricted, and he quite failed to take into account that, say, the Orange Pekoe from Darjeeling, which had been so good a feature of "our strongly recommended" last year, might this season be a totally different tea, on account of an abnormal season. Of course, his mixtures sometimes proved successful, but there was always uncertainty, and the fastidious people who were wont to say, "they could not drink grocers' tea" were in the habit of sending to one or other of the old-fashioned London houses, which made a speciality of high priced and choice teas.

The pioneers of the change conceived the bold idea of supplying the grocers with ready-handed tea, and bold and enterprising firms pushed forward the scheme with rapid success. They secured the assistance of tasters able to detect the subtlest gradations of flavour, and able to judge to a nicety the exact degree to which a full, rough Assam, with its large percentage of theine, should be tempered with the softer growth of Ceylon's uplands, and the fragrant dash of some scented variety. By means of constant experiment they mastered the great secret, which is to produce a "negative" blend.

IN A POPULAR TEA,

at the present time there may be anything from twelve to twenty different kinds of the leaf, each represent-

ing some different qualification of strength, delicacy, flavour, or aroma. The importance of the water used is now recognised as it never was of yore, and different blends are prepared for districts where this can be broadly classed as hard or soft. In the mixtures prepared for Scotland and Ireland, for instance, the combinations are quite distinct. But between these clearly defined divergences there are endless lesser ones and it is found on experience that a blend embodying numerous constituents is more likely to prove universally suitable and palatable than one into which fewer varieties enter. Moreover, in the event of a failure in any of the crops represented, it is easier to replace a small proportion of the whole, and to maintain the level standard that the public now demands in what may be termed the "branded" teas of favourite firms.

It is pleasant to be able to state, on the highest authority of the wholesale houses, that never has better value been offered to the retail buyer than at the present time. The prices both of Indian and Ceylon teas have been steadily declining during the last twenty years, and adulteration has thus been stamped out. So much genuine, even if not high-class, tea is now available, that there has ceased to be the incentive there once was to mix other items with it, so that though flavour of the cheaper descriptions sold may not always appeal to a critical and fastidious tastes in tea, there is no occasion to fear it may contain foreign substances. The average housekeeper, too, has learnt to make tea upon better principles, and instead of extracting every grain of tannin it contains by long infusion, she uses more of the leaf and pours it out after two or three minutes' "drawing," to the advantage of the nerves and digestion of the consumer. This point is illustrated to some extent by the steady growth of the tea drunk per head of the population, which from the 4.91 lb of 1895 had attained last year to 6.17 lb., and is beginning to approach Australia—the greatest tea-drinking country of the world in ratio to its population—with its 7.80 lb.—*Daily Telegraph.*

SEYCHELLES VANILLA.

The Administrator of the Seychelles, in the course of his annual report on the trade for 1901, states that the falling off in the value of exports of coconuts, coconut oil and soap is attributable to neglect of existing plantations in favour of the cultivation of vanilla. Admirably suited as are the climate and soil of Mahé, Praslin, La Digue, Silhouette, and many other islands for the cultivation of this valuable orchid, the abandonment, or even partial neglect, of coconut-plantations is much to be deplored. In view of the many uses to which coconuts can be put, the danger of over-production is slight; but in the case of vanilla, the danger of over-production is considerable. There is capriciousness about the yield of vanilla, and even a greater capriciousness about its price, which renders it desirable that planters should have some other products of economic value to rely on when the yield is small or its selling-price unremunerative. This conclusion seems to be justified by the following statement, showing the quantity of vanilla exported from Seychelles and its declared value at the Customs from 1891 to 1901:—

	Quantity in Kilos.	Declared Value. Rs.
1891	40,929	373,190
1892	28,177	394,478
1893	28,869	346,428
1894	24,444	293,328
1895	4,553	61,844
1896	31,227	936,000
1897	30,691	920,780
1898	25,177	748,810
1899	41,835	1,338,720
1900	17,569	580,877
1901	71,899	1,108,792

Nearly the same amount of vanilla was exported in 1891 as in 1899, and yet the declared value of the vanilla of 1899 exceeded the declared value of the vanilla of 1891 by almost 1,000,000r. In 1901 the quantity of vanilla exported exceeded four times the quantity exported in 1900, and had prices been maintained, the declared value of the vanilla exported should have been over 2,000,000r., or four times what it was in 1900; but it will be seen that it was not quite twice as much, and, as has been pointed out before, the declared value probably exceeded the actual value.

The first year for which there is any record of vanilla being exported from Seychelles is 1877, and in this year the quantity was 60 kilos., valued at 1,195r. The next year the quantity exported rose to 147 kilos., valued at 2,950r., but fell in 1879 to 8 kilos., valued at 160r. In 1880 the export of vanilla amounted to 1,713 kilos., valued at 22,877r., and from that year Seychelles has never looked back as a vanilla-producing country.—*Chemist and Druggist*, Dec. 27.

THE BRAZILIAN RUBBER CROP.

DEVELOPMENT OF THE GUTTA PERCHA INDUSTRY.

In a report on the prospects of the Brazilian rubber trade the United States Consul at Para says the political troubles in the Acre territory have had a serious effect upon the rubber trade throughout that region, and will undoubtedly result in largely reducing the crop. The rubber produced on the Beni and the Acre is considered the best that comes to Para, and its loss will therefore be felt by shippers and importers alike.

It is said that the caoutchouc forests of Peru, from which nearly the whole supply of this product has heretofore been drawn, are practically exhausted, as the result of the wasteful methods pursued by the gatherers. It appears, however, that there is an almost inexhaustible supply of caoutchouc in the little-known regions about the Upper Madeira. In the near future,

GATHERERS MUST LOOK TO BOLIVIA

for their supply of this gum. It is understood that a strong effort will be made to prevent their destroying the trees as in Peru. Experts state that the tree can be tapped in a special manner and its gum extracted year by year for a long term before it becomes exhausted.

A serious obstacle to the successful production of rubber on the head waters of the Madeira is the system of taxation now in effect. Rubber merchants are charged 23 per cent ad valorem export duty by the State of Matto Graoso. The State of Amazonas also charges 23 per cent duty.

GUTTA PERCHA.

The supply of balata in sight is said to be so great that no fears of a shortage need be entertained for years to come, if the business is properly and intelligently handled. Experts report that there is not a tributary to the Amazon which does not show forests of this tree upon its banks. The importance of this new industry in Brazil may be realised when it is known that the market price of balata is equal to that of the best rubber and the cost of production is less than one-tenth that of rubber.

BALATA HAS ANOTHER ADVANTAGE

in that it does not necessitate the risk of life attendant upon the gathering of rubber. The balata grows upon high ground, as well as on the margins of the swampy streams where the fevers lurk. It is a common saying in Para that every ton of rubber from the upper river costs two lives. This can never be said of balata, for men may work at this industry with no greater risk than usually attends any labour in the Tropics; and four men will gather as many kilograms of balata per day as thirty men can obtain of boracha.

At present there are three syndicates in the field to produce gutta-percha, one English, one Belgian and one German.—*Commercial Intelligence*, Dec. 25.

MASKELIYA PLANTERS' ASSOCIATION.

THE ANNUAL REPORT.

The CHAIRMAN—after the notice calling the meeting was read, asked the Secretary to read the annual report.

Mr H A WEBB—Hon.-Secretary, read the report as follows:—

Your Committee begs to submit to you its 31st annual report.

Four General and four Committee Meetings were held, at which the attendance as usual was good.

MEMBERSHIP.—The number of estates subscribing to the Association, is 54 against 52.

FINANCES.—The balance at credit of the Association is R742'11 as compared with R705'10 in 1901.

CROP ESTIMATE for 1903 is:—Black Tea, 7,436,000 Green Tea, 350,000.—Total 7,836,000 against an estimate for 1902 of 8,000,000.

TOTAL ACREAGE in tea on the district is 18,096. Estimated yield in this is at the rate of 440 lb per acre.

SEASON.—The very bad flushing weather of the last half of the year has caused a great shrinkage on the output of the district and on many cases estimates will not be reached. This was not so much due to incessant rainfall as to the long-continued, cloudy, cold weather and the great want of sun. Prices have generally been rather lower.

LABOUR has been sufficient for the needs of the district, probably owing to the shortage in the crop before-mentioned.

UPCOT-GLENGUE CART ROAD—This subject, which has occupied the attention of the Association for a long time past, seems at last, in a fair way to be settled. For this the thanks of the Association are largely due to Messrs Craib and Cuff who have taken much trouble in the matter.

TRAVELLERS ROADS.—The following grants were made:—Hapugastenne Road, R100, Stockholm Road R60, Nyauza Road, R40, Glengue Road, R50, Balangoda Road R30, Browlow Road R10, Emelina-Brunswick Road, R25.—Total R315.

PLANTERS' RIFLE CORPS.—This continues to be well supported in the district and great interest is shown both at drills and on the two ranges.

REGISTER OF ESTATES.—The Tiu Ticket system has been working on the whole fairly well during the year and promises to be of assistance to planters. There have been a few complaints about minor details connected with it; but it is only natural that slight irregularities should occur at the inception of such a scheme, and they are being rectified as attention is called to them.

CEYLON NURSING ASSOCIATION.—This Association took the initiative in bringing the claims of the C. N. A. more prominently before the Planting Community, and it is hoped that much benefit to the Funds will result.

W. A. BRAYBROOKE,
H. A. WEBB,
GEO. GREIG.

The report was received with applause.

CALIFORNIAN ORANGES IN LONDON.—Mr. Thos. Christy, F.L.S., reports by a recent mail:—

You will, perhaps, be surprised to learn that the Navel Orange, which grows near California, is being sent to England this year in small boxes, most carefully packed, and the price in the market is 6d each—small ones 4d each. It, certainly, is a very fine orange. Those that have come in from Jamaica sell at 2d each, taking a whole case. They certainly arc well packed and have arrived here in fine order.

OUR COCONUT PRODUCTS IN 1902.

The tabular statements which we issued as a *Supplement* to all our subscribers last month, shew that the Coconut Products of the Island have had another good year as regards volume. In prices, too, 1902 has been a satisfactory year, although for the latter half of it they compare unfavourably with those which ruled during the last few months of 1901, when Copra ranged between R55 and R62 75 per candy—select parcels fetching even R65 and R66—against R52 50, which has been the top price for about three or four months past. But Coconut Oil in 1901 ran up from R375 on 1st October to R437 50 on 31st December, while last year it fluctuated but little between R370 and R380. Hence 1903 has not opened as brightly for the products of our most useful and valuable palm as the previous year which, however, was in many ways an exceptional one.

Turning to our tables it will be seen that the quantity of Coconut Oil exported—512,498 cwt.—was the largest during the decade; but it was exceeded eleven years ago (in 1892) when 550,977 cwt. were shipped. That figure has never been realised since; but the quantity of Copra exported in 1892 was little more than one-third of that for last year, and Desiccated Nut less than one-fourth. Most of our Oil in 1902 went to the United Kingdom—as, indeed, it generally does—save, we believe in 1897 and 1898 when India displaced the mother-country. But whereas the United Kingdom was responsible for 301,647 cwt. last year, or about three-fifths of the total export, India took only 64,370 cwt. or less than one-half of the quantity she had in 1901. Can any of our expert readers enlighten us as to the causes of the heavy falling-off, and the curious shifting of trade in the two years we have specially named? America takes second place with 92,996—a bigger leap from 27,205 cwt. in 1901, than India, which has third place, has taken backwards. Austria, with 24,774 cwt. comes next—being the only other country with more than 20,000 cwt. to its credit.

In Copra, the mother-country takes a decidedly back-place, having had only 12,908 cwt., out of 374,796 cwt. exported. Germany takes the lead, having displaced France which used at one time to lead, with 179,819 cwt. against 110,144 cwt. for France, Russia making a bad third with 33,136 cwt., and Belgium and Austria coming next. The United Kingdom may be said to be at the bottom of the list, as Holland with 476 cwt. and India with only 5 cwt. can scarcely count. If, therefore, the claim put forward on behalf of England, that she makes more Coconut butter than the Continental countries which are advertising it so largely, the manufacture must be direct from the Oil, and not from the raw material which France and Germany probably specially value for the residuum of poonac as food for stock. But notwithstanding the high prices which prevailed, and the large contracts of which we heard

a good deal early in the year, the total quantity of Copra exported is disappointing, having been only 374,796 cwt. against 439,865 cwt. in 1901, and 506,277 cwt. in 1898—the record year for Copra, as 1892 is for Oil. In Desiccated Coconut, however, 1902, with over 16½ million lb. sent away, stands *facile princeps*, the quantity exported the previous year having been about 2½ million lb. less. The industry, as our readers are aware, is a comparatively new one, having found a place in our export tables for the first time only in 1891, with but 416,330 lb. Its steady growth without any fluctuation, save for a small one in 1893-94, is evidence that the industry is on a sound footing, and that there is no accumulation of stocks, and no out-running of the supply over the demand. As a rule, we believe, the outturn is regulated by orders; and the gradual development is proof that the manufacture is growing in popularity for confectionery. The United Kingdom is here, again, our best customer, with nearly 10 million lb. to its credit, America coming next with 2,249,143 lb., and Germany showing kinship with both countries with 2,067,490 lb., followed by Australia with 795,050 lb.! Another hopeful future about the industry is that it is exported to thirteen out of the nineteen countries which find a place in our export tables, while Copra finds a market only in eight, at any rate in direct shipments.

In Coconuts in the shell again, the year is a disappointing one with about 12½ million nuts against nearly 15 millions in each of the two previous years, and considerably over 13½ millions in 1897 and 1898. As in Oil and in the Desiccated kernel, the mother-country comes first, having taken over three-fourths of the outturn. Africa, curiously, is the next best customer with 1,375,621 and Germany the next with 1,169,780. The nine other customers which follow have been content with much less than quarter-a-million nuts each. We cannot say that we regard with satisfaction the fact that 1902 is the record year for Poonac, with 247,697 cwt. sent away, since the cattle of the Island are not particularly well-fed, and they would be all the better of getting, as food, the refuse of all the Oil expressed in the Island. But as there is little chance of the village cattle being allowed the luxury, we cannot complain of buyers being found in Belgium and Germany, which are practically our only two customers for all the Poonac we do not use ourselves, save 200 cwt. which is distributed among four other countries. The exports of Coir, in the shape of Yarn, Rope and Fibre, call for no special remark—the quantities having been only fair average ones; but prices have ruled fairly high, and there is practically an unlimited quantity of Coir available, if only the demand grows. As it is, Singapore takes almost all our Rope—over 15,000 cwt., leaving less than 300 cwt. for four other countries. The United Kingdom is again our largest customer for Fibre and Yarn. Who will say, after this, that there is not room for the expansion of trade in low-country products in America—the way for which can be shown at the Louisiana Exposition.

HONEY AND WAX IN MADRAS FORESTS.

(From a Correspondent.)

Amongst the various items of minor forest produce, by no means the latest important of those collected in the Sattiyamangalam Hills of the Coimbatore District are honey and wax, of which there are

THREE SORTS,

found in different places and made by different kinds of bees. These are:—(1) Rock honey, made by very large bees, and found in holes and under ledges of rocks—this honey is coarse and dark, and the wax very dark-coloured and very large-celled; (2) honey made by smaller bees, and found in the hollows of rotten trees—the honey and wax are both lighter than those found on the rocks; and (3) honey made by very small bees, and found on the branches of trees—this is the best honey and the finest, whitest wax, much resembling the English heather honey, but with smaller cells. Of the rock honey, the average number of combs found on each rock is from 10 to 15, which give altogether about 150 measures of honey and 10 maunds of wax. These take about 10 or 12 days to collect, and for this amount the collectors are paid Rs 50 to Rs 80, and it brings in some Rs 240 to Government. From the hollows of trees the largest combs afford about one measure of honey and 2lbs of wax, while from branches the largest give only about a quarter measure of honey and less than half a pound of wax. Sometimes the rock honey is very poisonous, due to the bees gathering from the flowers of the *Thorova* (believed to be *Sapinum indicum*). A few of these flowers (easily recognisable) are always deposited in some of the cells, and the honey is always bitter in taste. Ordinarily, the bees gather from the flowers of *Vengai Nagai Cassia Fistula Shorea Albizzia*, Jasmine, &c.; they build over and over again on the same spots on the rocks, and the number of combs varies very little, depending on the number of flowers available, two or three, more or less, than the average number of combs being the most. The young bees from undisturbed combs take flight with the queens to other localities, and form fresh colonies.

THE BEES HAVE TWO WORKING SEASONS

in the year viz., June and July—this honey is collected in August when the rocks are dry; and September, October, and November—this honey being collected as soon as the hot dry weather set in. The collection of rock honey is always done when the rocks are dry and the chance of slipping are less. In the Sattiyamangalam Hills the collection is done only by Kurumbers, and their method of collecting is a curious one. A party consisting of never less than 10 men, sometimes as many as 15, is formed. Of these, two only are the collectors (Kurumbers), the rest, who may be either Sholigars, Uralis or others, are taken by the Kurumbers to carry their goods and chattels, erect sheds, light fires, and also to be company for them in the forests. The two Kurumbers are always brothers-in-law, that is to say, each man's wife is the sister of the other man. (The reason for this is that one of them is, for the time being, responsible for the life of the other; if the rope were not held very firmly, or were allowed to slip, the man on the ladder would be dashed to pieces against the rock, and so his wife (sister of the other) would become a widow, to the lasting shame of her brother who was responsible for the

catastrophe.) The expedition always starts on a Monday, which amongst these hill tribes is the auspicious day. On the eve of the start, the elder Kurumber and his wife invite the other Kurumber and his wife to their house to partake of a meal with them, after which each woman warns her husband and brother of the dangers which lie before them and of the precautions each must take in guarding the other during the collection of the honey. This done, the men and women take leave of each other, and this occasion of the farewell meal is the only time during which the

HONEY COLLECTORS

may see their wives for three days before setting out; should they violate this rule, they believe that they will most assuredly be badly stung, and two or three of the Kurumbers solemnly declare they have been stung, but *only* in such circumstances. When starting off on the Monday morning, the party take with them coconuts, plantains, camphor, etc., as offerings to their deity, also their implements of collection, which consist of a long ladder (*malkanni*) made of *karacha* (*Hardwickia binata*) with a stout rope made of the same material attached to it, a bowl made of basket work covered with mud, with a long handle, in shape much resembling a soup ladle, a sharp pointed stick, and a bundle of torches made of green and dried grass mixed. Having arrived at the scene of action, they look about for a large firm tree, and, having found one, make *puja* and offerings to it. They then fasten the rope attached to the ladder firmly round the tree and dangle the ladder over the edge of the rock and one of the Kurumbers holds on to it while the other, having offered more *puja* to his deity for his safety, climbs down the ladder until he finds himself on a level with the honeycombs. Arrived there, he plants his right foot firmly on one rung of the ladder, leans his left knee on the rung above and puts his head through the next two above, thereby securing himself, and leaving his hands free. Being firmly fixed he swings himself backwards and forwards, having in one hand a burning torch, and in the other the pointed stick, and as he swings in towards the rock he applies the torch to the combs, and by repeating this many times he succeeds in driving out the bees. Having got rid of them, he next drives the pointed end of his stick into the comb, and as soon as the honey begins to flow he calls out for the bowl, which is lowered from above by means of a rope, and hangs it under the comb until it is full. It is then drawn up again and the contents emptied into a chatty at the top of the rock. The bowl is then sent down again, and the process repeated until all the honey is extracted, and then the wax is removed by hand from the rock. The whole time the man is swinging backwards and forwards in his rope ladder he utters *manthrams* to keep off the bees and to prevent himself from being stung. At the end of each day's work he climbs up on to the top of the rock, and again

MAKES PUJA FOR HAVING BEEN KEPT IN SAFETY, and on the last day, when all the honey and wax have been collected, the two Kurumbers untie the rope from the tree, and drop the ladder down to the bottom of the rock, uttering, as it falls, words which mean "My mother comes down." They then make their way down to the bottom of the rock as best they can, taking with them three leaves full of the honey. They prostrate themselves on the rock and offer the honey to

their deity as a thank-offering for their safety. This over, they roll up the ladder and proceed homewards, and the end of the expedition is a hot bath.

In the Sattayamagalam Hills there are four sects amongst the Kurumbers, (1) *Hal* Kurumbers, who are field labourers, and magicians; (2) *Mulu* Kurumbers, a nomadic tribe, also magicians; (3) *Kuri* Kurumbers, sheep shearers, and wool weavers, and (4) *Andai* Kurumbers, bamboo workers. Of these only the two first are collectors of honey, and each pair of brothers-in-law keeps entirely to his own beat, so much so that those of one beat do not even know those of the next, even though living in adjacent villages, often less than 20 miles apart. There is no inter-marriage between any of the sects.—*M. Mail*, Jan. 7.

BRITISH CENTRAL AFRICA.

N. E. RHODESIA CLOSED TO THE RUBBER TRADE;
COFFEE SUFFERING FROM DROUGHT.

Blantyre, Dec. 31.

The Chartered Company has proclaimed the whole of North-Eastern Rhodesia closed to the rubber trade from January 1, 1903.

The officials of the Chartered Company are vigorously enforcing the new game laws. Consequently settlers residing near German territory are taking out licences to shoot there.

Glowing accounts have been received of the Harrison Expedition to the Victoria Nyanza. These reports state with regard to the Mombasa route to Lake Tanganyika that goods can be brought there in three months' less time than by the Zambesi route.—*London Times*, Jan. 1.

Blantyre, Dec. 30.—The long continued drought in the Shire highlands has wrought havoc with the coffee plantations, many of which, being of recent growth, will probably be destroyed. The native food crops are also backward in many districts, and if there is no rain it is feared that there will be a famine.—*London Times*, Dec. 31.

GOW, WILSON AND STANTON'S INDIAN, CEYLON, AND JAVA TEA REPORT FOR 1902.

13, Rood Lane, London, E. C., Dec. 31, 1902.

The tea industry has been passing through a series of years showing unsatisfactory results to producers, and 1902 proved perhaps worse than any of its predecessors. The year opened with the most gloomy forebodings, the market being over-weighted through surplus production, while it was generally anticipated that the output in 1902 would be even larger, and that prices in consequence would show a further fall. This cloud hanging over the market not only prevented a rise in prices throughout almost the whole year, but resulted in the lowest average ever recorded, that for Indian tea being for many months about a penny below the excessively poor rates of 1901;—perhaps lower than would have been warranted even had the anticipated increase in production taken place. But during

the later months of the year, it became evident that crops would not be as large as was originally expected. Even this created no impression upon the market until too late to materially affect the average price. Although the last few weeks showed a considerable advance, so much of the crop had already been sold that the benefit to producers will probably be counterbalanced by the expected shortage in supply.

Nevertheless, the outlook is at length decidedly more cheerful than for many years past; the certainty of moderate supplies gives time to work off the world's accumulated stock caused by recent over-production, while the fact that very little tea has been planted in either India or Ceylon for some few years back, obviates the probability of largely increased crops for some time to come, the planting of former years being mostly in bearing. It is now an ascertained fact that consumption at home has been but very little interfered with by the late increase in the duty, and that the normal rate of progress has been about maintained, while the lower prices of recent years have considerably increased the use of British grown tea in foreign and colonial markets. Consequently with a crop almost stationary and every probability of a continued increase in consumption, the conditions so long prevailing in the trade are likely to be entirely reversed. The natural result of over-production has been a continued fall in price, and conversely the outstripping of production by expanding consumption should be accompanied by a corresponding rise in value. Hence the industry looks now in a more healthy condition, and there is every reason to believe that for five or six years to come, *i.e.*, until any new lands which may be brought into cultivation commence to yield heavily, prices will be on a scale more remunerative to producers;—while should there be a decrease in the rate of duty the industry would, to some extent, be relieved of a very pressing burden, with the probable result of a further improvement in price.

GREEN TEA.—The quantity of green tea made in Ceylon has been gradually increasing and is finding favour in North America; India has this year also made some green tea which is being well taken and there is every probability that both countries will next year manufacture increased quantities, by which means the black tea market should be still further relieved.

INDIAN TEA CESS.—The Viceroy has decided to legislate for the purpose of raising a tax of one-fourth of a pie per lb. on the exports of Indian tea, for raising money to exploit new markets. Planters should therefore soon have larger funds at their command for promoting the use of Indian tea, both in India itself and in other markets. Foreign markets continue to expand satisfactorily, about 105 million pounds being taken against 95 millions last year.

PRODUCTION.—It is expected that the total crops of India and Ceylon will be about the same as last season.

INDIAN TEA.—The quality of the crop as a whole was hardly equal to that of last season, although Darjeeling showed a considerable improvement. The average price of Tea sold on garden account was 7'35d, against 7'50d in 1901, and from 1st June to end of December 7'24d, against 8'04d, for the same period last season.

CEYLON TEA.—There is not much change to notice in the quality, which on the whole was very fair and about up to the average. The average of Tea sold on garden account was 6·81d, against 6·86d in 1901, and from 1st June to end of December 6·66d against 7·05d for the same period last season.

JAVA TEA.—Production in Java has lately increased and imports were in consequence somewhat heavier, previous quality being maintained.

WATER SUPPLIES IN THE PLANTING DISTRICTS.

AN AUTOMATIC HYDRAULIC RAM WHICH WORKS A PUMP.

To secure a plentiful and pure water supply and to introduce it into their bungalows (which are usually built on a high elevation) is a difficulty which many planters have encountered, but one in a country where the chances of contamination are so numerous, which it is absolutely essential in the interests of health should be overcome. On Mount Vernon estate, a representative of the *Observer* has just seen a most ingenious and simple device for pumping water from a low to a high level and which is the first of its kind made and erected in Ceylon. At Mount Vernon by an inexplicable whim of nature, just below the Superintendent's bungalow which is situated on a hill, there runs a plentiful supply of river water while at the foot of the hill there rises a gushing spring of pure water. Under ordinary circumstances if it was wanted to introduce this spring water into the bungalow and have it pumped

automatically, a turbine or Pelton wheel with suitable gearing for driving the pump would have had to be erected. This, of course, is an elaborate and expensive method and entails complicated working parts. Messrs Brown and Davidson were entrusted with the work of introducing the water and Mr J A Dickson of that firm, while engaged on the work, was struck with the possibility of making the waste water automatically work a pump to drive the water up the hill. The idea was followed out and the work was completed at the end of last week and there is now on Mount Vernon an automatic Hydraulic Ram actuating a pump. The ram is working under a head of 30 feet and delivering 25 gallons per hour of pure spring water into a receiving cistern with a holding capacity of 250 gallons at a vertical height of 140 feet. The idea is entirely new and original, most ingenious in its conception and simple in its design and reflects credit on Mr. Dickson's ingenuity. Hitherto rams have been employed in various parts of the island for supplying water to bungalows and factories, but in these cases the same water as supplies the ram is delivered at the bungalow. About four times the amount of water which is pumped, however, in these cases goes to drive the ram. The method here employed is specially effective and simple as no pure water is wasted and there is absolutely no chance of the pure water being contaminated by the waste water which does the work. There should be a large demand for this simple and much less expensive automatic ram.

CACAO.

The Ligu cacao (*Theobroma bicolor*) is now fruiting at the Botanic Station, Dominica. Several plants of the Alligator cacao (*Theobroma pentagona*) has also flowered. Both of these species were obtained from Nicaragua by Mr J H Hart, Superintendent of the Botanic Gardens, Trinidad. On one estate in Grenada where very particular attention is given to cultivation and manuring the efforts of the proprietor have been rewarded by a yield of 130 bags (of 182 lb each) of cacao from about 16 acres. This is at the rate of 8 bags per acre.—*Agricultural News*, Dec 20.

SOME QUEER TEAS.

Tea-drinkers frequently express sympathy for the unfortunate people who lived before the days of tea-drinking. There may have been compensation, but we doubt it. A writer in the *Globe*, under the heading "Some Queer Teas," recently called attention to the great variety of beverages and decoctions made from herbs and plants quite unknown in China or India, called 'teas,' in imitation of the genuine article and drunk from various motives. He says:—"In early tea-drinking days, when fragrant Bohea was sold for from twelve to twenty shillings and more a lb, poor folk, who could not afford such a luxury, endeavoured to content themselves with decoctions from less expensive leaves. A great favourite of old was sage-tea, which was regarded not only as a pleasant but a particularly wholesome drink. John Wesley, who was a determined opponent of the Chinese leaf, strongly recommended sage as well as mint

and pennyroyal, as an excellent substitute; while another enemy of the cup that cheers ventured to prophesy about the middle of the eighteenth century, that the pernicious foreign leaves would quickly become cheaper, wherein he was right, and that tea would then go out of fashion and be replaced by sage, wherein he was hopelessly wrong. At the time when this wise person wrote, an ordinary breakfast among the poorer folk was bread and butter with sage-tea; but the cheapening of the real tea simply drove such substitutes as sage out of use. In revolutionary days in America various herbal substitutes for tea were used from patriotic motives. After the Boston mob had thrown the cargoes of the three East India tea ships into the harbour, and the colonists had taken a vow to buy no tea which had to pay the obnoxious duty, their wives and daughters—daughters of liberty, they called themselves—devoted their ingenuity to devising fragrant beverages to take the place of the boycotted leaf from the Far East, and some strange decoctions were made and perhaps enjoyed. The stalwart New Englanders drank 'tea' made from the leaves of rib-wort, strawberry plants, and currant bushes, sage, thoroughwort, and other herbs. So called 'Liberty Tea' was made from the four-leaved loosestrife, while 'Hyperion Tea,' says Mrs. Earle—an invaluable chronicler of Colonial life and habits—was from 'raspberry leaves,' and was said by good patriots to be 'very delicate and most excellent.' The beverage may have been so when tasted by patriotic palates, but we can feel pretty certain that many a colonial dame must have thought with longing of the cups of fragrant Hyson which she had been accustomed to enjoy before the embargo was laid on the imported leaf. One at least of the substitutes named above, thoroughwort, is still used in rural New England for medical purposes, if Miss Wilkins' stories may be accepted as authorities. No reader of those delightful sketches will forget how often thoroughwort tea, as a remedy, especially for an ailing or more often supposedly ailing child, is suggested and made by village wisdom. Rural medicine of the same kind is, of course, common enough also on this side the Atlantic. Herbal remedies might not be used quite so much, perhaps, nowadays as in times gone by, but 'teas' from herbs of various kinds are still brewed and firmly believed in by many country folk. Valerian, for instance, which is commonly known by the significant popular name of 'all-heal,' is one of these herbs, for the 'tea' made from its root is believed to be of efficacy in cases of consumption. An infusion of milk-wort—the plant whose pretty flowers, varying in colour from pink to a deep blue or purple, are so abundant on dry, upland pastures—is good for a cough. In Sussex villages 'gazel-tea' is a favourite prescription for a cold. Berries of any kind are called 'gazels,' but those usually employed for medicinal purposes are black currants. But much stranger things than black currants have been similarly used. For example, when Quecu Anne was known to be suffering from gout, a certain Martin Bowes wrote to the Prime Minister, the Earl of Oxford, suggesting as an easy cure a 'decoction, or tea, made of nettle-seed.' Not a few of the herbal teas which were drunk as beverages were, like the New England thoroughwort, also considered to have no small medicinal value."—*H & C Mail*, Jan. 2.

THE CURE FOR MOSQUITOES.

A POT OF BASIL.

There is a widely spread belief, both amongst natives and amongst the white sojourners in Western Africa, that the presence of a certain species of plant in a room drives away mosquitoes, and, in fact, a single plant is said to be sufficient to clear a room. On his recent return from Northern Nigeria, Major J A Burdon, of the Cameron Highlanders, brought with him and gave to me a few leaves of this plant. These, through the kindness of Mr. H H W Pearson, have been identified by the experts at Kew as belonging to *Ocimum viride*, Willd., a member of the order Labiatae, which occurs from Senegambia southwards to Angola.

Major Burdon, who is Resident of the Nupe Province, Northern Nigeria, and Hausa Scholar of Christ's College, Cambridge, has given me the following account of the plant:—

"A fragment of what turns out to be *Ocimum viride* was given me in August last at Lokoja, Northern Nigeria, by Captain H D Larymore, C.M.G., R.A., Resident of the Kabba Province. Capt. Larymore's notice had been drawn to the plant by a native living in a low-lying part of the native town at Lokoja, who had told him that the natives suffered very little from the swarms of mosquitoes which existed in that part, as they protected themselves from them by the use of this plant.

"Capt. Larymore made inquiries and obtained a few specimens of the plant, which grows wild, though not very abundantly, in the neighbourhood of Lokoja. These specimens he planted in pots and boxes and kept in and about his house. The specimens I saw were about the size of a geranium.

"He informed me that the presence of one of these plants in a room undoubtedly drove the mosquitoes out, and that by placing three or four of the plants round his bed at night he was able to sleep unmolested without using a mosquito net. This is very strong testimony to the efficacy of the plant, for the house in which Capt. Larymore was living is, as I had cause to know well in former years, infested with mosquitoes."

In the fifth volume of Sir W T Thiselton-Dyer's "Flora or Tropical Africa," *Ocimum viride* is described as follows:—

"*O. viride*, Willd.; Benth. in D C. Prod. XII. 34. A perennial 3-6 ft. high, with much-branched glabrous stems. Leaves distinctly petioled, oblong, acute, membranous, 3-4 in. long, glabrous on both sides, or obscurely pubescent beneath. Racemes, lax, copiously paniced, 3-6 in. long; rachis finely pubescent; bracts deciduous; pedicels not very short. Calyx 1-6 in. long; tube campanulate; upper lobe orbicular, as long as the tube; lower teeth short. Corolla half as long again as the calyx-lobes. Stamens but little exerted, the two upper with filaments toothed above the base.—Benth. in Hook. Niger Fl. 438; Henriques in Bolet Soc. Brot. X. 149. *O. febrifugum*, Lindl., in Bot. Reg. t. 753. *O. heptadon*, P. Beauv. Fl. Owar. II 59, t. 94."

The plant is figured on plate 753 of the ninth volume of the Botanical Register, 1823 under the name *Ocimum febrifugum*, or the "Sierra Leone Fever Plant." This work mentions that the plant is "in request at Sierra Leone for medicinal purposes," and describes the species as an "under shrub 3 feet high," "having in a high degree the smell of common balm."

The leaves of the plant are highly glandular, and in India an allied species, *O. Basilicum*

Linn., the "common sweet basil," produces a "yellowish green volatile oil lighter than water, which, on being kept, solidifies into a crystalline camphor, isomeric with turpentine camphor." (*Gmelin's Handbook*, xiv., 359). The seeds of this species are widely used in the east as a medicine, and their properties "are said to be demulcent, stimulant, diuretic and diaphoretic." "The juice of the leaves mixed with ginger and black pepper is given in the cold stages of intermittent fever." The leaves, like those of thyme, are used as a seasoning in cooking. Another Indian species, *O. sanctum*, Linn., the "sacred basil," is the most sacred plant in the Hindu religion, and is consequently widely cultivated.

In "Notes on the Medicinal Plants of Liberia," Mr E M Holmes records that when chewed or rubbed, the leaves of *O. viride* give off a strong odour of lemon thyme, and mentions that Dr Roberts, of Liberia, entirely substituted the use of the plant for that of quinine in cases of fever of all kinds, giving it in the form of an infusion.

There is thus a good deal of evidence that *O. viride* is a plant of considerable curative value, especially in cases of fever, but the question that interests a large number of people in West Africa is whether it is equally efficacious as a preventative. Does it really repel the mosquito which acts as the intermediary in conveying the malarial hæmatozoon from man to man? Further experiment on this point is needed, but there is at least some indication that in this easily cultivated plant man has another weapon with which to fight malaria.

A. E. SHIPLEY.

Christ's College, Cambridge.

NORTH BORNEO.

(From the *North Borneo Herald*, Dec. 16.)

FUEL.—It has been proposed that when coal is exhausted, the eucalyptus should be cultivated for fuel. In hot countries the gum-tree can supply 20 tons of fire-wood per acre a year. To this end the cultivation of the eucalyptus tree which grows to a great height and affords plenty of shade, should be introduced and encouraged in British North Borneo where the climate is eminently suitable for the purpose.

BORNEO TOBACCO.—Tobacco from our young colony of North Borneo, the *Pall Mall* is glad to see, is holding its own, and up to the end of last month, 15,885 bales of the 1901 crop were sold in Amsterdam at an average of 90 cents per half-kilo, while the average of the Sumatra crop was only seven cents more. On the other hand, however, the highest price obtained for Borneo was 181 cents which compares very favourably with 135 cents for the best Sumatra leaf. "El Mandano" is an excellent cigar made from leaf grown on the Bongon estate of the New London Borneo Tobacco Company (Limited), which has produced some of the best tobacco raised in the colony since the cultivation of the fragrant weed was introduced.

THE EAST COAST.—The following is from a most interesting account of His Excellency's tour of the above territory:—I came away very satisfied with all I saw and confident of the future prosperity of this part of the Territory. The tobacco estate belonging to Mr. Kortmann at Tawao is closed, but Mr Arensma's Company on the Segama is in full swing. I visited every estate

and was very hospitably entertained. The number of fields planted is 625 and the average yield over 9½ pikuls. If prices approximating those of 1902 are obtained there will be great jubilation in Darvel Bay. As it is every one is very contented. I visited Mr Phillip's coal workings at Serudong and was greatly pleased. He has cut along a seam of coal for 137' and its width is 3' 4". Mr Phillips has traced a tramway line for about 2,000 yards to the tidal river and, if the coal is in payable quantity, it could be transported in lighters to Sandakan where a wharf in deep water, could be erected at inconsiderable expense and where the coal would always find a ready market. I believe there is tin in Tawao and I know now that there is coal at Serudong. If therefore, the British Borneo Syndicate expends in those places some of the money it is bound to lay out in prospecting the territory, there is every hope that a bright future lies before the East Coast.

TEA IN AUSTRALIA IN 1902.

The year 1902 has been unsatisfactory for traders in this article. The removal of the duty by the Federal Government found dealers with more or less heavy duty paid stocks, on which a loss of 3d per lb. had to be faced. In addition, there was an impression amongst the trade that financial necessities would induce the Government to try and reverse the decision of Parliament, and in anticipation thereof large sales were effected at high prices. Tea, however, remains free of duty, and it has taken many months to get rid of these surplus stocks on a market which has been continuously adverse to all holders.

A further adverse element was the unexpected action of the Federal Government in condemning on a purely chemical analysis (which was part of the Customs Act) certain teas imported from India and Ceylon, because they contained a limited portion of ash in excess of the academical standard laid down by the act, although the tea extract they contained was largely in excess of the standard, and by the analysis they are admittedly "fit for human consumption." The contention of the trade is that reasonable notice should have been given to importers viz., time to advise their agents in the Far East, and that it is impossible to know whether teas comply with the act until their arrival in the States and analysis here. On these grounds permission has been requested to reshipe the teas in question.

It is now hoped that the Government will amend the clause relating to tea in the Customs Act—on the lines of the American Customs Act—which thoroughly protects the public without harshness to the trade. Over-importation during the past two years, due to tariff speculations, also contributed to depress the market, so that during the greater part of the year complaints were heard amongst all sections of the trade. For the past few months, however, imports have been restricted, and stocks are now getting into a more healthy position.

COLOMBO continues to be the main source of supply. Imports, however, will be fully 10 per cent less than last year. Prices in Colombo have risen considerably, owing to the London market recognising the strong statistical position of tea generally, and this market will, doubtless, follow

suit. With very moderate stocks held in the States, the new year should see a larger business passing on sounder lines, the present position being certainly in favour of stock holders.

Indian teas have been disappointing in quality. The earlier shipments were distinctly good, but with heavier arrivals the teas seemed lacking in point and distinctive quality, and they have certainly lost ground with the blenders as compared with Ceylon. The trade, however, are quick to notice all teas with point, as they form a valuable element in all blends owing to their superior keeping quality, as compared with Ceylon.

The Calcutta market has risen considerably in the last three months, especially in common teas. The crop is expected to be less than was estimated, and an early closing of the season is looked for Colonial imports will be 25 per cent. below last year.

China teas are getting into smaller and smaller compass. The year's imports will only be about 1,000,000 lb; the only demand has been for a little fine tea, fine buds, fine Panyongs and scented teas, which are in short supply. Kooloos are not so much used, and their sale has been slow and unprofitable. Stocks are now very much reduced, but the outlook for next year is very poor. —*Age* Jan. 2.

JAVA GOVERNMENT CINCHONA PLANTATIONS.

A sum of 289,000 fl. has been allotted to the Java Government cinchoua-plantations, in connection with the estimates for 1903. This sum is an increase of 189,000 fl. on the estimates for 1902. It is intended for the purchase of quinine, gathering, manufacturing, transport, and sale of cinchona, &c. In 1902 the production of Government bark was estimated at 1,000,000 Amsterdam lb but this year they hope to increase the output by 50 per cent.—i. e., 1,500,000 Amsterdam lb. In view of this, and also because more money is required for laying out new nurseries, upkeep of nurseries, &c., expenses of the Government plantations are estimated at 5,000l. There is also an increase of 3,250l. in the estimates for the purpose of meeting the extra cost of manufacturing the quinine produced by the Bandong Quinine Works. The revenue for 1903 is expected to realise 399,000 fl., chiefly derived from the sale of Java quinine. —*Chemist and Druggist*, Jan. 3.

EWART, MACCAUGHEY AND COMPANY'S ANNUAL TEA REPORT, 1902.

CEYLON.

The New Year brought in a strong market, particularly for common tea, which was quoted at 6½d per lb, while over say 6¾d per lb. there was considerable irregularity. With occasional fluctuations the general feature of January was firmness for tea up to 7d per lb and great irregularity over that figure. Worse quality towards the end of the month led to an easier market, and in February prices favoured buyers, common leaf receding to 5½d per lb or 5¾d per lb., while Broken Pekoes round about 6d per lb were remarkably cheap. Importers were inclined to meet the market when anything near to

valuations was bid, so that little tea was held up. Quality on the whole, if not fine, was fairly useful and the range of prices worked all in favour of a very large trade, the blenders particularly in buying freely from week to week. Good tea was coming along in March, and from 1s 1d per lb there were plenty of buyers, but plain ordinary Pekoe kinds from 6d per lb to 7d per lb ruled easy, and Colombo bought invoices were not receiving much attention. A large proportion too, although fine, was over light in cup for home requirements, and, lacking support from foreign buyers, went very cheaply. After the Budget in April we had an easier market, and from 5¾d per lb there was a general ½d per lb decline, while tea for price was at 5¾d per lb. The month closed with heavy offerings, mostly of poor quality, and averages began to look very bad, teas between 6d per lb and 7d per lb being a perfect drug on the market. The general feature pretty well followed Indians in that from 5d per lb to 7d per lb prices were anyhow, while over 11d per lb top rates were being paid. The middle of May brought more general enquiry and, as a whole, better quality. Common stood at 5d per lb, and tea far and away better at 5½d per lb, all grades over 10d per lb making fancy prices. June opened with an easy market under 7d per lb, although common stood at 5d per lb against 3¾d per lb or 4d per lb in the previous season. Fine kinds were dear, in fact, much of the tea that was being paid up for would in ordinary times not have been called fine at all. There were, however, no Darjeelings to speak of, and this fact largely helped up any Ceylon with the smallest approach to quality. Common dropped to 4½d per lb before July, with Pekoe quotations of 4½d per lb, and excepting one week in 1901 the average price of 6d per lb at the beginning of the month was lowest on record. Weekly offerings were at this time very heavy, 36,000 packages being nothing unusual, but towards the close there was a slight rally and the month finished with a healthier feeling. Quality came a little better again in August, and Auctions dropped to about 28,000 packages a week. A slightly better enquiry set in, as buyers could not let teas go past them at the tempting range of prices. A considerable Export business, too, came along, the unusually low prices having attracted attention all the world over. September came in badly for common and plain kinds of teas and, just as on the Indian market, everything without special character stood on a dead level of cheapness. Pekoes at 5d per lb to 5½d per lb were showing wonderful value, while commonest leaf was quoted at 4½d per lb. Good medium tea fell ½d per lb in the middle of the month and, with the blenders more or less standing out and few Export orders, only extra fine parcels were doing good. The early October sales showed conspicuously better quality from many estates and improved competition resulted. Common, too, advanced a little but there were still 4½d per lb quotations. Russian orders were invaluable in helping prices for flavoury kinds, and but for them, some of the fine light teas would have fared badly, particularly as outside influences not usually calculated upon, were upsetting everyone. A carefully engineered boycott demoralised the closing Auctions, but November brought along some recovery, and from 4¾d per lb at the opening, common tea went to 5¾d per lb at the close of the month, showing 1½d advance form lowest point, while in the case of medium to good kinds the rise was even more pronounced. Buyers made another attempt to get the market down in December, but on this occasion the importers would not humour them, and although some cheaper tea was sold the general instructions were to take out any invoices which did not reach previous quotations, and common leaf closed at 5¾d per lb. The feature of the year has without doubt, been the extraordinary value generally shown among teas from just above common to just under fine. The whole weight of offerings as a rule has ranged from 5d per lb to 9d per lb. The quantity of fine tea included was never excessive, and for a large portion of the year not sufficient for the ordinary weekly requirements of the trade.

INDIAN PATENTS.

No. 502.—Charles Géorge Landseer Judge, journalist, of 47, Free School street, in the town of Calcutta. An improved machine for colouring and finishing green teas by the process known as panning.

No. 503.—William Lennox, tea planter, of Luskerpore Tea Company, Limited, Chandpur Bagan, South Sylhet, Assam, in British India. A new, or improved sifter and ball breaker for tea leaf and the like.—*Home paper.*

SAMOA.

The Chief Justice and Governor of Samoa, under the German dispensation (the Hon. Dr. W H Solf), passed through Sydney this week to take up his duties after a 12 months' vacation. He came to Sydney in the "Tanglin" after visiting China, Java, the Philippine Islands, and New Guinea, and probably the information he obtained there will be turned to account at Apia, as, according to the ruler of Samoa, it is intended to introduce Chinese or Javanese labourers to do planting and general coolie work for the Samoans. Of course Fiji is already full of Indian, Chinese, and Japanese coolies working the sugar plantations, and at Noumea they are trying similar blends in the mines, but it is impossible to escape a feeling of regret that—as is inevitable—the Samoan type which R L Stevenson and all others who have lived at the islands learned to love should be subject to the intermixture and contamination inevitable where such labour is imported. Dr. Solf is quite a historical character in Samoan affairs. He was president of the Triple Alliance Council—England, America, and Germany—before the war, and German Governor since the main island was apportioned to Germany three years ago. He has faith in the industrial development of the country, and it is the spirit of the age to place industrial development first.—*Sydney Mail*, Dec. 21.

THE WYNAAD PLANTERS' ASSOCIATION.

THE ANNUAL MEETING.

We extract the following from the Minutes of the Proceedings of the Annual and General Meeting held at Meppadi Club, on the 7th inst.:-

Present:-Messrs. Abbott, Atzenwiler, Day, Mackinlay, Romilly, Taylor, Waddington, West, and B. Malcolm, Honorary Secretary. Mr. G Romilly in the Chair.

The Honorary Secretary read the Annual Report for 1902.

[FROM THE ANNUAL REPORT.]

PEPPER DISEASE.—After two years of almost incessant agitation we have received the good news that the Government of Madras has sanctioned Mr. Barber visiting the district, and arrangements for his tour have just been concluded. Though much valuable time has been lost, and the disease has made rapid strides, we must hope Mr Barber will succeed in suggesting a cure. No small share of our thanks are due to His Excellency the Governor for this aid, and we also owe our thanks to Mr Windle, of the Nilgiris, for representing the matter to His Excellency in person.

DUTIES: BRITISH IMPORT DUTY ON TEA.—The Resolution passed at the last U P A S I Meeting has so far resulted in the matter having been referred by the Indian Tea Association to its London Committee. That hesitating body is considering the best means of approaching the Chancellor of the Exchequer. It is to be hoped that it will be able to solve the problem in time to approach him before the new Budget is framed. Seeing the promise made to the Ceylon Association some two years ago it is difficult to understand the diffidence with which this matter is being taken up.

FRENCH IMPORT TARIFF.—It was decided at Bangalore "that as the matter was receiving the attention of Government, we confidently left it in its hands."

In the meantime the Ceylon Government has arranged matters for the Island and the Chairman of the U P A is taking action in referring the matter again to the Government of India.

COFFEE CESS.—A fair number of Members in this district have agreed to support this Cess on the condition that the scheme, when published, meets with their approval.

TEA CESS.—The Cess we agitated for is being allowed by the Government of India and it is intended that it should come into force on the 1st April. Our effort to obtain a larger share of representation for S. India has not been successful and it now remains with us to decide whether in our opinion both the representatives allotted us should be planters, or one of them a Member of the Madras Chamber of Commerce, which body has consented to appoint one of its number if required.

SALE OF TEA IN S. INDIA.—In this connection I may say that we hoped last year that the Ceylon import duty might be abolished. The representation to the Government of India to act in the matter has not been successful however. It becomes all the more necessary, therefore, that we should strain every nerve to capture our share of the Indian market. The demand for dust tea that exists is, at present, largely supplied by rubbish from Ceylon. We have the opportunity offered by Messrs Parry & Co. of Madras, who, with the Agencies they have in almost every town of any importance in S. India, afford a ready-made Distributing Agency which should enable the S. Indian planter to control the S. Indian tea trade. It is a matter for comment that one of the largest blenders in England, Messrs Brooke Bond & Co., are advertising the sale of their blends in Madras.

COFFEE CROP prospects are fairly good in the district; but prices unfortunately do not promise to improve. We must hope that the Leeming System, which has proved so successful on the Shevaroy's, and which there is every reason to think will answer here, will prove our salvation.

TEA has, on the whole, had a good flushing season and prices are improving.

PEPPER CROPS are decidedly good and prices maintain a good level.

Our numbers have fallen off considerably during the past year—six members having left, and one new member joined.—*M Mail*, Jan. 21.

THE MOSQUITO PLANT CURE.—From *Nature* of January 1st, interesting latest particulars are given on page 555, regarding the West African plant, Basil, which is said to have a wonderful effect in keeping off mosquitoes. The Peradeniya Staff should import and keep as large quantities of the plant as possible on sale.

TO THE PLANTING WORLD.

Seeds & Plants of Commercial Products.

Hevea Brasiliensis.—Orders being booked for the coming crop August-September delivery 1903, booking necessary before the end of April, quantities of 100,000 and over at special low rates. Plants available all the year round, 100,000 and over at special low rates. A leading Rubber planter in Sumatra, who purchased 50,000 seeds in 1899, and 100,000 in 1900, writes us, under date 15th November, 1900:—"I received your letter of 20th October, from which I learn that you added another case of 5,000 seeds to replace the loss, &c. I am satisfied hereby, and even after this adding I am satisfied by the whole delivery of this year." Special offer, post free on application.

Castilloa Elastica.—True superior variety cultivated in Mexico, seeds from specially reserved old untapped trees. Orders booked for October-November delivery 1903, immediate booking necessary; large quantities on special terms; Plants in Wardian cases.

A foreign firm of Planters writes under date 11th October, 1901:—"We beg to enquire whether you would procure us 100,000 Castilloa seeds, in which month we might expect them, and what would be the average price." Special offer, post free on application.

Manihot Glaziovii.—Seeds and Plants available all the year round, 100,000 and over at special low rates. A Mexican planter in sending an order for this seed wrote on the 22nd August, 1900:—"If they arrive fresh and germinate easily I may send you larger orders, as they are for high ground where the Castilloa does not thrive."

Ficus Elastica.—Seeds available in May-June; booking necessary before the end of March; also plants.

Mimusops Globosa (Balata) wood of the tree is much sought for buildings, fruits sweet like a plum and eaten, oil from seeds, said to yield as much as 45 lbs. of dry rubber per tree per annum, the milk is drunk and when diluted with water used as cow's milk, grow from-sea-level up to 2,000 feet, orders being booked for seeds and plants, price on application.

Cinnamomum Zeylanicum (Cinnamon superior variety).—New crop of seed in April to June; booking necessary before the end of February, also plants.

Coffee Arabica-Liberian Hybrid.—A highly recommended leaf-disease resisting hardy new variety of Coffee (cross between Arabian and Liberian). New crop March-April; immediate booking necessary.

A foreign Agricultural Department writes dating 9th September, 1901:—"Please accept our order for 175 lbs. of Tea seed and for 2,000 Coffee beans. In regard to Coffee seed I would say that this will be the first importation made by this department, and we will leave the selection of the varieties to be sent to your judgment."

OUR DESCRIPTIVE PRICE LISTS.

The following six Descriptive Price Lists are now being forwarded with Circulars and special offer of Seeds and Plants of Rubber and other Economic Products:—

1. Tropical Seeds and Plants of Commercial Products, enlarged edition for 1902-1903.
2. Seeds and Plants of Shade, Timber, Wind-Belts, Fuel and Ornamental Trees, Trees for Road-sides, Parks, Open Spaces, Pasture Lands, Avenues, Hedges, and for planting among crops (Tea, Coffee, Cacao, Cardamoms, &c.)
3. Seeds and Plants of Tropical Fruit Trees including Mango grafts.
4. Bulbs, Tubers and Yams.
5. Orchids—Ceylon and Indian.
6. Seeds and Plants of Palms, Calamus, Pandanus, Cycads, Tree and other Ferns, Crotons, Roses, Dracinas, Shrubs and Creepers.

Special Arrangements made with foreign Governments, Botanical and Agricultural Departments, Planters and others for supplying seeds and plants of Commercial Products in larger quantities.

"SOUTH AFRICA."—The great authority on South African affairs of 25th March, 1899, says:—"An interesting Catalogue reaches us from the East. It is issued by WILLIAM BROTHERS, Tropical Seed Merchants of Henaratgoda, Ceylon, and schedules all the useful and beautiful plants which will thrive in tropical and semi-tropical regions. We fancy Messrs. Williams should do good business, for now that the great Powers have grabbed all the waste places of the earth, they must turn to and prove that they were worth the grabbing. We recommend the great Powers and Concessionaries under them to go to William Brothers."

Agents in London:—MESSRS. P. W. WOOLLEY & Co., 90, Lower Thames Street.

Agent in Colombo, Ceylon:—E. B. CREASY, Esq.

Agent in British Central Africa:—T. H. LLOYD, Esq., Blantyre.

Telegraphic Address:

J. P. WILLIAM & BROTHERS.

WILLIAM, HENARATGODA, CEYLON.

Tropical Seed Merchants,

Liber's, A.I. and A.B.C. Codes used.

HENARATGODA, CEYLON.

KNUCKLES, KELEBOKKA AND PANWILA P. A.

REPORT FOR THE YEAR.

There are now 28 estates on the register.

TEA.—Acreage in tea is 10,109 acres, of which 9,880 are in bearing.

Estimated crop for 1903 is 4,047,000 lb. which shows a yield of 409 lb. per acre.

Native leaf, 689,000 lb. leaf.

Accounts were laid on the table, and show a credit balance of R98'52.

DIMBULA PLANTERS' ASSOCIATION.

SEASON 1903: TOTAL ESTIMATE OF TEA CROP IN DIMBULA DISTRICT.

	Total Acreage in Tea.	Total Acreage in Bearing.	Total Estimated Crop.	Crop per Acre.

E. & O. E.

75 Acres were left to rest.

Eleven (11) Estates have not sent in returns for this year.

One (1) Estate sent only the acreage and did not mention the crop.

1902-1903.

THE DIMBULA PLANTERS' ASSOCIATION: COMMITTEE'S REPORT PRESENTED TO THE 28TH ANNUAL GENERAL MEETING.

19th Jan., 1902.

MEMBERSHIP.—The subscribers for 1902-1903, number 96 estates:—The total is (4) four subscribers less than 1901-1902; (3) three estates and (1) one private. The three (3) estates have failed to pay, although two (2) had promised to do so. The private subscription was not paid owing to absence in Europe of the payer.

MEETINGS.—There have been (4) four Committee and (4) four general meetings during the year. Several members of Committee have only attended (1) one meeting and it is to be regretted that keener interest is not taken in the affairs of the

Association and of general import. The average attendance for the year has been for Committee, 12. General meetings, 23. It will be observed that the average attendance in Committee for the year, has been less than half of the members appointed: a most disappointing result; whereas, the average attendance in general meetings has been considerably greater than in the previous year, which is satisfactory and encouraging.

ACREAGE AND CROP ESTIMATE FOR 1903.—The total Acreage of the District is 45,925 in tea; in bearing, 45,047½ acres. The estimated crop for 1903, as far as it has been possible to collect, is 21,786,535 lb. of Black Tea, or an average of 483 lb per acre. These figures show a decrease in tea of 861,084 lb. and a decrease in yield of 23 lb. per acre under 1902.

SEASON, 1902.—The bad flushing weather during the latter part of the year, has caused low yields, consequently estimates are short in most cases, Prices throughout the district have been generally well maintained and in a fair number of instances are higher than those during last year. Plucking has been careful, but owing to the shortfall, profits are probably less than in 1901 on the majority of estates.

LABOUR.—Owing to less crop being harvested during the year, labour has been enough to cope with work done on estates generally; which is satisfactory. Your Committee would, however, impress on employers of labour, the necessity of recruiting more labour from the Coast during 1903, in order to maintain their labour forces to required strength and to avoid as far as possible issuing further advances to those already in Ceylon. That special efforts be made to tap new districts and if considered advisable to appoint a special recruiting agent.

LABOUR FEDERATION.—There has been one case brought before the District Sub-Committee during the year between Ambegamuwa and Dimbula planters; the final decision exonerated the Dimbula planter as having been decided by one of his kanganies.

DISTRICT MINOR ROADS.—The amount granted by Government towards the upkeep of these roads for this year was R1,000; out of this R288'15 was spent on sign-posts. Consequently after paying the votes granted for District Roads amounting to R716'52, there is a debit balance of R4'67 which the Association is obliged to pay pending supplementary grant to meet the expenditure on sign-posts from District Road Committee. Your Committee would point out that owing to the heavy expenditure on sign-posts during the past two years, grants for upkeep of District Minor Roads have had to be reduced to a minimum, which has been detrimental to proper maintenance of the roads throughout the district.

SIGN-POSTS FOR DISTRICT MINOR ROADS IN DIMBULA.—Your Committee have to report that up to 31st December, 1902, R288'15 has been spent on the completion of the sign-posts undertaken. The total spent in 1901 and 1902 under this heading has been R757'33, which, so far has been deducted off the Annual Grants, allowed by Government for upkeep of District Minor Roads in Dimbula. It is hoped that the District Road Committee will be able to pay us an extra vote in 1903, towards the outlay under this heading. Your Committee would advise that the chaining of the Bridle Roads should be undertaken directly funds are available, in order that each District Minor Road may receive its Annual Grant in proportion to its mileage.

MAIN ROADS.—Your Committee are pleased to be able to report that the Main Roads in the District have been on the whole, well maintained during the year. It is satisfactory to note that the improvements suggested by the Association are likely to be provided for in the 1903 estimates,

It is hoped that the improvements ultimately decided on, may be carried out expeditiously and on economic lines.

HOSPITALS AND DISPENSARIES.—Your Committee are glad to report that, to the best of their knowledge, the Craigie Lea and Lindula Hospitals and Dispensaries have been sufficient to meet the demands made on them in their respective vicinities:—The promised Agra Patanas Hospital has not yet been sanctioned, although, it is highly desirable that the mortality amongst coolies should be reduced.

FIREWOOD SUPPLY.—There have been no complaints made to the Association during the year; it is, therefore, presumed that the fuel Depot at Talawakelle has worked well and continues to give satisfaction to those estates interested therein.

PLANTERS RIFLE CORPS.—The strength of the corps in our District continues satisfactory:—The interest and keenness shown in Shooting is marked:—The District is to be congratulated that their Distinguished Officer Commanding the Planters Rifle Corps, has been deservedly promoted to be Lieut.-Colonel:—Your Committee would urge on all Volunteers, the necessity for making themselves thoroughly efficient in the use of the Rifle, besides, making themselves competent in Drill.

TIN TICKET SYSTEM AND REGISTRATION OF ESTATES.—Your Committee are pleased to report that this new scheme inaugurated by Government about a year ago, has given satisfaction so far:—It is thought that advances have been reduced thereby and that as it becomes better known and more widely adopted, it is calculated to produce even better results than hitherto, when thoroughly understood:—It is hoped that every Estate in the District has registered, but should there yet be some who have not done so, your Committee would urge on them to do so without delay.

COOLY BOLTERS.—Your Committee regret to report that the prevalence of Bolting and repudiating Advances amongst Canganies and Coolies, at one time during the year, threatened to assume serious proportions; but happily it has somewhat abated of late:—Your Committee would urge on employers the necessity for studying the cause of this serious evil, with a view to checking its further spread if possible:—It is thought that to some extent it might be reduced, if employers of labour would desist from retaining coolies, who want to leave their Estates, against their will:—It should not be forgotten that "The Indlaw" in the eyes of the law, is a free Agent; therefore, if his services cannot be retained by fair persuasion, it is best to pay him off and recover advances; to prevent him taking the Law into his own hands, and thus create a bad precedent on an Estate:—It has been brought to the notice of your Committee that some Proctors have unsettled Labour, but it would remind employers, that if coolies do not derive any benefit from the advice given by those gentlemen, it is not anticipated that labour will adopt this method on a large scale.

MEMORIAL WINDOW.—Your Committee have to report that the Memorial Window subscribed for by the friends of the late Mr. Sandys Thomas has been erected in the Lindula Church during the year:—It is a handsome window and adorns the Sacred Edifice which was frequented by the Deceased.

BULK PETROLEUM AND LIQUID FUEL INSTALLATION.—Your Committee are pleased to report that Installation for Kerosine Oil and Liquid Fuel are under erection at Talawakelle Station and when completed will meet a long felt want in the District:—It is hoped that everyone who can conveniently make Talawakelle their outlet will support Messrs. Delmege, Forsyth & Coy's enterprise.

DIMBULA HALL.—The question of Rebuilding the Hall was considered again during the year, but nothing definite was agreed upon.

THE CEYLON NURSING ASSOCIATION.—Your Committee would remind managers of Estates of the

suggestion made, to endeavour to induce their Proprietors to subscribe to this Association:—It is hoped that some have been successful, but those who have not received permission to support this worthy institution, may yet try once again when the time is opportune.

OBITUARY.—[?].

MR. T. FAIRHURST'S ADDRESS ON "OOLONGS."

(Before the Dimbula P. A. Annual Meeting.)

Mr. Chairman and Gentlemen,—When I met Mr. Welldon in the train the other day, he asked me if I would lay before you what little knowledge I possess concerning China Oolongs. I have pleasure in doing so, but regret that my knowledge refers more to the tea as ready for shipment than to its actual manufacture. In China, European merchants are confined to the Treaty ports—travel in the interior of the country being discouraged by the Chinese and only entered upon with what amounts to a "safe-conduct" in the form of a letter from some high official to all Government officers in the interior. The purchase of land by Europeans, outside of the Treaty Ports is forbidden by Chinese Law, and so it happens that we who live at the threshold of the tea districts, know so little of the methods of manufacture. Even were the necessary permission to visit those districts obtained, the very rough nature of the country, necessitating travelling in comfortless boats up rivers encumbered by rapids, making progress very slow, together with contact with the frequently unfriendly dwellers by the river, would deter most men. We, therefore, only come into contact with the tea after it is manufactured and packed, as is the case in Colombo. The nearest tea district to Foochow lies about 20 miles distant, and the leaf is frequently brought into that town in a half-finished state. Thus we see a little of the later processes, such as firing or drying and sorting. Some years ago it was possible to see the final stages of green tea manufacture, but at Foochow only a low grade of green tea was made, very highly coloured, and when the United States legislated against the excess of colouring matter, the manufacture in Foochow ceased. All other teas than those of the near district which I have mentioned, are manipulated and packed on or near to the spot where they are grown. Touching Oolongs in particular, Foochow and Amoy in China, and Tamsui in the Island of Formosa, are the ports of shipment. As regards Formosa Oolongs, these, as their name indicates, are grown in the Island of Formosa—the principal market is at an inland town distant about 15 or 20 miles from the port of Tamsui. The leaf in a partially prepared state is purchased by Europeans or their Agents and brought down to Tamsui for final manufacture. This is done not only by Europeans but by Chinese and the teas thus prepared are sent by steamer to Amoy on the China Coast, for final shipment to the different markets in the United States and England. The teas so shipped from Tamsui by Europeans are mostly already ordered by their constituents, whilst those shipped by the Chinese are intended for sale on the Amoy market to the European buyers.

The teas grown in the island of Formosa, are all of one variety ranging from common to extra choicest. The best "chops" are frequently scented with a flower belonging to the Jasmin tribe. The soil of the island of Formosa is volcanic and very rich, and it is to this that the teas grown there owe their special and peculiar flavours. This is proved by the fact that the tea trees in Formosa are grown from seed imported from Amoy—the produce of the parent trees on the China side possessing nothing of the peculiar Formosa quality and like all Chinese teas deteriorating so much, that the produce of the Amoy gardens has practically ceased to be cultivated.

I myself some years ago, to my after regret,

IMPORTED INTO CEYLON SOME SEED FROM THE
FORMOSA TREES,

and the resulting plants reverted to the worst China type. I am of opinion that this type of Oolong, known as "Formosa Oolong," can never be produced in Ceylon to possess the true characteristics of the type. But it is different with the Oologs made and grown at Foochow. Of these there are three varieties, and I see no reason why their manufacture should not be successfully attempted in Ceylon. These varieties differ materially in make and flavour. The best are usually brought to market in what are called "String chops," that is they consist of "lots" varying from 500 to 3,000 half-chests, which must be bought *altogether*. There are usually 5 grades in each "string," "common" to "choice," and they are sold at an average price for the "lot," which the European buyer calculates by working out each grade at his idea of its value. The lower grades are large in leaf approximating to the leaf of an up-country Pekoe Souchong of long leaf. The size of the leaf decreases as the quality improves, until the best would resemble in size, a boldish pekoe. The infused leaves show a greenish colour, very even in the finer ones, but becoming mixed with darker leaves in the lower grades. The liquor is soft and fine in the better teas, becoming coarse in the commoner ones. Black leaves in Oologs are highly detrimental, and cause danger of rejection by the United States Tea appraisers. No Tea intended for the United States market should contain more than 10 per cent of dust. The price paid for these in China is based on, say b.o.f. New York up to about 1/3. The only other kind which requires special notice is a variety made more after the style of Congou or Black Teas as regards the size of dry leaf, but of course showing the same light-coloured infused leaf and liquor as the variety previously spoken of. The flavour however differs greatly, for whilst, with all their softness, the first kind mentioned as "Stringchops" possess a good deal of pungency—the last named variety—known as "Suey Kut" Oologs, taste more like the Black Teas from the Suey Kut district, and have little distinctive Oolong character. The leaf, especially of the finer sorts, resembles closely the teas which were being made in Ceylon 3 years ago, as Ceylon Green Teas. Their value ranges from about 10 cents, say 5d, to 1s, 2d.

The remaining kinds of Oolong grown in Foochow are mostly of large leaf, and varying quality, many being below the standard insisted on by the United States.

The average crop of the Formosa Oologs amounts to about 15 to 17 million pounds, and of the Foochow Oologs to about 5 millions. But both crops are liable to sudden increase according to demand, and this has been exemplified during the season of 1902 by an increase in the Foochow production of 50,000 $\frac{1}{2}$ -chs. equal to 2 $\frac{1}{2}$ million pounds, owing to the speculative demand from America contingent on the abolition of the Tea Duty there.

I think that the class of Oolong known in Foochow, as

"SUEY KUTS" COULD EASILY BE IMITATED
IN CEYLON,

but whilst "Suey Kuts" were on their first introduction into America, much liked and eagerly bought, there is not now the same demand for them. As regards that, I would suggest enquiries being made from some of the leading New York brokers, whilst as to the processes of manufacture—of both Foochow and Formosa Oologs—the best way would be to ask the information from the British Consuls at Foochow and Tamani. And the information would be more readily obtained if the request for it is forwarded through the Government of Ceylon, English Consuls abroad not being very well disposed to incur trouble over trade matters, which

are regarded as somewhat outside their province. I would also recommend that a similar application should be made through the German Consul in Colombo to the German Consuls at the ports named. All Green Teas and Oologs should be packed in half-chests containing 54 to 60 pounds Tea net. My own connection with China has practically ceased, but I could give the names of one or two firms in Colombo who could, I think, procure large samples of Oologs, and possibly assist in obtaining particulars of their manufacture. I will now reply categorically to the

QUESTIONS WHICH YOUR CHAIRMAN HAS AD-
DRESSED TO ME.

"How many kinds of Oologs are sold in America?"—The reply is, three from Foochow and one from Formosa shipped at Amoy.

"Where are they manufactured and what is the range of prices?"—In Foochow and Tamsui the range of prices paid being from 5d to 1s 3d or 1s 4d for Foochow, and from 6d to 3s for Formosa. Many of the finest of the Formosas are sent to the London market.

"Could we in Ceylon manufacture Oologs that would give an average of say 1s per lb?"—To this I should answer decidedly, No!—since the average of the "Suey Kut" Oologs, which would be more easily made, runs only about 9d per lb. if so much.

"Are 15 to 18 millions of Oologs sold in America?"—A circular of the Foochow Chamber of Commerce dated 19th December last, gives the export of Oologs to America from Foochow as 6 $\frac{1}{2}$ millions, and the annual export of Formosa Oologs would be about 12 to 14 millions.

"Could Ceylon hope to displace say 5 or 6 millions of these Teas?"—I think that Ceylon could certainly hope to place that quantity, provided the quality was right, and the average I have named—say 8d to 9d, a paying one.

"Are Oologs artificially scented and is the process of scenting them difficult?"—So far as I know only the finer or finest kinds are scented. The process is not difficult or very expensive, provided the scenting flower is at hand.

"Can you tell us how it is done?"—The scenting flower is added in certain percentages to the Tea before final firing. After the tea and flower have been left together for half or one day, they are fried or dried together and afterwards the flower is sifted out before the tea is packed.

"Is Formosa a country to which we should be likely to obtain admission in case of wanting to study the manufacture of Oologs?"—Anyone can enter Formosa and visit the tea centres. A person so doing could doubtless pick up the process by watching, but as there are no inns or hotels in those parts, he would perforce be the guest of one of the European firms engaged in the trade, and if they knew his purpose, they might do their best to thwart it, besides which, the guests attempting it would be placed in a very uncomfortable position.

"Is the crop of Green Teas going from Japan this year, due to labour difficulties or is it climatic?" I am unable to say, but should think it was mostly climatic.—"Are we likely to see a great fall in the price of Green Teas in America, supposing 15 to 17 millions were shipped this year from Ceylon and India?" I should say most certainly such an export would cause a reduction of possibly 3 to 5 gold cents per lb. (1 $\frac{1}{2}$ d to 2 $\frac{1}{2}$ d) unless the quality so pleased as to throw the greater fall on to the Teas from Japan and China. "How do Ceylon greens compare with Japan and Indian greens? If the comparison is unfavourable to Ceylon, will not our teas suffer severely in the event of a large Japan crop?" I have not seen enough Ceylon greens to form an opinion. Those I have seen compare favourably with Japanese and Chinese in leaf, but are, in my opinion, too thin in liquor. If the American verdict was the same and the

importations from Japan and China large, there would undoubtedly be danger of a severe fall in Ceylons—which could only be tided over by a liberal cess allowance, until the industry had hit upon the desired quality and colour. For information regarding the method of manufacturing Green Teas, I would recommend application being made to the English and German Consuls at Ningpo, in which district all Green Teas are grown and made. "In Western America beyond St. Louis, is there not still a large continent where Black Teas are consumed and where Ceylons are unknown?" Undoubtedly there are many large cities such as San Francisco and others within a radius of 1,000 miles (Chicago included) where Black Teas are largely used and where the "Thirty Committee" Commissioner has done little or nothing, (excepting at Chicago), but those markets have been and are being exploited by firms in Colombo having Agents there. More might be done by the means at the disposal of the "Thirty Committee" in the country indicated. There is one danger ahead which I would notice. Should the Export to London fall off and become lower than the requirements of that market, an opening would be given to China to send larger supplies of common Black Tea, China can increase or decrease that supply at will, witness the large increase during 1902, in the Export of Oolongs, which excess will have been made from the "Suey Kut" Congon leaf by which the supply of Black Teas has been curtailed to the extent of 2½ millions of pounds. The fact also that the larger crop of Oolongs has been made out of the leaf usually converted into common Black Tea shows that the manufacture of Oolongs in Ceylon as well as Greens can be as well carried out on low-country estates as on those of high elevation.

FINAL.—In conclusion I would merely add that I have always been of opinion that the money expended by the "Thirty Committee" in the Eastern States in pushing Black Tea has been simply and absolutely wasted, and would have been of far greater use had it been applied to exploitation of the same Tea in Russia. The Eastern States are the ones which use Oolongs and Green teas, and funds may, I think, still be employed in pushing them there advantageously. A great effort should be made at the St. Louis Exposition to bring Ceylon Greens and Oolongs into notice, whilst at the same time it can do no harm to show also Ceylon Black Teas.

It would be a great pity, I think, to discontinue the campaign in the Eastern States on behalf of Green Teas and Oolongs, as those are the kinds used by ¾ths of the population of those States, and to cease the effort now would be to destroy what good has already been done.

I do not think that China will be able to compete with Ceylon as regards Black Teas so long as Europeans are prevented from holding land in the interior, and even should that privilege be eventually granted, it is a question how far the China leaf will lend itself to machinery.

The result of an experiment made at Foochow, where a small Factory with Jackson's machinery was erected, was a decided improvement in the appearance of the dry leaf, and a thicker liquor in the cup, but the flavour was destroyed, the taste being mawkish and dull, and the peculiar flavour, which the leaf tried, should have developed was entirely absent.

AMBEGAMUWA PLANTERS' ASSOCIATION.

ANNUAL REPORT FOR 1902—1903.

In presenting this report for 1902 your Committee have pleasure in stating that the Association has well maintained its strength and usefulness during the past year.

The number of votes in the Register is 38, being one less than last year.

The financial position of the Association is as follows:—

	EXPENDITURE.	R. c.
Debit balance from last year...	..	2 95
38 Subscriptions at R7.50 to Parent Association	285 00
Petty Disbursements	124 47
		412 42
38 Subscriptions at 10	380 00
Leaving a debit balance of	R32 42

The accounts of the Association were duly audited by Messrs. Wiggin and Blacklaw.

MEETINGS.—During the year there have been five General Meetings, four meetings of the Standing Committee and four meetings of the Local Labour Federation Committee, all of which have been well attended.

MINOR ROADS.—The Inter-District Roads in the District are generally in good order. The District Road Committee grant for 1902 is R355.

A Resolution was passed at a General Meeting held on the 21st November, asking the District Road Committee to have the bridge across the ravine on Binoya Estate near Rozelle Station, put in permanent repair. And your Committee have pleasure in informing you that the matter has been taken in hand by the District Road Committee.

P. B. F. AND N. A. HATTON.—These funds have been well supported by the Association during the year.

CROP ESTIMATE.—The returns for the district for the official estimate of Tea Crop of 1903 were collected as usual.

The figures arrived at being as follows:—

a Total acreage in Tea ..	16,026 acres
b Acreage in bearing ..	14,752 "
c Total tea crop ..	5,587,500 lb.
d Estimate of Green Tea ...	660,000 "
e Estimate of Native Leaf (included in c) ..	325,000 "
f Acreage abandoned ..	24 acres
The total tea crop being ...	388,500 lb.

less than last year's estimate, equal to a decrease of 22 lb per acre.

HOSPITAL AND DISPENSARY VISITORS.—On the recommendation of the Association Mr E H Hutchinson was appointed unofficial visitor to Watawala Dispensary.

OBITUARY.—Your Committee has with much regret to record the death of your late Chairman, Mr Oliver Collett who, on several occasions, occupied the office of Chairman and whose keen interest and ability in all Association matters were much appreciated by all.

PREDACEOUS INSECTS AND HOW THEY CATCH THEIR PREY.

THE GOVERNMENT ENTOMOLOGIST'S LECTURE.

The following is the full text of Mr. E. E. Green's lecture on Saturday, July 17th.

The subject of this lecture may perhaps be called a cruel one. Nature in many of her moods, is cruel,—from our standpoint. But in spite of her apparent cruelty—Nature is always interesting, if we will take the trouble to scrutinise her operations. It is said that every-one likes to know what his neighbour has for dinner. The most popular hour at the Zoo is when the animals are being fed. I propose, therefore, to introduce you to some of our common insects at their meals. I have purposely chosen my chief examples from insects that occur commonly in Ceylon, so that you may yourselves be able to watch their habits—if you wish—and perhaps to find out other interesting traits connected with them.

INSECTS.—In common with other animals—may be broadly divided into two groups,—Carnivorous and Herbivorous. The carnivorous insects may again be divided into those that prey upon living animals, and those that feed upon dead animal matter. The first of these divisions may be further subdivided into Predatory and Parasitic forms. It is with some examples of the first of these subdivisions that I shall concern myself tonight. And, more particularly, with such as have special organs of prehension for the capture of their prey. As typical examples of such insects, we may take the various species of Mantidae. I have here a slide showing a representative, but by no means complete, group of these insects. In several of them you can see the specialised front legs that will be described in detail presently. You will see that they vary considerably in size,—from this small species which is only three quarters of an inch in actual length to this elongated species that measures five inches from snout to tail. Our knowledge of the names of the various Ceylonese Mantidae is very incomplete. So I can refer specifically to a few only. This one, with the ocellated spots on its front wings, is called *Creobroter pictipennis*. It is really

A VERY PRETTY LITTLE FELLOW,

Its front wings are bright green with a gamboge-coloured eye-spot picked out in black. Its hind wings are delicately shaded with purplish grey. This bizarre-looking creature that appears to have bits of leaves attached to its elbows and knees rejoices in the appalling name of *Gongylus gongyloides*. The insect seems to be compounded of bits of twigs and fragments of leaves. But they are all really parts of its body. It is usually of a yellowish green colour, though individuals of a yellowish-brown tint are not uncommon. This form and colouration, while protecting the insect from the attacks of its enemies (birds, lizards, &c.), stands it in good stead in its own hunting operations. The term "hunting" is however scarcely applicable; for the Mantidae do not usually chase their prey, but stationing themselves in some suitable situation, often near some tempting flower or fruit, they remain perfectly motionless but wide awake, awaiting the advent of some passing insect. The *Gongylus* takes advantage of its resemblance to foliage by establishing itself at the end of the spray of some plant—frequently close to a flower. From thence it snatches butterflies and other winged insects. I have actually seen one of these Mantises catch a butterfly on the wing, as it was hovering over the flower. The under-surface of the expanded portion just behind the insects head is coloured a delicate pink, and may perhaps itself be mistaken for part of a flower,—a most fatal mistake for the insect that makes it. Observe this slender part between the head and the abdomen. The food must be bitten very small to allow of its passage down such pipe-stem waist.

THE "PRAYING MANTIS"

(*Mantis religiosa*) is so-called from the devotional attitude that it assumes, its arms doubled and held up in front of face. Needless to say, its mental attitude is by no means devotional. As one writer has punningly remarked, instead of saying "Let us pray" (pray), it is more probably murmuring "Let us prey" (prey). Another remarkable form of Mantis is the *Chaeradodis squilla* which carries a green sunshade over its head. Not that it anticipates a snstroke. The green shield is more probably for the purpose of disguise,—to make it look more rustic and innocent. The Mantis is one of the most rapacious and callous of insects. It will seize a grasshopper or any unwary insect that comes within its reach and—ignoring its struggles—will calmly eat off all the outlying portions before attacking the vital parts of its victim. It may possibly occasionally pick up some higher game, such as an infantile lizard or frog. I have vivid recollection of a tragedy that occurred in a vivarium in which I had a happy family consisting of several species of lizards and frogs. I rashly introduced a Mantis, one day, thinking that it would support itself on the flies and

other small insects that were supplied for the other occupants. Next morning the cleaned skeleton of what had been a small green tree-frog testified to the dangerous nature of the newcomer, which was promptly removed and placed on a creeper in the verandah, where it afterwards itself fell a victim, being caught and devoured by a large green lizard. And now we must examine the special weapon with which the Mantis is provided. I have here a slide showing the front limbs of a small species. You will notice how well they are adapted for their purpose,—to seize and hold a straggling insect. The leg is divided into the usual parts. The greatly thickened portion is the femur—or thigh. The thickening is to strengthen the parts and to give attachment to the powerful muscles required for the gripping action. Its inner edge is armed with stout spines, like the teeth of a steel rat-trap. The other jaw of the trap is represented by the tibia or shin. It also has a double row of spines which interlock with those of the femur, and it terminates in a stout claw. The foot proper is represented by these small terminal joints which are usually turned back to be out of the way. They are not of much importance to the insect and are frequently missing, having been lost perhaps in a fight with a neighbour,—or perhaps accidentally eaten by the insect itself, which seems to get along very comfortably without them. This is what is called the raptorial type of leg. The other legs of the Mantis have homologous part, but they are slender and adapted only to walking. The Mantis is predatory throughout its whole life. The baby Mantis when first hatched from the egg, is possessed of these specialized front legs and knows how to use them. This slide shows a young *Gongylus* as it appears when it first steps out into the world. This same raptorial form of front leg occurs in a number of different insects,—often in widely separated families. The Mantidae—just noticed—belong to the family *Orthoptera*, which include the herbivorous Leaf and Stick insects: the Locusts, Grasshoppers and Crickets; and the Cockroaches. It appears also in the Bug family (*Hemiptera*), the Net-winged family (*Neuroptera*) and amongst the 2-winged flies (*Diptera*). As examples of *Hemiptera* possessing

RAPTORIAL LEGS,

may be mentioned the *Emesa*, which looks like a very thin stick-insect, a veritable skeleton and, and an allied genus, *Ploiaria*, which simulates a small "Daddy-long-legs" (*Tripula*). These little bugs capture their prey in the same manner as do the Mantidae; but, while the latter have biting jaws and tear their food to pieces, the bugs have a sharp beak constructed for sucking, and absorb the juices only of their victims. There are also aquatic bugs, *Ranataria* (sometimes called the "water-mantis"), the water-scorpion (*Nepa*), and the giant water-bug (*Belostoma*). This last insect is common in the Kandy lake, and probably in Colombo also. It measures nearly three-and-a-half inches in length and is proportionately stout. It preys upon small fish, frogs and tadpoles, as well as upon beetles and other terrestrial insects that tumble into the water, gripping them with its strong front legs and driving its cruel beak into their flesh. I have kept them alive in an aquarium for several months at a time, feeding them upon beetles, grasshoppers and cockroaches, the latter insects being especially appreciated. They have well-developed wings and frequently leave the water at night for a short flight. At such times they are often attracted by the electric lamps, and may be picked up in the road in a dazed condition. In the family *Neuroptera*, we have the *Mantispa*, showing the same form of raptorial limb. As its name implies, it resembles the *Mantis* in form and habits; but differs widely from that insect in the nature of its development. A young *Mantis* is merely a diminutive edition of the adult insect minus its wings. But a young *Mantispa* undergoes a grub stage, and a remarkable grub stage too, for it undergoes what is

called hypermetamorphosis, that is it passes through more than the three normal stages of metamorphosis. When first hatched it is an active little creature with well-developed legs. But soon it settles down into the degraded condition of parasitism in the egg-cocoons of certain spiders, where it assumes the form of a fat fleshy grub and loses the use of its limbs. From thence it passes into the normal pupal stage, and eventually re-enters active life as this delicate net-winged little insect that you see before you. It preys upon small flies, catching and eating them in exactly the same manner as does the true Mantis. We find the same form of limb recurring in the 2-winged flies (*Diptera*). It is very noticeable in that remarkable little species the "Telescope Fly" (*Diopsis*), so-called because its eyes are placed on stalk-like projections from the sides of the head. In this insect the femur of the front leg is armed with a row of sharp spines upon which the tibia closes. The *Diopsis* runs about on the leaves of plants in shady places and pounces upon smaller insects that happen to be exercising themselves in the same situations. In another group of flies, the *Empidae*, it is the hind legs that are modified for grasping, and in these we find a somewhat similar arrangement of the femur and tibia of the third pair of limbs. The *Empis* fly often pounces upon its victim and bears it along with it, taking its meal in mid-air. The big "robber flies" (*Asilidae*) catch and carry, their prey in the same manner, but use their feet only in holding it. Their legs are consequently without any special modification. These flies suck the juices only of their victims.

Amongst

THE WASP TRIBE

(*Hymenoptera*), grasping apparatus is found both on the front and hind limbs. Of the former type, the *Gonatopus* may be taken as an example. In this instance the prehensile apparatus is a modification of the claws of the front-leg to form a strong pair of nippers. This picture was made from a specimen caught by sweeping with a butterfly net amongst coarse grass. Although it figures so large on the screen, the *Gonatopus* is really a very minute insect, only a small fraction of an inch in length. The feeding habits of this insect are not known. In its larval stage it is a parasite on the bodies of small insects popularly known as "frog-hoppers." The eggs are laid on the body of the frog-hopper, and it is in holding on to these acrobatic little insects that the gripping apparatus of the *Gonatopus* is brought into play. In some other parasitic Hymenoptera, e.g., *Stephanus indicus*—the hind limbs are modified in the same way as those of the *Empis* fly already described. This character is very well marked in a little wasp that breeds in the egg-cocoons of the common Mantis. It is a brilliant little insect with a burnished metallic green body. Its extravagantly long ovipositor is required to allow of the eggs being placed in position in the heart of the cocoon. But little is known of the feeding habits of these minute insects and it is uncertain whether this structure is employed for the capture of prey or solely for grasping the insects in which they wish to deposit their eggs. It can hardly be required for this purpose in the case of the insect that oviposits in the egg-cocoon. I must now bring to your notice some insects in which

THE MOUTH PARTS

are especially modified for reptorial purposes. One of the most remarkable of these modifications is the apparatus carried by the larvae of dragon-flies. The adult dragon-fly is well-known to all of you. One species is perhaps

THE COMMONEST INSECT IN COLOMBO

or, at any rate, the one most in evidence. No-one can have driven from the Colombo station to the Fort without being struck by the sight of the thousands of dragon-flies hovering in the air along the edges of the lake, or resting in long lines on the telegraph wires. The adult dragon-fly takes its food

on the wing, its prey consisting of all sorts of smaller winged insects. Those dragon-flies that we see along the lake edge are doubtless growing fat on a plentiful diet of that troublesome Colombo pest of which we have lately heard so much—the Lake-fly. But perhaps very few of you have seen the insect in its larval stage, or would recognise it, if you did see it. The dragon-fly larva lives in the water and feeds upon worms and small aquatic insects, and perhaps picks up an occasional young fish. Some years ago I was present when the stew-ponds at Nuwara Eliya were emptied. Hundreds of young trout fry had been turned into the ponds some months previously; but they had completely and mysteriously disappeared. The drag-net brought up not a single troutlet. But it contained numerous ugly looking larvae which I identified as the grubs of one of our largest dragon-flies. I think it very probable that these larvae were responsible for the disappearance of the young fish. The dragon-fly larva has a broad head with prominent goggle eyes; six well developed jointed legs; and a body that is short and stout or long and slender—according to the species. But they may always be recognised by the presence—on the underside of the head—of an elbowed process, provided with a strong pair of forces at its extremity, and capable of being shot out in front to seize any desired object. Its application reminds one of the lazy-tongs used by our grandmothers to pick up pins or other small objects without rising from their seats. When at rest this apparatus is folded close against the underside of the head, the front part almost completely covering the face of the insect, on which account it is often referred to as the mask. I have here a photographic representation of a young dragon-fly larva with the apparatus retracted; another showing it fully extended; and a third giving a larger view of the head and apparatus itself. It would be difficult—without entering into minute technical details of the mouth-parts of insects in general—to explain the exact relations of this organ, and I will merely say that it consists of a modification of the lower lip (labium) and the chin (mentum) with the labial palpi. The dragon-fly larva is a very common insect and may be dredged up in a hand-net, from the bottom of any shallow pool or along the edges of the lake. It would repay anyone to keep one or two of these insects in a shallow vessel—such as a finger-bowl or soap-plate—to observe their habits. Drop a fly or a small worm into the water, at a little distance from, but within sight of the larva. You will see the latter creep stealthily towards the object until it is within striking distance, when the extensible pincers will be suddenly shot forward and the victim will be seized, pulled in and promptly devoured. Another most interesting insect—also a member of the family Neuroptera—is

THE APHIS-LION

(the larva of *Myrmelco*). It is of special interest more from its habits than its structure. It has no extensible apparatus, nor does it run after its prey. It waits until its food actually tumbles into its jaws. To ensure this happy result, the ant-lion constructs small funnel-shaped pits in loose sand or fine earth, in spots sheltered from rain. The ground beneath the eaves of a bungalow or outhouse is an almost sure find for them. At the bottom of the pitfall lurks the little larva, its body completely buried, its head alone exposed—with the sickle-shaped jaws widely extended. There the little creature waits, patiently motionless, until some wandering ant falls headlong into the trap, when it is seized, dragged under the sand and sucked dry. If the ant escapes the first snap of the jaws and tries to climb the sloping walls of the pit, the shifting sand gives way beneath its feet and its discomfiture is completed by a volley of sand jerked at it by the concealed insect. A second tumble to the bottom usually results in its capture. The empty skin of the ant is finally jerked out of the hole and the trap repaired for the reception of the next

unwilling visitor. In this diagram I have endeavoured to shew a section of one of the pitfalls. And here is a photograph of the insect removed from its den. If we examine the weapons with which it is provided, we find that each curved jaw is composed of two parts—the mandible and the maxilla—one of which slides in a groove cut in the face of the other. The two parts combine to form a tube through which the juice of the victim are absorbed. When fully grown the larva constructs a globular cocoon of sand and eventually emerges in the form here shown. It looks rather like a small dragon-fly, but the body is shorter in comparison to the length of wing, and it has clubbed antennae which are not seen in the true dragon-fly. The perfect insect may often be seen flying feebly round the lamp at night, or resting—in the daytime—on the verandah walls. An allied insect with similarly constructed jaws is

THE "APHIS-LION"

—a name given to the larvae of the lacewing flies (*Chrysops* and *Hemerobia*). This larva—as you may see from its picture—covers its body with the empty skins of its victims, and walks about—a veritable "wolf in sheep's clothing"; though its covering is really more for protective than aggressive purposes, for its victims—the Aphides—are sluggish insects and quite incapable of resisting or escaping from their rapacious enemy. Aphides—as you doubtless know—are the small green or brown plant-lice that crowd upon the young shoots of roses and many other plants. The Aphis-lion calmly establishes itself on the edge of the crowd, picks up Aphis after Aphis, sucks it dry and neatly, adds its empty skin to the trophy of scalps carried on its back. These habits, though unpleasant for the aphis, are of great service to the agriculturist. I have here a photograph of the little animal—un-robbed. Mosquitoes are not usually looked upon as friends of man. But we have one species—the largest and most brilliantly coloured representative of the family in Ceylon—that may fairly claim that title; for its larva is carnivorous and feeds entirely upon other mosquito larvae. Its scientific name is *Toxorhynchites immisericors*. It is common in the Peradeniya Gardens, where it particularly frequents the clumps of Giant Bamboo. I have recently been studying its life history—which was hitherto unknown. It breeds in the water that accumulates in the hollow stumps of the bamboo. Though it is popularly termed the 'elephant mosquito,' I think that title must have been gained more on account of its comparatively large size than from its ferocity. I have never been bitten by one myself, and have met only one person who professes to have experienced the bite of this species. In the adult stage, it feeds principally on fruit. I have kept specimens alive in captivity and have watched them sucking the juice of plantains. I have freely offered them my arm on the chance of their wanting a change of diet, but they have never availed themselves of my kindness, though other captive mosquitoes have not been so forbearing. The carnivorous larva of this species carries a remarkable raptorial organ on its head. ^{Up to the larva of the common mosquito, the} ^{of Mantis is the} ^{green} ^{in the front of the head} ^{which—by a rapid lashing movement—create a current} ^{in the water which brings the suspended food to their} ^{mouths. They are termed "whorl organs."} In the larva of our *Toxorhynchites* these delicate whorl organs are replaced by two groups of sharp curved hooks, opposing each other. With this apparatus it seizes the smaller larvae of other mosquitoes when they incautiously approach within reach, and holds them firmly while they are being devoured. It is a sluggish insect and progresses through the water with difficulty by a series of awkward contortions. But it does not require any great activity. There is a super-abundance of this commodity on the part of its prey: for the other mosquito larvae are constantly jerking themselves

about in the water, and—in the confined space of a bamboo stump—are sure, sooner or later, to run up against the apparently torpid larva of *Toxorhynchites*. In an instant the hooks—which ordinarily lie back on each side of the head—are closed upon the victim. It seldom misses its stroke.

IN THE ANT TRIBE

we have an example of predatory insects that hunt in packs. They might be called the wolves of the insect world. The fierce "Red Ant" (*Ecophylla smaragdina*) scours the country in the neighbourhood of its nests, communicating with its fellows by means that we do not properly understand. With their strong jaws they can overpower quite large caterpillars and other soft-bodied insects, I have recently had bitter experience of the rapacity of another large ant (*Myrmecaria subcarinata*), when a horde of these insects found their way into one of my breeding cages and tore to pieces a number of full-grown silk worms. There is a comparatively small but very active reddish ant, named *Plagiolepis gracilipes*, whose acquaintance you may often have made in your sugar basins. Though decidedly fond of sweets, this species is really very useful in the house, for they are the sworn foes of cockroaches. I have on several occasions watched a cockroach-hunt conducted by these ants. The cockroach, as it hurries across the floor in search of cover, is surrounded by a cloud of skirmishers. They never attempt to grip their quarry. Their aim appears to be to dash in and give a quick bite at the sensitive antennae of the cockroach and dart back again. They must secrete some very subtle poison, for after one or two tiny wounds, the cockroach turns over on its back in a paralysed condition, when the skirmishers close in and drag away their victim to their nest. This sugar ant is remarkable for its ability to overcome more formidable species of the same tribe, though unprovided with any apparent weapon of offence. Its jaws are small and weak, as you can see from this enlarged photograph of its head. Yet it defeats, in single combat, the ferocious Red Ant whose jaws are powerful enough to cut it in half at a single stroke. It pursues the same tactics just noticed in the description of the cockroach-hunt. Some ants make their hunting excursions in orderly array, like an army, and apparently have recognised signs or words of command—imperceptible to our senses. Of this type is that elongate shining-black ant (*Lobopelta* species) which is possessed of a powerful sting. I was once watching an army of these ants. They were travelling in column—some 4 or 5 deep. Suddenly the leading files halted; the rest of the column closed up, till they were all packed together in a dense mass—one above the other. When the last straggler was in his place, the secret signal was given, and a combined dash was made to a large fallen leaf lying in the drain. I had seen nothing suspicious about this leaf. But doubtless one of the scouts of the black army had brought word that a large and succulent worm was concealed beneath it. As soon as it found itself discovered, the worm—which was of a slippery and active sort—commenced a violent series of jerks and twists in its endeavour to escape. But soon its entire surface was hidden beneath the thickly clustering ants, and a hundred stings had been plunged into its body. In less time than it has taken me to describe the episode, a procession had been formed and the limp corpse of the worm was being conveyed back to head quarters. But if I were to attempt to describe the remarkable habits of ants in general, I should be wandering from my proper subject, and I should keep you here all night. My allotted time and your patience must both be exhausted. The ways of ants would form a sufficient subject for a separate lecture. It only remains for me now to thank you for the kind patience with which you have listened to my somewhat discursive remarks upon predatory insects.

Correspondence.

To the Editor.

LUOERNE; AND PAPAYA: QUESTIONS FROM FAR PARAGUAY.

Ascension, Paraguay, Nov. 21, 1902.

DEAR SIRS,—Can you advise me of any remedy for slugs that destroy alfalfa (Lucerne)? I have had the leaves eaten off twelve acres by these pests, and no one here seems to know of a remedy; so I hope you will kindly be able to suggest one in the next number of the *Tropical Agriculturist*.

I should also be obliged by your advising me if the milk of the paw-paw has any commercial value, and if so, how it should be prepared for export?—Yours truly,

C. T. M. FEATHERSTON.

Casilla de Correo 63.

[As to the first question, Mr. E. E. Green is good enough to write:—"The best remedy appears to be dusting the plants thickly with lime—or spreading it on the surface of the ground surrounding the plants."—As to the milk of the papaw, there is a great deal of information in past numbers of the *T.A.*, and our correspondent should see that a "set" of the volumes is filed by the Paraguay Government, or in a local Public Library, for ready reference.—Ed. *T.A.*]

THE NEW MEDICINE FOR MALARIAL FEVER.

London, Jan. 1.

DEAR SIR,—I enclose you today an exact copy of a letter I have received from one of the correspondents who read my report in the *Ceylon Observer*. As I only received the letter today, I do not send you the original because I am having some printed copies made of it for distribution in the United States, where they suffer so frightfully from malarial fever, and it was Dr. Beling of the New Jersey State Hospital who first worked at it for malaria in that country. I am sending him out a copy of the report.—I remain yours faithfully,

THOS. CHRISTY.

Prospect Cottage, Bures, Suffolk, Dec. 31, 1902.

Thos. Christy, Esq., Dear Sir,—I called at your office on the 25th November, and you were good enough to let me have a bottle of Cassia Beareana. I began on the 26th to take 20 drops in plenty of cold water once a day. I have done so daily, and have kept perfectly free from ague and fever. I find it stimulates and strengthens my nerves, clears my brain, and in fact, I may say, it is my only a long day since I have enjoyed such a month of perfect health—no low, morbid feelings, but bright and cheerful; a free and easy feeling as if I had power to hold myself erect. I cannot sufficiently express my gratitude to you for writing to the *Ceylon Observer*; otherwise I might not have heard of this cure. I intended going to Liverpool to see Dr. Koss. I have sent a pamphlet and an account of the effect Cassia Beareana has had upon

myself, to Dr. Wontersz, Govt. Doctor at Nuwara Eliya, as it was by his advice I came home. I only hope he will try it in the hospitals.—I remain, dear Sir, yours truly,
(Sgd.) MARION EDLEY.

REJECTED TEAS FROM MELBOURNE: ACCEPTED IN LONDON.

Melbourne, Jan. 3.

DEAR SIR,—Some prominence was given just before the holidays to the fact that some of the teas, which were not allowed to enter this port, when released and sent to London, were allowed not only to pass in there, without difficulty, but were pronounced by the broker who had charge of them, to be of good quality. It was remarked that "the justice and promptitude shown in London compared very favourably with the harshness and long delay experienced in Melbourne."

I enclose you an extract from the *Age* of Jan. 2nd, reviewing the tea trade for 1902 and also alluding to the position of the

REJECTED TEAS.

[We give the tea "review" on page 556.—Ed. *T.A.*]

GAME PROTECTION IN PERAK.

Ceylon Game Protection Society, Jan. 20.

DEAR SIR,—I thank you for your kindness and courtesy in sending me the portion of the Perak Government Gazette on the subject of game protection in the State of Perak. It seems to me that Protection there is to be on a far more extensive scale than in Ceylon and that the fines to be imposed for breaches of the ordinance are far heavier.—Yours faithfully,

THOMAS FARR,
Hon. Secretary, C. G. P. S.

POINTS FROM THE GREEN TEA DEADLOCK IN CEYLON: FOR CESS PAYERS TO CONSIDER.

Jan. 20.

DEAR SIR,—There are one or two points in the green tea deadlock that are worth pointing out to the payers of the cess, who make good teas in connection with the appeal for a further increase of the cess.

I. What class of teas will benefit most by a reduction of exports to the London market? Teas for price.

II. Will good teas improve in values? On past experience—hardly at all.

III. What do these two facts point to? They show pretty clearly that with improved values for "teas for price" it will pay better to pluck coarse upcountry than fine. It has been done in the past and will be done again.

IV. What will the effect of this be? It is very clearly shown in brokers' reports and the recent telegrams to Kandy from the London Association.

Consequently I feel compelled to ask proprietors of estates making good teas to hesitate and carefully consider the position

and not rashly agree to a proposal which will hardly benefit them in the slightest and may prove most harmful to our industry as a whole.

As one making good teas myself, I consider any increase of the cess as a form of the worst "class legislation" because the proposers cannot show that it is for the good of the whole. Past experience shows us this cannot be the case.—Yours faithfully,

INCOG.

CEYLON EXPORTS OF COCONUT OIL TO INDIA.

Colombo, Jan. 22.

DEAR SIR,—A few days ago, in an article on Exports for last year with comparisons with previous years, you enquired why Export of Coconut oil to India had dropped off so much, as that country used to be about the best customer of Ceylon. The reason, I understood, to be that an import duty was imposed; which made this an unpaying business to the Chetties who were almost the sole exporters of oil from here to India, and so the business has nearly died out.—Yours faithfully,

JAMES GIBSON.

COMB HONEY IN COLOMBO.

Colombo, Jan. 22.

DEAR SIR,—I send you a sample of comb honey from an improved bee-hive I am working.—I am, Sir, C. D.

[We can testify that the comb is very well filled with superior honey of good flavour.—Ed. T.A.]

PLANTING NOTES.

A BACTERIOLOGICAL INSTITUTE IN SIAM.—It is stated in the *Semaine Medicale* that in order to give France a manifest proof of its friendly feeling, the Siamese Government has decided "to create at Bangkok a bacteriological institute to be under the exclusive direction of French physicians, and to institute forthwith in connexion with the health department, a service of sanitary works, having at its head a French engineer, and reinforced by engineers, also French."—*British and Colonial Druggist*, Jan. 9.

A REVIEW OF THE AUSTRALIAN TEA TRADE—during 1902 will be found in our daily of today. Traders there have had an adverse year and the causes which are named as having depressed the market, will be read with interest. "Colombo continues to be the main source of supply," the report states, although the imports this year are fully 10 per cent less than last year. Ceylon too has gained ground over India in the past year, the quality of the latter's tea being disappointing. China teas are gradually dropping out. Notwithstanding the fact that stocks are very much reduced the outlook for the year is characterised as poor.

CARDAMOM CULTIVATION: THE CESS CIRCULAR.

The following is the letter that has been addressed to cardamom growers in Ceylon:—

Rangalla, Jan. 12.

Dear Sir,—A Sub-Committee (consisting of Messrs. J Westland, J A Spence, W Reeve Tatham and myself,) appointed by the Committee of the Planters Association of Ceylon, to inquire into the best methods of pushing the sale of Cardamoms in foreign countries, recommend that the following circular be sent to all Cardamom growers with a view to ascertaining what support will be given. To enable the Committee to lay this matter before the Planters Association Meeting to be held on 17th February, an early reply is requested.—Yours faithfully, WILLIAM SINCLAIR, Chairman, Sub-Committee.

Circular.

That in view of the large extension in Cardamom Cultivation whereby the supply in the near future is likely to exceed the demand, it is most desirable that means should be adopted to make this product better known in foreign markets. To allow of this being done funds are necessary. It is therefore proposed that all cardamom growers be asked to subscribe 50 cents per cultivated acre, to form a fund for the purpose of pushing and making better known this product.

(Signed) WILLIAM SINCLAIR, J. WESTLAND, J. A. SPENCE, W. REEVE TATHAM, Sub-Committee.

A NEW RUBBER VINE.

The U S Consul at Tegucigalpa (Honduras) has been informed of the discovery in the Pijo mountains of a vine growing in an uncultivated state which is said to produce rubber of excellent quality. The vines grow to 100 feet in length, varying in diameter from 4 in. to 2 feet, and they are said to belong to the African family of rubber vines. In Honduras, no one seems to know the name of the vine or the botanical family to which it belongs. The discoverer (Senor Davadi, Governor of the Department of Comyagua) regards it as superior in quality to the Para rubber of commerce, and asserts that his convictions are borne out by the analyses made by American and European chemists.

The vine thrives at great altitudes as well as in the lower valley levels. Such luxuriance of growth has this plant attained that it is quite capable of being cut in commercial quantities. It may be quickly propagated in the rich soil of the Department by means of seedlings, and the growth being so much faster than that of rubber trees, Senor Davadi thinks the quantity of gum obtained would be large. The trees require six years' attention before sapping can begin. It has been proposed to form a company for the exploitation of rubber in the Yoro district, but though the names of several prominent men have been connected with the enterprise, nothing has as yet been done to begin operations.—*Commercial Intelligence*, Jan. 10.

DUMONT COFFEE COMPANY.

A circular has been issued stating that the coffee crop for the current year, owing to the trees having borne a very heavy crop last year which was followed by a severe drought, has fallen considerably below the manager's estimate of 60,000 cwt, the yield only amounting to 4,265, cwt, against 143,395 cwt in 1901. The market price of ordinary Santos coffee has averaged 28s 9d per hundredweight since the selling season began, but the average price realised to date on 15,702 cwt sold on the company's account is 40s 3d per hundredweight. Owing to the unsatisfactory harvest and the low price of coffee, the directors regret no further distribution can be made at present on account of arrears of preference dividends.—*H. and C. Mail*, Jan. 2.

QUININE AND CINCHONA.

Speculation in quinine has again been on a smaller scale this year, the shellac-market having overshadowed it to a great extent, and the latter has proved a more remunerative article. There has been practically no inducement to speculate for a rise in quinine, as the bark-shippments from Java up to November have again been extraordinarily heavy, even out-distancing the figures for 1901. So far the total shipments from January to November have been ;—

1900	9,680,000	Amst. lb.
1901	11,499,000	do.
1902	12,028,000	do.

These figures have completely nonplussed the "outside" market, and various theories have been propounded to account for them. Rumours of a combination among the Java planters have been hinted, and that the output was to be restricted, but as each successive month saw heavy shipments such rumours were naturally discredited. Taking the average unit paid for bark at Amsterdam, we find it is the lowest for the past three years. In January it opened at 7.45c., advancing at three consecutive auctions to 8.65c in May (the highest point), when makers quoted 1s 3d. From this period there was a gradual decline to 4.90c. in August, when makers reduced quinine to 10½d. In August the unit rose to 6.80c, and subsequently declined to 6.25c. this month. There have been fewer fluctuations in makers' quotations, and they close 1d per oz. lower than in January. The top price was 1s 3d (from April to June), but at the end of the latter month a reduction of 2d was made, and by September it was down to 10½d. It was barely a fortnight at this figure, for before the end of the month it stood at 1s 1d, and another ½d added in October brought it up to 1s 1½d.—to-day's price. In the "outside" market spot values close about 2½d lower than at the commencement of the year. The highest price paid was 1s 2d in March and the lowest 9½d in September, when the makers quoted 10½d. This low figure was merely temporarily, however, and with everybody wanting to buy there was a gradual advance to 1s ½d by the end of the month. From that point it went down to 10½d in November, and although the market subsequently advanced to 11½d, the position has an element of weakness in it.—*Chemist and Druggist*, Dec. 27.

COCONUT OIL MEAL.

The coconut palm (*Cocos nucifera*) is found throughout the tropics, and large quantities of the nuts are exported from the West Indies, Ceylon, West Africa, the Pacific Islands etc. Jamaica in 1900 exported coconuts to the value of £41,000

whilst Trinidad's annual output is from twelve to fourteen million nuts, worth about sixteen thousand pounds. The kernel of the nut contains a high percentage of a valuable oil, which is largely used for cooking, illuminating, etc., and as the source of 'nucoline' or coconut butter utilised as a substitute for lard and butter in cooking (see *Agricultural News*, page 53).

Professor A H Church, F.R.S, in his book on *Food* records the following analysis of the fresh kernel of the coconut :—

		<i>In 1 lb.</i>	
	<i>In 100 parts.</i>	<i>oz.</i>	<i>gr.</i>
Water	.. 46.6	7	200
Albuminoids, etc.	5.5	0	385
Oil	.. 35.9	5	325
Sugar, etc.	.. 8.1	1	130
Cellulose	.. 2.9	0	203
Mineral matter	1.0	0	70

The nutrient ratio of this kernel is 1:16. The fresh nut, it will be seen, contains nearly thirty-six per cent of oil, in addition to eight per cent of sugar and 5.5 per cent of albuminoids. In the ordinary process of manufacture the greater part of the oil is extracted and a residue obtained known as coconut oil cake. This substance in common with several other 'cakes' obtained from oily seeds such as cotton seed, linseed, groundnut, etc., has a high nutritive value.

The following analysis of coconut oil cake are taken from a paper from Mr M E Jappa, *Report, Agricultural Experiment Station, California, 1895-96*, page 113. As a basis of comparison the mean of three analyses of linseed oil cake (compiled from data in the same paper) are also reproduced,

Coconut Oil Cake.

	First sample.	Second sample.	Linseed oil cake. (Mean of three analyses).
Moisture	12.87	14.68	10.72
Pure ash	4.54	4.27	4.67
Crude protein	20.06	19.16	29.55
Crude fibre	11.50	8.55	8.24
Nitrogen free extract	40.90	42.81	36.73
[Starch, Sugar, etc.]			
Crude fat	10.13	10.53	10.07

The author remarks : 'coconut oil cake meal is another much valued concentrated food, and is finding more favour every year with the dairymen of California. While not rating as high in flesh formers as either linseed or cotton seed meal, it appears in many cases to be more relished by the animals.' Professor W A Henry in his recently published book, *Feeds and Feeding*, gives a summary of an interesting experiment made by the French War Department as to the value of coconut meal for horses. 'The results proved that coconut meal was equal and even superior to the same weight of oats.'—*Barbados Agricultural News*, Dec. 6,

COCONUT EXPORTS CALCULATED IN NUTS.

In our article on page 551, we dealt with the volume and the destination of the principal products of the coconut palm sent out of the island during last year. It has been usual with us to calculate what these exports represent in nuts, in our annual review of the Chamber of Commerce Circular; and the calculation has been found useful both by the Ceylonese and by the Europeans who are becoming interested in growing numbers in the coconut industry. The bases of our calculations have been challenged; but absolute accuracy cannot be expected in dealing with averages. The size and weight of nuts differ so widely in different districts, and even in the same district, and also on the same estate at different seasons and from different fields, that one can only use approximate averages. It may be that a closer approximation than ours, of 500 coconuts to a cwt of oil, 250 nuts to a cwt of copra, and three nuts to a lb. of desiccated kernel, may be worked out after consultation with the Managers of the various oil and desiccating mills, and the large owners of chekkus; but as our calculations for several years have been based on the above-named proportions, we adhere to them for purposes of comparison, leaving our readers to vary the computation according to the data within their reach.

Of oil, which continues to absorb the largest number of our coconuts, we sent away last year 512,498, or the equivalent of 236,249,000 nuts, being the largest quantity ever sent to the crushing mills if we except 1892, when the exportation of 550,977 cwt of oil worked out to 275,488,500 nuts. The 374,796 cwt of copra exported last year—the quantity was exceeded by 65,000 cwt in 1901 and by 132,000 cwt in 1898—represents, at 250 nuts to the cwt, 93,699,000 nuts. The record quantity of 16,227,565 lb. of desiccated coconut stands, at three nuts to the lb., for 48,682,695 nuts, or more than half the quantity absorbed for copra! We were certainly unprepared for the result, at which we have arrived; and it is proof, both of the excellence of the stroke that was made, when extraction of the moisture of the coconut kernel, while retaining its flavour for purpose of confectionery, was hit upon, and also of the enterprise with which the business has been conducted, that an industry only a dozen years old should be following so close on the heels of copra which was an article of export for generations. But the manifold uses of copra in Europe are of recent discovery, and even as late as 1895, the quantity exported represented only about 26 million nuts, a quantity which desiccation may double during the current year! If we add to the above totals for last year the 12,588,212 coconuts in the shell-exported, we get a grand total of 411,218,907 nuts, or the largest quantity ever sent away. Last year the total exceeded 393 millions, but 1898 (the record year for copra) held the pre-eminent and the influence of the growth of the copra trade and of desiccated kerne

may be gauged from the fact that in 1892, the year when we sent away almost 100,000 cwt of oil more than in any succeeding year, the exports calculated in nuts barely exceeded 330 millions. There is one other remark that we have to offer, suggested by the unprecedentedly large quantity of poonac that was exported last year, that its exclusion from our calculations is not quite justified. True, it is the refuse of the copra after oil has been extracted from it; but on the computation of 250 nuts to a cwt of copra, and 3 cwt of copra to 2 cwt of oil, every cwt of poonac should represent the refuse of 750 nuts; but the oil representing 500 nuts, the balance 250 nuts, must be shown in the poonac. In this way, the 247,697 cwt of poonac exported last year must be held to represent 61,924,250 nuts, and would help to raise the grand total to 473,143,157 nuts.

The export figures for the last five years work out as under, and we have added those for 1892, the year for the heaviest exportation of oil, for purposes of fuller comparison:—

	Oil cwt.	Copra cwt.	Desiccated lbs.	Coconuts.
1902	512,498	374,796	16,227,565	12,588,212
1901	453,531	439,865	14,055,493	14,850,781
1900	443,959	362,467	13,604,913	14,995,909
1899	400,979	325,401	13,571,084	11,723,392
1898	435,933	503,277	13,040,534	12,027,714
1892	550,977	134,590	3,849,724	9,717,386
				Grand Total

	Oil Nuts.	Copra Nuts.	Desiccated Nuts.	including nuts value.
1902	256,249,000	93,699,000	48,682,695	411,218,967
1901	226,765,500	109,966,250	42,166,479	393,749,616
1900	221,973,500	90,616,750	40,814,713	368,406,894
1899	200,489,500	81,350,250	40,713,252	334,276,894
1898	217,966,500	126,569,250	39,121,602	395,685,066
1892	275,488,500	33,647,500	11,549,172	330,402,558

We have excluded the poonac as it does not appear in our tables for the earlier years.

DISCOVERY OF ASBESTOS AND MICA IN VIRGINIA.—Dispersed over a district of 5,000 acres, various asbestos fibres of a thickness of 1½ ft. to 3ft. were discovered. It furthermore appeared that at greater depths (very probably on account of the dampness), the quality of the asbestos is better, without losing its thickness. For the purpose of exploiting these asbestos and mica layers, under the style of the American Asbestos Co., a company with a capital of 1,000,000dol. has been started, which has secured the concession for the working of a district 4,000 acres wide, and situated about twelve miles south of Bedford. The prices of asbestos in the United States vary between 10dol. and 75dol. per ton, according to the quality and length of the fibre. The resources of the United States of America hitherto consisted of only one asbestos field, otherwise they had to depend on Canada and Europe. The discovery of these new asbestos fields therefore, is of immense importance, especially as the demand for this material is continually growing. As a similar demand for mica is also apparent in the United States, the new discovery is also very important in that respect.—“Manufacturer’s Record” in “Gummi-Zeitung.”—*India-Rubber Journal*, Jan. 5,

CAMPHOR.

INDIAN AND CEYLON TEA SHARE VALUES.

IMPROVEMENT MAINTAINED.

From the following figures, compiled by Mr George Seton, of the Indian Tea Share Exchange, it will be seen, says the *Financial Times*, that the market value of the forty-five representative companies registered in the United Kingdom, which had recently risen considerably, remains virtually the same. There have been a good many moderate rises in value, but these have been counteracted by reductions in value, in a few cases of considerable extent. In a few cases, however, dividends have been deducted since the figures were last computed:—

Face value of 45 companies	£9,500,000
Market Value July 1, 1897 (highest point)	£12,000,000
do Jan. 1, 1902	7,000,000
do July 1, 1902	6,225,000
do Sept. 1, 1902 (lowest point)	6,050,000
do Oct. 1, 1902	6,150,000
do Nov. 1, 1902	6,300,000
do Dec. 1, 1902	6,600,000
do Jan. 1, 1903	6,600,000

As the total share and debenture capital of the one hundred and seventy companies altogether registered in the United Kingdom amount to

nearly £19,000,000, the fluctuations of the entire volume based on the above figures, may be thus estimated:—

	£
Face value of (about) 170 English companies	19,000,000
Highest market value, July 1, 1897	24,000,000
Lowest market value, September, 1902	12,100,000
Present market value, Jan. 1, 1903, say	13,250,000

This shows a depreciation of, altogether £10,750,000, or of nearly 45 per cent from top-point. Even these augmented figures it may be observed, take no account of the many private-owned estates nor of the Calcutta, Madras, Bombay and Colombo companies, registered with rupee capitals—the total amount of which it is difficult to compute, but in which the depreciation has doubtless been at least as great.

Mr. Seton adds that it appears probable that the advance, amounting to about 10 per cent., which has taken place since September, is now likely to stop there for a little, until it can be estimated, with some degree of accuracy, how the results of working for the year 1902 are likely to pan out, which can scarcely be sooner than the end of February in the case of the Ceylon companies, and March or April for the Indian companies.—*H & C Mail*, Jan. 16.

RUBBER GRASS OR BARK.

A foreign subscriber to *The India-rubber Journal* is very desirous of finding out the names of the firms who are importing from Mexico a grass or bark containing rubber. We shall be extremely pleased if any of our subscribers can help us with information on this matter.—*India rubber Journal*, January 5.

PLANTING NOTES.

PLANTING IN DOMINICA—100,000 fertile acres, 60,000 seedlings of tropical products delivered to planters in one year, the necessity of having at least £15,000 capital—these are some of the leading facts set forth in the interesting letter we quote tonight, from the Administrator of the Island of Dominica, —which is in area 300 square miles. A previous letter has fetched a number of settlers and Dominica is now a land of much promise.

THE BALATA INDUSTRY IN DUTCH-GUINEA.—The industry is restricted as to place and tapping by strict official orders. In spite of the unfavourable condition of trade during the first five months of 1901, the number of firms enjoying concessions has increased, and, as prices remain satisfactory, everything seems to point to a renewed future of balata. The yield of 1901 has been about the same as in 1900, the Nickerie district alone giving 145,000 kilos. The greatest danger to the industry lies in the killing of the trees through irrational tapping by the workmen. In order to gain the greatest possible quantity of balata, the tree is often not tapped on one side only, as officially wished, but on both sides, which causes it to die off; very often the trees are even felled.—*India Rubber Journal*, Jan. 5.

CEYLON TEA: MONTHLY SHIPMENTS TO UNITED KINGDOM AND ESTIMATE.

Estimate for	Jan, 1903—9½ to 10 mill. lb.
Total Shipments	Do 1903— 8,000,000 lb.
Do	Do 1902— 9,056,013 lb.
Do	Do 1901—12,617,540 lb.

[ESTIMATE for Feb. 1903—7½ to 8 million lb.]

THE DIRECTOR, GOVERNMENT CINCHONA PLANTATIONS, MADRAS—in his Budget for 1903-04, makes provision for the purchase of sufficient bark to yield 12,000 lb of sulphate of quinine, which together with 3,000 lb of sulphate of quinine, from estate barks will bring the total output to 15,000 lb. The cost of the purchased bark will depend on the price of the unit. The number of units to be purchased is 1,200,000 and estimating the price of the unit at 1½d the sum required will be £1,31,250. *M. Mail*, Feb. 2.

THE
AGRICULTURAL MAGAZINE,
COLOMBO.

Added as a Supplement Monthly to the "TROPICAL AGRICULTURIST."

The following pages include the Contents of the *Agricultural Magazine* for February :—

Vol. XIV.] JANUARY—FEBRUARY, 1903. [Nos. 7 & 8.

A USEFUL CEYLON DRUG.

WHAT is known as extract of Jambul is sold by chemists as a specific for diabetes, but few people are aware how familiar a tree yields this drug.

"Jambul" is an Indian name for *Eugenia* (*Syzygium*) *Jambolana*, the black plum commonly known as "Ma-dan."

The following information (taken from Dr. Watt's Dictionary) regarding the medicinal virtues of the tree are of interest:—

"The bark is astringent and used in cases of dysentery and the decoction as a tooth-gargle. A vinegar, prepared from the juice of the unripe fruit, is an agreeable stomachic and carminative; it is also used as a diuretic. The fresh juice of the bark is given with goat's milk in diarrhoea in children. The expressed juice of the leaves is used alone or in combination with other astringents in dysentery. The powdered seeds have had the reputation in recent years of being useful in the treatment of diabetes."

It is in this last connection that the tree appears to have received recognition in medicine as the source of a useful drug, and we read in the report of a Surgeon of the Indian Medical Department that the powder of the dried stone certainly does diminish the quantity of sugar in the urine very quickly, and, in some cases, even permanently.

We thus see that a familiar tree, commonly found on the sandy soils about Colombo and in the Negombo district, and the seeds of which are a favourite wild berry among children,

yields a valuable drug. As a fruit the "black plum" is by no means of a high order, and beyond being consumed *in situ* by children who go a-blackberrying, it is seldom seen within doors except, occasionally prepared, as a sort of sweet salad with lemon juice and sugar, in which form its bright red dye makes it a more attractive looking than it really is. There is an idea that this preparation is wholesome and tends to purify the blood. Apart from this use of this berry, which is the chief food of the pompadour pigeon (*bata-goyiya*) and the use of the bark as a tanning agent, the plant is not considered as a particularly useful member of the myrtle order, to which it belongs together with such fruit-producing trees as the rose-apple, Malay apple, guava, &c.

Mr. W. A. de Silva, who has an extensive knowledge of the uses of our indigenous plants, says of this tree:—"I heard some years ago that the seed of Ma-dan was exported to Europe, and that the fruit was a specific in diabetes." This was no doubt the time that products of the tree began to be examined as medicinal agents.

We are aware that there is a local European firm greatly interested in the commercial development of our neglected vegetable products, particularly those of a medicinal character, and we have no doubt that we shall hear of more of such products appearing under new names and in new and commercial forms among marketable commodities.

The pity is that some of the members of the local medical department, which counts men of acknowledged scientific skill among its numbers,

do not turn their attention to the study of the medicinal virtues of Ceylon plants, when so much can be done through the technical knowledge they possess, to develop the vegetable resources of the island.

OCCASIONAL NOTES.

We have had enquiries as to the English equivalents of the Indian weights in connection with the treatment of cattle, referred to in Indian works. We, therefore, give below the equivalents in avoirdupois weight.

1	Tola	6 $\frac{1}{7}$ $\frac{1}{5}$ drs.
5	Tolas 1 chittack	2 $\frac{2}{3}$ $\frac{1}{5}$ oz.
16	Chittacks 1 seer	2 $\frac{3}{5}$ $\frac{1}{5}$ lbs.
40	Seers 1 maund	82 $\frac{2}{7}$ lbs.
27 $\frac{1}{2}$	Maunds	1 ton.

According to the *Chemist and Druggist* plants are able to take up arsenic when it occurs in the soil or the manure, and may be present in measureable quantities in the early stages of succulent growth, but in no case is the faintest trace of arsenic found in the fruit or seed of any plant, so that there would appear to be a selective power in plants by which the arsenic, even if present, is rejected from the reproductive organs. Still, there is the possibility of arsenic being consumed where vegetables are eaten in the green state as is lettuce, water cress, and the like.

Professor Marshall Woodrow, late of the Indian Botanical Service, gives the following as the probable Etymology of "Jak," *Artocarpus integrifolia*, in the *Gardeners' Chronicle*:—"That appellation was probably given by our early voyagers from the resemblance between its top outer covering, studded with raised points, and the Jack Coat-of-arms used by soldiers in mediæval times, and it is more probable that after months of salt pork and beef, our sailors enjoyed the rather fulsome flavour of the massive fruit, and gave it the name most familiar to them."

Another Ramie fibre boom is predicted as a result of the invention of the "Faure" decorticator described as a strong and cheap machine suitable for hard work on plantations, and working economically and effectively. The Ramie Congress held in Paris last year passed it as being all that is required. A large demand is expected for decorticated fibre, and the cultivation of the plant is advised. The American and French Governments are pressing its cultivation hard. So writes Mr. H. A. Carter of Manchester to *Capital*.

The comparative strength of our common fibres is given in the following table, from the results

of several experiments with a three-strand one-eighth inch cord:—

	lb.
Cocos Nucifera stood a strain of	244
Hibiscus Cannabinus	290
Sansevieria Zeylanica	316
Gossypium Herbaceum	346
Agave Americana	362
Crotalaria Juncea	467
Calotropis Gigantea	552

Sterculia rupestris is the name of the so-called "bottle tree" of Australia, where the stem is said to be invaluable as a fodder during drought. The tree is allied to our Telambu (*S. fatida*) and Nava (*S. Balanghas*.)

The Japanese system of well boring would appear to be as desirable an introduction to Ceylon as to India. The Kazusa or artesian wells of the Japanese, by which they carry on the whole of their rice cultivation, amounting to tens of thousands of acres, are sunk to great depths at a comparatively trifling cost. A complete working outfit for sinking is calculated to cost about Rs. 200.

The last Veterinary Journal contains the report of the Director of the Pasture-Institute, Annam, on the Epizootic among cattle in the Malay Peninsula. The conclusions arrived at by M. Carrongean are: (1.) The Epizootic is not rinderpest, but bovine pasteurellon or hæmorrhagic septicæuria. (2.) It is manifest in three principal forms: (a) subacute or septicæuric, (b) acute, with various local modifications, (c) chronic. 3. They are all due to the same microbe, viz., an ovoid organism of the germ pasteurella. (4.) The microbe varies in virulency. (5.) The possibility of preventive inoculation is hopeful. M. Carrongean says that the pseudo-rinderpest destroys more buffaloes than oxen, whereas in true rinderpest the reverse is the case, a large percentage of buffaloes recovering. He mentions Younger, Galtier and Nocard as confirming this view, and quotes the last author to the following effect: "A disease that destroys a large number of cattle and but few oxen is not true rinderpest."

According to the *Lancet*, the substance known as Sericin, which forms 20 per cent of mulberry silk and gives to silk material its peculiar and delightful character, has been formed by synthesis; and in this way an important step towards the artificial manufacture of silk has been made.

The *Times of India* has an interesting letter on the Sewage question and the various methods of treating sewage. We learn that the manufacture of pondrette, or night soil mixed with ashes is carried on by a number of Mofussil Municipalities. At Poona the industry brings in an annual income of half a lakh of rupees. At other centres the application of night soil direct to the land in deep or shallow trenches on the Meagher system has been found to answer satisfactorily, and in part of the N. W. the use of

common sullage water of the city has enormously increased the value of land. But the discovery of the bacteriological treatment of sewage has opened out a new field for the Engineer and the practical agriculturist, and the system is being adopted at the Matunga Leper Asylum in Bombay by Mr. C. C. James of the Municipality, who has proved that not only can a high degree of purification be brought about by a very small outlay, but that the resultant effluent is of great manurial value.

Mr. George Weerakoon, Mudaliyar, writing for a fruit of the cho-cho, says:—"I grew the plant 15 years ago, and at one time had several vines bearing no end of fruit. I got it from Hakgala Botanic Gardens, but I do not see the plant in these parts (Matara district). The tender fruit makes an excellent pickle not unlike the English cucumber. Even the leaves are eaten in the form of a *mellum*."

Recorded by ALEX. PERERA,

CATTLE AND THEIR FOOD.

Mr. George Weerakoon, Mudaliyar of the Wellabodde Pattu, referring to our remarks with reference to fodder for cattle writes:—"According to the Administration Reports for 1901 there have been 210 cases of cattle stealing in the district, and the Magistrate remarks that prosecutions are uncommon for the reason that cattle are intentionally allowed to stray by their owners. The Government Agent of the Province recommends as a remedy that owners should combine and kraal their cattle. Of the 50,150 head of cattle in the district, a large number are the property of poor villagers who are obliged to drive

their animals abroad to find their own food as the owners have none to give them. If kraaling be resorted to, the question arises, how are the animals to be fed?"

The straw from the two paddy crops of the year is of course available, and if carefully harvested and stored it keeps well and forms an excellent fodder to fall back on. But, I would suggest that every cattle owner should provide himself with a small extent of grass land laid down preferably under Guinea grass, which is a wonderfully fast growing crop and spreads rapidly. It is known as "ginigiressa," and though (like "Uguressa," *Flacourtia Ramontchi*), is considered indigenous is really an introduction, no doubt, as its name implies, from Guinea. The scientific name of the grass is *Panicum maximum*."

Guinea grass (also called "Rata-thana" in Sinhalese) is highly valued in India as a food for milch cattle, and is also the chief cattle fodder upcountry. But wherever there is low damp land the cultivation of Mauritius or water-grass should never be overlooked. We have supplied planting stock for cultivation under irrigation in Poona, and are also making a point of introducing it into places where it does not exist, through the agency of School Gardens. The last application is for seed, which it is not easy to procure, for growing in the Gold Coast.

Guinea grass and Mauritius grass are our only cultivated fodders, and when commercially grown under favourable conditions are a source of considerable income to many. Indeed, Guinea grass in the Kandy district and Mauritius grass in the Colombo district are bringing in large revenues to grass farmers.

We have already referred to the different varieties of plants and trees that might be made use of in times of scarcity, but we should like to make some reference to the preservation of grass, which, during the rains, yields a supply of produce larger than the existing demand, so that the total available stock of grass food may be distributed more equally than at present.

Here are some very simple directions how to make good dry grass or hay:—Grass for stacking should always be cut when green and in flower, not later, as then the nutriment in the stalks and leaves will have been exhausted in the production of the fruit. The most convenient and easy method of preparing grass staking is as follows:—

Cut when green and in flower, tie up in bundles of about 8 to 10 lb. weight and place three of such bundles on their broad ends leaning against each other; by this arrangement the grass will not become damaged by rain, and the central grass of each bundle will ferment and acquire nutritious properties from forming saccharine and starchy matter.

When the bundles are sufficiently dried they may be stacked. Dry grass thus prepared will be found very nutritious and sweet, and animals will eat it readily. It will be nearly as good as the hay made in England and other countries. Proper hay-making requires much practical experience.

If the weather is hot, and sun powerful, grass will be dry enough, as a whole, in 2 or 3 days, and can be then stacked, but it should be stacked in

small ricks, in case of any heating taking place, for if grass be stacked when too green or wet, it will surely heat too much and go beyond the fermenting process of making sugar &c., and will take fire.

A little heating makes the grass sugary and gives a very sweet odour, the odour of hay.

THE NEW CURE FOR MALARIA.

The plant affording the root used as the remedy is a small tree from 20 to 30 feet high and having a trunk of 6 inches diameter at full growth. It has been named *Cassia Beareana*, and is therefore one of the leguminosæ. As used in East Africa by the natives, the root is chopped into pieces, each about an inch long, and about a dozen pieces are boiled in a gallon of water for half an hour or so. The result is a red coloured fluid which is partaken of by the patient, either hot or cold, as often as he feels thirsty. Under ordinary circumstances a tea cup full is given every couple of hours. A pamphlet of notes by Dr. O'Sullivan Beare, Vice-Counsel in East Africa, gives full details of the medical virtues of the new drug. We have already written for seeds of the plant, and are also hoping to receive a sample of the fluid extract of the root. Anyone desirous of reading the pamphlet referred to (a reprint from the *Lancet*) could have the loan of it on application to us.

Mr. Thos. Christy of Old Swan Lane, writing to us under date 8th September, regrets that he has no seeds of *Cassia Beareana* to send us, and adds that he has made a consignment of the Fluid Extract to the Colombo Apothecaries Company. This will enable local practitioners to give the new cure a good trial, particularly at places like Kurunegalle, Anuradhapura, and other malarious climes.

LIME AND ITS RELATION TO AGRICULTURE.

This is the subject of a useful paper in the Journal of the Department of Western Australia for December, by Mr. Percy Wicken. That the benefits of lime are little recognised in Ceylon is well known, and of late we have been pleased to have enquiries as to the use of the different forms of lime from more than one land owner, and it is for their benefit and for the information of the rest of our readers that we would quote from the article referred to above.

Lime, as most people know, is the product of burning various substances containing it, such as limestone, shells, coral, etc.

Good limestone contains from 50 to 55 per cent. lime. Such limestone, when burnt, produces the best quality of caustic or quicklime, containing from 90 to 98 per cent of the pure substance. Fresh lime, when removed from the kiln, will weigh from 90 to 95 lb. to the bushel, and when slaked, will make about 3 bushels in volume. Magnesian limestone or dolomite (which is found in Ceylon) varies much in composition, containing from 20 to 80 per cent of the carbonate of lime.

The average of such limestone will produce a lime which contains from 70 to 85 per cent of lime, and weighs 75 to 85 lb. per bushel. In slaking the lime will make 2 bushels for one by volume.

Oyster shells contain from 90 to 95 per cent carbonate of lime, and will produce a comparatively pure lime which should contain from 85 to 95 per cent of the pure substance. Fresh burnt oyster shells weigh about 60 lb. per bushel, and slaked so to make 2½ bushels for one by volume.

The quantity of lime taken up by a heavy crop may vary from 101 lb. in a crop of cereals to 90 lb. in the case of a leguminous crop such as clover. This requirement is provided in a great many soils. But it is the chemical effect of lime that gives it its value making plant food already in the soil readily available, through its action in decomposing the mineral matter in the soil. It also hastens the decomposition of organic matter and promotes the formation of nitrates from the humus present. The presence of lime is necessary for the life and action of the nitrifying ferments. After green manuring, it is specially valuable. We thus learn that lime is not a substitute for, but a reinforcement of, manure, and it should be borne in mind that the use of lime must be supplemented with fertilizers.

Lime is of great value where land has an acid reaction, due to the presence of excess of decomposing organic matter yielding organic acids—a condition most noticeable on low wet lands.

The easiest way to determine the need for lime is to get a few pieces of blue litmus paper and place a piece in contact with the moist soil. If the soil is sour it will turn red, and the degree of acidity will be determined by the quickness with which it changes colour and the deusity of the redness.

Lime also helps to keep off fungoid and insect pests. Clayey soils can stand more frequent and heavier applications of lime than soils of a lighter character, and tends to improve the mechanical condition of such heavy soils. According to their character, soils of the lighter description are dressed with about 2 tons per acre, while cold heavy clays will take as much as 12 tons per acre—such applications being made at intervals of from 5 to 6 years.

It is generally accepted, however, that lighter and more frequent dressings are preferable to heavy dressings at considerable intervals. The best way of applying lime is to make small heaps on the surface at regular intervals and cover these with earth. The moisture in the earth soon causes the lime to slake, and when it reaches the powdery condition it should be spread evenly and harrowed in.

THE MEAT SUPPLY OF COLOMBO.

DEAR SIR,—The meat supply in this flourishing city of ours is just as unsatisfactory as it could possibly be. The fact is that cattle in the East are worked in a fashion that will not be tolerated in a western country, and when their work as beasts of burden is done they are requisitioned to supply the craving of the 'inner man'! Is it not shock

ing that we should have to subsist on the flesh of animals that have been well-nigh flayed alive under the rod of the cart driver, their tails twisted out of joint, their necks galled with many a sore? I should like to see bulls classed under two heads: (1) Draught bulls, (2) Bulls for meat, and the one should not encroach on the functions of the other. It may be said that such a regulation will reduce the meat supply. If so, there should at least be a rule to the effect that the cart bulls must have been out to pasture or stalk-fed for a certain period after giving up the yoke and before coming under the pole-axe. An age limit should also be placed on animals brought to slaughter.

In the meat stalls, beef should be labelled so as to distinguish ox meat from buffalo meat. Further, I would have ox meat classified as 1st, 2nd or 3rd quality beef. All this should be done by the meat inspector or whoever has to supervise the slaughter of cattle and inspect meat stalls. For instance, let the prices be regulated something in this way: Ox meat, 1st 20 cts, 2nd 18 cts, 3rd 15 cts. Buffalo meat, 1st 18 cts, 2nd 15 cts, 3rd 12 cts. In this way we shall not be at the mercy of the cook and the meat seller.

The question is, are the proposals I have made practicable? That is a question for the representatives of the people, who have or should have the health and well-being of their constituents at heart, to decide. A conscientious officer can do a great deal even without the aid of the Law and the Municipal prophets. I have heard it said that by the enforcement of stringent measures and close inspection, the medical officer of the town of Matale has materially improved the quality of the beef sold there, and that the people do not object to pay a higher price for good meat, seeing that $\frac{1}{2}$ a lb. supplies as much nutriment as twice that quantity of poorer stuff. Cannot the capital city of the Island emulate the example of the little town of Matale?

Yours truly,

A. C.

[We are doubtful whether the classification of animals as suggested by our correspondent is feasible, but there is something in his suggestion regarding the classification of meat; and of one thing we are convinced, and that is that conscientious inspection of cattle and meat can, to a great extent, remedy the evil complained of.—*Ed. A.M.*]

THE JACK (*ARTOCARPUS INTEGRIFOLIA*).

(Concluded.)

The jack tree is also useful as a timber tree. The wood is bright yellow when first cut and is hard. It soon turns darker on exposure, however, and when old and polished, compares very favourably with mahogany in durability, beauty of grain, and colour. From India and the South Seas the timber is sent to England, where it is used for cabinet and furniture making, and largely in the manufacture of bush backs. It takes a very high polish, and works up very like satinwood. In India the wood of the roots is used for carving,

and small boxes and articles of this wood, after seasoning and being artificially scented (generally by being packed together with sandal wood) are passed off as of this more valuable wood. The principal use of the jack tree in the northern portion of this State would be as fodder, and in this way it would probably prove as valuable as the Algaroba or Mesquit bean tree. The leaves are readily eaten by stock, and it is a tree that will grow in a dry as well as in a hot climate. In some of the dry parts of India it is extensively lopped annually to feed cattle. The fruit also are greedily eaten by all kinds of stock; pigs and calves are very fond of them. The fruit, however, unless allowed to become over ripe and drop, should be split open. As a shade tree in paddocks it is always green and cool.

Like all other artocarpuces, the jack exudes a considerable quantity of viscid milky juice, from which the best bird lime is made in India. This sap is also used, mixed with other material, for caulking small boats and canoes. A yellow or khaki dye is extracted from the wood, bark and roots (and Bernays says, also by boiling the saw dust). As an ornamental tree in the tropical landscape gardening it is in demand, and in farmyards or their vicinity is a grateful as well as handsome shade, and if used for no other purpose adds considerably to the too little used compost manure heap by its shed leaves and fruits.

As a shade for coffee it is popular in some parts, especially steep land, where the soil is a bad retainer of moisture. I have also seen the leaves plaited or pinned together with thorns to make plates for the native's meals of rice, &c. Altogether the tree is thought highly of and considered second only to the bread-fruit in economic value in its native land, where it is one of the few trees left standing and preserved when new scrub land is opened for cultivation.

In India several seeds are often sown together, and the young plants subsequently grafted together into one stem by approach, making a stronger and somewhat quicker growing tree. This is supposed to make the tree come into bearing earlier also, but this is very doubtful. Bernays states that whole fruits are planted for subsequently grafting as above. I have not seen this done, but, if the whole 100 or 200 seeds germinated, the subsequent grafting or inarching must prove a somewhat complicated process. In the same article by Bernays which is about the best I have yet met with on this too little appreciated tree, a method of growing a long stem is described, which I have carried out with some success. By this method of cultivation the seedling jack is made to grow up a hollow bamboo till $2\frac{1}{2}$ to 3 feet high; then the stem which is thin and pliable, is twisted round like a spring or corkscrew—more often in one large circle—on the ground and covered in with earth. This stem grows with the tree, and, if bearing on the stems and branches is discouraged, will often bear on the buried portion of the stem. This procedure is not invariably successful, however. It is an experiment easily made, and the root fruit, if obtained is so vastly superior to others as to be well worth the time and trouble. The first indication of a root fruit is a slight upheaval of

the ground, which subsequently cracks, and before ripening one-half of the fruit becomes visible. The root-fruited tree is, I think rightly, considered a distinct variety. The seed of true fruit is said to invariably produce true root-bearing stock, which the seed of artificially induced crops will not do, of course. The jack-tree is said not to bear at all if the roots reach permanent water; but this also is not authenticated. It may be propagated by cuttings, but seed is so readily germinated that recourse to the more troublesome method is unnecessary. The seed, however, quickly loses its vitality, especially upon becoming dry, and so this cause failure to germinate them can be often ascribed. For seed, the ripest fruit should be taken. Fruit that has dropped from the tree and squashed gives good seed for immediate planting, but, should seed be required to despatch even on a comparatively short journey, fruit not quite ripe should be chosen. Some say only fruit from the stem should be taken for seed, but I have raised equally good plants and trees from fruit from the branches.

As stated the seeds germinate freely. Frequently on opening the fruit, especially if over ripe, the seed will be found to have already germinated, and to have a root one or two inches long. The spike will be quite small, however, and possibly only just emerging from the germ. But if this root be broken, and it is very brittle, that seed is lost. The seed which is about one inch long and half an inch in diameter will be found within a small cocoon-like bag inside the edible pulp. This peculiar bag is quite loose, and feels not unlike thin wash leather; it should not be removed either when setting for germination or for cooking. Beneath this again is another thin skin, generally red or reddish, and adhering to the seed itself. In roasting or boiling it readily flakes off like the inner skin of a peanut, which it resembles in colour and texture.

It seldom takes long to germinate, generally showing up in a few days. As may be gathered from the foregoing, the root growth is especially rapid and a plant 6 inches above ground will be found to have quite a foot of taproot. When about the size when plants are usually transplanted, it has often too much root to safely allow to its removal without a great deal of trouble. For this reason it is often advisable to set the seeds in the field, or where the tree is intended to be allowed to grow. The seedling is very hardy, but if planted out where most useful—*i.e.*, in the paddock—will require guarding for a year or two until out of reach of stock, for they will promptly eat it down if they can get at it.

The tree requires a soil fairly free from large rocks or bed rocks rather than a loose soil. I have known them thrive among boulders, but die out even at ten years of age when sheet rock was met with 8 feet below the surface. They do not require rich soil nor heavy rainfall. Once established they draw moisture from great depths to the surface, and, while immediately under them the shade may be too dense for grass, pasture luxuriates in their immediate vicinity. For a hardwood tree it is quick growing, attaining a height of 15 to 20 feet in four years, and usually coming into bearing about that time.—*Queensland Agricultural Journal.*

DISEASES INCIDENTAL TO PREGNANCY AND OF PARTURITION IN THE COW.

(Continued.)

ABORTION.

Definition—The expulsion of the foetus and the foetal membranes before the natural period. Abortion may be considered under two heads, non-contagious and contagious, and I will just consider the sporadic or non-contagious form. The normal period of utero-gestation in the cow is about nine and a half months, some more, some less, and an abortion usually takes place from the third to the seventh or eighth month. After that month it may be termed a premature birth.

Causes.—These are very numerous and they may be divided into internal and external. Of the internal causes the general health of the cow is of the greatest importance, any contagious or febrile disease in the system of the mother is a cause or factor in bringing about abortion, such as tuberculosis, pneumonia, indigestion, gastric tympany, excitement, nervousness, ergotised food, and of course the infecting bacillus.

External Causes.—Cold and wet, changes of temperature, thunder and lightning, frights, narrow doorways, pressure over the uterus, over-exertion, foul smells, icy-cold water, too much food, putrid stagnant water, sewage, frosted turnips, potatoes or roots of any kind, or rotten roots, mouldy bad hay, &c. &c.

I now come to the contagious form of abortion, and in giving the treatment for the sporadic variety I fancy it would be better to consider the treatment of both together, which I intended doing. This is by far the most serious disease of the two under consideration, and it is due to a special bacillus, which I believe was first demonstrated in the year 1895 by Professor Bang, he having made a series of post-mortems of cases, and also made several examinations microscopically of the liquid between the walls of the uterus and the envelopes of the foetus. In cases that showed premonitory symptoms of abortion he had the cow killed and the experiments carried out as before mentioned, and in every case that he examined this liquid from the womb of the affected cow he could demonstrate the presence of this bacillus in great numbers, and they were unixed with any other organisms. So, gentlemen, this surely places the theory of contagion beyond doubt. Professor Bang also cultivated this bacillus outside the animal body. He found that it was not easily cultivated by the ordinary methods, but he succeeded in growing it in blood serum rendered solid by the addition of gelatine and agar, and when it was grown in this medium it exhibited quite remarkable characters, absolutely distinguishing it from any other known pathogenic organism. In subsequent cases Professor Bang demonstrated the same bacillus in the discharges from the uterus or vagina of cows that had aborted. So you see, gentlemen, that contagious abortion is really a disease due to a specific organism. Another way in which its contagiousness has been demonstrated is by taking part of the discharge from an abortive cow and putting

it into the genital passages of a pregnant cow, and in nearly every case the cow will abort some time afterward. I also believe that this bacillus is able to multiply outside the animal body, even in soil, dirt, or manure, and this may go a great length to demonstrate the first outbreak in a herd that was previously free from this disease, and it is sometimes very difficult to know where the contagion comes from in the first case in a herd of cows. But in reality it comes from some source, from an apparently healthy, newly bought cow, or from the land they are grazing on having been previously grazed by some infected cow; or from feeding stuff or fodder imported or brought to the byre from an infected place. There is always a cause for everything that happens in this life.

This bacillus is supposed to gain an entrance by the vulva into the womb, or become absorbed through the mucous lining of the vulva into the circulation (because abortion can be produced by injecting the bacillus hypodermically), it then gets into the circulation, locates itself in its *habitat*, so to speak, and sets up the symptoms that we see terminate in the expulsion of the foetus and membranes prematurely.

Causes.—The primary cause is of course the bacillus. How does it get there? It is sometimes due to an infected bull, during copulation. Sometimes to a newly purchased cow brought from a tainted herd; this will bring it into a byre that was never known to have a previous case, and generally when one cow aborts there are several if not all in the same house. One reason given for this is the contagious nature of the disease, and if a cow retains the after-birth there is always a discharge of infective material, and this soils the tail and thighs, and by means of the tail the infective material is switched about to the other cows in the same house. It may also be disseminated by the discharges into the gutters running past the other cows. By inserting infective material into the genital passages of a healthy pregnant cow, you will generally have abortion in from fifteen to thirty days. As a rule the cow's health is not much affected; it is purely and simply a disease of an infective nature that affects the vagina and womb, foetus and foetal membranes of pregnant cows, mares, and ewes.

Prevention and Treatment.—I intend to make this as short as possible. To consider measures of prevention we must think about what will keep stock in health as well as the measures that are necessary to bring an outbreak to a speedy termination. With regard to the former, every person that buys a cow, is exposed to getting his herd infected. When buying a new cow, isolation for a period is a safe plan. On buying a new stud bull isolate for a time, and disinfect penis and genitals for some time before using him for stud purposes. There is a big risk in keeping a bull for the service of outside cows: he should be disinfected and washed after each service.

To bring an outbreak of this disease to a speedy end there are a great many difficulties which present themselves to us. The first is that for weeks, and probably for months, a cow may be affected, and capable of infecting other cows

without presenting any symptoms pointing to her dangerous state. It, therefore, often happens that before the existence of the disease in the herd is suspected and realized a lot of the cows have become affected. A cow is infected before she has aborted, but she is more dangerous after and for several weeks, as she then liberates an army of bacilli capable of infecting all the other cows in the herd. When she aborts, it is a good plan to burn the foetus and membranes; if this can't be done bury them away from access to cows, and disinfect them before burial, and over the grave put some quicklime.

The cow-house will require to be disinfected often and thoroughly, and the cows therein will also require to have the vagina washed out and tail and thighs, udder, and even up the sides, over the back, &c., in fact as far up as the tail reaches, well sponged or brushed with a reliable antiseptic to destroy the bacilli, and the more thoroughly and frequently this is done the better chance of eradicating the disease. There are various agents that may be used for this purpose; some taint the milk and are not practicable. Sulphate of copper is good to use and does not taint the milk—six ounces to one gallon soft water, also sprinkle the floor and gangway with powdered lime; and as a further precaution the outer genitals, root of tail, and in fact the whole tail, it is well to sponge once a day with a solution of Jeyes' carbolic, or hydrarg. perchlor.

℞ Hyd. perchlor.	ʒiiss.
Acid hydrochlor.	ʒiiss.
Aqua	Cii. 2 gallons.

This solution is dangerous, and any of it that is left should be buried, and it can't be prepared in metallic vessels, for it corrodes them. This disease in its treatment involves a great deal of trouble and labour. When the number of the cows that have aborted is many and there is no chance of isolating them, the best plan is to put the aborted cows at the lower end of the house, so that the urine does not run past the healthy ones; this will reduce the risk of infection. If a cow aborts this year it does not follow that she will abort next year; in fact, experience shows that it is the exception, not the rule.

In regard to the manure, is it not possible that the abortion bacillus will retain its vitality for a length of time in it? I would recommend in this case that the manure be mixed with a sufficiency of lime and left for a good long time before being put on to land that cows will be grazed on afterwards. I must say that wooden cow-houses, when they get rotten, and without paved gutters, the want of cleanliness, houses badly lighted, badly ventilated, badly drained, and in some cases not drained at all, all militate against the V.S. in stamping-out any contagious disease in this country.

INVERSION OF THE UTERUS.

This is a very serious condition in any female animal.

Causes.—Retention of foetal membranes, irritation of mucous membranes of the organ at the time of parturition, wounds, scraps, hard calving, injuries during calving, over-feeding, tympany, indigestion, icy cold water to drink after calving.

Treatment.—Now when a cow does put out her uterus, the first thing to do is to get to the case as soon as possible after you have been notified about it. Some farmers know to wrap it up in a damp, hot blanket, and send at once for the V.S., and when he arrives the first thing he should do is to remove the cleansing if necessary. Cleanse the organ, dry it with a cloth, and put some antiseptic and soothing dressing upon it, preferably an oily preparation, and return it by gentle manipulation, and put on a truss or West's uterine clamp, not screwed up too tightly to prevent the animal urinating or to hurt the vulva. The cow generally strains a good deal after this. To combat this we give some anodyne mixture, chloral hydrate, chlorodyne; raise the hind quarters with freshly cut sods. There is some danger of metritis, so a little tr. aconite and a mild laxative will prove very beneficial.

RETENTION OF FETAL MEMBRANES; SEPTICÆMIA.

This disease is due generally to cow calving before the natural period, or from debility, weakness, want of blood, and mostly happens in hot weather. Dealers' cows that are "faired" and "trained" are very liable to retain the cleansing, and so are very liable to have septic poisoning.

Causes.—The anatomical arrangement of the uterus in the cow, difficult parturition, abortion. Aged cows retain the membranes longer than young ones as a rule. Contraction of the cervix uteri will prevent expulsion of the foetal membranes. Cows driven long distances to fairs and trained long distances produces fatigue and reduces the general health of the animal.

Symptoms.—Usually part of the membranes protruding, but if not, there is a certain amount of shifting of the feet, uneasiness, urinating and passing fæces often; then there is twitching and curling of the tail. One very prominent and reliable symptom is the tail is carried further off from the body than usual, in a kind of an arched manner. If putrefaction has commenced there will be a dirty, sanious, offensive discharge from the vulva, mingled with shreds of putrid membrane. At this stage there is generally constitutional disturbance, the animal is dull, dejected, appetite lost or bad, respirations hurried, temperature elevated, secretions suspended. The complications that follow this state of affairs are generally septicæmia, metritis, metro-peritonitis, vaginitis, leucorrhœa, &c.

Treatment.—If the membranes are not expelled in three or four days or less they are better removed, and the uterus irrigated with a solution of ozophene, chinisol, or suitable disinfectant. There are various preparations that can be used for this purpose—carbolic acid, chinisol, ozophene, Jeyes' fluid, pot permanganate. I find about two irrigations sufficient. If cow strains badly I give anodynes. If in weak health and low of condition, tonic and external antiseptics are indicated. If septicæmia is feared, give plenty external antiseptics, with tonics, stimulants, and good food, easy of digestion and assimilation, and try to keep the animal's strength with milk, eggs, gruel, &c. Sulphites, hyposul-

phites, sulpho-carbolites, quinine, hydro-naphthol are indicated, and to prevent infection of healthy subjects patients should be isolated, the excreta promptly burned, and covers, &c. used by them disinfected before being used with other cattle.

INVERSION OF THE VAGINA,

Or "showing of the reed," as the farmers call it in this district, is often seen in cattle. The causes are injuries, rupture of the internal bands that hold the organ *in situ*, constipation, protracted parturition, fatigue from long travelling after parturition, abortion, placental retention. Old cows when heavy in calf show it often. Low stand behind, and too much fall for the stand, so that when the cow lies down the whole weight of the calf, stomachs, bowels, &c. are thrown back on the os uteri, and this tends to relax passages and to force out the vagina.

Symptoms.—Generally makes its appearance when the animal is lying, and mostly seen in pregnant cows. The vagina differs in appearance from the uterus, as there are no cotyledons on it, and it is also of less volume with a small round orifice in the centre.

Treatment.—Cleanse and return it after dressing with a little ol. carbolic. This is not a very dangerous affection, although it is sometimes very troublesome. I had a case here a short time ago; this was a prize Kerry cow, and she wore a truss for three months before calving, and she calved here a few weeks ago but did not cleanse; the os contracted very shortly after calving, and I could not remove the cleansing, but I irrigated the uterus with a solution of ozophene 1.30, and she has done well.

LEUCORRHEA,

Commonly know as "The White," is a chronic discharge from the vagina and womb, of a white flaky colour; sometimes inodorous, at other times of a rusty colour, and muco-purulent, and very offensive.

Causes.—Debility, difficult parturition, uterine excitement, polypus, prolonged irritation of the genital passages, and as a sequelæ to tuberculosis. Sometimes the bull gets balautis, and gives the cow he serves the disease, and sometimes she aborts.

Symptoms.—Discharge from vulva, which is generally pale, bloodless, and flaccid, in other cases where discharge is flaccid, mucous membrane is rough and reddened and thickened, with stricture of the vagina as an accompaniment; animals so affected are frequently in œstrum, but very uncertain as to breeding, and if they do become pregnant they very often abort. Some constitutional disturbance is usually present, the milk diminished, the appetite very indifferent, and the animal fails in condition.

Treatment.—In the primary stages, cleanliness, frequent injections of tepid water with weak solutions of alum; zinc sulph., pot. permanganate. The administration of a saline laxative, followed by tonics and laxative diet. In secondary or chronic cases, injections of tannic acid, ferri sulph., boric acid, iodoform, or if the discharge is offensive acid carbol. 1.40 or ozo-

phene 1·30 may be used. Internally, mineral tonics, iron or copper, for preference with quinine, with generous laxative nutritious diet, will generally result in a cure.

(To be Concluded.)

HANDBOOK ON SERICULTURE.

Through the courtesy of the Under-Secretary to the Government of Bengal, we have been favoured with a copy of a valuable little work entitled, "Handbook of Sericulture," by N. G. Mukerji, M.A., M.R.A.C., F.H.A.S. of the Bengal Civil Service, and our contemporary at Cirencester Agricultural College.

In his preface the author expresses the hope that the work will supply the want of a reliable book on Sericulture, and give an impetus to the silk industry in India and the British Colonies. He remarks that the principal drawback to Sericultural enterprise everywhere has been, of late years, the wholesale death of silk worms from certain diseases when they are reared on a considerable scale. The author has been employed by the Government of Bengal for nearly ten years in the investigation of silk-worm epidemics, and embodies in his work the information he has derived from actual experiments, confirmed by actual trials conducted successfully and with pecuniary profit by intelligent cocoon-rearers in most of the silk districts of Bengal.

We learn that a Sericultural School has been established in the Presidency with the object of teaching cocoon-rearers how to avoid silk-worm epidemics, and is doing very good work in disseminating the knowledge that was derived from experiments.

The book is divided into four parts: (1) The mulberry and the mulberry silk-worm. (2) Diseases of silk-worms and of the mulberry plant. (3) The commercial cocoons. (4) Manufacture and commerce.

The following information referring to the various kinds of silk-worms is culled for the benefit of our readers:—

All varieties of silk-worms fall under two heads: (1) Those which make reelable cocoons and (2), Those which make unreelable cocoons, *i.e.*, such cocoons as have to be carded and combed like cotton or wool before thread can be spun out of them. All varieties of domesticated mulberry silk-worms and most varieties of wild silk-worms that are found on the mulberry tree belong to the first of these two classes.

The domesticated mulberry silk-worms are the European (1) Silk-worm or *Bombyx mori*, (2) The Barapalu or *B. Textor*, (3) The Nistari, Mad-rasi or Canary silk-worm (*B. crasis*), (4) The Deshi or Chotapalu (*B. Fortunatus*), (5) Chenapalu (*B. Sinensis*).

Besides these there is a variety of silk-worm called *B. arracanensis* reared in Burmah, and another called Barapet reared in Assam. These seem to belong to the *B. Textor* variety, and in the Midnapur there is a variety called Bulu or

Blue which makes small greenish white Cocoons. These and the Chotapat of Assam seem to belong to the *B. Sinensis* variety. Among wild mulberry cocoons the Theophilus make good reelable cocoons. The Ocinar, Trilocha, and Rondotia varieties of wild mulberry silk-worms spin very inferior cocoons.

Other silk-worms besides those that feed on the mulberry produce serviceable cocoons. Of these reelable are (1) *Bombyx lasiocampaolus*, (2) *Atheroea Jamamai*, (3) *A. Pernyi*, (4) *A. Assama* or *Muga*, (5) *A. Roylli*, (6) *A. Mylitta* or *Tusser* proper. All these cocoons may be classed the generic name of *Tusser*. Other reelable cocoons have also been discovered, but they are so rarely found that it is impossible an industry.

Cocoons that cannot be reeled are mostly useless. Of this class the Eudi or Eri are the best, *Attacus Atlas* cocoons also fall under this group, and they also are spun by castor-leaf-eating silk-worms. The *Atlas* cocoons contain almost ten times as much silk as the mulberry or Eri cocoons, but the silk is not so soft as the latter. *Atacus Ricini* and its wild form *A. Cynthia* are other unreelable cocoons. The *Cricula* variety of silk-worms produces a cocoon that is made into thread by certain races in Chota Nagpur. There are hundreds of other varieties of inferior silk-worms of which the produce is not used or is even likely to be used. In France a variety of spiders spins cocoons in pear trees, and the silk from these is woven.

Of all the varieties mentioned above the European mulberry cocoons are the best.

A few years ago a good deal was heard about *Lasiocampa Otus* found in Dalmatia, but the cocoons have not been found to be a superior commercial article.

English cocoons were nearly all originally derived from China. At present the best cocoons are found in Italy and France.

The Paipitsan cocoon, the best of the Chinese, is the origin of the white Shanghai of Italy which is recognised as the best of all cocoons. In France a class of cocoons called *moricauds* (negroes) is spun by a hardy black worm. There are numerous other superior French and Italian cocoons. At Smyrna a Mr. Griffiths has by scientific selection established a superior class spun by very hardy black and zebra caterpillars.

We must here conclude our notice of this very useful work, the text of which is illustrated by pictures and diagrams, and take the opportunity of thanking the author for the valuable information he has placed at our disposal.

GENERAL ITEMS.

The earth-nut or pea-nut (*Arachis hypogaea*) has come to be considered one of the best foods for poultry, whether laying hens or growing chickens, excelling maize, wheat or oats. Unlike the first two it does not over-fatten, and keeps the birds in good health. They are thrown with tops and all, and keeps hens busy all day.

To harden tender shoulders and backs of animals, daily washing of the parts with an infusion of wattle or other tanning bark is recommended as a cheap and efficient treatment.

The famous "Latakia" Tobacco, known as "Abou-Riha," is so named from the district of Lattakia, in Syria, where the variety is principally grown. The chief peculiarity in its cultivation is that the plants, which are very closely planted, are hardly watered at all, and in the process of curing the leaves are made to absorb the fumes of the resinous and scented wood called "Elozr."

Among the reports of the Agricultural Department of Queensland we read in that the Manager, State Nursery, Kumerunga, under the head of Bananas:—"Very little has been done beyond preserving the better varieties of these. A number have been distributed to applicants, and a small collection was despatched to Ceylon." These latter, consisting of varieties, were received for the Colombo Stock Garden, where they are doing well.

The following recommendations given in the *Queensland Agricultural Journal* for getting rid of

the black ants, indicates how great a pest it is:—
 (1) Sprinkle shelves &c. with oil of penny-royal.
 (2) Wash with Carbolic soap. (3) Dissolve a piece of Ammonia, the size of a hen's egg, in a quart of water, and brush the shelves with it.
 (4) Pour gasoline into their nests (if outside) and set fire to it. (5) Lay carpet rug strings soaked in corrosive sublimate in their path. (6) Make the following mixture: White lime (slaked) 6 quarts, kerosine oil $\frac{1}{2}$ pint, turpentine 1 wine glass, soft soap 5 lbs., cowdung 3 quarts, water 16 quarts. This latter is for washing fruit trees. The preparation of these remedies is troublesome enough, but after all we are told that none of them are permanent and will require repeating often!

The following recipe from the same paper is for making a cheap cooling paint for iron roofing:—Take unslaked lime and slake it with sufficient water to cover it. Stir into it old brine from a salt beef cask or other source, sufficient to give the lime the consistency of oil paint. Strain before using and apply with an ordinary limewash brush. [How would this do for the dreadful Calicut tile in warm weather?—
 ED. A. M.]

COLOMBO, MARCH 2ND, 1903.

No. 9.

REPORT ON HEVEA BRASILIENSIS IN THE MALAY PENINSULA.

BY STANLEY ARDEN,

*Superintendent, Experimental Plantations, Federated
Malay States, 1902.*

(Continued from page 515.)

REA of trunk to be tapped—The latex is present in all parts of the tree, but it is evident from the mere observation that when tapping the greatest yield is obtained from the base of the trunk, and experiments have been carried out with a view to

determining the difference in yield at various heights of the trunk.

Table I shows the result of tapping five trees with V-shaped incisions, commencing at a height of 6 feet and working by stages of 6 inches towards the base. There were three incisions made on each tree at the same level and equi-distant apart.

TABLE I.

ft. in.		oz.	Av. per incision
15 incisions at	5 0 from base	gave 1'50 dry rubber	.1
15 do	5 6 do	1'50 do	.1
15 do	5 0 do	1'75 do	.116
15 do	4 6 do	2'50 do	.166
51 do	4 0 do	4'75 do	.316
15 do	3 6 do	4'50 do	.3
15 do	3 0 do	5'25 do	.35
15 do	2 6 do	6'50 do	.433
15 do	2 0 do	7'00 do	.466
15 do	1 6 do	9'25 do	.616
15 do	1 0 do	11'25 do	.75
15 do	6 do	11'25 do	.75

It seemed probable, however, that the "wound effect" might account to some extent for the increased yield obtained from the lower part of the trunk; so his experiment was repeated on the same trees, this

time commencing at the base and working upwards to a height of 6 feet. The result was:—

TABLE II.

ft. in.		oz.	Av. per incision
15 incision at	6 from base	gave 12'50 dry rubber	.833
15 do	1 0 do	10'50 do	.7
15 do	1 6 do	9'50 do	.633
15 do	2 0 do	7'50 do	.5
15 do	2 6 do	5'50 do	.366
15 do	3 0 do	4'75 do	.366
15 do	3 6 do	4'25 do	.283
15 do	4 0 do	3'75 do	.25
15 do	4 6 do	4'00 do	.266
15 do	5 0 do	3'75 do	.25
15 do	5 6 do	3'00 do	.2
15 do	6 0 do	2'75 do	.183

It will be noticed that in this experiment the yield between 4 and 6 feet was nearly doubled; while the yield from the lower 4 feet of the trunk is about the same as was obtained in the previous experiment.

Taking the results of the two experiments together and stating the yield for three sections of the trunk, we have:—

		oz.	Av. per incision
120 incisions base to 2 ft. up	gave 78'75 of dry rubber	.65	
120 do	2 to 4 ,, do	39'25 do	.32
120 do	4 to 6 ,, do	20'75 do	.17

This experiment shews very clearly what part of the trunk contains the largest amount of latex and demonstrates the necessity of confining the attention as much as possible to the first four feet from the base.

Other experiments with similar objects in view were conducted on trees tapped on the herring-bone system: the result of tapping five trees, 3 to 6 feet up the trunk, being shewn in Table III.

In each case the oblique incisions, were 1 foot long and 1 foot apart, there being six such incisions, three on each side of the vertical channel, which was 3 feet long, the wounds being renewed on 14 consecutive days.

TABLE III.

5 trees tapped every (14 days) from 3 to 6 feet up. Total weight of wet rubber 130½ ounces. Average per tree 26·02 ounces.

Table IV shows the yield from the same trees tapped in precisely the same manner, but ranging from the base of the tree to a height of 3 feet.

TABLE IV.

Tapped every day, base 3 feet up. Total weight of wet rubber 178½ ounces. Average per tree 34·77 ounces.

A noticeable point about this experiment is that trees Nos. 7, 8 and 14 gave a better return when tapped from 3 to 6 feet high than when tapped from the base to a height of 3 feet; in fact Nos. 7 and 8 failed to yield at the base after being tapped on 12 occasions or after the whole tree had been tapped 26 times. The inference to be drawn is, that as the experiment was conducted first on the high area, that the latex obtained was in part drawn from the lower portion of the trunk.

I might here incidentally mention that these are the only trees I have succeeded in "draining," and that they look none the worse for it, but after a lapse of 12 months are bearing seeds freely.

The increase in yield at the base of tree No. 19 is very marked, being nearly three times the amount obtained at the higher area, and suggests a more complete communicative system in the lower regions of the trunk.

On the occasion of my next visit to S'tiawar, another experiment was made on the same lines, this time the lower area being operated on first. The trees utilized were of the same age and dimensions as in the previous experiment and care was taken that the incisions, which were renewed on 14 occasions, were of the same length and distance apart.

The result of this experiment is shown in Table V and VI.

TABLE V.

Tapped every day at base 3 feet up. Total weight of wet rubber 221½ ounces. Average per tree 44·35 ounces.

TABLE VI.

Tapped every day, 3 to 6 feet up. Total weight of wet rubber 195½ ounces. Average per tree 39·10 ounces.

In this case trees Nos. 13 and 26 gave a larger return when tapped at a height of 3 to 6 feet, which is significant considering that in the case of tree No. 26 over 2½ pounds of wet rubber had previously been extracted from the lower three feet of the trunk.

Adding the results of these two experiments together we have:—

140 incisions on 10 trees, base 3 feet,	gave 395½ ounces of	wet rubber
140 " " 3 to 6 feet,	325½ " "	" "
By difference 70 " "		" "

The result then is an average of just 7 ounces of wet rubber per tree in favour of the lower three feet of the trunk.

Judging from the results of these experiments I am led to believe that although it appears, at least in some cases, that the latex obtained is drawn from the whole of the laticiferous system, that this is only true to a small extent; otherwise, I fancy the disparity in yield between trees tapped first at the base and afterwards higher up the trunk, or *vice versa*, trees tapped at a height of 3 to 6 feet up the trunk and afterwards at the base, would be much more marked.

This gives rise to the question as to whether it is possible to obtain a maximum yield by confining the operations to any one particular area, having regard to the labour entailed and the injury inflicted on the tree. A glance at the foregoing tables will show that this does not appear to be the case, for it will be seen

that although in one experiment 221½ ounces of wet rubber were obtained from five trees when tapped within 3 feet of the base, there still remained 195½ ounces which were obtained immediately afterwards by tapping the tree higher up the trunk. But it will also be noticed that in the majority of cases there was no indication of a cessation of flow of latex when the operations were suspended, and it seems quite probable that the whole of this latex might have been obtained by confining the incisions to one of the two areas. This, however, would have necessitated the renewing of the incision on at least 28 occasions, probably more and the result would have been a huge wound, and the life of the tree would have been endangered thereby.

It is inadvisable, as already stated, to make the incisions of an undue length, while if the oblique incisions are placed more than 1 foot apart, the result is a long vertical channel, in which a large amount of latex will coagulate before reaching the tin; so that the method which suggests itself as being expedient is that of making V incisions or small herringbone incisions on various parts of the trunk not exceeding a height of 6 feet.

Unfortunately, experiments in this direction are far from complete owing to the lack of trees of a suitable age, but I append the result of tapping five nine year old trees with V incisions, and the result of an experiment on the same trees, 12 months later, with small herring bone incisions. In the first experiment the two lines forming the V were 6 inches long in each case. There were five incisions made on each tree, ranging from the base to a height of 6 feet, each side of the trunk being utilized, so that in an oblique direction the wounds were about 2 feet apart. The latex was collected separately from each wound, which was renewed on 12 occasions at intervals of two days. The result is shown in Table VII.

TABLE VII.

Average yield of wet rubber 46·2 ounces. Average yield per tree of dry rubber (including scrap) 28½ ounces.

A noticeable feature in this table is the yield of tree No. 41 which averaged over six ounces of wet rubber each day the incision was renewed; it will also be noticed that the total yield on the last day was in excess of that obtained on any previous occasion.

The following year the same trees were tapped with small herring-bone incisions. There were three incisions on each tree, the vertical channel being 1 foot long, and the "feeders," two on the left of the vertical channel and one on the right, situated midway between the other two, were 8 inches long 1 foot apart. The incisions were renewed on eight consecutive days, but the latex being required for experimental purposes the weight *per tree* cannot be given. The weight *per day* and the *average weight per tree* of dry rubber obtained is shown in Table VIII.

TABLE VIII.

TEN YEAR OLD TREES.

Trees No. 41, 42, 43, 44, 45. Tapped by small herring-bone incisions on eight consecutive days.

1st day	..	7½ ounces dry rubber including scrap
2nd "	..	8½ " "
3rd "	..	11½ " "
4th "	..	13½ " "
5th "	..	11½ " "
6th "	..	13½ " "
7th "	..	14½ " "
8th "	..	15 " "

Total weight...95½ ounces.

Average weight of dry rubber per tree 19·1 ounces.

Had the incisions in this instance been renewed on 12 occasions, as was the case in the former experiment the yield would almost certainly have exceeded that obtained by tapping with V incisions. As it is, a comparison between the two systems shows that the

first eight renewals of the **V** incisions gave 131½ ounces of wet rubber, as against 95½ ounces of dry rubber when tapped with small herring-bone incisions. Assuming that the loss on drying was 50 per cent and counting "renewals" as 'incisions' the figures read:—

	ounces	ounces
200 (V) incisions gave 131½ wet rubber	=	65.75 dry rubber
120	(V)	95.50

As there were five **V** incisions on each tree, and the two lines forming the **V** were each 6 inches long, the exposed surface totalled up to 5 feet per tree. When the same trees were tapped with small herring-bone incisions, the total length of the incisions was 6 feet, regardless of the central channel which was not opened after the first day; so that although the length of incisions in the latter case only exceeded those of the former by one-fifth, the yield increased by one-third. The fact that the trees were twelve months older at the time they were tapped with herring-bone incisions, probably accounts to some extent for the extra yield obtained when tapped by the latter method.

When compared with the yield from those trees tapped by herring-bone incisions, confined to the lower 3 feet of the trunk this system may be considered very successful. The total length of the incisions was the same in each experiment, viz., 6 feet, but if the yield for the first eight days of the trees enumerated in Table V be totalled up, we shall find that 30 feet of incisions (made on five trees and renewed on eight occasions) gave 105½ ounces of wet rubber (say 52 ounces dry) as against 95½ ounces of dry rubber obtained from 30 feet of incisions (on five trees and renewed on eight occasions) made on various parts of the trunk. In short, nearly twice the amount of rubber was obtained from the same length of incisions, when the whole area of the trunk was operated upon, and the cost of extraction therefore reduced by about one-half. This, however, is only the result of a single experiment and the results cannot by any means be considered conclusive. So far as they go they strengthen the supposition that if a maximum yield is to be obtained at a minimum cost, which—assuming the operations are always conducted in the same careful manner—is paramount to a maximum yield with a minimum injury to the tree, tapping must not be confined to any particular area. Other experiments in this direction are in progress and the results will be made known from time to time. One point which has not yet been noticed, is the rapidity with which the wounds heal, when made a considerable distance apart.

(d). *Length and distance between the incisions.*—The length of the vertical channel in some of the experiments already alluded to, was 3 feet but incisions of this length are not recommended, the objection being that part of the latex coagulates before reaching the tin, especially in hot dry weather. The length of the "feeders" will depend upon the girth of the tree, but for the same reason it is inadvisable to make them more than 1 foot long even on the largest trees.

When tapping young trees, they should be shorter in proportion to the circumference of the trunk, so as to avoid any risk of checking the growth of the tree by preventing a free passage, for the conveyance of the crude sap absorbed by the roots, to the green parts of the plant, there to be elaborated into starch and other organic compounds which supply the essential constituents for the formation of new structures and replace the material consumed during the growth of the plant,

It may be taken for granted, that in a given area, the greater the number of incisions the greater the yield; also that if the same number of incisions be made over an area, say twice the size, the yield would be considerably more; but I do not hold, however, even assuming this to be the case, that it is expedient to make the incisions closer than 1 foot apart, as the extra yield obtained is not in proportion to the extra labour entailed; while on the other hand if the oblique incisions are made more than this distance apart, the result will be a vertical channel of an undesirable length. Further, cicatrization of the wounds is considerably delayed, if the incisions are made too close together, as the amount of growing tissue in their immediate vicinity is necessarily limited.

(2). *The effect of wounding on the flow of latex.*—Perhaps the most important point of all to be considered, is that of taking full advantage of what has previously been alluded to as "wound effect." This phenomenon, which appears to be well known to the natives of Brazil, was first scientifically observed by Mr. J. C. Willis, Director of the Peradeniya Gardens, and is mentioned in a circular issued by the Ceylon Botanical Department*: the result of a series of experiments on the effect of wounding on the flow of latex by Mr. Parkins, being set forth in a later circular, issued by the same Department † and to which I am indebted for many valuable suggestions.

The function of the latex is not yet properly understood, but it is quite distinct from the sap, occurring in comparatively few plants and is probably unessential to the life of the tree. The effect of wounding the tree appears to cause an increased flow of latex towards the injured part, for if the wound be reopened on the following day, the yield is nearly always found to be considerably in excess of that obtained on the occasion of the original tapping, sometimes three or four times as much. Also, if the wound is opened again on the third day, the yield is found to exceed that of the second, and generally the yield of the fourth day exceeds that of the third and so on.

(a). *The number of times the incisions can be advantageously renewed.*

Many experiments have been made with a view to determining the number of times it is advisable to re-open the wound, but it was found that all trees were not affected in a similar manner, so that it is impossible to lay down any hard and fast rule; for although in some cases the maximum yield has been obtained on the fourth day, in others it was not reached until the fourteenth tapping.

Generally, however, the flow shows a marked increase between the first and second tapping, then a steady increase until the fifth or sixth tapping is reached, afterwards remaining more or less stationary until the operations ceased; in the large majority of cases there were no signs of falling off, even after the incisions had been renewed a dozen times, but by his time the wound had of course become very large and it was deemed advisable to stop operations.

Below I have summarised the results of several experiments, made with a view to ascertaining the number of times the incisions should be renewed. The trees experimented upon were tapped on the herring-bone system, previously described, and the incisions renewed by taking off a very thin layer from each side of the wound with a sharp knife on 14 occasions.

* Royal Botanic Gardens, Ceylon. Series 1—No. 4.

† do do do —No. 12,

The result was as follows:—

TABLE IX.

Showing result of "wound-effect" on 30 trees tapped on 14 occasions.

30 trees.	1st tapping gave	Average per	'33 oz.
	10 oz. dry rubber.	incision	
do	2nd 16½	do	'55 "
do	3rd 26	do	'86 "
do	4th 28½	do	'95 "
do	5th 36	do	1'2 "
do	6th 39½	do	1'32 "
do	7th 37½	do	1'24 "
do	8th 40½	do	1'35 "
do	9th 39½	do	1'32 "
do	10th 45½	do	1'51 "
do	11th 43½	do	1'45 "
do	12th 48	do	1'6 "
do	13th 47½	do	1'50 "
do	14th 47½	do	1'53 "

It will be seen from the above table that there was a steady increase in the flow of latex until the tenth renewal, and that from then until the operation ceased the yield each day was greater than had been obtained on any previous occasion. It should be mentioned, however, that this was only the case in a few trees, which gave a considerably increased yield on the last four occasions, and that in the majority of cases the yield from the tenth to fourteenth day was about the same as that obtained between the sixth and tenth day.

The difference in yield between the first and second occasion does not stand out so prominently in the Table as it should. This is due to the fact that some of the trees had recently been experimented upon (for owing to lack of material some trees had to suffice for several experiments) so that what is termed a "first tapping" when made on the opposite side of a tree recently tapped, has often given a much larger return than a "first-tapping" made on a hitherto untapped tree.

This, then, all goes to prove what was stated previously, that all trees are not affected to the same degree, and that if advantage is to be taken of the "wound-effect," the incision must be renewed at least eight times. It might, of course, be renewed oftener but the result would be an ugly wound, pre-disposing the tree to disease, and cannot therefore be recommended.

(b). *The length of time that should elapse before renewing the incisions.*

Here there does not appear to be the same difference in the behaviour of trees in responding to the wound-effect, and it was generally found that an increased flow was obtainable after a lapse of twenty-four hours. With a view to determining whether any beneficial results followed by allowing the trees to "rest" for a few days before renewing the incisions, some trees were tapped every day, others every third day and others at weekly intervals.

The result of tapping 10 trees by herring-bone incisions on 14 consecutive days is shewn in the following Table.

TABLE X.

TAPPED EVERY DAY.

Total weight of wet rubber 351½ ounces. Average yield per tree 35'15 ounces.

Table XI shews the yield from 10 trees tapped on the same principle on 14 occasions at intervals of two days. Care was taken that the trees were of the same age and as nearly as possible of the same dimensions and that the incisions were exactly the same length and distance apart; each being measured and marked with pencil before the incision was actually made.

TABLE XI.

TAPPED EVERY THIRD DAY.

Total weight of wet rubber 374 ounces. Average yield per tree 37'4 ounces

It will be seen that the result is in favour of the trees tapped at intervals of two days to the extent of 22½ ounces of wet rubber, which is equal to about 1 ounce of dry rubber per tree.

The result of tapping 10 similar trees at weekly intervals is shewn in Table XII, the operations extending over a period of five weeks.

TABLE XII.

TAPPED EVERY WEEK.

Total weight of wet rubber 104½ ounces. Average yield per tree 10'7 ounces.

Time did not permit of this experiment being carried on longer so it will be necessary to compare the results with those obtained on the first six occasions in Tables X and XI. These are as follows:—

60 incisions made on six consecutive days gave 99½ ounces wet rubber.

60 " at intervals of two days " 111½

60 " " " one week " 104½

There does not appear therefore to be any great advantage by renewing the incisions at long intervals, and I am of opinion that the response to the wounding is generally, if not always, discernible after the lapse of a single day. Judging from the above figures this, at first sight, does not appear to be the case but a perusal of the foregoing tables will shew that the smaller amount obtained from the trees tapped daily, is mainly due to the inclusion in this experiment of tree No. 20, which gave less than one-fifth the amount obtained from tree No. 2, for no apparent reason. This disparity in the yield of trees growing under the same conditions, and tapped in precisely the same manner, is in some instances most marked and demonstrates the necessity of conducting experiments over a large number of trees, if definite conclusions are to be arrived at. A further experiment was made in this direction; the trees which had previously been tapped on six occasions at weekly intervals, were now tapped on six consecutive days on the opposite side of the trunk, the incisions being of the same length and distance apart as on the former occasions, the result being shewn in Table XIII.

(To be concluded.)

ORANGE CULTIVATION.

There are some orange groves planted here within the last four or five years in which we see illustrated almost every mistakes that is to be made in orange growing here, but which may not be mistakes elsewhere, that is, in more temperate lands, with less forcing soils and climate. The first, most common and most serious error is in the planting; the trees have been planted too deeply in the soil, the roots buried until the earth is packed two inches up the stem above the neck of the tree. This is an error in tree planting everywhere, and we have seen it made in the north in forestry in the setting out of firs and in horticulture in the setting out of orchards of fruit trees, and berry bushes. It is not fatal on light sandy soils, and the trees grow, fruit, and continue to give returns, but they never make a quick, large, or robust growth and are always much subject to the many troubles that affect plants. On heavy soils deep planting is fatal to profit. In our forcing climate and heavy rich soils, where weeds grow rapidly and luxuriously, and there is need of constant hoeing, trees are better planted even higher out of the soil than ever we had experience of before, because,—1st, on accounts of the heavy rains that beat upon the soil, and pack it tight, so that if the earth is packed high round the stems the roots are choked, whereas if the neck is clear of the earth with the top main roots running close to the surface, the water running down the stem, sinks in and follows the interstices, along the roots; thus air, moisture, and drainage pass continually through the soil to every root and rootlet; 2nd, to allow for the constant hoeing of weeds; in doing this there is a continual drawing away of soil along with the weeds,

which are heaped around the outside circle of the tree both actions combining to cause the tree more and more to stand in a hole; then the rains fall and drain off slowly, leaving the ground soggy and when some dry weather sets in, this soil becomes baked hard and sour; 3rd, to allow for the forking or ploughing around the trees, and the ploughing in of the weeds, consequently the raising of the soil. Take the level of a piece of uncultivated land, and when it has been ploughed up and harrowed smooth, take the level again, it will be found three or four inches higher than before. As it hardens it settles again about two inches in six months, only to be stirred up again by further cultivation, and probably the ploughing in of weeds raises it two or three inches further. Anyway the soil is further raised by cultivation, little, but appreciably enough to make a row of orange trees planted on a level with the surface of the field when uncultivated, appear by and by, after cultivation to stand in a hollow. Again after the planting out of a field with orange trees planted at first in holes, drainage is found to be necessary, the earth from the drains is of course flung up in a ridge or scattered around, and the water in heavy rains runs towards the orange trees, more than into the drains. We have done things too casually heretofore and looked at tree planting as if it was a thing that any unskilled person could do, and again, we have learned that the experience of agriculturists tutored in other lands where many of the conditions are diametrically opposed to here, is of little use unless it is adapted to the circumstances prevailing here. Long ago when a boy wandering in the woods, we noticed that the fir tree grown from a cone had the upper part of its top roots clear of the ground so that you barked them when you stepped roughly on them, the wild crab-apple grew the same way, so did every tree in nature grown from a seed. Here you can see the wild orange growing in the same fashion, see too the long holes of the cotton tree ending in roots running along the surface so that you trip over them. It is the nature of trees that are surface feeders to grow like this, and they send out many superficial roots spreading in a fibrous network all along close to the surface, and such trees can grow and thrive in poorer soils, by means of the abundance of their feeders, than trees that send out few roots. The latter are generally deep growers and send down a very long vigorous taproot, and when delicate, like cocoa require a deep, free, moist, rich soil to be at their best. Another error in orange growing is the indiscriminate use of the fork by those who have the mind to cultivate. Cultivation is recommendable, when judicious, the fork is a worthy implement, where there is a head as well as hands governing it. The late Secretary, Mr. George A. Donet, had much to do with the bringing of the fork into general use to supersede the hoe in breaking the land we should like to see the rake in common use here, especially for the cultivation of fruit. We see horrible destruction of the feeding roots of orange trees by forking, and damage done that would kill fruit trees in places less richly endowed by nature in climate and soil. Trees over three years planted are hoed, then forked right up to the stem, so that you see big clods turned over matted with broken and wrenched up roots. If this is done in dryish weather, the hot air and wind penetrate right into the root system drying out the broken ends of roots so that if they ever form callus and send out rootlets at the break, it will be a slow business. Altogether, these trees would have been very much better off without such cultivation. Fruit trees grow best in a soft firm soil, and the roots should never be broken unless at the ends where they are growing out, and then the cut should be clean, as from clean cut ends more roots will start out quickly and in healthy condition, than from broken rough edges. Orange trees should be hoed around from the stem to a little further out than the sweep of the branches as it will be found that the roots go out further, often very much further. The hoeings after exposure to the sun and air to kill the weeds, should

then in dry weather be raked back to the hoed surface and raked backwards and forwards until the surface is loose. The soil beneath is seldom other than moist in this country, and the raking so loosens the surface while the weeds form such a soft mulch, that the soil will not bake through three months of dry weather which does not often occur anywhere here. At other times when moist weather prevails and the earth is soft, the weedings instead of being piled around to tempt roots to creep up into them should be spaded in so that the ground where the roots will extend may at once be loosened and manured. An annual cultivation like this done in November after the heavy rains are over and the crop is off is most suitable for early bearing trees. The weeds will supply pretty much all the humus and nitrogen necessary, and an application of wood ashes at the same time will provide the necessary phosphoric acid and potash, so that the new rootlets may have abundance of food-material at hand. This slight root pruning done by careful spading at the outside terminus of the root system of fruit trees about November will at once send the sap back into the tree; blossoms will break out in January and by the time the bloom is set, the new roots will be vigorously feeding in the well prepared and fertilized soil, and ready to meet the greatest demands that the swelling fruits may make upon them. The applications of fertilizers may be made if desired when the fruit sets and again when it is nearly full. Forking in fruit groves should only be done to prepare land, and where there are no roots to be wrenched and torn. The rake and the spade are the implements where hand labour is to be used; the former to stir the surface soil beneath the trees, and give young weeds no rest, and the latter to turn over the soil outside the trees. Where horse labour is used, of course the sharp plough will do the cutting of the tips of the roots, and the harrow-toothed cultivator is the best implement for running close to the trees and stirring the soil. The spade and the rake or the plough and harrow cultivator, together with the hoe, which is indispensable for weeding; these are the implements for orange groves. These thoughts are the result of personal practice and wide but minute observation, and the recommendations made are meant to be, and of course, should be, accompanied by the keeping of the trees clean by spraying or washing if necessary, for orange growing in groves. It would be difficult to put such cultivation into practice on scattered pasture-grown trees, though it might pay to thoroughly cultivate these trees. Failing root cultivation, the washing being carried out as given in the report published below, should not fail to be done. Certainly, we were not prepared to believe that the mere cleaning and washing of branches and trunks as done in these experiments, without any cultivation of the trees standing in grass, could have been so quickly responded to in healthy leaf and blossom. But the results in fruiting will be the best test. Anyway, we welcome every idea and practice that will help to put our citrus trade on a better basis. It is pretty much casual and chance at present.—*The Journal of the Jamaica Agricultural Society.*

RECIPES FOR COOKING WEST INDIAN YAMS.

(From Imperial Department of Agriculture for the West Indies).

Yams require a deep, rich soil, and under favourable conditions produce large crops. The following recipes for cooking and preparing yams are issued for distribution in the hope that if carefully carried out, those not already acquainted with this nutritious food may ensure that it is presented to them in an attractive and pleasant form.—D. Morris Commissioner of Agriculture for the West Indies, September 10, 1902.

The 'Yam' so familiar to all classes throughout the West Indies is practically unknown in Great

Britain. Beyond the comparatively small number of people who have visited the tropics few have definite knowledge as to the nature of the plant, or of the wholesome and palatable character of the food it provides.

Although grown throughout the tropics, it is in the West Indies that Yams are to be found at their best and in the greatest variety and abundance. During the time of the year they are in season they form a standard dish at the planter's table, in addition to being one of the staple foods of the estate labourer and, in fact, of all classes throughout the West Indies. The majority of visitors to the West Indies become even in the course of a brief stay, very partial to the yam.

For those who have not visited the tropics the general character of the yam plant may perhaps be best described by saying that it closely resembles in habit the black bryony of English hedgerows. The plants are near relatives and agree in their twining stems and shining heart-shaped leaves. Both, moreover, have and underground tuberous 'root,' but whilst that of the bryony is uneatable, the yam 'root' supplies man with one of the most wholesome vegetables the world affords.

The varieties of yams are legion. Some are distinguished by the names of places whence they were first obtained, others by descriptive names, such as 'horn yam,' 'snake yam' etc. Yams vary greatly in size and appearance. Usually they are covered by a deep brown skin, and their flesh is firm and of various shades of white, yellow, or in some few cases distinctly purple. Some are not more than 6 inches long and one pound or so in weight, whilst other varieties measure 3 or 4 feet in length, 6 or 9 inches in diameter, and weigh 30, 40, 50, or even 100 pounds.

Their cultivation is comparatively simple. The upper portion of a yam called the 'yam head' is put in the ground. It produces fresh leafy shoots, and the new yams slowly form and mature beneath the ground. In Barbados the foliage is allowed to trail over the surface of the ground, whilst in Jamaica, Trinidad, etc., a stout stick is stuck in by each plant up which it climbs, so that a yam patch somewhat resembles a miniature hop field. The different varieties of yams take varying periods to come to maturity. Some kinds are ripe in five months, whilst others do not reach perfection for nine months or even a year.

The following hints prepared by Mrs. J. R. Bovell, are published for cooking yams and presenting them in an attractive form at table.

ROASTED YAMS.—Lay a yam before the grates of the stove or in the oven, turning it occasionally until cooked. Scrape off the outer skin, cut into pieces or mash with butter and serve hot.

BAKED YAMS.—Pare a yam, put it in the oven and bake until soft, take it out of the skin, mash with butter, put back into skin, cut in pieces and serve hot.

BOILED YAMS.—Pare a yam, put it into boiling water, cook until tender, serve whole.

YAM CHIPS.—Pare and boil a yam until tender. Cut in chips, fry in boiling lard and serve hot.

YAM RICE.—Pare and boil a yam until tender, pass through a colander on to a hot dish, shake the colander lightly every few seconds to cause the yam to fall off in short grains like rice and serve very hot.

YAM RISsoles.—Pare, boil and mash a yam, add pepper and salt and, if liked, a little minced parsley, shape into rissoles, cover with egg and bread crumbs and fry until a light brown.

YAM BORDER.—Pare, boil and mash a fair-sized yam about two pounds in weight, add to it two tablespoonfuls butter, half a cup boiling milk, one tablespoonful salt, the yolks of two eggs well beaten; beat the mixture until very light. Butter a border mould, pack the yam in it and let it stand for eight minutes. Beat the whites of the eggs to a froth, add salt, turn out yam, cover with the whites and put in an oven to brown. Take from oven and fill the centre with meat or fresh fish heated in a sauce.

YAM au Choux.—One pound boiled yam, one boiled cabbage, two tablespoonfuls cream, one ounce butter, with salt and pepper to taste.

Rub the yam and cabbage through a wire sieve, mix together with butter, cream and seasoning. Pipe upon a dish and serve with fried croutons of bread around. Serve very hot.

PORCUPINE YAM.—Two pounds yam, boil and mash with one egg and salt to taste. Shape and roll in beaten egg and vermicelli; fry. Serve hot with parsley.

YAM FRITTERS.—Pare and boil half a pound of yam until soft, beat lightly with a fork. Beat the yolks of four and the whites of three eggs, add two table spoonfuls of cream, two tablespoonfuls of wine, one dessert-spoonful of lemon juice and half a teaspoonful grated nutmeg beat all altogether until extremely light. Put plenty of lard into a frying pan and drop a table-spoonful of the batter at a time into it, and fry the fritters a nice brown; serve with wine sauce served separately, or only sprinkle powdered sugar over them.

YAM PUDDING.—Half a pound yam, two eggs, one lemon, two ounces butter two ounces sugar. Pare and boil the yam and rub it through a sieve while hot. Beat the butter and the yam together and allow the whole to cool. Break the eggs and separate the yolks, from the whites. Beat the yolks until light, add sugar juice of lemon the grated rind and the yam. Whisk the whites to a stiff froth and stir lightly in before baking. Put in a well buttered dish and bake in a brisk oven for twenty minutes.

YAMS en Brun.—Cut up one pound of yam already boiled and fry a light brown, sprinkle thickly with chopped parsley and shallot or mushroom, pepper, salt and lime juice, and serve very hot.

BALATA GUM IN BRAZIL.

The United States Consul at Para states that attention has recently been directed to the possibilities of the balata fields on the Amazon. A gutta-percha merchant in the Guianas, examining this region about a year ago, found the balata tree growing in abundance near Para, and on the Amazon and its tributaries for thousands of miles. The Brazilians had no knowledge of its gum producing qualities. After persistent effort, he succeeded in interesting persons in the United States and Para, bought a concession, and has lately begun the practical work of producing gutta-percha for the market. As in the case of rubber there is practically no limit to the supply of gutta-percha on the Amazon, and as it can be produced at a fraction of the cost of rubber, it offers a much higher percentage of profit.

The Consul quotes the following report on this subject from Mr. William Gerdeau, who has had a practical experience of many years in the Guianas where he represented American and English gutta-percha importers and managed balata estates:—"Pursuant to your request I submit the following report of my personal investigations of the balata fields of Brazil during my recent explorations of this region: "The balata or bulle tree known in the Brazilian language as the macaranduba, grows in great abundance throughout the Amazon valley but up to this time no attempt has ever been made to introduce the gutta-percha trade in this country. "For more than 30 years this trade has been carried on with immensely profitable results in the Guianas and the Orinoco Valley, but those fields are now almost exhausted and very little gutta-percha has recently been shipped. "It is my opinion that this balata trade can be made to rival the rubber trade in this country, as it can be produced here in unlimited quantities and its quantity is if not better at least as good as the Guiana balata. "I have found the balata trees scattered and in groves, sometimes amounting to forests many miles in extent, all over the States of Para and Amazonas, and I am informed on trustworthy authority that vast

areas of these trees are growing on the Purus and Acre Rivers and other tributaries of the Upper Amazon River. "The method of bleeding the balata tree is entirely different from that used to extract the gum of the rubber tree, and only experienced and expert bleeders can be employed. But on the other hand, these trees yield many times as much sap as the rubber trees, and one man can easily produce as many kilograms of gutta-percha in a day as 20 men can extract of rubber. The trees will average 3½ lb. gutta-percha each, and a competent bleeder can prepare 40 to 50 lb. per day. The gum is first fermented and then dried in the sun, after which it is ready for shipment. "I am surprised to find that this valuable gum, which is so easy of access and so cheaply prepared for market has never become known to the trade here. Many great fortunes have been made in Guiana from this trade, and I believe the time is now ripe for capital to develop the trade here. I found the Brazilians cutting down these valuable trees for firewood and building material being ignorant of their true properties. "Concessions of balata fields of any extent can readily be secured from the Brazilian Government, and private balata lands can be purchased for a fair price. It only requires some capital and practical knowledge of the business to develop one of the greatest industries in Brazil."—*Board of Trade Journal*.

DIEBACK IN COCOA.

It is a very general belief that the alluvial soils along river banks form the very finest areas for the cultivation of cocoa. This is as a rule true, but there may be certain exceptions not generally taken into account, and the rule that wherever bananas grow very easily the same soil is good for cocoa is not an absolute rule at all. They require the same conditions of climate and soil, but cocoa requires more; it should have a deep soil. The banana is a surface feeder, and an alluvium three feet deep, provided there is gravel and free drainage below will suit excellently, whereas clay below does not suit it so well, necessitating elaborate drainage, while on the contrary cocoa does not so much mind a clay below so long as it is not sour but objects more to a gravel. There are some sub-soil to loamy alluvium that are clays; the cocoa thrives there well; other subsoils are sand the cocoa does not object; others are gravels but with plenty of earth, that is a gravelly earth, the cocoa stands this but when there is a bed of pure gravel below, the taproot of the cocoa finds it objectionable, stops growing and dies back, when the top of the trees respond by dying back too. On inspecting a place whereon to grow cocoa, the sub-soil should be a subject of close examination. Another cause of dieback besides the existence of a coarse gravel below, is the too close proximity of vigorous growing bananas. Deep shade is beneficial to young cocoa, but when the plants are well established which is at a year old, it does not do to have them surrounded by dense walls of bananas with the soil crowded with their vigorous greedy roots. The young cocoa, with its taproot striking downward has not many superficial feeders like coffee or oranges, it cannot make a good fight for itself and is often starved. In old banana plantations where there is a large growth and cocoa is to be planted, it is a good plan to plant the cocoa in the line of the bananas and re-plant the bananas between the old rows when the cocoa is two years old. At any rate the cocoa must have light and air, but not direct sunshine above, and plenty of room without severe competition to feed on the soil below. When cocoa trees begin to die back, it often enables them to overcome their weakness by cutting back slightly, and fertilising. This encourages the making of more lateral roots which thus give larger feeding powers.—*Journal of the Jamaica Agricultural Society*.

THE GARDENERS WIL.

WAUKEN, my muse! yer loodest wail,
Lend to proclaim the waefu' tale,
O' a' the ills that do assail
The gardener's occupation.
If ere by chance ye meet a chiel,
Wi' careworn face an' eeu that reel,
An' doonbent head, then mark him weel—
His wark is cultivation.

Auld Milton said—I have heard tell
When Adam's curses cam' pell mell,
That maistly on the ground they fell,
As aff his head they glinted.
I weel believe't: the son o' toil,
Wha's lot hae fa'en to till the soil,
For want o' care will never spoil—
Ifis sorrow's never stinted,

Lang syne, when Adam sawed his seeds,
Ere he began his evil deeds,
He ne'er was hathered pu'in' weeds—
Sae says the auld narrator.
But noo, as sunne's we tak'a spade,
An' get oor bit o' gairden made,
Gaints us we quickly find arrayed
The very pooers o' natur'.

If even the seasons had the grace
To come in turn an' keep their place,
We wadna' hae sae much to face,
Nor view wi' consternation
In summer, when we look for heat,
We're cursed wi' shoovers o' hail an' sleet;
An' autumn's early frosts complete
The work o' devastation.

The rain has ruined oor crap o' Peas
The blight has spoilt oor Apple trees,
Oor grozers covered wi' green flees;
An' then the festive snails
Did quickly seal oor Cabbages doom;
Sma' wonner tho' we fret an' fume
To see oor best Chry'shan'mum bloom
Nabbed by the forky-tailies.*

Oor foes are mair than mind can grasp—
The grub the weevil, bug, an' wasp,
Worms for the Carrot an' the Rasp—
In trnth their name is legion.
But, faith, I'll shak' the gairden mud
Frae aff my feet afore I'm wud,
An' quickly pack ilk stick an' dud,
An' try some ither region.

Hortus, in the "People's Journal," N.B.

THE USEFUL TAMARISK:

Our readers, who chiefly know Tamarisk as a valuable seaside plant, will be interested in the following account, quoted in a recent number of the *Agricultural Gazette of New South Wales*, of the usefulness of the Tamarisk as mentioned by Dr. Seven Hedin in his work *Through Asia*. The latter author says that in his journey across the terrible sandy desert of Takla-Makan, the last vegetation he saw—that is the plants which encroached the furthest into the desert—were the Tamarisk bushes; and the first he met with again, after passing through the worst of the desert, were the Tamarisk bushes.

"We were now," he writes, "entirely amongst the sand. The last of the Tamarisks which still defied the visitation of death was left behind. There was not a blade, not a leaf to be seen, nothing but sand, sand, sand—fine yellow sand, whole mountains of it stretching over boundless spaces as far as the eye, with the field-

* Earwigs.

glass to help it, was able to reach." After travelling for days and days through similar country, at last, "All of a sudden, Kasim stopped short, gripped me by the shoulder, and with widely staring eyes, pointed towards the east without uttering a word. I looked and looked in the direction towards which he pointed, but could see nothing unusual; but Kasim's eagle-eye had discovered on the verge of the horizon the green foliage of a Tamarisk—the beacon upon which all our hopes of safety were now concentrated. We steered our course straight for the solitary tree, taking the utmost precaution not to lose its bearings. At length we reached it. Our first act was to thank God for bringing us so far safe. We revelled in the green freshness of the tree, and like animals, chewed away at its sappy leaves. It was really alive. Its roots evidently went down to the water stratum. We were now within reasonable distance of open water. The Tamarisk shot up from the top of a sand-due and there was not a yard of flat, hard ground anywhere near it. A strange existence these Tamarisks (*Tamarix elongata*) lead. Their branches and tough elastic stems, seldom exceeding 7 feet in height, are bathed in burning sun-hine, while their roots penetrate to an almost incredible depth, and like syphons suck up nourishment from the subterranean supplies of moisture. In fact, that solitary tree reminded me of a Water-Lily swimming, as it were, on the billowy surface of the desert ocean. . . . I gathered a handful of the leaves, which were not unlike the needles of the Pine, and thoroughly enjoyed the sweet fresh scent they gave off."—*Gardeners' Chronicle*.

RUBBER IN PERU.

PERU (MOLLENDO).—In a recent Consular report it is stated that the rubber industry still occupies a good deal of attention, and although the quantity shipped this year only exceeds last year's output by 15 tons, this is accounted for by the fact that large quantities are being prepared in the interior ready to ship when the dry weather sets in—from the beginning of April. A few remarks on the difficulties that attend this industry may be of interest. From the time of landing here, about 15 days will be occupied in travelling by train, steamer, mule, and canoe to get to the rubber districts. The first range of the Andes has to be crossed at 17,500 feet above the level of the sea before the descent into the valleys can be effected. Srata, in Bolivia, is the place at which nearly all the roads into the rubber and mining districts converge. The traveller will often be delayed for several days, as all the owners of beasts of burden take advantage of the scarcity of means of transport, and extort the highest possible freights for their animals. Once hwork has been started, the cheaper plan is to buy mules and horses. All supplies have to be carried in, as scarcely anything can be purchased there. However stores are gradually being established on the different claims. The descent is very dangerous in some places, the incline being from 30 to 45 degrees, and the animals often slip and are thrown over the precipices. This part of the road, 23 miles in length, takes 12 hours, when Pararani is reached, 4,600 feet above sea-level. From Pararani to Mapiri the road is more practicable, and rubber, Peruvian bark, and coffee plantations are met. Mapiri is the centre of these regions, and from there one strikes off to wherever the claims may be. At least 90 per cent of the travellers fall sick with malarial fevers, more or less intense, although seldom fatal. From Mapiri, Guany is reached in canoes, or rafts, made of nine sticks fastened with vines; three of these rafts form what is called a callopo, capable of carrying 1½ tons of cargo. The distance is 62 miles, and can be done in one day, going down stream, but coming back it takes three days, the current running six miles an hour. The Indians can only pull at the rate of ½ miles per hour. From Guany there are roads that lead to

the placer mines on the rivers Tipuani, Covahuira, Challana, etc., in which regions gold is found in abundance, but machinery is badly required, especially to dredge the rivers.—*Imperial Institute Journal*.

THE PITCHER PLANT AS A PLANT PROTECTOR.

One of the greatest enemies to Orchid plants in the West Indies is *Blatta americana*—the American cockroach. Numerous are the traps devised and the poisons compounded for the destruction of this insect, and yet it does not appear to decrease in numbers, and regular plans of trapping and poisoning must be adopted by the cultivator if he is to keep his Orchids free from these—a most ubiquitous—enemies.

There are however, natural checks which deserve attention. First among these comes a large spider, commonly though erroneously* known in Trinidad as the "Tarantula."

This spider, with other large species, are very bitter enemies of the cockroach, and assist not a little in preserving the balance of Nature. When it is mentioned that one of these creatures is large enough to capture and kill a full grown mouse—an occurrence once witnessed in the Barbarium, and recorded in the *Bulletin*, January, 1895—it is easily understood how the cockroach falls an easy prey to it.

Poultry and larger lizards also feed upon the cockroach. To the barn-yard fowl it appears to be a specially delicate morsel, as is recognised by the negro proverb "When cockroach gib' dance, him no ax fowl."

We have recently observed the help given to the cultivator in the destruction of these depredators by the various species of *Nepenthes* or pitcher plants. As they assume full development, the Pitchers developed on the end of the leaves become filled with liquid, into which the cockroach is apparently attracted and eventually drowned. The liquid contained in the pitchers is of a similar character to the gastric fluids of the human stomach, and renders any animal-matter fit for absorption by the plant, so that the cockroach is ultimately digested as plant food.

The *Nepenthes* have been found to be so useful for this purpose that they have been deemed advisable to largely increase the number of these plants among Orchids, as the damage done by the cockroach has been largely decreased by their aid. The various species of *Nepenthes* thrive well in the climate of Trinidad, and are grown in suspended baskets made of Cedar-wood, in a similar manner to Orchids.—*Bulletin of the Trinidad Botanical Garden, October, 1902*

MANURES FOR VINES.—As a result of numerous experiments recorded in the *Comptes Rendus*, Messrs. Guillon and Gourand show (1) that on a calcareous soil the effects of the application of chemical manures do not show themselves till after a considerable interval, (2) that potash salts are the most effectual then phosphatic compounds and hastily nitrogenous manures; (3) farmyard manures is highly valuable; (4) chemical analysis of the soil does not give sufficient indication of the kind of manure that should be employed. Experiments followed out during several years are alone capable of guiding the cultivator in his selection.—*Gardeners' Chronicle*.

* *Lycosa tarantula*, the true tarantula, is only found in Southern Europe, and differs in many respects from the West Indian insect, which has been determined as *Eucyrtella vesicicola*, Walk., and is sometimes spoken of as a species of *Mygale*.

VANILLA GROWING AND CURING.

(Concluded from page 522.)

GATHERING THE CROP.

Nine months after the flowers appear the beans should be fit to gather. Before this they show the approach of maturity by changing from a dark to a light green, and here very many are harvested when they reach that stage. Many of the beans so gathered spoil in the curing and the balance are always liable to mould when packed.

The bean of *V. pompona* which is not liable to split upon the vine should be left, until it has assumed a distinct yellow tint. It can even be left until the lower end begins to turn brown. Beans gathered in that stage will not spoil in the drying. The plantation should be gone over carefully twice a week and the ripe beans removed singly, being careful to separate the bean at its junction with the stem as the upper end is very easily broken. The practice obtaining here, of cutting off the whole bunch as soon as the first bean shows signs of ripening is a bad one. As several weeks elapse between the opening of the first and last flowers so it is with the ripening of the beans. Consequently when the first bean on the bunch is ripe the latest should not be in a fit condition to pick.

V. planifolia owing to the tendency of the bean to split cannot be left so long on the vine. This must be gathered when the lower part of the bean begins to turn yellow or even when the line up the side of the bean becomes yellow.

CURING.

This is the most important and difficult part of the work of the planter, and if neglected, will render all the previous work abortive. Any one can grow Vanilla but it requires care and experience and constant attention to cure it well. The following are methods which have proved successful with me, and by following them the beginner cannot go far astray, but a year or two of practical experience will be of more service to him than all that can be written. I will first give the methods employed by me in curing *V. pompona* which, however, cannot be applied to *V. planifolia* without incurring too great a loss in split beans. When the beans are first gathered they are taken to the house and spread out, where the sun cannot strike them, six or eight inches deep, upon the floor or shelves, until they turn brown. This takes from one to three weeks, depending upon the state of maturity of the beans, when picked. Beans picked too soon, will sometimes lie for six weeks before turning brown. Those which have been thoroughly ripe when gathered begin to turn brown at the blossom end, those which have been picked before maturity, at the stem end or in the middle. When the beans have arrived at a uniform state of colour (a deep red brown) they can be exposed to the sun. I use wooden trays for this purpose, three by six feet and two inches deep in them. For the first two or three days' exposure it is immaterial whether the beans be covered with blankets or not. They should be turned two or three times during the day, bringing the bottom beans uppermost each time, so that no one part of any bean is exposed for too long a time to the sun. This applies to the whole period of curing and is of the utmost importance. If neglected, some of the beans are sure to be burnt red by the sun.

About three p.m., or whenever rain threatens, before the sun has lost its power, and while the beans are still hot, the trays are removed to the house, stacked one upon the other and covered with blankets. The beans thus retain their heat through the night. At the close of the third or fourth day the beans are removed from the trays and packed while hot into tins and closely covered. (Here we use old forty pounds biscuits tins for the purpose.) In these tins they are allowed to remain for a couple of days, when they are

again spread on the trays and exposed to the sun as before. Upon being removed from the tins it will be found that the beans have sweated and are covered with moisture, while there will be considerable water in the bottom of the tins. After the first sweating the beans must never be exposed to the sun unless covered with blankets. Some authorities are unanimous in stating that black blankets are essential, but I have never seen a black blanket used. The kind that we almost invariably use are condemned French Army or Navy blankets, and these are of a dark olive green. The heat, dampness and oil of the Vanilla, very quickly rot the blankets which are used for this purpose. From this time onwards these processes are alternated a day in the sun and a day or two in the tins, until the beans are nearly dry. When, however, the beans have begun to shrivel and are soft and pliant, they may be left for a couple of weeks at a time in the tins, without sustaining any damage, only the tins must be kept as nearly air-tight as possible.

As some beans dry more rapidly than others (the best beans always takes the longest time) towards the end of the drying operation, they must be sorted over and the dry beans picked out and this must be done before each exposure to the sun. The bean must not be too dry. It must be of a dark chocolate brown pliable but not "mashy" when rubbed between the fingers. The corrugations formed in drying must show distinctly and not disappear when the bean is bent and drawn over one of the fingers and it should have an oily look and feel. When the beans have arrived at this sorting stage they should never be exposed for too long a time at once to the sun, not for more than half a day at a time and during that time should be turned at least twice. This is to prevent their being burnt by the sun. One thing deserves particular attention, however. The beans must never be spread upon the trays, exposed to the sun, less than one inch in depth. If spread singly the stalk end of some is sure to burn. Another method which I have tried follows the course pursued in the preceding until the beans have lost about half their weight or rather more and have become sensibly wrinkled. They are then spread singly upon frames, covered with wire cloth, thin sacking or netting in a house with plenty of ventilation and allowed to dry there. The frames require looking over every second day, to pick out the dry beans. Either process makes good vanilla. The second is the safer but requires more house room and requires a little longer time. There appear to be many ways of curing *V. planifolia*. Three of these I have tried and will describe. These are, by means of the oven, hot water and exposure to the sun. The object of all is as far as possible to prevent the splitting of the bean. *V. planifolia*, unlike *V. pompona* which seldom splits on the vine, and never after it is gathered, is liable to split during the process of curing and this greatly depreciates its value. Hence more care has to be taken with it, than with *V. pompona*. For all these processes the bean is taken as soon as gathered from the vine, and is not allowed to get brown as is *V. pompona*.

THE OVEN PROCESS.—For this an ordinary brick or stone "bake oven" is required, which is heated in the ordinary fashion as for baking. The heat is then allowed to decrease until it reaches a temperature of from 150 degrees to 180 degrees. The right temperature for any particular oven can only be ascertained by experiment. The Vanilla has already been prepared by putting it, carefully laid head and tail, and as far as possible beans of the same length in the same package in packages of one thousand beans, wrapped first in green banana leaves and then in rocking, thoroughly saturated with water and secured tightly around the package. These packages are then arranged in the oven upon a platform of battens, to keep them from touching the bricks and then that is closed and left for from twenty-four to thirty-six hours. The time here is also a matter of experiment as

the capabilities of each oven are different. Upon removal from the oven the beans should have become of a uniform light brown colour. They are then spread between blankets and exposed to the sun for six or eight days being rolled up in the blankets at night. At the end of that time they should have become soft and wrinkled and are removed to the house and spread on frames to complete the drying process. They remain on the frames for about a month.

By Hot Water.—The freshly-gathered beans, in small baskets are plunged for from fifteen to twenty seconds in water on the verge of boiling, that is at a temperature of from 185 degrees to 195 degrees Fahrenheit. They are then allowed to drain for a few minutes, but before the beans can become cold they are put in a pile and allowed to sweat for from twenty to thirty minutes. They are then treated as in the previous process, by exposure to the sun, &c.

By Sun Alone.—The fresh beans are spread thickly between blankets and turned several times during the day and rolled up in the blankets at night, for the first two or three days. The after treatment is the same as with the others. In all these processes the beans require to be rolled up in the blankets about three p.m., while still hot and packed in some tight receptacle which will retain the heat, until they can be exposed to the sun on the following day. What has been said about the sorting out of the dry beans of *V. pompona* applies equally to these.

As soon as the dry beans have been picked out they are packed in tins and tightly covered, both to prevent any further drying and to render the ends of the beans as pliant as the rest, preparatory to the measuring, which is the next in order. For this a measuring board is required. The most convenient that I have found is simply a piece of quarter or half inch board, three inches wide and fourteen inches long, with a small quarter inch cleat nailed on one end. From this cleat a scale of quarter inch interval is marked on the middle of the board from four to eleven inches. Neither of these extremes is frequently used. By drawing the half-inch marks twice as long as the quarter inch and the inch marks as long again, they are more easily distinguished apart. However, even when cut in with a chisel the marks are very soon obliterated by the oil and coloured matter from the Vanilla. The difficulty is obviated and the numbers can always be seen, clear and distinct, by simply marking the scale upon a piece of paper pasted upon a two inch strip of glass so that the scale can be read through the glass and bed the glass, paper side down, in soft putty in a hollow in the measuring board, so that the surface of the glass is level with the surface of the board. No matter how discoloured this may become a rub of a cloth brings out the scale as clear as new. Having his board prepared, the measurer sits at a table with the cleat end of the board next him and (having previously sorted the beans with the blossom ends all one way takes a handful in his left hand, places one of these with the blossom end touching the cleat, holds it there with the left and straightens out the stem end upon the scale and reads its length. Having previously arranged in his mind a place on the table for each size, the bean is put into its place and another measured and so on until all the beans are measured. It is convenient to arrange the work table as shown in the following diagram:—

9 $\frac{3}{4}$, 9 $\frac{1}{2}$, 9 $\frac{1}{4}$, 9 in.	Measuring, 6 in., 6 $\frac{1}{4}$, 6 $\frac{1}{2}$, 6 $\frac{3}{4}$	
8 $\frac{3}{4}$, 8 $\frac{1}{2}$, 8 $\frac{1}{4}$, 8 in.	Board, 5 in., 5 $\frac{1}{4}$, 5 $\frac{1}{2}$, 5 $\frac{3}{4}$	*
7 $\frac{1}{2}$, 7 $\frac{1}{4}$, 7 in.	4 in., 4 $\frac{1}{4}$, 4 $\frac{1}{2}$, 4 $\frac{3}{4}$	

A good plan for the beginner is to write a label for each size and place these on the table as a guide. In a short time however, nothing of this sort will be required. If one has a large quantity it is advisable to devote a separate tin to each size. With small

quantities, when the day's measuring is finished, the beans are simply tied in large bundles by a string around the middle and a label of the size is attached to each. These bundles are then packed away together in a tin. With Vanilla as with all other things, the neatness of the package has a great deal to do in aiding the sale, and great care should be taken in the making up of the bundles. It is surprising how different the same beans will appear when carelessly tied and when proper care is taken.

For different markets, different sizes of bundles are preferred. For the French, the beans are tied in bunches of fifty beans and tied with three strings, one at each end and one in the middle. For the New York market, bunches of from seventy to ninety beans, tied at the two ends only are preferred, and for that of London, bunches of the same size, tied with a single string in the middle. For my part I prefer the bunches tied with two strings. Those tied with one string only, in the middle, look very neat, but if one has many crooked beans, it is almost impossible to make them look neat. Those tied with two strings cause no trouble, and "tell it not in Gath," it is besides possible to conceal a few split beans in each bunch. This is necessary with *V. pompona* as there is but one grade and no market for splits. Of course with *V. planifolia*, where quality tells, I would bunch all the first class by themselves and would then tie with one string. To make a bunch, take first sufficient beans to form a moderate handful. These will be found to range in number from seventy, for the longest, to ninety for the shortest beans. It is advisable to have the bundles of the same thickness, both for looks and convenience in packing. From this handful select the best and straightest beans (sixteen for a bunch of fifty up to twenty-one for a bunch of ninety) and lay them to one side. These are to form the wrapper. It will be found that the stem ends of the bean almost invariably turn to one side. In making up the bunch it is necessary that these should all be turned inwards to the centre. Thus, holding the bunch in one hand, squeezing and rubbing the beans together, with both hands and frequently tapping the flower end of the bunch upon the table, in order to keep the ends of the beans level, the other end is examined, and all beans, whose ends are seen to point outwards are turned so that they point to the centre. This being done and the beans again squeezed together, the wrapper beans are put on one after the other until the bunch is encircled by them. After again squeezing the bunch and tapping the lower end, a string is tied moderately tightly around the middle, in order to keep the beans in place until the ends are tied. The flower end is tied first. By tapping this end on the table the ends of the beans are all brought level, when a string is tied fairly tightly around the bunch about a quarter of an inch up. The bunch is then drawn through the hand, using considerable pressure, from the flower end, watching at the same time that every wrapper bean is straight and in place and then another string is tied about the stem ends. The middle string is then untied and the bundle is finished. This gives a neat bundle.

The string usually used here is common white cotton twine. The best tying material is either *Raphia* or bast. I use the inner bark of the paper mulberry, soaked for a couple of days in water, and then bleached in the sun. This is nearly as good as *Raphia* and is cheaper, costing only the labour to prepare it, the "purao" or paper mulberry being our most common tree. The French method slightly differs from mine. It is a good one when the bundles are to be tied with one string only. By it after selecting the wrapper three beans, others, the straightest, are selected, to form a core and the others placed singly around these, circling round and round them and finishing off with the wrappers taking care always that the stem ends point to the centre. Mine is, however, the quickest and is fully as good when the bunches are to be tied with two strings. Here, for shipping the bunches are

wrapped singly in a paraffine paper, packed tightly in tins holding about eighty-five pounds each. These are soldered, air-tight and then crated, usually two in a crate, Good Vanilla packed in this way will keep for years. The advantage of wrapping each bundle in wax paper is that in case a bad bean has been packed and becomes mouldy the mould does not extend beyond its particular bundle.

NOTES.

DISEASES.—Vanilla is subject to several diseases, one of which attacks the partially grown bean, causing it to rot and fall off before maturity and another attacks the lower part of the vine, causing it to wither and dry up, while the upper part continues growing although in a partially withered condition until it can send down air-roots when these reach the ground the plant revives. Any beans which were on it at the time however are a loss. I know of no remedy for either, except replanting. The disease which attacks the bean appears to be worst in rainy weather, and in dense shade.

I think that most of our Vanilla is grown in too deep shade. If the ground is kept shaded and cool by a covering of leaves, rubbish or weeds, the vine itself will stand a very considerable amount of sun. Beans grown in the shade are usually longer than those grown in the sun but they do not carry their thickness to the stem end as do the others, and therefore require more care in curing, as the thin end is very liable to burn. In the blooming season I find it advisable to start fertilising the flowers in a different part of the plantation each day. I think that the flowers fertilised in the morning give the best beans, a shower may come up and stop the work when it is only partly finished, or a very heavy bloom may necessitate some flowers being left unfertilised. Hence beginning in different places is likely to make the crop more uniform than if work was begun in the same place every day. A species of slug has been found eating a few of the flowers, but does but little damage. Our worst enemy is a lovely little green dove which eats the buds before they expand. These are natives of Tahiti, and have learned that Vanilla flowers are edible, by some chance, and the knowledge is evidently inherited. The gun is the only remedy. I have seen it stated that the beans have to be dipped in hot water to destroy insects and their eggs and afterwards kept covered with gauze to keep insects from them. I have not found this correct. The reason for dipping in hot water, I have already mentioned, namely, to harden the skin, keep the bean from splitting, and hasten its drying. I know of no insect which attacks the drying or the dry bean. This statement, however, does not apply to the poison of the Vanilla bean, and which some claim is due to a mite living upon the dry Vanilla. As to the existence of the poison, I can vouch. As to the cause, I am in doubt; but I incline to think that the poison is a vegetable one, and is inherent to the bean. The sap of the vine is in itself acrid or poisonous, although it is not always noticed. On rainy days or when cutting the vines, either in pruning or making cuttings, it makes itself felt by an irritation and itching of the skin of those parts most exposed to it, the hands and face especially. This, however, does not last for any length of time after quitting work.

The other poison, that of the bean, is different in its action, and differs also in its action upon different persons. Some few are exempt. On others, myself for one, after constantly handling the drying and dry bean very small watery pustules make their appearance, usually between the fingers and upon the back of the hand. These itch incessantly. In the worst cases, sores break out upon the head, body and limbs, and the itching is intolerable. Lately a remedy has been discovered, and having tried it upon a number of fellow sufferers effecting a cure in every case, it may be held to be a specific. As a boy I used to be poisoned regularly every spring by the poison ivy

or oak (*Rhus toxicodendron*), and it appeared to me from the similarity of the symptoms that the remedy used for that, might have an effect upon the Vanilla poison. The lotion is made as follows. Mix equal parts of carbolic acid, glycerine and rose-water, and rub upon the parts affected. The effect is instantaneous, and it at once allays the itching, and in a short time effects a cure. As a preventive, when handling much Vanilla, workers may use Calvert's 20 per cent carbolic soap for cleaning hands and face, and if this practice is followed, they will seldom be troubled with a renewal of the affection. It is a matter of tradition here that a kanaka, inserted a four inch wire nail in many of his dry beans, thus selling nails at the price of Vanilla and profiting much thereby. This is a most reprehensible proceeding, and one which cannot be recommended. It is, however, recommended to use great care in not getting the beans too dry. Get them just dry enough not to spoil when packed. Every pound of moisture which the beans lose after that point is reached is just so much clear loss to the grower. It is recommended by some to rub oil over the beans when they are dry. The only oil which should be used is that which can be got from split and damaged beans. By rubbing these with a woolen rag in a short time that will become saturated. The good beans can then be rubbed with this and the few occasional drops which come from some of the beans will keep the rag sufficiently oiled. In beans cured in the sun the skin is always oily. Beans cured by the use of hot water or the oven only need the oiling. For first class beans it is worth while resorting to what the French call "dressing." That is when nearly dry drawing the beans through the fingers, thus straightening them and distributing the seeds and oily matter evenly throughout the length of the beans. For the cheaper grades it takes too much labour. Throughout this article I have referred to the fruit of the Vanilla plant as the "bean." This I know is incorrect, but as they are invariably so called, it has been considered best to conform to custom. As regards the cost of making and keeping up a plantation it is not worth while going into figures, conditions being so different in different countries. I may state that in four years from the time of planting on a leased plantation in Tahiti the returns showed on the right side of the balance sheet. The yield per acre is of course variable, depending upon the number of plants grown their age, &c. A plantation will give two hundred pounds of cured beans is a good one, although two hundred and fifty pounds can be grown. After the plantation is made there is work enough on five acres to keep two men constantly employed, besides which extra labour is required during the flowering season, and also for drying the beans. I recommend planting both *V. planifolia* and *V. pompona* in places where labour is limited or hard to get as by so doing, the two varieties flowering at different times, double the area can be handled with the same amount of labour during the flowering seasons. By keeping a record of the number of flowers fertilised the planters can tell very nearly what weight of beans to expect, when the bean matures. I estimate that each thousand flowers fertilised ought to produce five hundred pounds of cured beans. This allows 25 per cent for loss, and I have found this fairly correct. Ordinary beans weigh on the average one pound for each packet of one hundred and fifty beans.

Green beans run at about forty to the pound, and the loss of weight in drying is about seventy-five per cent.

[NOTE BY EDITOR.—It is not quite clear whether the *Vanilla pompona* spoken of by Mr. McFarlane is the same as that so known in the West Indies, and wanting an accurate botanical description it is difficult to ascertain whether it is so or not. It is quite correct, however, as regards the splitting. Our *V. pompona* does not split, but it appears to be a larger plant, and produces a larger bean (triangular in shape) than the one he describes.—*Trinidad Bulletin for August.*]

PLANTING IN PHILIPPINES.

Sir:—I came to these parts early in 1871, with the intention of devoting myself to agriculture and, after two years of inspection and study of different districts, finally located in Bangui, (to-day a town in this province, but then scarcely more than a settlement), where soil, temperature and situation fulfilled my aspirations.

I secured from the state 600 hectares of ground which contained soils suitable for growing sugar, coffee, indigo, tobacco, cotton, rice and all the plants indigenous to the country, feeling confident that I should also be able to secure a large portion for those of colder climes.

Many were the difficulties with which I had to contend, but my courage was sufficiently great to enable me to do so. I canvassed among the farmers and in three years succeeded in collecting 200 colonists together with their families from the various pueblos. The crops to which I devoted my attention at first were: rice, to supply food; cotton, to furnish clothing; indigo, to provide colouring matter; and tobacco, as a luxury. These imperative necessities having been attended to, I decided to grow.

COFFEE.

which had from the beginning been my main object, being encouraged thereto by the magnificent results achieved by early experiments. One difficulty presented itself which caused me many a misgiving; this was the slight elevation of the land above sea level; but, taking into account the fact that the winds before reaching the plantation, necessarily crossed a fine forest of magnificent trees and, therefore, had become purified of the elements prejudicial to the growth of coffee I decided to undertake its cultivation.

In four years I succeeded in planting 600,000 trees, which were the envy of all who beheld them and which promised excellent returns for labour and money expended. In 1889, when the plantation commenced to bear fruit, there appeared an insect known as the Bagombon (a species of grub), which entered the plant in a larval condition, leaving no external evidence of its mode of entrance. This insect completely destroyed the inner structure of the plant, though outwardly there was no visible sign of destruction, until the plant had been converted into a limp, serrated stalk, the plant then assuming a yellow colour and having been brought to so weak a condition that the slightest breeze was sufficient to overthrow it. The work of destruction, I have observed, takes a downward course, beginning at the top of the stalk, so that but little is left in a sound condition that would enable it to sprout again. This has been the cause of very great loss to me in three or four years, whereas a single crop would have reimbursed me for all expenditures.

After having replanted a large portion of the land in 1889, another disease appeared, which has not up to the present time been identified, but which destroyed nearly all of the plantations of the adjacent country. On my own plantation I first noticed it in September 1889. It made its appearance in sections and in a manner which greatly surprised me. I at first attributed it to the vast rainfall during the months of August and September, but was soon convinced of the seriousness of the matter. The weather improved, and new spots appeared. Then I undertook a series of experiments in my endeavors to effect a cure, which consumed my savings and proved fruitless. I then solicited the aid of an intelligent person from the Agricultural School, who might study the disease. They sent an engineer, and he came to the conclusion that the trouble was caused by a fungus or a parasite the remedy against which was either sulphur or sulphate of copper. I experimented with both of these, but with absolutely no result whatever, due in my opinion, not to the inefficacy of the sulphur or sulphate of copper, but to the fact that this was the season of the year in which the rainfall was greatest, and any work done in the morning was washed away by the rain in the afternoon. Under these conditions and

lamenting the continuous great losses, we discussed the possible origin of so fatal a disease and began to suspect (though somewhat tardily) that the almost total disappearance of the first insect which disappeared simultaneously with the appearance of the second evil and which, while troublesome was not injurious, favored the development of the disease. This coincidence did not occur to me until after the lapse of some time. I endeavoured to act the part of a benefactor and would have succeeded, but for the revolution which destroyed the entire work of thirty years.

Another subject to which I have devoted much attention is the cultivation of

CACAO,

There being no large plantations in which to study this plant, and the half dozen trees usually affording shelter to the homes of the natives being insufficient for my purpose, I did not wish to undertake the work of planting on a large scale. I planted some 29 trees at different points, in different latitudes and in various soils. This study caused me so much trouble that I was on the point of abandoning it, but my inclination for the work triumphed and I succeeded in attaining my object. In 1894 I found myself in possession of the land required; after 18 years of investigation I succeeded in finding the soil. I planted some 20,000 trees and would have planted as many as 100,000 had I had sufficient funds to secure that number. This plantation is a beautiful one and bears well, though not for me, unfortunately. The cultivation of this tree requires conditions which are only to be found in large forests. If the plantations have a somewhat interior location and communication with same be somewhat difficult, it would be necessary in order to defend the fruit against the depredations of monkeys and other two and four-footed animals, to have six guns (impossible to obtain at the present time) and an equal number of men who would be willing to live there, the latter being even more difficult to secure than the former.

One of the most important considerations in the cultivation of cacao is the selection of seed. Great care must be exercised in this selection, for otherwise while beautiful trees may be grown, they will not bear fruit. This selection should always be made by the person interested and not entrusted to another, if the owner does not wish to run the risk of failure.

In my opinion, a plantation of cacao is one of the most profitable undertakings, if the soil be selected with care, permitting the white man to work with comparative comfort in shaded soils.

As is the case with coffee plants throughout the province one may see cacao trees which thrive in the shadow of banana trees or of buildings. Therefore, no hard and fast rule can be laid down governing the point of location; however, as I have said, the pueblo offering the best conditions for its cultivation, is Bangui.

TOBACCO.

The cultivation of this product was monopolized by the State until the year 1882, when it was declared free. Until that time its cultivation was carried on under the direction of competent persons employed in all the towns by the State, and the output for the entire provinces fluctuated between 500,00 and 800,000 bales of a quality superior to that produced to-day. After it had been declared free many of the labourers forsook its cultivation and began a custom which soon became a vice,

Commercial houses were not lacking to take the place of the planter, with advantage to the State, when suddenly appeared the great destroyer of Philippine agriculture, the China-man, who received the article, in any form whatsoever, though at the lowest price. In view of the fact the planter, having but little need to economise labour, forsook every rule of careful cultivation, simply trusting in Providence to bestow upon him the few pesos he required. The efforts of these commercial houses were fruitless to preserve the quality, if not the quantity; they found themselves compelled to reduce the prices—all of which caused

interest throughout the province in its cultivation to languish. Notwithstanding this, the Chinaman profited by the state of affairs, and proceeded to gather to himself anything and everything in the shape of tobacco.

I cultivated it for some years, long enough to recognize the requirements of its cultivation, but abandoned it when I found that it was utterly impossible to direct the colonists,

INDIGO

This product largely cultivated, the natives simply growing a sufficiently yields well in this province, but it never has been large quantity to enable them to provide themselves with their trousers and shirts. Not so, however, in the neighborhood of Ilocos Sur, where there was a great abundance of this product until the Chinaman—the ever evil-doing Chinaman—commenced its adulteration, resulting in a loss of confidence in the market and a consequent depreciation of the article, until its cultivation.

COTTON.

This is generally grown in soil of poor quality and in a manner leaving much to be desired. The variety is a good one, but the yield very scarce, due to faulty cultivation. Within the last few years it has been grown in greater quantity, but always for domestic use. Now, due no doubt to the importation of fibres from foreign countries, there is constant improvement in its cultivation.

CORN.

Corn is planted in all of the pueblos, but on a small scale, this province being essentially a rice-growing section. Only in times of scarcity of corn in the market, is the crop used for food purposes, it being generally fed to fowls and hogs.

On my farm in Bangui I have experimented with seeds from various countries, which yielded very well for two years; in the third year, however, it began to degenerate, due more to deficient cultivation than to the climate or soil.

SUGAR-CANE.

This is planted in all the pueblos throughout the province in small quantities, though only for vicious purposes, that is, the sap is allowed to ferment with the flowers and leaves of the tree called lama, resulting in a beverage which is preferred to the best qualities of foreign countries. Some planters convert a portion of their crop into panocha, which they send to Cagayan.

The soil, in spite of deficient methods of cultivation, yields much sugar, it being very suitable for growing this crop.

RICE.

This is the most important crop of the province and is planted in moist lands, which abound in all of the pueblos; and even in dry lands it can be grown; if one takes advantage of the rainy season. Different seeds must be used for dry and moist lands, and of these two distinct classes there are again many varieties. This plant is cultivated according to methods acquired during a period of four hundred years, in all of which time there was no human intervention to cause them to relinquish their ancient methods.

Aside from the crops mentioned, there are also grown on a small scale lentils, cotton, beneseed, resin and others, of less importance—all for consumption in the interior.

For twenty years the pueblos of Batac, Badoc, Bangui and Sinain have been planting some wheat, which did not yield badly and furnished an excellent quality of this article to the foreign colony in this province until the arrival of flour from other parts, which speedily ruined all chances of cultivating it to advantage.

Now as regards vegetables, tomatoes are grown throughout the entire province and are used extensively by the natives; also egg-plant; amargoso,

squash, cucumbers and others. The foreign plants grown are lettuce, endive, pepper, spinach and beet. These latter are used by the foreigners for food.

On my farm in Bangui I always had a pretty little garden in which I planted Spanish greens, which yielded abundantly. Among others I several times planted large quantities of potatoes and obtained fruit of a better quality than that coming from China; the same with beans, which were of a superior quality whether fresh or dried.

I place myself entirely at your service, and remain.

(Signed), EMILIO A. Y. LALLAVE.

—The Manila Times.

FRUIT TREES IN POTS.

A LITTLE OBJECT LESSON.

W. S. CAMPBELL.

The efforts now in progress, in many of our public schools, to make use of portions of the school-grounds for nature teaching and simple experiments in plant growing are greatly to be commended for, doubtless, such work, when properly systematised and carried out cannot but have an important bearing upon our future horticulture, agriculture, and forestry.

With a view to assist such praiseworthy work in a slight degree, as well as to serve as a sort of guide for those readers who may carry out experiments interesting, useful, and at the same time so simple as to be within the scope of anyone, I will give some results, acquired under extremely disadvantageous conditions and surroundings, of fruitgrowing in pots, as well as information as to the methods adopted.

I may say that when I came to live in town, or rather close to town, after having lived all my life on a large area of land, and was confined to a small garden-plot and a miserable back-yard, I felt choked and wretched. The garden was so absurdly small that it seemed hardly worth while to take off my coat to keep it in good order; and it used to make me laugh when I saw the time it took the jobbing gardeners to tidy up the wee gardens of my neighbours. To my astonishment I found that none of the neighbours, performed any gardening work, beyond an occasional watering with a hose.

After a time it occurred to me that I might as well put my few square feet of space to some better use than the usual prim and absurd little cow-pat designs, concocted of echeveria, altemantheras, and suck-like plants, and I may say that I have succeeded to a remarkable degree.

Hundreds of valuable plants, economic and ornamental, have been given away by me to persons in several States of the Commonwealth; and lately I have sent away a vast number of plants of Mr Farrer's introduction, the new *Paspalum*, *P. virgatum*, which, I think, will prove valuable for cold districts where the famed *P. dilatatum* will not thrive so well.

In this garden, which is generally but designedly in a lovely muddle, are growing a wonderful variety of species of plants such as grasses, saltbushes, fruits in pots, roses, annuals, perennials, bouvardias, cannas—seedlings and otherwise,—dahlias, rice, water-lilies bulbs of numerous varieties, some native plants of New South Wales, straw-berries, violets, nardoo, Japanese roses, seedling roses from Kew Gardens seed, and many other things besides, with seedling grasses, of value for distribution, but which more often than not give this garden an appearance of neglect and wildness.

The soil is naturally poor sand, and I discovered to my disgust that apparently all the rubbish after building such as broken-up slates, stones, old iron, and I do not

know what besides, had carefully been hidden a foot or so below the surface. However, I manage to make the plants grow as I wish without much trouble. My worst enemies are the winds which often sweep like cyclones around here, smashing up everything in a glorious confusion, and the cost of pots to replace those broken often amounts to something serious.

Notwithstanding such little troubles I have managed "fair to middling" as the saying is, with my pot-plants, and I wish to invite particular attention to the fruits in pots, especially to the little peachtree shown in the illustration; indeed, this is chiefly the object of the article.

Fruit in pots are but rarely grown in this State. Occasionally grape vines are shown in pots bearing large bunches of grapes; but this work is a dodge, and not worth describing here. In the countries where fruits in pots are chiefly grown the plants are sheltered generally under glass, and the pots are set in earth, and not infrequently the roots are allowed to grow through the drainage holes into richly prepared soil, which allows a great extension of root.

As this sort of practice did not suit my Design, I grew the pot-fruits in the garden, but not plunged in the soil, and I prevented the roots from growing through the drainage holes, my object being to ascertain possibilities of the production of fruit-trees having limited or rather restricted root-areas.

The little peach tree referred to has been grown in a 7-inch pot. The plant when given to me must have been about one year old from the bud, and I had to cut away most of its roots to jam it into a 5 inch pot with a few broken crocks and a little soil. Here it grew as much as I wanted for a year, and then I shifted it to its present 7-inch pot, in which it has been growing for about two years, bearing fruit.

The crop this year, which is shown in the photograph consisted of eight peaches, the average size of each being slightly more than 8 inches in circumference, the total weight of the eight being over 2½ lb. These peaches were beautifully coloured, luscious, and perfect far better than many peaches retailed in Sydney at one penny each at the time.

To ripen the fruit was my greatest difficulty, for I was obliged to keep the plant out of the sight of the numerous youngsters who are constantly passing along the street which bounds my garden, and in whom the instinct to provide themselves with fruit—apparently inherited from our Pithecanthropos or man-ape ancestor, is markedly conspicuous at an early age—and it has been a marvel to me how my peaches escaped detection.

In keeping the plant out of view as much as possible I was obliged to deprive it to some extent of the sunlight so necessary for its proper development and the ripening of its fruit.

Every fruit that set ripened; not a single fruit, strange to say, fell off, and I attribute this to an abundant use of water as soon as the fruits became as large as peas. As may be supposed the evaporation by this plant, growing in a comparatively small pot, was considerable, and it quickly appealed for water, if needed, by its drooping leaves.

Perhaps I have gone ahead rather too fast, for I forgot to describe the potting soil used. This was chiefly sandy loam, vegetable matter, a little charcoal and about a couple of handfuls of bone-meal. About one part of vegetable matter (old cow-dung for want of something better) to two parts of sandy loam. A better mixture, for anyone who could obtain it easily, would be loam, coarse gritty sand, and vegetable matter composed of rotted leaves. However it will not very much matter what the soil is, provided a good deal of vegetable matter is used in making a potting soil. Vegetable matter is of far more importance for cultivated plants, and particularly so in the field or garden, than is generally imagined, and I feel sure that in the near future a proper appreciation of this important subject will effect a marked change for the better in agricultural and horticultural production in Australia.

But to our pots again. The addition of a little bone-meal will be found of advantage, about a handful or two to the soil required for a 7-inch pot is sufficient. If bone meal cannot be obtained burn some bones and use the ashes instead: you will lose the nitrogen but the phosphate will remain. Whether the bone-meal or burnt bone is used for manure or not, its physical effects are useful, and so is the charcoal broken up into pieces about the size of wheat grains.

When shifting the peach from one pot to another in the winter, I washed its roots thoroughly, and cut about half of them away, and pruned the branches a little. About an inch of broken up pots was used for drainage in the bottom of the pot, a layer of broken up old cow-dung on top of this to keep the soil from washing down, then a little soil on which the peach roots were held, and the prepared soil, rather dry, was shaken in amongst the roots and pressed down well particularly round the sides of the pots, to prevent water and liquid manure soaking through too fast. Potting can be effected very quickly and neatly by anyone experienced in the work, but the operation is not easy to describe. When the potting was completed and the soil well pressed down, the surface of the soil was about an inch from the top of the pot to allow a good quantity of water or liquid manure to be poured in and soak gradually through the soil.

As soon as the peaches began to grow I began to use liquid manure, twice and sometimes three times a week, filling up the inch of space once and sometimes twice at a time after the plant had been watered.

I used a mixture of a handful of nitrate soda, a handful of 'blood and bone' manure, or occasionally five bone-meal, a handful of sulphate of potash, and three or four handfuls of fowl-dung in an eight-gallon water-can of water. This formed a good sort of stock-pot. I used this liquid diluted at the rate of a gallon of liquid to a gallon of water. Sometimes I did not dilute it at all, when it was freshly made. I think it is better to use nitrate than sulphate of ammonia because the nitrate can be made use of by the roots sooner than the sulphate. Sulphate of potash was used because I found that muriate of potash sickened to death some nice strawberry plants in pots I was making experiments with. It may do as well as the sulphate fruit-trees, and may be worth trying, but I should not advise its application for strawberries except for experiment on a small scale.

I may say that I have found the use of fowl-dung for liquid manure alone most useful, far more beneficial, somehow, than chemical analysis would make one suppose. I used it largely, for many years, for garden purposes, with excellent effect, especially when made into a liquid.

Good liquid manure can be made from the dung of any of the domestic animals, particularly so from that of sheep; and for the growing of plants in pots, such as the peach referred to, one could hardly use anything better. But it is always as well to strain it before use in pots.

The apple shown in the accompanying photograph is eleven or twelve years old. I brought it from Melbourne eight years ago where it was raised from the ground, and I have grown it in a 12-inch pot ever since, occasionally, about every two years, repotting after cutting back the roots rather hard. It flowers well, but in consequence of my confined space and being obliged to keep it close to a fence, and in an unsuitable position, the outside flowers only are pollinated. No other apples are grown in the vicinity, so that the flowers have not the benefit of foreign pollen. Besides this the climate is not at all suitable for apples and I am rather surprised that it bears the excellent fruit it does. I adopt the same treatment for the apple as for the peach so far as the soil, watering, and manuring is concerned. This little tree has been grafted on a blight-proof stock, as well as on a dwarf Paradise stock, and no signs of American blight have ever appeared, but this may be due to isolation to some extent.

To grow dwarf trees in pots satisfactorily, a good deal of time and patience is necessary, but as they grow, and even before they bear fruit, most useful lessons could be taught with their assistance. Other kinds of plants also might be used for nature teaching, and endless interest might be inspired by a good teacher who can infuse some little enthusiasm into his subject.

I should like to add that in school grounds, where space is available, a few dwarf apples and pears might easily be grown as garden plants. Quite a number of varieties could be grown in a small area, if planted about 6 feet apart. They had better be grafted on blight-proof as well as dwarf stocks. In order to keep them within bounds, should they give indications of too strong growth, their roots must be pruned, one side or one-half the roots one year, and the other half the next year. The root pruning can be effected by means of a sharp steel spade. A little practice will soon enable any one to root-prune with ease. As for the pruning the heads of the trees, one need only study Mr. Allen's exhaustive articles on the subject, and if he cannot learn all he needs from these, why then he must be a dull person indeed?—*The Agricultural Gazette of New South Wales.*

THE PLANTAIN FIBRE INDUSTRY.

A MADRAS OFFICIAL BULLETIN.

The following are extracts from Mr. Proudlock's interesting "Note on Simple Machines for Extracting Plantain Fibre," just issued by the Madras Government:—

The objects of the present "Note" are (1) to again draw attention to the common plantain as a latent source of an immense quantity of fibre which has hitherto been practically wasted and which might be turned to account by the Indian ryots; and (2) to furnish some information about the two types of primitive machloes which are believed to be in common use by the peasants in the Philippine Islands for extracting the fibre of *Musa textilis* (which is the plantain largely grown there for the production of the fibre known in commerce as "Manilla Hemp"), as they are equally well suited for extracting the fibre from the common plantain.

Although "Manilla Hemp" is yielded by a species of plantain, the fibre is altogether superior to that yielded by the varieties of plantain which are cultivated in India primarily for the sake of their edible fruits. So valuable is the fibre of *Musa textilis* that it practically rules the market in white fibres; while the fibre obtainable from varieties of the edible plantain is, as a rule, valued as very little more than half the price of "Manilla Hemp."

The existence of fibre in the common plantain has probably been known in India from ancient times, and its value and utility have been brought prominently to public notice at intervals from time to time. In the early part, and in the middle of the last century, the subject came under the notice of many eminent men in India, foremost among whom was Dr. Forbes Royle who, in his "Fibrous Plants of India," pages 61-90 has given a great deal of valuable standard information about plantains and bananas and their products; while in this Presidency, Dr. Hunter, among others, seems to have taken a keen interest in the subject. At that time owing to the temporary suspension of the supplies of Russian Hemp to the English market by the occurrence of the Crimean war, the Government instituted an enquiry as to the different kinds and relative values of fibres obtainable in this Presidency. The information obtained was interesting and valuable at that time; and it will be found embodied in "Selections from the Records of the Madras Government," No. XXIII, "Reports on the fibres of Southern India" published in 1856. On page 158, it is stated: The fibre is easily cleaned, but some simple machinery is requisite of the description invented by

Mr. Underwood or by Major Maitland, both of which appliances have been found on trial to be efficient." I have not yet seen any detailed description or plans of either of these simple machines, but so far as I am aware, they are not now in use by the ryots in any part of this Presidency.

Coming down to the present time, it would appear that the main reasons why the ryots do not yet make use of the fibre contained in the stems of the common plantain are: (1) their general ignorance of its existence; (2) the comparative abundance of other species of fibre-yielding plants which can be easily and profitably grown by them and with whose fibres and with the means of extracting them they have long been familiar; and (3) the want of some simple but efficient machine or appliance, suited to their means, for extracting the fibre.

The patterns of the two simple machines are shown in diagrams made from the descriptions given in the "Kew Bulletin." Additional Series II, I—Vegetable fibres; and in Volume IX, Part I, New Series 1891, pages 57-62 of the "Journal of the Agri-Horticultural Society of India." I especially desire to acknowledge my indebtedness to Mr. A. Brown's "Sketch of a knife used by the Natives at Gubat, Philippine Islands for extracting the fibre from *Musa textilis*" on page 62 of the journal referred to. The essential principles in Mr. Brown's sketch and in my sketch of machine No. 1 are the same, although it will be observed that the fittings are slightly different in my sketch.

METHODS OF WORK

After describing these two machines in detail Mr. Proudlock continues:—

It must not be expected that an ordinary cooly can become really expert at the work of cleaning plantain fibre with one of these primitive machines without a considerable amount of practice. With a view, therefore, to getting a man to become expert at the work he should be kept steadily at it day after day for a month or more on daily wages. As soon as the employer is satisfied that the man can turn out what he considers to be a satisfactory quantity of fibre per day, he might suggest contract work to his man at so much per pound of fibre. The employer can easily calculate and settle for himself what rate he can afford to offer to his cooly or coolies for the fibre after ascertaining its current market value.

Planters, zemindars and especially the ryots and villagers who have plantains growing on their estates and in their gardens might, with the aid of these primitive machines very easily and without much expense obtain all the fibre necessary to make cords and ropes for their own requirements. Should either or both of these patterns of primitive machines ever be adopted by the ryots and villagers, it is probable that considerable improvements will be effected in them in course of time by engineers or by others of an inventive turn of mind.

The fibre can also be extracted by scraping the plantain strips with a bamboo scraper on a hard smooth board 5' x 6' x 2" precisely in the same way as agave fibre is occasionally extracted from the fresh leaves of the plant by the villagers in the Coimbatore District.*

SUGGESTIONS.

There can be no question as to the vast numbers of plantain stems that are available in this country; and it would be a good thing if even a tithe of the enormous quantity of fibre which could be obtained from them could be turned to account. The following suggestions are accordingly put forward as been likely, if adopted, to encourage the establishing of an industry in the extraction and utilisation of plantain fibre:—

(1) That the professional fibre-cleaners and ryots be visited in their villages and that practical demonstrations be given to them, as well as to the pupils o

* Vide Bulletin No. 30 "Extraction of *Agave Americana* fibre at Coimbatore."

industrial schools, by trained men in extracting plantain fibre by means of No. 1 machine.

(2) That machines be supplied at practically cost price to those who may wish to buy them.

(3) That competitions be subsequently organised in districts or centres where plantains are largely grown, at which prizes should be offered to the most expert hands in extracting plantain fibre by means of No. 1 machine and also for the best samples of cordage made of the fibre.

(4) That merchants likely to purchase the fibre if it were obtainable in quantity be encouraged to attend such competitions so that producers and purchasers may be brought together in order that a demand for the fibre may if possible be created.

If any real encouragement is to be given for the purpose of introducing the industry among the Indian villagers no half-hearted measures will be productive of much good. It is, therefore, advisable that whatever it is decided to do in furtherance of the scheme should be carefully planned properly directed, and perseveringly carried out in a thorough manner till such time as definite and reliable results are ascertained.

As has already been stated, the fibre obtained from the common plantain is not so strong as that which is obtained from *Musa textilis* the 'Manilla Hemp' of commerce, and it will not therefore fetch anything like the price of the latter. It can, therefore, never compete favourably with 'Manilla Hemp' in the European markets. But, once the natives of India take to extracting and utilising the fibre of the common plantain it is almost a foregone conclusion that an industry in the much more valuable fibre of *Musa textilis** would follow in course of time.

In conclusion, the industry in extracting fibre for cordage from plantain stems after they have each borne their bunch of fruit is more certain to be of local interest and of benefit to the Indian cultivators than it is ever likely to attain any importance as an article of export.

A NEW APPLICATION FOR RAMIE FIBRE.

It has been the fate of Ramie or China grassfibre to have alternately long periods of a smouldering existence and then to burst into a flame of popularity. This has been going on for the last hundred years, and notwithstanding that, there can be no doubt as to the value of the fibre, and to its adaptability to a great variety of uses, Ramie cannot yet be included amongst

* The manilla Hemp was successfully cultivated at the Saidapet Farm in 1882-84 and fibre extracted therefrom by scraping the sheaths with a blunt knife by hand. The stems yielded 1 to 2½ per cent. of their weight of fibre. A rope of Manilla Hemp, ¾ inch thick sustained a weight of about 500 lb. The cost of extracting fibre by hand was of course excessive—C.K.S.

A native gentleman of Valovanur, South Arcot named Venkataramier, states that a specimen of common plantain fibre has been valued in London at from £25 to £35 per ton. He estimates the production of clean fibre at 1½ lb. per stem or nearly one ton per acre, and the cost of extracting the fibre by manual labour at R55 and the charges for bailing, transport, freight etc., at R 45. Large profits are possible, if these figures are correct. Certain experiments made at the Saidapet Farm in 1882-83 in extracting fibre from the ordinary plantains showed that the average weight of a plantain stem was hardly 40 lb. and gave not more than 3 per cent. of fibre. The matter is well worth further attention.—C.K.S.

commercial fibres. Quite recently notice have appeared in the *Lancet* and other publications on the application of the fibre for the manufacture of under clothing, a factory having been set up at Carlskrona, in Sweden, special for this purpose. Ramie underclothing is said to be superior to wool, cotton, linen, or silk; further, that it is more durable, is unalterable in its texture, does not shrink, and its properties are unchanged in spite of wear and washing. The fabrics which we have seen are certainly well made, one pattern in particular being so open and withal strong that though the thread itself is not elastic, the meshlike structure makes the material quite elastic—a property that is said to be retained permanently. In consequence of these characters many advantages over other materials are claimed for it, namely, that it does not hinder perspiration but facilitates it and secures complete ventilation, receiving warmth from and returning it to the skin; further, that it is cooling during oppressive heat, and warming in cold weather; and above all, that it 'prevents the germination of diseases of the skin, rheumatism, &c.' Though the manufacturers are introducing it exclusively for underclothing and hosiery, some of the patterns would seem to have recommendations for ladies' blouses or summer dresses, the pattern being of an open or network character, would look well over a dress of a bright colour. With the view of furthering the use of Ramie we may perhaps say that the English agents for these materials are Messrs. Hall, Nilsen & Co., 47 Mosley Street, Manchester, John R. Jackson, Claremont Lympstone, Devon.—*The Gardeners' Chronicle*.

A PLAGUE OF RATS.

Mr. E. E. Fernandez in the May 1902 number of the *Indian Forester* gives an interesting extract from the diary of an Extra-Assistant Conservator regarding damage to trees by rats. Similar damage has been found by me in the Jhalod and Godhra oranges of the Panch Mahals district. The rats here have, however, confined themselves to eating teak bark, gnawing down to the wood. In rare cases they have attacked bamboos; however, where such instances were found I noticed the stem was never nibbled clean through, but only one side attacked; also that the stem was rarely attacked at the butt, but two or three feet up the stem. I so far have found no case in which *Butea frondosa* was damaged. These rats first were reported in June 1901 and soon after that time efforts were made to exterminate them, rewards being offered for every 100 killed. Though about half a million were killed and brought in for reward in the Jhalod range alone, it had little effect in stopping the damage they were doing to crops. They cleared off the best portion of the crops in four out of five of the ranges of this division, causing severe distress throughout the affected areas. They were extremely objectionable in camp, running over and through the tents, especially at night; this one could put up with, had they not at the same time eaten ones boots, carpet and especially every sort of provision not kept in a tin-lined box. These were not the only troubles they gave the public in general; walking became difficult in places owing to one sinking into their holes at every other step, and riding across country became nearly out of the question. About the 1st February 1902 they were noticed to be on the decrease, by the 15th it was only on rare occasions you saw them, and by the end of the month they had completely disappeared. The only thing that can be hoped is that we will be spared from them next year.

R. S. P.

CAMP SULIAT, PANCH MAHALS,

7th May 1902.

—*Indian Forester*.

PUSSELLAWA PLANTERS' ASSOCIATION

REPORT FOR 1902.

Your Committee beg to submit to you the tenth annual Report.

MEMBERSHIP.—The number of estates on the Register is fifty. During the year one estate has withdrawn and three have joined the Association. There is one private subscription.

FINANCES.—The balance at credit of the Association is R199'41, as compared with R249'99 in 1902.

MEETINGS.—Three general and three committee meetings have been held during the year, at which the average attendance was good.

CROP ESTIMATE FOR 1903.—Acreage in bearing, 21,042; Total crop (Black), 9,555,550; Green tea, 215,000; Native leaf (M.T.), 1,653,500; Native holdings, 5,000; Yield per acre, 438 lbs per acre; Total crops as against 1902, 11,424,050; Acreage in bearing including native, 23,305; Total crop, 11,248,200; Green tea, Nil; Yield per acre, 413 lb. Fifty acres have been returned as abandoned during the past year.

SEASON.—The latter half of the past year has been generally unfavourable for flushing, especially in the higher portions of the district, owing to the unusually continuous and heavy rains of the North-east monsoon. Estimates in many cases, have not been fully realised.

LABOUR.—Labour has been fairly plentiful, but advances show a tendency to increase, and your Committee regrets that the sub-Committee appointed by the Parent Association to consider the Labour question, could not see its way to recommend any alteration in the present laws affecting the relations of employers and employed.

ROADS.—The main and minor Roads in the District have been maintained in good order during the year, and the thanks of the Association are due to the Provincial Road Committee for the grants given towards the up-keep of the latter, and to those members who undertake the supervision of the repairs. The new grant-in-aid cart-road between Ulapane and Riverside has been connected during the past year and is making fair progress.

TOLLS.—The deputation appointed to ask for the abolition of the Gampola Bridge toll was received by His Excellency the Lieut.-Governor in the absence of Sir Joseph West Ridgeway, and the latest advice from the Colonial Secretary (dated 5th December, 1902) is that the matter is still under the consideration of Government.

Your Committee trusts that the final result will be to release the District from a portion of the heavy tax levied on it at present in the form of tolls.

BLIGHTS AND PESTS.—The district has been remarkably free from "Grey Blight, or Rust" during the past year; but your Committee regrets that the "Shot-Hole-Borer" is still very prevalent on some estates, and appears to be spreading. Barring prunings has been tried, but does not seem to have been of much use; at present prunings are being buried with Basic Slag, but it is too early yet to form any opinion as to what this will effect. Helopettis was noticed on two or three estates round Gampola, but it disappeared without doing any harm.

OBITUARY.—Your Committee desires to express its deep regret at the sudden death of Mr Shelton Agar, an old and valued member of the Association.

By Paid Alex. Philip 5 estates subscriptions to Parent Association at R7'50	37'50
Do Cheque donation to G W Sturgess, Holy. Secretary Society for Cruelty to Animals	10'00
Do Cheque to Alxe. Wardrop for donation to Victoria Memorial Eye Institute..	50'00
Do District Road Grants	1,080'00
Do Stationary, Advertising Clerk, Pettios and Postages	79'98
Do Balance at 31 December, 1902, as per Bank, book at credit of Association..	199'41
Total	1,456'89

RAKWANA PLANTERS' ASSOCIATION

ANNUAL REPORT FOR THE YEAR 1902.

Your Committee have pleasure in presenting their report for the year 1902.

OBITUARY.—Before passing on to the various items of the report, your Committee consider it their duty to record their deep feelings of sorrow at the irreparable loss sustained by the District of Rakwana in the death of Mr Robert Bartrum, of Stubton, which sad event occurred on the 25th September last.

The late Mr Bartrum, who was one of the oldest residents in this district, and one of the staunchest supporters of this Association, will long be missed by his fellow-planters of Rakwana.

REGISTER OF ESTATES.—The number of estates on the roll of the Association for the past year was fifteen (15.) which was an increase of two on that for the year 1901.

NUMBER OF MEETINGS.—There have been four General, and five Committee meetings held during the past year, all of which have been very well attended. The amount of business transacted has been considerable, and the wants of the district have been kept prominently before the Government, with the result that, in nearly every instance, they have been promptly attended to.

OFFICIAL ESTIMATE OF TEA CROP FOR 1903.—The estimate of tea crop for this year is 40,000 lbs. in excess of the estimate for 1902, in spite of a considerable acreage having been abandoned. The acreage to come into bearing is, however, next to nothing, being only 28 acres.

DISTRICT ROADS.—Your Committee have to inform you that all the minor roads in the district, in charge of the Association, have been repaired for the past year, and are in order. An additional vote of R100 was obtained for the Springwood-Elchico road, bringing up the Government moiety to R300. A vote of R67 was also obtained from the District Road Committee for repairing the Stubton Ford, the estates interested contributing a further sum of R33, bringing the amount up to R100. This work has been greatly hindered by wet weather, but is now nearing completion. Your Committee are also pleased to record that the District Road Committee have voted the sum of R335 for the reconstruction and repair of all the bridges requiring attention on the Rakwana-Depedene road. The Superintendent of Depedene estate has been entrusted with this work. The lower section of the Rakwana-Bnatota road, from the Rakwana-ganga bridge to the turn-off to the Government bungalow has been, at the request of this Association, taken over by the Public Works Department from 1st Jan,uary of last year.

GOVERNMENT CART ROAD.—Your Committee are pleased to note that the Government cart road through the district has been maintained in a duo stato of efficiency during the past year.

MADANPA PASS DEVIATION.—Your Committee are somewhat disappointed with the progress already made in connection with this much-needed deviation—only one mile of the road having been made ready for traffic during the year 1902, besides about ¾ of a mile more of earthwork completed. Your Committee hope that now, the most difficult por-

Do Kachcheri order from Chairman, District Road Committee, Nuwara Eliya	100'00
January 1st to Balance	1,456'89

tion of the road having been constructed, more speedy progress will be made with the remaining section, where the work to be done is comparatively easy; and that the entire road will be open for traffic before the close of the present year.

The officials concerned are to be congratulated on the excellent construction of the first completed mile.

GOVERNMENT BUILDINGS.—A palatial set of pioneer lines and an overseer's bungalow have been erected on the Government reserve in Stubton estate. Your Committee fear that this work has been done somewhat at the expense of that section of the cart-road above the Bulatota Pass, which is to be gravelled instead of metalled from 1st January, 1903.

A new Post Office of ornate and substantial appearance has been built in Rakwana during the past year, and great credit is due to the Provincial Engineer for the expeditious way in which the work has been carried out.

RAKWANA HOSPITAL.—The addition to the female ward was completed and opened during the past year, and is found of great use and benefit.

Dr. Wm. C. Pieris, the late D. M. O., left the district early in the year, and was succeeded by Dr. T. Ohlmus as Medical Officer at the Rakwana Hospital.

GODAKAWELA FIELD HOSPITAL.—Your Committee regret to state that there appears to be an inclination on the part of Government to close the above hospital and to transfer its patients—mostly cases of "parangi" and malarial fever—to the District Hospital at Rakwana, where it is proposed to erect two separate wards for the treatment of "parangi" cases.

Your Committee have protested strongly against this proposal, and will continue to do so, until Government see the advisability of giving up the idea, and continuing to, either keep up the present Field Hospital at Godakawela, or to build the proposed two new wards at Palawela, which is far more centrally situated.

ANNUAL CERTIFICATE:—FACTORY MACHINERY INSPECTION.—Your Committee regret to inform you that no definite reply as yet been received from Government to the resolution on above subject passed at the general meeting of this Association held on July 5th, 1902, which resolution was sent in to Government on the 21st July last. All the reply vouchsafed up to the present has been that "the revision of the new rules" was still "under the consideration of Government."

RAILWAY EXTENSION TO RATNAPURA.—Your Committee have much pleasure in informing you that the sum of R25,000 has been voted in the Supply Bill of 1903 for the survey of the proposed extension of the Kelani Valley Railway to Ratnapura. The surveyors are already at work, and it is reasonable to suppose that the survey will be completed in about eight months from now, which will be about the time that the last section of the Kelani Valley Railway will be opened to Yatiyantota, so that no delay should take place in moving the plant and engineering and working staff on to the new extension. Your Committee think it would be a graceful act on the part of His Excellency the Governor, and the crowning point to his hitherto uniform progressive policy, to announce to us before he leaves the island towards the end of this year that the Ratnapura Railway has been sanctioned, and will shortly be commenced.

COLOMBO-RAKWANA AND BALANGODA MAIL SERVICE.—Your Committee consider that the thanks of this Association are due to the Postmaster-General for so promptly acceding to their wishes in providing the two districts with a through mail and passenger service to and from Colombo in the one day.

The discontinuance of the Sunday coach, however, is felt to be a great deprivation and inconvenience, but it is hoped that steps will soon be taken to have it reinstated.

KELANI VALLEY RAILWAY TIME-TABLE.—Your Committee regret that no alteration has as yet been made in the above time-table, in order to enable the coach to leave Avissawella and arrive at Rakwana at an earlier hour than it does at present, and to also obviate the necessity of the return coach leaving Rakwana at such an early hour as 5 a.m.

Your Committee intend to continue to press the matter, and are in hopes that the General Manager will be induced, before long, to make the required slight alteration in the present Railway time-table.

APPOINTMENT OF RESIDENT HEADMAN AT THE VILLAGE OF ITTAKANDE.—Your Committee are pleased to inform you that, at the request of this Association, Government were pleased to appoint a Resident Peace Officer to the village of Ittakande—a very desirable and necessary appointment.

LABOUR SUPPLY.—Your Committee are of opinion that the labour supply of the district is totally inadequate to present requirements, and regret to note that coolies are not coming in from the Coast as in former years.

There appears to be a tendency on the part of planters to draw their supplies from other estates, and there are some Companies who are still giving out unlimited advances, which tends to demoralise labour, and to discourage legitimate recruiting from the Coast.

ADVANCES.—Your Committee regret that, owing to the scarcity of labour from the Coast, advances have shown an upward tendency, but that, compared with some other districts, the average rate per head is fairly moderate.

TIN-TICKET SYSTEM.—Your Committee are of opinion that this system is not workable in a district like Rakwana, which is 54 miles from the nearest railway station. When the railway is extended to Ratnapura there will be some chance of the system finding favour in this district.

WEATHER.—The past year has been an abnormally wet one, and most estates in the district are, in consequence, short of their estimates.

HEALTH.—The general health of the coolies in the district has been fair, and the mortality normal, and there has been a complete immunity from all serious epidemic diseases.

HELOPELTIS.—It is much to be regretted that this pest has proved very rampant throughout the district during the past year, and that it appears to be increasing in virulence year by year.

RICE.—Rates of rice throughout the year under review, though somewhat high, have been unusually even. The monthly rates laid down by this Association have been adhered to, and accepted by the Chetties.

CART HIRE.—The rates of cart hire to and from Colombo remain the same.

ACCOUNTS FOR 1902.—The accounts for the past year have been submitted by the Honorary Secretary, and your Committee are pleased to inform you that the balance standing at the credit of the Association on the 31st December, 1902, is R177'05.

OUTLOOK FOR THE NEW YEAR.—Your Committee are gratified to note the better tone apparent in the tea market, and are confident that, if the warning note re *coarse plucking* lately sounded by the Tea and Produce Committee of the Ceylon Association in London, is heeded by all those concerned—especially Colombo Agents and V.A.'s—a bright future should be in store for the industry.

The increased manufacture of green teas being another factor towards enhancing the value of blacks, and thus restoring the industry to its former position, should be strenuously encouraged.

Your Committee, therefore, consider that Government ought to be asked to come to the rescue in providing the "Thirty Committee" with sufficient funds to make up the deficit in the green tea bonus of 1903—a step which would not only directly help on the planting enterprise, but which would also prove indirectly beneficial to the Colony at large.

DIKOYA PLANTERS ASSOCIATION.

REPORT FOR 1902.

MEMBERSHIP.—There are 79 members on the roll, 75 estates and 4 private subscribers, as against 80 members last year, one estate having withdrawn, being one of a group whose interests are already represented.

FINANCE.—Your Committee are glad to be able to report that the finances are in a satisfactory condition, all outstandings having been paid, and a sum of R7'90 is in hand, as against a debit balance of R57'82 at the end of last year.

The accounts have been audited by Mr Hamlin and certified as correct.

LABOUR.—Whilst as a whole the District has been sufficiently supplied, your Committee would strongly urge on its members, in view of the shortage which undoubtedly exists, the desirability of recruiting fresh labour from the coast, and not relying on their neighbours for their requirements.

LABOUR FEDERATION.—During the year two Committee meetings and one General meeting have been held. The Committee had some serious differences of opinion to arbitrate on, and are glad to say that in each case the parties concerned agreed to abide by the decision of the Committee, which course is to be strongly recommended. A scheme for Local Federation was brought forward and was fairly well supported, but as the required support of 75 per cent of the acreage was not obtained, it fell through.

HOSPITAL.—Your Committee regret that, notwithstanding the urgent claims this District has for a new hospital, during the year under review no steps have been taken to rectify this most unsatisfactory state of affairs, beyond surveying a site for the proposed New Building. It is, however, with satisfaction that your Committee are able to report that the hospital was personally inspected by His Excellency the Governor on January 20th, 1903, who is now fully alive to the pressing need there is of at once taking in hand this most important work. The thanks of the Association are due to His Excellency for giving this matter his personal attention, and it is to be earnestly hoped that before long the District will be in possession of a hospital not only suitable for the purpose it is intended for, but worthy of the requirements of the District.

TIN TICKET SYSTEM AND REGISTRATION OF ESTATES.—This has been working satisfactorily during the year, and, with the few minor improvements in details now being made, will prove to be a still greater boon to Planters. Your Committee would urge all members of the Association to give the system a thorough and careful trial. The registration of estates is now compulsory, whether estates avail themselves of the scheme or not.

DISTRICT AND MINOR ROADS.—The main roads are in good order, having been much improved by widening the bad corners and narrow portions. A sum of R900 has been received and distributed on minor roads which have all been well kept up.

RAILWAY MATTERS.—The improvement—more especially in the Goods Department—which was hoped for in our last annual report, has not been noticeable. Hatton station is however, being enlarged, and is better regulated,

HATTON POLICE MAGISTRATE.—During the year the Government was petitioned to relieve the Magistrate of his work at Nuwara Eliya and Nawalapitiya. The Dimbula, Maskeliya and Ambegamwa Planters' Associations supported this Association, and Government has now relieved the Magistrate of his Nawalapitiya work, which should lead to less delay in dealing with cases.

POLICE.—The Police appear to have generally done their work both well and efficiently, and it is worthy of comment, that since the establishment of a Guard-room at Kotiyagala, petty thefts, such as fowl-lifting, etc., have practically ceased.

PESTS AND DISEASES.—Your Committee are glad to report that on the whole the District has been free from any serious outbreak of either

NURSING ASSOCIATION.—A scheme by which Superintendents and Assistant Superintendents of estates can now receive the full benefits of the Association, by estates subscribing a reduced sum to the funds, has lately come into force. Your Committee would commend this scheme to all Proprietors and Agents of estates, for whilst by joining they would assist in putting the Nursing Association of Ceylon on a sound financial basis, they would also at the same time provide for the efficient nursing of their Superintendents in time of sickness.

OFFICIAL CROP ESTIMATE.—The returns have been received from all estates except 9 for which an average based on previous returns has been struck. The figures are as follows:—Total tea 29,329 acres; tea in bearing 23,611 acres; estimated crop 13,022,450 lb. This gives an average of 455 lb. an acre, against 465 lb. last year. Your Committee are of opinion that last year's estimate of 13,000,000 lb. owing to the abnormal season was not realised.

OBITUARY.—Your Committee regret the losses to the District caused by the deaths of Messrs R H Tennant and John Fyler.

STATEMENT OF ACCOUNTS.

EXPENDITURE.—To accounts paid on account, 1901, R61'86; 79 subscriptions at R7'50 paid A. Philip, R592'50; clerk for 12 months, R120; advertising R61'78; rent of room, R75; labour federation expenses, R5'25; postages, R36; stationery, R15; telegrams, R1'70; cheque book, commission, etc., R14'55. Total R983'64. Balance in hand R7'90. Grand total R991'54. *District Road Account.*—To amount spent on roads R833; balance in hand R67.—Total R900.

RECEIPTS.—By amount brought forward R4'04; 75 estate subscriptions at R12'50, R937'50 and 4 private subscriptions at R12'50, R50, R987'50. Grand total R991'54. *District Road Account.*—By amount of vote R900.—Total R900.

By amount carried forward as per Bank pass-book, R74'90.

“OOLONGS” TEA—AND THEIR MANUFACTURE.

Having sent a copy of the pamphlet concerning Formosa Oolongs to Mr. Fairhurst, he is good enough to write to us as follows:—“I only saw it (the pamphlet) on the morning of the Dimbula Planters' Association meeting when it was too late to alter my paper. I do not suppose that anyone in Ceylon has tried the process indicated in the

pamphlet, and I should imagine that there would be difficulty in so doing and great loss of time, an article of which the Chinese take little account. As the crop of Oolongs in Formosa and China is gathered only three or four times during the season—the bushes yielding nothing in the winter, the loss of time is of far less consideration there than it would be in Ceylon where the gathering of the crop would be continuous. As I said in my remarks—I do not think that Ceylon can successfully imitate the Formosa Oolongs; but I think it can do so as regards the Foochow Oolongs. But as Foochow can largely increase its production of Oolongs, I doubt whether the average price, which Ceylon might expect for its manufacture of them, would be good enough to induce estate to make them. And I also doubt whether Oolongs made by machinery would compete successfully with those made by hand—that, however, remains to be proved and is, I think, worth trying. Since reading my paper I have seen a sample of green tea (young hyson) which, I consider, is an excellent tea, and which is an exact imitation in make, liquor, and aroma, of the China article and will, I think, certainly pay well.”

“GOOD CULTIVATION AND DISEASE.”

Mr. Carruthers writes with reference to the following paper as follows:—

“A few notes I have jotted down when reading Marshall Ward's recent paper on most interesting experiments with rust on Brome grass—perhaps the *T.A.* would like the *MS.* I want to kill the idea of 'feed up your plants and no disease will come' which makes men allow insects and fungi to go on unhindered.”

A recent paper by Professor Marshall Ward, describing the results of some experiments on the relations between some species of grass belonging to the genus *Bromus* and the rust fungus *Puccinia dispersa*, which attacks these grasses, is of wider interest because it throws additional light on the question of predisposition of plants to disease. A belief is very general among horticulturists and agriculturists both in Europe and the tropics that most, if not all, diseases of plants can be avoided by keeping the plants well nourished. This is, of course, true of diseases due to unhealthy conditions. Such diseases as come from starvation, freezing, excess of sun, excess of water, &c., &c., will be prevented if these conditions are not allowed to exist; but these are not the diseases that the farmer and planter most fears. He fears most those of which he does not understand the exact cause; and as he knows well the causes of the evils just mentioned and the way to prevent them he is not troubled, and proceeds to prevent and cure them by giving his plant healthy conditions and plenty of food.

The fact the planter has learned by experience—that by keeping his plants in a high state of health he wards off these “environmental” or “physical cause” diseases—has unfortunately led him to believe that in other diseases, caused by the attacks of

specific organisms such as insects, fungi, or bacteria, feeding the plant and giving it healthy conditions, will be of use. While there can be no harm in carrying out this treatment, yet if these are the only measures taken against such diseases as finger and toe, cacao canker, rust in wheat or any other such disease, the effect can only be to prolong the struggle without altering the final result, just as to feed up an animal suffering from the attacks of internal parasites, without removing the cause of the illness, would only bring a temporary appearance of health, if even that. Professor Ward's experiments consisted in starving some of the Brome plants by various methods—chiefly mineral starvation—and by keeping another series in a vigorous state of health by ample nutrition. The plants showed the effects most plainly in their reduced root system, narrow and pale-coloured leaves, and stunted growth, their lack of health. When, however, the healthy and unhealthy plants were both submitted to similar infection of the rust fungus, the fungus grew equally on both strong and weak plants. The starved ones did not, as might be supposed, afford too little food for the fungus and thus be immune to attack, neither did they, as the practical man's belief often leads him to think, fall an easier prey than the well-fed plants. And still further it was found that though the size and quantity of the fungus on the starved grasses was less than on the healthy ones, owing to their obtaining less food, yet the spores formed by the fungus from the weak plants were equally virulent in their capacity of infecting other plants.

The moral of this and much other scientific work on plant pathology is that the motto of the planter should be—not: Keep your plants well fed and tended, to prevent disease—but: Keep your plants well-fed and tended, in sanitary conditions, and remove chances of infection—to prevent disease.

J. B. CARRUTHERS.

THE GOLD COAST COLONY.

The official report on the Gold Coast Colony for the year 1901 has been issued as a Parliamentary paper in the series of Colonial Reports [CJ. 788-45]. The revenue from ordinary sources amounted to £471,193 8s. In addition to this must be reckoned grants in aid of £25,000 for the Northern Territories and £197,700 for the Ashanti disturbances. The net increase in the general revenue, exclusive of grants in aid, over the revenue of 1900 was £138,340 19s. Under the head of Customs there was an increase of £68,264 5s 11d, this being attributable to the marked expansion of the colony's import trade. There was a falling-off of £411 15s 5d in the revenue from the Northern Territories which is ascribed to the stoppage of the caravan trade with Ashanti and the failure to obtain the annual supply of trade goods owing to the Ashanti rebellion. There was a total increased expenditure of £110,847 8s 10d; the expenditure on the Ashanti disturbances during the year was £124,392 5s 2d. The Government loan for the Ashanti war, received partly in 1900 and partly in 1901; was £400,000. The total value of exports and imports combined amounted in 1901 to £2,360,760, the highest figure yet reached except in 1899. But whereas in the last few years imports and exports have shown a more or less equal proportion of value, the large total for 1901 is

entirely due to imports, as the exports have shown a conspicuous decline. The United Kingdom claimed 73½ per cent of the imports, and 45 per cent of exports; Germany 10½ per cent of imports 28 per cent of exports; and the United States 5½ per cent of imports and four per cent of exports. Rubber exports showed a marked decrease (224,126) in 1901, which was due in part to the low prices on the European markets and in part to wasteful handling of the rubber vines; with care and attention there is every hope that the rubber trade may revive and its values and quantities regain the standard of former years. Palm-oil and palm-kernels, the other two staple articles of export, also showed a decrease, and the trade in kola-nuts still manifests signs of having been severely affected by the Ashanti rebellion in 1900. Cocoa is the only article of export which showed an increase for 1901, and this amounted to £15,537 in value. A further increase is confidently expected for the current year.—London *Times*, Jan. 1

PLANTING IN DOMINICA.

[TO THE EDITOR OF THE "TIMES."]

Sir,—Two years ago you were so good as to give publication to a letter from me in which I attempted to indicate the advantages offered by the island of Dominica for the profitable investment of moderate capital. Thanks to the kind assistance thus given by you, the island obtained an advertisement from which it has considerably benefited. Over 100 persons, possessing the requisite means, placed themselves in communication with me; and a good number of young men have since gone out to Dominica and have become planters there. I am happy to be able to state that with one exception, who "threw up the sponge," they are all doing very well and appear to be entirely satisfied with their prospects. Several have taken up considerable blocks of the Crown lands, and they are rapidly transforming areas of primeval forest into promising plantations of cocoa, limes, oranges, and rubber. They have already got through the rough part of their work, and are settled in smart cottages and bungalows where the amenities of a decent mode of living are very apparent.

THE NEW ROADS

recently constructed into the mountains and valleys the interior have opened up and rendered accessible many thousands of acres of splendid lands, and there is still room in Dominica for scores of the right kind of men. For the benefit of those who may not have seen the communication which appeared in your issue of September, 1900, I beg that you will allow me to recapitulate, as concisely as I can, a few of the special advantages which are offered by the colony which we are now trying to develop.

THE CLIMATE IS EXCELLENT,

and especially suited to persons who have a tendency towards pulmonary affections. Yellow fever is unknown and malaria very rare. The districts bordering on the leeward coast of the island are rather warm in summer, but in the mountains of the interior and on the windward coast the temperature all the year round is delightful. While it is exceedingly difficult to purchase a plantation already yielding crops of cocoa or limes, there are over a hundred thousand acres of very fertile land in the possession of the Crown which can be purchased for 10s an acre with facilities for payment. There is, at present, no tax on land, and other imposts are very light. There is a good supply of labour at rates varying from 8d to 1s 2d a day, and the population is steadily increasing. The rainfall is abundant and a great number of streams afford water power.

THE FARE TO DOMINICA

by the Royal Mail Company's boats costs £25, return ticket £40 and the journey takes 13 days. There are several other lines of steamers calling at the island and it has frequent communication with the United

Kingdom and with America. There is an open market for all the local products, and the trade of Dominica has doubled itself in the last six years. Some idea of the recent extension of agriculture may be obtained from the fact that during last year over 60,000 seedling plants of cocoa, limes, oranges, rubber, vanilla and other products were distributed to planters from the nurseries in the Botanic Station. All these plants were sold below the cost of production, and the Imperial Department of Agriculture is always ready to give advice and assistance to any planter requiring it. The island is now in a sound financial condition, and means have been found to carry out a number of works of public utility. An excellent steamer plies constantly round the coasts; new roads have been made in many directions, and the old ones put in fair order; bridges are being built over the largest rivers, and telephone lines are being extended round the island. A good public library was built and opened last year as a memorial to her late Majesty, and a social club has just been established in Roseau.

THE VALUE OF PROPERTY

is increasing rapidly, and there is every prospect of further improvement. A long period of depression is being succeeded by an era of prosperity; and, instead of that feeling of discouragement which exists in those West Indian islands where sugar is the staple industry, we find in Dominica a cheery and sanguine spirit ready to give cordial encouragement to every scheme that gives promise of working for the good of the island. Owing to its excellent climate, abundant rainfall, fertile soil, and other natural assets, Dominica offers advantages for tropical agriculture which are rarely found combined elsewhere. To men of independent spirit the life of a planter has many attractions, and it is generally conceded by all who know the place that, if its possibilities were more generally known in England, all the unoccupied land now available would very quickly be taken up. To the tourist the island is a source of unalloyed pleasure. It is undoubtedly the most beautiful of all the Antilles. Considering the size of Dominica—about 300 square miles—the scenery is remarkably grand and imposing. The rivers and streams are full of waterfalls and cascades; the mountain sides are clothed with the richest vegetation; luxuriant groves of tree ferns struggle with a variety of palms for the mastery of the soil; and altogether the island is a veritable mine of beauty.

I may add that Dominica has been

ABSOLUTELY UNAFFECTED BY THE RECENT

VOLCANIC DISTURBANCES

in Martinique and St. Vincent; and competent scientific authorities have recently expressed the opinion that little or no danger need be feared on this score. If any of your readers care to make further inquiries into the subject of Dominica with a view to becoming planters there, I shall be happy to reply to any inquiries that may be addressed to me, care of Messrs. Grindlay and Co., of 51, Parliament-street, S.W. I would not, however, advise any one to entertain the project of becoming a planter unless he can dispose of a *minimum* capital of £1,500. With many thanks for the space you have been good enough to accord me.—I am,

H. HESKETH BELL, Administrator of Dominica.
December 29.

—London *Times*, Jan. 3.

AN OIL BURNER.

Speaking of the oil burner patented by Mr. Allan Renny, of Penang, our northern contemporary says:—

The question of oil fuel is one which for a considerable period has occupied, and continues to occupy, the attention of locomotive and marine

engineers, ship building firms, and indeed steam users generally. Various forms of burners have been placed on the market, and though considerable efficiency has resulted, there is no reason for believing that finality or anything approaching it has yet been reached. To obtain the fullest advantage which liquid fuel possesses over solid fuels it is important that the burner should provide means for the complete combustion of the oil, and thus avoid the deposit of a solid residue. Mr. Renny claims for his invention that it affords a simple means for the more efficient and economical combustion of liquid fuel for the production of steam, for smelting and for other purposes, and that it overcomes many of the objections attached to oil fuel burners as hitherto constructed. The apparatus consists of a casing fitted with an oil inlet and having two internal diameters with two nozzles attached, one being fitted within the other and forming with the outer casing passages for air, steam, and oil. If necessary it may be worked by air pressure instead of steam, though the latter is stated to be the more economical. We understand that Mr. H. Cowdell, of the Cradley Heath Boiler Works, Staffordshire, is the English agent for this burner, and that applications have been received from several important firms for permission to adopt it. Under these circumstances there is not the least doubt that the burner will receive the fullest trial, and we trust these trials will bear out the satisfactory results which were obtained during the experiments carried out in this Settlement.—*S F Press*, Jan 21.

THE ANOPHELES MOSQUITO.

A Reuter telegram from Liverpool, dated January 9, says:—"A letter has been received by the hon. secretary of the Liverpool School of Tropical Medicine from the leader of the Sierra Leone expedition of the school, Dr. Logan Taylor (who has been sent on an expedition to the Gold Coast by the school), with reference to the progress of the expedition in Sierra Leone. Dr. Logan Taylor says:—"I am getting a report ready for the school about the Sierra Leone work and will let you have it soon. We had to stop most of the men at the end of August, only keeping on the oiling gang after that. I am well pleased with the work this gang has been doing during my absence, as when I went round to inspect their work I found both in untouched and drained streets a very noticeable absence of anopheles larvæ in places where we used to be able to get any number. This is due, of course, to their not being able to breed owing to the pools being either swept out or oiled regularly. The result of this is, that, compared with the corresponding time last year, in some of the notoriously bad streets, where in a single house we could find as many as six, seven, or a dozen anopheles mosquitoes in the early morning, this year with great difficulty, after searching house after house, we could get one, or perhaps two, adult insects. I can keep on an oiling gang of men and the headman Shaw until the end of February or so, by which time I should be free of the Gold Coast, and am leaving 11 men to peg away at Grassfields District until I return to Freetown. An extra £500 has been put down in next year's estimates for continuing drainage work. The engineers are working at the hill railway, and also at the new waterworks. I may say that since the men of the Liverpool School expedition stopped clearing up

yards and emptying out the water containing culex larvæ no one else has taken up the work, and these insects are getting bad again; in fact, the rubbish is beginning to accumulate in the yards just as before, and several of the Europeans were complaining to me of being much annoyed by culex and stegomyia. This means that, unless the Government or the school will keep on the work, the money the school has spent on it will be almost thrown away. My destination now is Cape Coast, where I am to go and take charge of the sanitary work of the town and see that my former recommendations are carried out. The people at Accra have been very kind, and the principal medical officer and the medical department are doing everything to assist me."—*London Times*, Jan. 10.

RUBBER PLANTING IN TENASSERIM.

The Rubber Planting experiments in the Tenasserim division by the Forest Department have been continued on an extended scale, 772 acres of land having been cleared and 663 planted with *Hevea* during the past year. The area of the experimental garden has been extended by some 42 acres, and the Kambe rubber plantation, Rangoon, has been taken over by the Forest Department from the Cantonment Committee.—*Madras Mail*, Feb. 4.

"DE INDISCHE MERCUUR."

This excellent and ably edited agricultural and commercial weekly, published by Mr. J. H. de Bussy of Amsterdam, has attained its twenty-fifth birthday, which has been commemorated by the issue of a special number, with an artistic cover, containing a number of contributions by well-known Dutch writers on agriculture with facsimiles of their signatures, a history of the "Indische Mercur" by Mr. de Bussy, &c., &c., and numerous illustrations. Among the papers is a reprint of the *in memoriam* notice, by Mr. F. W. Van Eeden, of Mr. J. C. B. Moens, formerly the director of the Government cinchona plantations in Java, who died in 1836, and who once paid a visit to Ceylon. We congratulate our contemporary on having reached the quarter-century of its existence, and wish the "Indische Mercur" a long career of usefulness.

UDAPUSSELLAWA PLANTERS' ASSOCIATION.

REPORT FOR 1902.

P. A. MEETING.—There has been four general meetings held during the year and which have been fairly well attended, the average attendance being about 14, the number of estates on list is 26, being same as last year.

FUNDS.—The funds of the Association are in a satisfactory condition.

TEA.—The yield for the year has been a fairly average one, though there has been a falling off during the past three months. The district prices have been well maintained and have on several occasions shown stand out prices.

ROADS.—The main road during the past year has been kept in very fair order, considering the railway works are being carried on and credit is due to those

in charge for having kept the road open at all times.

MINOR ROADS.—Generally are in good order.

POSTAL.—It is to be hoped that Government will give the District a Post and Telegraph office at Ragalla when the railway reaches this point.

LIGHT RAILWAY.—Beyond a certain amount of earth cutting little has been done during the past year, and this Association hope to see more rapid progress in the near future. A connecting road from Maturatta to Brookside is a necessity, if the railway is to receive Maturatta Produce.

TATAPARAI SCHEME.—So far as it has been tried appears to work satisfactorily.

LABOUR.—Is none too plentiful though in a fairly settled condition, advances are normal.

RIFLE CORPS.—Has now being formed and consists of 17 members. Range has also been settled upon at Dickson's corner and is now being made.

CONCLUSION.—Although the prices for the first six months were not so good as last year a very decided improvement has now set in, and it is to be hoped we have heard the last of depression in the tea industry as a decided better tone appears generally both at home and in Ceylon.

NUWARA ELIYA PLANTERS' ASSOCIATION.

REPORT FOR 1902.

The past year has not been an eventful one as far as this Association is concerned, and consequently it has not been necessary to call many meetings.

The number of members who have paid subscriptions individually or on account of estates is 19, as against 18 last year.

The annual official estimate of tea crop for 1903, is as follows:—

	Estates	Total Acreage	Bearing Acreage	Estimated
				Crop lb.
Nuwara Eliya	} 20	} 6,720	} 6,615	} 3,118,500
Ramboda				
New Galway				
Kandapola				

—the estimate yield being at the rate of 471 lb. per acre, as against 466 lb. for 1902.

The past season has not been altogether a satisfactory one as regards yield, the main factor in bringing about this result has been the abnormally wet sunless weather during the latter part of the year, coupled with a considerable amount of damage done in certain properties, by frost in the first quarter of the year. The price for high-grown tea has continued to be disappointing

LABOUR.—During the first half of the year was fairly plentiful, but few estates are as fully supplied as could be wished to meet the demand, which may be expected in the ordinary course during the second quarter of the year.

INCREASED ADVANCES.—Your Committee regret that owing to the scarcity of labour coming in from the coast, advances are increasing and at the moment stand at rather a higher figure than they did at the same time last year.

THE TIN TICKET SYSTEM AND REGISTRATION OF ESTATES—has worked satisfactorily during the year, and will prove, we trust, a great boon to planters generally.

PESTS AND BLIGHTS.—Your Committee is glad to report that the district has been free of them during the year.

HEALTH.—The general health of the coolies in this district has been quite satisfactory and there has been complete immunity from any serious epidemic.

RICE—during the year was rather cheaper, but the price is still rather high.

RAILWAY EXTENSION FROM NUWARA ELIYA TO KANDAPOLA.—The resolution passed at the last meeting of the Association having been forwarded to Government, Mr. Oliver, the Chief Resident Engineer of the Northern and Udapussellawa Railway extension, was dispatched to meet a deputation of this Association com-

posed of Messrs. W A Mooyart-Denison, C J Bayley and S P Blackmore, with whom were associated the Provincial and District Engineers (Public Works Department) who kindly attended to the invitation of your Committee. The deputation pointed out to Mr Oliver some of the most dangerous places where the railway encroached on the cart-road. These, he proposed himself to have fenced off with wire, and in a few instances to limit projecting corners. In the opinion of your Committee these minor protections are quite inadequate to make the road (the only road of any merit as a drive for residents at the Sanatorium) safe for horse traffic, which it must be made, for local purposes.

FINANCES.—The finances are in a satisfactory condition. The credit balance is R97'51, as against a balance last year of R85'76.

(Signed) S. P. BLACKMORE.

PRICE OF RUBBER.

A very determined effort is being made to raise the price of india-rubber. We are favoured daily with all sorts of reports about it, and if we had taken it seriously every time we were told it was "a penny up," we should now be in despair. We hope in the interests of the Trade to have no higher price; manufacturers do not want 1897-1898 to be repeated.

A meeting is supposed to be held annually which is kept strictly secret of various rubber dealers. The chairman produces a lot of tickets which have got quite faded and black from age and long usage, and taking one at a time, the meeting discusses its chances. The first is headed "flood," and describes how that the rains have been so heavy that the floods have not yet subsided. The rubber gatherers are waiting, but as yet the water covers the earth, and nothing can be done. So much time has been lost that it will be quite impossible to gather sufficient rubber before the rainy season begins again, and a short crop and high prices are inevitable. The next card is quite topsy-turvy. Here the rains have been so slight that the rivers are quite unnavigable. The rubber is there, but getting it down to the ports is the difficulty. The rivers are not likely to rise before the season ends so a short crop, etcetera. The next card is a terrible picture. We would turn from it in horror. It depicts fever-stricken men left to die in misery and solitude, while others are escaping by any possible means from the pestilential land. It would be simply inhuman to expect rubber to be gathered under such conditions. The crop will not simply be short; it will be a mercy if there be any crop at all. These are the three chief trump cards. There are others of lesser importance, but which have at times come in handy. The shortness of silver does duty occasionally, though that might reasonably be expected to work the other way. If a gatherer has to bring two pounds to get his silver dollar instead of one, there should be all the more rubber. But the card is used all the same. Then the native is getting so well off that he will not work. They have all done duty many times before; one or other of them has turned up every year, when the crop was 5,000 tons, and when it has got to 25,000 tons. The only one we have any sympathy with is the shortness of silver. We often feel that way ourselves. The meeting drags them all out, considers carefully which is the most likely to be swallowed this year and adopts it. Then, through the whole of the india,

rubber manufacturing world, for some weeks nothing else is heard but this. Somehow, rubber buyers always seem to take the bait. They remind us very much of that stockbroker whom one of our contemporaries recently spoke of. The man had a dream; dreamed that he was dead, and had passed to the regions beyond, where, as a new comer he was shown round by an older inhabitant. They came to a place where the fire was terribly hot, but men were walking about in it unharmed. To his inquiry who these were his companions expressed surprise. "Why do you not know them? They are your clients. They are so green they will not burn."

Rubber manufacturing for some years has not been very profitable, and with increased competition and indifferent trade, the outlook is none too bright. The attempt to rig the price of the raw material must be nipped at once or it may do harm. The remedy is easy, in our opinion. Let the larger manufacturers agree that if Pará goes over 3s 6d they will close their works till it comes down. They will not be closed long, and as their chief lines are in things the rival firms are unable to tackle, they will lose no trade by it. They will do themselves and the whole trade a service.—*India-rubber Journal*, Jan. 5.

MR. WILLIAM JACKSON AND HIS PATENTS.

Mr. William Jackson of Tea Machinery fame now informs us that he cannot say much about his new "Planet" Tea Rolling machine, that would be of general public interest at the moment, beyond the fact that his experimental tests in New Peradeniya factory, with this machine, have satisfied him that a satisfactory Roller will be the outcome of his exertions.

Mr. Jackson leaves for England as soon as he possibly can, to have the results of his experiments put into practical form, and hopes to have the improved "Planet" at work in the Island before the end of the year.

His liquid-fuel burning arrangement, as applied to a Paragon Dryer at Labookellie, Ramboda, is giving every satisfaction we hear. This apparatus requires no steam for its use, is very simple and easily handled by the cooly-attendant, and maintains an even temperature of 200 deg. or more if desired, with a consumption of about four-and-a-half gallons Liquid fuel per hour. This includes time for getting up heat when starting, and loss by machine occasionally running empty. The Liquid fuel costs about 12 cents per gallon in Colombo and the actual cost will vary on different gardens, in relation to the cost of transport, but generally speaking the cost per gallon on gardens, within reasonable range of the railway, will be from 20 to 30 cents.

The advantage of this compressed-air system of burning liquid fuel, are clearly set out in circulars that may be obtained from Messrs. Walker Sons & Co., Ltd., or the apparatus may be seen daily at work on the Labookellie Garden, by appointment with the Manager there.

RANGALA PLANTERS' ASSOCIATION.

REPORT FOR 1902.

Your Committee in discharging its duty begs to submit the third annual report of the Rangala Planters' Association.

REGISTER.—The number of subscribers is twenty-one.
MEETINGS.—There have been three general and two committee meetings during the year, at which the attendance was good.

ACCOUNTS.—A statement of the accounts is laid upon the table, shewing a balance of R36 55 to credit.

OFFICIAL ESTIMATES.—The total crop of 1903 is estimated at 2,093,000 lb., out of which 150,000 will be made into green teas.

TEA.—The feeling of confidence expressed in the last annual report was not altogether warranted, and the season has not been so favourable as was anticipated; owing to the inclemency of the weather yields have, with a few exceptions, been less and prices have ruled somewhat lower. The year closes with a firmer and more confident tone.

CARDAMOMS.—The crop for the last year has been the largest secured, being 56,000 lb. over the previous season. The pickings during the latter half of the year were exceptionally heavy, the dry spell of weather in the early part of the year suiting the higher-lying estates. Most of the crop secured from September to December is still in store, and the quantity being large, will add considerably to the exports for 1903, which it is estimated, will slightly exceed last year's outturn. Very little new land has been added to the planted area, only a few acres here and there having been opened up. The cultivation in native lands has quite come to a standstill owing to the fall in prices.

LABOUR.—The labour-supply in the district remain much the same as usual, and whereas some estates are short-handed, others have maintained the labour forces up to requirements. Your committee would recommend special efforts being made to recruit for new districts; with the tin-ticket system and a competent recruiting Agent this seems feasible.

HOSPITAL.—The unofficial Hospital Visitors report satisfactorily on the Hospital at Teldeniya and the Ferndale Dispensary. Their reports and recommendations will be laid before you.

POST AND TELEGRAPH.—The telegraph line was opened to the public in February and has proved a great benefit; but a new Post Office at Teldeniya to combine both the Postal and Telegraphic business is desirable.

LIGHT RAILWAY.—A sub-Committee was appointed to collect statistics in connection with the proposed extension to Teldeniya and the project is under consideration.

POLICE.—The scheme for amalgamating the present Police Forces into one central station at Teldeniya was suggested by the Government Agent; it is hoped that the alteration which promises a more thorough system of patrols in co-operation with the headmen, will have the desired effect of better efficiency.

LABOUR FEDERATION.—No cases have been brought before the General Committee and matters are working harmoniously.

CEYLON PLANTERS' RIFLE CORPS.—The C.P.R.C. has been well supported during the year, and the shooting as compared with the previous year has greatly improved, there being seven marksmen, four extra-efficient, two efficient, and two non-efficient, whereas in 1901, there were one marksman, five extra-efficient, seven efficient, and five non-efficient. It is to be hoped that all new-comers will join the corps. The new drill ground is in a central position, and if possible a new range will be made.

MAIN ROADS.—These have been kept in good order through the year.

MINOR ROADS.—The sums voted by the District Road Committee have been advisedly spent and these roads are much improved.

THE GANGAWATTA ESTATE COMPANY OF CEYLON (LTD.)

REPORT OF THE DIRECTORS.

Acreage : Tea in full bearing ...	335 acres
" partial bearing ...	2 "
" not in bearing ...	8 "
Grass land ...	10 "
Total ...	355 acres.

The Directors beg to submit their Sixth Annual Report and Statement of Accounts for the year ended 31st December, 1902.

The total Crop of tea secured for the year, including 12 lb. carried over from season 1901, amounted to 188,135 lb., against an estimate of 170,000 lb. a most satisfactory result in the face of a season, the second half of which has been almost universally unfavorable.

The whole of the crop, save 10,500 lb. on which a safe average is struck, has been sold, in Colombo, and has realised R67,175'94, or an average of 37'82 cents per lb. as compared with 38'62 cents in the previous year.

The yield is 560 lb. per acre.

The cost of production, including 1'98 spent on manure, works out 25'13 per lb as against an estimate of 26 cents. In the expenditure is also included a sum of R1,075'29, cost of repairing the dam, an unexpected item, and of course unprovided for.

92 acres were manured on the Bitterne Division with artificial manure. This completes the first round of manuring the property.

The Working Account shows a net revenue of R23,475'94, to which has to be added a balance from last season of R158 and R2'50 transfer fee. Out of this an interim dividend of 3 per cent has been paid absorbing R5,355. After providing for interest (including interest on mortgage), for Superintendent's Commission, Auditor's and Secretariat Fees, there is an available surplus of R13,947'55, which the Directors propose should be apportioned as follows : -

	R. c.
To Final dividend of 4 per cent ...	7,140 00
To depreciation Account ...	1,050 00
To Reserve Account ...	4,503 67
To Directors' Fees ...	1,000 00
To Balance to next season ...	253 88
Total ...	13,947 55

The Estimate for 1903 points to a crop of 180,000 lb, expected to cost R47,584'75, including cost of manure R5,180'00.

In terms of the Articles of Association Mr W Anderson retires by rotation from the Board of Directors and is eligible for re-election.

The appointment of an Auditor for the current year rests with the Meeting.

The Directors wish to record the loss they have sustained by the sad death of their colleague, Mr Shelton Agar, since their last Meeting.

KALUTARA PLANTERS' ASSOCIATION,

THE ANNUAL REPORT, 1902.

Your Committee beg to present the annual report for 1902.

MEMBERSHIP.—The number of estates on the register is 28, one less than the number last year.

MEETINGS.—Two General, three Committee, and three Sub-committee meetings were held.

CROP ESTIMATE.—

	Total	Acreage	Total
	acreage.	in bearing.	tea crop.
1903 ...	16,692	16,045	6,977,265
	Green Tea.		Native Tea.
	2,206,265		139,500

—139 acres of tea-land were abandoned during the year.

	1902.
Estimated Crop ..	6,970,743
Actual Crop ..	6,672,519

LABOUR.—The supply of the district has been fully good during the year, but more use has been made of the resident Sinhalese than in late years. Recently instances have occurred of the agents of other districts trying to recruit labour from us, and the general feeling at the close of the year was that the force was becoming unsettled, with a more or less general demand for increase of advances, which at present stand at a low average rate per head.

THE MARKET.—for low country teas was very weak during the first part of the year, but latterly there has been some improvement, and the present year opens with much brighter prospects.

GREEN TEA.—During the year 1,149,500 lb. of green tea have been made, which have found a ready sale at remunerative prices.

PARA RUBBER.—Several small clearings have been opened, and there are now about 360 acre- in the district planted with rubber only, and it is estimated that there are 300,000 trees and plants of various ages growing through the tea.

CROP.—The output of the district shews a very considerable increase over that of the previous years, amounting to 7 tons of cured rubber, against 3½ tons in 1901. The excellent quality of our rubber has been well maintained and although the extreme price realised early in 1901 has never since been obtained prices for Ceylon rubber in London continue to be considerably higher than the average paid for rubber from any other part of the world.

SEED.—There has been a brisk demand for seed and plants during the year. Out of 1,300,000 seeds sold, only 414,000 were sent out of the Island, all the rest were despatched to various parts of Ceylon, the Kelani Valley taking the greater quantity, as well as most of the 460,500 plants, which were sold by various estates.

EXTENSIONS.—Next year some 450 acres will be opened in rubber, and most estates are now planting it more or less generally through the tea. The amount of land suitable for rubber cultivation is not large, so that the output will necessarily be limited.

In view of the great probability of rubber being stolen, a sub Committee consisting of the Chairman, Secretary, and Messrs Tipple & Bagot, was formed in April to consider this question. The matter was referred to the Committee of the Planters' Association of Ceylon and is now in the hands of our Member in Council.

TELEGRAPH EXTENSION TO NEBODA.—Your Committee are glad to be able to report that the telegraph office at Neboda, which this Association has been agitating for since 1893, is to be opened very shortly.

POSTAL ARRANGEMENTS.—The postal service, which year Committee stated in last year's report was most unsatisfactory, has been altered and now gives general satisfaction. The thanks of the Association are due to the Postmaster-General for running the two services as asked for.

PROVINCIAL ROADS.—The very meagre expenditure allowed on these roads has made it impossible for the Department to maintain them in a satisfactory condition. To maintain the roads in even passable order at least double the money is required, and your Committee hope that during the ensuing year more liberal votes will be sanctioned.

DISTRICT ROADS.—The residents much appreciate the work which has been done on the Tebuwana-Anguratota bridle path, but the great proportion of the road is unfit for traffic, three bridges being in an unsafe condition. The minor roads generally are in fair order, but on some, notably the Tudugala-Tebuwana road, over which there is considerable transport of leaf and tea, the amount allowed for upkeep and repairs is quite inadequate.

CRIME.—Your Committee regret to report a marked increase of crime in the district, chiefly in the form of burglaries, highway robbery, cattle lifting &c. Efforts to bring the criminals to justice are but very partially successful, and your Committee cannot think that if a better watch were kept on the movements of numerous bad and doubtful characters, who live in the district without having any visible means of support, much might be done to improve matters.

The C P R C.—Your Committee are glad to report that the Planters' Rifle Corps has been well supported during the year.

The KALUGANGA NAVIGATION COMPANY.—A steamer service under this title has been running between Kalutara and Anguruwatota since April of this year, and your Committee would report the very high appreciation of the district for this great step in transport facility. From the point of view of the shareholders the results have not been at all satisfactory, but the district is to be congratulated on the data and figures of traffic which the 8 months' working showed. Under new auspices and on a basis more fitted to obtain traffic there seems no reason why this service should not become permanent and be a success in the future.

FINANCE.—The balance in the Bank at the close of the year amounted to Rs39.29; there is a further sum of Rs50 on loan to the Kalutara Cricket and Sports Club.

DOLOSBASE AND YAKDESSA P. A.

ANNUAL REPORT 1902.

MEMBERSHIP.—The number of subscribers to the Association was 35 including 2 private votes.

MEETINGS.—There were two general and three Committee meetings held during the year.

FINANCE.—The balance at credit was R178.15 plus R5.94 due to the Association by the Nawalapitiya short cut making a total of R184.09.

SEASON.—The past season has not been a good one. Crop has been generally short owing to unfavourable weather and other causes. The market at the same time has been the lowest on record.

THE ESTIMATE OF CROP FOR 1903 is as follows:—

Average in tea	16,316	
do do bearing	15,901	
Black tea	5,907,500	
Green tea	285,000	6,192,500
Native leaf		154,000
Total		6,346,500

This being 389 lb. per acre against 400 in 1901.

LABOUR.—The supply during the year was sufficient on most estates a few only being short. Your Committee is pleased to be able to state that the services of the Federation Committee were not requisitioned.

TIN TICKETS.—Your Committee considers that the Tin Ticket system has worked admirably.

PESTS.—Your Committee regrets that the district has not been free from pests during the past year. Helopeltis appeared on some estates and Borer has doubtless accounted for some of the shortage on others.

RIFLE CORPS.—A section has been formed during the year and a Rifle Range established at Penny-lan.

CEYLON NURSING ASSOCIATION.—Your Committee recommends Superintendents to ask their Proprietors or Agents to allow them to subscribe annually on estate account to this excellent institution.

MATALE PLANTERS' ASSOCIATION. THE ANNUAL REPORT.

In bringing forward the report for the past year, your Committee has pleasure in being able to state that the position of the Association continues to be satisfactory. The number of estates on the register is 63 against the same number last year; the finances are in a satisfactory condition, the meetings have been well attended and the various subjects discussed have been followed with keen interest.

Following our custom the reports on the different products of the district have been written by members specially interested in each. The position of tea has if anything, improved since last year and we may add that the Association is satisfied with the manner in which the XXX Committee deal with the interests of our staple, Cocoa is agriculturally in a sound position and prices are better than last year though still rather uncertain. The heavy rains of the last three months of 1902 did a great deal of damage and caused serious loss to what promised to be a very favourable crop, also producing recrudescence of canker. The crop picked for the year, however, was a satisfactory one and probably the largest the district has ever sent away. The cocoa stealing question is in the hands of the Planters' Association, that body having on the 4th November last unanimously adopted a resolution brought forward by your Chairman. His Excellency the Governor intends to appoint a Commission to enquire into the question. The delay which this will cause is very disappointing and in the opinion of your Committee unnecessary, as the facts on which the Association rests its case, have been put into pamphlet form and can be enquired into at any time. These facts were accepted as establishing a grievance, when a deputation waited on the Lieutenant-Governor on 28th June last, and we were then told that what was necessary to enable Government to take up the case, was a favourable expression of native opinion: that expression of opinion has been obtained. A large and influential deputation of native cocoa growers, headed by Mr Daniel Joseph, waited on the acting Colonial Secretary in September last and obtained a favourable reply. Lists were circulated amongst the native proprietors for signature and were signed by over 600 owners. The following paragraph headed these lists in English, Sinhalese and Tamil and was drafted word for word by the A G A of Matale, and approved of by him, before the lists were sent round for signature. That paragraph is also word for word the resolution which was passed by the P A on the 4th Nov., last, so that the Planters and A G A of Matale, who has devoted special attention to this question, are at one on this point; and the conditions demanded by the Lieut-Governor have been fulfilled and yet the case has been delayed. Assuming however that a Commission is necessary, it is difficult to understand the delay in appointing one which has taken place since the opening of the Legislative Council, and by which, any legislation is postponed for another year and until His Excellency Sir J. West Ridgeway has left the island. Your Committee can only express its disappointment and surprise. The paragraph referred to is:—

SPECIAL LEGISLATION FOR CACAO STEALING.—“We, the undersigned, are of opinion that the law, as it now stands, is not sufficient for the protection of cacao-proprietors. We would, therefore, respectfully suggest some amendment of the Prædial Products Ordinance, which, while continuing to make the possession of green cacao without a satisfactory account of such possession an offence, might also provide against the dishonest possession of ripe and cured

cacao. We should also be grateful for any protection against 'receivers' which the Government may be disposed to grant."

Your committee is of opinion that the cultivation of Para rubber and coconuts, as being valuable adjuncts to that of cocoa, can be largely extended in this district. The growth of *Castilloa* rubber in Matale is also very satisfactory.

The unlicensed sale of toddy in this district continues almost unchecked and causes a deplorable amount of drunkenness amongst our coolies, and is a constant incentive to theft of produce from the estates. The A. G. A. of Matale recognises the evil in the last Administration Report of the Central Province and remarks "I have no reason to believe that offences of this kind could be put down except by fresh legislation."

RAILWAY—Your Committee wishes to thank the General Manager for the alteration of the afternoon train, so as to give an additional train to Colombo in the day. A serious washaway occurred on the Matale line in November last, and caused great inconvenience by the stoppage of traffic. Your Association addressed Government on the subject with the result that the aerial railway lately in use at the Boer Camp will probably be acquired by Government for use on such occasions. Your Committee also hope to see an emergency gang of coolies under skilled supervision, formed by the Railway authorities, to take slips and washaways in hand directly they occur. In accordance with the request of this Association a Goods Shed has been erected at Ukuwela.

POST OFFICE.—Your Association addressed the other Associations of the island on the subject of the extension of hours for postal money order business and received an encouraging amount of support.

LABOUR.—Sinhalese are largely employed in the district, and where they are available it may be said to be fairly well supplied with labour, but the supply of Tamil labour is insufficient. Difficulties between kanganies and superintendents, or between superintendents, are happily few and far between in Matale, so that the Labour Federation does not receive the attention that might otherwise be the case.

The C M I AND THE C P R C are well supported in Matale, the number being 11 for the former and 24 for the latter, and efficient are: C M I 11 and C P R C 19.

TEA.—Extensions both in India and Ceylon are very limited, and consumption is increasing in every country. The American demand for our greens is highly encouraging, and the rapid increase in the consumption of our teas in Russia is a most promising nature. The industry appears to be on a sounder footing than it has been for years. The yield for 1902 has been somewhat larger than last year, on most estates, owing to the very favourable weather during the early part of the year, and the falling off in yield during the last quarter was owing to the continued wet weather, and there has been no serious drought or pest in the district during the year under review. The rainfall on one estate which might be taken as typical, was at the end of August, only 3.90 inches ahead of last year, but at the end of December was 34.92 inches in advance of 1901. Manuring has perhaps been done to about the same extent as last season, with beneficial results, but it is to be hoped that this will not be overdone, with the tempting prices now ruling for our teas. The style of plucking in vogue on most estates in 1901, has been generally adhered to during the past year, and will, we hope, be continued. Prices ruled very low for the first nine months, but took a welcome turn upwards during the last quarter, and the year closed with fairly good prices, and good prospects for the new year, should the output be kept within reasonable limits. Very little green tea has been made in the district, and we are of opinion that the increase in the tea cess will be very beneficial to Matale.

The comparative figures for the year under review, and for 1903 are as follows:—

1902	Total, acreage in Tea.	Acreage in bearing.	Balance young plantings.	Estimated Crop 1903 including greens.	Tea returns.
1902	19,566	17,345	2,221	7,613,215	—
1903	19,459	18,403	1,056	8,362,575	148,000
Increase	—	1,053	—	749,360	—
Decrease	160	—	1,164	—	—

1902	Black Tea Estimate.	Yield per acre.	No. of Estates.	Native leaf.	Tea banded.
1902	7,613,215	413	79	no return	407
1903	8,214,575	454	80	61,750	330
Increase	601,360	36	1	—	—
Decrease	—	—	—	—	77

COCOA.—The agricultural position has improved in the district during the past year, and it is noteworthy that those estates which suffered first from canker and disease, are now better than they have been before. Those that were attacked late, are recovering, whilst some estates which have only recently been attacked, have their struggle before them. It is satisfactory to know from our experience, that this struggle will in all probability be successful. Speaking generally Forastero has maintained a comparative immunity from disease, and it is probable that as the acreage of red cocoa decreases this immunity will be more marked, as less disease will be harboured on estates, and hybridisation with the weaker variety will not be so frequent. It will be seen, therefore, that a constant importation of a fresh stock of plants from the West Indies, and elsewhere, is very important to maintain the strength necessary to resist disease amongst our trees. At the representation of the Cocoa Committee, Government has arranged for a fresh importation of plants, but this should be made an annual occurrence, so that later on a fresh and healthy supply of seed could be always available. The past year promised to be a record one, as regards crop in Matale, and although probably more cocoa has been sent away last year than ever before, the Autumn crop has been a disappointment on some estates. This is entirely owing to unfavourable weather in the North-East Monsoon. Considerably more rain fell in October, November and December than in the preceding nine months of the year, and the consequence was a recrudescence of canker especially amongst the pods, by which the crop suffered very seriously, both in quantity and quality. Prices have been better during the past year, and a satisfactory point is that our Forastero Cocoa is now going readily in consumption in England. Also it is to be noted that a considerable quantity, cwt. 8,641 was shipped East from Colombo, thereby giving our produce another outlet and taking what is probably inferior cocoa off the home market. The acreage of European cocoa estates in Matale is as nearly as can be ascertained 8,465 acres, of which 7,000 are in bearing—that of native owned cocoa is given by the A. G. A., Matale, at 2,230 acres. This is not supposed to be more than approximately correct, and having been estimated by headmen, whose ideas of area are vague, is probably exaggerated. The native cocoa is younger than that on estates, so that even accepting the above as correct, it is a liberal estimate to take 1,500 acres as in bearing. The Railway returns have unfortunately not yet been received in a complete form, but such figures as are available point to an average yield of 2 cwt per acre. Cwt 1,137 were sold to natives by Europeans. Cocoa stealing has been fully dealt with elsewhere, and it is sufficient to point out that the legislation, which the A. G. A., of the

district and the growers of cocoa, both European and native, agree in thinking necessary, is nothing new. By Ordinance 22 of 1886 cinchona was protected in the following manner:—

‘Whenever the bark of the branch, root or stem of the cinchona shall be found in the possession of any person who is unable to account for his possession thereof, such a person shall be deemed and judged guilty of an offence and shall on conviction, be liable to the punishments provided for theft of prædial products under section 368.’ To which lashes might be added. This protection was obtained for the up-country planters by Mr Thomas North Christie, and never pressed unduly on any honest man. Your Committee wishes to point out that the Madras Act has failed, because it is found impossible to exercise sufficient check over the owners of native gardens, and this is precisely the difficulty here. The Grenada Ordinance had to be amended, so as to make it similar to the Cinchona Ordinance mentioned above, with the addition that any person convicted under it *must* be lashed in addition to any other punishment. In fact, it seems, in dealing with such a subject that the protection given to cinchona in Ceylon, is the only feasible protection, as we find the Mauritius Ordinance for the protection of vanilla to be exactly similar. Your Committee recognises and appreciates the efforts made by the A G A, of Matale, Mr Alexander, to suppress cocoa theft, but individual effort is not the proper thing to rely on in such a matter. Officials are changed, then often the previous policy is reversed; as an instance, we quote from the P.A. report of 1895, in dealing with this subject.

‘The acting Government Agent, Central Province, has threatened the headmen that unless cocoa stealing is prevented and put down, a force of police will be quartered and maintained at the expense of any village where such thefts prevail.’ This promise has not been kept. If it had been, it is probable that the demand for special legislation, would not have been necessary.

CARDAMOMS.—Extension among European and native cultivator go on apace, almost every pocket of forest suitable is destined for this cultivation. At present, Matale district alone has probably 2,000 acres under cardamoms, or about 1-5th of the total cardamom acreage of the island. The cardamom estimate for 1902 was 600,000 lb, for the island, but the total crop shipped was 615,922 lb, and a large portion remains to be shipped during the early months of 1903 which will add considerably to this year’s crop. The total estimates for 1903 are not likely to be short of 700,000 lb.

COCONUTS.—Coconut planting in Matale is steadily increasing both amongst natives and Europeans, but on European-managed estates they are generally grown as an adjunct to other cultivations, so that it is difficult to give an accurate idea of the area under this product. It is found that a distance of 25’ to 30’ apart is the most suitable for planting in this district and where trees are in full bearing, the yield has been found to be exceptionally good. There is no doubt that all the lower parts of the Matale Valley are well adapted to this cultivation, which should pay handsomely.

PARA RUBBER.—Report by Mr F J Holloway:—The chief points to be cleared up concerning this product are in what soil, and at what elevation can Para rubber be profitably grown:—On Kemitagalla there are trees growing from 500 feet to 1,500 feet above sea level, and on keeping a careful record of yield at the highest and lowest elevation, the result has been that the yield is practically the same, although the trees are smaller in growth higher up age for age. And so to soils, they seem to yield well in most soils, except in a sandy one, where they will not yield anything. As to yield I will quote from my letters to the ‘Times of Ceylon’ and Ceylon Observer of Aug. 22nd, 1902:—

Number of trees tapped once... 3,903
Dry rubber from 1st tapping ... 2,128

or just over half a pound per tree, some of these trees were tapped again and gave equal results, thus making 1 lb rubber per tree per year. Each tree should be tapped twice a year and will yield more as it gets older. Trees tapped were 8 to 11 years old.

And now as to cost of production.

Dry rubber gathered from January	
to May, best quality 1,302 lb	
Scrap ...	60 lb equal to 1,362 lb.
Cost of tapping and curing 1,362 lb rubber	R570 63
Transport rail fare, boxes, &c.	.. 31 13
Tapping knives, tins, &c.	.. 36 60

Total cost in Colombo.. R638 36
on an average cost of 46-86 cts per lb sold at an average price of R2.63 per lb. The cost has been further reduced to 45 cents at end of October, and later sales averaged 3s 11d. The average quantity brought in by a cooly per day was nearly one lb when dry. Seed being plentiful and cheap, it would not cost R7 per acre to plant up this rubber on the suitable portions of existing estates. The exports of dry rubber will probably exceed 12 tons this year. The price of Para rubber has risen from 3s 0½d at the beginning of the year to 4s at the time of writing, but the latter price has only been procured by Ceylon marks—no other part of the world fetching anything within 6d of this price.

CASTILLOA RUBBER grows well all over the lower parts of Matale, and seems to thrive in a dry climate, and on hillsides, as well as in flat and damp situations. On Ambanganga estate, which is devoted to the cultivation of this variety of rubber, the growth is exceptionally fine and promising. As far as experiments have gone in tapping trees of this variety the yield has been satisfactory, and there is every reason to look for good results.

The Hon. SECRETARY then brought up the following statement of accounts, which was passed:—

1902			
December 31st.	R. c.		R. c.
By balance from 1901	.. 94 51		
Do 63 subscriptions at R5	.. 315 00	—Total	409 51

B H JENKYNs, Hon. Secretary, December 31st, 1903.
Audited and found correct.—J B TENNANT, January 15th, 1903.

MORAWAKKORALE PLANTERS’ ASSOCIATION.

THE ANNUAL REPORT.

The following Report of the Committee for the year 1902 was read and adopted on the motion of the CHAIRMAN:—‘Your Committee, in submitting the first Annual Report of the Morawakkorale Planters’ Association, is able to congratulate you on the satisfactory status of the Association.

SCHEDULE.—The number of Estates on the register amounts to eight.

MEETINGS.—Five Committee Meetings and five General Meetings have been held during the year.

GENERAL.—Your Committee have carefully watched the interests of the district during the year.

FINANCES.—A statement of accounts is laid upon

the table showing R12'65 in hand, which is satisfactory at the end of the first financial year.

CROP.—For 1903 is estimated at 1,255,720 lb. against 1,243,918 lb. in 1902. Acreage in bearing, 3,175 acres at an average of 395 lb. per acre, and 110,000 lb. tea from native gardens. Nearly all estates in the district have fallen short of their estimates; the weather was not nearly so favourable for flush as 1901.

PRICES.—The tea industry has passed through another trying period in its history, but the closing months of the year brightened considerably. While viewing the present position with satisfaction, it is to be hoped that the producers may not be tempted by the temporary rise to adopt a coarser style of plucking. Your Committee would urge Superintendents in this district to continue the same style of plucking which has been in vogue for the past year.

CARDANOMF.—The area has not been extended to any great extent.

TELEGRAPH EXTENSION—from Rakwana to Deniyaya:—Your Committee record with great satisfaction the sanction, through 1903 estimates, of extending the line from Rakwana to Deniyaya and trust the Postmaster-General will have the work pushed on with all possible haste as this outlying and important district is under great disadvantages in this respect.

POSTAL ARRANGEMENTS.—Since the departure on sick leave of the late Postmaster, your Committee have noticed a great improvement. Letters and parcels have been handed over very promptly after the arrival of the mails, which have also come in with far greater punctuality than previously. The new Post Office is nearing completion, but in the opinion of your Committee the cost of the same is rather exorbitant.

JURY SERVICE.—With reference to this matter a resolution was forwarded to Government pointing out the great hardship entailed on residents in this remote district by their being called upon to serve once every year, and not infrequently twice, at the Matara Sessions. This resulted in the persons liable to serve in Tangalla being added to the list of jurors. In spite of this, however, two members of this Association were summoned to serve twice this year. Your Committee are of opinion that some further action on the part of Government is necessary to relieve residents of this unjustifiably heavy tax on their time and convenience.

GOVERNMENT CART ROAD FROM AKURESSA TO VIHARAHENA—has been in a most disgraceful state for several months of the year. The fault of this road chiefly lies in there being no foundation to it. An extra grant has been passed in Council for R3,000, but your Committee are of opinion it is insufficient for what has to be done. A "Special Report" was to have been made after which they hope a more liberal vote will be allowed.

MINOR AND GRANT-IN-AID ROADS.—In fair order with the exception of the Deniyaya-Hayes Road, which was originally constructed so badly.

MEDICAL ARRANGEMENTS.—Deniyaya Hospital:—It is to be regretted that Government have not thought fit to entertain the suggestion of erecting a Village Ward which, your Committee thinks, is an absolute necessity.

HOSPITAL VISITORS.—Your Committee consider that the thanks of the Association are due to the Hospital visitors for the past year.

LABOUR.—The Labour supply has been insufficient for requirements in some instances.

ADVANCES.—In mostly all cases, may be considered satisfactory, for an outlying district such as this. Your Committee are happy to state advances are on a downward tendency.

PESTS.—With the exception of *Helopeltis* which has attacked some estates rather severely, no pests have been recorded.

CEYLON NURSING ASSOCIATION AND THE BENEVOLENT FUND.—An appeal on behalf of these having been received, it is to be hoped members of the Association will give them their support,

In conclusion your committee congratulate the members of this Association on the results obtained during the first year.

Signed. E. R. E. Geddes, *Chairman*,
 " Roland J. Trimeu, *Hon'y. Secy*,
 " Edw. C. Anderson,
 " Rodney Mylius, } *Committee*
 " Geo. Thain Davidson, } *Members*.

SCIENTIFIC NOTES.

A German newspaper records the following explanatory incident, apropos of a recent act of the Kaiser, in appealing to his people for support in a good work. Dr. Dohrn of Naples, having appealed with little result to the German Minister of Education for financial aid in the extension of his world-famed biological station, sought an interview with the Kaiser. Remarking sympathetically that he could not provide all that Dr. Dohrn desired from his private purse, the Kaiser furnished him with a donation form, headed by himself and a contribution of £1,000, commanding that it should be circulated among the leaders in Berlin society, for return to the Kaiser in person. The result was that within a few days the magnificent sum of £15,000 was subscribed.

A message from the *Times* correspondent at Ottawa states that the promoters of the Canadian Marconi Company hope by the end of next summer to have a complete system of wireless telegraphy in operation throughout Canada, extending from the Gulf of St. Lawrence to the Pacific Coast.

Mr. Marconi was entertained at a banquet at Sydney on December 30 by the citizens of Cape Breton Island. Reuter reports that in responding to the toast of his health, Mr. Marconi said that when his system of wireless telegraphy was further developed, it would be possible for ships in distress to signal passing ships. The cable companies, when they began, charged pounds per word; they were now down to shillings, and his starting at ten cents might soon lead to a charge of one cent 3/4 per word and thus bind England and her colonies more closely together.

The *Daily Mail* states that Sir Ernest Cassel has offered to give £40,000 towards the study and investigation of ophthalmia in Egypt.

Prof. Robert Koch and two assistants, Surgeon Dr. Kleine of the Prussian Headquarter Staff, and Dr. Neufeld, of the Prussian Institute for Infectious Disease, are on their way to investigate cattle plague in Rhodesia. To the Berlin correspondent of the *Daily Mail*, Prof. Koch has remarked:—"I contemplate my mission with more or less misgiving, because the Rhodesian plague is of an absolutely mystifying character. Such symptoms as I have so far examined indicate that the disease is wholly indifferent from any species of rinderpest that has ever come under medical observation. What is peculiarly baffling is that the Rhodesian plague dates only from the late war. The cattle imported from Egypt, Australia and South America which it was supposed would prove immune, have fallen early victims to its ravages, which threaten to denude the entire colony of live stock. While in South Africa, I shall not neglect the opportunity of continuing my tuberculosis experiments with the view of adducing still more positive evidence of my theory of the non-communicability of bovine tuberculosis to human beings, which I, of course, adhere to resolutely."

The outbreaks of typhoid fever at Winchester and at Southampton again direct attention to the possibility of the typhoid infection being spread through the agency of shell fish, in these instances through oysters. Dr. Nash, in a report on an outbreak of typhoid fever at Southend-on-Sea, finds that the incidence of the disease was thirty-six times as great among shell-fish consumer as among those who do not eat shell-fish, and expresses the opinion that if the eating of shell fish were abandoned in Southend, the incidence of typhoid fever would lessen by fully one-half. In the Southend outbreak, cockles were mainly responsible for the spread of the infection.—*Nature*, Jan 8.

In a letter to Wednesday's *Times*, Sir Norman Lockyer states that several months ago he discussed with Mr Shaw, the secretary of the Meteorological Council, the desirability of obtaining information regarding barometric pressures from ships crossing the Atlantic, by utilising wireless telegraphy. It now seems probable that this idea will soon be practically realised, for in reply to an ethergram from Mr Marconi, Sir Norman Lockyer asked for help in this matter, and on January 13 received the following message:—"By wireless telegraphy.—Thanks for suggestion, hope to be able to do so soon, big westerly gale here Monday.—MARCONI." Sir Norman remarks that all friends of Science will be grateful to Mr Marconi for such generous and invaluable assistance which will undoubtedly be of enormous advantage to British meteorology.

An exhibition is being held in London of the results of what is described as a new process for the preservation of animal tissues, by the injection of a fluid, the composition of which is not made public. The process is said to afford a satisfactory method of embalming animal bodies and of preserving museum specimens in a condition closely resembling life. The period which has elapsed since the application of the process to the various preparations exhibited is said by the inventor to range from a few weeks to thirty years.

In a letter from Dr. Logan Taylor, the leader of the Sierra Leone expedition of the Liverpool School of Tropical Medicine, reference is made to the progress of the expedition in Sierra Leone. A very decided absence of anopheles larvæ in places where it was formerly easy to get any number has been noticed, and is due to their not being able to breed owing to the pools being either swept out or oiled regularly. Compared with the corresponding time last year, in some of the notoriously bad streets where in a single house as many as six, seven or a dozen anopheles mosquitoes could be found in the early morning this year, after searching house after house with great difficulty, one, or perhaps two, adult insects alone were discovered. Since the members of the Liverpool School expedition stopped clearing up yards and emptying out the water containing culex larvæ, no one else has taken up the work, and these insects are getting bad again, and unless the Government or the school will keep on the work, the money the school has spent on it will be almost thrown away.

Symons's Meteorological Magazine for December last contains a climatological table for the British Empire for 1901, so far as it can be shown by nineteen representative stations, but it is not

claimed that the records quoted furnish more than a few useful samples of the various climates included in the British dominions. The highest temperature in the shade was 110° at Adelaide, in February. A new station has been included, viz. Dawson, where a temperature of 50° in the shade was recorded in December, but the observations are incomplete. The highest mean temperature was 82°·1 at Colombo, and the lowest 36°·4 at Winnipeg. The driest station was Adelaide, mean humidity 59°; and the dampest Colombo, mean humidity 82°. The highest temperature in the sun was 168°, at Trinidad. The greatest rainfall was 114 inches, at Lagos, and the least 18 inches, at Adelaide. None of the extremes referred to can claim distinction as "records," but at individual stations the sun temperatures at London, 139°·8, and at Malta, 162°·9, are the highest observed there, and at London the number of rainy days, 123, is the lowest since these interesting tables were commenced.

The first three parts of the second volumes of the *Records of the Botanical Survey of India* have been issued. Mr J J Wood has compiled a list of plants mainly from the province of Chutiá Nagpur. This part includes a map of the district and two sectional diagrams. Mr Grammie has recorded the results of his investigations into plants used during periods of drought. For the purpose of making bread, seeds of species of *Indigofera*, *Cyanotis* and *Panicum* are used. Other sources of nourishment are the leaves of *Amarantus*, *Rivea* and *Leptadenia*. A systematic enumeration of the species of *Calamus* and *Dæmonorops*, by Mr O Beccari, is based mostly on plants growing on in the Malayan Peninsula and the adjacent islands, and only a few species belong to India or Ceylon.

"Tiree marble," with notes on others from Iona, by Mr Ananda K Coomaraswamy. [Now appointed Government Mineralogist for Ceylon.—*Ed. T.A.*] The gneiss near Balephetrish has a general south-westerly and north-easterly trend, and the limestone occurs in it as lenticles. Descriptions of the varieties of the limestone in this locality are given. The inclusions comprise those of gneiss containing quartz, felspars, hornblende, augite, scapolite and sphene as characteristic minerals, and mineral aggregates, consisting of sahite, coccolite, scapolite, sphene, apatite, calcite and mica. The contact-phenomena are not specially well displayed. The dynamic phenomena include the rounding of the minerals and the formation of "augen." The carbonates are present as a fine-grained granular matrix. Although there are exceptions, gneiss-inclusions and mineral aggregates have usually been protected from the effects of extreme pressure. The description of minerals includes carbonates, pyroxene, amphibole, fosterite, scapolite, sphene, mica, apatite and spinel. Various marbles are described from Iona, where they are associated with actinolite-felspar schists and others; they are included in the gneiss.—*Nature*, Jan. 15th.

"FOLIAR PERIODICITY IN CEYLON."—Mr. Herbert Wright's paper on this subject which appeared in full in our columns has since been reproduced in "Indian Planting and Gardening" and "West Indian Bulletins"; while abstracts have been given in "Annals of Botany, London" and in several home and Ceylon papers,

GLASGOW ESTATE COMPANY, LTD.

THE ANNUAL REPORT.

DIRECTORS:—Messrs. G H Alston, G C Walker and J G Wardrop.

E-STATE INSPECTOR:—Mr J K Clark, ESTATE SUPERINTENDENT:—Mr R W Kerr.

ACREAGE :

Tea in full bearing	630	acres
Tea partial bearing	41	do
Tea not in bearing	9	do
Grass	2	do
Jungle, &c	62	do

Total Estates .. 714 acres

The Directors have now to present their Annual Report and the Accounts of the Company for the past year.

The tea crop secured was 380,500 lb., against an estimate of 400,000 lb., thus showing a shortfall of 19,500 lb., which was due to the continued rain and absence of sunshine during the last 4 months of 1902. The average nett price realised was 41'66 cts. per lb., as against 43'66 cents for the previous season, which may be considered satisfactory.

The amount at credit of profits and loss account for the year's working was R73,902'54. The balance brought forward from last year amounted to R2,251'09 from which falls to be deducted R300'00, being extra fees for the Directors for 1901 working, in terms of the resolution passed on 18th February, 1893.

The sum therefore available for distribution is R75,853'63 and the Directors now recommend that a final dividend of 15 per cent be paid for 1902, making with the Interim Dividend of 7 per cent paid on 5th August last, a total of 22 per cent for the year, and that the balance of R1,353'63 be carried forward to the current year's accounts. It will be noticed that there has been no addition to the capital expenditure and any additions or alterations to machinery or buildings have been paid for out of revenue.

The estimate for the current year is 392,000 lb. Tea on an expenditure of R96,147'00. A sum of R3,000'00 will be required for a new Roller necessary to deal with the increasing crops from the estate. As notified in the circular posted to Shareholders on the 12th ultimo the entire crop has been sold at 50 cents per lb. *f.o.b.* Colombo, which may be considered very satisfactory.

During the year under review the Hon. Mr W H Figg resigned his seat on the Board, and the Directors appointed Mr G H Alston to the vacancy.

In terms of the Articles of Association Mr G H Alston now retires from the office of Director, but is eligible for re-election.

Colombo, 28th January, 1903.

UPPER MASKELIYA ESTATES CO., LTD

THE ANNUAL REPORT.

DIRECTORS:—Messrs Jas Polson, W D Gibbon and G H Alston, Estate Superintendent:—Mr L A Wright,

ACREAGE :

31st Dec. 1902.

	Brunswick	and Caskien.	Total.
	Bloomfield.		
Tea in full bearing	446	207	653
Tea not in bearing	10	—	10
Grass, Timber Trees, &c	62	—	62
	518	207	725

The Directors herewith submit to the Shareholders the Accounts of the Company for the past year.

The Crops amounted to 358,032 lb Tea, being 18,032 lb in excess of the Estimate, and realised a nett average of 33'75 cents which included the bonus granted on the manufacture of Green Tea.

The amount at credit of the year's working is R42,645'85 equal to 12'17 per cent on the paid up Capital of the Company, to which has to be added R1,561'88 brought forward from last year, making a total of R44,210'71 available for distribution.

The Directors now recommend that a final dividend of 7 per cent be paid forthwith, making with the Interim Dividend of 5 per cent paid on the 5th August last a total of 12 per cent for the year, and that the balance of R2 210 71 be carried forward to the current year's working.

The estimate for the present year is 350,000 lb of Tea on an expenditure of R94,885'05 which includes a sum of R11,767 to be spent on Manuring.

The Crop for the current year has been sold by contract as intimated in the Circular issued to Shareholders on the 1st of December last. The Thirty Committee bonus having now been reduced to 4 cents per lb the buyers have to pay the Company 37½ cents per lb of Green Tea.

In accordance with the Articles of Association Mr James Polson now retires from the Board, but is eligible for re-election.

Colombo, 28th January, 1903.

CEYLON PROVINCIAL ESTATE CO., LTD.

THE DIRECTORS' REPORT.

DIRECTORS:—J Paterson, Esq., Edward S Grigson, Esq., F L Clements, Esq.

The Directors beg leave to submit their Report for the year ended 31st December, 1902, together with a Statement of Accounts for the same period.

The Tea Crop secured during the twelve months amounted to 471,617 lb, against an estimate of 510,000 lb and is equal to an average yield of 484 lb per acre from the area in full and partial bearing. In the case of Glassaugh the Crop was fully up to estimate in the matter of quantity, but Brownlow fell short of expectations to the extent of close upon 40,000 lb. The finer or more careful system of plucking referred to in the last Annual Report was continued throughout 1902, and the Brownlow shortage is partly attributable to that circumstance, but chiefly to unfavourable weather in the latter half of 1902.

The Revenue and Expenditure Account shows the year's profit to have been R93,098'14.

The cost of production in 1902 has been 21'65 cents per lb, which includes 1'06 cents spent in manuring, as compared with 25'02 cents and 1'69 cents respectively for Season 1901.

The Crop has sold at an average nett price of 44'20 cents per lb. against 41'10 cents in 1901, and 42'56 cents in 1900.

During the past year the Company's liabilities have been decreased by the repayment of a loan of R20,000 thus reducing the "Loans on Mortgages" item in the Balance Sheet from R127,473'57 to R107,473'57. R10,000 of the sum repaid was set aside from the 1901 profits, and the balance of R10,000 has been met out of the past year's surplus as shewn in the Profit and Loss Account.

Including a sum of R3,144'58 carried forward from Season 1901, the Profit and Loss Account shows a balance at credit of R46,193'63 after payment of an interim dividend of 3 per cent interest on Mortgages, Bonus allowances to Superintendents, and provision made to the extent of R17,500 for Mortgage redemption and depreciation of Buildings and Machinery.

The Directors now recommend the payment of a final dividend of 6 per cent which will absorb R39,960 and make 9 per cent for the twelve months, and that the balance remaining, after payment of Directors' Fees, be carried forward to Season 1903.

There was no expenditure on Capital Account during the past season.

The Estimates for the new season point to a yield of 489,000 lb of Tea, to cost 25.14 cents per lb, inclusive of an allowance of about 2 cents per lb for manuring and burying prunings.

The following is a definition of the Company's properties as at the 1st January of this year:

	Glassaugh.	Brownlow.
Tea in full bearing	.. 469 acres	503 acres
Do in partial bearing	.. 21 do	— do
Do not in bearing	.. 2 do	— do
Total in Tea	.. 492 do	503 do
Fuel trees	.. 14 do	2 do
Forest	.. — do	33 do
Grass	.. — do	27 do
Scrub and Waste	.. 13 do	20 do
	519 acres	535 acres

Mr J Paterson retires from the Board in terms of the Articles of Association, and is eligible for re-election.

The appointment of an Auditor for 1903, rests with the Meeting.

By Order of the Directors.

GEORGE STEUART & Co., Agents and Secretaries.
Colombo, 30th January, 1903.

THE HIGH FOREST ESTATES CO., LTD.

REPORT OF THE DIRECTORS.

DIRECTORS.—Messrs. R F S Hardie, G H Alston, J G Wardrop; Estate Inspector:—Jno. Gordon, Estate Superintendent:—D Lyall.

ACREAGE.

Tea in full bearing	..	645 Acres.
do partial bearing	..	453 "
Clearings	..	15 "
Wind Belts and Timber Clearings	..	94 "
Grass, Scrub, &c.	..	48 "
Jungle and Patna	..	356 "
Buildings and Roads	..	19 "
Total	..	1,630 Acres.

The Directors have now to place before the Shareholders the Accounts of the Company for the past year. The crop secured amounted to 451,045 lb. Tea, being 22,045 lb in excess of the estimate.

The average nett price realised for the Tea was 42.63 cents per lb, against 46.30 cents per lb. in 1901, and the cost of laying down the Tea in Colombo was 25.14 cents per lb.

The old fields under Tea have been resurveyed, all wind belts, ravines, building sites, roads, &c. being deducted and placed under their different headings, and the acreage given above as under tea is now the correct one.

With reference to the remarks in last year's report, as there is no chance of recovering the Coast Advances referred to, the Directors have now written off R3,678.67 from the amount set aside for Reserve Account.

After writing off a sum of R14,020.63 for Depreciation of Buildings and Machinery, equal to over 1½ per cent on the Capital, the amount at credit of Profit and Loss Account for the year's working is R57,859.89, equal to 6.09 per cent on the paid-up Capital of the Company, to which has to be added the balance of R20,949.21 brought forward from 1901. The Directors now recommend the payment of a final dividend of 3½ per cent, making with the interim dividend of 2½ per cent paid on the 5th August last, a total dividend of 6 per cent for the year, and that the balance of R21,809.10 be carried forward to the current season's accounts.

The expenditure on Capital Account during the past year amount to R26,808.00, for the upkeep of young Tea not in bearing, and for necessary additions to Buildings and Machinery. After completion of the additions and alterations now being made very little Capital expenditure in this direction will be required.

The estimate for the current years is 441,000 lb. Tea on an expenditure of R206,623.56, and R12,701.00

on Capital Account, for completing the additions and alterations, mostly paid for in 1902.

During the year Mr. G B Leechman resigned his seat on the Board on his departure from the Island, and Mr. R F S Hardie was appointed in his place.

In terms of the Articles of Association Mr. Hardie now retires from the office of Director, but is eligible for re-election.

The appointment of an Auditor for the current year will rest with the meeting.—By order of the Directors, WHITTALL & Co., Agents and Secretaries. Colombo, 28th January, 1903.

THE AGRA OUVAH ESTATES CO., LTD.

DIRECTORS:—Messrs J G Wardrop, G H Alston and Jas. Polson Estate Inspector:—Mr R K Clark, Estate Superintendent:—Mr Wilson Smith.

ACREAGE.

31st December, 1902.

Agra Ouva. Fankerton.

	acres.		acres.
Tea in full bearing	322	Tea in full bearing	165
Grass and Jungle	9	Timber clearing	20
		Grass, Patana & Scrub	8
Total Estate	331	Total Estate	193
	Grand Total		524 acres.

The Directors now have to present to the Shareholders the Account for the past year.

The crop secured amounted to 333,789 lb being 9,961 short of the estimate, due to the abnormal weather experienced during the last few months of the year.

The average nett price realised for the Tea was 45.33 cents per lb, against 45.65 cents per lb in 1901. The cost of laying down the Company's tea in Colombo was 25.46 cents per lb.

The amount at credit of Profit and Loss Account for the year's working is R63,658.09, equal to 16.98 per cent on the paid up capital of the Company, to which has to be added a sum of R2,069.16 brought forward from 1901, making a total sum of R65,727.25 available for distribution. On 5th August last an interim dividend of 7 per cent was paid, absorbing R26,250, and the Directors now recommend the payment of a final dividend of 10½ per cent, making 17½ per cent for the year and that the balance of R102.25 be carried forward to this season's account.

The estimate for the present year is 343,750 lb Tea on an expenditure of R83,934.67, which includes a sum of R5,336 for manuring.

During the year the Hon Mr W H Figg resigned his seat on the Board, and Mr G H Alston was appointed to fill the vacancy. In terms of the Articles of Association Mr J G Wardrop retires from the office of Director, but is eligible for re-election.

The appointment of an Auditor for the current year rests with the Meeting.

U.S.P. ESSENTIAL OILS.—Kremers continues his observations on the proposed volatile oils of the U S P. 1900, his last instalment (*Phar. Rev.*, 1902, 544) dealing with oils of chenopodium and cinnamon. The oil of American wormseed has been little investigated, but observations since the last U S P indicated that the sp. gr. should be lowered from 0.970 at 15° C. to 0.910, and that the oil does not give a clear solution with ten times its volume of 70-per-cent. alcohol. The optical rotation is -18.55° for 100 mm. The note on cinnamon oil is necessarily more lengthy, and a trifle confusing to those who apply this name solely to oil of Ceylon cinnamon, since the note deals with oil of cassia, which is official in thirteen pharmacopœias, and oil of cinnamon in eight pharmacopœias. The author suggests the inclusion of Ceylon cinnamon oil in the U S P, as it is far superior to cassia oil. He deals fully with the characters of the latter oil, its assay and adulterants.—*Chemist and Druggist*, Jan. 17,

THE NEBODA TEA COMPANY OF CEYLON, LIMITED.

THE REPORT OF THE DIRECTORS FOR 1902.

DIRECTORS:—Messrs Joseph Fraser, Chairman, and Robert Morison, Director; Solicitors to the Company: Messrs. F J and G de Saram; Agents and Secretaries: Messrs. Somerville & Co.

ACREAGE:

Toa in full bearing ..	495 acres.
Forest Land, &c. ..	17½ "
Total.	666 acres.

The Directors submit report and accounts to end of December, 1902.

The crop secured was 228,597 lb, an increase of 19,550 lb over that of 1901. Gross average sale price in Colombo was 32.05 cts as against 30.34 cts in 1901. Cost of production, including manning was 24.01 cts, without manning 20.59 cts.

On the 495 acres Tea the average yield per acre was 461 lb. It is estimated that with medium fine plucking 1903 will shew an increase in this yield, and the estimate has accordingly been put down at 250,000 lb. During the year Factory appliances have been improved by the addition of two large Sirocco Fans, which will, it is hoped, put an end to the trouble and loss hitherto experienced in wet weather.

Profit and Loss Account shews a credit balance on the year's working of R18,071.60. Out of this R2,000 has been written off for Machinery depreciation, and an interim dividend of 3 per cent was paid in July last. The Directors now recommend the payment of a further 3 per cent making 6 per cent for the year, and the carrying forward of the balance to next year's account.

In terms of the articles of Association Mr Joseph Fraser retires from the Board, but is eligible for re-election.

The meeting will appoint an Auditor for the current year.

By order of the Directors.—SOMERVILLE & Co.,
Agents and Secretaries.
Colombo, 30th January, 1903.

THE AGRA TEA COMPANY OF CEYLON, LTD.

THE REPORT AND ACCOUNTS FOR 1902.

The acreage of the Company's property is as under:—

Tea in full bearing ..	321 acres
Tea in partial bearing ..	6 do
Tea not in bearing ..	9 do
Total in Tea ..	336 do
Forest ..	21 do
Grass, Waste Land, &c. ..	10 do

Total area of estate .. 367 acres

The estimated crop for 1902 was 200,000 lb. of tea, and the actual quantity realised was 197,050 lb., or a deficiency of 2,950 lb. This crop realised R31,532.96, equivalent to 41.38 cents per lb. as against 39.64 cents in 1901. The expenditure, as shown in the accompanying accounts, was R52,626.47, or nearly 27 cents per lb., as against 29 cents per lb. in 1901. The expenditure during the past year includes rather over 3½ cent for manure.

After deduction of R4,000 for Depreciation of buildings and machinery, the profit on working account for the year amounts to R24,183.83, representing about 6 per cent on the value of the property as shown in the balance sheet.

After payments of interest on loans, viz, R5,269.60, the net profit for the year amounts to R17,564.30, to which has to be added the sum of R3,652.83

brought forward from 1901, bringing the balance at credit of profit and loss account up to R21,217.18. During the past year the sum of £500 has been paid to the Standard Life Assurance Co. in reduction of the mortgage, which now stands at £5,500.

In view of the fact that £1,000 has to be found in June next for the purpose of paying the instalment which will then be due to the Standard Life Assurance Co., the Directors do not feel justified in recommending any dividend at the present time. They hope, however, that in the event of the price of tea being maintained during the ensuing year, they may be able to recommend a small dividend, 12 months hence. They therefore propose to transfer R20,000 to the credit of the Reserve Account, thus bringing the total of that Reserve up to R50,000, and leaving R1,217.18 to be carried forward to next season's accounts.

The estimated crop for 1903 is 205,000 lb. of tea to be produced at 27½ cents per lb., which allows for about the same expenditure on manning as last year.

In terms of the Articles of Association, Mr Joseph Fraser retires from the Board of Directors, but is eligible for re-election.

The appointment of an Auditor will rest with the meeting

THE PITAKANDE TEA COMPANY OF CEYLON, LIMITED.

REPORT AND ACCOUNTS FOR 1902.

DIRECTORS:—Messrs. Joseph Fraser (Chairman). Edward C Mitchell and Robert Morison.

SOLICITORS:—Messrs. F J and G De Saram.

Forest and Grass Land	283
Wast Land and Buildings	30

Total area of Estate .. 1,441

The Directors submit their report and accounts for 1902.

The tea crop secured amounted to 430,399 lb. being 42,929 lb. more than last year. The net average price realised was 35.15 cents, whilst the cost f.o.b. was 28.601 cents, including manure and burying prunings, or 22.180 cents exclusive of these items.

The net profit for the year was R23,297.23, to which has to be added R2,132.22 brought forward from 1901. An Interim Dividend of 4 per cent was paid in July, and the Directors now recommend a final Dividend of 4 per cent, making 8 per cent for the year, and leaving balance of R629.45 to be carried forward to next year.

In terms of the Articles of Association, Mr Edward C Mitchell retires from the Board of Directors, but, being eligible, offers himself for re-election.

The appointment of an Auditor rests with the meeting.—By order of the Directors, Colombo Commercial Co., Ltd.,
(JOHN G. WARDROP, Manager.) Agents & Secretaries.
Colombo, 27th January, 1903.

HAPUTALE PLANTERS' ASSOCIATION, 27TH ANNUAL REPORT.

Your Committee has the pleasure of laying before you the 27th Annual Report, and in so doing congratulate you upon the continued prosperity of the Association.

The number of estates on the register is 47, the same as last year. Finances are in a satisfactory condition and the meetings (three Committee and three General) held during the year have been satisfactorily attended.

OFFICIAL ESTIMATE.

	Acres in Tea.	In bearing.	Total Crop.	Green Tea.	Native Leaf.	Yield per acre.	Abandoned.
1903	18,710	15,780½	6,194,975	455,000	682,000	392	No return
1902	18,608½	14,806	5,928,565	145,000	487,000	406	173½
Decrease	—	—	—	—	—	8	—
Increase	102½	97½	266,410	310,000	195,000	—	—

SEASON.—The past season has been an abnormally wet one, resulting in a general shortage of output, which should have a beneficial result of prices in the near future.

COFFEE.—Everything points to a further reduction of the acreage under this product, and a corresponding decrease in the crop.

ROADS.—Your Committee regrets the inconvenience the District has been put to by the long deferred erection of that bridge connecting the Leangawela cart road with the Koslande bridge path. The main and minor roads have been kept in satisfactory repair during the year, and your Association's thanks are due to those who have supervised the work. Your Committee hopes that the bridge path, connecting the Ohiya cart road with the Horton Plains road, will be opened to the public at as early a date as possible. The construction of the Haputale-Dambatenne cart road has been sanctioned by Government, and the work is soon to be taken in hand.

LABOUR.—The District has been well, on the whole, supplied, but your Committee regrets that the roving disposition of coolies—so much complained of in other districts—is more apparent than in previous years.

ESTATES REGISTRATION SCHEME.—In the opinion of your Committee this scheme is working satisfactorily and has greatly simplified the importation of labour.

CRIME.—Your Committee is glad to state that the representation made by the Association to Government in June last, regarding the prevalence of crime and drunkenness in the district has not been without effect, and your thanks are due to the Government Agent for the stringent measures taken by him on several occasions. The illicit sale of arrack and toddy still continues, but in a less degree; fines inflicted seem to have little effect on offenders, and, it is hoped, that no efforts will be spared to put a stop to the illicit sale of both intoxicants.

MEDICAL.—The District Medical Officer reports that the general health of both Europeans and natives during the past year has been satisfactory, that there have been no epidemics of any kind, but that the late long period of wet weather has been the cause of an increase in pneumonia and dysentery cases.

VOLUNTEERS.—During the past year sections of the C M I and C P R C have been formed, numbering respectively 14 and 25.

REPRESENTATIVE IN COUNCIL AND CHAIRMAN OF THE PARENT ASSOCIATION.—To these two officials your Committee beg to convey its thanks and appreciation of valuable work done and services rendered.

FINANCES.—The amount shown at the credit of the Association is R27'58 as against R160'82 for last year. During the year the following donations were made:—Ceylon Nursing Association R50, Victoria Memorial Eye Institution R50, The Society of Prevention of Cruelty to Animals R25.

KELANI VALLEY PLANTERS' ASSOCIATION,

THE ANNUAL REPORT.

MEETINGS.—Five committee meetings and two general meetings have been held during the year.

FINANCE.—The balance to the credit of the Association at the end of December 1902 is R595'34 as against R601'37 last year. Donations have been made to the Memorial to the late Mrs W E Davidson and to the Coronation Celebrations. A detailed statement of accounts is circulated amongst members.

SCHEDULE.—The number of subscribers to the Association is 74 as against 72 in the previous year. During the year two estates have resigned owing to amalgamation (one estate has rejoined and three estates have joined as new members.)

CROP.—The estimated crop for 1903 is 16,707,550 lb. including 5,240,800 lb. green teas. Acreage in bearing is 36,394, or an average yield of 459 lb. per acre. Your Committee view with satisfaction the substantial increase in the green tea estimate, viz, 4½ million in excess of last year.

LABOUR FEDERATION.—Four cases have been brought before the K V L F during the year. One appeal for readmission has also occupied a considerable amount of time of the Committee. This appeal has finally been allowed. Certain alterations and additions to the local rules, deemed necessary by the Committee in consequence of one of these cases, have been duly passed at a general meeting of the Federation, and your Committee trust that the amended rules will work smoothly.

PRICES.—The prices obtained for black tea have been much about the same as in 1901. Plucking if anything, has been finer, as is shown by the reduced yield per acre. It may be pointed out that the style of plucking in the district is now practically settled in Colombo and London, as there are few estates in private hands. Your Committee view with regret that the action of the London Association in connection with the proposed increase of development of the green tea industry which is now the only solution of the over production problem.

K.V.R.—It is with feelings of the greatest satisfaction that your Committee are able to report the formal opening of the first section of the line in September, for passenger and goods traffic to Avisawella. Your Committee considers that this Association is deeply indebted to the Chief Resident Engineer, and also wish to put on record their appreciation of the tireless energy of the Assistant Engineers, Messrs Edwards, Fraser, Waghorn and Bowen, who, in the face of many difficulties have made it possible for Mr Phillimore to redeem his promise as intimated to you last year. The large passenger and goods traffic already being carried over this section of the line, augurs well for its further success when opened to Yatiyantota, and proves the accuracy of the figures and statistics collected at the commencement. The works on the remaining section of the line, between Avisawella and Yatiyantota are being prosecuted with vigour, and have been practically completed to Karawanella, and the whole line will be finished within a few months, when it is hoped that H.E. the Governor to whose action the realisation of the Kelani Valley Railway has been due, will honour the district by formally opening the line in person. The arduous Polatagama cross-country road will be ready for traffic on completion of the line to Yatiyantota and will form an outlet for the West Dolosbage traffic. In conclusion your Committee are pleased to report that a farther extension of the Railway to Ratnapura is being considered, and that the preliminary survey will be finished within five months.

ROADS.—Continual and heavy rains during the latter half of the year have done considerable damage throughout the district and this has caused much inconvenience. Your Committee cannot help feeling

however that more money is urgently needed for general maintenance, for the keeping of the roads in a better state of repair. Your Committee have to express their regret, a regret which is doubtless shared by the Director of Public Works, and the Provincial and District Engineer, that the causeway built over the Avissawella river at Algodde has proved an absolute failure. A further cause for anxiety is the N.E approach to the Ruigala Oya bridge.

TELEGRAPHS.—Your Committee are glad to be able to report that the necessity for a telegraph office at Dehiowita has been recognised, and that this important section of the district will no longer be left without rapid means of communication with the outside world.

LABOUR.—There has been a fine supply of labour throughout the year, and the tin ticket system is working satisfactorily. The labour question, however, continues to give cause for anxiety, and it cannot be denied that Canganies and coolies generally are much more inclined to bolt, give notice, and repudiate their debts, than formerly.

PEST.—A Report on *Helopeltis* in the Kelani Valley has been received from Mr. Green with certain suggestions and recommendations. Four estates have been selected to forward to Mr. Green, periodically, specimens of prunings. It is hoped that by careful attention to directions this pest may disappear.

COACH SERVICES.—The Yatiyantota-Veyangoda coach ceased to run at the end of the year. An additional coach between Avisawella and Yatiyantota has been started. Your Committee regret that repeated applications for an extension of this service to Kitulgalle have been unsuccessful. The last communication from the P M G was to the effect that no funds were available for a subsidy.

C. P. R. C.—The Kelani Valley section of the C P R C which was started last year, has on the whole, been well supported. A good range has been made at Dehiowita, and a marked improvement in shooting may be looked for in the future.

RUBBER.—During the past year one clearing has been opened in this product, and a considerable acreage planted up through the tea on various estates. The cultivation of rubber in this district is still in its infancy but there can be little doubt that it will eventually prove to be an important item in crop returns of the Kelani Valley.

BALANGODA PLANTERS' ASSOCIATION.

ANNUAL REPORT FOR 1902.

REGISTER.—The estates on the roll now number 15; there are also 2 private subscribers.

MEETINGS.—Three general meetings were held during the year, the average attendance being 9. The attendance should be improved and I should only be too happy for any suggestion as to longer notices, &c., that would make this better.

FINANCES.—I lay on the table a statement of accounts for the year.

CROP.—The estimate for 1903 is as follows:—

Total acreage in tea	5,761 lb.
Acreage in bearing	4,776 lb.
Total tea crop	2,050,000 lb.
Estimate of green tea to be made	409,000 lb.
Estimate of Native Leaf	14,500 lb.
Acreage of tea land abandoned during the past year	64 acres.
Average 429 lb. made tea per acre.			

This shows an increase of 10,000 lb in crop and 110 acres of tea in bearing. There is, however, to be noted an item of 409,000 lb, green tea as against nothing last year. This is good and it is to be hoped that some satisfactory solution of the Cess difficulty may be arrived at so as to allow full payments to be made to those who really are helping us out of the overproduction difficulty. The average yield for the district is about the same as last year. I hope that the better prices at present ruling will not tend to coarse plucking being resorted to.

WEATHER.—The season was an abnormally wet one, but none the less suitable for the greater portion of the district—1903 has also been ushered in with plenty of rain, so that possibly we are in for a wet cycle.

ROADS, GOVERNMENT CART ROAD.—This is in excellent order, the gravelling of the less frequented portion being a great improvement. There is, however, one matter which I am bringing up later in the form of a motion and that is the straying of cattle on the road. The thoroughfares Ordinance inflicts a possible £5 fine and I think we should invoke the Government Agent's aid.

BALANGODA-CHETNOLE ROAD.—This road was begun in November and the rate of progress so far is satisfactory. The earth work has been practically completed on the first two miles and the culverts &c. on one. The first two miles should be ready for traffic in June when the third mile will be begun. It has not been touched as yet. There is a sum of R30,000 available for this year.

COURTHOUSE.—The Court has sat in the new Courthouse for most of the year, but it is only a temporary building and I think we should ask for one of those ornate if not palatial buildings that Government, I understand, are favouring the other end of the province with. The session dates have been altered to Tuesdays and Wednesdays in the second and fourth weeks so as to allow the Magistrate to travel by coach. By the courtesy of the District Judge programmes for the first six months have been issued.

POSTAL.—Our thanks are due to the P.M.G. for having so promptly acceded to our request about the alteration of the Mail Service and we are now asking for the coach to run on Sundays as well. The new order of things has so far worked well and the coaches come in to time.

HOSPITAL MATTERS.—I regret that the three improvements urged for some time namely:—(1) The removal of the mortuary, which is situated at present close to one of the wards. (2). A covered way between the Kitchen and wards and (3). The laying down of water supply—still remain to be done. I think they are all reasonable and should be attended to without loss of time.

We were deprived of the services of two nurses for a portion of the year, but the staff has now been brought up again to its proper strength.

Mr. Kirby places his resignation before the meeting and you will be asked to nominate some one to serve as Hospital Visitor. Your thanks are due to the Visitors for their services during the year.

LABOUR FEDERATION.—No cases have yet been brought before the Committee, which is eminently satisfactory.

THE TIN TICKET SYSTEM.—I have not heard any complaints in the district about the working

of the system and it seems to me simple enough. At the same time there is no doubt we are short of labour and any scheme to remedy this evil (such as Mr. Westland's) should receive our support. The ruling rate for advances seems to be very high.

RATNAPURA RAILWAY EXTENSION.—You will be asked to pass a vote of thanks to H.E. the Governor for sanctioning the survey of the line and also to Mr. Stiven for his work as Hon. Secretary on the Extension Committee. Surveyors are now at work from four different points and I do not see why the railway should not be sanctioned before His Excellency hands over the reins of Government. My name has been put forward by the Ratnapura and Rakwana Associations as Chairman of the Railway Extension Committee in place of Mr. Wright, who is not in the island, and I have accepted subject to your approval.

RESTHOUSE AT KOTIYAGALA.—I am sorry to say that I do not think we shall get this. We have tried the two P. R. C.'s and finally the Hon. the Colonial Secretary, but have failed. The matter is however on the Agenda paper today and we might have one more try.
